Briefing Paper for Departmental Clearance of Federal Register Notices

I. Title of notice document:
Hoopeston Wind Farm Draft Habitat Conservation Plan; Draft Environmental Assessment

II. Title(s) of any document(s) the notice is making available to the public:
Hoopeston Wind Farm Draft Habitat Conservation Plan and Draft Environmental Assessment for the Proposed Habitat Conservation Plan and Incidental Take Permit

III. Document tracking number: **format: [FWS–R3–ES–2016-N094]**

IV. Summary of action (briefly describe **what** the action/project does or would do, if approved):

The purpose of this notice is to make available, to the public, the draft documents listed above for comment. (b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP by the Hoopeston Wind Project in Vermilion County, Illinois. Take of these species has been requested by Hoopeston Wind, LLC for operation of the wind turbines at this project location. Review by the public is necessary step required by NEPA before the permit can be issued.

V. Is timing critical? ☒ Yes ☐ No If yes, answer the following questions. If no, go to the next section.

a. By what date must the FR notice publish?
February 8, 2016

b. What is driving the timing?

The documents to be noticed in the Federal Register must be open for public review before a permit can be issued and the subsequent implementation of the Habitat Conservation Plan can begin. (b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(b) (5) DPP(

Briefing Paper
Departmental Clearance

Title of Document: **Endangered and Threatened Wildlife and Plants; Nonessential Experimental Population of Red Wolves (Canis rufus) in North Carolina**

RIN, if applicable: **RIN 1018–BB98**

Popular Short Name, if applicable: Advance notice of proposed rulemaking; notice of intent to prepare an environmental impact statement.

Summary (Clearly and very briefly explain what the document does and, if applicable, where the subject of the document is located):

This document gives notice to the public that the Fish and Wildlife Service (FWS) will prepare a draft environmental impact statement pursuant to the National Environmental Policy Act (NEPA), in conjunction with development of a proposed rule to revise the existing nonessential experimental population designation of red wolves in North Carolina under section 10(j) of the Endangered Species Act (ESA). As such, we are announcing the initiation of a public scoping process to engage Federal, Tribal, State, and local governments; special interest groups; and the public in the identification of issues and concerns, potential impacts, and possible alternatives to the proposed action. Information obtained during the public scoping process will be used to develop the draft environmental assessment and promulgate a proposed rule.

Is timing critical? ☒ Yes ☐ No

If yes, date the document must publish or other action must occur: As soon as posible

What is driving the timing? Scheduled Event; Two public scoping meetings need to be scheduled as soon as possible. We must give the public at least 15 days notice of the meetings. Additionally, our target due date for the draft environmental assessment and proposed rule is December 2017.

What happens if the deadline is missed?

We will have to reschedule the public meetings, including rebooking facilities where the meetings will be held. Additionally, a delay in the scoping process will delay our development of a draft environmental assessment and proposed rule, which leaves us less time to draft these actions and meet our December 2017 target date. Although this action is not court-ordered, it is part of active litigation. If we do not move forward with our commitment to complete a proposed rule by December 2017, it could set us up for additional work and leave us vulnerable to more litigation in the future.

Background: *[Briefly provide any background information, in understandable language, that will help a reader quickly understand what the document is trying to do and why, along with additional information that is useful. Assume the reader knows little about the subject matter. Minimize use of acronyms or abbreviations and do not use them at all unless they are clearly defined. Is the document a high-profile, litigated matter?]*

Based on evaluations of the red wolf recovery program and the nonessential experimental population (NEP) in North Carolina, it became clear that the management of the nonessential

experimental population of red wolves under the existing experimental population rule ("10(j) rule") is not longer supported by local landowners and the State. The Service is initiating a revision of the current 10(j) rule, which will include changing the goal of the NEP project from solely that of establishing a self-sustaining wild population to a goal of also supporting viability of the captive wolves of the red wolf breeding program. Per our regulations, to allow public participation and input, we must announce initiation of the public scoping process and the dates and times of public scoping meetings.

The proposed revision, as currently envisioned, would recognize that the size, scope, and management of the NEP will be re-focused on maintaining a wild population on only Federal lands within Dare County, North Carolina and on protecting the species by increasing the number and genetic diversity of wolves in captivity. These revisions will allow removal of isolated packs of animals from non-Federal lands at the landowners' request, incorporation of these animals into the wild/captive metapopulation, and better management of the remaining wild animals in accessible areas to minimize risks of hybridization. Management of wolves occupying Federal lands in Dare County will include population monitoring, animal husbandry, and control of coyotes and hybrids.

Issues: *[Controversial? What are the significant **issues**, **who will care**, and **how strongly** will they care?]*

We anticipate both support and opposition to the revision of the 10(j) rule. North Carolina Wildlife Resources Commission (NCWRC) supports a revision of the current 10(j) rule as they have recognized, along with the FWS, that improved management of the nonessential experimental population of the Red wolf is needed. The FWS will engage NCWRC in both the drafting of a proposed 10(j) rule and draft EIS.

We anticipate opposition to the revision of the 10(j) from several members of Congress and NGOs, as they have expressed concerns and objections to our proposed path forward for the red wolf recovery program. In particular, they object to a perceived abandonment of management of red wolves in the wild and shift in focus away from establishing a self-sustaining population.

Additionally, there may be public outcry via news stories and social media due to the perceived abandonment of the red wolf recovery program associated with our intent to revise the current 10(j) rule for the NEP project.

Communications:

Media POC: Press release to be issued by Region 4: Jeff Fleming, 404-679-7287

Other outreach: County governments within the NEP project area, other Federal agencies, private landowners and the community adjacent to the NEP project area, and other interested parties, such as NGOs, will be contacted.

Is there an information collection associated with this document? ☐ Yes ☒ No

If yes, does it have a currently approved OMB Control Number? ☐ Yes ☒ No

OMB Control Number(s): Click here to enter OMB Control Number.

Does the document require a ☐ new OMB Control Number or ☐ a renewal of an existing approval?

If a new number or renewal is required, what is the current status? Click here to explain status.

If a regulatory action, has it been on a 90-Day List for the current stage? ☐ Yes ☒ No

If yes, on which 90-Day List did it first appear at the current stage?

NATIONAL MITIGATION BANKING ASSOCIATION

January 30, 2017

Mr. Gary Frazer
Assistant Director, Ecological Services
U.S. Department of the Interior
1849 C Street, NW
Washington, DC 20240

Dear Mr. Frazer,

On behalf of the National Mitigation Banking Association (NMBA), please accept this invitation for you and other officials of the Fish and Wildlife Service (FWS) to join NMBA for our First Annual Policy Conference on March 21st and 22nd in Washington, DC. The Policy Conference will open with a reception at the U.S. Capitol from 3:30-5:30 pm on March 21st, followed by an all-day conference from 8:30 am-5:30 pm on March 22nd at the University Club. Invited attendees include mitigation bankers, conservation experts, investment managers, non-governmental organizations, and other senior federal agency officials.

We ask you and your colleagues at FWS to join NMBA for the Policy Conference because FWS works closely with stakeholders in the mitigation banking industry to implement the Endangered Species Act and ensure the integrity and success of mitigation projects across the country. We are planning multiple panels and segment sessions that review recent regulatory actions related to the ESA, the 2008 Mitigation Rule, and the recently enacted Water Infrastructure Improvements for the Nation Act from the perspectives of legislators, nationally recognized counselors, and the private sector. The goal of our Policy Conference is to productively facilitate discussion on more efficient and effective mitigation projects that enhance and conserve our nation's natural resources.

Thank you for your consideration of our invitation. We are hopeful the FWS will expeditiously process our request for agency officials to attend the Policy Conference. Please do not hesitate to reach out with any questions.

Sincerely,

Sara L. Johnson

U.S. FISH AND WILDLIFE SERVICE

RED WOLF RECOVERY PROGRAM

STANDARD OPERATING PROCEDURE

Title: **Trapping and handling a live red wolf** ***SOP Number:*** **6.1**

Exceptions: The only permissible exceptions to the procedure described herein are those specified under an approved separate study. Otherwise, deviations from this SOP will only be permissible by having a new version approved.

Background: The capture of live wild red wolves is a necessary management action to facilitate monitoring, for translocations of wolves, and to address health, behavior and complaint issues. Trapping via leg-hold traps is currently the most efficient and effective means of capturing wild red wolves. Traps need to be maintained and trap lines conducted in such a way as to increase capture success with minimal damage, avoid non-target captures, and to facilitate relationships with private landowners.

Purpose: This SOP identifies practical traps and trapping techniques that continue to improve efficiency, selectivity, and the welfare of trapped animals. Guidelines are provided for trap preparation and use in the field, and procedures on running a trapline on refuge lands anytime, or on State and private lands outside of the designated trapping season. State trapping regulations are followed when trapping on private and State game lands outside of trapping season, as outlined in trapping permit issued by North Carolina Wildlife Resources Commission.

Trap Specifications and Preparation

1. #3 soft-catch traps (manufactured by Oneida-Victor) with 4 coil springs, a 6” jaw spread, and rubber pads on slightly offset jaws are used (other brands may be used but specifications should be similar). The use of rubber pads increases the surface area of the jaw on a trapped animal’s foot and may minimize animal injury.
2. Pan-tension set at a minimum of six pounds may improve selectivity and foot position in the trap and help prevent the capture of smaller non-target species.
3. The anchoring system is critical in that it must always be strong enough to hold the targeted wolf. Drags are typically used to allow the captured animal to find cover, and to give the foot time to swell, thus decreasing the chance of pulling out. A minimum of 8 feet of heavy chain (e.g. #5 straight-link) is used with a well-designed drag that is strong enough to prevent parts from bending or breaking and heavy enough to limit the distance

a wolf or other large animal can move from the capture site. When stakes are used, two 24" stakes with cross-staking should be used to ensure the stakes will not pull from the ground after the catch. Cable or chain stakes may also be used when sufficiently anchored. A drag may also be used as a backup in addition to a stake in case the stake is pulled from the ground.

4. Traps are to include in-line shock springs on anchoring systems, whether they are stakes or drags, in order to reduce injury and/or prevent escape. Shock springs should be of high quality and adequate strength to resist a captured animal's ability to destroy the spring (e.g. JC Conner t-bar shock spring).
5. In order to prevent injury to the captured animal, proper swivels should be used to prevent the chain or cable of an anchoring system from binding at the stake or drag (e.g. Minnesota Brand crunch proof in-line swivels).
6. Inspect traps, chains, swivels and all connections thoroughly for damage or potential separation prior to setting.
7. All traps must be labeled with an attached identification tag or stamp.

Set Location and Procedures

1. Traps should always be set and used in a fashion that limits the risk of capturing non-target animals, including domestic animals, while increasing the chances of capturing the targeted wolf or wolves.
2. Traps should be set in locations that prevent entanglement with fences, structures, or other objects that might result in injury, and that will minimize the chance that objects or debris will prevent swivels from functioning properly. Care should be taken to prevent entanglement near canals, bridges, and water control structures as well to prevent injury and even drowning. If using drags, consider that animals captured on drags may travel far from the location where captured. Also be cognizant of potential rain or snow events that may make following 'drag marks' and finding the trapped animal more difficult.
3. If environmental conditions could potentially harm target animals in traps, cease trapping or check the traps as frequently as needed. Note that an increase in the frequency of monitoring traps will often decrease the likelihood of a capture due to disturbance, particularly during corpuscular hours when wolves and wildlife are generally more active. Heat-related injury is a major concern when trapping wolves. Capture efforts should be coordinated in such a fashion as to avoid temperatures in excess of 80°F, as canids are extremely susceptible to hyperthermia when stressed at these temperatures. As such, trapping efforts cease during consistently high temperatures, a procedure consistent with other large carnivore programs and AZA guidelines (Henry et al. 1995, AZA Canid TAG 2012). Trapping efforts are also suspended when temperatures drop below 32°F, as freezing weather greatly increases the risk of injury via frozen tissue in a trapped foot. **In the case of instances where wolves represent a human safety concern, or are a threat to livestock/pets or personal property, traps may be set in inclement weather. However, care must be taken to minimize injuries to captured animals to the greatest extent possible. For example, traps may be checked throughout the night in freezing weather, or covered after monitoring in the morning when temperatures and humidity are high (e.g., >80°F).**
4. All traps must be physically checked a minimum of every 24 hours, preferably each

morning.

5. Animals should be removed from foot-hold traps as quickly and safely as possible. Extended time in these traps can cause foot tissue damage through decreased circulation to the trapped foot. Extended time in a trap also increases potential for an animal to injure itself during escape attempts. Note that not all injuries, especially tissue damage to the trapped foot or even broken toes, are immediately apparent.
6. Captured canids not immediately released should be placed in a secure transport kennel until processing can occur.
7. Non-target animals captured will be released alive, or disposed of in accordance with any applicable federal or state permits.
8. Captured animals intended for release, relocation, or captivity will be handled (see SOP Immobilizing and Processing a Live Canid) and transported appropriately to achieve Program objectives.
9. When trapping on public lands, coordination must take place with the appropriate land managers. Prior to setting on private lands, written consent of the landowner or his/her designee must be obtained and filed with Recovery Lead.

U.S. FISH AND WILDLIFE SERVICE

RED WOLF RECOVERY

STANDARD OPERATING PROCEDURE

Title: The sterilization and monitoring of coyotes on the Albemarle Peninsula ***SOP Number:***

Commented [PMB1]: Should we include red wolves in the title?

Commented [BA2]: Yes – just hadn't gotten that far. Wanted to see if working wolves into this protocol would work.

Purpose: The purpose of this SOP is to provide instruction and guidance on the sterilization and monitoring of coyotes used for the control of hybridization in the red wolf population and for coyote and red wolf population and placeholder analysei~~s~~.

Exceptions: The only permissible exceptions to the procedure described herein are those specified under an approved separate study. Otherwise, deviations from this SOP will only be permissible by having a new version approved.

Procedure: The protocols below, unless otherwise stated, refer to coyotes and red wolves collected by Red Wolf Recovery Program (Program) personnel within the Red Wolf Recovery Area (Beaufort, Dare, Hyde, Tyrrell, and Washington counties), sterilized, and released with GPS collars provided by and for study by the North Carolina Wildlife Resource Commission (WRC).

Commented [RH3]: Does this still exist? ES staff?

Capture and Processing

1. Authorization to capture coyotes on private lands and State Game Lands comes from the WRC Research Permit (attachment A). All conditions of the Permit must be followed. A copy of the Permit must be carried when engaging in the covered activities. Licensed trappers operating under a cooperative agreement with the Program may conduct activities authorized under this Permit and must carry a copy of this permit and a signed copy of the cooperative agreement.
2. Coyotes and wolves are captured by Program personnel using padded foot-hold traps including: #3 soft-catch traps, MB_500.
3. Biological and genetic samples are to be taken from each captured canid according to the standard operating procedure: The Collection and Handling of Biological Samples for NCWRC (see attachment _)

Selection of Animals and Location

Coyotes and hybrids

1. The selection of coyotes used for sterilization and GPS monitoring will be made by Program staff and be determined by field management needs. Although supposed breeding age coyotes believed to be territory holders will be targeted, every effort will be made to deploy as many GPS collars on sterile coyotes as possible, including coyotes believed to be transient.
2. If coyotes captured on private lands are determined suitable for sterilization and monitoring, signed permission to release such coyotes will be required by the landowner where it was captured.

Red Wolves

~~2.~~

~~3.~~ All red wolves captured and released will be equipped with monitoring devises. These can include VHF or GPS collars or abdominal transmitters. Young animals will generally not be targeted for capture. In the event that young animals are captured any animals weighing less than xx pounds or with neck diameters less than yy will have abdominal transmitters inserted prior to release. Wolves greater than 8 months of age and that are in good health ~~meeting these weight and size requirements~~ will be fitted with an appropriate sized radio ~~transmitter~~ collars so that the population can be closely monitored. First preference will be to utilize VHF collars given the superior battery life and durability of these devises which allow us to meet program management needs while limiting the likelihood of needing to recapture the animal. Red wolves captured on private lands and slated for release may be eligible for GPS collars provided they meet the criteria of an appropriate study design. Only wolves 9~~8~~ months of age or older, and of adequate size and health as determined by Program staff, will be outfitted with a GPS collar. In addition, established breeders of a wolf pack *~~,~~ would not be eligible for a GPS collar. This will allow the Program to manage these wolves long-term without recapture and help ensure hybrid events and pack stability are maintained.

Sterilization

1. Coyotes and hybrids are to be taken to a local veterinary clinic for surgical sterilization.
2. Male and female coyotes are to be reproductively sterilized by vasectomy and tubal ligation, respectively.

GPS Collar Programming and Monitoring

~~4.~~3. WRC will program all GPS collars prior to deployment. Changes to the programming can be made as needed based on the data received, performance of the collars, and changes in data needs or requirements.

~~5.~~4. WRC will be responsible for downloading data and can provide assistance to the Program regarding location information as it relates to field needs. VHF function will also allow Program staff to monitor general locations to aid in field management.

