**Knieskern's beaked-rush**

**DESCRIPTION:** Knieskern's beaked-rush (*Rhynchospora knieskernii*) was listed as a threatened species on July 18, 1991, pursuant to the Endangered Species Act of 1973 (87 Stat. 884, as amended; 16 U.S.C. 1531 et seq.). Knieskern's beaked-rush belongs to the sedge family and is endemic to the Pinelands region of New Jersey. This grass-like plant was generally considered to be an annual species; however, it is currently suspected to be a short-lived perennial in locations where habitat conditions are stable, allowing uninterrupted growth year after year. Knieskern's beaked-rush grows from 1.5 to 60 centimeters high (0.6 to 24 inches), has slender culms (stems) branching from the base, and short, narrowly linear leaves. Small spikelets (flower clusters) are numerous and occur at distant intervals along the entire length of the culm. The achene (fruit) is obovate, narrow at the base, 1.1 to 1.3 millimeters long (0.04 to 0.05 inches), and equal in length to the six downwardly-barbed or rarely, upwardly-barbed attached bristles. Fruiting typically occurs from July to September (U.S. Fish and Wildlife Service, 1993).

**HABITAT:** Knieskern's beaked-rush is an obligate hydrophyte (wetland plant) that occurs in groundwater-influenced, constantly fluctuating, successional habitats. An early successional species and colonizer, Knieskern's beaked-rush is intolerant of competition, especially from woody species. It is found on naturally occurring early successional habitats and disturbed areas such as burns, bog-iron deposits, gravel and clay pits, road cuts, mowed roadsides, utility and railroad rights-of-way, cleared home sites, eroded areas, cleared edges of Atlantic white-cedar swamps, wheel ruts, and muddy swales (Gordon, 1993; U.S. Fish and Wildlife Service, 1993; Radis, 1995). In the past, fire may have played an important role in creating and maintaining suitable habitat for Knieskern's beaked-rush. Occurrence records indicate that this plant is found in wet open areas within fire-dependent open pitch-pine forests. Periodic disturbance, either natural or human-induced, which maintains a damp-to-wet site in an early ecological successional stage, may be necessary for the successful colonization, establishment, recruitment, and maintenance of this species.
Human-disturbed sites exhibit some of the same characteristics as bog-iron sites, including a high water table, temporary inundation, and open, early-successional habitat with relatively bare substrate. Plant species associated with Knieskern's beaked-rush include warty panic-grass (*Panicum verrucosum*), poverty-grass (*Aristida longispeca*), and spatulate-leaved sundew (*Drosera intermedia*) (Gordon, 1993).

**THREATS:** Originally, the primary threat to the species was the loss of wetlands to urban and agricultural development. However, current State and federal wetland protection laws have reduced the loss of wetlands over time. Presently, vegetative succession is a major factor threatening Knieskern's beaked-rush. Human-induced threats to the species include alteration of wetland hydrology, off-road vehicle activity, trash dumping, and possibly roadside grading (U.S. Fish and Wildlife Service, 1993). Gordon (1993) found that fire can be both beneficial and detrimental to the species depending on the timing, duration, and intensity of the burn.

**SURVEY REQUIREMENTS:** The Service requests that a qualified biologist conduct a comprehensive search for Knieskern's beaked-rush in any potentially suitable early successional wetlands or disturbed wet areas that may be impacted by project activities. Surveys should be conducted from July to September. Random transect surveys are inappropriate since the species may be present in small wet pockets, which may be overlooked by this survey method. Please report in writing the survey method used, the qualifications of the surveyor, and the results of the survey to:
