Presented at:

**Climate Change, Natural Resources and Coastal Management, a
Workshop on the Coastal Ecosystems of California, Oregon and
Washington (29-30 January 2009)**

San Francisco, California

Purpose

Illustrate links between interannual variations in eelgrass and some climate-related indicators, speculate on mechanisms of effect, discuss importance to carbon budgets

► Points-

- Interannual variations can be large
- Factors controlling eelgrass growth are climate-linked
- Warming could alter these factors
- Changes in eelgrass will affect fisheries resources and ecological processes
- It is important to include nearshore systems discussions of climate effects on the biosphere

Strong latitudinal gradient anomalies explained by water temperature (1980)

1956-59 seaweed records affected by Strong El Nino (1976)

A Resurvey of E. Yale Dawson's 42 Intertidal Algal Transects on the Southern California Mainland after 15 Years

Ronald M. Thom and Thomas B. Widdowson

Abstract.—The 42 intertidal transects established by E. Y. Dawson on the southern California mainland from 1956–1959 were resurveyed for their algal flora during 1973–1974. Although there were no losses of conspicuous species, the relative abundances of various forms had changed over the time period. The flora in the Orange County area had changed the most, with the greatest change being toward the turf and crustose species and away from the massive species. The Santa Barbara, Ventura, and San Diego floras were modified to an intermediate extent.

Department of Biology, California State University, Los Angeles, California 90040. Present address of Thom: College of Fisheries, University of Washington, Seattle, Washington 98195. Present address of Widdowson: Department of Biology, Victoria University, Victoria, British Columbia, Canada.

As part of an oceanographic and biological survey of the Puget Sound area, 44 transects were surveyed in 1982–3. Forty-two of these transects were located on the southern coast of the Sound, and two were located on the northern coast.

A GRADIENT IN BENTHIC INTERTIDAL ALGAL ASSEMBLAGES ALONG THE SOUTHERN CALIFORNIA COAST¹

Ronald M. Thom²

Department of Biology, California State University, Long Beach, California 90840

ABSTRACT

Based on records of 42 intertidal transects established by E. Y. Dawson on the southern California mainland from 1956–1959, a latitudinal gradient in the algal flora is described.

Marine Biology 104, 129–141 (1990)

Assemblages in this area. All of these previous works have focused on human-caused (e.g., pollution) changes in the algal populations within this densely populated section of coastline.

1982-3 El Nino affected Puget Sound nearshore habitats and water properties (1990)

Dynamics of benthic vegetation standing-stock, irradiance, and water properties in central Puget Sound *

Fisheries Research Institute, WH-10, University of Washington, Seattle, Washington 98195, USA

Abstract

The standing stock of benthic macroalgae, sediment-associated microalgae and eelgrass (*Zostera marina* L.) was sampled in conjunction with irradiance and water properties from June 1982 to March 1984 to examine the relationship between the standing stock of benthic primary producers and the physical and chemical properties of the water column. The standing stock of benthic primary producers peaked in August and September 1982, and was related to the standing stock of sediment-associated microalgae. The standing stock of eelgrass was related to the standing stock of sediment-associated microalgae. The standing stock of benthic primary producers was related to the standing stock of sediment-associated microalgae. The standing stock of eelgrass was related to the standing stock of sediment-associated microalgae.

and productivity. These dynamical changes are produced by purely physical factors such as solar energy, and an interaction of chemical and biological factors (e.g. nutrients, grazing) (Valiela 1984, Lobban et al. 1985). Partitioning of the relative influence of factors has generally been accomplished through controlled experiments focused on one or two species and on light, temperature and nutrient interactions (e.g. Gordon et al. 1980, De la Cruz et al. 1981). In a few instances, experimental and field data have been used to develop models relating light, temperature, and nutrient dynamics of dominant estuarine species (e.g. McIntire and Marsh et al. 1981).

Eelgrass

(*Zostera marina*)

- Most widespread of ~65 seagrass species
- One of 5 species in the PNW
- Flowering/rooted plant that forms meadows
- Spreads by rhizomes and seeds

Indices and Hypotheses

- **SOI** = Southern oscillation index
- **ONI** = Oceanic Niño Index
- **MEI** = Multivariate ENSO Index
- **PDO** = Pacific decadal oscillation
- **Mean Sea Level Anomaly** = Difference between long-term mean sea level and actual mean sea level

-
- **H₀** = no correlation between climate indexes and eelgrass variation
 - **H₁** = there is a correlation (so what is mechanism?)

Indexes and Mechanisms

- “Large scale climate indices (e.g., PDO, SOI) do a poor job of capturing the details of environmental changes at the scale of many (perhaps most) meaningful ecosystem interactions”
- There is a need to better understand the biophysical mechanisms underlying ecosystem changes
- Need to work at the correct scale
- Climate may act on ecosystems at a variety of dimensions
- Studies of physiological mechanism are needed to predict climate effects on ecosystems at species and community levels.

Climate Change and Seagrasses

(Short, F.T. and H.A. Neckles. 1999. The effects of global climate change on seagrasses. *Aquatic Botany* 63:169-196)

- ▶ Temperature
- ▶ Sea level rise
- ▶ Water movement
- ▶ Salinity intrusion
- ▶ Increasing carbon dioxide
- ▶ UV-B radiation