Formatted: Underline

Formatted: Underline

Commented [RH4]: I thought we're still in limbo about these landowner agreements…they've been perpetually 'under review' in the RO or with the SOL. Can we release animals with signed permission, or only with explicit landowner agreements?

Formatted: Indent: Left: 0.5", Hanging: 0.5", No bullets or numbering

Formatted: Underline

Formatted: Indent: Left: 0.25", No bullets or numbering

Commented [PMB5]: Can we establish some sort of minimum sizes like this or does it need to be more case-by-case?

Commented [BA6]: I would like to keep an age component here as regarless of size, if it's a young wolf, say lest than 8 months or so, it still has a period of growth remaining that will cause problems with a collar. We can be general in stating the wolf has to be large enough size/neck to accomadate the appropriate sized collar.

Commented [RH7]: ?

Data Management

Approved:

Field Coordinator Date

Commented [RH8]: This is a big deal and requires careful consideration. I would like to see something in here stating that per our policy that radio frequencies are confidential and not subject to FOIA (http://www.fws.gov/policy/272fw2.html). As such, both agencies should agree in writing not to release this information to the public.

Similarly, how will these data be shared between agencies? How will they be shared with the public? Do commissioners get weekly map updates as they do now? Will information be available on the web? What is the time lag? I am concerned about animal safety.

Appendix A.

Updated September 1, 2016

Table 1. Causes of mortality in wild red wolves (*Canis rufus*) 2013-2016.

Cause of Death	# of Total Mortalities 2013	# of Total Mortalities 2014	# of Total Mortalities 2015	# of Total Mortalities 2016
Natural				
Health-related		3	1	
Intraspecific competition				
Human-related				
Management-related actions		2		
Non-management-related actions	1	2	2	
Vehicle strike	3	3		1
Suspected or confirmed gunshot	9	4	4	
Poison			1	
Unknown				
Lack of biomaterial		1	5	2
Suspected illegal take	2		3	
Pending necropsies			1	1
Total Mortalities	15	15	17	4
Population Estimates				
Known wild red wolves (End of Year)	66	62	45	45
Estimated total wild red wolves	90-110	90-110	50-75	45-60

Definitions:

Health-related: mortality as a result of acute illness, disease (e.g., heartworm, mange), starvation, and old age.

Intraspecific competition: injuries caused by other red wolves.

Lack of biomaterial: mortalities in which not enough of the carcass remains (e.g., partial skeleton or hair mat) to determine cause of death.

Management-related actions: mortality related to USFWS conservation actions, including trapping, denning, monitoring, handling, and animal processing.

Non-management-related actions: mortality related to private trapping.

Pending necropsies: cause of death initially undetermined; waiting for official necropsy results

Suspected or confirmed gunshots: mortality related to gunshot. Most of these cases are ongoing investigations with the USFWS Office of Law Enforcement. Confirmed cases include official necropsy results and/or x-rays showing evidence of gunshot, or when the mortality was reported by the shooter as mistaken identity (e.g., coyote) or as a threat to life or property.

Suspected illegal take: evidence of foul play exists (e.g., a cut or removed radio-telemetry collar), but cause of death has not yet been determined. These cases may include ongoing investigations with USFWS Office of Law Enforcement. Take is defined as "harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct" (Endangered Species Act of 1973, as amended).

Vehicle: mortality sustained from the collision with a motor vehicle (including farm equipment)

For more information on the Red Wolf Recovery Program activities, please visit our website.

Potential Follow-up Studies to Conduct in Louisiana

To make informed decisions regarding the canid population and possible existence of red wolves in Louisiana, we propose the following as very preliminary steps:

1. Collect hair and scat samples – This method will be used for general sampling of areas. It is low effort, little training is needed, and can be conducted throughout the year. However, it is likely that a lot of non-target hair samples will be collected.
    - Replicate the study conducted by Murphy et al. (2018), but potentially adjust protocol to increase usable sample size.
    - Arkansas State University (ASU) is planning to conduct a general survey (hair and scat samples) of canids in the region (AR, LA, MO, and eastern OK).
        - Could collaborate with them on this particular sampling. At the very least, we should coordinate efforts and methodology.
    - Possibly include new areas not sampled in Murphy et al. (2018).
    - These surveys could inform potential areas for future trapping efforts.

2. Targeted trapping efforts – This method will be used in areas of interest (i.e., areas where potential red wolves are identified via hair and scat sampling). Trapping can only be conducted January through February and by persons authorized, trained, and equipped to safely and effectively conduct canid capture operations.
    - Based on the results of Murphy et al. (2018), trapping efforts should be initiated in Sabine NWR.
    - Protocol (see page 2) will include:
        - Recording locations (GPS)
        - Body measurements
        - Blood drawn
        - Vaccinations (?)
        - Photos
        - Radio collar animals that fall within accepted morphological measurements of red wolves.
    - Blood will be sent to University of Idaho for genetic testing

Potential partners: Refuges, Louisiana Department of Wildlife and Fisheries (LDWF), ASU, USDA-Wildlife Services, Animal Welfare Institute, other universities

Draft Trapping Protocol for Louisiana

- If possible, a good initial step would be for Sabine NWR to pre-bait areas (with road kill or something similar) in areas where there appears to be active canid use, and place remote sensing cameras. This will prime these areas for trapping shortly after and give a visual of what animals visit those areas.
    - Additionally, hair snares should be placed at those pre-bait sites and other canid use areas. This provides a lower effort/lower need for training way of obtaining samples for genetic testing. All hair samples will be sent to the appropriate lab for analysis. It is likely that a lot of non-target hair samples will be collected.

- If local Sabine NWR staff, Wildlife Services, State of Louisiana personnel, university researchers or private trappers are authorized, trained and equipped to safely and effectively conduct canid capture operations, trapping could begin in January. If not, two staff from the Eastern NC ES Sub-office's Red Wolf Recovery Program, in coordination with Refuge staff, will conduct canid capture operations throughout the appropriate habitats of the refuge in February.
    - If they are not able to operate independently, staff/personnel can provide additional support during trapping efforts.
    - Trapping window should be a minimum of two weeks, if not longer. Trapping past February is not recommended due to breeding season, subsequent denning and birth, and then heat issues.

- All canids captured will have the capture location GPS'd, full measurements taken (e.g. body length, skull, weight, etc.), blood drawn, vaccinated (?) and the canid photographed. All capture and handling operations will be conducted in accordance with the SOPs utilized in the North Carolina nonessential experimental population. Coordination with Refuge staff will determine the appropriate steps if non-canids are captured. For example, if the animal should be released immediately or if they would like them processed for other purposes.

- Blood samples will be sent directly to the University of Idaho for genetic testing.

- All animals will be released at or in close proximity to where they are captured as soon as they are able to be released. Unless

- All, or a sampling of animals, that fall within the accepted morphological measurements of red wolves will be radio collared before release for the purposes of tracking their movements to determine general habitat use and home range (e.g., how much of their movement is on the refuge) and to more easily facilitate recapture should it become desired.
    - Radio collars and frequencies to be used would need to be coordinated with Sabine NWR, university researchers and or the State of Louisiana.

- Collared canids should be monitored for general location and mortality from the air or ground at least once a week to get a sense for their movements.

Commented [WE1]: Joe, this was in the original draft plan…should something be included here?

NOTE TO REVIEWERS

ACTION: Possible follow-up canid studies to conduct in Louisiana

STAFF ORIGINATOR: Emily Weller SUPERVISOR: Aaron Valenta

IS THE ACTION LITIGATION DRIVEN? No
IF SO, WHO SUED US AND WHEN:
ANY COURT-ORDERED DEADLINES? No

ACTION REQUESTED:

SIGNATURE_____ REVIEW AND COMMENT__X_
SURNAME___ FYI ONLY _____

VERY BRIEF BACKGROUND ON ISSUE/ACTION:

Following the Murphy et al. (2018) study that identified a possible red wolf in Sabine National Wildlife Refuge, Louisiana, members of the red wolf recovery program offer these suggested follow-up actions in Louisiana: 1) general hair and scat sampling and 2) targeted trapping efforts. While we have a general plan and protocol, details will need to be finalized with partners. Additionally, before sampling begins, and particularly before trapping begins, criteria should be developed for identifying red wolves. In particular, criteria should be defined under genetics, morphology, and behavior, as these were used in the National Academy of Sciences study on red wolf taxonomy and its determination that the red wolf is a distinct species.

Potential Follow-up Studies to Conduct in Louisiana

1. Collect hair and scat samples – This method is for general sampling of areas for genetic testing. It is low effort, little training is needed, and can be conducted throughout the year. It is likely that many non-target hair samples will be collected.
   - Replicate the study conducted by Murphy et al. (2018), but potentially adjust protocol to increase usable sample size.
   - Arkansas State University (ASU) is planning a study (hair and scat samples) of canids in the region (AR, LA, MO, and possibly eastern OK) (no timeline yet).
     - Could collaborate with them on this particular sampling. At the very least, we should coordinate efforts and methodology.
   - Possibly include new areas not sampled in Murphy et al. (2018).
   - All samples will go to a qualified laboratory for analysis.
   - These surveys could inform potential areas for future targeted trapping efforts.

2. Targeted trapping efforts – This method will be used in areas of interest (e.g., Federal lands, areas where potential red wolves are identified via hair and scat sampling, or areas with animals suspected of higher red wolf DNA). Trapping provides opportunity to gather genetic, morphology, and behavioral data.
   - Due to the breeding season, trapping would likely be limited to December through February and be based on weather conditions. Trapping will only be conducted by persons authorized, trained, and equipped to safely and effectively perform canid capture operations.
   - Potential red wolves have been identified in Sabine NWR (Murphy et al. 2018); therefore, trapping efforts should be initiated there first.
   - See draft trapping protocol below
   - Blood samples will go to a qualified laboratory for genetic testing.

Potential partners: FWS Refuges, Louisiana Department of Wildlife and Fisheries (LDWF), ASU, USDA-Wildlife Services, Animal Welfare Institute, other universities; Ecological, Evolutionary and Conservation Genetics (University of Idaho) or other qualified laboratory

Draft Trapping Protocol

- To prime target areas for trapping and get a visual of what animals visit those areas, target areas will be pre-baited, if possible, with road kill or something similar, and remote sensing cameras set up.
  - Due to the presence of alligators, and based on local expertise, it might be preferred to pre-bait with scent lures and not carcasses.
  - Areas where there appears to be active canid use should also be pre-baited.
  - Hair snares will be placed at pre-bait sites and other canid use areas.

- Trapping can begin in December, weather permitting, if Sabine NWR staff, ES staff, Wildlife Services, LDWF personnel, university researchers or private trappers are authorized, trained and equipped to safely and effectively conduct canid capture operations.
    - If not, two staff from the Eastern NC ES Sub-office's Red Wolf Recovery Program, in coordination with Refuge staff, could potentially conduct canid capture operations throughout the appropriate habitats of the refuge during portions of the trapping season.
    - Trapping window should be a minimum of two weeks, if not longer. Trapping past February is not recommended due to breeding season, subsequent denning and birth, and issues related to the health and safety of the trapped individuals in hotter temperatures.

- All capture and handling operations will be conducted in accordance with the SOPs utilized in the North Carolina nonessential experimental population. The following will be recoded for all captured canids:
    - Recording locations -GPS
    - Sex
    - Body measurements
    - Weight
    - Breeding condition
    - Blood drawn
    - Photos
    - PIT tags
    - Vaccinations – if determined to be appropriate by FWS Refuge and LDWF staff

- Animals that fall within accepted morphological measurements of red wolves will be radio collared for the purposes of tracking their movements to determine general habitat use and home range (e.g., how much of their movement is on the refuge) and to more easily facilitate recapture should it become desired.
    - There may be instances where we may want to radio collar individuals outside of the morphological measurements (i.e. suspected mate of a red wolf).
    - Radio collars and frequencies to be used would need to be coordinated with Sabine NWR, university researchers and/or LDWF.
    - Collared canids should be monitored for general location and mortality from the air or ground at least once a week to get a sense for their movements.

- All animals will be released at or in close proximity to where they are captured as soon as they can be safely released. Unless an individual needs to be held for purposes such as receiving veterinarian care for injuries or disease.

- No canids will be euthanized unless it is determined to be the best course of action for the health of the animal (e.g. severe trap injury).

- Coordination with Refuge and/or LDWF staff will determine the appropriate steps if non-canids are captured. For example, if the animal should be released immediately or if they would like them processed for other purposes.

Points to Consider Prior to Implementation

- Before collecting data, especially before trapping animals, we need a study design (sampling plan and criteria).
- Possibly assemble a team to determine criteria for red wolf
    - Nucharin Songsasen, head of the research group formed at the Smithsonian Workshop, is willing to form a team to answer this question
- NAS study used a 3-part test (genetics, morphology, and behavior).
    - Genetics – consult geneticists on which specific alleles or percentages of red wolf lineage are needed to meet the genetics portion.
        - In NC, it is 87.5% red wolf ancestry (founders), although it was 75% in the beginning stages of the program.
        - However, alleles that may be representative of red wolf genetics not accounted for by the founders, but present on the landscape, will not be accounted for in genetic results.
    - Morphology – consult with Nowak, Hinton, etc. for morphological and weight specs.
    - Behavior – telemetry (for home range size) and other data are needed to evaluate the behavioral portion.

Collaring canids

- Should we have an intermediate set of morphological standards in case no "full standard" animals are captured or at least have the understanding that some "larger" non-red wolf canids might be collared in an effort to study the local current canid population.

Potential red wolves

- Should we hold an animal that is within the morphological characteristics of a red wolf and looks/acts like a red wolf, for at least as long as the blood work would take, if not permanently, to ensure that we do not lose this genetic line? One new individual to the SSP population could substantially boost genetic diversity.
    - If this is a potential option, we need to do some advanced planning (e.g., coordination with SSP), possibly NEPA, etc.
    - Will need to weigh the pros and cons of removing that animal

Trapping team

- The Eastern NC ES Sub-office has limited staff who have trapping obligations in NC, as well as St. Vincent NWR. We need to plan our team(s) ahead of time to ensure that we have an adequate number of authorized, trained, and equipped people to safely and effectively perform canid capture operations.
    - We could potentially provide training, if needed.

Cost

- Funding
    - Particularly genetics testing

  If we hold potential wolves until genetic test results, it may be beneficial to line up funding this FY so that samples can be sent and tested right away.

AGENDA

N.C. WILDLIFE RESOURCES COMMISSION
July 12, 2018, 9:00 a.m.
1751 Varsity Drive
NCWRC Conference Room, 5th Floor
Raleigh, North Carolina

CALL TO ORDER - *Chairman John Coley*

This meeting is being recorded as a public record and is audio streaming live at www.ncwildlife.org. As a courtesy to others please turn off all cell phones during the meeting.

