INTRODUCTION

The net accumulation of a chemical by an organism as a result of uptake from all environmental sources is termed bioaccumulation (USEPA 1995). Determining the extent of bioaccumulation in organisms is widely used as a method to monitor and assess pollutant distribution and bioavailability geographically and over time (Crawford and Luoma 1993; Schmitt et al. 1999). Phillips (1980), identified three benefits from using fish and other aquatic organisms in monitoring programs. First, concentrations of contaminants are often greater in tissue than in water and therefore, the probability of detecting trace amounts of contaminants in the environment is increased. Second, resident organisms provide a time-integrated assessment of a contaminant in question. Third, the direct bioavailability of contaminants that accumulate can be measured and temporally and spatially compared.

According to the critical body burden concept of McCarty (1986) and Escher and Hermens (2004), chemicals will have a specific effect (lethal or sublethal) upon fish once they have attained a specific internal tissue concentration. The internal concentration is independent of external influences and mode of exposure (i.e., in water or in the diet) and should occur at the same level regardless of the organism or species used. The objectives of this portion of the Rio Grande Silvery Minnow Health Study were to identify the body burden of chemicals in Rio Grande silvery minnow and review the extent of contamination, evaluate any possible health consequences associated with the concentrations, and provide baseline contaminant data. We analyzed Rio Grande silvery minnow carcasses (*Hybognathus amarus*; silvery minnows) for a variety of inorganic and organic chemicals, as well as lipid and moisture content. Organic chemicals analyzed included aliphatic hydrocarbons, polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), dioxins and dibenzofurans, polybrominated diphenyl ethers (PBDEs), and a variety of organochlorine insecticides, including 1,1,1-trichloro-2,2-di(4-chlorophenyl)ethane, also known as DDT.

METHODS

Chemical Analyses, Quality Control and Methods of Interpretation of Contaminants in Fish

Lusk (2012) described the methods, dates, and locations of silvery minnow carcasses collected from six sites along the Rio Grande during 2006-2008. Study location and collection sites referred to in this report are described in Table 1 and depicted in Figure 1 and Figure 2. Silvery minnows that were dissected for fish health assessments (Davis and Lusk 2012) or pathogen assessments (Woodland 2012) were wrapped in aluminum foil or placed in polyethylene bags and frozen (4°C Centigrade). Later, carcasses were removed from bags and foil and composited by site and date (up to 70 individual fish) in chemically clean jars and shipped frozen to the Service's contract laboratories for a variety of chemical analyses. These carcass composites (i.e., whole body minus the gonads or gills and some body fluids removed during their necropsy) were variously analyzed for 19 elements, methyl mercury, moisture and lipid contents, and 353 organic compounds including a variety of organochlorine (OC) pesticides, PCBs, PBDEs (flame retardants), dioxins, as well as aliphatic and aromatic hydrocarbons. A list of the chemicals and elements analyzed, abbreviations and names used, analytical methods used, and method detection limits for the chemical analyses, are provided in Table 2.

Briefly, silvery minnow carcass composites were homogenized and aliquot samples were digested and extracted for a variety of chemical analyses using gas chromatography, mass spectroscopy, atomic fluorescence or cold-vapor atomic absorption spectroscopy (Trace Element Research Laboratory 2010; Appendix 3A; and, TDI Brooks International, Inc., 2010; Appendix 3B). Percent lipid and percent moisture content were also determined. A single grab sample of water was also collected for analyses, and while the water and its results were not relevant to this study; however, the water sample provided for additional measures of laboratory quality control.

Quality-control measures included the analysis of method and procedural blanks (to measure contamination during sample preparation and analysis and to determine detection limits), duplicate samples (to measure precision), fortified (spiked) samples (to measure matrix interferences), and laboratory standards and certified reference material (to measure accuracy). Contaminants in silvery minnow carcasses are reported as micrograms per gram ($\mu\text{g/g}$; i.e., approximately parts per million) or micrograms per kilogram ($\mu\text{g/kg}$; i.e., approximately parts per billion) dry-weight and wet weight-weight concentrations; the latter was calculated from the moisture content of the sample.

Data Treatment and Statistics

Data were imported into spreadsheets (Microsoft Office Excel 2007, Microsoft Corp., Redmond, WA) or imported and analyzed using the statistical software Statistica (version 9.0, StatSoft, Tulsa, OK) or imported into a database using Microsoft Office Access 2007 (Microsoft Corp., Redmond, WA). Prior to final statistical analysis, the assumptions of normality and equal variance were formally tested by the Shapiro-Wilks test and Levene's test, respectively. Data that did not meet these assumptions were transformed to their natural logarithms and retested. If data were normally distributed comparisons were made using a one-way analysis of variance (ANOVA). Post-hoc comparisons between sites were conducted using a students' t-test (Bailey

1981) or Tukey's Honestly Significant Difference (HSD) test (for equal sample sizes) or Tukey-Spjøtvoll/Stoline tests (for unequal sample sizes) (Statsoft Inc., 2010). If the natural log-transformation did not satisfy the assumptions, data were transformed to ranks and a Kruskal-Wallis and median test was applied to test the ranks (Statsoft Inc., 2010). Other parametric and nonparametric statistical tests were also employed and are so indicated in the text. For statistical purposes, as well as simplicity, when less than 25 percent of the analytical results were below the laboratory Method Detection Limit (MDL), the censored results were replaced with a value one-half the method detection limit prior to further statistical treatment. All censored data from comparison studies (e.g. Schmitt et al. 1999) were replaced with a value one-half the MDL (when reported) prior to comparison. Analytical results where chemicals were detected less frequently were only briefly summarized and results were provided in the appendices. Statistical significance probability (p) was set at $p < 0.05$ for all tests. Some of the fish tissue contaminant data were reported in either dry weight or wet weight concentrations and were so indicated. To convert dry weight concentrations into wet weight concentrations, the following equation was used:

$$\text{Wet weight} = (\text{dry weight}) * (1 - (\text{percent moisture}/100)) \quad \text{Equation 1}$$

Moisture content was determined by both inorganic and organic analytical laboratories. Values of moisture content conducted on same samples by the different laboratories were normalized and averaged. These average moisture contents were reported and evaluated. Only dry weight concentrations were reported by Mora (2001); therefore, a value of 72.1 percent moisture (average was derived using Schmitt et al. 1999) was used in Equation 1 to convert concentrations in lower Rio Grande fish into wet weight.

PCBs are a complex mixture of 209 isomers and congeners with 1 to 10 chlorines attached to the biphenyl structure in various arrangements with congeners identified by a suffix according to the nomenclature systems of Ballschmiter and Zell (1980) and Schultz and Malisch (1983). Aroclors are commercial PCB preparations that were produced up until 1977 by the Monsanto Chemical Company that contained various amounts of chlorine by weight. Total PCBs refers to the sum of the aroclors. Sum total PCBs refers to the summation of all PCB congeners and includes values where one-half the limit of detection (LOD) was substituted for PCB congener data below the LOD regardless of detection frequency. Certain PCB congeners are considered "dioxin-like" as they can have a fraction of the toxicity of dioxin (2,3,7,8-TCDD) and are often modified by their Toxic Equivalent Factors (TEFs; Van den Berg et al. 1998). TEFs from Van den Berg et al. (1998) for PCB congeners were used to calculate Toxicity Equivalents (TEQs) for fish. The TEQ scheme refers only to adverse effects (e.g., cancer) following interactions with the cellular Ah receptors (Wenning et al. 2011). For the purposes of the TEQ calculation, all values for dioxins, dibenzofurans, and PCB congeners below LOD were substituted with a zero.

Interpretation of Chemical Residues

Identification of contaminants of concern in whole body fish collected for this study was accomplished on a site or stream segment basis. Data from two sites each were combined into three groups (upper, middle, and lower) for further analysis at the segment scale. The evaluation methods included a comparison of the concentrations of chemicals in tissues collected from sites

or segments to various concentrations reported in the literature that affect fish (Jarvinen and Ankley 1999; USDI 1998; USACE 2010), to concentrations in fish collected from the Rio Grande or other watersheds (Roy et al. 1992; Simpson and Lusk 2000; Mora 2001; Abeyta and Lusk 2004; Schmitt et al. 2004; Buhl 2011), or to fish collected nationwide (Schmitt et al. 1999).

The significance of the concentrations of chemical contaminants in fish is not always clear, as elevated chemical concentrations are found in apparently healthy individuals. Identifying the presence of a chemical in silvery minnows was not considered sufficient information to conclude that the chemical would produce an adverse effect. The likelihood that a chemical substance in silvery minnows would produce an adverse effect is likely a function of the physical and chemical properties of the substance, the concentration of the chemical in the tissues, and the length of time the fish is exposed to the compound. Because environmental contaminants vary so widely in their potential to produce toxicity, comparison with an average literature-based contaminant-specific concentration was used to reach a determination regarding the potential for contaminant to produce adverse effects or identified the need for more research.

The Environmental Residue-Effects Database (USACE 2010 and references cited therein) were used for the majority tissue residue effects data comparisons. Emphasis was placed on contaminants that were known to pose serious health risks to fish or studies involving freshwater or marine fish in either carcasses or whole body fish in those studies cited in the USACE (2010) database. Those studies indicated concentrations above which a toxic effect due to a contaminant was likely to occur (i.e., adverse effects) including physiological, biochemical, growth, reproductive, and lethal effects. Those study also identify concentrations below which no adverse effects were likely to occur. For those cases where the concentrations in fish associated with adverse effects overlapped those concentrations where no adverse effects were identified, then comparisons were made to the average concentration associated with each type of effect (i.e., adverse or not). Where literature-based adverse effects thresholds were exceeded, then the corresponding adverse effect was further reviewed in relation to silvery minnow health.

Differentiating petrogenic from biogenic compounds in the interpretation of hydrocarbon residues in fish tissues is important. We compared the proportions of odd- and even-numbered long chain hydrocarbons to determine if sources were petrogenic (crude oil, diesel, light oil, etc.) as petrogenic compounds have approximately equal proportions of odd- and even-numbered long chain hydrocarbons (Hall and Coon 1988). We used ratios of pristane and phytane to n-heptadecane and n-octadecane, respectively, that when elevated indicate whether fish were recently or chronically exposed to petroleum compounds (Farrington et al. 1976; Anderson et al. 1978; Hall and Coon 1988).

RESULTS AND DISCUSSION

Quality Control of the Chemical Analyses

The U.S. Fish and Wildlife Service (USFWS) uses several contract laboratories to provide routine chemical analyses of chemical residues in biota and environmental samples (USFWS 2010a). The laboratories that conducted the chemical analyses of silvery minnow carcasses for this study were responsible for establishing the precision and accuracy of their analytical procedures. Quality assurance included cataloging silvery minnow sample collection, storage, and data transfer (Appendix 3C). Quality control procedures included analysis of procedural blanks, duplicate, and spiked samples as well as analysis of standard reference materials for inorganic chemicals (Appendices 3A and 3B). Data from such procedures were evaluated and documented by laboratory chemists and USFWS Analytical Control Facility (USFWS 2010a) and specific examples of quality control review are further described below.

Quality control described below was reviewed for the silvery minnow carcass samples only. Concentrations of mercury in the procedural blanks were slightly above the MDL in fish analyzed and reported by Trace Element Research Laboratory (2010; Appendix 3A). However, the concentrations of mercury detected in the procedural blanks (0.0028 $\mu\text{g/g}$ dry weight) were within a factor of two of the MDL (0.002 $\mu\text{g/g}$ dry weight) and were considered to be within the acceptable control limits. Concentrations of mercury in the procedural blanks were also 100 times less than the average concentration detected in silvery minnows and therefore were considered unlikely to affect interpretation. Concentrations in 10 of 41 duplicate element analyses of fish samples were below the MDL; thus no measure of the method precision was calculated. Quality control of analysis was maintained as the relative percent difference measured for the remaining 31 duplicate analyses averaged 6.1 percent with a range of 0 to 16.8 percent. Percent recovery of 41 spiked element analyses averaged 106 percent recovery with a range of 86 to 127 percent recovery of spiked amounts. Analysis of mercury in standard reference materials was within 87 to 107 percent of certified values, which indicated that mercury was accurately measured. Additional elements were analyzed in standard reference materials, and except for manganese (117 percent) and strontium (70.1 percent), the analysis of standard reference samples were within the acceptable range (80-110 percent) of certified values.

Concentrations of Aroclors (i.e., PCB-1242, PCB-1248, PCB-1254, PCB-1260) and PCB-total were detected in procedural blanks, but results were less than 10 times the MDL and were considered to be within the acceptable control limits (TDI-Brooks International, Inc. 2010; Appendix 3B). Concentrations in 91 of 224 duplicate analyses of fish samples were below the MDL and thus no measure of their method precision was calculated nor statistical analyses were conducted. The relative percent difference measured for the remaining 133 duplicate analyses averaged 6.3 percent with a range of 0 to 43.5 percent. Relatively high duplicate analysis results were found with biphenyl (43.5 percent) and heptachlor epoxide (29.1 percent); without these two duplicate analytes, the range of 131 duplicate analyses averaged 5.9 percent and ranged from 0 to 22.2 percent. Analysis of duplicate moisture content was 0 percent. Analysis of duplicate lipid content ranged from 0.7 to 12.6 percent and averaged 4.8 percent. All spike results for organic chemicals in silvery minnows were within normal limits (60 to 120 percent), except for

endosulfan II, n-heptacosane, and n-pentacosane, where the spike recoveries were low and therefore, the results of these three analytes may be biased low. As endosulfan II was not detected in greater than 75 percent of the samples analyzed, it was not further analyzed. Standard reference materials for organic chemicals were not analyzed as costs of analysis for over 350 organic chemicals in standard reference materials exceeded available funding.

Inorganic Contaminants, Methyl Mercury, and Lipid or Moisture Content

All analytical data on the concentrations of inorganic chemicals, methyl mercury or moisture content in silvery minnows are found in Appendix 3D and selectively summarized in Table 3. Nineteen inorganic contaminants were analyzed in carcass samples (Appendix 3D), however, molybdenum was below the MDL in all samples, and 4 elements (B, Be, Cd, and Cr) were detected in less than 75 percent of the samples analyzed. These 5 elements (B, Be, Cd, Cr, and Mo) were not compared statistically nor evaluated further. Concentrations of methyl mercury (MeHg) were also detected in all silvery minnows analyzed (Table 3). There were insufficient toxicity residue effects data available to assess the effects of iron, magnesium, manganese, and strontium in silvery minnows. The remaining inorganic contaminants in silvery minnows are discussed below. Average concentrations are provided below plus or minus one standard deviation (average \pm 1SD).

A number of metals (Al, Cu, Fe, Mg, Mn, Ni, Pb, V, Zn) appeared to decrease in those fish collected on a downstream basis; however, this trend (or decrease) was not statistically significant (Table 3). Some of the differences in the metal contaminants in silvery minnows (Cu, Fe, Mg, Mn, Ni, Pb, V, and Zn) may partly be attributable to their ingestion of sediment (Buhl 2011). Silvery minnow feeding behavior from sediment substrates could increase their metal uptake by way of gill respiration or through dietary routes (Magaña 2009; Buhl 2011). Several of these elements were reported in underlying parent material (USGS 2008) and also generally decrease in a downstream direction. However, sediment samples reported by NMED (2009) collected near the same sites of fish collection did not show consistent or decreasing trends downstream for a number of elements (Cu, Fe, Mg, Mn, Ni, Pb, V, and Zn). Though three of these elements (As, Fe, and Mg) increased in water samples collected downstream (NMED 2009). Therefore, concentrations of these elements (Cu, Fe, Mg, Mn, Ni, Pb, V, Zn) in silvery minnows may reflect the general elemental composition of the geology around them, or reflect elevated sources, or reflect dietary exposures, which were not quantified by this study. Two elements (Cu and Ni) appeared to be elevated in silvery minnows collected near Site 2 (Table 3), though statistically insignificant in silvery minnows from other sites, this suggested there may be additional sources of copper and nickel near Site 2 as compared with other sites. Several heavy metals (Pb, Zn, Cu, Cr, As, Cd, and Ni) are common pollutants associated with urban stormwater (USEPA 1999), and Site 2 was below stormwater discharges from the Albuquerque urban area.

Aluminum

Aluminum concentrations in silvery minnow carcasses were elevated (82.3 \pm 75.0 μ g/g wet weight), and although concentrations of aluminum generally decreased downstream, aluminum concentrations were not significantly different by site (H=10.54, p=0.06). Aluminum concentrations in silvery minnows (Table 4) were similar to aluminum concentrations in a

variety of fish collected from the Rio Grande by Roy et al. (1992; 45.3 ± 60 $\mu\text{g/g}$ wet weight), Mora (2001; 43.9 ± 106.8 $\mu\text{g/g}$ wet weight), or Schmitt et al. (2004; 16.1 ± 11.6 $\mu\text{g/g}$ wet weight), and to silvery minnows analyzed after 26 days accumulation in the Rio Grande (Buhl 2011; 15.1 ± 7 $\mu\text{g/g}$ wet weight). Aluminum concentrations in silvery minnows were similar to those in fish sampled from the San Juan River (Simpson and Lusk 1999; 152 ± 193 $\mu\text{g/g}$ wet weight).

Aluminum concentrations in whole fish associated with adverse effects (USACE 2010; average 32, range 8 to 77 $\mu\text{g/g}$ wet weight) or with no effects (average 11, range 2 to 9 $\mu\text{g/g}$ wet weight) ranged widely for freshwater fish (Cleveland et al. 1991; Handy 1993; Peterson et al. 1989). The majority of aluminum concentrations in silvery minnows were above the average concentration associated with adverse effects (32 $\mu\text{g/g}$ wet weight). Interestingly, Poston (1991) showed no effects on growth, survival, or feeding in Atlantic salmon (*Salmo salar*) fed up to 200 $\mu\text{g/g}$ wet weight dietary aluminum and salmon carcass concentrations reached 6 $\mu\text{g/g}$ wet weight.

Sites that are acidic (i.e., with pH less than 7) and that have elevated aluminum in water can result in adverse effects to plants, invertebrates and fish (Sparling et al. 1997). Aluminum burdens in fish exposed to acidic conditions have been implicated in reduced growth and survival for both brook trout (Smith and Haines 1985) and smallmouth bass (Kane and Rabeni 1987). For example, adverse effects in Atlantic salmon occurred when aluminum concentrations of 20 $\mu\text{g/g}$ wet weight were reached in fish when exposed to aluminum in water at a pH less than 5.0 (Peterson et al. 1989).

