## 1 Value of Aquatic Resources

2  
3 The Region's fish and other aquatic resources are among the richest and most diverse in the  
4 Nation. (XXXXXX want rich and diverse info here – suggests healthy watershed paragraph on  
5 next page, but it doesn't quite work)These resources, and the recreational, commercial, and  
6 intrinsic values they provide, have produced enormous economic, ecological, and social benefits.  
7

8 The Service's 2006 National Survey of Fishing, Hunting and Wildlife-Associated Recreation  
9 (USFWS 2007a) shows that recreational fishing contributes several billion dollars annually and  
10 tens of thousands of jobs to the nation's economy. Over 87 million U.S. residents 16 years old  
11 and older fished, hunted, or wildlife watched in 2006. During that year, 30.0 million people  
12 (approximately one out of every eight individuals) fished, 12.5 million hunted, and 71.1 million  
13 participated in at least one type of wildlife-watching activity including observing, feeding, or  
14 photographing wildlife; visiting public parks because of wildlife; and maintaining plantings and  
15 natural areas around the home for the benefit of wildlife.

16 Wildlife recreationists' enthusiasm was reflected in their spending which totaled over \$120  
17 billion in 2006. This amounted to 1% of the U.S. Gross Domestic Product. This spending  
18 supports hundreds of thousands of jobs in industries and businesses. Of the total amount spent,  
19 \$37 billion was for trips, \$64 billion for equipment, and \$21 billion for other items such as land  
20 leasing and ownership.

21 Sportspersons (anglers and hunters) spent a total of \$76 billion in 2006—\$42 billion on fishing,  
22 \$23 billion on hunting, and \$11 billion on items used for both hunting and fishing. Wildlife  
23 watchers spent \$45 billion on trips, equipment, and other items. (USFWS 2007a). In 2007,  
24 hunters, anglers and boaters paid an estimated 524 million in federal excise taxes. Federal excise  
25 taxes and state license revenues generated by hunters and anglers annually provide more than  
26 80% of the funding for most state fish and wildlife agencies; among other benefits, this allows  
27 states to own and manage 15.4 million acres of habitat, contributing to increases in native fish  
28 populations (National Shooting Sports Foundation 2007).  
29

30 Table II.1. describes participation rates for fishing, hunting and wildlife watching for New  
31 England (Maine, Vermont, New Hampshire, Massachusetts, Connecticut, Rhode Island), the  
32 Middle Atlantic (New York, New Jersey and Pennsylvania) and South Atlantic (West Virginia,  
33 Virginia, Maryland, Delaware, District of Columbia, and states south) compared with national  
34 rates. As shown in the table, New England and Middle Atlantic rates of participation in fishing  
35 are lower than the national average; South Atlantic rates are slightly higher than the national  
36 average. For hunting, New England, Middle Atlantic and South Atlantic participation rates are  
37 lower than or equal to the national average. For wildlife watching around the home and away  
38 from home, the Middle and South Atlantic participation rates are lower than the national average,  
39 but the New England participation rates exceed the national average.

1

	Fishing	Hunting	Watching Around the Home	Watching Away from Home
National	13	5	30	10
New England	11	3	38	12
Middle Atlantic	8	5	27	9
South Atlantic	14	4	28	7

2 Table II.1: Percentage of population age 16 and over participating in fishing, hunting, and wildlife associated  
3 recreation in the Northeast Region (based on information contained in USFWS 2007a). See text for definitions of  
4 geographic areas.

5

6 Fish and other aquatic resources are particularly important to States and Tribes, which rely upon  
7 diverse, sustainable natural resources to support commercial and recreational fishing, tourism,  
8 environmental health, subsistence, and other economic needs (XXXXsays important to all, not  
9 just states and tribes).