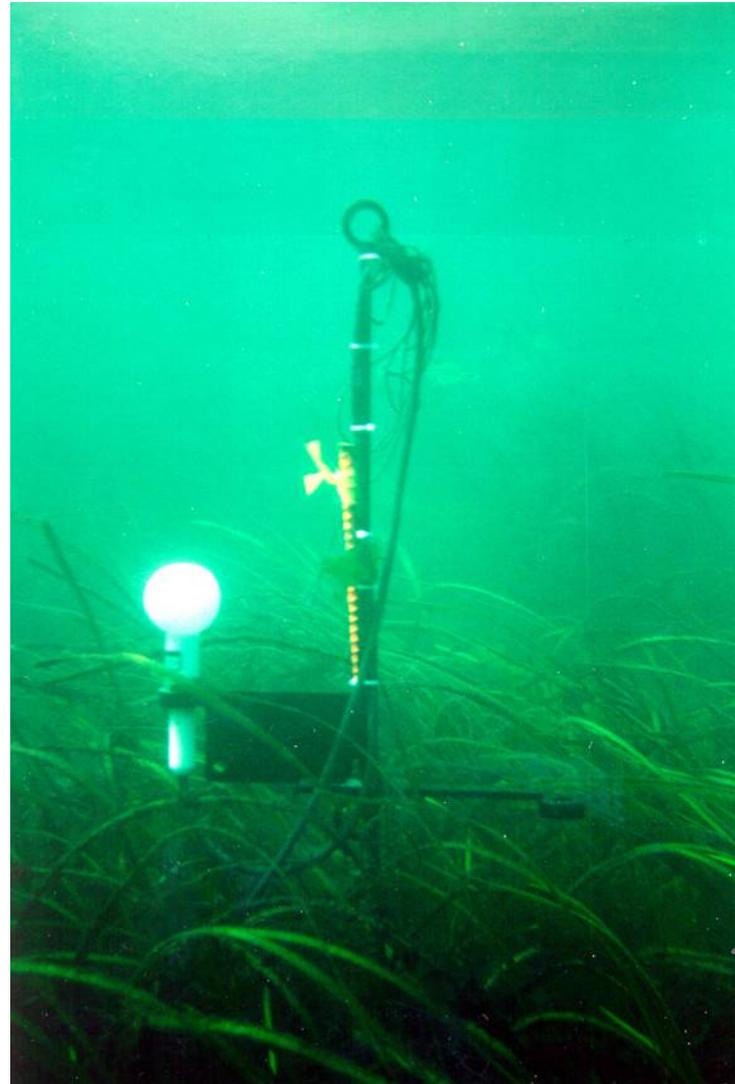

Data Sets

- ▶ Willapa Bay (1998-2001) - annual sampling at 6 sites
- ▶ Clinton Ferry terminal (1996-2008) - annual sampling at 3 sites
- ▶ Sequim Bay mouth (1991-2008) - summer sampling in 14 of the 18 years; experimental studies
- ▶ Morro Bay – Mapping (1960-2007) & depth v. density (2006)

