Review of draft PDM plant for *Trichostema austromontanum* ssp. *compactum*

I found the proposed rule well thought out and described.

I have just a few suggestions for monitoring activities that may be included. My main concern is with the size of the soil seed bank. It would be useful to have some baseline data on its size, distribution through the soil profile, and geographic range. I understand that the plant is self-compatible, so pollen limitation is unlikely to be an important limitation, but it would be good to know average seed set per plant, again, to be able to estimate fluctuations in the size of the soil seed bank, and, thus, the future stability of the population.