10

11 Healthy watersheds are the foundation of sustainable communities and economies. Among the  
12 many human benefits derived from healthy watersheds and functioning natural ecosystems are  
13 clean air and water, food, waste assimilation, medicinal compounds, outdoor recreation and  
14 spiritual renewal (Daily et al. 1997). Aquatic ecosystems provide enormous ecological benefits.  
15 For example, wetlands fulfill vital roles in the life history of most fish species in near-shore  
16 marine environments. In the Northeast, 41 percent of commercial marine fish species depend on  
17 estuarine habitats; for Chesapeake Bay this figure is 78 percent (Chambers 1992 cited by Loftus  
18 et al. 2000). Freshwater mussel communities play a significant role in aquatic ecosystems by  
19 improving water quality and as indicators of aquatic ecosystem health. Research has shown  
20 positive correlations between regular time spent in a natural environment and improved health  
21 status for both children and adults (Louv 2005; additional literature reviewed by Bunch 2007). A  
22 significant factor motivating participation in recreational fishing is the social and emotional  
23 benefits experienced (Responsive Management 2007). The economic value of such natural  
24 “goods and services” is significant and has been estimated to be twice the world’s gross national  
25 product (Costanza et al. 1998). As described above, fish and wildlife resources alone provide  
26 tremendous economic benefits.

27

28 These economic, ecological and social realities highlight the importance of holistic, ecosystem-  
29 based approaches to restoring and sustaining critical land and water resources and the human  
30 communities that depend on them.

31

32

33 **Status of Regional Aquatic Ecosystems, Fish and Mussel Populations, and Participation in**  
34 **Fishing**

35

36 Status of Regional Aquatic Ecosystems

37

38 The Northeast Region encompasses a complex natural environment heavily influenced by human  
39 disturbance. While the 13 Northeast states comprise less than 7 percent of the U.S. landmass,  
40 almost 25 percent of the nation’s population resides here. The historical pattern of development  
41 in the Northeast has resulted in significant fish and wildlife impacts, and serious threats remain.