PLEDGE OF ALLEGIANCE – *Commissioner David Hoyle, Jr.*

INVOCATION - *Commissioner Richard Edwards*

RECOGNITION OF VISITORS

MANDATORY ETHICS INQUIRY - North Carolina General Statute 138A-15(e) mandates that the Commission Chair shall remind all Commissioners of their duty to avoid conflicts of interest and appearances of conflict under this Chapter, and that the chair also inquire as to whether there is any known conflict of interest or appearance of conflict with respect to any matters coming before the Commission at this time. It is the duty of each Commissioner who is aware of such personal conflict of interest or of an appearance of a conflict, to notify the Chair of the same. *Chairman John Coley*

APPROVAL OF MINUTES – Take action on the April 26, 2018 Wildlife Resources Commission meeting minutes as written in the exhibit and distributed to members **(EXHIBIT A)**

ADMINISTRATION

Financial Status Report - Receive a financial status report on the Wildlife Operating Fund and Wildlife Endowment Fund – *Melissa Earp, Finance Office Chief* (**EXHIBIT B)**

RECOGNITION OF 2018 NATIONAL FISHING AND BOATING WEEK LICENSE WINNERS - Present Lifetime Unified Sportsman License donated by Russell Rhodes of Neuse Sport Shop in Kinston and Lifetime Freshwater Fishing License donated by the N.C. Council of Trout Unlimited, from drawings at fishing events held during the 2018 National Fishing and Boating Week – *Chairman John Coley*

PHOTOS

COMMITTEE REPORTS

Small Game and Wild Turkey Committee Report – *Garry Spence, Chair*
Fisheries Committee Report – *Tommy Fonville, Chair*
Big Game Committee Report – *John Litton Clark, Chair*
Habitat Nongame and Endangered Species Committee Report for June 20, 2018 – *Mark Craig, Chair*
Habitat Nongame and Endangered Species Committee Report for July 11, 2018 – *Mark Craig*
Land Use and Access Committee Report – *Tommy Fonville, Vice Chair*
Committee of the Whole – *Chairman John Coley*

AGENCY SPOTLIGHT – **CANID RESEARCH ON THE ALBEMARLE PENINSULA –** *Andrea Shipley, Mammalogist*

WILDLIFE EDUCATION DIVISION

Education Division Update – Receive a staff update on activities of the Wildlife Education Division – *Kris Smith, Wildlife Education Division Chief*

INLAND FISHERIES DIVISION

Fisheries Division Update - Receive a staff update on activities of the Inland Fisheries Division – *Todd Ewing, Aquatic Wildlife Diversity Supervisor*

WILDLIFE MANAGEMENT DIVISION

Wildlife Management Division Update – Receive an update on the activities of the Wildlife Management Division – *Dr. David Cobb, Wildlife Management Division Chief*

Temporary Rulemaking Final Adoption – Consider final adoption of temporary rules regarding the importation of cervid carcasses and carcass parts – *David Cobb* **(EXHIBIT C)**

Alligator Management Plan Addendum – Consider an addendum to Alligator Management Plan options - *Allen Boynton, Wildlife Diversity Coordinator* **(EXHIBIT D)**

LAND AND WATER ACCESS SECTION

Land Acquisitions and Property Matters

Phase II Land Acquisition – Consider final approval to proceed with acquisition of the following property – *Brian McRae, Land and Water Access Section Chief* (**EXHIBIT E**)

- Knox Landing – Caldwell County

Easement Request – Consider a request from NC Department of Transportation for an easement across Shocco Creek Game Land – *Brian McRae* (**EXHIBIT F)**

Property Exchange Request – Consider updated request and proposed final plan for the Dare Challenge project property exchange – *Brian McRae* **(EXHIBIT G)**

Temporary Rulemaking – Consider final adoption of temporary rulemaking for Green Swamp Bear Sanctuary – *Brian McRae* **(EXHIBIT H)**

Temporary Rulemaking - Consider final adoption of temporary rulemaking for game lands – *Brian McRae* **(EXHIBIT I)**

- Extended archery season at South Mountain and Buffalo Cove game lands
- Introductory gun either-sex season at Cold Mountain Game Land

WATER SAFETY RULEMAKING

Final Adoption – 15A NCAC 10F .0300 – Local Water Safety Rules – Consider final adoption of 13 amendments to water safety rules and final readoption of four water safety rules as part of the 2016 Periodic Review of Rules - *Betsy Haywood, No-Wake Zone Coordinator* **(EXHIBIT J)**

Final Adoption, No-Wake Zone – Queens Creek, Hubert, Onslow County – Consider final adoption of an amendment to 15A NCAC 10F .0320 – Onslow County, for a no-wake zone at a boating access area on Queens Creek in Hubert – *Betsy Haywood* **(EXHIBIT K)**

CONSIDERATION OF NONGAME WILDLIFE ADVISORY COMMITTEE APPOINTMENTS – Pursuant to North Carolina General Statute § 113-335, consider appointment of members to the Nongame Wildlife Advisory Committee – *Gordon Myers, Executive Director* **(EXHIBIT L)**

COMMENTS BY CHAIRMAN – *Chairman John Coley*

COMMENTS BY EXECUTIVE DIRECTOR – *Gordon Myers*

ADJOURN

U.S. Fish & Wildlife Service

Alligator River
National Wildlife Refuge

Yours to enjoy...
Alligator River National Wildlife Refuge encompasses a broad expanse (152,000 acres) of mysterious wildlands and waters. Visitors are welcome to explore this unique upland swamp refuge. Designated wildlife drive and trails offer the best wildlife viewing opportunities. Black bear, deer, river otters, and red wolves, along with a variety of birds, reptiles, and amphibians may be seen. During the winter months, large numbers of waterfowl and other migratory birds are present. Wildlife viewing is best from a safe distance. If you plan to venture into areas not designated as roads or trails on this map, please inform a responsible person of your plans. Be aware that poison ivy, ticks, insect pests, poisonous snakes (cotton-mouths, copperheads, and timber rattlers), and other natural nuisances and hazards may be encountered. This is your National Wildlife Refuge. Please enjoy your refuge experience, but handle with care.

Tips for Wildlife Viewing
Wildlife are usually most active at dawn and dusk.

Walk or drive slowly and quietly; stop frequently to watch and listen.

Be friendly to other visitors; often they will share information!

Bring binoculars or spotting scopes and field guides.

Bring insect repellent and a non-alcoholic drink.

You Can Help
By obeying regulations and respecting the refuge, wildlife, and other visitors.

By volunteering your time. Contact the Volunteer Coordinator at 252/473 1131 ext. 227.

By joining the Coastal Wildlife Refuge Society, P. O. Box 1808, Manteo, NC 27954

100% of your membership fees and donations support refuge programs.

In addition to these provisions, all State laws, County codes, and Title 50 of the Code of Federal Regulations apply on the Refuge. If you have any questions about the legality of any activity, please contact the Refuge Manager.

Regulations
General
The Refuge is open during daylight hours only (1/2-hour before sunrise to 1/2-hour after sunset).

Camping, open fires, feeding or baiting of wildlife, swimming in Refuge canals, or entering any area posted with "Area Closed" signs is prohibited.

All domestic pets (dogs, cats, horses, etc.) must be properly confined, leashed (10-foot maximum), or haltered and under owner control at all times.

Littering or dumping of garbage, refuse, sewage, debris, or other wastes or poisons is prohibited.

The use of a spotlight, automotive headlight, or other artificial light to spot, observe, locate, or take any animal is prohibited.

Taking, possessing, injuring, disturbing, damaging, destroying, or collecting any plant or animal (or attempting these actions) is prohibited.

Destroying, defacing, damaging, disturbing, or removing any private or public property, including any natural object or artifact, is prohibited. The use or possession of metal detectors or similar devices is prohibited.

Disturbing, molesting, or interfering with any person engaged in an authorized activity is prohibited. Engaging in any act of indecency or disorderly conduct (as defined by State or local laws) is prohibited.

Entering or remaining on the Refuge when under the influence of alcohol or a controlled substance is prohibited.

Begging or soliciting in any form or conducting a commercial enterprise on the Refuge is prohibited.

Refuge visitors are reminded that the Wildlife Drive (see map) is adjacent to several hunting areas. Please be aware that hunting is allowed during specific seasons, and be cautions and courteous when visiting areas shared with other refuge users.

Hunting/Trapping/Fishing/Weapons
Taking or possessing of bear, turkey, bobcat, any furbearer, or any part thereof, is prohibited, except when transporting same along an NC State road or U.S. highway.

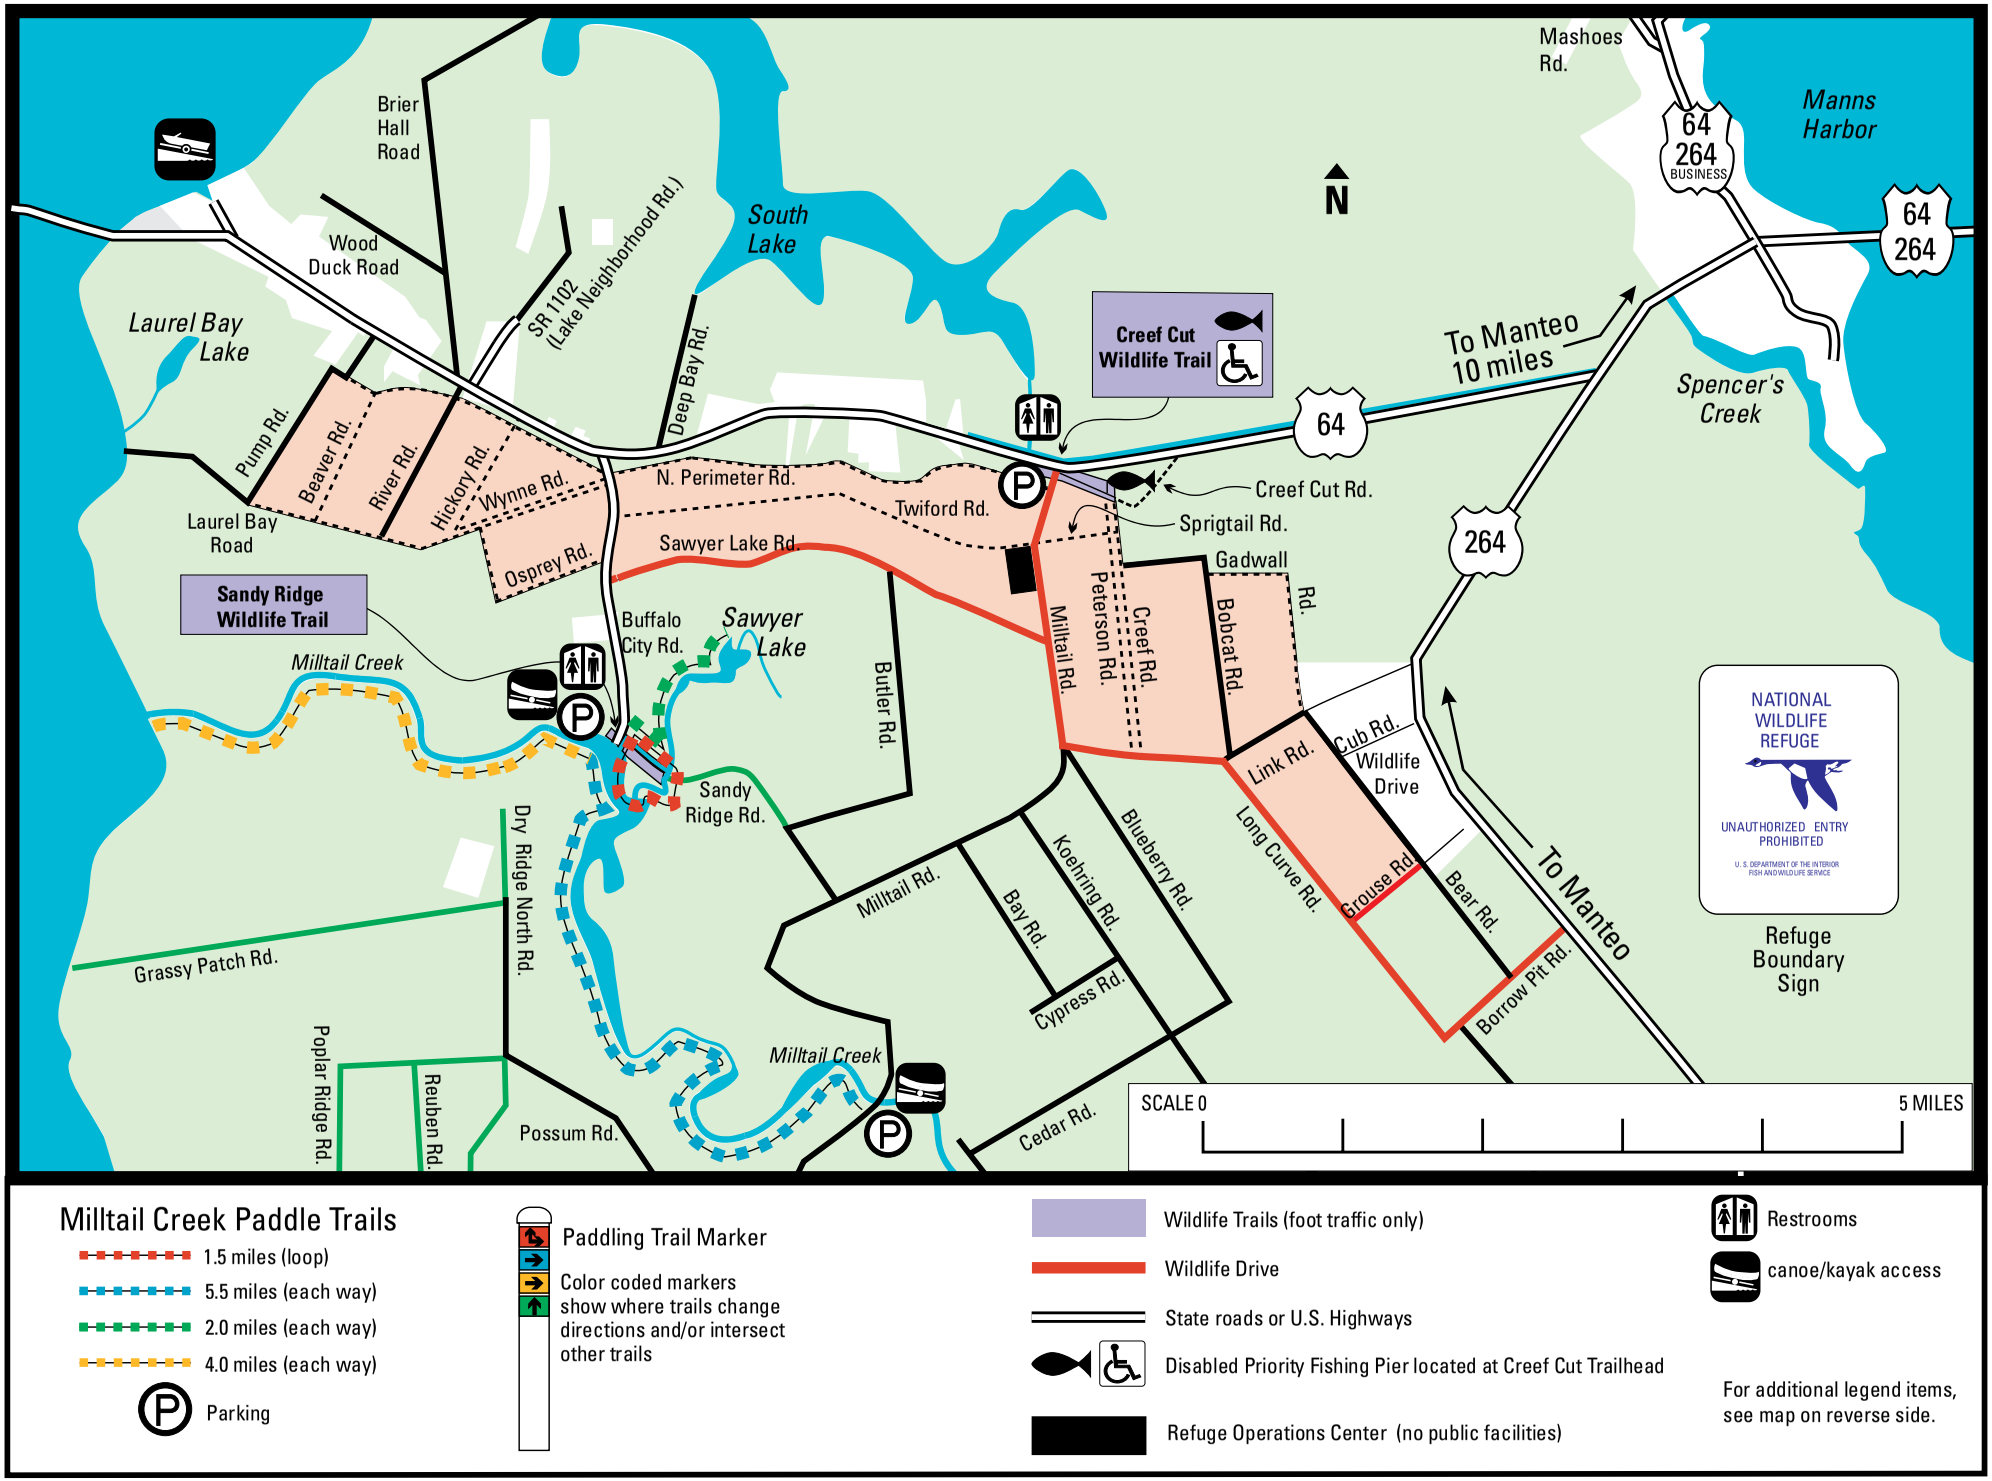
Carrying, possessing, or discharging fireworks or explosives is prohibited.

Firearms may be discharged only by persons engaged in public hunting.