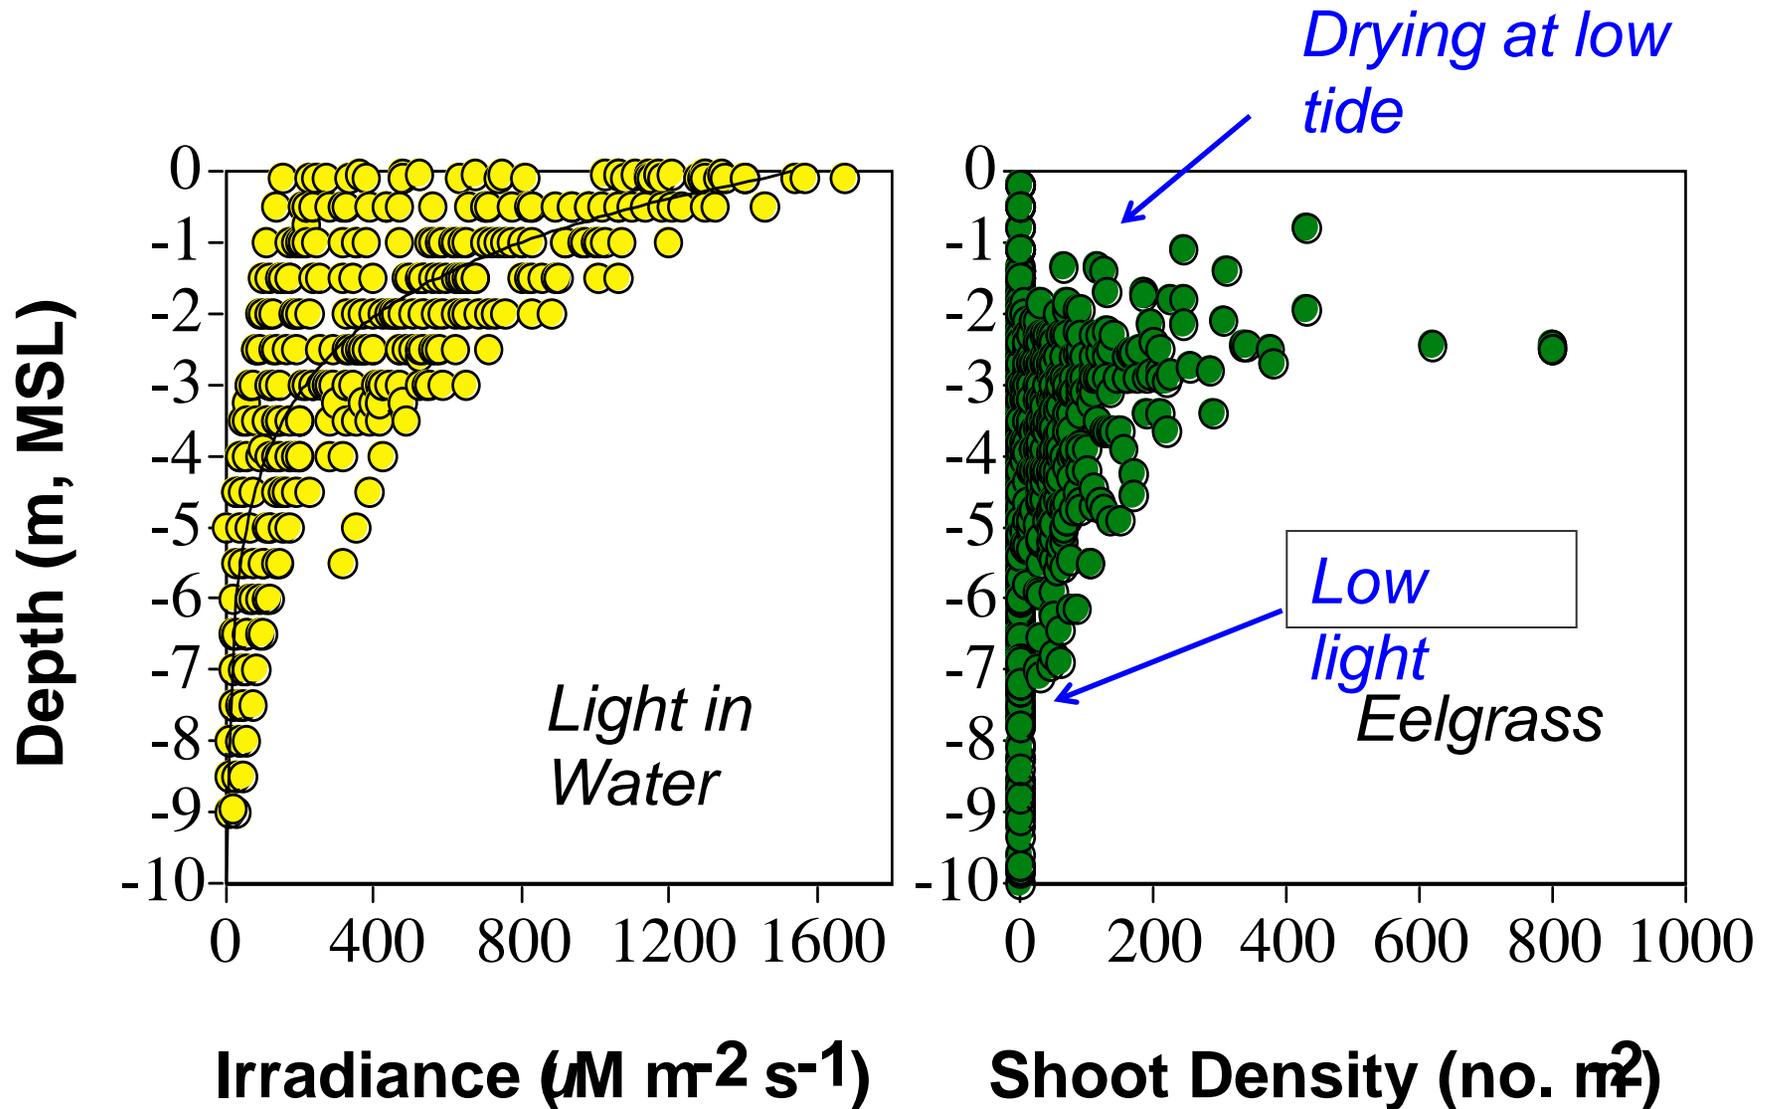

Factors Affecting Eelgrass

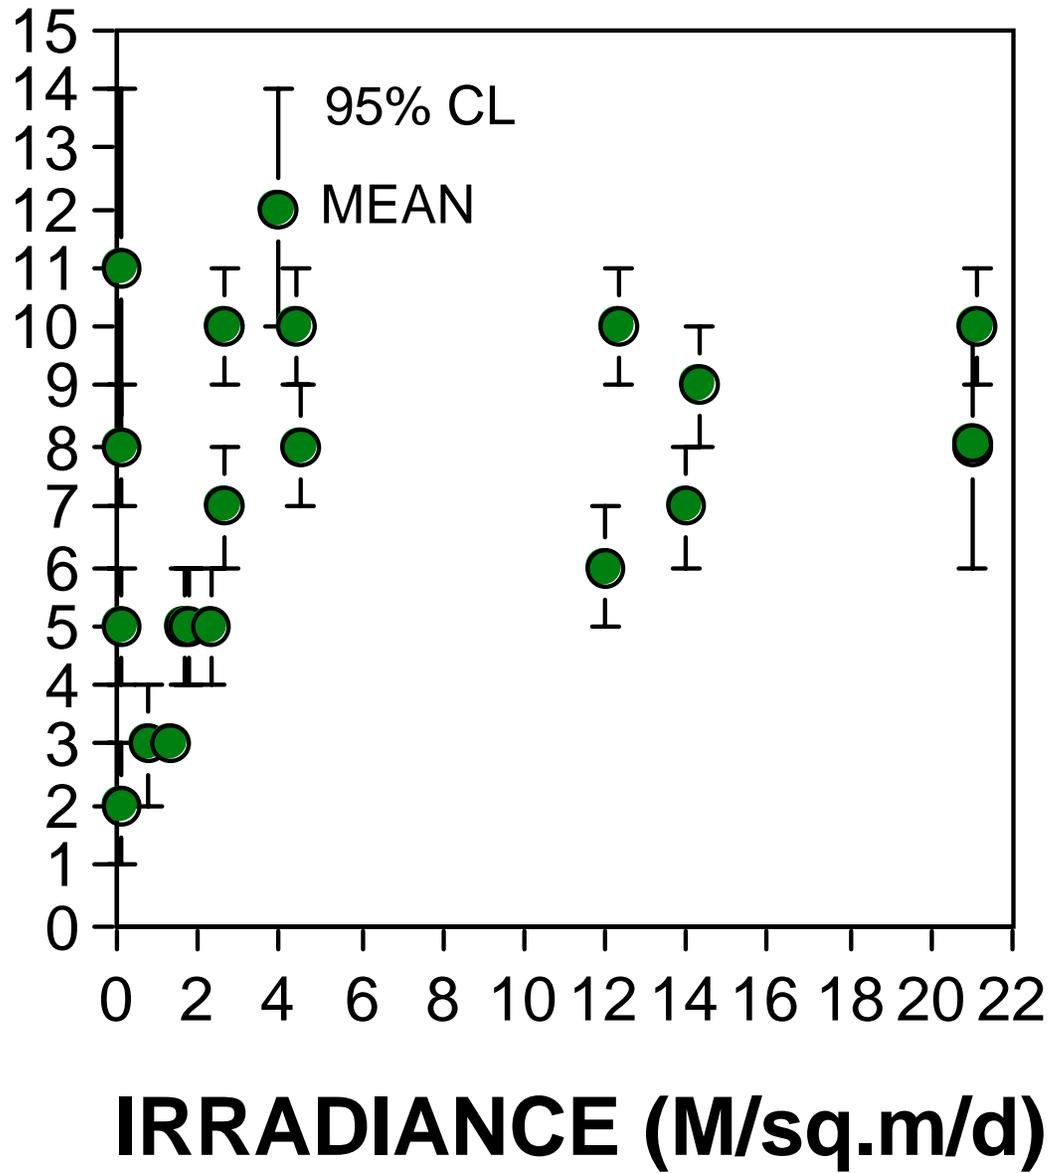

- ▶ *Light*
- ▶ *Temperature*
- ▶ *Desiccation*
- ▶ Salinity
- ▶ Substrata
- ▶ Nutrients
- ▶ Wave energy
- ▶ Eutrophication
- ▶ Grazing and Bioturbation