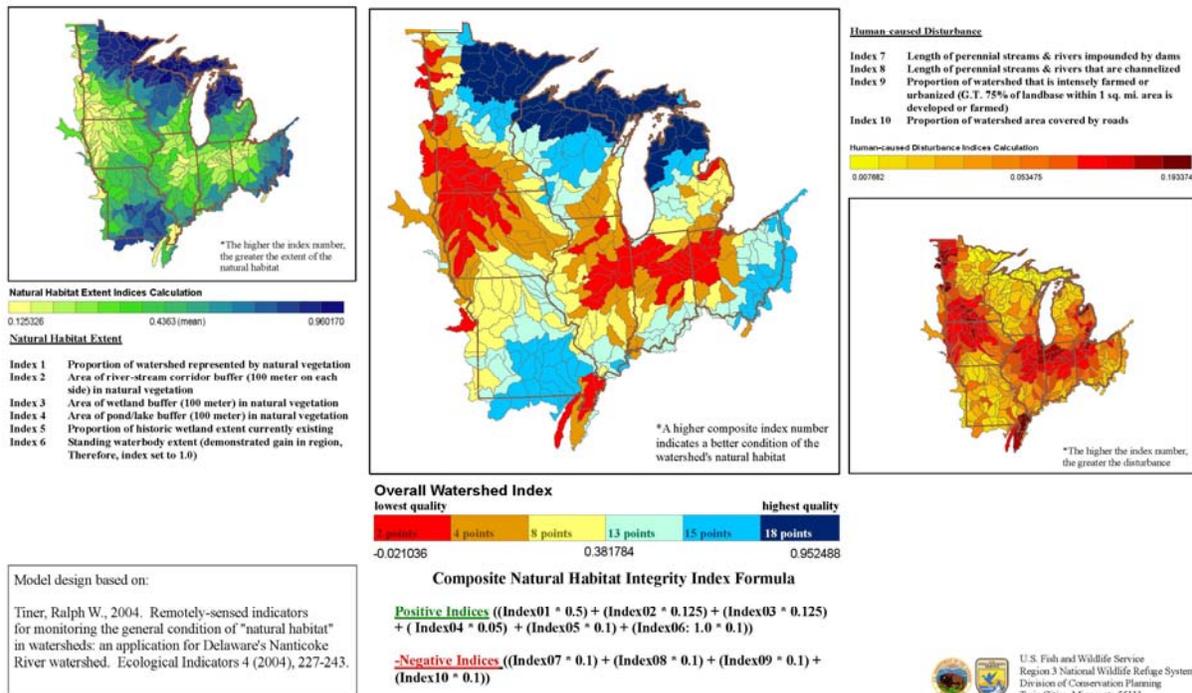

1 Population growth and suburban sprawl in many areas will continue to put pressure on fish and  
 2 wildlife populations. Global climate change will alter habitats and ecosystem dynamics, creating  
 3 significant and unpredictable changes in distribution and abundance of aquatic species.

4  
 5 The Northeast Region has undergone significant ecosystem modification. Noss et al. (1995)  
 6 identified 41 critically endangered, endangered or threatened ecosystems in the Northeast  
 7 Region, second only to the South. These include elimination of 96% of virgin forests, significant  
 8 losses of wetlands, loss of free-flowing rivers, eutrophication of lakes, acidification of surface  
 9 waters, loss of estuarine submerged aquatic vegetation and other estuarine communities, and  
 10 contamination of surface waters by toxic chemicals.

11 [Add R5 watershed health analysis map when available, same approach as R3 example below.]  
 12

# Watershed Health

## An Evaluation of Watershed Health in Region 3

13  
 14  
 15  
 16  
 17 Many of the over 10,000 dams in the Region, including hydroelectric projects, block fish from  
 18 reaching historical rearing and spawning habitats and have significantly altered stream flow,  
 19 temperature, and natural hydrologic conditions affecting a myriad of fish and invertebrates such  
 20 as freshwater mussels. The highest density of dams nationally is found in the Northeast and  
 21 Southeast U.S. (Graf 1999). Culverts also impede stream connectivity, with extensive negative  
 22 impacts.

1  
2 Dozens of species of non-native fish and mollusks have been introduced to Northeast waters.  
3 Some of these, such as zebra mussels, Asian and European clams, carps, eels and crabs can cause  
4 significant harm to native fish and other aquatic resources. Native resources are especially  
5 threatened by these invaders because of their rapid spread through connected waterways. Since  
6 the unintentional introduction of zebra mussels into the lower Great Lakes and their subsequent  
7 spread southward into major Northeast and mid-continental rivers the number of native mussel  
8 species has declined substantially. In the Northeast Region, the largest numbers of non-native  
9 aquatic species occur in western West Virginia and Virginia, the Potomac River basin, and the  
10 lower Connecticut River (Figure II.2).