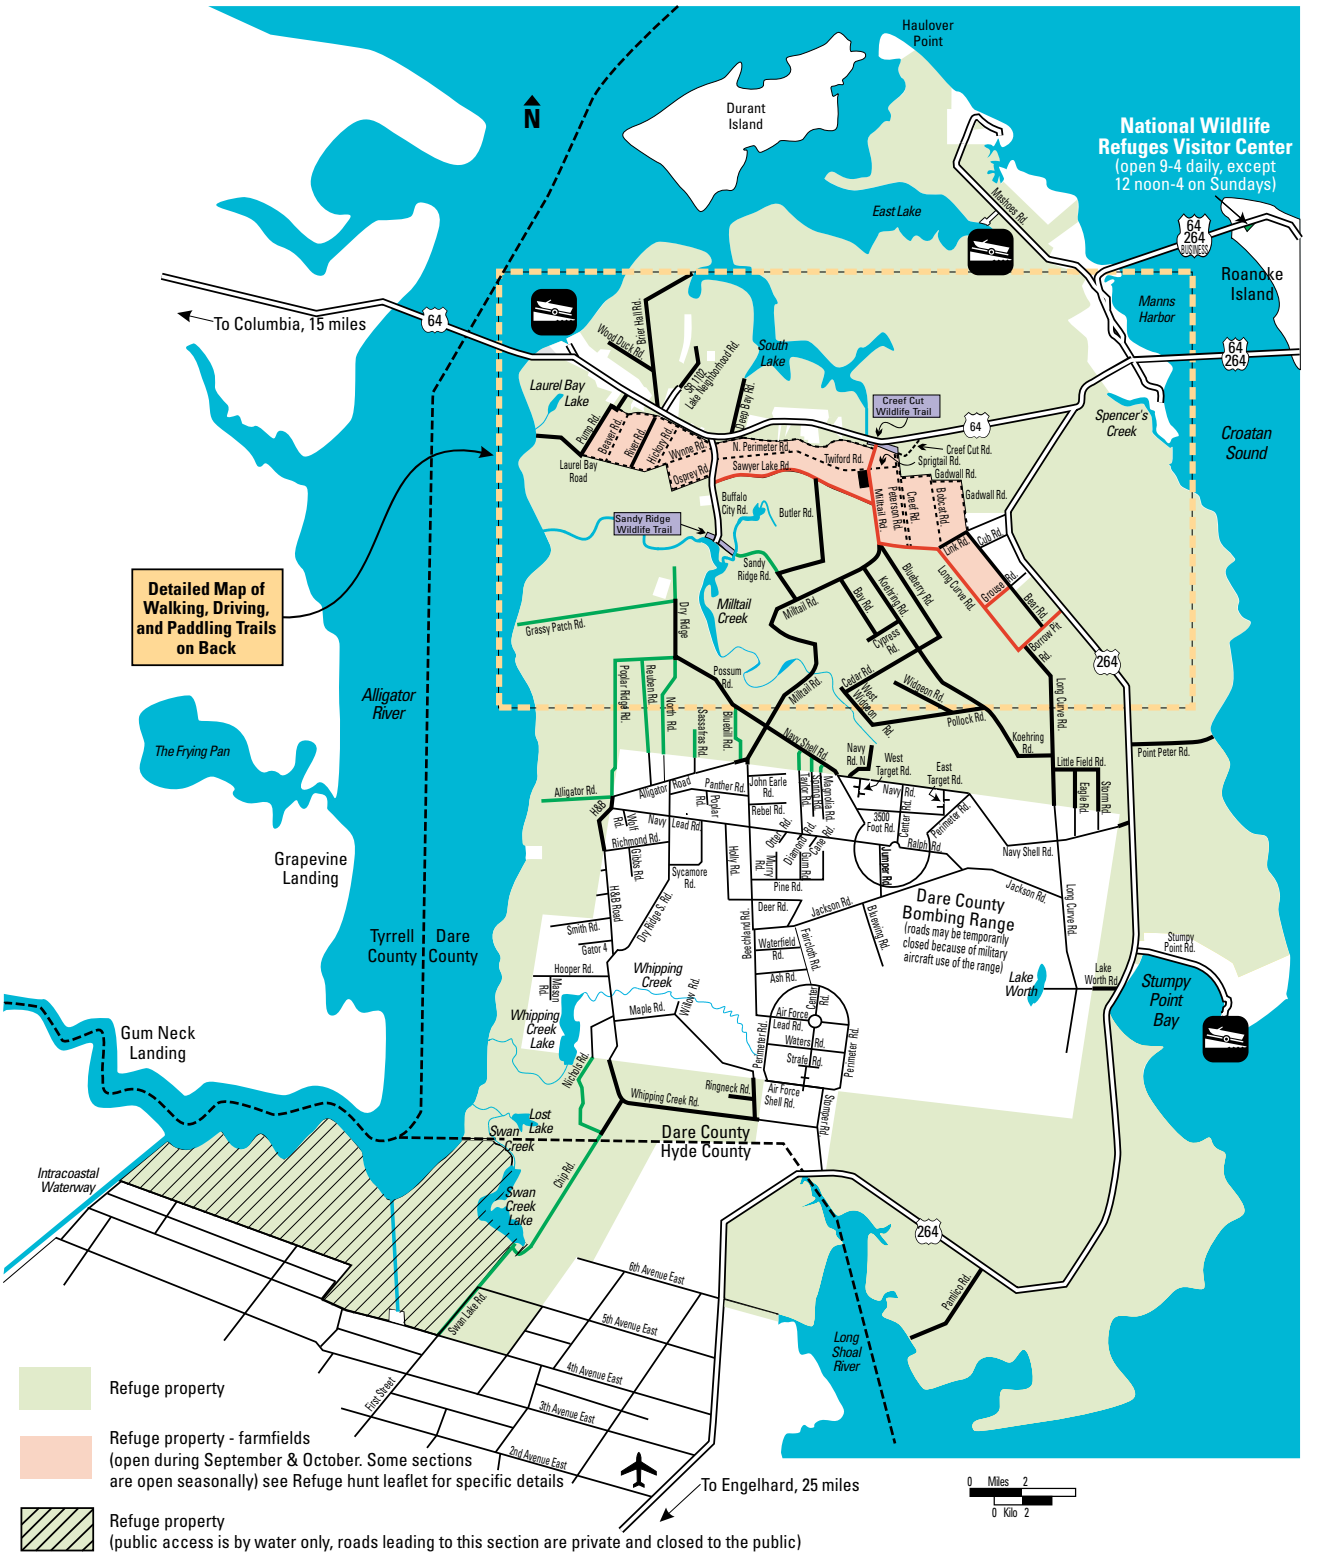
Possession of firearms is permitted in accordance with State law.

Hunting and fishing are subject to State and local regulations, seasons, and bag limits. A Refuge permit is required for hunting.

Vehicles/Roads/Trails
The speed limit on all Refuge roads, unless otherwise posted, is 35 miles per hour. State traffic laws that govern the use and operation of vehicles apply on the Refuge.



Motorized vehicles are allowed only on designated roads.



Refuge roads closed to motorized vehicles are open for walking and bicycle riding, unless posted as closed to all entry. Horseback riding is allowed only on roads open to motorized vehicles. Groups of 6 or more horses must have a Refuge Special Use Permit.

Operating any vehicle or boat that does not bear valid license plates or identification numbers and that is not properly lighted, certified, registered, or inspected according to State laws is prohibited. ATV's (3-wheelers, 4-wheelers, dirt bikes, etc.) are prohibited.

Stopping or parking a vehicle (either attended or unattended) on a road, trail, or firelane such that it blocks the free movement of other vehicles is prohibited.

Refuge Roads!

- Refuge roads, including the Wildlife Drive, are unpaved.
- Refuge roads closed to motorized vehicles are open for walking and bicycle riding, unless posted as closed to all entry.
- Only roads open to motorized vehicles are open for horseback riding. Groups of more than 6 horses riding together must have a Refuge Special Use Permit.
- Road surface conditions may vary greatly due to weather conditions.
- Roads may become impassable at certain times,even for 4-wheel drive vehicles.
- Unless otherwise posted, the speed limit on all refuge roads is 35 mph.
- Please use good judgement and caution when driving on any refuge road.

Refuge is open only during daylight hours.

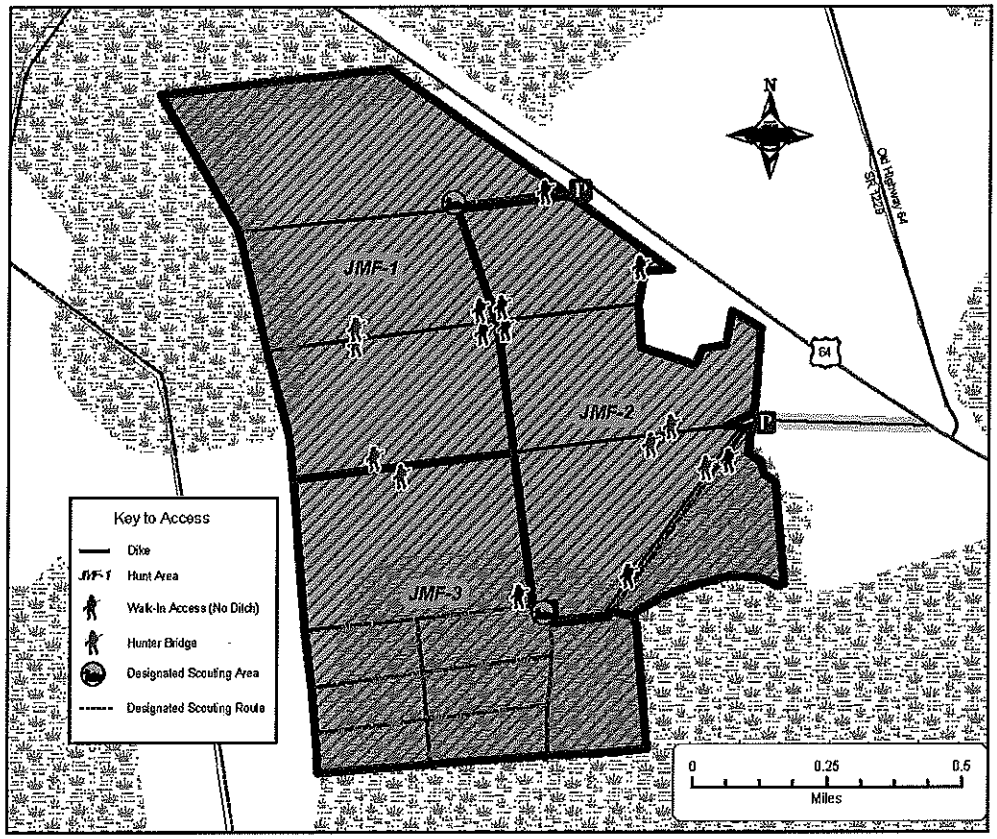
Special Use Permit
Wildlife Resources Commission

Brady Smith
[redacted]

Is authorized **access** under this Special Use Permit on the Commission-owned Land below:

LAND AUTHORIZED: J. Morgan Futch Game Land, Tyrrell County

Conditions of Permit:



1. Brady Smith is authorized to use an ATV J. Morgan Futch Game Land for the purpose of utilizing Special Trapping Opportunity permit awarded to Brady Smith.
2. Mr. Smith must possess a copy of this Special Use Permit when on J. Morgan Futch Game Land.
3. The NCWRC will not be held responsible for any accidents or injuries that occur while using this permit.
4. The WRC reserves the right to terminate this agreement at anytime.
5. ATV access only will be through the northern most gate by a combination lock code **3102**.

DATE PERMIT ISSUED: February 12, 2018
DATE EFFECTIVE: February 12, 2018

DATE PERMIT EXPIRES: February 28, 2018

Map Created by: Andrea J. Shipley
9 March 2018

On the afternoon of 12/4/2018 NCWRC agency staff were notified of a landowner in the possession of a collared canid that had been trapped in a foothold trap near Pinetown North Carolina, which is in Beaufort County north of highway 264 in between Washington and Belhaven. The captured individual had been placed in a kennel and transported to a private residence prior to our agency being notified. Via telephone conversation the trapper expressed a general interest in wildlife research, and verbally agreed to transfer the canid to our agency staff to determine the collar origin, and for either agency USFWS or NCWRC staff to proceed accordingly with further protocol steps regardless of whether the collar was that of the USFWS or the NCWRC.

Upon arrival Steven Nagy and myself were shown to the location of the kennel, which had been wrapped in burlap to protect from wind and reduce animal stress. The animal was removed from the trapper's kennel using a catch pole and physically restrained on a tarp laid on the ground, and eyes covered with a bandana. The foot was checked for trap injuries which were very minimal with no visible lacerations and some local swelling and was treated with rubbing alcohol. The individual was scanned for a pit tag which was not able to be detected. The collar was checked for presence of identifying information and the brass contact information plate used for NCWRC collars on this project was found mounted to the collar. The collar was then checked for any needed adjustments. It was discovered that the collar had become tight due to animal growth since the original collaring and release date. A visible raw area was also present on the side of the neck beneath the collar but whether this was a result of the collar being tight over time or an acute injury resulting from the recent capture event could not be determined. The raw area was treated with rubbing alcohol and an antiseptic blue lotion. The collar was loosened to the appropriate fitting, and the stop nuts were replaced with new ones to secure the collar in place. The canid was then transferred into a NCWRC kennel before leaving the residence.

After giving an update to USFWS RWRP staff the animal was transported and released at the original location of capture and collaring on 1/26/2018, north of Engelhard. The identity of the individual (CAN-18-003M) was confirmed using location data sent from the collar via satellite. The landowner of the original capture site (K. Davis) was notified before re-release.

Species identification of individuals who are suspected to have red wolf ancestry
Final Report
2/6/19

Jennifer Adams, PhD and Lisette Waits, PhD
Laboratory for Ecological, Evolutionary and Conservation Genetics
University of Idaho

Objectives– 1) Determine the species composition of four hair samples collected from the Albemarle Peninsula provided by Andrea Shipley, Mammalogist, North Carolina Wildlife Resources Commission.

Methods

Laboratory Analysis

DNA was extracted from the hair samples using the DNeasy Blood and Tissue Kit (Qiagen, Inc.) in a laboratory dedicated to low quality DNA samples. One negative control was included in the extraction to monitor for contamination of reagents. Microsatellite genotypes were generated for each sample using 17 loci divided into two PCR multiplexes. Multiplex one contained the following loci, AHT103, AHT121, CXX20 CXX109, CXX172, CXX173, CXX200, CXX250 and CXX377 (Ostrander *et al.* 1993; Holmes *et al.* 1995; Mellersh *et al.* 1997). Multiplex two contained the following loci, CXX225, CXX403, FH2001, FH2004, FH2054, FH2062, FH2010, and FH2145 (Ostrander *et al.* 1993, 1995; Mellersh *et al.* 1997). Two to four replicate microsatellite PCRs were performed each hair sample. PCR products were visualized using a 3130xl DNA Sequencer (Applied Biosystems) and allele sizes were scored using Genemapper 5.0 (Applied Biosystems).

Statistical Analysis

The genetic ancestry of the samples was estimated using the Bayesian assignment test approach implemented in the software STRUCTURE 2.2 (Pritchard *et al.* 2000; Falush *et al.* 2003). The samples were combined with genotypes from 36 dogs, 62 coyotes from North Carolina and Virginia and 121 red wolves from the wild population in North Carolina. The number of populations (K) was set to 3 (ie. A red wolf population, coyote population and a dog population), and the percentage of ancestry (q) was estimated from each population. Program STRUCTURE 2.2 was run for 5 replicates with the admixed model of ancestry and the correlated allele frequency model with a burn-in length of 100,000 repetitions and 400,000 MCMC repetitions.

Results

DNA was successfully isolated for all 4 of the samples (Table 1 and Appendix 1, attached excel spreadsheet). Results of the STRUCTURE analysis indicate that two individuals shared ≥ 90% of their ancestry with coyotes (Table 1). Individual MV-18-015F shared 72% of its ancestry with the red wolf group, 16% of its ancestry with the dog group and 12% of its ancestry with the coyote group. Individual MV-18-017F shared 87% of its ancestry with the red wolf group and 12% of its ancestry with the

FEB 19 2019

coyote group. Both of these individuals could be classified as red wolf backcrossed individuals. Individual MV-18-017F is close to a 7/8^{ths} red wolf (where a 75% red wolf backcrosses to the red wolf population).

Regarding the presence of dog ancestry in one RWBC, we believe the dog ancestry is coming from admixed coyotes as evidenced by the presence of a coyote/dog F1 in the report from 101118.

DECISION MEMORANDUM FOR THE SECRETARY

DATE: January 9, 2018

FROM: Pete Benjamin, Project Leader, Raleigh Ecological Services Field Office

SUBJECT: Relocation of Juvenile Red Wolf

I. INTRODUCTION

As part of the Red Wolf Recovery Program, the Service has used Island National Wildlife Refuges to breed wolves. The role of these sites was to propagate pups in a somewhat controlled, but natural environment that will provide them "wild experience" as juveniles for the purpose of being strategically inserted into the North Carolina Experimental Populations (NENC NEP) on the mainland. Island breeding has been suspended, pending a revised 10j Rule for the NENC, however, 1 juvenile from 2016 remains on St. Vincent National Wildlife Refuge (NWR). The purpose of this memo is provide the alternatives to inform the decision whether or not to capture and move juvenile male offspring (M2192) from the Island of St. Vincent to pre-empt the predicted dispersal and if so where to place him.

II. BACKGROUND

In 1990, the Service implemented an island propagation site on St. Vincent NWR, an island off the Gulf Coast of Florida, to aid in red wolf recovery. There are currently three red wolves on St. Vincent NWR, two adults (M1804 and F2050) and their juvenile male offspring (M2192), who is a few months shy of two years old. Within the NENC NEP, male juvenile red wolves typically disperse from their family group at around the age of two years old. In the past, offspring on St. Vincent NWR were captured at around 18 months of age and relocated within the NENC NEP before they naturally dispersed. Based on the age of the juvenile currently residing on St. Vincent and typical dispersal age, it is expected that in the relative short-term he will either disperse on his own or be pushed out by the adult red wolves.