Aluminum is only sparingly soluble in water between pH 6 and pH 8 (ATSDR 2008). New Mexico Environment Department (NMED 2009) reported approximately 2 percent of aluminum was dissolved (0.1 ± 0.2 mg/L) in the water column compared to the total concentration of aluminum (5.3 ± 8.0 mg/L) in the Rio Grande. The minimum average pH in this study (Lusk 2012) was often slightly basic (pH > 8) and few studies conducted have explored aluminum toxicity to fish in alkaline conditions. Considering that aluminum is often a gill toxicant and damage to the gill is greater in acidic water than in neutral or basic waters (Gensemer and Playle 1999), the toxicity residue relation for aluminum under acidic conditions in toxicity effect studies may not be representative of those under slightly basic conditions found in the Rio Grande.

It is also possible that a portion of the aluminum concentrations measured in silvery minnows may have come from ingested or sorbed sediment. Brumbaugh and Kane (1985) reported that whole-body aluminum concentrations in smallmouth bass (*Micropterus dolomieu*) were higher and more variable in fish analyzed with the gastrointestinal tract intact compared to those with the gut contents removed, presumably because of sediment in the gut.

Aluminum concentrations in silvery minnows as well as in other fish collected from the Rio Grande are at concentrations of concern and exceed adverse effect thresholds reported in literature-based studies associated with acidic conditions. Additional research should be conducted to determine if the elevated aluminum concentrations are associated with adverse effects in silvery minnows.

Arsenic

There was a significant difference in dry weight concentrations of (log transformed) arsenic (ANOVA, $F(5,27) = 4.60$, $p = 0.004$) in silvery minnows collected from among the six sites. Post hoc comparisons (using Tukey HSD test) indicated that average arsenic concentrations were highest in fish collected from Site 1 and Site 2 compared with those from Site 6 (Table 3). Arsenic concentrations in fish tissues often increased proportionately to increased dietary and water exposures and duration (Gilderhus 1966; Rankin and Dixon 1994; Buhl 2002). NMED (2009) reported arsenic dissolved in water samples collected near Site 1 ($2.9 \pm 0.8 \mu\text{g/L}$) and near Site 6 ($4.4 \pm 1.3 \mu\text{g/L}$). Between these two sites the average dissolved (log transformed) arsenic concentrations were statistically different ($t(25) = 3.38$, $p = 0.002$). Chapin and Dunbar (1994) reported that arsenic in the Rio Grande reflects the contributions of groundwater and the Jemez River, due to inputs of high-arsenic waters from the Jemez volcanic field. NMED (2009) reported arsenic concentrations in sediment samples collected near Site 1 ($3.3 \pm 1.1 \mu\text{g/g}$) or near Site 6 ($4.0 \pm 2.2 \mu\text{g/g}$), and while average arsenic concentrations generally increased downstream, they were not statistically different. This suggested that differential exposure to arsenic in water or sediment from these two sites might not reflect exposure and arsenic accumulation in silvery minnows collected from these two sites. Arsenic in silvery minnows may instead reflect dietary arsenic or other biological factors (Valette-Silver et al. 1999; Dutton and Fisher 2011).

Average arsenic concentrations in silvery minnow carcasses ($0.9 \pm 0.1 \mu\text{g/g}$ wet weight, Table 4) were higher than average arsenic concentrations in a variety of fish collected from the Rio Grande by Roy et al. (1992; $0.2 \pm 0.5 \mu\text{g/g}$ wet weight), Abeyta and Lusk (2004; $0.2 \pm 0.2 \mu\text{g/g}$ wet weight), Schmitt et al. (2004; $0.2 \pm 0.1 \mu\text{g/g}$ wet weight), but similar to those in silvery minnows after 26 days accumulation (Buhl 2011; $0.6 \pm 0.2 \mu\text{g/g}$ wet weight). Average arsenic concentrations in silvery minnows were elevated compared to those in fish collected from the San Juan River (Simpson and Lusk 1999; $0.1 \pm 0.1 \mu\text{g/g}$ wet weight) and to those in fish collected nationwide (Schmitt et al. 1999; $0.2 \pm 0.3 \mu\text{g/g}$ wet weight). Depending on the form of arsenic in fish tissue, elevated arsenic in fish tissues from the Rio Grande may be appropriate for fish consumption advisories (Wilcox 1997). However, arsenic concentrations in silvery minnows were not considered high enough to represent a hazard to the fish itself, or piscivorous wildlife (Schmitt et al. 2004). For example, McGreachy and Dixon (1992) suggested a threshold for adverse effects of arsenic in fish occurred when concentrations exceeded 3 to 4 $\mu\text{g/g}$ wet weight. Also, Gilderhus (1966) reported significant abnormal ovary and oocyte development occurred in adult fish at 1.7 $\mu\text{g/g}$ wet weight, growth reduction occurred at 2.2 $\mu\text{g/g}$ wet weight, and mortality occurred at 11.6 $\mu\text{g/g}$ wet weight when compared with control fish. While elevated, arsenic in silvery minnows did not exceed levels of concern and likely reflected dietary sources.

Barium

There was a significant difference in the dry weight concentrations of barium (ANOVA, $F(5,27) = 18.97$, $p < 0.05$) in silvery minnows collected from among the six sites. Post hoc comparisons (using Tukey HSD test) indicated that the average barium concentrations were highest at Site 1 and Site 2 and decreased significantly in fish collected downstream (Table 3). NMED (2009) reported barium concentrations in sediment samples collected near the upper sites ($174 \pm 57 \mu\text{g/g}$), near the middle sites ($123 \pm 49 \mu\text{g/g}$), or near the lower sites ($170 \pm 49 \mu\text{g/g}$); and

average concentrations were not statistically different. NMED (2009) reported barium concentrations in water samples collected near the upper sites (0.10 ± 0.03 mg/L), near the middle sites (0.13 ± 0.05 mg/L), or near the lower sites (0.18 ± 0.14 mg/L); and average concentrations were also not statistically different. Barium concentrations in silvery minnows did not reflect those in water or sediment, and also may reflect dietary concentrations. Barium is accumulated by several algal species, including diatoms and desmids (Havlik et al. 1980; Brook et al. 1988; Sedláček et al. 1989). Diatoms are often part of the diet of larval and adult silvery minnows (Shirey 2004; Magaña 2009; USFWS 2010b).

Average barium concentrations in silvery minnows (15.5 ± 4.8 μ g/g wet weight,) appeared higher than average barium concentrations in a variety of fish collected from the Rio Grande by Roy et al. (1992; 2.9 ± 2.5 μ g/g wet weight,), Mora (2001; 3.5 ± 5.4 μ g/g wet weight) and Schmitt et al. (2004; 1.2 ± 0.9 μ g/g wet weight), but similar to those in silvery minnows after 26 days accumulation in the Rio Grande (8.7 ± 3.6 μ g/g wet weight) as reported by Buhl (2011). Barium concentrations in a variety of fish (other than silvery minnows) collected from the Rio Grande did not appear to differ from those in fish collected from the San Juan River (Simpson and Lusk 1999; 3.5 ± 3.4 μ g/g wet weight), from fish collected from the Colorado River (Hinck et al. 2006; 2.5 ± 3.7 μ g/g wet weight) or from fish collected nationwide (3.3 ± 6.1 μ g/g wet weight). Therefore, barium may also reflect a dietary exposure and accumulation in silvery minnows as compared with accumulation found in other fish collected from the Rio Grande and other watersheds. There were insufficient data available to assess the effects of elevated barium in silvery minnows. Additional research should be conducted to determine if elevated concentrations of barium in silvery minnows are associated with adverse effects.

Copper

Copper concentrations in whole fish associated with adverse effects (average 6.6, range 0.7 to 40 μ g/g wet weight) or with no effects (average 5.1, range 0.02 to 16.3 μ g/g wet weight) ranged widely and overlaps for freshwater fish (Handy 1992; Bonham et al. 1987; Jarvinen and Ankley 1999; Kamunde et al. 2005; Kolok et al. 2005). The majority of copper concentrations in silvery minnows (1.8 ± 2.5 μ g/g wet weight) were below the average concentration associated with adverse effects (6.6 μ g/g wet weight). However, several high copper concentrations in silvery minnows collected from Site 1 and Site 2 (8.5-11.8 μ g/g wet weight) were above this level of concern. Additional research should be conducted to determine if the elevated concentrations of copper are associated with adverse effects in silvery minnows at these sites.

Lead

Lead concentrations in whole fish associated with adverse effects (average 3.5, range 0.2 to 6.0 μ g/g wet weight) or with no effects (average 1.3, range 0.2 to 6.0 μ g/g wet weight) overlaps for freshwater fish (Hodson et al. 1978; Weber et al. 1991; Borgman et al. 1993). Lead concentrations in silvery minnows (0.1 ± 0.1 μ g/g wet weight) were below the average concentration associated with adverse effects (1.3 μ g/g wet weight). However, silvery minnows collected in summer 2006 from Sites 1 through 4 had lead concentrations (>0.2 μ g/g wet weight) greater than those found in trout associated with decreased iron concentrations in blood (Hodson et al. 1978). It was unclear why lead was elevated in silvery minnows during summer 2006, or

whether decreased iron may have occurred in silvery minnows that could reduce oxygenation and swimming performance (Hodson et al. 1978). Additional research could be conducted on the physiological effects of episodic or elevated lead concentrations in silvery minnows.

Mercury and Methyl Mercury

Methyl mercury averaged 88 (± 10) percent of the total mercury in silvery minnows. While not statistically significant, mercury (Hg and MeHg) in silvery minnows (on a dry weight basis) appeared to increase downstream (Table 3). The highest concentrations of mercury ($0.10 \mu\text{g/g}$ wet weight) were found in silvery minnows collected from Site 6. Wiener and Spry (1996) described concentrations between 0.01 and $0.1 \mu\text{g/g}$ wet weight as typical in fish collected from environments (without conditions such as low pH or warm temperature) that promote mercury accumulation. Beckvar et al. (2005) reviewed the available residue-effects literature and identified mercury concentrations less than $0.2 \mu\text{g/g}$ wet weight in whole body fish as protective. No silvery minnows exceeded this level of concern.

Nickel

Nickel concentrations in silvery minnows (range <0.1 to $3.6 \mu\text{g/g}$ wet weight) were highest in fish collected at Site 1 and Site 2 (Table 3). Few studies have been conducted evaluating the effects of nickel in whole fish (Jarvinen and Ankley 1999), but recently, Lapointe and Couture (2010) reported increased metabolic rates and enzyme activity in larval fathead minnow (*Pimephales promelas*) at whole body nickel concentrations greater than $2.6 \mu\text{g/g}$ wet weight. That is, elevated nickel exposure and accumulation increased energetic demand and metabolic costs in fathead minnows. While there may be differences between the species life histories, diet, contaminant exposure history, nickel concentrations measured in silvery minnows collected from Site 1 and Site 2 during summer 2006 suggest that they were at concentrations associated with increased metabolic rates in fathead minnows. Additional research should be conducted to determine the effects of elevated nickel concentrations in silvery minnows at upstream sites.

Selenium

While not statistically significant, selenium concentrations (on a dry weight basis) were elevated in silvery minnows collected near Site 5 (Table 3). Site 5 is below the confluence of the Rio Puerco, which drains a watershed that contains selenium-rich soils (Seiler et al. 1999). However, selenium concentrations in silvery minnows were less than the whole-body toxicity threshold of $4 \mu\text{g/g}$ dry weight advocated by Lemly (1996) and Hamilton (2002, 2003). Concentrations in silvery minnows were also lower than those linked with reduced growth (5.4 to $7.0 \mu\text{g/g}$ dry weight) in fathead minnows exposed to dietary selenium (Ogle and Knight 1989). Selenium concentrations in silvery minnows ($0.5 \pm 0.1 \mu\text{g/g}$ wet weight) were similar to those in fish collected from the Rio Grande reported by Roy et al. (1992; $0.4 \pm 0.3 \mu\text{g/g}$ wet weight), Mora (2001; $0.3 \pm 0.2 \mu\text{g/g}$ wet weight), Abeyta and Lusk (2004; $0.8 \pm 0.7 \mu\text{g/g}$ wet weight), Schmitt et al. (2004; $0.7 \pm 0.4 \mu\text{g/g}$ wet weight), and in silvery minnows after 26 days accumulation (Buhl 2011; $0.8 \pm 0.2 \mu\text{g/g}$ wet weight), or in fish collected nationwide ($0.5 \pm 0.5 \mu\text{g/g}$ wet weight).

Vanadium

Vanadium concentrations in silvery minnows ranged from 0.1 to 0.8 $\mu\text{g/g}$ wet weight. No toxic threshold has been proposed for vanadium concentrations in fish, but Hilton and Bettger (1988) reported that a dietary toxic threshold to juvenile rainbow trout (*Oncorhynchus mykiss*). Reduced feeding and growth were seen in trout with carcass concentrations averaging 0.4 $\mu\text{g/g}$ wet weight. At higher concentrations in trout (>5.3 $\mu\text{g/g}$ wet weight), feed avoidance was increased, body weight was reduced, and mortalities were apparent (Hilton and Bettger 1988). Hilton and Bettger (1988) observed that the major physiological effect of vanadium in the trout was increased *in vivo* lipid oxidation. Silvery minnows from several upstream sites had vanadium concentrations above 0.4 $\mu\text{g/g}$ wet weight when reduced feeding and growth were observed in trout. However, as the physiology of trout, a carnivore, and silvery minnow, an initial herbivore and later omnivore, may substantially differ, and there are few studies with which to compare, additional research should be conducted to determine whether growth or metabolic effects occur in silvery minnows associated with elevated vanadium residues.

Zinc

Average zinc concentrations in silvery minnows (38 ± 6 $\mu\text{g/g}$ wet weight) were similar to those in a variety of fish collected from the Rio Grande and reported by Roy et al. (1992; 33 ± 16 $\mu\text{g/g}$ wet weight), Schmitt et al. (2004; 39 ± 24 $\mu\text{g/g}$ wet weight), and in silvery minnows after 26 days accumulation (Buhl 2011; 50 ± 18 $\mu\text{g/g}$ wet weight), but higher than fish collected from the Rio Grande in Texas (Mora 2001; 13 ± 13 $\mu\text{g/g}$ wet weight). Zinc concentrations in a variety of other fish collected from the Rio Grande were similar to those in fish collected from the San Juan River (Simpson and Lusk 1999; 29 ± 23 $\mu\text{g/g}$ wet weight), in fish collected from the Colorado River (Hinck et al. 2006; 47 ± 31 $\mu\text{g/g}$ wet weight), and in fish collected nationwide (Schmitt et al. 1999; 39 ± 24 $\mu\text{g/g}$ wet weight).

Zinc concentrations in whole fish associated with adverse effects (average 58, range 5 to 220 $\mu\text{g/g}$ wet weight) or with no effects (average 72, range 0.3 to 300 $\mu\text{g/g}$ wet weight) ranged widely and overlapped in both marine and freshwater fish (Spehar 1976; Spehar et al. 1978; Farmer et al. 1979; Pierson 1981; Sherwood et al. 2000; Dube et al. 2005; USACE 2010). No zinc concentrations in silvery minnows were above the average concentration associated with adverse effect (58 $\mu\text{g/g}$ wet weight). However, zinc concentrations in silvery minnows from all sites were higher than that (40 $\mu\text{g/g}$ wet weight) associated with reduced growth in flagfish (*Jordanella floridae*) (Spehar 1976). Additional research should be conducted to determine if elevated concentrations of zinc are associated with reduced growth in silvery minnows.

Lipid and Moisture Content

Lipids are one of the main energy sources in fish. The stored energy available to a fish, as reflected in its body composition and energy reserves, may also influence its survival and reproduction (Breck 2008). Organic chemicals partition primarily into lipids within an organism and lipid content represents the capacity of an animal to accumulate those chemicals (Di Toro et al. 2000) as well as provides some resistance to chemical toxicity (Lassiter and Hallam 1990). However, when lipids are mobilized as an energy source, lipid-soluble chemicals tend to

partition from the lipid reserves into the bloodstream and increase the potential adverse effects on an organism (de Freitas and Norstrom 1974; Paterson et al. 2007). Lipid contents are often used to normalize organic pollutant concentrations, to reduce the variability within and between species and sexes, and normalization improves toxicity relationships for lipid soluble compounds when lipid and contaminant concentrations vary proportionally (Hebert and Keenleyside 1995).

Lipid content of silvery minnows ranged from 4.1 to 10.8 percent and averaged 6.9(±1.4) percent, but did not vary significantly by site or season or sample year (Table 5). However, lipid results may have been confounded by compositing fish of different size classes. Similar lipid content in fish collected from the Rio Grande was reported by Roy et al. (1992; 6.0±3.4 percent) and Schmitt et al. (2004; 4.5±2.9 percent) and in fish collected nationwide (Schmitt et al. 1999; 6.2±4.2 percent).

Moisture content in silvery minnows were not significantly different by site (Table 3). The average moisture content in silvery minnows in this study (71.9±1.9 percent) were similar to those in a variety of fish collected from the Rio Grande by Roy et al. (1992; 73.0±4.9 percent), Schmitt et al. (2004; 72.9±3.0 percent), and silvery minnows after 26 days accumulation (Buhl 2011; 73.0±1.7 percent), or in fish collected nationwide ((Schmitt et al. 1999; 72.1±4.5 percent).

A Pearson product-moment correlation coefficient was computed to assess the relationship between the moisture content and lipid content in silvery minnows. There was a significant negative correlation between the two variables ($r = -0.731$, $n = 27$, $p < 0.05$). This suggests that increases in moisture content are correlated with decreases in lipid content in silvery minnows and vice versa. Therefore, a relationship between lipid content and moisture content was modeled using linear regression analysis to predict lipid content:

$$\begin{aligned} \text{Percent Lipid} &= 78.6877 - (0.9945 * \text{Percent Moisture}) && \text{Equation 2} \\ \text{Percent Moisture} &= 45.2892 - (0.5366 * \text{Percent Lipid}) && \text{Equation 3} \end{aligned}$$

If lipid content and moisture content are related as described by Equation 3, then a lipid content of 3 percent would translate to a moisture content of 78.8 percent; which would likely be the maximum moisture content of healthy silvery minnows. Mortalities occurred when lipid content was 3.2 percent or less in fish (Simpkins et al. 2003). Silvery minnows were not found to have lipid contents less than 3.2 percent.