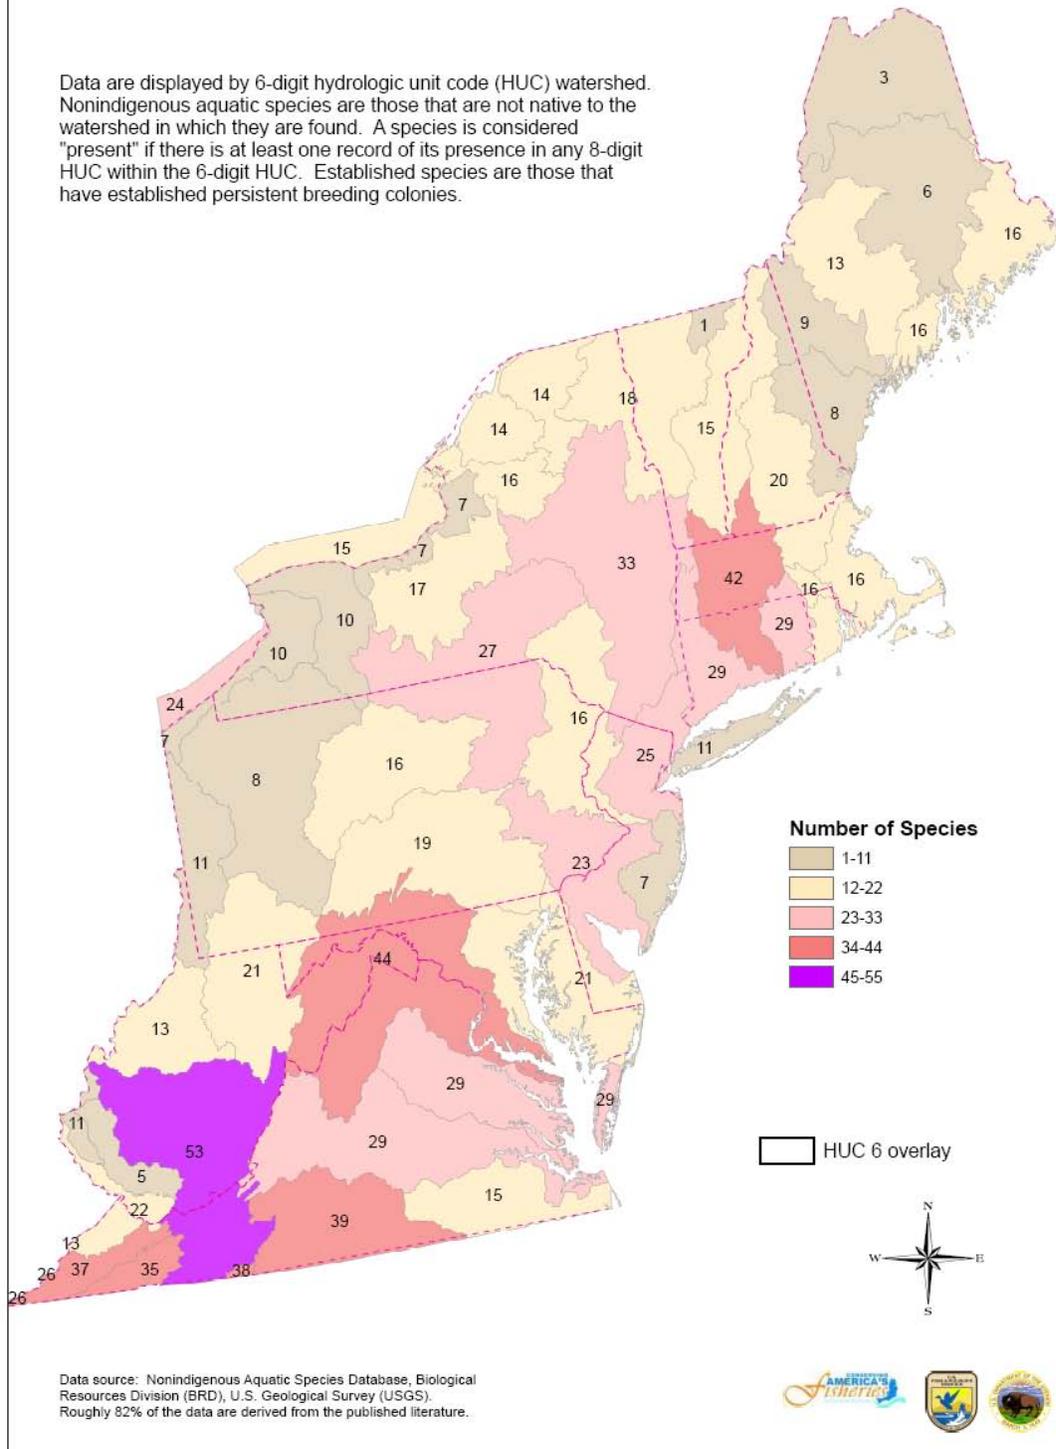

11  
12 State Wildlife Action Plans have identified serious threats to aquatic species.  
13 [Add regional threats from Karen Terwilliger SWAP synthesis when available.]  
14