III. ANALYSIS AND POSITIONS OF INTERESTED PARTIES

Ecological Services staff charged with managing the Red Wolf NENC NEP and Refuge staff from both St. Vincent NWR and Alligator River NWR along with our partners managing the captive population have coordinated to explore the following alternatives.

1. Status Quo: Under this alternative the juvenile male offspring (M2192) would be left at St. Vincent NWR until another alternative can be identified or the wolf attempt leaves the island forcing the need to attempt to capture that red wolf and then hold him in captivity until another alternative is identified. The obvious short coming of this alternative is that

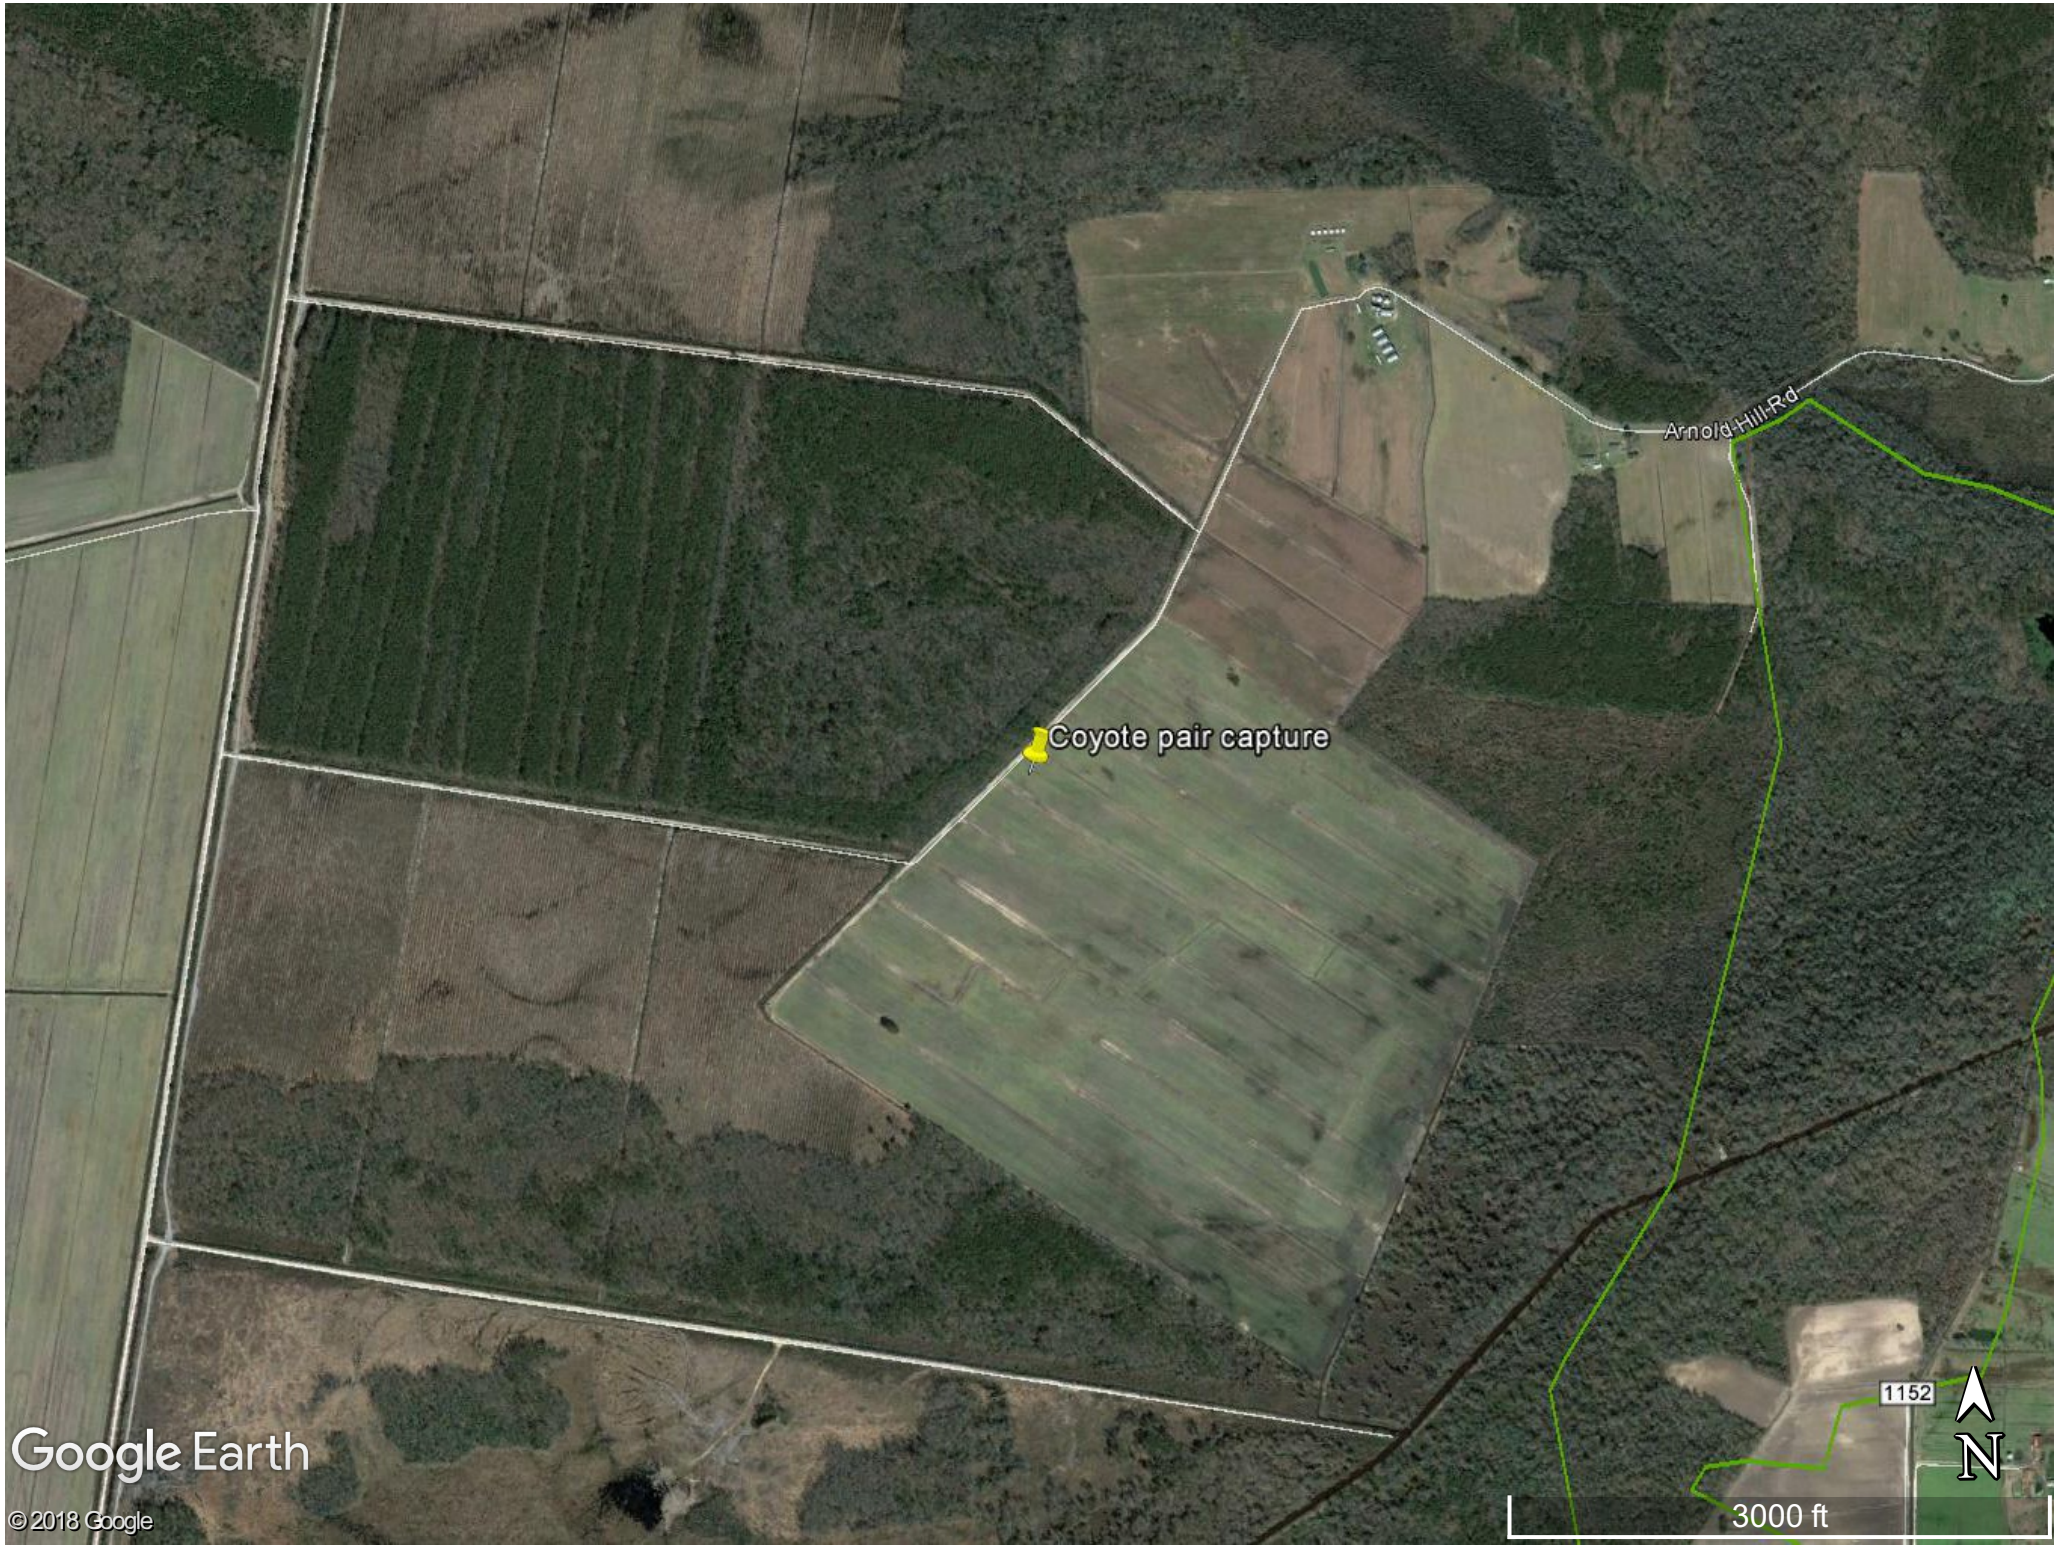
it merely delays the inevitable choice of one of the other alternatives and is likely to drain resources with a predicable dispersal off the island.

2. SSP / Alternate Captive Facility: Under this alternative M2192 would become part of the captive breeding program. Moving a wild adult male into a captive facility has not been done since the original founders were collected from the wild. So this would be an unprecedented use of the Island animals. Nevertheless, Will Waddell was contacted to see if there was space within an SSP facility to take in the juvenile male. His response indicated that they were still working on trying to place several wolves within the SSP population so there is currently no space available for this red wolf at a SSP facility (see attached email). While we are working to encourage other non-SSP facilities to take on holding Red Wolves, at this time only the SSP facilities are holding animals. At this time that leaves our Service Sandy Ridge Facility. While this facility does have space it is not designed for long term holding of wild wolves and without repair and investment is not capable of containing a wild wolf for more than a short term as illustrated by escapes in 2016 of wild wolves being held there temporarily. In fact, efforts are being made to transfer the remaining wolves held at Sandy Ridge to facilities better equipped to care for their needs, although as discussed previously there is currently no other space available. However, this is the only captive alternative and depending on holding time may make the animal no longer releasable as wild.

3. Relocation of M2192 into the NENC NEP onto Alligator National Wildlife Refuge: This alternative is consistent with what has been done in the past with red wolf offspring from St. Vincent NWR, and with the original intent of the island propagation sites. Further there is a female red wolf residing on Alligator River NWR currently paired with a sterilized coyote that is need of a mate. With the decline in the wild red wolf population in the NENC NEP, the availability of suitable red wolf mates has declined. In fact, due to the location of her home range on the northern portion of Alligator River NWR peninsula, she is related to the vast majority of male red wolves in that area since she originated as a Milltail Pack pup. There was a young male red wolf originally captured on Ventures that had traveled north within her home range and in close proximity to her periodically throughout the summer and fall. We had hoped he would pair with her, but unfortunately he was hit and killed by a vehicle in November. Alligator River NWR Refuge Management have indicated they have no objections to the release and do not foresee any compatibility issues with what is being proposed (see attached email).

IV. RECOMMENDATION

Alternative 3: Relocate of M2192 into the NENC NEP onto Alligator National Wildlife Refuge



Because of the availability of the juvenile male red wolf on St. Vincent that will need to be relocated at some point relatively soon and the benefit to red wolf recovery to have another red wolf/red wolf breeding pair on Alligator River NWR, we would like to relocate the juvenile male to within close proximity of the existing female on Alligator River NWR. If the pairing is successful it seems most likely that this new pair would continue to inhabit the established territory within the Refuge. As such, we would in essence be moving this individual from one NWR to another NWR. With breeding season very quickly approaching there is a degree of urgency to accomplish this transfer soon to have the greatest chance for success. This position is supported by the Managers of the NCNEP and the Refuge Managers at St. Vincent and Alligator River.

Decision:

Status Quo _____

MEMORANDUM

November 20, 2013

TO: All Interested Parties

FROM: "for" Cynthia K. Dohner, Director, Southeast Region, U.S. Fish and Wildlife Service
Gordon S. Myers, Executive Director, N.C. Wildlife Resources Commission

SUBJECT: Collaborative Conservation of Red Wolves and Other Canids on North Carolina's Albemarle Peninsula

---

Recovery of the federally-listed red wolf has been a priority for the U.S. Fish and Wildlife Service (FWS) for more than 20 years and is focused in North Carolina on the Albemarle Peninsula (AP; i.e., Hyde, Tyrrell, Washington, Beaufort, and Dare counties). Comprehensive stakeholder involvement and collaboration with other management agencies is critical to successful recovery of any at-risk species. The North Carolina Wildlife Resources Commission (WRC) is a key collaborator in this regard, as it has jurisdiction over all state-trust wildlife resources in N.C.

Since 2009, the FWS and WRC have worked to broaden our collaboration in the conservation and management of all canid species (including red wolves) on the AP. As these efforts have solidified, specific actions have been jointly identified by our two agencies that will improve conservation outcomes. These actions are categorized into five areas; collaboration, research, outreach, regulatory, and enforcement. Specific action items are outlined and prioritized within each of these categories in Attachment A.

This memo establishes the FWS's and WRC's commitment to initiate, or to continue, the efforts outlined in Attachment A. The common goal in this effort is to establish clear expectations and accountability for collaboration regarding the action items on Attachment A, thus resulting in enhanced and seamless canid conservation and management on the AP. This approach provides the best opportunity to achieve recovery goals for red wolves, while at the same time managing other canids to balance biological variables with social expectations. The dynamics of these canid species are complex and offer unique opportunities for innovation. Appropriate staff from each agency is hereby tasked with immediately developing a timeline to implement these actions. Through this commitment, we will continue to advance our collective conservation goals.

Attachment A

Action Items for Collaborative Conservation of Canids on North Carolina's Albemarle Peninsula (AP)

(*Note: Action Items are prioritized within category.*)

Collaboration

1. The N.C. Wildlife Resources Commission (WRC) and U.S. Fish and Wildlife Service (FWS) will formalize in writing the collaborative management of canids on the AP. This agreement should:
    a. include a clear mission statement, goals, objectives, and implementation strategies (ask and answer the "Why?");
    b. set a goal to define success regarding canid management on the AP;
    c. espouse a philosophy of canid management operating within the context of a three-legged stool (i.e., federal and state governments and stakeholders);
    d. as available, commit funding and staffing resources for field personnel to contribute to the conservation of the red wolf and management of coyotes;
    e. as available, commit funding to conduct research pertinent to canid management on the AP;
    f. establish polices and goals for developing a collaborative genetic archive for AP canids, a data sharing portal accessible by staff in both agencies, and reciprocal sharing of all historical data (including phenotypic and genotypic data and literature) of the red wolf;
    g. establish a foundation for developing and implementing an adaptive approach to canid management on private lands on the AP;
    h. initiate development of a collaborative canid research program;
    i. describe plans to conduct the next five year Red Wolf Program review;
    j. outline options for holding annual workshops with federal and state enforcement staff;
    k. outline plans to hold semi-annual coordination meetings regarding canid management on the AP; and
    l. develop milestones for future development of a management plan for all canids in the AP.

2. The FWS will initiate a review of the current Red Wolf Recovery Plan to determine if the state-of-our-knowledge or field conditions have changed such as to warrant its revision. Review and comments from the WRC will be considered in this evaluation.