Aliphatic and Aromatic Hydrocarbons

Analytical data for contaminant concentrations of organic chemicals and lipid content in silvery minnow carcasses are found in Appendix 3E and selectively summarized in Table 5. Three hundred and fifty-three organic contaminants were analyzed in carcass samples (Appendix 3E), however, 256 chemicals (73 percent) were detected in less than 75 percent of the samples analyzed, and therefore, those organic chemicals were not compared statistically nor evaluated further with the exception of n-undecane. However, all aliphatic hydrocarbons were used to help identify sources and interpret results. Several of the organic contaminants in silvery minnows are further discussed below.

Aliphatic Hydrocarbons

Aliphatic hydrocarbons (1.2 ± 2.9 $\mu\text{g/g}$ wet weight) were detected in all silvery minnows collected from five sites during January 2008 (Appendix 3E, Table 5). Differentiating petrogenic from biogenic compounds is important to demonstrate a pathway between the sources of hydrocarbons and their deposition in fish tissues. In general, the origin of organic matter can be obtained by analyzing the composition of aliphatic hydrocarbons, their peaks and ratios, or through the composition of the carbon preference index (Bray and Evans 1961). None of the hydrocarbons detected in silvery minnows had equal proportions of odd- and even-numbered aliphatic hydrocarbons indicative of petrogenic sources such as oil spills (Hall and Coon 1988). Also, all ratios of pristane-to-n-heptadecane or phytane-to-n-octadecane were low in silvery minnows, indicating no recent or chronic exposure to petroleum compounds in their diet (Anderson et al. 1978, Farrington et al. 1973, Hall and Coon 1988). Pristane-to-phytane ratios were also low (0.73 ± 0.03), except at Site 1 (>1.1), which indicated that petrogenic aliphatic hydrocarbons were not those present in silvery minnows. Petrogenic hydrocarbons have much lower pristane-to-phytane ratios ranging from 0.14 to 0.36 (Roushdy et al. 2010). Pristane-to-phytane ratios (approximately 0.8) are indicative of carbonate-dominated habitats (ten Haven et al. 1987).

The presence of aliphatic hydrocarbons with a maximum of 20 to 35 carbons and with dominance of odd numbers of carbon atoms can be used to indicate the prevalence of higher land plant waxes though source identification is not always certain (Tornabene 1980; Cranwell 1984; Jeng and Huh 2008). By using the presence of higher chain hydrocarbons, we estimated that 34 and 39 percent of the aliphatic hydrocarbons in silvery minnows at Site 3 and Site 4 were from terrestrial plant sources. Up to 12 percent of the aliphatic hydrocarbons in silvery minnows at Site 1 were from terrestrial plant sources; whereas, silvery minnows from Site 2 and Site 6 contained less than 5 percent of aliphatic hydrocarbons of terrestrial plant origin.

The contribution of phytoplankton and diatoms in silvery minnows can be difficult to recognize due to the low abundance of aliphatic hydrocarbons in certain species of algae (Tornabene 1980). However, significant amounts of 15, 19, and particularly 17 carbon chain aliphatic hydrocarbons, has been interpreted as an indicator of hydrocarbons of algal origin (Cranwell 1984; Jeng and Huh 2008). Using these carbon chain aliphatics as indicators, silvery minnows collected in January 2008 at Site 2 and Site 6 contained approximately 92 and 91 percent of aliphatic hydrocarbons from algal origin; whereas silvery minnows at Site 1 contained 28 percent; and, silvery minnows at Site 3 and Site 4 contained approximately 60 percent of aliphatic hydrocarbons from algal origin. These hydrocarbon indicators suggested a wide variety of plant materials can be present in silvery minnows at different locations and during different seasons.

Silvery minnows in January 2008 collected from Sites 2 through 6 contained 5 percent (or less) of petrogenic aliphatic hydrocarbons (that is, they had few aliphatic chains with less than 15 carbons associated with oil, gasoline, or diesel fuels) (Neff 1979). However, silvery minnows collected at Site 1 contained an inordinate amount of n-undecane (18.5 $\mu\text{g/g}$ wet weight) with over 58 percent of their hydrocarbon burden being indicative of petrogenic origin. This is the highest concentration of n-undecane ever reported in freshwater fish. N-undecane is indicative of diesel range organic compounds such as kerosene-based fuels, solvents, paints, and soot

(Technical Resources International, Inc. 2003), perhaps from idling traffic on the 550 Bridge above Site 1, or from other unknown sources nearby.

Aromatic Hydrocarbons

A variety of aromatic hydrocarbons were detected in silvery minnows (total PAHs were 66 ± 11 $\mu\text{g}/\text{kg}$ wet weight) from five sites collected in January 2008 (Table 5, Appendix 3E). PAHs are found everywhere in the environment and are formed by burning organic matter (Neff 1979; Eisler 1987). PAHs are commonly found in used motor oil, exhaust from internal combustion engines and emissions from fossil fuel powered energy plants, grilled foods, forest fires, and volcanoes, as well as most products made from coal and petroleum (National Research Council 1983; Eisler 1987). PAH concentrations in freshwater varies widely, depending upon such factors as proximity of the waterbody to the source, source type, and season. PAH concentrations in fish depend upon their proximity to the source of pollution, the physical and chemical properties of the PAH molecule, environmental variables, the PAH content of the diet, and biological factors (Moore and Ramamoorthy 1984; Eisler 1987; McElroy et al. 1989).

Several PAHs, especially those containing 4 to 6 aromatic rings in their structure, have been shown to be mutagenic, carcinogenic, and inducers of tumors in animals exposed to high doses of PAHs in the laboratory. Studies directly linking PAHs to these effects in wild fish are few in number (Albers 2003). From studies conducted in the Great Lakes basin, the International Joint Commission recommended that concentrations of the PAH benzo[a]pyrene not exceed 1.0 $\mu\text{g}/\text{g}$ in fish. Average PAH concentrations in silvery minnows (1.5 ± 2.6 $\mu\text{g}/\text{kg}$ wet weight) were nearly 10 times lower than this threshold of concern. Concentrations of PAHs in silvery minnows tended to reflect the patterns of PAHs in sediment samples (NMED 2009) with higher concentrations detected at the middle sites near Albuquerque, New Mexico (Table 5).

Certain PAHs, particularly naphthalene and its alkylated derivatives, such as 1-methylnaphthalene, 2-methylnaphthalene, 2,6-dimethylnaphthalene, C1-methylnaphthalene, C2-naphthalene, C3-methylnaphthalene, C4-methylnaphthalene, but also phenanthrene, fluoranthene, and fluorene, were relatively elevated in silvery minnow carcasses compared to the other PAHs (Table 5, Appendix 3E). Many of these PAHs either components of weathered oil or were combustion-related hydrocarbons. For example, combustion related hydrocarbons such as phenanthrene and its derivatives averaged 2.7 percent, fluoranthene and its derivatives averaged 1.4 percent, chrysene and its derivatives averaged 0.7 percent, and pyrene and its derivatives average 0.6 percent of the total PAHs measured in silvery minnows. Naphthalenes and its derivatives were the highest percentage (average 6 percent) of the total PAHs measured in silvery minnows. Biphenyl occurs in weathered coal tar, crude oil, and natural gas and averaged 4 percent of the total PAHs measured in silvery minnows.

Naphthalene and its alkylated derivatives were consistently detected in silvery minnows (15 ± 2 $\mu\text{g}/\text{kg}$ wet weight) (Table 5). Naphthalenes are not generally reported in fish, but were detected at concentrations below 3 $\mu\text{g}/\text{kg}$ wet weight in fish from the Pacific Coast (Easton et al. 2002). Naphthalene is a white solid with a strong smell and is also called mothballs. Naphthalene is a component of fossil fuels such as gasoline, diesel, oils and coal; it is also formed when natural products such as wood or tobacco are burned. Naphthalene has a short half life in water.

Naphthalene derivatives were detected at low concentrations in sediment samples collected by the NMED (2009) from Site 3 (5.6 µg/kg wet weight) and were less than naphthalene sediment toxicity thresholds (Buchman 2008). Notably, the pattern of accumulation of naphthalene and its derivatives was similar in silvery minnows collected along the Rio Grande suggesting exposure to widespread atmospheric sources of PAHs (Table 5).

High concentrations of PAHs in fish have been associated with decreases in health measures, increased lesions, increased genetic alterations, and altered populations (Albers 2003). PAHs in fish tissues from uncontaminated areas were generally less than 10 µg/kg wet weight and from contaminated areas were generally greater than 100 µg/kg wet weight (Eisler 1987). PAHs in fish are usually low because fish rapidly metabolize PAHs or excrete them, though there is a metabolic cost associated with the increased enzyme activity (Albers 2003; Colavecchia et al. 2004). Therefore, silvery minnows were considered moderately contaminated with PAHs (average total PAHs 66±11 µg/kg wet weight). However, effects of PAHs in silvery minnows are difficult to generalize as the incidence of lesions, effects of any genetic alterations and metabolic pathways of PAHs in fish varies by species (Albers 2003). Additionally, few studies have been conducted on wild fish (Albers 2003). Additional research should be conducted to determine the growth effects or lesions associated with elevated PAHs in silvery minnows.

Organochlorine (OC) Pesticides, Dioxins, PCBs, and PBDEs

A variety of OC pesticides (total OCs 54±26 µg/kg wet weight) were detected in silvery minnows collected variously from all six sites during 2006 to 2008 (Table 5, Appendix 3E). The DDT metabolite, p,p'-DDE, accounted for the majority (43±14 percent) of the sum total of the OC pesticides detected in silvery minnows. Trans-nonachlor (11±4 percent), alpha chlordane (9±4 percent), and endosulfan sulfate (6±2 percent) were also detected at greater concentrations than the remainder of the OC pesticides (<1 to 5 percent) and are discussed below.

Total DDTs

DDT became widely used in the 1940s and was extremely effective controlling pest vectors until it was banned by the USEPA in January 1973 due to its long residual life in the environment and its accumulation in food chains (Beckvar and Lotufo 2011). The term total DDT refers to the sum of DDT and its metabolites (DDE, DDD, and DDMU), including the ortho para (o,p' or 2, 4) and para para (p,p' or 4, 4) isomers. Total DDT in silvery minnow carcasses was mostly DDE (83 percent), DDD (12 percent) and DDMU (3 percent). However, approximately 2 percent of the parent chemical (DDT) was still detected suggesting use of DDT in the environment and transport to the Rio Grande watershed has not ceased. Similar proportions of DDT (8 percent) and its metabolites DDE (80 percent) and DDD (13 percent) were reported in fathead minnow by Jarvinen et al. (1976).

Average concentrations of total DDT in silvery minnow carcasses (18±7 µg/kg wet weight) were similar to those found in fish sampled throughout the Rio Grande (Schmitt et al. 2004; 43±16 µg/kg wet weight), but generally less than those found in fish sampled nationwide (Schmitt et al. 1999; 240±800 µg/kg wet weight). No significant linear relationships was found between the concentrations of total DDT in silvery minnows and their lipid content. An ANOVA tests found

significant differences in wet weight concentrations of total DDT ($F(2,9)=14.2$, $p=0.002$) in silvery minnows collected from the middle sites (Site 3 and Site 4) than in those collected from the upper (Site 1 and Site 2) or lower sites (Site 5 and Site 6). As there are no known sources of total DDT near Site 3 and Site 4, it is possible that the rate of bioaccumulation or diet of silvery minnows is greater in this section of the river. Concentrations of total DDT in silvery minnows were below the lethal effects threshold of $600 \mu\text{g}/\text{kg}$ wet weight reported by Beckvar and Lofuto (2011). However, recent research have focused on endocrine disruption and other sublethal effects that have been observed at concentrations of total DDT similar to and up to two orders of magnitude lower than in lethal studies with older fish life stages (Beckvar and Lofuto 2011). Therefore, additional research could be conducted to determine if total DDT detected in silvery minnows are associated with any adverse sublethal effects.

Endosulfan

Designed in the 1950s, endosulfan is an organochlorine insecticide that can be used on a wide variety of vegetables, nuts, fruits, cotton, and ornamental plants. Endosulfan is a member of the class of the cyclodiene pesticides and consists of two isomers (endosulfan I and II), and a sulfur metabolite (Beckvar and Lotufo 2011). Endosulfan was recently banned in the United States due to continued risk to farm workers, wildlife, fish quality, and the environment, with a complete phase out of agricultural use of the chemical by 2016 (USEPA 2010).

Concentrations of endosulfan sulfate in silvery minnow carcasses ($2.4\pm 1.5 \mu\text{g}/\text{kg}$ wet weight) were higher than endosulfan concentrations in larger-bodied fish ($< 0.2 \mu\text{g}/\text{kg}$ wet weight) collected from the Rio Grande by NMED (2009). No significant linear relationship was found between concentrations of endosulfan in silvery minnows and their lipid content. There was a significant positive relationship ($r = 0.668$, $n = 10$, $p = 0.017$) between concentrations of endosulfan sulfate in silvery minnows and their average weight in composite samples. However, average weights of the composited fish were not significantly different by site or by section of river, even though some of the larger fish were in collections of fish from Site 3 and Site 4. An ANOVA test found significant differences in carcass wet weight concentrations of endosulfan sulfate ($F(2,9)=13.6$, $p=0.001$) collected from the middle sites (Site 3 and Site 4) than in those collected from the upper or lower sites (Table 5). The NMED (2009) sampled endosulfan in sediments collected from the Rio Grande during 2006 to 2008, and three of the highest concentrations ($0.05 \mu\text{g}/\text{g}$ wet weight) were found in the Rio Grande near Site 3. Reasons for elevated endosulfan sulfate in silvery minnows from the middle sites are unclear. There were elevated sediment concentrations of endosulfan sulfate near Site 3, but also bioaccumulation rates or diets in silvery minnows from the middle sites may differ in this river section.

Several fish species experienced mortality associated with whole body concentrations of endosulfan sulfate as low $31 \mu\text{g}/\text{kg}$ wet weight (Beckvar and Lotufo 2011). Morphological changes in the liver and enzyme activity reductions in brain, liver, and skeletal muscle were reported in fish at concentrations as low as $1 \mu\text{g}/\text{kg}$ wet weight, becoming more severe at concentrations greater than $5 \mu\text{g}/\text{kg}$ wet weight (European Food Safety Authority 2011). As concentrations of endosulfan and endosulfan sulfate in silvery minnows exceeded levels of concern, particularly in those collected from Site 3 and Site 4, additional research should be conducted to determine the effects of elevated concentrations in silvery minnows.

Trans-nonachlor

Trans-nonachlor is the common name for 1,2,3,4,5,6,7,8,8-nona-chloro-3a,4,7,7a-tetrahydro-4,7-methanoindan, and it is a member of the class of the cyclodiene pesticides (e.g., “technical chlordane”) that were often used for management of subterranean termites (Isoptera). Chlordane mixtures (including alpha chlordane) were first produced in 1948, though commercial uses were later banned (1988) in the U.S.A. due to concerns about the risk of cancer (USEPA 2004).

Trans-nonachlor is the most bioaccumulative component of chlordane (USEPA 2004). Average concentrations of trans-nonachlor in silvery minnow carcasses (5 ± 3 $\mu\text{g}/\text{kg}$ wet weight) were similar to those found in fish sampled throughout the Rio Grande (Schmitt et al. 2004; 10 ± 13 $\mu\text{g}/\text{kg}$ wet weight), but generally less than those found in fish sampled nationwide (Schmitt et al. 1999; 39 ± 102 $\mu\text{g}/\text{kg}$ wet weight). No significant linear relationships was found between concentrations of trans-nonachlor in silvery minnows and their lipid content. An ANOVA test found significant differences in wet weight concentrations of trans-nonachlor ($F(2,9)=24.6$, $p<0.001$) in silvery minnows collected from the middle sites (Site 3 and Site 4) than in those collected from the upper sites (Table 5). Unless there are sources of trans-nonachlor (and many other organic chemicals) in the vicinity of Site 3 and Site 4, it is likely that bioaccumulation rate in fish at these sites was greater in this section of the river. Concentrations of trans-nonachlor in silvery minnows do not exceed levels of concern (Eisler 1990; Beckvar and Lotufo 2011).

PCBs

PCBs do not occur naturally in the environment. PCBs have been used as hydraulic lubricants, insulators, heat transfer fluids, dielectric fluid for transformers and capacitors, pesticide extenders, dust-reducing agents, flame retardants, sealants, and organic diluents (Hutzinger et al. 1974). PCBs accumulate from air, water, and in animals through the food web because they are highly lipid-soluble and persistent in the environment. PCBs were introduced in the U.S.A. in 1929 and certain uses were banned in 1979 (USEPA 1979). PCBs have been shown to adversely affect reproduction, thymic atrophy, enzyme induction, nervous systems dysfunction, behavioral abnormalities, liver injury, estrogenic activity, endocrine disruption, immune system suppression, deformities, hepatotoxicity, and tumor promotion in fish, wildlife, and experimental animals, and it is toxic to people (Eisler and Belisle 1996; Hoffman et al. 1996; Niimi 1996; ATSDR 2000; NMED 2009; Wenning et al. 2011).

Average total PCB concentrations in silvery minnows (15.3 ± 10.1 $\mu\text{g}/\text{kg}$ wet weight) were higher than average concentrations in channel catfish (*Ictalurus punctatus*) fillets (4.6 ± 5.3 $\mu\text{g}/\text{kg}$ wet weight), or in white bass (*Morone chrysops*) fillets from Cochiti Reservoir (Gonzales and Fresquez 2006), but less than average total PCB concentrations in whole body carp (90.7 ± 13.0 $\mu\text{g}/\text{kg}$ wet weight) or in white bass fillets (177 $\mu\text{g}/\text{kg}$ wet weight) collected from the Rio Grande (NMED 2009, New Mexico Water Quality Control Commission 2010). Average concentrations of total PCBs in silvery minnows were in the low range of average total PCB concentrations reported in whole body cyprinids (range 18-320 $\mu\text{g}/\text{kg}$ wet weight) collected across the U.S.A. (Stahl et al. 2009). Interestingly, the pattern and ratios of the different PCB congeners in silvery minnows were generally consistent between sites, but varied by sample year, suggesting PCB

congener patterns may vary by season, reflect atmospheric deposition patterns and sources, or reflect different rates of bioaccumulation, diet, or elimination processes in these fish.

Total PCB concentrations in whole fish associated with adverse effects (average 118, range 0.1 to 1502 $\mu\text{g/g}$ wet weight) or with no effects (average 431, range 0.1 to 4668 $\mu\text{g/g}$ wet weight) ranged widely and overlapped for marine and freshwater fish (USACE 2010; Wenning et al. 2011). No total PCB concentrations in silvery minnows were above the average concentration associated with adverse effect (118 $\mu\text{g/g}$ wet weight). However, effect studies using total PCB concentrations ranged so widely as to make comparisons with concentrations in silvery minnows unsatisfactory. For example, toxicity studies for PCB-153 and PCB-180 with effects in common carp (*Cyprinus carpio*) were 0.04 $\mu\text{g/g}$ wet weight and 0.06 $\mu\text{g/g}$ wet weight, respectively, while the same two PCB congeners have higher effect concentrations for fathead minnow, ranging from 6,030,000 and 4,565,000 $\mu\text{g/g}$ wet weight, respectively. Concentrations of PCB-153/163 and PCB-180/193 in silvery minnows were 1.4 ± 0.9 $\mu\text{g/g}$ wet weight and 1.3 ± 0.9 $\mu\text{g/g}$ wet weight, respectively, and therefore, exceed the effect studies involving carp but do not exceed the no effect studies involving fathead minnow.

During a review of the PCB toxicity thresholds for endangered fish, Meador (2000) derived a concentration associated with adverse effects at 2400 $\mu\text{g/kg}$ dry weight on a per lipid basis. Average total PCB concentrations in silvery minnows (838 ± 499 $\mu\text{g/kg}$ dry weight on a per lipid basis) were below this threshold. Also, Olsson et al. (1999) reported skeletal deformities including craniofacial malformations associated with fish injected with 360 $\mu\text{g/kg}$ PCB-190 wet weight on a per lipid basis. Silvery minnows had PCB-190 concentrations lower than 36 $\mu\text{g/kg}$ wet weight on a per lipid basis. This suggests that PCB-induced deformity would be unlikely in the silvery minnows unless they were more sensitive than the zebrafish (*Danio rerio*) used by Olsson et al. (1999), therefore, PCB-90 is unlikely the cause of the deformed opercula commonly observed in silvery minnows (Davis and Lusk 2012). However, given the wide range of effect concentrations in fish, additional research could be conducted to determine if individual PCB congener concentrations in silvery minnows are associated with adverse sublethal effects.

Dioxins, Dibenzofurans, and TEQs

Certain PCB congeners are able to line up in a flat configuration and are considered “dioxin-like” as they may have a fraction of toxic equivalency (TEQ) to dioxin (i.e., 2,3,7,8-TCDD) (Wenning et al. 2011). Dioxins and dibenzofurans were not detected above the LOD in silvery minnows. Toxic equivalency factors (TEFs) from Van den Berg et al. (1998) were used for certain PCB congeners (PCB-105, PCB-118, PCB-156/157, and PCB-167) in silvery minnows to calculate TEQs. TEQs for silvery minnows ranged from 0.08 picograms TCDD per gram (pg /g) wet weight in silver minnows collected from Site 6 to 1.2 pg/g wet weight in fish collected from Site 3. TEQs in silvery minnows averaged 0.3 ± 0.3 pg/g wet weight and averaged 4.3 ± 4.1 pg/g wet weight on a per lipid basis. TEQs in silvery minnows were below those reported by Gonzales and Fresquez (2006) in fillets from fish collected from Abiquiu and Cochiti Reservoirs (range 3 to 300 pg/g wet weight), in fish collected from the Rio Grande (Schmitt et al. 2004; 1.8 ± 1.2 pg/g), or in large bodied fish collected from the Rio Grande (NMED 2009; 2.1 ± 0.9 pg/g wet weight). Steevens et al. (2005) proposed no effect and low effect tissue residue benchmarks from 57 to 700 pg /g wet weight on a lipid basis to protect early life stage fish. Concentrations in

silvery minnows would fall well below that range of potential effects in fish. Therefore, dioxin toxicity or its toxic equivalence using PCB congeners is not expected in silvery minnows at the tissue concentrations detected.

PBDEs

Total BDE in silvery minnows carcasses averaged 138 ± 142 $\mu\text{g}/\text{kg}$ wet weight and ranged from 11 $\mu\text{g}/\text{kg}$ wet weight at Site 1 to 477 $\mu\text{g}/\text{kg}$ wet weight at Site 4 (Table 5, Appendix 3E). On average, 76 percent of total BDE in silvery minnow carcasses was BDE-47, followed by BDE-100, BDE-154, BDE-49/71 and BDE-28, at 9, 3, 2.5 and 2 percent, respectively, similar to BDE congener patterns detected in other feral fish (Wenning et al. 2011). Patterns of the relative ratios of BDEs were similar in fish by site within a sample year than between sample years. For example, BDE-206 was not detected in silvery minnows collected in 2006, but was detected in silvery minnows collected during 2008 (Appendix 3E).

Little information is available, at present, on the toxicity of PBDEs in fish (Wenning et al. 2011). BDE-47 concentrations in whole fish associated with adverse effects (average 180, range 70 to 410 $\mu\text{g}/\text{g}$ wet weight) or with no effects (average 140, range 3 to 410 $\mu\text{g}/\text{g}$ wet weight) ranged widely and overlapped for freshwater fish (Chen et al. 2010, Chou et al. 2010, USACE 2010). BDE-47 in silvery minnow carcasses averaged 110 ± 117 $\mu\text{g}/\text{kg}$ wet weight and ranged from 6 $\mu\text{g}/\text{kg}$ wet weight at Site 1 to 385 $\mu\text{g}/\text{kg}$ wet weight at Site 4 (Appendix 3E, Table 5). None of the BDE-47 concentrations in silvery minnows were above the average concentration associated with adverse effect (180 $\mu\text{g}/\text{g}$ wet weight). In a fathead minnow study, Muirhead et al. (2006) reported that egg laying in breeding pairs stopped after accumulation of BDE-47 in 10 days and cessation of spawning appeared to have occurred when peak body levels of 15 $\mu\text{g}/\text{g}$ wet weight were reached in male fathead minnow. BDE-47 was not elevated above these thresholds of concern in silvery minnows. However, additional research on the effects of BDEs is warranted as there are few studies on the effects of PBDEs in fish. Marr et al. (2010) described research into the effects of BDE-47 on silvery minnows being conducted by the U.S. Geological Survey's Columbia Environmental Research Center.

CONCLUSIONS

Concentrations of inorganic contaminants in silvery minnows were similar to those in other fish species collected from the Rio Grande and were generally low, except for aluminum and zinc. Aluminum and zinc were moderately elevated in silvery minnows throughout the Middle Rio Grande, but were similar to concentrations in fish from other watersheds in New Mexico. Several elements, arsenic and barium, decreased in silvery minnows in a downstream manner, though concentrations of these elements in water or sediment did not also decrease downstream. Certain elements, including copper, lead, and nickel, were elevated in silvery minnows collected from the upper sites above levels of concern for these elements in laboratory studies involving sublethal effects. Research into the sublethal effects of aluminum, copper, lead, nickel, and zinc on silvery minnows is warranted.

Generally, organic contaminant concentrations in silvery minnows were low, except for PAHs. Certain PAHs, mostly naphthalenes, were moderately elevated in silvery minnows sampled throughout the Middle Rio Grande. One aliphatic hydrocarbon, n-undecane, common in fuels and diesel soot, was also elevated in silvery minnows collected at Site 1, the Rio Grande at Bernalillo, New Mexico. It was unclear why concentrations of several organochlorine pesticides, PCBs, and PBDEs, were elevated in silvery minnows collected from Site 3 and Site 4. Flame retardant chemicals, such as PBDEs used in furniture foam, were higher in silvery minnows than were total DDTs or total PCBs, but were below levels of concern compared with laboratory studies. Research into the sublethal effects of PAHs on silvery minnows is warranted.

- Water Quality Monitoring
- ▬ Diversion Dams
- Freeway System
- 🐟 Fish Collection Events
- Surface Waters

Figure 2. Location of the Six RGSM Health Study Sites along the Middle Rio Grande in New Mexico.

Table 1. Site number, site name name, latitude and longitude (in decimal degrees) of a central point, and description of the RGSM Health Study sampling sites.

Site Number	Site Name	Latitude and Longitude (central point - decimal degrees)	Site Location Description
1	Rio Grande at Bernalillo, New Mexico	35.3181, -106.5589	approximately 0.1 mi upstream to 0.8 mi downstream of the Highway 550 Bridge crossing
2	Rio Grande at Alameda, New Mexico	35.2101, -106.6172	approximately 0.7 mi upstream and 1.1 mi downstream of AMAFCA North Diversion Channel mouth
3	Rio Grande at Los Padillas, New Mexico	34.9716, -106.6897	Just north of the Interstate 25 Bridge to approximately 5 mi upstream
4	Rio Grande at Los Lunas, New Mexico	34.8228, -106.7149	approximately 0.6 mi to 2.4 mi north of the Main Street (Highway 6) Bridge crossing
5	Rio Grande at La Joya, New Mexico	34.3073, -106.8493	approximately 2.4 mi to 3.8 mi north of the confluence with the Rio Salado
6	Rio Grande near San Antonio, New Mexico	33.8775, -106.8495	approximately 0.5 mi downstream and 1.2 mi upstream of Bosque del Apache National Wildlife Refuge (BdANWR) North Boundary

Table 2. Chemical names, abbreviations, analytical methods, limit of detection. ["<", less than; "NA", not available]

Chemical Grouping	Analytical Method¹	Limit of Detection²	Chemical Name or Abbreviation³	CAS⁴ Number	Alternative Chemical Name
Aromatic hydrocarbon	GCMS	<0.45	1,6,7-trimethylnaphthalene	2131386	1,6,7-trimethylnaphthalene
Aromatic hydrocarbon	GCMS	<0.20	1-methylnaphthalene	90120	1-methylnaphthalene
Aromatic hydrocarbon	GCMS	<0.51	1-methylphenanthrene	832699	1-methylphenanthrene
Aromatic hydrocarbon	GCMS	<0.64	2,6-dimethylnaphthalene	28804888	2,6-dimethylnaphthalene
Aromatic hydrocarbon	GCMS	<0.20	2-methylnaphthalene	91576	2-methylnaphthalene
Aromatic hydrocarbon	GCMS	<0.24	acenaphthalene	208968	acenaphthalene
Aromatic hydrocarbon	GCMS	<0.41	acenaphthene	83329	acenaphthene
Aromatic hydrocarbon	GCMS	<0.20	anthracene	120127	anthracene
Aromatic hydrocarbon	GCMS	<0.37	benzo(a)anthracene	56553	benzo(a)anthracene
Aromatic hydrocarbon	GCMS	<0.45	benzo(a)pyrene	50328	benzo(a)pyrene
Aromatic hydrocarbon	GCMS	<0.32	benzo(b)fluoranthene	205992	benzo(b)fluoranthene
Aromatic hydrocarbon	GCMS	<0.46	benzo(e)pyrene	192972	benzo(e)pyrene
Aromatic hydrocarbon	GCMS	<0.53	benzo(g,h,i)perylene	191242	benzo(g,h,i)perylene
Aromatic hydrocarbon	GCMS	<0.41	benzo(k)fluoranthene	207089	benzo(k)fluoranthene
Aromatic hydrocarbon	GCMS	<0.31	biphenyl	92524	phenylbenzene
Aromatic hydrocarbon	GCMS	<0.94	C1-chrysenes	NA	Any or all methyl chrysene isomers
Aromatic hydrocarbon	GCMS	<0.68	C1-dibenzothiophenes	NA	Any or all methyl dibenzothiophene isomers
Aromatic hydrocarbon	GCMS	<1.26	C1-fluoranthenes & pyrenes	NA	Any or all methyl fluoranthene and methyl pyrene isomers
Aromatic hydrocarbon	GCMS	<0.81	C1-fluorenes	NA	Any or all methyl fluorene isomers
Aromatic hydrocarbon	GCMS	<2.26	C1-naphthalenes	NA	Any or all methyl naphthalene isomers
Aromatic hydrocarbon	GCMS	<0.60	C1-phenanthrenes & anthracenes	NA	Any or all methyl phenanthrene and methyl anthracenes isomer
Aromatic hydrocarbon	GCMS	<0.94	C2-chrysenes	NA	Any or all ethyl chrysene isomers
Aromatic hydrocarbon	GCMS	<0.66	C2-dibenzothiophenes	NA	Any or all ethyl dibenzothiophene isomers
Aromatic hydrocarbon	GCMS	<0.80	C2-fluorenes	NA	Any or all ethyl fluorenes isomers
Aromatic hydrocarbon	GCMS	<1.61	C2-naphthalenes	NA	Any or all ethyl naphthalenes isomers
Aromatic hydrocarbon	GCMS	<0.58	C2-phenanthrenes & anthracenes	NA	Any or all ethyl phenanthrenes and ethyl anthracenes isomers
Aromatic hydrocarbon	GCMS	<0.91	C3-chrysenes	NA	Any or all propyl chrysene isomers

Table 2. Chemical names, abbreviations, analytical methods, limit of detection. ["<", less than; "NA", not available]

Aromatic hydrocarbon	GCMS	<0.66	C3-dibenzothiophenes	NA	Any or all propyl dibenzothiophene isomers

Table 2. Chemical names, abbreviations, analytical methods, limit of detection. ["<", less than; "NA", not available]

1-Tissue processing and analytical methods are fully described in Appendices 3A and 3B. Analytical method identifiers: GCMS, gas chromatography, mass spectroscopy; ICP-AES, inductively coupled plasma mass spectroscopy; AFS, atomic fluorescence; GC-ECP, gas chromatography, electron capture detection; ICP-MS, inductively coupled plasma mass spectroscopy; CVAAS, cold-vapor atomic absorption spectroscopy.

2-Limit of detection reported is the lowest method detection limit for the sample batch.

3-Chemical name used in this report. PCB and BDE congeners are designated using the Ballschmieder-Zell numbering system. Certain PCB or BDE congeners will co-elute during analysis.

4-Chemical Abstract Service (CAS) number. "NA" indicates that no CAS number is available at the time of this report.

Table 3. Moisture content, methyl mercury and element concentrations in Rio Grande silvery minnow carcasses collected from six sites (Table 1; Figure 2) along the Middle Rio Grande, New Mexico, during 2006-2008, and all site data combined.

[Moisture content, methyl mercury and element concentration data are the mean±1 standard deviation with the number of fish composite samples and range of concentrations in parentheses. Means within a row that have no upper case letters are not significantly different. Means within a row with upper case letters and sharing the same upper case letter are not significantly ($P < 0.05$) different. “±”, plus or minus; “MRG”, Middle Rio Grande; “NM”, New Mexico; Site 1, MRG at Bernalillo, NM; Site 2, MRG at Alameda, NM; Site 3, MRG at Los Padillas, NM; Site 4, MRG at Los Lunas, NM; Site 5, MRG at La Joya, NM; Site 6, MRG near San Antonio, NM; “µg/g”, microgram per gram; dry, dry weight basis; wet, wet weight basis; “<”, less than; “%”, percent]

Table 5. Carcass concentrations of organic chemicals and lipid content in Rio Grande silvery minnow collected from 6 sites along the Middle Rio Grande, New Mexico, during 2006-2008, (Table 1, Figure 1) and grouped into river sections including the Upper Sites, Middle Sites, and Lower Sites, as well as all data combined.

[Organic chemical concentration data are mean \pm 1 standard deviation with the number of fish composite samples and range of concentrations in parenthesis. Means within a row that have no upper case letters are not significantly different. Means within a row with upper case letters and sharing the same upper case letter are not significantly ($P < 0.05$) different. “ \pm ”, plus or minus; “MRG”, Middle Rio Grande; “NM”, New Mexico; Site 1. MRG at Bernalillo, NM; Site 2. MRG at Alameda, NM; Site 3. MRG at Los Padillas, NM; Site 4. MRG at Los Lunas, NM; Site 5. MRG at La Joya, NM; Site 6. MRG near San Antonio, NM; $\mu\text{g}/\text{kg}$, microgram per kilogram; wet weight; <, less than]

Organic Chemical ($\mu\text{g}/\text{kg}$ wet weight)	Upper Sites (Site 1 & Site 2 combined)	Middle Sites (Site 3 & Site 4 combined)	Lower Sites (Site 5 & Site 6 combined)	All Sites Combined

1. ECDMS Analytical Results Report 5/27/2010

Catalog Number	Purchase Order Number	Lab ID	Catalog Submitter	ECDMS User ID
2020128	94420-09-Y004	TERL	Lusk, Joel - Albuquerque, NM	r2alfo

Catalog Title	Rio Grande Silvery Minnow Health Study
Lab Name:	Trace Element Research Laboratory

Notes, Symbols and Abbreviations Used
Based on the report options selected the report should be printed in landscape mode
Notes, Symbols and Abbreviations Used The following may appear before a reported result (e.g. < 1234). < - Less than symbol indicates that the actual result is less than the reported detection limit. > - Greater than symbol indicates that the actual result is greater than the reported result.
All results are reported as 3 significant digits.
All results are reported as parts per million (ppm), or percent, unless otherwise noted.

11. QA/QC Anomalies

1. Blank Frequency Anomalies

The required number of blank analyses were performed.

11.2. Duplicate Frequency Anomalies

The required number of duplicate analyses were performed.

11.3. Spike Frequency Anomalies

The required number of spike analyses were performed.

11.4. Reference Material Frequency Anomalies

The required number of Standard Reference Material analyses were performed.

11.5. Mass Spec Frequency Anomalies

No Carbamate, OC, or OP data exists in this set of results; therefore, the anomaly test was not performed.