15 One of the most significant threats to Northeast Region aquatic species is global climate change.  
16 The Intergovernmental Panel on Climate Change (IPCC 2007) has concluded that "... Warming  
17 of the climate system is unequivocal." Specific impacts to the Northeast Region are likely to  
18 include further pressure placed on native freshwater fish communities as warmer conditions  
19 increase water temperatures, reduce winter snow and ice cover, and alter the timing, duration and  
20 volume of seasonal stream flow. Coldwater species likely to be affected include brook trout,  
21 lake trout, Atlantic salmon, and several types of whitefish. Studies in New England have already  
22 documented shifts in the timing of winter/spring and fall peak flows and associated measures  
23 such a last-frost dates, lake ice-out dates, and spring air temperatures (Northeast Climate Impacts  
24 Assessment 2007).  
25

INTERNAL REVIEW DRAFT

## Number of Established Nonindigenous Aquatic Species in Northeast Region Watersheds, 2007

Data are displayed by 6-digit hydrologic unit code (HUC) watershed. Nonindigenous aquatic species are those that are not native to the watershed in which they are found. A species is considered "present" if there is at least one record of its presence in any 8-digit HUC within the 6-digit HUC. Established species are those that have established persistent breeding colonies.

## Status of Regional Fish and Mussel Populations

Fish faunal intactness describes the extent to which freshwater fish communities have retained their historical composition. EPA (2007) reviewed data on the percent reduction in native fish species diversity in the contiguous United States between 1970 and 2003. Reductions in diversity at the watershed level may be due either to the overall extinction of a species, or, more commonly, to the extirpation of a species from certain watersheds. Species extirpations are most often due to pollution, habitat alteration, fisheries management, and invasive species. In the Northeast Region, reduction in native species diversity since 1970 was generally less than 9%, with the exception of the Great Lakes, which underwent greater reductions (over 50% for Lake Ontario).

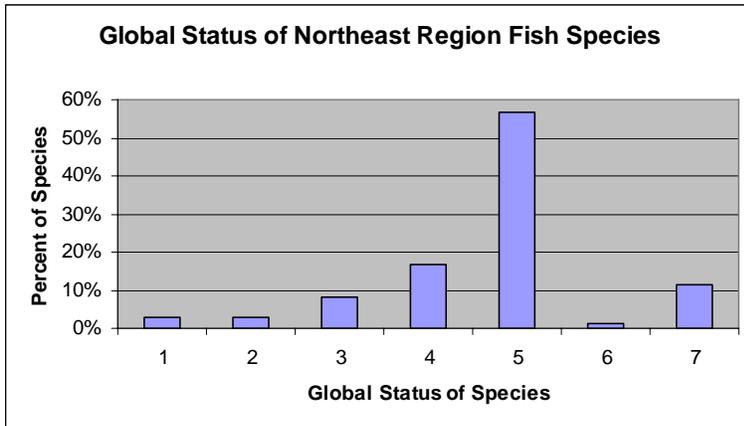

13 Figure II.3. Historical diversity of native fish species in the contiguous U.S., 1970 (EPA 2007)

14 Figure II.4. Percent reduction in native fish species diversity in the contiguous U.S. from 1970 to 1977-2003 (EPA  
15 2007)  
16

1 Within the Northeast Region, approximately 74 percent of the total of 362 fish species are  
 2 considered secure or apparently secure. Approximately 14 percent are considered critically  
 3 imperiled, imperiled, or vulnerable (Figure II.5).  
 4