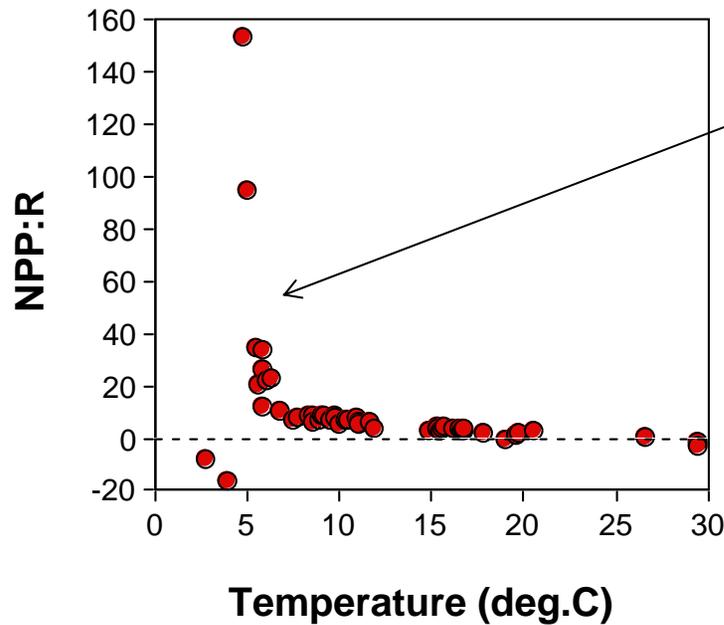

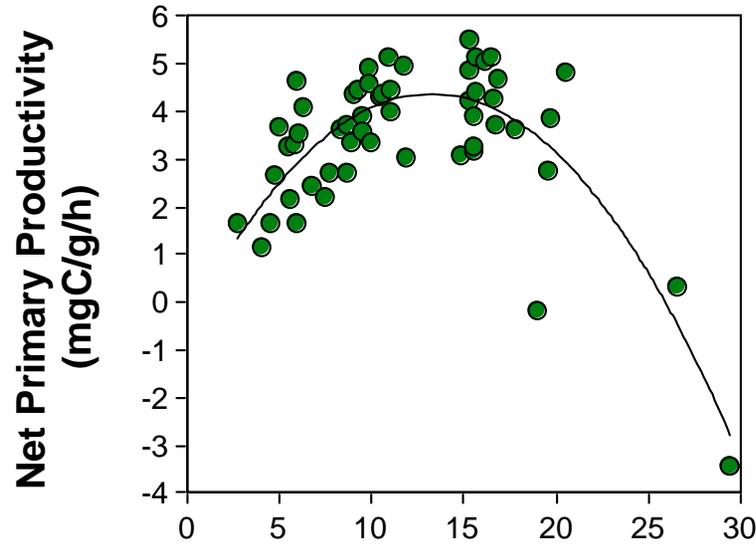

Light and Desiccation

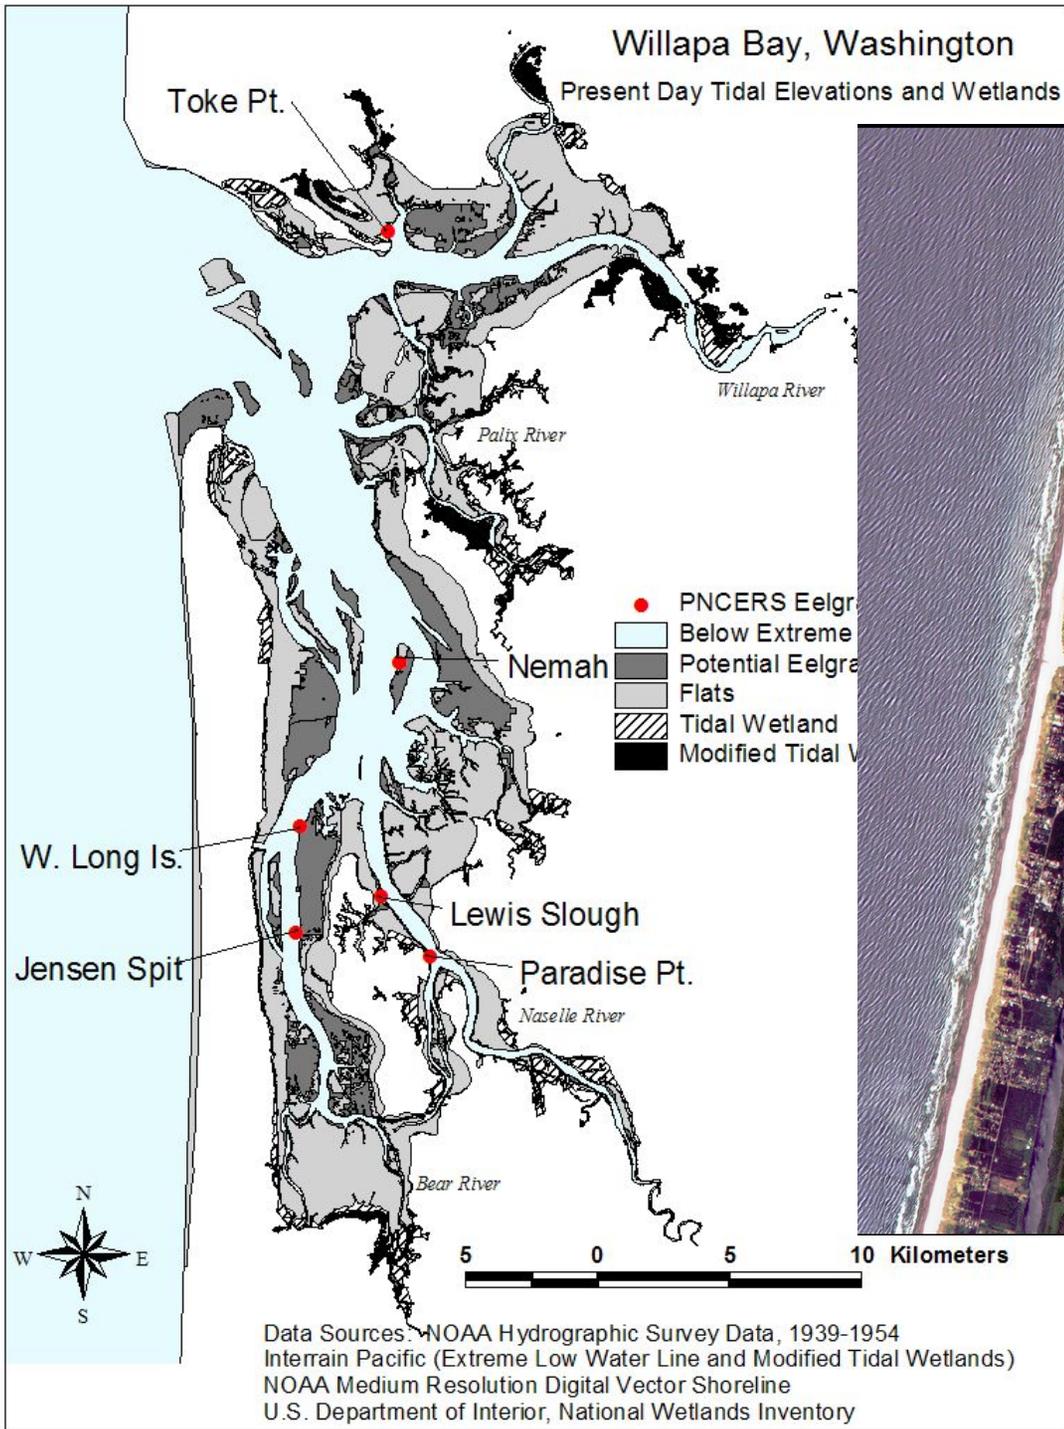

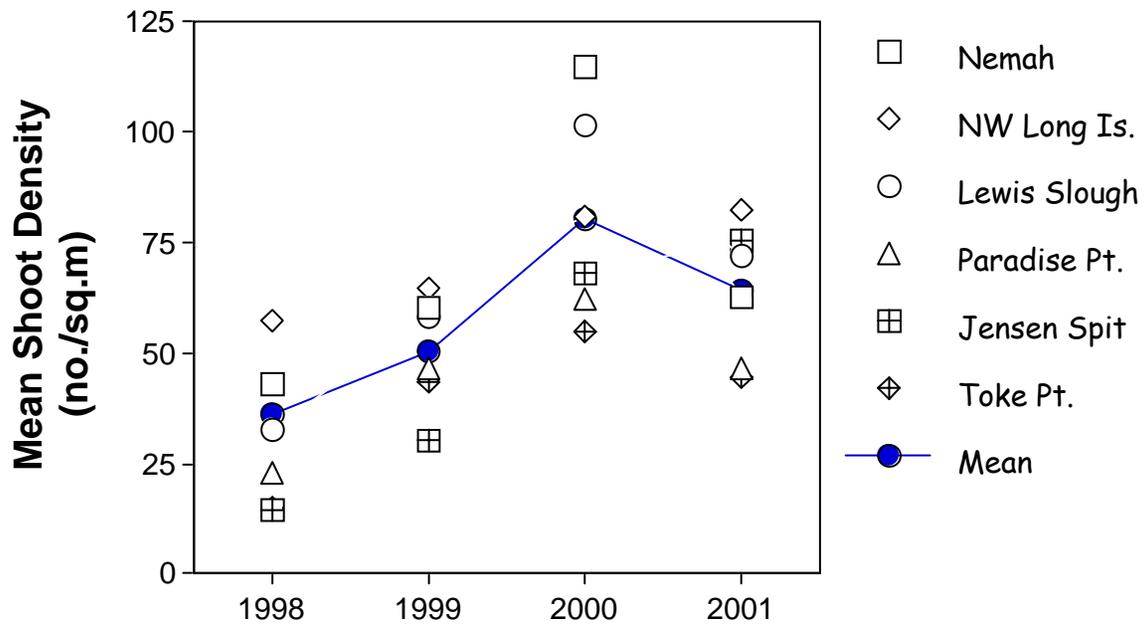

ZOSTERA GROWTH (mg dry/shoot/d)