11.6. Limit of Detection Anomalies

Limits of Detection were within the contract requirements.

11.7. Blank Anomalies

Procedural Blank analyses were acceptable.

11.8. Duplicate Anomalies

All duplicate results were within normal limits.

11.9. Spike Anomalies

All spike results were within normal limits.

11.10. S.R.M. Anomalies

All SRM results were within normal limits with the following exceptions.

Analyte	S.R.M. ID	Certified Value	95% Confidence Interval	LOD (ppm/%)	Result (ppm/%)	% Recovery	See QA/QC Note No.
Manganese	NIST 2976	33.0	2.00	0.207	38.6	117	1
Strontium	NIST 2976	93.0	2.00	0.0459	65.2	70.1	2

S.R.M Names

SRM ID	SRM Name
NIST 2976	Mussel Tissue

11.11. QA/QC Notes

QA/QC Note Number and Comments

Sample IDs 7-08-2, 7-08-3, 7-08-5 and 7-08-6 had ratios of greater than 1 for MeHg:Hg in the data report. To express MeHg as Hg you have to divide the MeHg based values by approx. 1.075. In doing this, the ratio values for all samples that were analyzed for MeHg and Hg are acceptable.

1-2 The values are acceptable for Mn and Sr in SRM Nist 2976 and should have no effect on the interpretation of the data.

QA/QC Approved: Brenda Montgomery, Inorganic Analytical Chemist

12. Analytical Methods

Below are the analytical methods used by TERL to produce the results included in this report.

Method Codes:	001 005
----------------------	---------

<p>LABORATORY: Trace Element Research Laboratory</p> <p style="text-align: center;">Digestion of biological tissue.</p> <p>Liquid or solid biological tissue samples are wet digested with nitric acid and converted into acidic digest solutions for analysis by various atomic spectroscopy methods. When possible, tissue is freeze dried in order to minimize loss of analytes and to facilitate subsequent sample preparation steps, and then homogenized to a fine powder by ball-milling in plastic containers. Approximately 0.20 to 0.25 g of powdered tissue is weighed into a Teflon reaction vessel and 3 ml of HNO₃ are added. The closed reaction vessel is heated in a 130 C oven until digestion is complete. Samples are then diluted to a final volume of 20 ml with quartz distilled water and stored in 1 oz. polyethylene bottles for later analysis by instrumental techniques.</p>
Method Code: 005
<p>LABORATORY: Trace Element Research Laboratory</p>

Analysis of trace metals by inductively coupled plasma optical emission spectroscopy (ICP).

Liquid samples are nebulized and the resulting aerosol is transported to the plasma torch. Element-specific atomic-line emission spectra are produced by a inductively coupled argon plasma. The spectra are dispersed by a grating spectrometer, and the intensities of the lines are monitored by photomultiplier tubes or solid state detectors. Samples are quantitated by comparison with external standards. One or more internal standards may be incorporated to compensate for physical effects resulting from viscosity and varying levels of total dissolved solids in the samples. Background correction is required and is measured adjacent to analyte lines on samples during analysis.

LABORATORY: Trace Element Research Laboratory

Digestion of biological tissue.

Liquid or solid biological tissue samples are wet digested with nitric acid and converted into acidic digest solutions for analysis by various atomic spectroscopy methods. When possible, tissue is freeze dried in order to minimize loss of analytes and to facilitate subsequent sample preparation steps, and then homogenized to a fine powder by ball-milling in plastic containers. Approximately 0.20 to 0.25 g of powdered tissue is weighed into a Teflon reaction vessel and 3 ml of HNO₃ are added. The closed reaction vessel is heated in a 130 C oven until digestion is complete. Samples are then diluted to a final volume of 20 ml with quartz distilled water and stored in 1 oz. polyethylene bottles for later analysis by instrumental techniques.

Method Code: 016

LABORATORY: Trace Element Research Laboratory

Analysis of trace metals in water samples by inductively coupled plasma-mass spectroscopy (ICP-MS).

Concentrations of trace elements in water samples are determined with an atomic spectroscopy method that relies on ionization of sample constituents in a high temperature argon plasma and separation of positively-charged ions on the basis of their

mass:charge ratios (m:z) by a quadrupole mass spectrometer. The method offers extremely low detection limits but is subject to interferences from atomic and molecular ions having values within 1 AMU of the target ions. Sample preconcentration and matrix elimination can sometimes eliminate these problems, along with those resulting from high total dissolved solids.

LABORATORY: Trace Element Research Laboratory

Digestion of water, soil, sediment, and biological tissue
for mercury analysis.

Before samples are analyzed by the CVAAS method in use in this laboratory, the mercury is converted to the Hg²⁺ form. Mercury is digested by a modified version of EPA method 245.5 and 245.6. Sediment and tissue samples can be analyzed either freeze dried or on a wet basis. Sediment samples are homogenized by mixing before subsampling, while tissue samples are homogenized in the original sample containers either after freeze drying or with a Tekmar Tissumizer and subsampled. Samples are digested with nitric acid, sulfuric acid, potassium permanganate, and potassium persulfate in polypropylene tubes in a water bath at 90-95 C. Before analysis, hydroxylamine hydrochloride is added to reduce excess permanganate and the samples are brought to volume with distilled-deionized water.

Method Code: 007

LABORATORY: Trace Element Research Laboratory

Analysis of mercury by cold-vapor atomic absorption
spectroscopy (CVAAS).

In this procedure, divalent mercury (Hg⁺⁺) in aqueous samples (digests of water, tissue or sediment samples) is reduced to the elemental state (Hg⁰) by a strong reducing agent (stannous chloride). Gaseous Hg⁰ enters the sweep gas and is introduced into an atomic absorption cell, where light produced by a mercury vapor lamp is absorbed by the free Hg atoms. Mercury in the sample is determined by comparing light absorption of the sample with that of external calibration standards.

LABORATORY: Trace Element Research Laboratory

Digestion of water samples for "total recoverable" metals
(other than mercury).

Water samples are digested for two hours at 85 degrees Centigrade in polyethylene containers with ultrapure nitric and hydrochloric acids. Acid strength, on a vol:vol basis, is 1% HCl and 0.5% HNO₃. Sample aliquots for digestion are taken after vigorous shaking to assure resuspension of solids that may have settled. The original sample must have had preservative added (usually HNO₃) in order to ensure that metals do not adhere to the walls of the container.

Method Code: 005

LABORATORY: Trace Element Research Laboratory

Analysis of trace metals by inductively coupled plasma
optical emission spectroscopy (ICP).

Liquid samples are nebulized and the resulting aerosol is transported to the plasma torch. Element-specific atomic-line emission spectra are produced by a inductively coupled argon plasma. The spectra are dispersed by a grating spectrometer, and the intensities of the lines are monitored by photomultiplier tubes or solid state detectors. Samples are quantitated by comparison with external standards. One or more internal standards may be incorporated to compensate for physical effects resulting from viscosity

and varying levels of total dissolved solids in the samples. Background correction is required and is measured adjacent to analyte lines on samples during analysis.

Determination of methyl mercury in water

Determination of methyl mercury in water by distillation, ethylation, trapping, gas chromatography, and atomic fluorescence. Methyl mercury in water is distilled to separate it from interfering species and then ethylated with sodium tetraethyl borate. Methyl ethyl mercury is trapped on a Tenax column and then separated on an isothermal GC column. Following pyrolysis of the separated species, Hg is detected by atomic fluorescence.

Notes, Symbols and Abbreviations Used
Based on the report options selected the report should be printed in landscape mode
Notes, Symbols and Abbreviations Used The following may appear before a reported result (e.g. < 1234). < - Less than symbol indicates that the actual result is less than the reported detection limit. > - Greater than symbol indicates that the actual result is greater than the reported result.
All results are reported as 3 significant digits.
All results are reported as parts per million (ppm), or percent, unless otherwise noted.

* See "Laboratory Notes" section.** SD = Spiked Duplicate Result; SB = Spike Blank Result*** For a spike to be a valid measure of method accuracy, this ratio must be higher than 1.0.

9. Laboratory Notes

Analyte	Sample Number	Result Modifier
1,2,3,4,6,7,8-HpCDD		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
1,2,3,4,6,7,8-HpCDF		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
1,2,3,4,7,8,9-HpCDF		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
1,2,3,4,7,8-HxCDD		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
1,2,3,4,7,8-HxCDF		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
1,2,3,4-Tetrachlorobenzene		
	10-06-1	The analyte is < detection limit for performing the MS confirmation
	10-06-2	The analyte is < detection limit for performing the MS confirmation
	10-06-3	The analyte is < detection limit for performing the MS confirmation
	10-06-4	The analyte is < detection limit for performing the MS confirmation
	10-06-5	The analyte is < detection limit for performing the MS confirmation
	10-07-1	The analyte is < detection limit for performing the MS confirmation
	10-07-2	The analyte is < detection limit for performing the MS confirmation
	10-07-3	The analyte is < detection limit for performing the MS confirmation
	10-07-4	The analyte is < detection limit for performing the MS confirmation

	10-07-5	The analyte is < detection limit for performing the MS confirmation
	10-07-6	The analyte is < detection limit for performing the MS confirmation
	4-08-6	The analyte is < detection limit for performing the MS confirmation
1,2,3,6,7,8-HxCDD		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
1,2,3,6,7,8-HxCDF		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
1,2,3,7,8,9-HxCDD		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
1,2,3,7,8,9-HxCDF		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
1,2,3,7,8-PeCDD		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
1,2,3,7,8-PeCDF		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
1,2,4,5-Tetrachlorobenzene		
	10-06-1	The analyte is < detection limit for performing the MS confirmation
	10-06-2	The analyte is < detection limit for performing the MS confirmation
	10-06-3	The analyte is < detection limit for performing the MS confirmation
	10-06-4	The analyte is < detection limit for performing the MS confirmation
	10-06-5	The analyte is < detection limit for performing the MS confirmation
	10-07-1	The analyte is < detection limit for performing the MS confirmation
	10-07-2	The analyte is < detection limit for

		performing the MS confirmation
	10-07-3	The analyte is < detection limit for performing the MS confirmation
	10-07-4	The analyte is < detection limit for performing the MS confirmation
	10-07-5	The analyte is < detection limit for performing the MS confirmation
	10-07-6	The analyte is < detection limit for performing the MS confirmation
	4-08-6	The analyte is < detection limit for performing the MS confirmation
2,3,4,6,7,8-HxCDF		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
2,3,4,7,8-PeCDF		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
2,3,7,8-TCDD		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
2,3,7,8-TCDF		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
Aldrin		
	10-06-1	The analyte is < detection limit for performing the MS confirmation
	10-06-2	The analyte is < detection limit for performing the MS confirmation
	10-06-3	The analyte is < detection limit for performing the MS confirmation
	10-06-4	The analyte is < detection limit for performing the MS confirmation
	10-06-5	The analyte is < detection limit for performing the MS confirmation
	10-07-1	The analyte is < detection limit for performing the MS confirmation
	10-07-2	The analyte is < detection limit for performing the MS confirmation

	10-07-3	The analyte is < detection limit for performing the MS confirmation
	10-07-4	The analyte is < detection limit for performing the MS confirmation
	10-07-5	The analyte is < detection limit for performing the MS confirmation
	10-07-6	The analyte is < detection limit for performing the MS confirmation
	4-08-6	The analyte is < detection limit for performing the MS confirmation
BHC (Total)		
	10-06-1	The analyte is < detection limit for performing the MS confirmation
	10-06-2	The analyte is < detection limit for performing the MS confirmation
	10-06-3	The analyte is < detection limit for performing the MS confirmation
	10-06-4	The analyte is < detection limit for performing the MS confirmation
	10-06-5	The analyte is < detection limit for performing the MS confirmation
	10-07-1	The analyte is < detection limit for performing the MS confirmation
	10-07-2	The analyte is < detection limit for performing the MS confirmation
	10-07-3	The analyte is < detection limit for performing the MS confirmation
	10-07-4	The analyte is < detection limit for performing the MS confirmation
	10-07-5	The analyte is < detection limit for performing the MS confirmation
	10-07-6	The analyte is < detection limit for performing the MS confirmation
	4-08-6	The analyte is < detection limit for performing the MS confirmation
DDMU		
	10-06-1	The analyte is < detection limit for performing the MS confirmation

	10-06-2	The analyte is < detection limit for performing the MS confirmation
	10-06-3	The analyte is < detection limit for performing the MS confirmation
	10-06-4	The analyte is < detection limit for performing the MS confirmation
	10-06-5	The analyte is < detection limit for performing the MS confirmation
	10-07-1	The analyte is < detection limit for performing the MS confirmation
	10-07-2	The analyte is < detection limit for performing the MS confirmation
	10-07-3	The analyte is < detection limit for performing the MS confirmation
	10-07-4	The analyte is < detection limit for performing the MS confirmation
	10-07-5	The analyte is < detection limit for performing the MS confirmation
	10-07-6	The analyte is < detection limit for performing the MS confirmation
	4-08-6	The analyte is < detection limit for performing the MS confirmation
HCB		
	10-06-1	The analyte is < detection limit for performing the MS confirmation
	10-06-2	The analyte is < detection limit for performing the MS confirmation
	10-06-3	The analyte is < detection limit for performing the MS confirmation
	10-06-4	The analyte is < detection limit for performing the MS confirmation
	10-06-5	The analyte is < detection limit for performing the MS confirmation
	10-07-1	The analyte is < detection limit for performing the MS confirmation
	10-07-2	The analyte is < detection limit for performing the MS confirmation
	10-07-3	The analyte is < detection limit for performing the MS confirmation

	10-07-4	The analyte is < detection limit for performing the MS confirmation
	10-07-5	The analyte is < detection limit for performing the MS confirmation
	10-07-6	The analyte is < detection limit for performing the MS confirmation
	4-08-6	The analyte is < detection limit for performing the MS confirmation
Heptachlor		
	10-06-1	The analyte is < detection limit for performing the MS confirmation
	10-06-2	The analyte is < detection limit for performing the MS confirmation
	10-06-3	The analyte is < detection limit for performing the MS confirmation
	10-06-4	The analyte is < detection limit for performing the MS confirmation
	10-06-5	The analyte is < detection limit for performing the MS confirmation
	10-07-1	The analyte is < detection limit for performing the MS confirmation
	10-07-2	The analyte is < detection limit for performing the MS confirmation
	10-07-3	The analyte is < detection limit for performing the MS confirmation
	10-07-4	The analyte is < detection limit for performing the MS confirmation
	10-07-5	The analyte is < detection limit for performing the MS confirmation
	10-07-6	The analyte is < detection limit for performing the MS confirmation
	4-08-6	The analyte is < detection limit for performing the MS confirmation
OCDD		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
OCDF		
	EQ0900410-02	Lab reported Spike Blank Duplicate. ACF

		changed it to a Spike Duplicate.
PCB# 1		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 104		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 105		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 114		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 118		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 123		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 126		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 15		

	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 155		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 156/157		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 167		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 169		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 188		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 189		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 19		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF

		changed it to a Spike Duplicate.
PCB# 202		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 205		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 206		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 208		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 209		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 3		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 37		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 4		

	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 54		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 77		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
PCB# 81		
	EQ0900409-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
	EQ0900415-02	Lab reported Spike Blank Duplicate. ACF changed it to a Spike Duplicate.
Pentachlorobenzene		
	10-06-1	The analyte is < detection limit for performing the MS confirmation
	10-06-2	The analyte is < detection limit for performing the MS confirmation
	10-06-3	The analyte is < detection limit for performing the MS confirmation

Code List

If appropriate, labs are instructed to use the following codes when entering laboratory notes. The labs may use one or more of the codes in each note displayed above.

Code	Comment
A	Values reported based on Aldrin response factor.
C	Sample possibly compromised due to improper handling / packaging.
D	Sample was deleted from the catalog by the submitter.
H	Due to sample characteristics it was difficult to obtain adequate sample homogeneity - precision was impacted.
I	Interferences occurred during analysis.
L	Sample compromised or destroyed during shipment - sample not analyzed.
M	Compound identity was confirmed by GC/MS.
N	Sample was not analyzed.
P	Sample destroyed during preparation at lab - sample not analyzed.
Q	Insufficient sample quantity to perform requested analysis.
R	Sample is highly decomposed - results may be impacted.
S	Sample was substituted by the submitter.
T	Retention time relative to Aldrin.
U	GC/MS identifies the unknown compound to be _____ (fill in analyte).
W	Insufficient sample quantity to perform duplicate / spike analyses.
Y	Sample was analyzed but results may be impacted (see 'C')

10. QAQC Summary

1. Procedural Blank Summary

Procedural Blank Summary of Blank Equivalent Concentration (BEC) Data

Within a lab sample matrix, there must be three or more Blank results for a given analyte in order to generate a report.

10.2. Duplicate Summary

Duplicate Summary of Relative Percent Difference (RPD) Data

Within a lab sample matrix and concentration range, there must be three or more Duplicate results for a given analyte in order to generate a report.

10.3. Spike Summary

Spike Summary of Percent Recovery (PR) Data

Within a lab sample matrix, there must be three or more Spike results for a given analyte in order to generate a report.

10.4. SRM Summary

Standard Reference Material Summary of Percent Recovery (PR) Data

Within an SRM ID, there must be three or more Recoveries for a given analyte in order to generate a report.

11. QA/QC Anomalies

1. Blank Frequency Anomalies

The required number of blank sample analyses were performed with the following exceptions.				
Analyte	Number of Samples	Number of Blanks	Frequency (%)	See QA/QC Note No.
PCB-1242	13	0	0	1
PCB-1248	13	0	0	2
PCB-1254	13	0	0	3
PCB-1260	13	0	0	4

11.2. Duplicate Frequency Anomalies

The required number of duplicate sample analyses were performed with the following exceptions.					
Analyte	Lab Matrix	Number of Samples	Number of Duplicates	Frequency (%)	See QA/QC Note No.
1,2,3,4,6,7,8-HpCDD	Animal Tissue	8	0	0	5
1,2,3,4,6,7,8-HpCDF	Animal Tissue	8	0	0	6
1,2,3,4,7,8,9-HpCDF	Animal Tissue	8	0	0	7
1,2,3,4,7,8-HxCDD	Animal Tissue	8	0	0	8
1,2,3,4,7,8-HxCDF	Animal Tissue	8	0	0	9
1,2,3,6,7,8-HxCDD	Animal Tissue	8	0	0	10
1,2,3,6,7,8-HxCDF	Animal Tissue	8	0	0	11
1,2,3,7,8,9-HxCDD	Animal Tissue	8	0	0	12

11.10. S.R.M. Anomalies

No SRM data exists in this set of results; therefore, the anomaly test was not performed.