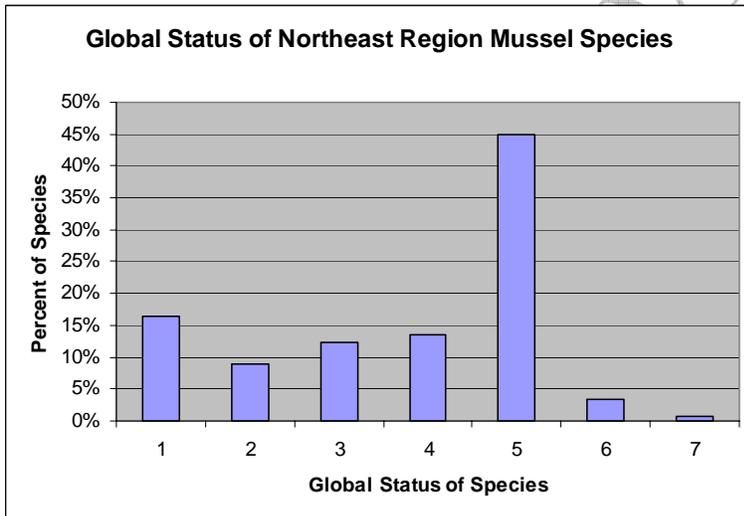

Status Categories

- 1=NatureServe G1 category (Critically Imperiled)
- 2=NatureServe G2 category (Imperiled)
- 3=NatureServe G3 category (Vulnerable)
- 4=NatureServe G4 category (Apparently Secure)
- 5=NatureServe G5 category (Secure)
- 6=NatureServe GH or GX category (Possibly Extinct or Presumed Extinct)
- 7=Unranked

5  
 6 Figure II.5 (analysis of NatureServe (2007) data).  
 7

8 Approximately 59 percent of the total of 142 Northeast Region mussel species are considered  
 9 secure or apparently secure. Approximately 37 percent are considered critically imperiled,  
 10 imperiled, or vulnerable (Figure Figure II.6).  
 11

12  
 13 Figure II.6 (analysis of NatureServe (2007) data). Status categories the same as Figure II.5.  
 14

15 [Could do these analyses by state.]  
 16

17 Among the species managed by the Atlantic States Marine Fisheries Commission, Atlantic  
 18 striped bass, Atlantic herring, Atlantic menhaden, northern shrimp, the Gulf of Maine population  
 19 of winter flounder, the Gulf of Maine and Georges Bank populations of American lobster, and  
 20 the mid-Atlantic population of Atlantic croaker are considered to be healthy. Spanish mackerel,  
 21 bluefish, spiny dogfish, tautog and Atlantic sturgeon) are considered to be rebuilding. The  
 22 Southern New England/Mid-Atlantic population of winter flounder, Southern New England

1 population of American lobster, summer flounder, weakfish, and American shad are considered  
2 to be depleted. The status of the South Atlantic population of Atlantic croaker, scup, black sea  
3 bass, red drum, spot, spotted seatrout, American eel, horseshoe crab, and river herring is  
4 unknown (ASMFC 2007).

5  
6 Stock abundances of river herring (alewife and blueback herring) and American shad are well  
7 below historic levels of the early 20<sup>th</sup> century. Research on the biology, habitat requirements and  
8 stock status of American shad is in progress. NOAA recently listed river herring as Species of  
9 Concern, which should make research on these species a higher priority. The goal for both of  
10 these species is restoration to sustainable levels. Populations of American eel have declined, and  
11 in 2005 Atlantic Coast American eel stocks were the subject of a status review in response to a  
12 petition to list the species as threatened or endangered under the Endangered Species Act of 1973  
13 (NOAA 2007). In 2007 the U.S. Fish and Wildlife Service concluded that protection of the eel  
14 under the ESA was not warranted. While the eel population has declined in some areas, the  
15 species' overall population is not in danger of extinction or likely to become so in the foreseeable  
16 future, the Service decided. (USFWS 2007b)

17  
18 Horseshoe crabs play a vital ecological role in the migration of shorebirds along the entire  
19 Atlantic seaboard, as well as providing bait for commercial American eel and conch fisheries  
20 along the coast. Additionally, their blood is used by the biomedical industry. Little is known  
21 about the status of the horseshoe crab population. The challenge of fisheries managers is to  
22 ensure that horseshoe crabs are managed to meet all these diverse needs, while conserving the  
23 resource for its self-perpetuation (USFWS 2007c).

24  
25 By 1950 the abundance of Atlantic salmon in New England rivers was severely depleted. A  
26 widespread collapse in Atlantic salmon abundance started around 1990. All stocks are at very  
27 low levels. The Gulf of Maine Distinct Population Segment of Atlantic salmon was listed as  
28 Endangered in 2000. Most Atlantic salmon populations are still dependent on hatchery  
29 production, and current marine survival regimes are compromising the long-term prospects of  
30 even these hatchery-supplemented populations (NOAA 2007).