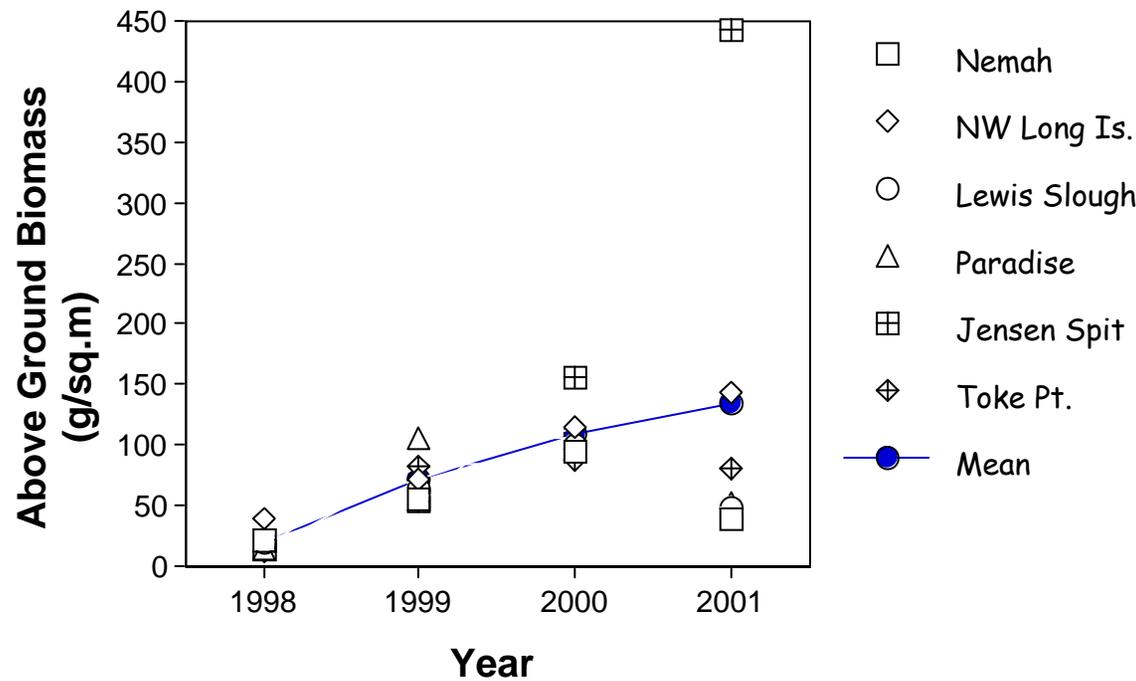

Temperature

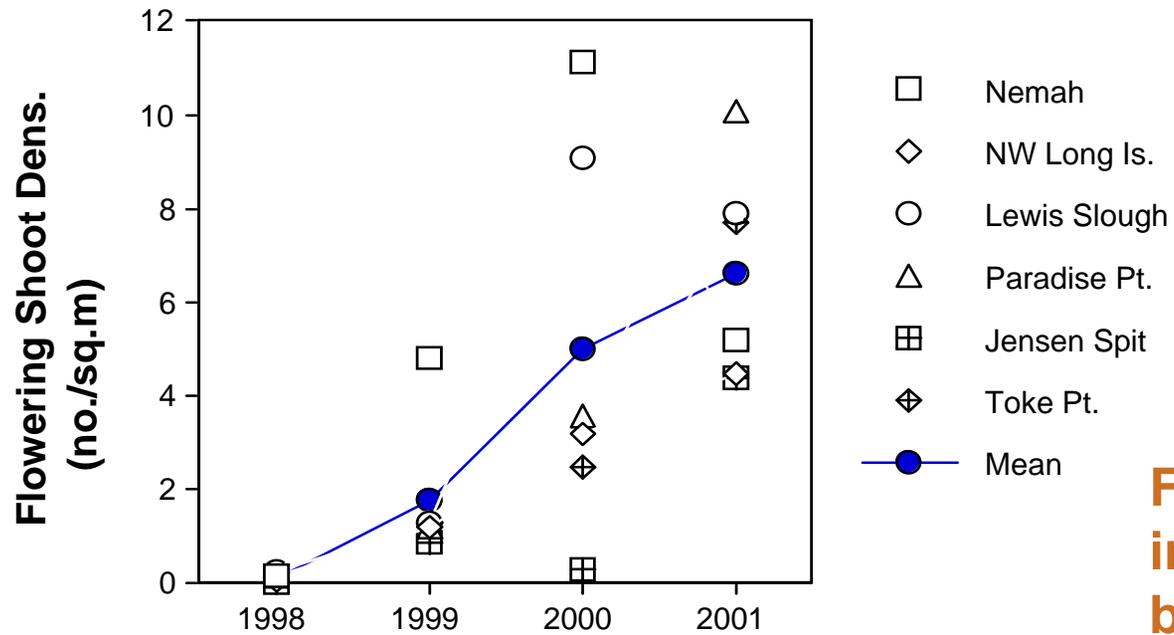

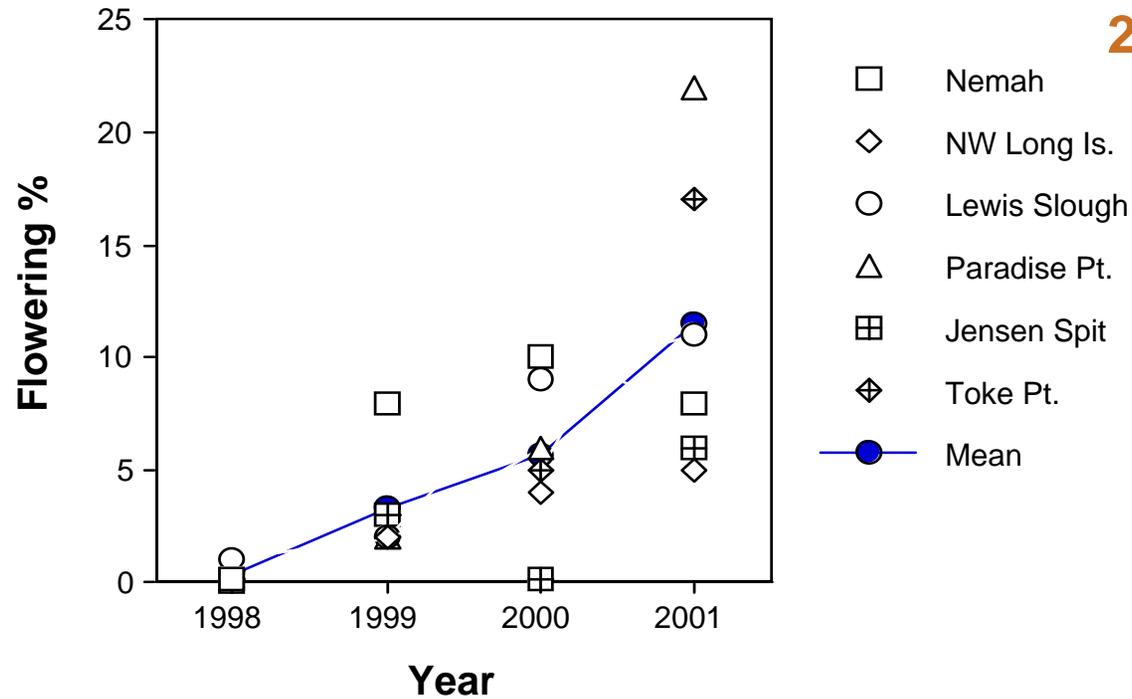

Density increased ~2.5X between 1998 and 2000

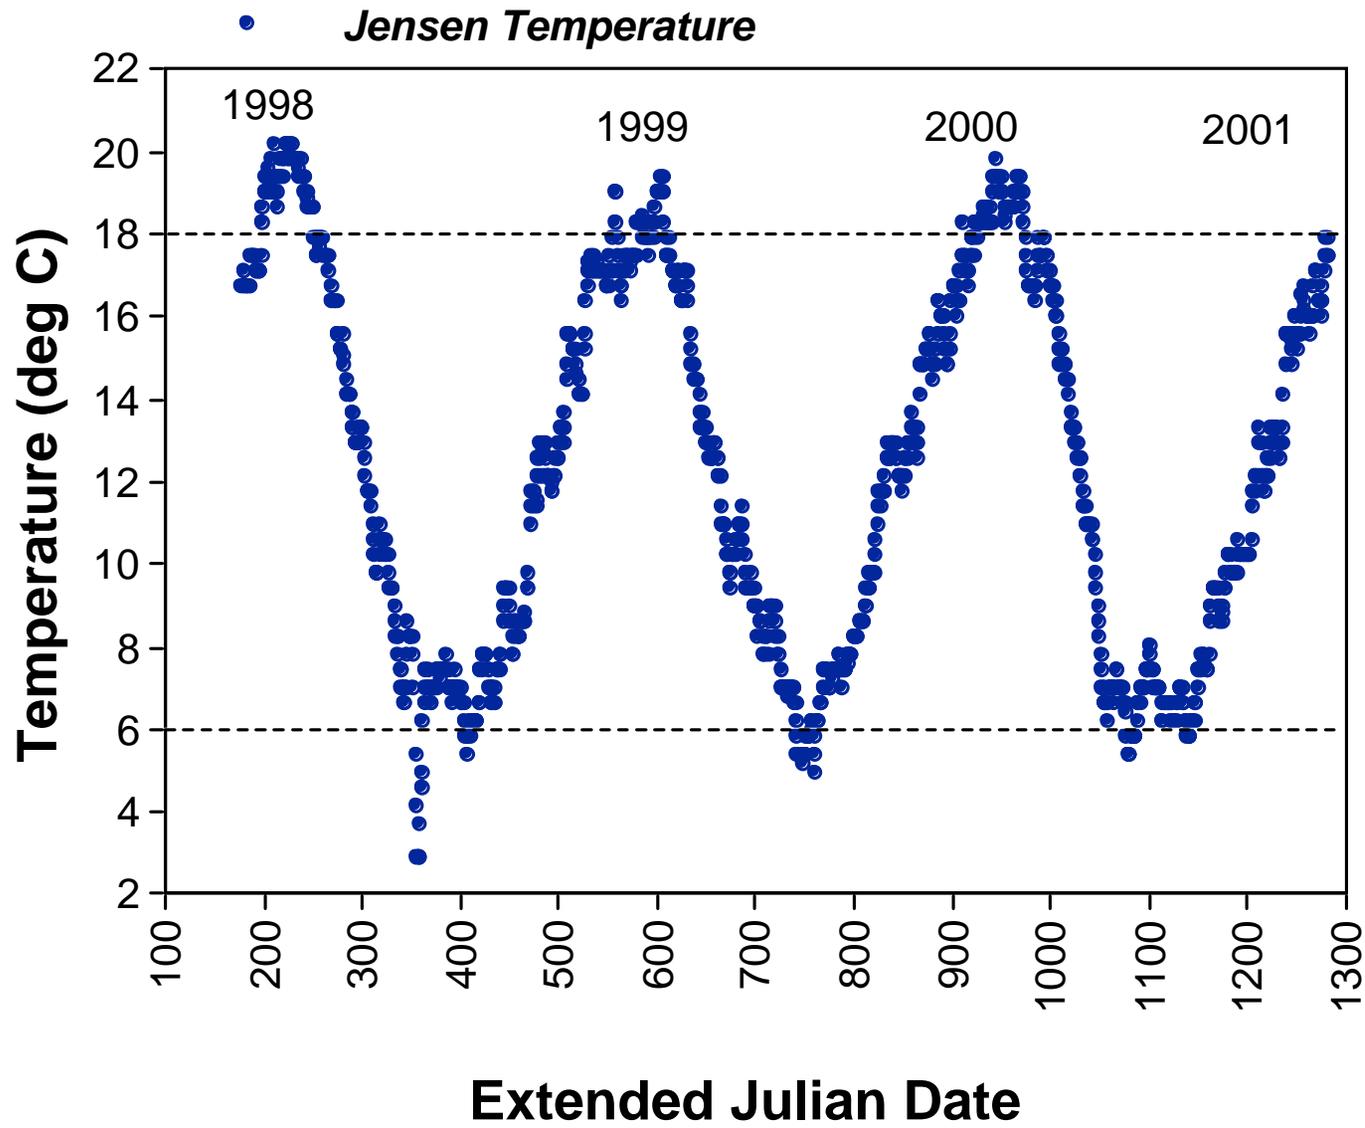