11.11. QA/QC Notes

QA/QC Note Number and Comments
Additional TDI Comments:
06385810 (Water) Insufficient sample for analysis. per Juan.
ACF Comments:
1-4 Other PCB blank analyses were performed. This is acceptable.
5-371 A blank spike duplicate analyses was performed. This is acceptable.
372-790 A Blank spike analyses was performed. This is acceptable
791 Analyte detectable levels were to low for mass spec confirmation.
792-810 These LODs were higher than the ECDMS default. They are acceptable.
811-814 These analytes were reported present in the blank. Results that are less than ten times the amount found in the blank are considered non-detects.
815-817 The spike recoveries for these analytes were low. Results may be Biased low.
QA/QC reviewed 04/06/2010 Walter Riley

12. Analytical Methods

Below are the analytical methods used by TDI to produce the results included in this report.

Method Codes:	001
----------------------	-----

Lab Matrix	Analyte
Animal Tissue	% Lipid
	% Moisture

Method Code: 001
<p>LABORATORY: TDI Brooks International, Inc.</p> <p style="padding-left: 40px;">Tissue Extraction Method (PAH and OCs)</p> <p>Tissue samples are either immediately processed or stored frozen (-20°C) until processing. Tissues are processed as appropriate for the tissue type (e.g. dissection, shucking). Processed tissues are homogenized using a variety of mechanical methods (Waring blender, Hobart meat grinder or Tissuissiser), depending upon the tissue amount and type. After homogenization, an approximate 1 g aliquot is removed and dried in an oven at 105°C to a constant weight to determine % moisture. The remaining samples are stored in certified pre-cleaned jars frozen (- 20°C) until analysis. Prior to extraction, tissue samples may be lyophilized or a wet aliquot is chemically dried using a dessicant such as Hydromatrix or sodium sulfate. Samples are then extracted using a Dionex ASE200 Accelerated Solvent Extractor (ASE). The dried sample or the sample and dessicant material is loaded into 22 or 33 mL stainless steel ASE extraction tubes. The extraction are performed using 100% dicholormethane at 100°C and 2000 psi. The extracted organics dissolved in the solvent are collected in 60 mL glass vials. The extract is concentrated to approximately 10 mL in the collection vials and then transferred to 25 mL Kurdena-Danish (KD) concentrator tubes. The sample extract is concentrated to 3 mL in a water bath at 55-60°C. If lipid weight is required, a 100 mL aliquot is removed and weighed using a microbalance. Interfering non-contaminant organic material (primarily lipids) must be removed prior to instrument analyses.</p> <p>The extract is processed through silica gel/alumina chromatography columns and High Performance Liquid Chromatography (HPLC). The remaining 2.9 mL of sample extracted are loaded on top of 300 mm x 19 mm glass liquid chromatography columns packed with 10 g of deactivated alumina and 20 g of deactivated silica gel. The columns are loaded in 100 % dichloromethane. The dichloromethane is replaced by adding 40 mL of pentane. The extract is carefully added to the top of the chromatography columns. The column is flushed at a rate of 1-2 mL per minute using 200 mL of 50:50 pentane/dichloromethane and collected into 250 mL flasks. The eluent collected in the 250 mL flask is evaporated to 2 mL using a waterbath at 55-50°C. The samples is transferred into 4 mL amber vials. Extracts subsequently processed by HPLC to further remove lipid interferences. Lipid removal is accomplished by flushing samples with dichlormethane through size exclusion Phenogel 10 m GPC 100 A columns. Approximately 40 mL is collected using a fraction collector, which is concentrated to 0.5 mL using a water bath at 55-60C. The concentrated extract is then analyzed by GC/MS for polynuclear aromatic hydrocarbons (PAHs) or GC/ECD for selected organochlorines (OCs).</p>

Additional column chromatography is required to separate PCBs from toxaphene/pesticides when toxaphene analysis is required and to separate planar PCBs. If toxaphene analyses is required, an aliquot of the extract prior to HPLC clean up is processed through a 3% deactivated silica gel column. The column is packed in dichloromethane which is then flushed with 50 mL of pentane. The sample extract is transferred to the top of the column and flushed with 100 mL of pentane. The fraction contains PCBs and DDTs. The column is then flushed with 120 mL of 50:50 pentane/dichloromethane. This fraction contains toxaphene and chlorinated pesticides. Both fractions are reduced to 1 mL using a water bath at 55-60°C. The extracts are then ready for instrument analysis.

If planar PCB analyses are required, the PCB/DDT fraction prepared by 3% silica gel column is further processed by column chromatography packed with 2 g of 1:19 (5% by weight) mixture of activated carbon/Celite. The column and flushed with 25 mL of 1:4 dichloromethane/cyclohexane mixture. The sample is added to the top of the column and flushed with 50 mL of 1:4 dichloromethane/cyclohexane mixture, followed by 30 mL of 9:1 dichloromethane/toluene. This is followed by the addition of 40 mL of toluene. The toluene fraction contains the planar PCBs and is concentrated to 1 mL in a Zymark TurboVap II concentrator at 42°C and 20 psi. The sample is ready for instrument analysis.

Tissue Extraction Method (PAH and OCs)

Tissue samples are either immediately processed or stored frozen (-20°C) until processing. Tissues are processed as appropriate for the tissue type (e.g. dissection, shucking). Processed tissues are homogenized using a variety of mechanical methods (Waring blender, Hobart meat grinder or TissuMisser), depending upon the tissue amount and type. After homogenization, an approximate 1 g aliquot is removed and dried in an oven at 105°C to a constant weight to determine % moisture. The remaining samples are stored in certified pre-cleaned jars frozen (-20°C) until analysis. Prior to extraction, tissue samples may be lyophilized or a wet aliquot is chemically dried using a desiccant such as Hydromatrix or sodium sulfate. Samples are then extracted using a Dionex ASE200 Accelerated Solvent Extractor (ASE). The dried sample or the sample and desiccant material is loaded into 22 or 33 mL stainless steel ASE extraction tubes. The extraction are performed using 100% dichloromethane at 100°C and 2000 psi. The extracted organics dissolved in the solvent are collected in 60 mL glass vials. The extract is concentrated to approximately 10 mL in the collection vials and then transferred to 25 mL Kurdena-Danish (KD) concentrator tubes. The sample extract is concentrated to 3 mL in a water bath at 55-60°C. If lipid weight is required, a 100 mL aliquot is removed and weighed using a microbalance. Interfering non-contaminant organic material (primarily lipids) must be removed prior to instrument analyses.

The extract is processed through silica gel/alumina chromatography columns and High Performance Liquid Chromatography (HPLC). The remaining 2.9 mL of sample extracted are loaded on top of 300 mm x 19 mm glass liquid chromatography columns packed with 10 g of deactivated alumina and 20 g of deactivated silica gel. The columns are loaded in 100 % dichloromethane. The dichloromethane is replaced by adding 40 mL of pentane. The extract is carefully added to the top of the chromatography columns. The column is flushed at a rate of 1-2 mL per minute using 200 mL of 50:50 pentane/dichloromethane and collected into 250 mL flasks. The eluent collected in the 250 mL flask is evaporated to 2 mL using a waterbath at 55-50°C. The samples is transferred into 4 mL amber vials. Extracts subsequently processed by HPLC to further remove lipid interferences. Lipid removal is accomplished by flushing samples with dichloromethane through size exclusion Phenogel 10 m GPC 100 A columns. Approximately 40 mL is collected using a fraction collector, which is concentrated to 0.5 mL using a water bath at 55-60C. The concentrated extract is then analyzed by GC/MS for polynuclear aromatic hydrocarbons (PAHs) or GC/ECD for selected organochlorines (OCs).

Additional column chromatography is required to separate PCBs from toxaphene/pesticides when toxaphene analysis is required

and to separate planar PCBs. If toxaphene analyses is required, an aliquot of the extract prior to HPLC clean up is processed through a 3% deactivated silica gel column. The column is packed in dichloromethane which is then flushed with 50 mL of pentane. The sample extract is transferred to the top of the column and flushed with 100 mL of pentane. The fraction contains PCBs and DDTs. The column is then flushed with 120 mL of 50:50 pentane/dichloromethane. This fraction contains toxaphene and chlorinated pesticides. Both fractions are reduced to 1 mL using a water bath at 55-60°C. The extracts are then ready for instrument analysis.

If planar PCB analyses are required, the PCB/DDT fraction prepared by 3% silica gel column is further processed by column chromatography packed with 2 g of 1:19 (5% by weight) mixture of activated carbon/Celite. The column and flushed with 25 mL of 1:4 dichloromethane/cyclohexane mixture. The sample is added to the top of the column and flushed with 50 mL of 1:4 dichloromethane/cyclohexane mixture, followed by 30 mL of 9:1 dichloromethane/toluene. This is followed by the addition of 40 mL of toluene. The toluene fraction contains the planar PCBs and is concentrated to 1 mL in a Zymark TurboVap II concentrator at 42°C and 20 psi. The sample is ready for instrument analysis.

Aromatic Hydrocarbon Determination by Selected
Ion Monitoring (SIM) Gas Chromatography/
Mass Spectrometry (GC/MS)

Polycyclic aromatic hydrocarbons (PAH) and their alkylated homologues are analyzed in sample extracts by a HewlettPackard, model 5890 GS and model 5972 MS operated in SIM using a capillary column. The GC is operated in splitless mode and the capillary column is an Agilent Technologies HP-5MS (60 m x 0.25 mm ID and 0.25 mm film thickness). The carrier gas is helium at

a flow rate of 1 mL/minute. The temperature of the injection port is 300°C and transfer line is 290°C. The initial oven temperature is 60°C, the ramp rate is 7°C/minutes to a final oven temperature of 310°C and held for 20 minutes. For analyte identification, the extracted ion current profiles of the primary m/z and the confirmatory ion for each analyte must be at a maximum in the same scan or within one scan of each other and the retention time must fall within 5 seconds of the retention time of the authentic standard or alkyl homologue grouping. The pattern of alkylated PAH homologue groupings is established by analysis of reference oil standards. The relative peak heights of the primary mass ion compared to the confirmation or secondary mass ion must fall within 30 % of the relative intensities of these masses in a reference mass spectrum.

Chlorinated Hydrocarbon Determination by Gas Chromatography/Electron Capture Detection (GC/ECD)

Chlorinated hydrocarbons are determined in samples by GC/ECD. Samples are extracted as previously described and analyzed on a HewlettPackard (HP), model 5890 GC equipped with an ECD. Between 1 to 5 mL of sample is injected using an HP, model 7673A autosampler. The instrument is set up with dual columns. The primary capillary column is a J&W DB-5 (30 m x 24 mm ID and 0.25 mm film thickness). The second column, a confirmation column, is a J&W DB-17HT (30 m x 0.25 mm ID and 0.15 mm film thickness). The inlet system is splitless and the carrier gas is helium at a flow rate of 1 mL/min. For the analysis of standard halogenated hydrocarbons, the temperature of the injection port is 275°C and the detector is 325°C. The initial oven temperature is 100°C with a hold time of 1 minute. The ramp rate is 5°C/minute to 140°C with a hold time of 1 minute, followed by a ramp rate of 1.5°C /minute to 250°C with a hold time of 1 minute and finally a ramp rate of 10°C/minutes to 300°C with a final hold time of 5 minutes. For planar PCBs the instrument is operated in the splitless mode with helium as the carrier gas with a flow rate of 1 mL/minute. The temperature of the injection port is 275°C and the detector is 325°C. The initial oven temperature is 100°C, which is held for 1 minute. The ramp rate is 10°C/minute to 150°C, followed by a ramp rate of 6.0°C/minute to 270°C with a hold time of 3 minutes. The retention time of sample analytes must fall within 15 seconds of the retention time of analytes in a calibration standard or a retention index solutions. The levels of arochlors and toxophene are determined using retention index solutions of both complex mixtures. Arochlors are determined in a similar method to that described in EPA SW-846 Test Methods for Evaluating Solid Waste Physical/Chemical Methods, Method 8082 (1997).

Tissue Extraction Method (PAH and OCs)

Tissue samples are either immediately processed or stored frozen (-20°C) until processing. Tissues are processed as appropriate for the tissue type (e.g. dissection, shucking). Processed tissues are homogenized using a variety of mechanical methods (Waring blender, Hobart meat grinder or Tissuissiser), depending upon the tissue amount and type. After homogenization, an approximate 1 g aliquot is removed and dried in an oven at 105°C to a constant weight to determine % moisture. The remaining samples are stored in certified pre-cleaned jars frozen (-20°C) until analysis. Prior to extraction, tissue samples may be lyophilized or a wet aliquot is chemically dried using a desiccant such as Hydromatrix or sodium sulfate. Samples are then extracted using a Dionex ASE200 Accelerated Solvent Extractor (ASE). The dried sample or the sample and desiccant material is loaded into 22 or 33 mL stainless steel ASE extraction tubes. The extraction are performed using 100% dichloromethane at 100°C and 2000 psi. The extracted organics dissolved in the solvent are collected in 60 mL glass vials. The extract is concentrated to approximately 10 mL in the collection vials and then transferred to 25 mL Kurdena-Danish (KD) concentrator tubes. The sample extract is concentrated to 3 mL in a water bath at 55-60°C. If lipid weight is required, a 100 mL aliquot is removed and weighed using a microbalance. Interfering non-contaminant organic material (primarily lipids) must be removed prior to instrument analyses.

The extract is processed through silica gel/alumina chromatography columns and High Performance Liquid Chromatography (HPLC). The remaining 2.9 mL of sample extracted are loaded on top of 300 mm x 19 mm glass liquid chromatography columns packed with 10 g of deactivated alumina and 20 g of deactivated silica gel. The columns are loaded in 100 % dichloromethane. The dichloromethane is replaced by adding 40 mL of pentane. The extract is carefully added to the top of the chromatography columns. The column is flushed at a rate of 1-2 mL per minute using 200 mL of 50:50 pentane/dichloromethane and collected into 250 mL flasks. The eluent collected in the 250 mL flask is evaporated to 2 mL using a waterbath at 55-50°C. The samples is transferred into 4 mL amber vials. Extracts subsequently processed by HPLC to further remove lipid interferences. Lipid removal is accomplished by flushing samples with dichloromethane through size exclusion Phenogel 10 m GPC 100 A columns. Approximately 40 mL is collected using a fraction collector, which is concentrated to 0.5 mL using a water bath at 55-60°C. The concentrated extract is then analyzed by GC/MS for polynuclear aromatic hydrocarbons (PAHs) or GC/ECD for selected organochlorines (OCs).

Additional column chromatography is required to separate PCBs from toxaphene/pesticides when toxaphene analysis is required and to separate planar PCBs. If toxaphene analyses is required, an aliquot of the extract prior to HPLC clean up is processed through a 3% deactivated silica gel column. The column is packed in dichloromethane which is then flushed with 50 mL of pentane. The sample extract is transferred to the top of the column and flushed with 100 mL of pentane. The fraction contains PCBs and DDTs. The column is then flushed with 120 mL of 50:50 pentane/dichloromethane. This fraction contains toxaphene and chlorinated pesticides. Both fractions are reduced to 1 mL using a water bath at 55-60°C. The extracts are then ready for instrument analysis.

If planar PCB analyses are required, the PCB/DDT fraction prepared by 3% silica gel column is further processed by column chromatography packed with 2 g of 1:19 (5% by weight) mixture of activated carbon/Celite. The column and flushed with 25 mL of 1:4 dichloromethane/cyclohexane mixture. The sample is added to the top of the column and flushed with 50 mL of 1:4 dichloromethane/cyclohexane mixture, followed by 30 mL of 9:1 dichloromethane/toluene. This is followed by the addition of 40 mL of toluene. The toluene fraction contains the planar PCBs and is concentrated to 1 mL in a Zymark TurboVap II concentrator at 42°C and 20 psi. The sample is ready for instrument analysis.

Determination of Aliphatic Hydrocarbons in Soil/Sediment

Sediment samples are extracted as described in method 005. Aliphatic hydrocarbons are determined by quantifying target analytes with a gas chromatography/flame ionization detection (GC/FID)

Aliphatic hydrocarbons are analyzed using a HewlettPackard, model 5890 Gas Chromatograph (GC) with a Flame Ionization Detector (FID) operated in a splitless mode. A HP-1MS capillary column (30m x 0.25 mm ID and 0.25 mm film thickness) is used to resolve peaks. The carrier gas is helium at a flow rate of 1.5 mL/min. The temperature of the injection port is 300°C and transfer line is 300C. The initial oven temperature is 60°C, the ramp rate is 12°C/min to a final oven temperature of 180°C. Normal alkanes with 10 to 34 carbons and the isoprenoids pristane and phytane are determined using this procedure. For analytes of interest, a response factor relative to the internal standard is determined at each calibration level. All 5 response factors are averaged for a mean relative response factor. Data are surrogate corrected.

Tissue Extraction Method (PAH and OCs)

Tissue samples are either immediately processed or stored frozen (-20°C) until processing. Tissues are processed as appropriate for the tissue type (e.g. dissection, shucking). Processed tissues are homogenized using a variety of mechanical methods (Waring blender, Hobart meat grinder or Tissuissiser), depending upon the tissue amount and type. After homogenization, an approximate 1 g aliquot is removed and dried in an oven at 105°C to a constant weight to determine % moisture. The remaining samples are stored in certified pre-cleaned jars frozen (- 20°C) until analysis. Prior to extraction, tissue samples may be lyophilized or a wet aliquot is chemically dried using a dessicant such as Hydromatrix or sodium sulfate. Samples are then extracted using a Dionex ASE200 Accelerated Solvent Extractor (ASE). The dried sample or the sample and dessicant material is loaded into 22 or 33 mL stainless steel ASE extraction tubes. The extraction are performed using 100% dicholormethane at 100°C and 2000 psi. The extracted organics dissolved in the solvent are collected in 60 mL glass vials. The extract is concentrated to approximately 10 mL in the collection vials and then transferred to 25 mL Kurdena-Danish (KD) concentrator tubes. The sample extract is concentrated to 3 mL in a water bath at 55-60°C. If lipid weight is required, a 100 mL aliquot is removed and weighed using a microbalance. Interfering non-contaminant organic material (primarily lipids) must be removed prior to instrument analyses.