3. The WRC, with support and participation of the FWS, will establish a "Canid Forum" (similar to that established for manatees in Florida) to facilitate communication and discussion regarding canid management and citizen science opportunities on the AP.

Research

1. The FWS and WRC will provide funding and logistical support for research identified by the Red Wolf Recovery Implementation Team, Red Wolf Program staff, other FWS staff, or the WRC that promote the conservation and recovery of the red wolf and other canids on the AP. Studies could include:
    a. tests of the "placeholder theory" on the AP, including behavior of sympatric canids,
    b. determining carrying capacity of canids on the AP,
    c. determining genetic profiles of canid species on the AP,
    d. evaluating predator-prey dynamics,
    e. studies of canid habitat use,
    f. epidemiology of diseases impacting canids on the AP,
    g. development of stochastic simulation models of sympatric canid population dynamics and habitat use, and
    h. canid dispersal dynamics

2. The FWS and WRC will conduct jointly-supported research to determine the attitudes and opinions of N.C. private landowners and other citizens concerning canids on the AP (i.e., human dimensions studies).

Outreach

1. The FWS and WRC will collaborate with other partners to design and implement broad-based outreach and marketing programs with clear goals, objectives, strategies, and measurable outcomes, including development of consistent agency messages and educating the public about canids on the AP.

Regulatory

1. The FWS and WRC will initiate a review and, if needed, subsequent rule-making to clarify concepts or rectify conflicts in current federal or state rules (including the current 10(J) rule).

2. The WRC will review and evaluate statutory requirements for listing red wolves as state threatened in the five AP counties.

3. As data demonstrating a relationship between coyote hunting and red wolf mortality become available, the FWS and WRC will evaluate, and if appropriate implement, adaptive approaches to regulate of take of coyotes that may result in incidental take of red wolves.

4. The WRC will evaluate the status, management, and regulation of Controlled Fox Hunting Preserves.

5. The WRC will develop BMPs (due care provisions) for coyote hunting, trapping, and live sale.

6. The WRC will compile, compare, and contrast canid hunting and trapping regulations and programs in other states, including, but not limited to, other states with other species of wolves.

Enforcement

1. The FWS and WRC will develop coordination strategies to improve enforcement of federal regulations protecting red wolves.

Cross-fostering offspring with nonbiological parents could prove useful to augment populations of endangered carnivores. We used cross-fostering to augment captive-born and wild-born litters for the endangered red wolf (*Canis rufus*). Between 1987 and 2016, 23 cross-fostering events occurred involving captive-born pups fostered into captive litters (n = 8 events) and captive-born pups fostered into wild recipient litters (n = 15 events). Percentage of pups surviving 3 and 12 months was 91.7% for captive-born pups fostered into captive recipient litters. For pups fostered into wild litters, percentage of pups surviving 5 months was > 94% among fostered pups (pups fostered into a wild red wolf litter or replaced a hybrid litter), pups in recipient litters (wild-born litters receiving fostered pups), and pups in control litters (wild-born litters not in a fostering event) when using pups with known fates. Including pups with unknown fates as deaths, percentage of pups surviving 5 months was > 54% among fostered pups, pups in recipient litters, and pups in control litters. Among wild litters, percentage of pups surviving 12 months was > 82% among fostered pups, pups in recipient litters, and pups in control litters when using pups with known fates. Including pups with unknown fates as deaths, percentage of pups surviving 12 months was > 48% among fostered pups, pups in recipient litters, and pups in control litters. Although survival to 12 months was similar among the groups, average life span was different with pups in control litters living 3.3 years, pups in recipient litters living 4.6 years, and fostered pups living 5.6 years. Of fostered pups surviving > 12 months in the wild, 9 animals whelped or sired 26 litters. Cross-fostering was successful at augmenting litter size for red wolves without any deleterious effects on recipient litters, illustrating fostering as a tool for increasing populations of endangered carnivores.

Key words: augmentation, *Canis rufus*, cross-fostering, population, red wolf, survival

Maintaining or increasing population size is often the key conservation objective for threatened and endangered species. However, many rare or threatened mammalian species may have low birth rates, and low survival and recruitment of young (e.g., Laurenson 1994; Fuller et al. 2003; Groom et al. 2017). Increasing survival rates of young carnivores born into wild populations involves many variables (i.e., sufficient food of high quality, protection from intra- and interspecific predation, disease, human-caused mortality, or extreme weather) that may act independently or in concert with each other (e.g., Mech and Goyal 1995; Fuller et al. 2003; Angerbjörn et al. 2004; Bohling and Waits 2015; Hinton et al. 2017). Although increased survival is essential for population growth, fundamentally a population must produce new individuals to grow.

The red wolf (*Canis rufus*) was declared extinct in the wild in 1980 (U.S. Fish and Wildlife Service 1989) and is currently listed as critically endangered (IUCN 2017). To mitigate the decline of red wolf population numbers, a breeding program was established in 1973 at the Point Defiance Zoo and Aquarium, Tacoma, Washington (Phillips et al. 2004). This managed

on 01 August 2018

breeding program, operated under the Species Survival Plan of the Association of Zoos and Aquariums, was developed as a cooperative breeding program to enhance long-term population management for approved species (Hutchins and Wiese 1991). The red wolf Species Survival Plan was designed to function as a source population for initial and ongoing red wolf restoration efforts (U.S. Fish and Wildlife Service 1989). Only 14 individuals were considered "pure" red wolves and were the founders for the red wolf breeding program, with descendants of 12 founders serving as source individuals for reintroduction into the Alligator River National Wildlife Refuge, North Carolina (Phillips et al. 2003).

Low genetic diversity, increased genetic drift, and inbreeding depression can be significant issues whenever low numbers of breeding animals are involved, such as captive breeding programs (Rabon and Waddell 2010) or some wild populations (Brzeski et al. 2014), which can result in reduced litter sizes (Lockyear et al. 2009; Rabon and Waddell 2010). In addition, the expansion of coyotes (*Canis latrans*) into the northeastern North Carolina experimental population area and the risk of hybridization represented another threat to red wolf restoration (Kelly et al. 1999; Stoskopf et al. 2005; Fredrickson and Hedrick 2006; Bohling and Waits 2015). To mitigate introgression of coyote genes into the red wolf population, an adaptive management plan was implemented that 1) sterilized and released coyotes to serve as nonbreeding placeholders (Gese and Terletzky 2015), 2) removed coyotes from the area, 3) translocated red wolves (McLellan and Rabon 2006), and 4) cross-fostered captive-born pups into wild litters (Stoskopf et al. 2005). Combined with intensive field management (Gese et al. 2015) and genomic testing protocols (Miller et al. 2003), wild-born pups could be identified as red wolf, red wolf-coyote hybrid, or coyote, leading to the option of replacing hybrid individuals with red wolf pups from the captive breeding population.

Cross-fostering, the raising of young by nonbiologically related individuals, has the potential to increase population sizes of threatened or endangered species (Kitchen and Knowlton 2006; Stoskopf 2012). Fostering of offspring from natal to surrogate parents has been conducted with Columbian ground squirrels (*Spermophilus columbianus*—Murie et al. 1998), captive coyotes (Kitchen and Knowlton 2006), many bird species (Powell and Cuthbert 1993; Drewien et al. 1997; Oswald et al. 2013), and has been observed without human facilitation in black bears (*Ursus americanus*—Benson and Chamberlain 2006). Fostered young that were raised successfully have been both captive-born (Kitchen and Knowlton 2006) and orphaned in the wild (McNutt et al. 2008). Most research on cross-fostering of canid species has been limited to small sample sizes (< 4 litters) or anecdotal records, although fostering in African wild dogs (*Lycaon pictus*—McNutt et al. 2008), coyotes (Kitchen and Knowlton 2006), and wolves (*Canis lupus*—Schultz et al. 2007; Jansson et al. 2015; Scharis and Amundin 2015) has greatly advanced our understanding of factors required for successful cross-fostering. Kitchen and Knowlton (2006) reported that the age at which captive-born fostered pups were introduced to captive recipient litters influenced survival rates and that fostered pups > 6 weeks old did not survive. Survival of fostered gray wolf pups has been ambiguous. Some pups > 4–5 months old survived into adulthood while other pups, of the same litter, did not survive (Bradley et al. 2005; Schultz et al. 2007). Fostering young pups increases the probability of survival and success. For example, captive-born gray wolf pups that were only 4–6 days old were fostered into captive recipient litters, were readily accepted by the foster female, and had high survival (Scharis and Amundin 2015). The Mexican wolf (*Canis lupus baileyi*) population in the southwestern United States was founded by 7 individuals resulting in a highly inbred population (Harding et al. 2016). Cross-fostering of 2 wild pups (1 female and 1 male) to a wild recipient litter of 3 pups resulted in the survival of all 5 pups for at least 8 months, suggesting that cross-fostering has the potential to increase litter size and subsequently population size of this endangered canid (Harding et al. 2016).

The potential benefits associated with fostering nonmaternal offspring include improved genetic fitness for a population and reduced inbreeding depression (Jansson et al. 2015), in addition to the numerous advantages associated with living in groups (Kokko et al. 2001; Ausband et al. 2016; Lehtonen and Jaatinen 2016). The gray wolf in Sweden is descended from 5 individuals and is highly inbred, but Jansson et al. (2015) suggested that augmentation of wild recipient litters from captive fostered litters should potentially reduce the inbreeding coefficient.

We summarized data on age, litter size, sex ratio, and survival to 3 and 12 months of age for captive-born pups fostered into captive recipient litters, and survival to 5 and 12 months of age for captive-born pups fostered into wild recipient litters. To successfully augment a wild population, fostering should not be deleterious to the recipient litter; therefore, we examined the same parameters for pups within the recipient litter in the wild. In addition, as a "control," we documented the same metrics for an equal number of litters of wild-born red wolf pups not involved in a fostering event (i.e., control litters). These parameters were used to evaluate the success and utility of cross-fostering red wolf pups that were captive-born into litters of captive-born and wild-born red wolves.

Materials and Methods

Red wolf pups involved in fostering events were born and fostered at 11 facilities across the United States: Beardsley Zoo, Connecticut; Brevard Zoo, Florida; Cape Romain National Wildlife Refuge, South Carolina; Dan Nicholas Nature Center, North Carolina; Great Smoky Mountains National Park, Tennessee; Lincoln Park Zoo, Illinois; Miller Park Zoo, Illinois; North Carolina Zoo, North Carolina; Oglebay Zoo, West Virginia; Point Defiance Zoo and Aquarium, Washington; and the Red Wolf Recovery Area, North Carolina. Pups fostered into wild wolf litters were released into 2 locations: 1 fostering event in the Great Smoky Mountains National Park, Tennessee, and 14 fostering events augmenting wild red wolf litters in the Red Wolf Recovery Area located on the Albemarle Peninsula in northeastern North Carolina. For descriptions of

on 01 August 2018

the study areas and history of recovery efforts in these 2 sites, see Lucash et al. (1998) for Great Smoky Mountains National Park, Tennessee, and Bohling and Waits (2015) and Gese et al. (2015) for the Red Wolf Recovery Area, North Carolina.

We considered the location of source and recipient litters, litter sizes, and age of the pups as initial factors before fostering attempts; age of captive-born pups was known from birth date. We introduced captive-born fostered pups only to captive recipient litters that had successfully raised at least 1 litter to adulthood (Green et al. 2002). History of successfully raising litters of wild recipient parents was not available. We attempted to match as closely as possible the ages of foster pups and pups in recipient litters and in all fostering events; the eyes of fostered and recipient litter pups were closed or had just opened (i.e., pups were 10–14 days old—Kreeger 2003). Fostered pups transferred to captive recipient litters did not have their scents masked nor did animal care staff; however, fostered pups transferred to wild recipient litters were handled by personnel wearing latex gloves.

Captive-born pups fostered into captive recipient litters.—We housed wolves as mated pairs in outdoor enclosures (450–900 m^2) containing natural substrate, foliage, and artificial dens. Half (4 of 8) of the sires and half (4 of 8) of the dams of fostered pups had at least 1 litter before the fostering event. The time between removing a fostered pup from a natal litter to placement into a recipient litter ranged from several minutes to approximately 6 h. Short-duration fostering events required a simple transfer of a fostered pup(s) from one enclosure to another enclosure within the same facility. The event with the longest interval (6 h) required animal care staff from the Brevard Zoo (Florida) accompanying 2 female pups on a commercial airline to a recipient litter at the Beardsley Zoo (Connecticut).

Identification of fostered pups following placement in a recipient litter was possible based on sex (e.g., 1 male pup fostered to recipient den with 3 females) or by a small patch of pelage marked with animal tattoo ink (Ketchum Mfg. Co. Inc., Lake Luzerne, New York). We observed the activity level of all pups daily for 5–7 days following placement in a recipient litter. To assess development, we obtained weights for all pups in recipient litters to ensure neonate growth was consistent among litter mates. Before fostering, we determined that if a fostered pup was isolated from the litter by recipient parents or if consistent weight loss was recorded, the pup would be removed. No fostered pups were rejected other than a single pup that disappeared the day following placement. The percentage of fostered pups surviving to 3 and 12 months of age was the measure of success for the captive fostering events.

Captive-born pups fostered into wild recipient litters.—Reproductive female red wolves in the wild were foot-hold trapped, fitted with a very high frequency (VHF) radiocollar (Telonics, Inc., Mesa, Arizona) and monitored daily from late March to May to identify den sites; fostering events occurred in April and May. Females that were not radiocollared but occupied known den site locations that had previously raised pups, or that were in breeding pairs with stable territories and had an adult female with proven rearing success, were also monitored. All female and male wolves involved with fostering captive pups were born in the wild with the exception of 1 female and 3 males. Additionally, most adults receiving fostered pups in the northeastern North Carolina population had at least 1 litter before the fostering event with the exception of 1 female and 2 males (but were paired with experienced mates). Only the pair involved with the fostering event in the Great Smokey National Park had not raised a prior litter. If a wild litter was genetically determined to be red wolf-coyote hybrids, the hybrid litter was removed and captive-born red wolf pups were placed in the den site (i.e., litter replacement). If a wild litter was considered small in number (but not a hybrid litter), captive-born pups were fostered into the wild litter (i.e., litter augmentation). To avoid facilitating a competitive advantage to either captive or wild pups, we matched the sex ratio and age of the fostered pups as close as possible to the age of the wild-born litter of pups (Kitchen and Knowlton 2006); age of wild-born pups was estimated from body measurements and estimated whelping date. We moved captive-born pups to the den location of the recipient wild litter as soon as possible to promote acceptance of the fostered pups into the litter. We implanted each captive pup with a passive integrated transponder (PIT) tag (Eidap, Inc., Sherwood Park, Alberta, Canada) inserted subcutaneously between the shoulders prior to placement in the den. All capture and handling procedures were in accordance with guidelines endorsed by the American Society of Mammalogists (Sikes et al. 2016).

After placing pups into a den, the wild dam was monitored daily by radiotelemetry for 3–5 days to confirm her return to the den site. Although it is common for wild red wolves to move their pups at this age, we continued to observe the movements of the dam remotely and only attempted to verify the survival of the fostered pups during the fall trapping season approximately 5 months following the fostering event. At this time, juvenile wolves were large enough to be safely trapped and equipped with radiocollars. The outcome of captive-born to wild fostering events was considered successful only when a fostered individual was trapped, equipped with a radiocollar, and released at the capture location. If the pups were not captured in the fall, the fate of the pup was classified as "unknown fate." We estimated the number of pups surviving to 5 and 12 months of age for both the fostered pups and the pups in the recipient litter as a measure of success of the fostering event, as well as a measure that cross-fostering is not deleterious to the pups in the recipient litter. Recapturing, radiocollaring, and telemetry flights of fostered and recipient pups continued as part of the overall red wolf monitoring program to assess survival, causes of death, timing and distance of dispersal movements, and reproduction, mainly litter size (Gese et al. 2015). Radiocollared wolves were monitored 2–3 times/week, allowing for the early detection of a mortality signal and facilitating recovery of the carcass to determine the cause of death. If applicable, a field necropsy was conducted, or if the cause of death was not apparent, the carcass was examined by a veterinary pathologist.

Wild-born red wolf pups as "control" litters.—As a comparison to fostered pups and pups in the recipient litters, we evaluated the fate of the pups from an equal number (n = 15 litters) of wild-born red wolf litters not involved in a cross-fostering event (i.e., control pups). We then compared the percentage of pups surviving to 5 and 12 months of age, and the life span of pups surviving > 1 year among the 3 categories: fostered, recipient, and control pups. For clarity, fostered pups were pups that were captive-born and placed into a wild red wolf den (either complete replacement of a hybrid litter, or augmentation of an existing red wolf litter). Pups in recipient litters were wild-born pups in which fostered pups were placed. Control pups were wild-born pups that were not involved in a fostering event. The control litters from the Red Wolf Recovery Area were randomly chosen from the entire data set of red wolf litters, but stratified to match the number of fostered litters within each year and management zone (Gese et al. 2015) to reduce the influence of annual and geographical variation in survival rates. Similar to the fostered and recipient pups, the surviving control pups were recaptured, radiocollared, and relocated as part of the overall red wolf monitoring program to assess survival, causes of death, timing and distance of dispersal movements, and reproduction, mainly litter size (Gese et al. 2015). Radiocollared wolves were monitored 2–3 times/week allowing for the early detection of a mortality signal and facilitating recovery of the carcass to determine the cause of death. If applicable, a field necropsy was conducted, or if the cause of death was not apparent, the carcass was examined by a veterinary pathologist.

Statistical analyses.—For captive-born pups fostered into wild litters, we examined differences in the percentage of pups from the 3 treatment groups (i.e., fostered pups, pups in recipient litters, pups in control litters) surviving to 5 and 12 months of age with contingency tables and chi-square tests (Zar 1996). This comparison was performed for pups with known fates (i.e., complete fates), as well as adding pups with unknown fates that were assumed to be deaths. Chi-square tests also were used to examine where dens, in terms of landownership (federal, state, private), of fostered and control litters were located; the proportion of fostered and control pups that dispersed; the proportion of different causes of death between fostered and control pups; and the proportion of landownership (federal, state, private) between fostered and control pups in relation to where they died. We determined landownership using state GIS databases (Gese and Terletzky 2015). Differences in litter size, age at the time of dispersal, and distance of dispersal movements between fostered and control pups were determined with a Student's t-test (Zar 1996).

Results

Captive-born pups fostered into captive recipient litters.—There were 8 events involving 12 fostered pups between captive-born red wolf pups and captive-born red wolf recipient litters (Table 1). The mean age of fostered pups was 10.7 ± 2.7 days (*SD*) with the youngest pups 8 days old and the oldest pups 16 days old. Single pups were the most common (62.5%) number of pups fostered, followed by 2 fostering events with 2 pups (25.0%), and a single fostering event involving 3 pups. There was an equal sex ratio (6 F:6 M) among the 12 fostered pups. The mean age of pups in captive recipient litters was 8.9 ± 5.6 (*SD*) with the youngest litters 4 days old and the oldest litter at 19 days old. Recipient litters, before fostering pups, consisted of 3 litters of a single pup, 3 litters of 3 pups, 1 litter of 2 pups, and 1 litter of 4 pups. The sex ratio of the 18 pups in recipient litters was 7 females to 11 males (Table 1). The largest age difference between fostered pups and recipient litter pups was 7 days with the fostered pups being older. Including the fostered pups, the sex ratio of the 30 pups in recipient litters was 13 females to 17 males.

The overall percentage of fostered pups surviving in the recipient litters to 3 months of age was high (91.7%; 11 of 12 pups). This single unaccounted pup may have been eaten by the recipient litter dam, although 1 of the 2 siblings from this individual's natal litter was stillborn and the other disappeared 8 days postpartum. Thus, this pup may have been medically compromised; however, the cause of mortality could not be verified because of the disappearance of the body 1 day following insertion into the recipient den. The percentage of fostered pups surviving to 12 months of age remained 91.7% (Table 1).

Captive-born pups fostered into wild recipient litters.—There was a total of 15 events involving 31 captive-born pups fostered into wild recipient litters (Table 2). Four recipient litters were

[a] Age difference is the number of days older or younger the fostered pups were as compared to pups in the recipient litter.
[b] Known fate of 3 out of 5 pups.
[c] Known fate of 2 out of 4 pups.
[d] Known fate of 1 out of 2 pups.
[e] Known fate of 2 out of 3 pups.
[f] Known fate of 1 out of 3 pups.

determined to be hybrids and these pups were removed. Thus, the fostered pups were considered litter replacements. The other 11 events involved litter augmentation (i.e., adding fostered pups to an existing red wolf litter). The mean age of fostered pups was 10.8 ± 3.7 days with the youngest pups at 5 days old and the oldest pups at 18 days old. Pairs of pups were the most common (56.2%) number of pups fostered, followed by a single pup being fostered (31.2%), 3 pups in 1 event, and 5 pups in another event (Table 2). The number of captive-born pups fostered had more females than males (21 F:10 M). The mean age of pups in wild recipient litters was 10.9 ± 4.2 days with the youngest litter at 4 days old and the oldest litter at 18 days old. The largest age difference between the fostered pups and the wild recipient litter pups occurred when the fostered pups were 14 days older. Before having the hybrid pups removed and the fostered pups added, the mean size of wild recipient litters was 3.4 (± 2.1 *SD*) pups and ranged from litters with a single pup to a litter with 9 pups. However, after removing the 4 recipient litters determined to be hybrids, the mean litter size was 2.4 (± 0.8) pups at the time of fostering. For the wild recipient litters, the sex ratio was 10 females to 15 males (Table 2). The resulting litter size containing fostered and recipient pups ranged from 2 to 5 pups, well within the range of litter sizes for red wolves (Lockyear et al. 2009).

The fate of 8 pups fostered into the 15 wild litters was unknown at 5 and 12 months of age (Table 2). Overall, the percentage of "known fate" pups fostered into wild red wolf litters, or replacing hybrid litters, surviving to both age 5 and 12 months was high (Table 3). However, if pups with unknown fates are considered deceased, then the percentage of fostered pups surviving to 5 and 12 months was lower (Table 3). Unfortunately, the fate of some pups remained unknown as they were never recaptured in the recovery area. One litter with complete survival information had 1 fostered pup die before 3 months of age, but a second fostered pup survived to at least 12 months. Both pups were handled 28 days after placement in a recipient den; however, 1 pup disappeared after movement of the litter by the recipient parents (Table 2). Notably, of 16 fostered pups known to survive > 12 months of age, these individuals lived to an average age of 5.6 years, and 9 animals whelped or sired a total of 26 litters in the wild.

Table 3.—Percentage of fostered, recipient, and control red wolf (*Canis rufus*) pups with known fates and unknown fates assumed to be deaths surviving to 5 and 12 months of age.

Fate Treatment group	*n* pups	% surviving to 5 months	% surviving to 12 months
Known fate			
Fostered	18	94.4	88.9
Recipient	15	100	93.3
Control	35	100	82.0
Known fate and unknown fate assumed dead			
Fostered	31	54.8	51.6
Recipient	25	60.0	56.0
Control	66	59.1	48.5

Since cross-fostering is meant to assist population recovery of this endangered carnivore, we examined whether augmenting existing litters could be deleterious to the recipient litter. For pups of known fate in the recipient litters, the percentage

Downloaded from https://academic.oup.com/jmammal/advance-article-abstract/doi/10.1093/jmammal/gyy087/5058104
by University of Missouri-Columbia user
on 01 August 2018

of pups surviving to 5 months (100%) and 12 months (93.3%) was similarly high as the fostered pups (Table 3). When considering the pups with unknown fates as deaths, the percentage of pups in the recipient litters surviving to 5 months (60%) and 12 months (56%) was similar to the percent survival of the fostered pups. Of 15 recipient pups known to survive > 12 months of age, these individuals lived to an average of 4.6 years of age.

Why some fostered individuals survived far into adulthood, while others did not live to 12 months of age is not readily apparent (Table 2). The percentage of fostered pups surviving to 12 months of age within the 4 litters that were replacements for the hybrid litters that were removed (i.e., no competition from a recipient litter) was 85.7% (6 of 7 pups) for pups with known fates, and 46.1% (6 of 13 pups) when including pups with unknown fates. For 8 litters of fostered pups that were equal to (0 age difference), greater than (> 1 day age difference), or only 1 day different (−1 day age difference) from the pups in the recipient litter, survival to 12 months was 100% (7 of 7 pups) for pups with known fates and 58.3% (7 of 12 pups) when including pups with unknown fates. For the 3 litters in which the fostered pups were much younger than the recipient litter (i.e., −4 days age difference), the number of known fate pups surviving to 12 months of age was 75% (3 of 4 pups) and when including pups with unknown fates as deaths, the percent survival was 50% (3 of 6 pups).

Comparison of fostered, recipient, and control litters.—We analyzed data from 15 litters containing 66 wild-born red wolf pups as the "control" group for comparison to the fostered pups and pups in recipient litters. The percentage of pups surviving to 5 months of age was similar among fostered pups, pups in recipient litters, and pups in control litters when using pups with known fates ($\chi^2_2 = 3.042$, $P = 0.218$; Table 3) and was similar across groups when including pups with unknown fates as deaths ($\chi^2_2 = 0.199$, $P = 0.905$; Table 3). The percentage of pups surviving to 12 months of age also was similar among fostered pups, pups in recipient litters, and pups in control litters when using pups with known fates ($\chi^2_2 = 1.308$, $P = 0.520$; Table 3) and was similar across groups when including pups with unknown fates as deaths ($\chi^2_2 = 0.420$, $P = 0.810$; Table 3). Even though the percent of pups surviving to 12 months of age was similar among the 3 groups, life span differed ($F_{2,58} = 4.49$, $P = 0.015$) with pups from the control litters living an average 3.3 years (± 1.97 *SD*; $n = 32$ pups), recipient pups living to a mean of 4.6 years (± 2.62; $n = 14$ pups), and fostered pups living to an average of 5.6 years (± 3.16; $n = 15$ pups).

The greatest difference among the groups was the fostered pups living 2.3 years longer than the control pups. We examined several factors that may explain this disparity. First, we examined where dens were located as differences in landownership could create more risky landscapes. Results showed similar use of federal, state, and private lands between the 2 cohorts (Table 4). Second, we examined if smaller litter sizes could give pups a competitive advantage later in life, and found that the fostered litters were slightly smaller than the control litters (Table 4). Third, we examined the possible influence of dispersal since dispersal into unfamiliar areas carries a decrease in survival. We had anticipated that the control pups would have a higher dispersal rate, but found the percentage of pups dispersing was dissimilar with more fostered pups dispersing from their natal home range (Table 4). The age at which the pups dispersed and the distance they dispersed was similar (Table 4). Last, we examined aspects of mortality and found the causes of mortality were similar between fostered and control pups (Table 4), suggesting that different life spans were not related to agents of mortality. Human-caused sources of mortality included gunshot, foul play, poisoning, trapping, and vehicle collisions. The type of landownership where pups were killed also was similar between fostered and control pups (Table 4), suggesting equal exposure to risk on the landscape.

Discussion

The survival of captive-born red wolf pups fostered into captive and wild recipient litters was high for animals of known fate. When we considered red wolf pups with unknown fates as having perished, then the percentage of pups surviving to

Table 4.—Landownership at the den, litter size, dispersal rate, age at dispersal, distance of dispersal, causes of mortality, and landownership at death site for fostered and control red wolf (*Canis rufus*) pups, with test statistic and *P*-value.

Metric	Fostered pups	Control pups	Test statistic	*P*-value

12 months of age declined, but was still greater than 50% survival. Stoskopf (2012) surmised that 30–35% survival to maturity among a cross-fostered litter was a positive contribution to a population. Most individuals fostered from captivity into wild red wolf litters were known to have survived past weaning, remained with their surrogate pack, and several demonstrated movement and dispersal behaviors comparable to wild-born red wolves. For example, following dispersal from her natal home range, 1 fostered female red wolf died at 23 months of age from complications associated with pregnancy. This individual's fostered male sibling also dispersed from his natal range and sired a litter of 8 pups.

Overall, of the fostered red wolf pups known to have survived a year in the wild, these individuals lived to an average age of 5.6 years, and several of these animals produced or sired litters in the wild as adults. The several fostered pups growing to adulthood, successfully mating, and producing wild red wolf litters indicate the utility of cross-fostering, as these individuals learned the behavioral skills necessary to survive and reproduce, thereby contributing to the red wolf population. Equally important to the recovery of any endangered species was the finding of similar survival rates among the pups in the recipient litters, further demonstrating that fostering was not deleterious to the existing wild litter that received the fostered pups.

Why the control pups had a lower life span compared to the fostered and recipient pups remains unclear. Where the pups were placed, when they dispersed, how far they dispersed, what they died from, and where they died did not appear to be factors determining the observed difference in life span between fostered and control pups. Whether the slight difference in litter size among the fostered litters translated to longer life span remains a possibility. Therefore, we concluded that while survival up to 12 months of age was similar between the cohorts, why fostered animals lived on average 2 years longer than the control animals requires further investigation.

The release of adult red wolves from the captive program to initiate new packs or supplement the wild population has had mixed success (van Manen et al. 2000; Phillips et al. 2003; Gese et al. 2015). Furthermore, acclimation to humans and human-related activates may have resulted in increased mortality risk (e.g., vehicle collision, gunshot—Hinton et al. 2017). Regardless of the age when captive-born individuals were introduced into a wild population, mortality risks were unavoidable for free-ranging animals. Introducing pups from captivity into wild red wolf litters can provide fostered individuals the benefit of learning survival and social skills from wild parents and other pack members, can be used as replacements for hybrid (red wolf-coyote) litters, and can augment population size in the recovery area and potentially facilitate increased genetic diversity in an inbred population. The recovery program also successfully fostered a litter of pups from one wild litter following the death of the breeding female into another wild litter, thereby keeping that litter alive and integrated into the wild population.

Kitchen and Knowlton (2006) recommended cross-fostered coyote pups be placed in recipient litters as young as possible (< 1 week) to facilitate acceptance by the pack. In our study, the pups that did not survive to 5 months were not older than 9 days, nor was the age difference between the fostered pups and the recipient litter pups more than 9 days. Conversely, we recorded a 16-day-old pup was successfully accepted into a captive recipient litter and an 18-day-old pup was successfully accepted into a wild recipient litter. The fostering success of pups older than a week but younger than 3 weeks suggests that the age of fostering is more plastic than previously thought. We did not attempt cross-fostering with pups older than 18 days, so we were not able to assess the oldest day at which fostering could be successful. However, Kitchen and Knowlton (2006) reported that fostered coyote pups > 6 weeks old did not survive in their recipient litter.

Stoskopf (2012) made several recommendations to reduce den disturbance (e.g., scent transfer, timing insertions when adults are away from the den, minimizing the number of personnel involved on-site) and thereby increase the success of fostering pups into wild litters. We further recommend the fostered pups be well fed (i.e., bottle fed) before insertion as they cry when hungry and could potentially attract predators while the recipient female is away from the den. We also recommend minimizing the time spent at the den to avoid overly disturbing the parents and risk abandonment of the litter, and consider the weather conditions at the time of fostering (e.g., dry conditions if the pups are in a day bed exposed to the elements, rather than in an excavated den). To ensure success and survival of cross-fostered pups, we recommend that pups be fostered between the ages of 4 to 21 days (but urge using pups < 14 days old, if possible), and that fostered pups be of similar age to the recipient litter (Kitchen and Knowlton 2006; Stoskopf 2012). The similar survival rates among the fostered pups that varied in age relative to the recipient litter, or had no competition from a recipient litter, indicated there was no competitive advantage when the fostered pups were similar in age or older. However, the numbers of litters were small, thereby inference was limited, and future investigations among other canid species are warranted.

We concluded that cross-fostering was successful at augmenting litter size for red wolves without any deleterious effects on recipient litters, illustrating cross-fostering as a potential management tool for increasing populations of other endangered carnivores. Most research on cross-fostering of canid species has been limited to small sample sizes or anecdotal records, although fostering in African wild dogs (McNutt et al. 2008), coyotes (Kitchen and Knowlton 2006), and gray wolves (Schultz et al. 2007; Jansson et al. 2015; Scharis and Amundin 2015) has advanced our understanding of the factors required for successful cross-fostering within these canid species. We demonstrated that cross-fostering red wolf pups was an effective rearing technique that has assisted captive and wild population management and could complement other management strategies (Stoskopf et al. 2005; Gese et al. 2015; Gese and Terletzky 2015) when supplementing endangered canid populations is required. Cross-fostering pups also could provide a simple process for maintaining genetic diversity of both captive and wild populations where units are disjunct from one another.

Acknowledgments

This paper is dedicated in the memory of CFL: our friend, colleague, biologist, and champion for red wolves. Funding, capture protocols, and permitting for all field aspects and data collection were under the auspices of the U.S. Fish and Wildlife Service. Additional support for data analysis and manuscript preparation provided by Point Defiance Zoo and Aquarium, Tacoma, Washington, and the U.S. Department of Agriculture, Wildlife Services, National Wildlife Research Center, Logan Field Station, Logan, Utah. We gratefully acknowledge all of the U.S. Fish and Wildlife Service personnel associated with the red wolf recovery effort for their diligence in documenting their efforts, locating the animals, and providing access to their data, including A. Beyer, B. Fazio, R. Harrison, D. Hendry, B. Kelly, C. Lucash, F. Mauney, S. McLellan, M. Morse, R. Nordsven, D. Rabon, L. Schutte, and K. Whidbee. The authors thank K. B. Beck for field assistance. We thank members of the Red Wolf Recovery Implementation Team (K. B. Beck, T. K. Fuller, F. F. Knowlton, D. L. Murray, M. Stoskopf, L. P. Waits), and K. Goodrowe-Beck, B. B. Fazio, R. Harrison, B. T. Kelly, and D. Rabon for providing many informative discussions and insights on cross-fostering. We thank R. Harrison, E. Heske, K. Monteith, and 2 anonymous reviewers for helpful reviews of the manuscript. The findings and conclusions in this article are those of the authors and do not necessarily represent the views of the U.S. Fish and Wildlife Service.