Biomass increased ~5X between 1998 and 2000

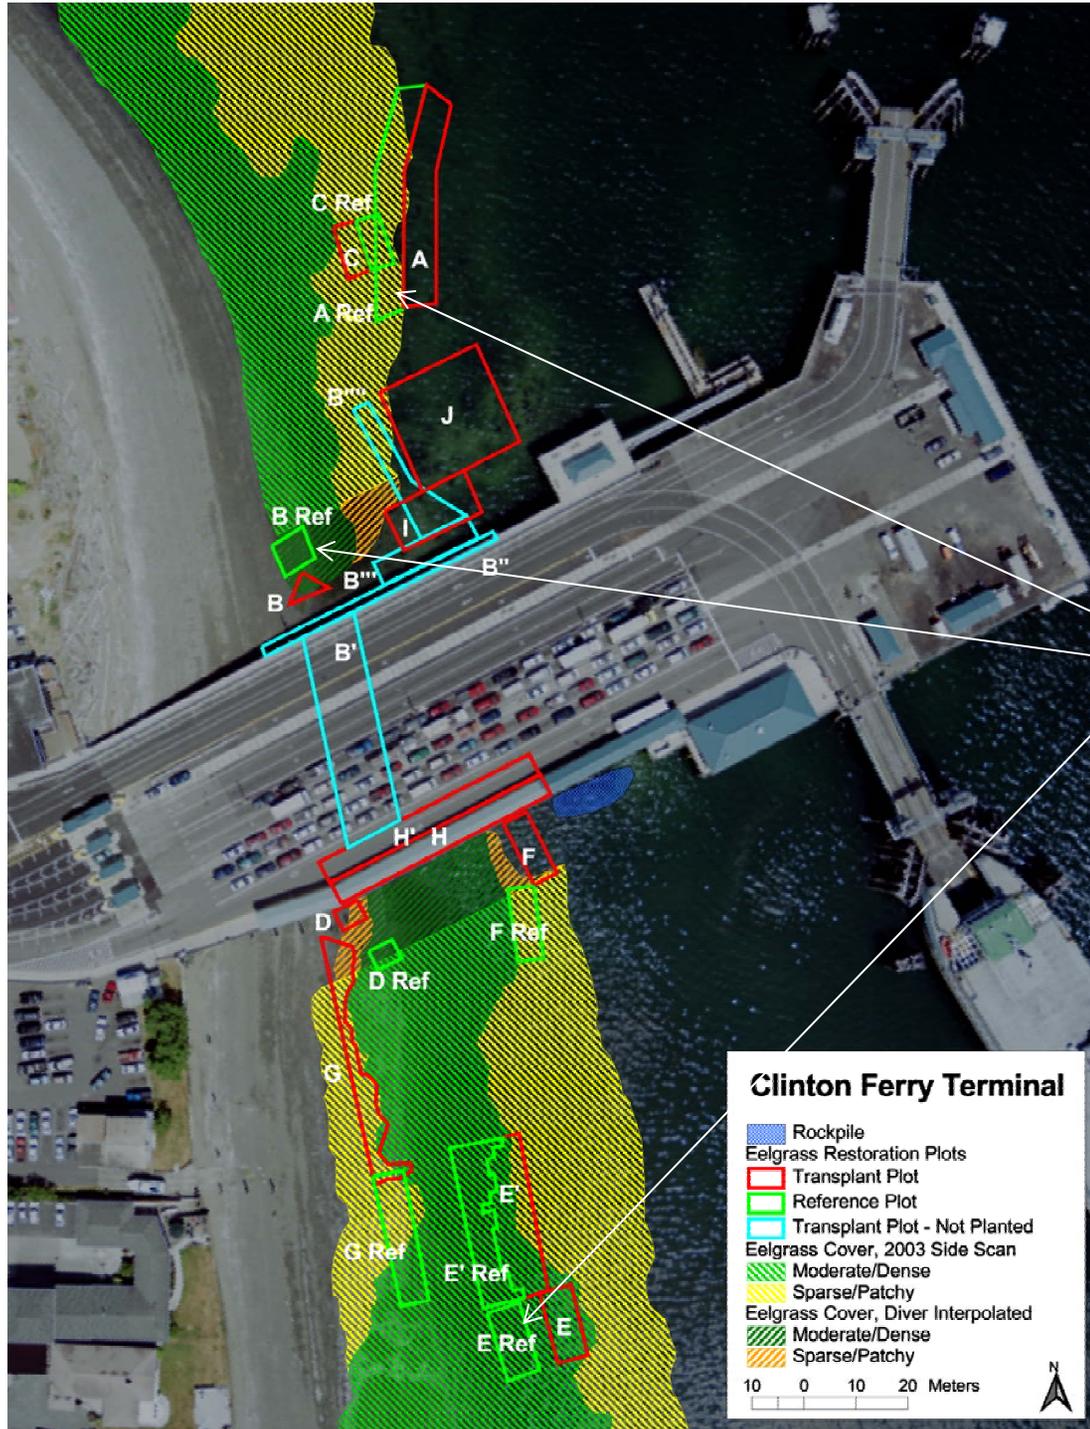

Flower production increased ~35X between 1998 and 2000

Eelgrass

Total Annual NPP Estimates

| <i><u>System</u></i> | <i><u>Eelgrass area</u></i> | <i><u>NPP</u></i> |
|----------------------|-----------------------------|-------------------|
| Puget Sound | 10,522ha | 63,132 mT C |
| Willapa Bay | 5,810 | 34,860 |
| Coos Bay | 510 | 3,060 |

Marine angiosperms contribute 4% of total ocean NPP (Duarte and Cebrian 1996)

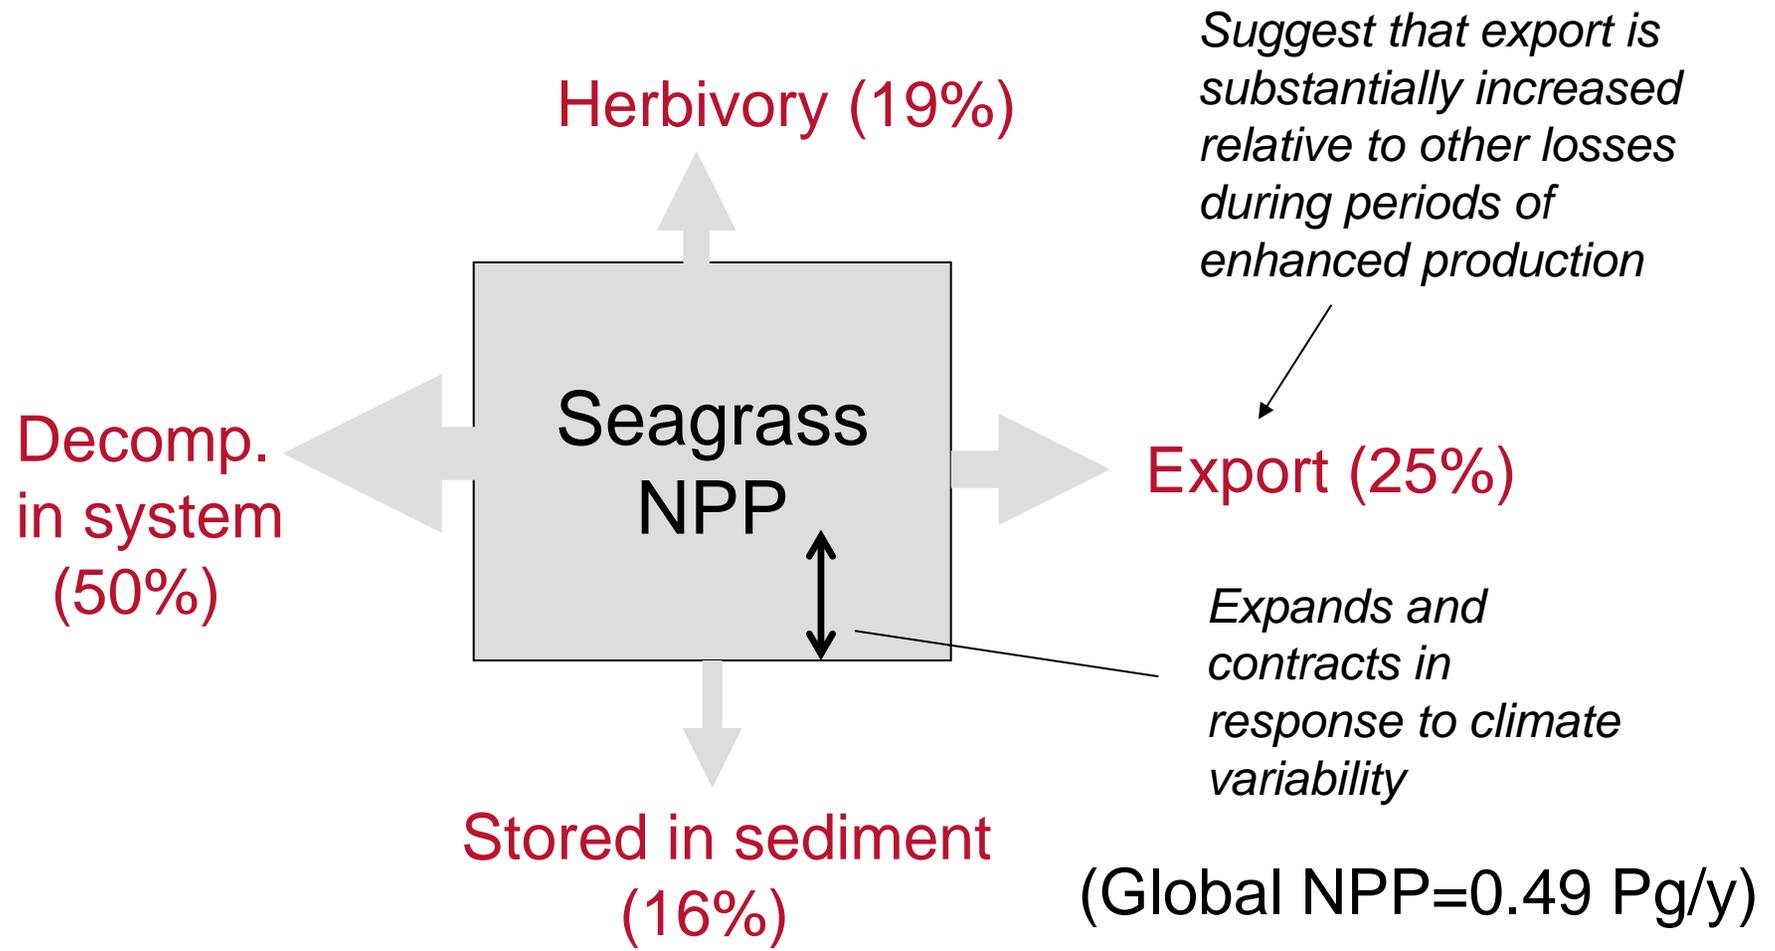

Padilla Bay - eelgrass detritus

**Eelgrass and Seaweed Transport at ~-35m
MLLW in Central Puget Sound**

Fate of Seagrass NPP (after Duarte and Cebrian 1996)

Conclusions (1 of 2)

- ▶ Weather affects plants, seagrasses are no exception
- ▶ Light, temperature and desiccation are reasonable factors to focus on relative to eelgrass response to climate change
- ▶ Climate driven mechanisms include mean sea level variation, factors that affect light, and temperature extremes
- ▶ Small changes in light or temperature can have a big effect on growth and abundance
- ▶ Eelgrass density and cover can vary dramatically between years
- ▶ Coupling monitoring programs (e.g., WADNR), models (EPA Newport), and experimental studies is critical to predicting future eelgrass changes

Conclusions (2 of 2)

- ▶ Elimination of eelgrass in some PNW bays goes largely unexplained (Westcott Bay, Hood Canal, Homes Harbor)
 - Suggest regional regime shifts
 - Marginal conditions (temperature, light, hypoxia) in these bays vulnerable to shifts
 - May be driven by altered circulation forced by such things as sea level variations, ocean forcing
 - Disease - another possible issue
 - WADNR, UW, USGS are investigating large losses
- ▶ Plan for resilience through (1) nurturing sources of renewal^a (e.g., rhizomes, seeds), (2) pathways for dispersal (i.e., genetic stock), and (3) space for recruitment
- ▶ Argue for more emphasis on the coastal ecosystem in the global carbon budget