The extract is processed through silica gel/alumina chromatography columns and High Performance Liquid Chromatography

(HPLC). The remaining 2.9 mL of sample extracted are loaded on top of 300 mm x 19 mm glass liquid chromatography columns packed with 10 g of deactivated alumina and 20 g of deactivated silica gel. The columns are loaded in 100 % dichloromethane. The dichloromethane is replaced by adding 40 mL of pentane. The extract is carefully added to the top of the chromatography columns. The column is flushed at a rate of 1-2 mL per minute using 200 mL of 50:50 pentane/dichloromethane and collected into 250 mL flasks. The eluent collected in the 250 mL flask is evaporated to 2 mL using a waterbath at 55-50°C. The samples is transferred into 4 mL amber vials. Extracts subsequently processed by HPLC to further remove lipid interferences. Lipid removal is accomplished by flushing samples with dichloromethane through size exclusion Phenogel 10 m GPC 100 A columns. Approximately 40 mL is collected using a fraction collector, which is concentrated to 0.5 mL using a water bath at 55-60°C. The concentrated extract is then analyzed by GC/MS for polynuclear aromatic hydrocarbons (PAHs) or GC/ECD for selected organochlorines (OCs).

Additional column chromatography is required to separate PCBs from toxaphene/pesticides when toxaphene analysis is required and to separate planar PCBs. If toxaphene analyses is required, an aliquot of the extract prior to HPLC clean up is processed through a 3% deactivated silica gel column. The column is packed in dichloromethane which is then flushed with 50 mL of pentane. The sample extract is transferred to the top of the column and flushed with 100 mL of pentane. The fraction contains PCBs and DDTs. The column is then flushed with 120 mL of 50:50 pentane/dichloromethane. This fraction contains toxaphene and chlorinated pesticides. Both fractions are reduced to 1 mL using a water bath at 55-60°C. The extracts are then ready for instrument analysis.

If planar PCB analyses are required, the PCB/DDT fraction prepared by 3% silica gel column is further processed by column chromatography packed with 2 g of 1:19 (5% by weight) mixture of activated carbon/Celite. The column and flushed with 25 mL of 1:4 dichloromethane/cyclohexane mixture. The sample is added to the top of the column and flushed with 50 mL of 1:4 dichloromethane/cyclohexane mixture, followed by 30 mL of 9:1 dichloromethane/toluene. This is followed by the addition of 40 mL of toluene. The toluene fraction contains the planar PCBs and is concentrated to 1 mL in a Zymark TurboVap II concentrator at 42°C and 20 psi. The sample is ready for instrument analysis.

Polybrominated Diphenyl Ether (PBDE) Determination by Negative Chemical Ionization (NCI)-Selected Ion Monitoring (SIM) Gas Chromatography/Mass Spectrometry (GC/MS)

Polybrominated diphenyl ethers are analyzed in sample extracts by a Thermo Trace GC and DSQ-II MS operated in SIM using a capillary column. The GC is operated in splitless mode using a PTV injection port and the capillary column is an Agilent Technologies DB-XLB (15 m x 0.25 mm ID and 0.10 mm film thickness). The carrier gas is helium at a flow rate of 1 mL/minute and methane is used as the reactant gas with a flow rate of 2.0 mL/min. The temperature of the injection port is 40 degrees C (ramp to 300 degrees C) and transfer line is 290 degrees C. The initial oven temperature is 110 degrees C, the ramp rate is 7 degrees C/minutes to a final oven temperature of 280 degrees C and held for 20 minutes. For analyte identification, the extracted ion current profiles of the primary m/z and the confirmatory ion for each analyte must be at a maximum in the same scan or within one scan of each other and the retention time must fall with 5 seconds of the retention time of the authentic standard.

Summary of Method 1613B

This procedure uses matrix specific extraction, analyte specific cleanup, and HRGC/HRMS analysis techniques for dioxins and furans.

If interferences are encountered, the method provides selected cleanup procedures to aid the analyst in their elimination.

A specified amount of sample is spiked with a solution containing specified amounts of each of the fifteen isotopically labeled PCDDs/PCDFs. The sample is then extracted according to a matrix specific extraction procedure. Aqueous samples that are judged to contain 1 percent or more solids, and solid samples that show an aqueous phase, are filtered, the solid phase (including the filter) and the aqueous phase extracted separately, and the extracts combined before extract cleanup.

The extraction procedures are:

• 161607; Toluene: Soxhlet extraction for soil, sediment, fly ash, and paper pulp samples;

• 161607; Methylene chloride, liquid-liquid extraction for water samples

 Toluene: Dean-Stark extraction for fuel oil, and aqueous sludge samples;

 Toluene extraction for still bottom samples;

 Hexane/methylene chloride, Soxhlet extraction or methylene chloride, Soxhlet extraction for fish tissue samples

 Methylene chloride extraction for human adipose tissue samples

As an option, all solid samples (wet or dry) may be extracted with toluene using a Soxhlet/Dean Stark extraction system. The decision for the selection of an extraction procedure for chemical reactor residue samples is based on the appearance (consistency, viscosity) of the samples. Generally, they can be handled according to the procedure used for still bottom (or chemical sludge) samples.

The extracts are submitted to an acidic washing treatment and dried. Following a solvent exchange step, the extracts are cleaned up by column chromatography on silica gel and activated carbon. The extracts from adipose tissue samples are treated with silica gel impregnated with sulfuric acid before chromatography on acidic silica gel, and activated carbon.

Fish tissue and paper pulp extracts are subjected to an acid wash treatment only, prior to chromatography on alumina and activated carbon.

The preparation of the final extract for HRGC/HRMS analysis is accomplished by adding 20µL of a nonane solution containing 100pg/µL of the internal standard compounds, 13C12 -1,2,3,4-TCDD and 13C12 -1,2,3,7,8,9-HxCDD. The former is used to determine the percent recoveries of tetra- and pentachlorinated PCDD/PCDF congeners, while the latter is used to determine the percent recoveries of the hexa-, hepta- and octachlorinated PCDD/PCDF congeners.

Two µL of the concentrated extract are injected into an HRGC/HRMS system capable of performing selected ion monitoring at resolving powers of at least 10,000 (10 percent valley definition).

The identification of sixteen 2,3,7,8-substituted congeners, for which a 13C12-labeled standard is available in the sample and the labeled standard spiking solutions, is based on their elution at their exact retention time (within 0.005 retention time units measured in the routine calibration) and the simultaneous detection of the two most abundant ions in the molecular ion region. The identification of OCDF is based on its retention time relative to 13C12 -OCDD and the simultaneous detection of the two most abundant ions in the molecular ion region. Identification is also based on a comparison of the ratios of the integrated ion abundance of the molecular ion species to their theoretical abundance ratios.

Quantitation of the individual congeners, total PCDDs and total PCDFs is achieved in conjunction with the establishment of a multipoint (five points) calibration curve for each homologue, during which each calibration solution is analyzed once.

Tissue Extraction Method (PAH and OCs)

Tissue samples are either immediately processed or stored frozen (-20°C) until processing. Tissues are processed as appropriate for the tissue type (e.g. dissection, shucking). Processed tissues are homogenized using a variety of mechanical methods (Waring blender, Hobart meat grinder or Tissuissiser), depending upon the tissue amount and type. After homogenization, an approximate 1 g aliquot is removed and dried in an oven at 105°C to a constant weight to determine % moisture. The remaining samples are stored in certified pre-cleaned jars frozen (-20°C) until analysis. Prior to extraction, tissue samples may be lyophilized or a wet aliquot is chemically dried using a desiccant such as Hydromatrix or sodium sulfate. Samples are then extracted using a Dionex ASE200 Accelerated Solvent Extractor (ASE). The dried sample or the sample and desiccant material is loaded into 22 or 33 mL stainless steel ASE extraction tubes. The extraction are performed using 100% dichloromethane at 100°C and 2000 psi. The extracted organics dissolved in the solvent are collected in 60 mL glass vials. The extract is concentrated to approximately 10 mL in the collection vials and then transferred to 25 mL Kurdena-Danish (KD) concentrator tubes. The sample extract is concentrated to 3 mL in a water bath at 55-60°C. If lipid weight is required, a 100 mL aliquot is removed and weighed using a microbalance. Interfering non-contaminant organic material (primarily lipids) must be removed prior to instrument analyses.

The extract is processed through silica gel/alumina chromatography columns and High Performance Liquid Chromatography (HPLC). The remaining 2.9 mL of sample extracted are loaded on top of 300 mm x 19 mm glass liquid chromatography columns packed with 10 g of deactivated alumina and 20 g of deactivated silica gel. The columns are loaded in 100 % dichloromethane. The dichloromethane is replaced by adding 40 mL of pentane. The extract is carefully added to the top of the chromatography columns. The column is flushed at a rate of 1-2 mL per minute using 200 mL of 50:50 pentane/dichloromethane and collected into 250 mL flasks. The eluent collected in the 250 mL flask is evaporated to 2 mL using a waterbath at 55-50°C. The samples is transferred into 4 mL amber vials. Extracts subsequently processed by HPLC to further remove lipid interferences. Lipid removal is accomplished by flushing samples with dichloromethane through size exclusion Phenogel 10 m GPC 100 A columns. Approximately 40 mL is collected using a fraction collector, which is concentrated to 0.5 mL using a water bath at 55-60°C. The concentrated extract is then analyzed by GC/MS for polynuclear aromatic hydrocarbons (PAHs) or GC/ECD for selected organochlorines (OCs).

Additional column chromatography is required to separate PCBs from toxaphene/pesticides when toxaphene analysis is required and to separate planar PCBs. If toxaphene analyses is required, an aliquot of the extract prior to HPLC clean up is processed through a 3% deactivated silica gel column. The column is packed in dichloromethane which is then flushed with 50 mL of pentane. The sample extract is transferred to the top of the column and flushed with 100 mL of pentane. The fraction contains PCBs and DDTs. The column is then flushed with 120 mL of 50:50 pentane/dichloromethane. This fraction contains toxaphene and chlorinated pesticides. Both fractions are reduced to 1 mL using a water bath at 55-60°C. The extracts are then ready for instrument analysis.

If planar PCB analyses are required, the PCB/DDT fraction prepared by 3% silica gel column is further processed by column chromatography packed with 2 g of 1:19 (5% by weight) mixture of activated carbon/Celite. The column and flushed with 25 mL of 1:4 dichloromethane/cyclohexane mixture. The sample is added to the top of the column and flushed with 50 mL of 1:4 dichloromethane/cyclohexane mixture, followed by 30 mL of 9:1 dichloromethane/toluene. This is followed by the addition of 40 mL

of toluene. The toluene fraction contains the planar PCBs and is concentrated to 1 mL in a Zymark TurboVap II concentrator at 42°C and 20 psi. The sample is ready for instrument analysis.

Summary of Method 1668A

This procedure uses matrix specific extraction, analyte specific cleanup, and HRGC/HRMS analysis techniques for PCB congeners.

Aqueous samples (samples containing less than one percent solids) ¹⁴C Stable isotopically labeled analogs of the toxics and labeled earliest and latest level of chlorination (LOC) PCBs are spiked into the sample aliquot. The sample is extracted using a separatory funnel extraction and concentrated for clean up.

Solid, semi-solid, and multi-phase samples (excluding tissue) ¹⁴C The labeled compounds are spiked into sample material that corresponds to approximately 5g on a dry weight basis. For samples with high moisture content, the amount of wet weight material to add the labeled compounds to would necessarily be greater than 5g. All samples are homogenized properly and extracted in a Soxhlet extraction apparatus or Accelerated Solvent Extractor (ASE). The extract is concentrated for clean up.

Fish and other tissue ¹⁴C An aliquot of tissue sufficient enough to provide sample for PCB and lipid analysis is homogenized and spiked with labeled compounds. The sample is mixed with anhydrous sodium sulfate, allowed to dry for 12-24 hours, and extracted for 16-24 hours using a 1:1 dichloromethane/hexane solution in a Soxhlet extraction apparatus. The extract is split; with one aliquot concentrated for clean up and the other concentrated for lipid determination.

After extraction, a labeled clean up standard is spiked into the extract which is then cleaned up using back-extraction with sulfuric acid and/or base, and silica gel or Florisil chromatography.

After clean up, the extract is concentrated to 20µL. Immediately prior to injection, labeled injection internal standards are added to each extract and an aliquot of the extract is injected into the gas chromatograph (GC). The analytes are separated by the GC and detected by a high resolution (10,000) mass spectrometer. Two exact m/z's are monitored at each level of chlorination throughout a pre-determined retention time window.

An individual PCB congener is identified by comparing the GC retention time and ion-abundance ratio of two exact m/z's with the corresponding retention time of an authentic standard and the theoretical or acquired ion-abundance ratio of the two exact m/z's. Isomer specificity for certain of the CB congeners is achieved using GC columns that resolve these congeners.

Quantitative analysis is performed in one of two ways using selected ion current profile (SICP) areas:

For the toxics and the earliest and latest level of chlorination CBs (Toxics/LOC), the GC/MS is multi-point calibrated and the concentration is determined using the isotope dilution technique.

For all other congeners, the GC/MS is calibrated at a single concentration and the concentrations are determined using the internal standard technique.

For the labeled congeners, the GC/MS is calibrated using replicates at a single concentration and the concentrations of these labeled compounds are determined using the internal standard technique.

The quality of analysis is assured through reproducible calibration and testing of the extraction, clean up and GC/MS systems.

Water Extraction Method (PAH and OC)

Water samples are either immediately processed or stored refrigerated (4 degrees C) until processing. The pH of samples is adjusted to <2 by the addition of 1 mL of hydrochloric acid. Samples are serially extracted using separatory funnels and dichloromethane. For a 1 L sample, 100 mL of dichloromethane is added. The sample is then shaken for three minutes. The organic layer is allowed to separate from the aqueous phase. The organic layer is drained into a 500 mL round bottom flask

through a glass funnel containing a glass fiber filter and combusted sodium sulfate. This process is repeated twice more. The extract is concentrated to approximately 10 mL in the 500 mL round bottom flasks in a water bath at 55-60 degrees C and then transferred to 25 mL Kurdena-Danish (KD) concentrator tubes. The sample extract is concentrated to 3 mL in a water bath at 55-60 degrees C. If extractable organic material weight is required, a 100 micro litter aliquot is removed and weighed using a microbalance. Interfering non-contaminant organic materials may be removed prior to instrument analyses.

If the extract is colored then sample clean up may be required. The extract is processed through silica gel/alumina chromatography columns. The sample extract is loaded on top of 300 mm x 19 mm glass liquid chromatography columns packed with 10 g of deactivated alumina and 20 g of deactivated silica gel. The columns are loaded in 100 % dichloromethane. The dichloromethane is replaced by adding 40 mL of pentane. The extract is carefully added to the top of the chromatography columns. The column is flushed at a rate of 1-2 mL per minute using 200 mL of 50:50 pentane/dichloromethane and collected into 250 mL flasks. The eluent collected in the 250 mL flask is evaporated to 2 mL using a waterbath at 55-50 degrees C. The samples is transferred into 2 mL amber vials. The concentrated extract is then analyzed by GC/MS for polynuclear aromatic hydrocarbons (PAHs) or GC/ECD for selected organochlorines (OCs).

Additional column chromatography may be required to separate PCBs from toxaphene/pesticides when toxaphene analysis is required and to separate planar PCBs. If toxaphene analyses is required, an aliquot of the extract after silica/alumina clean-up is processed through a 3% deactivated silica gel column. The column is packed in dicloromethane which is then flushed with 50 mL of pentane. The sample extract is transferred to the top of the column and flushed with 100 mL of pentane. The fraction contains PCBs and DDTs. The column is then flushed with 120 mL of 50:50 pentane/dichloromethane. This fraction contains toxaphene and chlorinated pesticides. Both fractions are reduced to 1 mL using a water bath at 55-60 degrees C. The extracts are then ready for instrument analysis.

If planar PCB analyses are required, the PCB/DDT fraction prepared by 3% silica gel column is further processed by column chromatography packed with 2 g of 1:19 (5% by weight) mixture of activated carbon/Celite. The column and flushed with 25 mL of 1:4 dichloromethane/cyclohexane mixture. The sample is added to the top of the column and flushed with 50 mL of 1:4 dichloromethane/cyclohexane mixture, followed by 30 mL of 9:1 dichloromethane/toluene. This is followed by the addition of 40 mL of toluene. The toluene fraction contains the planar PCBs and is concentrated to 1 mL in a Zymark TurboVap II concentrator at 42 degrees C and 20 psi. The sample is ready for instrument analysis.

Summary of Method 1668A

This procedure uses matrix specific extraction, analyte specific cleanup, and HRGC/HRMS analysis techniques for PCB congeners.

Aqueous samples (samples containing less than one percent solids) ^{13}C Stable isotopically labeled analogs of the toxics and labeled earliest and latest level of chlorination (LOC) PCBs are spiked into the sample aliquot. The sample is extracted using a separatory funnel extraction and concentrated for clean up.

Solid, semi-solid, and multi-phase samples (excluding tissue) ^{13}C The labeled compounds are spiked into sample material that corresponds to approximately 5g on a dry weight basis. For samples with high moisture content, the amount of wet weight material to add the labeled compounds to would necessarily be greater than 5g. All samples are homogenized properly and extracted in a Soxhlet extraction apparatus or Accelerated Solvent Extractor (ASE). The extract is concentrated for clean up.

Fish and other tissue ^{13}C An aliquot of tissue sufficient enough to provide sample for PCB and lipid analysis is homogenized and spiked with labeled compounds. The sample is mixed with anhydrous sodium sulfate, allowed to dry for 12-24 hours, and extracted for 16-24 hours using a 1:1 dichloromethane/hexane solution in a Soxhlet extraction apparatus. The extract is split; with one aliquot concentrated for clean up and the other concentrated for lipid determination.

After extraction, a labeled clean up standard is spiked into the extract which is then cleaned up using back-extraction with sulfuric acid and/or base, and silica gel or Florisil chromatography.

After clean up, the extract is concentrated to 20 μL . Immediately prior to injection, labeled injection internal standards are added to each extract and an aliquot of the extract is injected into the gas chromatograph (GC). The analytes are separated by the GC and detected by a high resolution ($>10,000$) mass spectrometer. Two exact m/z 's are monitored at each level of chlorination throughout a pre-determined retention time window.

An individual PCB congener is identified by comparing the GC retention time and ion-abundance ratio of two exact m/z 's with the corresponding retention time of an authentic standard and the theoretical or acquired ion-abundance ratio of the two exact m/z 's. Isomer specificity for certain of the CB congeners is achieved using GC columns that resolve these congeners.

Quantitative analysis is performed in one of two ways using selected ion current profile (SICP) areas:

For the toxics and the earliest and latest level of chlorination CBs (Toxics/LOC), the GC/MS is multi-point calibrated and the concentration is determined using the isotope dilution technique.

For all other congeners, the GC/MS is calibrated at a single concentration and the concentrations are determined using the internal standard technique.

For the labeled congeners, the GC/MS is calibrated using replicates at a single concentration and the concentrations of these labeled compounds are determined using the internal standard technique.

The quality of analysis is assured through reproducible calibration and testing of the extraction, clean up and GC/MS systems.

Catalog Description

Catalog Instructions

The priority where samples have multiple chemical analyses requested is 209 PCB by HRGC/HRMS, lipids, organochlorine pesticides, heavy metals (and As, Hg, Se), PBDEs, dioxins, aromatics and then other analytes. Note that the fish was dissected and stored in a freezer for up to 2 years, and therefore, moisture content has likely largely been lost and is NOT a priority for analysis although this "analyte" has been requested.

Sample Comments
These Rio Grande silvery minnow were seined from the Rio Grande at various sites and dates. They were held in a live well until necropsy. After being subdued by a blow to the head, individual health observations were made and recorded elsewhere. The gonads were removed for histopathology. During the necropsy, these organs as well as various fluids were lost from the sample. The remaining innards were tucked back in and each individual fish was wrapped in aluminum foil and stored in freezer for up to 2 years. Up to 30 fish (or more) were then composited into a labeled jar and shipped frozen for chemical analyses.

Field Preparation Comments
These Rio Grande silvery minnow were seined from the Rio Grande at various sites and dates. They were held in a live well until necropsy. After being subdued by a blow to the head, individual health observations were made and recorded elsewhere. The gonads were removed for histopathology. During the necropsy, these organs as well as various fluids were lost from the sample. The remaining innards were tucked back in and each individual fish was wrapped in aluminum foil and stored in freezer for up to 2 years. Up to 30 fish (or more) were then composited into a labeled jar and shipped frozen for chemical analyses.

Analysis Requested Comments
For those samples with multiple analyses, the priority for results is the 209 PCB by HRGC/HRMS, then the Organochlorine scan (with determination of percent lipids is Priority 2), then determination of PBDE and/or dioxin/furan, then the Metal Scan and/or methyl mercury is Priority 4 (moisture content is also requested but is not a priority).

Common Name	Rio Grande Silvery Minnow		
Family	Cyprinidae		
Genus / Kingdom	Hybognathus / Animalia		
Species	Hybognathus amarus		

Specimen Abnormalities

(These observations were not necessarily determined by a pathologist)

N/A

Sample Comments

These Rio Grande silvery minnow were seined from the Rio Grande at various sites and dates. They were held in a live well until necropsy. After being subdued by a blow to the head, individual health observations were made and recorded elsewhere. The gonads were removed for histopathology. During the necropsy, these organs as well as various fluids were lost from the sample. The remaining innards were tucked back in and each individual fish was wrapped in aluminum foil and stored in freezer for up to 2 years. Up to 30 fish (or more) were then composited into a labeled jar and shipped frozen for chemical analyses.

Field Preparation Comments

Seine collection, kept alive, subdued by blow to head, dissected for observations, gonads removed, individual frozen in foil, then all from site removed and composited for chemical analyses.

Analysis Requested Comments

For those samples with multiple analyses, the priority for results is the 209 PCB by HRGC/HRMS, then the Organochlorine scan (with determination of percent lipids is Priority 2), then determination of PBDE and/or dioxin/furan, then the Metal Scan and/or methyl mercury is Priority 4 (moisture content is also requested but is not a priority).

Up to 30 fish (or more) were then composited into a labeled jar and shipped frozen for chemical analyses.

Field Preparation Comments

Seine collection, kept alive, subdued by blow to head, dissected for observations, gonads removed, individual frozen in foil, then all from site removed and composited for chemical analyses.

Analysis Requested Comments

Please homogenize and composite all minnow in a sample. For those samples with multiple analyses, the priority for results is the 209 PCB by HRGC/HRMS, then the Organochlorine scan (with determination of percent lipids is Priority 2), then determination of PBDE and/or dioxin/furan, then the Metal Scan and/or methyl mercury is Priority 4 (moisture content is also requested but is not a priority).

Sample Comments

These Rio Grande silvery minnow were seined from the Rio Grande at various sites and dates. They were held in a live well until necropsy. After being subdued by a blow to the head, individual health observations were made and recorded elsewhere. The gonads were removed for histopathology. During the necropsy, these organs as well as various fluids were lost from the sample. The remaining innards were tucked back in and each individual fish was wrapped in aluminum foil and stored in freezer for up to 2 years. Up to 30 fish (or more) were then composited into a labeled jar and shipped frozen for chemical analyses.

Field Preparation Comments

Seine collection, kept alive, subdued by blow to head, dissected for observations, gonads removed, individual frozen in foil, then all from site removed and composited for chemical analyses.

Genus / Kingdom	Hybognathus / Animalia		
Species	Hybognathus amarus		

Specimen Abnormalities <i>(These observations were not necessarily determined by a pathologist)</i>
N/A

Sample Comments
<p>These Rio Grande silvery minnow were seined from the Rio Grande at various sites and dates. They were held in a live well until necropsy. After being subdued by a blow to the head, individual health observations were made and recorded elsewhere. The gonads were removed for histopathology. During the necropsy, these organs as well as various fluids were lost from the sample. The remaining innards were tucked back in and each individual fish was wrapped in aluminum foil and stored in freezer for up to 2 years. Up to 30 fish (or more) were then composited into a labeled jar and shipped frozen for chemical analyses.</p>

Field Preparation Comments
Seine collection, kept alive, subdued by blow to head, dissected for observations, gonads removed, individual frozen in foil, then all from site removed and composited for chemical analyses.

Analysis Requested Comments
Please homogenize and composite all minnow in a sample. For those samples with multiple analyses, the priority for results is the 209 PCB by HRGC/HRMS, then the Organochlorine scan (with determination of percent lipids is Priority 2), then determination of PBDE and/or dioxin/furan, then the Metal Scan and/or methyl mercury is Priority 4 (moisture content is also requested but is not a priority).

Specimen Abnormalities

(These observations were not necessarily determined by a pathologist)

N/A

Sample Comments

These Rio Grande silvery minnow were seined from the Rio Grande at various sites and dates. They were held in a live well until necropsy. After being subdued by a blow to the head, individual health observations were made and recorded elsewhere. The gonads were removed for histopathology. During the necropsy, these organs as well as various fluids were lost from the sample. The remaining innards were tucked back in and each individual fish was wrapped in aluminum foil and stored in freezer for up to 2 years. Up to 30 fish (or more) were then composited into a labeled jar and shipped frozen for chemical analyses.

Field Preparation Comments

Seine collection, kept alive, subdued by blow to head, dissected for observations, gonads removed, individual frozen in foil, then all from site removed and composited for chemical analyses.

Analysis Requested Comments

Please homogenize and composite all minnow in a sample. For those samples with multiple analyses, the priority for results is the 209 PCB by HRGC/HRMS, then the Organochlorine scan (with determination of percent lipids is Priority 2), then determination of PBDE and/or dioxin/furan, then the Metal Scan and/or methyl mercury is Priority 4 (moisture content is also requested but is not a priority).

Bosque Del Apache National Wildlife Refuge , New Mexico
Sevilleta National Wildlife Refuge , New Mexico

Catalog Description

Catalog Instructions

The priority where samples have multiple chemical analyses requested is 209 PCB by HRGC/HRMS, lipids, organochlorine pesticides, heavy metals (and As, Hg, Se), PBDEs, dioxins, aromatics and then other analytes. Note that the fish was dissected and stored in a freezer for up to 2 years, and therefore, moisture content has likely largely been lost and is NOT a priority for analysis although this "analyte" has been requested.

N/A

Sample Comments
These Rio Grande silvery minnow were seined from the Rio Grande at various sites and dates. They were held in a live well until necropsy. After being subdued by a blow to the head, individual health observations were made and recorded elsewhere. The gonads were removed for histopathology. During the necropsy, these organs as well as various fluids were lost from the sample. The remaining innards were tucked back in and each individual fish was wrapped in aluminum foil and stored in freezer for up to 2 years. Up to 30 fish (or more) were then composited into a labeled jar and shipped frozen for chemical analyses.

Sex	Mixed (composite)	Age	Adult
Egg Condition	N/A		
Taxonomical Group	Fish		
Common Name	Rio Grande Silvery Minnow		
Family	Cyprinidae		
Genus / Kingdom	Hybognathus / Animalia		
Species	Hybognathus amarus		

Specimen Abnormalities

(These observations were not necessarily determined by a pathologist)

N/A

Sample Comments

These Rio Grande silvery minnow were seined from the Rio Grande at various sites and dates. They were held in a live well until necropsy. After being subdued by a blow to the head, individual health observations were made and recorded elsewhere. The gonads were removed for histopathology. During the necropsy, these organs as well as various fluids were lost from the sample. The remaining innards were tucked back in and each individual fish was wrapped in aluminum foil and stored in freezer for up to 2 years. Up to 30 fish (or more) were then composited into a labeled jar and shipped frozen for chemical analyses.

Field Preparation Comments

Seine collection, kept alive, subdued by blow to head, dissected for observations, gonads removed, individual frozen in foil, then all from site removed and composited for chemical analyses.

Analysis Requested Comments

For those samples with multiple analyses, the priority for results is the 209 PCB by HRGC/HRMS, then the Organochlorine scan (with determination of percent lipids is Priority 2), then determination of PBDE and/or dioxin/furan, then the Metal Scan and/or methyl mercury is Priority 4 (moisture content is also requested but is not a priority).

Analysis Requested

Organic Analysis
PBDE - Polybrominated Diphenyl Ethers
Inorganic Analysis
Metals Scan

Sample Comments
These Rio Grande silvery minnow were seined from the Rio Grande at various sites and dates. They were held in a live well until necropsy. After being subdued by a blow to the head, individual health observations were made and recorded elsewhere. The gonads were removed for histopathology. During the necropsy, these organs as well as various fluids were lost from the sample. The remaining innards were tucked back in and each individual fish was wrapped in aluminum foil and stored in freezer for up to 2 years. Up to 30 fish (or more) were then composited into a labeled jar and shipped frozen for chemical analyses.

Field Preparation Comments
Seine collection, kept alive, subdued by blow to head, dissected for observations, gonads removed, individual frozen in foil, then all from site removed and composited for chemical analyses.
Analysis Requested Comments
Please homogenize and composite all minnow in a sample. For those samples with multiple analyses, the priority for results is the 209 PCB by HRGC/HRMS, then the Organochlorine scan (with determination of percent lipids is Priority 2), then determination of PBDE and/or dioxin/furan, then the Metal Scan and/or methyl mercury is Priority 4 (moisture content is also requested but is not a priority).

Egg Condition	N/A		
Taxonomical Group	Fish		
Common Name	Rio Grande Silvery Minnow		
Family	Cyprinidae		
Genus / Kingdom	Hybognathus / Animalia		
Species	Hybognathus amarus		

Specimen Abnormalities

(These observations were not necessarily determined by a pathologist)

N/A

Sample Comments

These Rio Grande silvery minnow were seined from the Rio Grande at various sites and dates. They were held in a live well until necropsy. After being subdued by a blow to the head, individual health observations were made and recorded elsewhere. The gonads were removed for histopathology. During the necropsy, these organs as well as various fluids were lost from the sample. The remaining innards were tucked back in and each individual fish was wrapped in aluminum foil and stored in freezer for up to 2 years. Up to 30 fish (or more) were then composited into a labeled jar and shipped frozen for chemical analyses.

Field Preparation Comments

Seine collection, kept alive, subdued by blow to head, dissected for observations, gonads removed, individual frozen in foil, then all from site removed and composited for chemical analyses.

Analysis Requested Comments

Please homogenize and composite all minnow in a sample. For those samples with multiple analyses, the priority for results is the 209 PCB by HRGC/HRMS, then the Organochlorine scan (with determination of percent lipids is Priority 2), then determination of PBDE and/or dioxin/furan, then the Metal Scan and/or methyl mercury is Priority 4 (moisture content is also requested but is not a priority).

Sample Comments

These Rio Grande silvery minnow were seined from the Rio Grande at various sites and dates. They were held in a live well until necropsy. After being subdued by a blow to the head, individual health observations were made and recorded elsewhere. The gonads were removed for histopathology. During the necropsy, these organs as well as various fluids were lost from the sample. The remaining innards were tucked back in and each individual fish was wrapped in aluminum foil and stored in freezer for up to 2 years. Up to 30 fish (or more) were then composited into a labeled jar and shipped frozen for chemical analyses.

Field Preparation Comments

Seine collection, kept alive, subdued by blow to head, dissected for observations, gonads removed, individual frozen in foil, then all from site removed and composited for chemical analyses.

Analysis Requested Comments

Please homogenize and composite all minnow in a sample. For those samples with multiple analyses, the priority for results is the 209 PCB by HRGC/HRMS, then the Organochlorine scan (with determination of percent lipids is Priority 2), then determination of PBDE and/or dioxin/furan, then the Metal Scan and/or methyl mercury is Priority 4 (moisture content is also requested but is not a priority).

Bosque Del Apache National Wildlife Refuge , New Mexico
Sevilleta National Wildlife Refuge , New Mexico

Catalog Description

Catalog Instructions

The priority where samples have multiple chemical analyses requested is 209 PCB by HRGC/HRMS, lipids, organochlorine pesticides, heavy metals (and As, Hg, Se), PBDEs, dioxins, aromatics and then other analytes. Note that the fish was dissected and stored in a freezer for up to 2 years, and therefore, moisture content has likely largely been lost and is NOT a priority for analysis although this "analyte" has been requested.

Egg Condition	N/A		
Taxonomical Group	Fish		
Common Name	Rio Grande Silvery Minnow		
Family	Cyprinidae		
Genus / Kingdom	Hybognathus / Animalia		
Species	Hybognathus amarus		

Specimen Abnormalities

(These observations were not necessarily determined by a pathologist)

N/A

Sample Comments

These Rio Grande silvery minnow were seined from the Rio Grande at various sites and dates. They were held in a live well until necropsy. After being subdued by a blow to the head, individual health observations were made and recorded elsewhere. The gonads were removed for histopathology. During the necropsy, these organs as well as various fluids were lost from the sample. The remaining innards were tucked back in and each individual fish was wrapped in aluminum foil and stored in freezer for up to 2 years. Up to 30 fish (or more) were then composited into a labeled jar and shipped frozen for chemical analyses.

Field Preparation Comments

Seine collection, kept alive, subdued by blow to head, dissected for observations, gonads removed, individual frozen in foil, then all from site removed and composited for chemical analyses.

Analysis Requested Comments

Please homogenize and composite all minnow in a sample. For those samples with multiple analyses, the priority for results is the 209 PCB by HRGC/HRMS, then the Organochlorine scan (with determination of percent lipids is Priority 2), then determination of PBDE and/or dioxin/furan, then the Metal Scan and/or methyl mercury is Priority 4 (moisture content is also requested but is not a priority).

These Rio Grande silvery minnow were seined from the Rio Grande at various sites and dates. They were held in a live well until necropsy. After being subdued by a blow to the head, individual health observations were made and recorded elsewhere. The gonads were removed for histopathology. During the necropsy, these organs as well as various fluids were lost from the sample. The remaining innards were tucked back in and each individual fish was wrapped in aluminum foil and stored in freezer for up to 2 years. Up to 30 fish (or more) were then composited into a labeled jar and shipped frozen for chemical analyses.

Field Preparation Comments

Seine collection, kept alive, subdued by blow to head, dissected for observations, gonads removed, individual frozen in foil, then all from site removed and composited for chemical analyses.

Analysis Requested Comments

Please homogenize and composite all minnow in a sample. For those samples with multiple analyses, the priority for results is the 209 PCB by HRGC/HRMS, then the Organochlorine scan (with determination of percent lipids is Priority 2), then determination of PBDE and/or dioxin/furan, then the Metal Scan and/or methyl mercury is Priority 4 (moisture content is also requested but is not a priority).

Taxonomical Group	Fish		
Common Name	Rio Grande Silvery Minnow		

Family	Cyprinidae
Genus / Kingdom	Hybognathus / Animalia
Species	Hybognathus amarus

Specimen Abnormalities <i>(These observations were not necessarily determined by a pathologist)</i>
N/A

Sample Comments
These Rio Grande silvery minnow were seined from the Rio Grande at various sites and dates. They were held in a live well until necropsy. After being subdued by a blow to the head, individual health observations were made and recorded elsewhere. The gonads were removed for histopathology. During the necropsy, these organs as well as various fluids were lost from the sample. The remaining innards were tucked back in and each individual fish was wrapped in aluminum foil and stored in freezer for up to 2 years. Up to 30 fish (or more) were then composited into a labeled jar and shipped frozen for chemical analyses.

Field Preparation Comments
Seine collection, kept alive, subdued by blow to head, dissected for observations, gonads removed, individual frozen in foil, then all from site removed and composited for chemical analyses.
Analysis Requested Comments
Please homogenize and composite all minnow in a sample. For those samples with multiple analyses, the priority for results is the 209 PCB by HRGC/HRMS, then the Organochlorine scan (with determination of percent lipids is Priority 2), then determination of PBDE and/or dioxin/furan, then the Metal Scan and/or methyl mercury is Priority 4 (moisture content is also requested but is not a priority).