31  
32 Endangered Atlantic Salmon - The Gulf of Maine Distinct Population Segment (DPS) of Atlantic  
33 Salmon was listed as Endangered on December 17, 2000. At the time of listing, eight small  
34 rivers within the DPS (Dennys, Ducktrap, East Machias, Machias, Narraguagus, Pleasant, and  
35 Sheepscot rivers and Cove Brook) had extant populations. Estimated returns to rivers within the  
36 DPS from 1991 to 2002 are shown in Figure II.7. In 2006, seventy nine adult fish were  
37 estimated to return to the rivers within the DPS (U.S. Atlantic Salmon Assessment Committee  
38 2007). Even with current conservation efforts, returns of adult Atlantic salmon to the Gulf of  
39 Maine DPS rivers remain extremely low. The 2006 status review (Fay et al. 2006) reports an  
40 estimated extinction risk of 19% to 75% within the next 100 years for the Gulf of Maine DPS  
41 even when current levels of hatchery supplementation are considered. Because of recent genetic  
42 information, the review concludes that the DPS should be expanded to include salmon in the  
43 Androscoggin, Kennebec, and Penobscot Rivers, as well as hatchery fish used in the recovery  
44 effort.

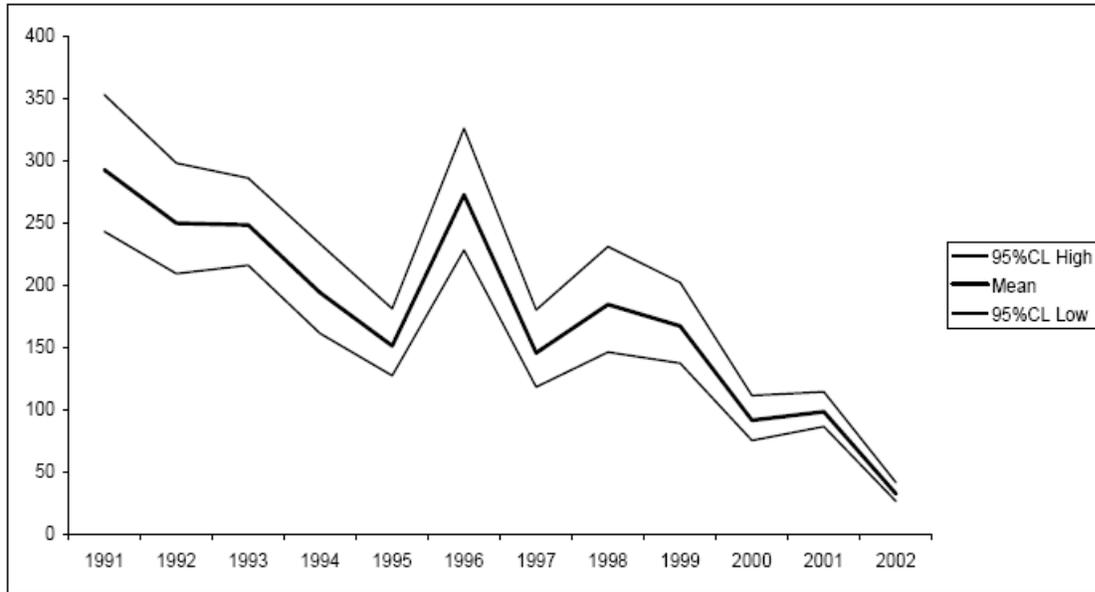

Figure II.7: Estimated Adult Atlantic Salmon Returns to Rivers within the Gulf of Maine Distinct Population Segment, 1991-2002. (Source: NMFS and USFWS 2005)

A growing number of aquatic species in the Northeast Region are declining at alarming rates. In the Northeast Region, 38 fish and mussel species are listed as endangered, threatened, or candidate by the Service. (Table II.1). The greatest concentration of listed species is in Southwest Virginia, where there are numerous endangered mussel species (Figure II.8).

Mussels, sentinels of ecological degradation - Mussels have been especially hard-hit by ecological degradation. With a total of 297 species, North America has the world's greatest diversity of freshwater mussels (G.M. Davis 1977). As filter feeders, mussels are exposed to toxins or other deleterious environmental conditions at a more acute level than many higher trophic level species. Minute levels of some toxins, or chronic environmental stresses such as siltation, low oxygen, or high ammonia levels can cause catastrophic losses in mussel communities long before they are noticed in higher fish populations. 75% of unionid mussels in the U.S. are classified as rare or extinct, in comparison to 11-15% of terrestrial vertebrates (Master 1990), resulting primarily from inundation of riffle habitat resulting from impoundment of major river systems (Bogan 1995).

1  
2 Requiring clean, cold headwater streams, Eastern brook trout can be considered an indicator of  
3 the health of watersheds in the Northeast Region. Eastern brook trout are found throughout New  
4 England, and in the Appalachian portions of New York, Pennsylvania, Maryland, West Virginia  
5 and Virginia. In 2006, an assessment team compiled information on the status of and threats to  
6 Eastern brook trout (Hudy et al. 2006). The assessment team evaluated 5,563 subwatersheds  
7 where brook trout historically thrived to determine the current strength of brook trout  
8 populations. 5 percent of these watersheds support intact populations; 9 percent support reduced  
9 populations; 27 percent are greatly reduced; 19 percent are present but no quantitative data are  
10 available on populations; 21 percent are extirpated; 6 percent are absent with historical presence  
11 unclear; 13 percent are unknown. (Figure II.9)  
12

13  
14 Figure II.9: Eastern Brook Trout Population Status in the Eastern U.S. Range by Subwatershed (Trout Unlimited  
15 2006).  
16

1 Regional experts identified poor land management associated with agriculture as the most  
2 widespread impact on brook trout habitat (37% of subwatersheds), largely by removing  
3 streamside trees and increasing sedimentation and nutrient runoff. Other threats, in order of the  
4 percent of subwatersheds in which they significantly affect brook trout populations, include high  
5 water temperature (36%), sedimentation from roads (27%), presence of one or more non-native  
6 fish species (26%), urbanization (25%), riparian habitat loss and degradation (23%), presence of  
7 brown trout (19%), stream fragmentation from roads (17%), inundation and loss of connectivity  
8 due to dams (16%), and poor land management associated with forestry (14%) (Trout Unlimited  
9 2006).

### 10 Status of Regional Participation in Fishing

11  
12  
13 In 2006, six percent more people 16 years of age and older participated in wildlife-related  
14 recreation nationally than in 2001. The number of sportspersons (anglers and hunters) declined,  
15 but this decline was more than offset by an 8 percent increase in the number of wildlife watchers  
16 (USFWS 2007a). In the Northeast Region, the number of fishing licenses purchased has  
17 declined from about 4.6 million in 2001 to about 4.2 million in 2005 (Association of Fish and  
18 Wildlife Agencies and American Sportfishing Association 2007). The national decline in  
19 angling participation is due to demographic changes, changes in lifestyle, and lack of access due  
20 to urbanization and development (Southwick Associates 2007). The decline in angling is of  
21 concern because reduced license sales result in less financial support for state management  
22 agencies, many of which are funded solely by license sales. The decline in angling also is of  
23 concern because it may result in a declining constituency for healthy aquatic ecosystems.

24  
25 This downward trend may be perpetuated as parents fail to engage children in fishing, hunting  
26 and other outdoor activities. For many cultural reasons, today's children are spending less time  
27 outdoors, as evidenced by increased rates of obesity and other health problems (Louv 2005).  
28 Research shows that an adult's affinity for nature and support for conservation is directly related  
29 to unstructured childhood experiences in nature. (Bunch 2007). This disconnection of people  
30 from nature has serious negative implications for natural resource stewardship and for public  
31 health.