RED WOLF (*CANIS RUFUS*) AND COYOTE (*CANIS LATRANS*) ECOLOGY AND INTERACTIONS IN NORTHEASTERN NORTH CAROLINA

by

JOSEPH WILLIAM HINTON

(Under the Direction of Michael J. Chamberlain)

ABSTRACT

In recent decades, red wolf (*Canis rufus*) hybridization with coyotes (*Canis latrans*) has posed a serious threat to red wolf recovery efforts. Preventing hybridization has become a primary objective requiring intensive management efforts to prevent introgression. As the red wolf population increases, long-term recovery requires general understanding of red wolf and coyote ecology to develop appropriate management strategies for addressing hybridization. The primary objective of this study was to understand the underlying mechanisms that influence red wolf and coyote interactions by examining morphology, diet, and spatial ecology of both species. We examined external morphological characters of red wolves, coyotes, and their hybrids to determine if morphology could be an accurate discriminator among the 3 canid taxa. Using hind foot length, weight, width of head, and tail length, we were able to correctly identify 86% of canids to their *a priori* species groups as identified via genetic analysis. We also assessed factors affecting prey selection of red wolf packs, coyote pairs, and congeneric pairs of red wolves and coyotes and found that all three had similar and overlapping diets. Nevertheless, we detected differential use of prey; difference in diet was associated with body size. Larger individuals within and among different breeding pairs consumed more white-tailed deer, and less rabbits and small mammals. We observed red wolf and coyote preferences for agricultural habitats over forested habitats and space use patterns to be influenced by body size. Coyote home-ranges had an upper limit of approximately 50 km^2, whereas an upper limit for red wolves was

approximately 180 km^2. Home-ranges of congeneric pairs did not exceed 50 km^2 and we suggest the smaller coyote may constrain and limit space use patterns of congeneric pairs. We suggest that similarities in body size of individual red wolves and coyotes may contribute to successful congeneric pairing and hybridization via similar use of space, habitat, and prey. Therefore, lowering hybridization rates between red wolves and coyotes may require increasing the average body size of the red wolf population to facilitate differential use of limiting resources.

DEDICATION

Dedications are often only offerings from interested baseness to disdainful vanity. – Voltaire in *Dictionnaire Philosophique*

ACKNOWLEDGEMENTS

I am grateful to my advisor, Dr. Michael Chamberlain, for his guidance and support throughout my work. I am also indebted to Chris Lucash for his commitment, patience, and support to this project. The mentoring I received from Mike and Chris was important to temper my optimism, control my pessimism, and help me develop a more realistic approach to wildlife biology. I thank Frank van Manen for his assistance and support throughout this study. I also appreciate assistance from my committee members, John Gittleman, Nathan Nibbelink, and Doug Peterson for their insight and helpful comments on this dissertation. I owe many thanks to the members of the Red Wolf Recovery Program for their continual support and enthusiasm in this project and for the necessary funding and logistic support. Specifically, I would like to thank Rebecca Bartel, Arthur Beyer, Chris Lucash, Ford Mauney, Michael Morse, Ryan Nordsven, and David Rabon. I greatly appreciate those who extended their friendship to me. I'm also indebted to my wife, Jessica, and my family for their unconditional love and support.

CHAPTER 1

INTRODUCTION AND LITERATURE REVIEW

In recent decades, red wolf (*Canis rufus*) hybridization with coyotes (*Canis latrans*) has become a serious threat to red wolf recovery efforts. During the 1970s, the last remaining red wolves were removed from the wild because the last remnant population began hybridizing with an expanding coyote population. Shortly after reintroducing red wolves onto Alligator River National Wildlife Refuge in northeastern North Carolina, coyotes began expanding their range throughout North Carolina. The current red wolf population co-exists with coyotes and hybridization between the two species occurs. Red Wolf Recovery Team biologists and Red Wolf Recovery Implementation Team scientists identify red wolf-coyote interactions, related resource partitioning, and prevention of coyote gene introgression into the wild red wolf gene pool as critical factors vital to long-term recovery, management, and planning (USFWS 2007). Therefore, preventing hybridization has become a primary management goal (Kelly *et al*. 1999; Stoskopf *et al.* 2005; Rabon *et al.* 2013).

To prevent coyote introgression into the red wolf population, coyotes captured by United States Fish and Wildlife Service (USFWS) personnel within the Red Wolf Recovery Area (Recovery Area) are reproductively sterilized and used as space holders until red wolves move in and occupy those areas. This tactic provides a reproductive advantage to red wolves by reducing coyote reproduction within the Recovery Area (USFWS 2007; Stoskopf *et al*. 2005). More importantly, in the event that a red wolf forms a breeding pair with a sterilized coyote, this prevents introgression because the pair is incapable of successfully breeding. Despite intensive management efforts, red wolf/coyote hybrids are still captured within the Recovery Area indicating that canid management is not ubiquitous. To achieve long-term recovery of red wolves, it is imperative that the Red Wolf Recovery Program improves its general knowledge of red wolf

and coyote ecology to understand mechanisms facilitating red wolf-coyote hybridization. The primary objective of this research is to understand the underlying mechanisms that influence red wolf and coyote interactions in northeastern North Carolina by examining red wolf and coyote morphology, diet, and spatial ecology. Currently, a full understanding of red wolf ecology is lacking, which is fundamental to ensuring recovery and persistence of the species. Furthermore, most research conducted on coyotes has been done in the western United States and Canada and the few studies on coyote behavior in the southeastern United States have been conducted at small scales (Holzman *et al*. 1992; Chamberlain *et al*. 2000; Constible *et al*. 2006).

Among phylogenetically related species that coexist, body size is the most distinguishing feature among those animals (LaBarbera 1989). Within canid communities, competition is strongly asymmetrical with larger species displacing smaller competitors (Paquet 1992; White *et al*. 1994; Arjo and Pletscher 1999; Constible *et al*. 2006; Berger and Gese 2007). Red wolves and coyotes exhibit morphological and niche overlaps, in which red wolves are the larger species. Although competition for space and food resources is common among coexisting species with similar body sizes and ecological needs, competition between red wolves and coyotes extends beyond space and food because both species can use each other as a resource for reproduction when within-species mating opportunities are exhausted. As a result, interactions between the two species are complex because the outcome of red wolf-coyote interactions can range from lethal antagonism to congeneric pair-bonding resulting in hybridization. The functional significance of body size within these interactions remains unclear and the relationship between hybridization and body size is worth examination.

In this dissertation, I propose to examine the influence of body size on red wolf and coyote space and resource use, habitat selection, and interactions. Space use is thought to reflect the ecological requirements of a species and body size is known to have pervasive influence on spatial ecology through consumer-resource interactions (Yodzis and Innes 1992; Basset and DeAngelis 2007). It has been demonstrated that home range sizes of carnivores scales

allometrically with individual body size (McNabb 1963; Gittleman and Harvey 1982; Mace and Harvey 1983; Swihart *et al*. 1988) in which larger carnivores have larger home ranges relative to smaller carnivores because larger home ranges provide more food resources for greater energetic demands. Additionally, there is a positive relationship between body size and prey size among carnivores (Gittleman 1985; Radloff and Du Toit 2004). Differing in body size, red wolves (20-38kg) and coyotes (11-18kg) in northeastern North Carolina should have differential energy requirements and different capacities for searching for and processing food resources. This difference in body size may be the primary trait that promotes differential use of space, resources, and habitat between the two species. Therefore, it is likely that selection forces may act on morphological variation in which body size differences create niche partitioning and reduce competitive interactions between red wolves and coyotes.

If body size drives the outcome of competitive interactions between red wolves and coyotes, it is plausible to hypothesize that size may influence the rates of hybridization between the two species. Coyotes are capable of consorting with red wolves that result in the successful formation of congeneric breeding-pairs that are maintained for several years. The over-arching goal of this project is to understand the conditions that facilitate red wolf-coyote hybridization. Red wolf-coyote interactions indicate that both populations in northeastern North Carolina may be limited by the availability of mates and not space and food resources in which congeneric pair-bonding demonstrates weak reproductive barriers between red wolves and coyotes. In the same manner that body size may influence resource partitioning between red wolves and coyotes through differential use of resources, body size may influence reproductive partitioning through assortative mating (Pfennig and Pfennig 2010; Schemske 2010).

If red wolf and coyote mate selection is non-random, there should be a pattern of behavior in which individuals preferentially mate with certain members of the opposite sex. Benefits derived by choosing certain mates rather than others can be difficult to quantify because those benefits can be subtle (Halliday 1983). Successful production of offspring doesn't appear to

influence partner fidelity because sterilized coyotes are capable of maintaining pair-bonds with other coyotes and red wolves for multiple years (USFWS, unpublished data). However, red wolf and coyote mate choice and continued fidelity may result from behavioral mechanisms that result in similar use of space, habitat, and prey in order for both individuals to complement one another. In other words, differences in ecological requirements may serve as barrier to conspecific pair-bonding between red wolves and coyotes. If this hypothesis is correct, body size may create reproductive partitioning, along with resource partitioning, between red wolves and coyotes. For example, if coyotes have a much lower ceiling for home-range sizes then red wolves because of lower energy demands associated with smaller body sizes, then red wolves that exceed those spatial demands are likely to be reproductively isolated from the coyote population. The differences in space use and resource demands will not allow for successful maintenance of monogamous breeding pairs. However, red wolves that are below that ceiling are susceptible to consorting and breeding with coyotes because they can complement the spatial and resource needs of their coyote mates. Therefore, morphological traits, such as body size, that promote dissimilarity in space use and resource needs may create reproductive barriers between red wolves and coyotes.

Chapter 2 summarizes the history of red wolf recovery efforts, provides a synopsis of challenges to red wolf restoration, and suggests future research needed for to pursue full recovery of red wolves.

Chapter 3 examines external morphological characters of red wolves, coyotes, and their hybrids to determine if morphology could be an accurate discriminator among the 3 canid taxa. This would allow us to verify if red wolves and coyotes differed in morphology. To accomplish this we collected mean body measurements from 171 red wolves, 134 coyotes, and 47 hybrids for identifying canid taxa in the wild. We then used polytomous logistic regression analysis of 7 morphometric variables to allocate canids to their *a priori* species groups predetermined via genetic analysis.

Chapter 4 assesses factors affecting prey selection of red wolf packs, coyote pairs, and congeneric pairs. To accomplish this, my team and I collected and analyzed the prey remains in 1754 scats from 13 red wolf packs, 17 coyote pairs, and 8 congeneric pairs. We used several variables (i.e., body weight, social structure, age, etc.) that have not been traditionally used in analyses of scat remains to account for variation in diet. Furthermore, this study is the first to assess dietary behaviors of congeneric canid breeding units that are the source of hybridization. Additionally, this study represents the most comprehensive assessment of canid diet in the eastern United States.

Chapters 6 and 7 assess space use and habitat selection of red wolves and coyotes. Accomplishing this objective required capturing and fitting global positioning system (GPS) radio-collars to red wolves and coyotes. This permitted us to monitor resident and transient animals and assess ways in which both species move, interact, and use several primary habitats in northeastern North Carolina. This study represented the 1st broad scale study (> 5000 km^2) of coyote space use and habitat selection in the southeastern United States. We also provide for the 1st assessment of body weight influence on coyote and red wolf home-range size.

Finally, Chapter 8 examines whether body size is a reproductive barrier between red wolves and coyotes. To accomplish this, we used linear regression to evaluate the influence of body weight on ecological parameters such as home-range size and diet composition. Observed patterns are then used to discuss the effects of energetics on red wolf and coyote hybridization.

CHAPTER 2

RED WOLF (*CANIS RUFUS*) RECOVERY: A REVIEW WITH SUGGESTIONS FOR FUTURE RESEARCH

Hinton, J.W., M.J. Chamberlain, and D.R. Rabon. 2013. *Animals*. 3: 722-744.

Abstract

By the 1970s, government-supported eradication campaigns reduced red wolves to a remnant population of less than 100 individuals on the southern border of Texas and Louisiana. Restoration efforts in the region were deemed unpromising because of predator-control programs and hybridization with coyotes. The U.S. Fish and Wildlife Service (USFWS) removed the last remaining red wolves from the wild and placed them in a captive-breeding program. In 1980, the USFWS declared red wolves extinct in the wild. During 1987, the USFWS, through the Red Wolf Recovery Program, reintroduced red wolves into northeastern North Carolina. Although restoration efforts have established a population of approximately 70-80 red wolves in the wild, issues of hybridization with coyotes, inbreeding, and human-caused mortality continue to hamper red wolf recovery. We explore these three challenges and, within each challenge, we illustrate how research can be used to resolve problems associated with red wolf-coyote interactions, effects of inbreeding, and demographic responses to human-caused mortality. We hope this illustrates the utility of research to advance restoration of red wolves.

Introduction

Perceived threats to human enterprise have historically motivated efforts to exterminate large carnivores such as wolves, bears, and lions. In particular, wolves have been extirpated from much of their historical ranges in North America by government-supported eradication campaigns protecting agricultural and livestock interests. However, changes in American societal beliefs have resulted in profound changes to how wolves are perceived. The passage of the Endangered Species Act of 1973 (ESA) paved the way for restoration of wolf populations that were severely reduced or extirpated during the 19th and early 20th centuries. When the ESA was legislated, gray wolves (*Canis lupus*) and red wolves (*Canis rufus*) existed as declining remnant populations in the contiguous United States. Although gray wolf populations in Alaska and Canada were stable and the species was not threatened with extinction, red wolves were afforded no refuge. Red wolves were likely the first New World wolf species to come in contact with

Europeans and, consequently, the first to be persecuted. Prior to European colonization, red wolves were common in the eastern United States and they inhabited an area from the Atlantic coast west to central Texas, with the Ohio River Valley, northern Pennsylvania, and southern New York being its northernmost range and their distribution extending south to the Gulf of Mexico (Figure 1; Nowak 2002, 2003). At the turn of the 20th century, red wolves were extirpated throughout most of their range and approximately 100 individuals occupied coastal habitats of eastern Texas and western Louisiana (McCarley 1959, 1962). Declining because of aggressive predator-control programs and surrounded by an expanding coyote (*Canis latrans*) population, red wolves were incapable of maintaining self-sustaining populations. They began hybridizing with coyotes when they were unable to find conspecific mates and canid populations in the region gradually became genetically admixed (McCarley 1959; Paradiso and Nowak 1972; Carley 1975). This generated concerns that the last remaining red wolves would be genetically assimilated into the coyote genome through hybridization, so the southeast Texas and southwest Louisiana populations were targeted for restoration efforts (Carley 1975).

After the passage of the ESA, the United States Fish & Wildlife Services (USFWS) established the Red Wolf Recovery Program (Recovery Program) with the task of locating and preserving populations of red wolves in southeast Texas and southwest Louisiana (USFWS 1989). However, with rapidly declining red wolf populations and extensive hybridization, the USFWS decided to remove the last red wolves from the wild and place them in captivity. The Recovery Program's objectives soon changed to capture as many red wolves as possible for propagation in captivity, and to re-establish red wolf populations within the species' historic range in the near future (USFWS 1989). To find pure red wolves for the captive-breeding program, the Recovery Program captured as many wild red wolf-like canids as possible in southeast Texas and southwest Louisiana. From 1973 through 1980, approximately 400 canids were captured and 43 met the morphological standards to be considered red wolves. Breeding experiments were then conducted with those 43 individuals and, eventually, 14 individuals met the criteria established to

define the species. These individuals were used as the founders to begin the captive-breeding program (USFWS 1989). The red wolf was declared extinct in the wild in 1980, becoming the first species to be purposely extirpated in the wild to save it from extinction.

The captive-breeding program safeguarded the last remaining red wolves and served as the last repository of the red wolf genome. The primary objectives of the captive-breeding program were to certify the genetic purity of wild-caught red wolves, increase the number of red wolves in captivity, and maintain a captive red wolf population for re-establishment of the species in the wild (USFWS 1989). Red wolves readily reproduced in captivity with the first captive-born litters produced during 1977. Early efforts in the captive-breeding program then focused on developing procedures and protocols to ship, handle, and breed red wolves within a network of zoo facilities (Carley 2000). To maintain integrity within the captive-breeding program, the USFWS developed a Species Survival Plan® (SSP) that was accepted by the Association of Zoos & Aquariums (AZA; USFWS 1989). This ensured that the species would be preserved in captivity until a strategy was developed for reintroducing red wolves in the wild. To acclimate captive red wolves to wild conditions, the Recovery Program began conducting experimental releases of captive-born red wolves on island propagation sites such as Bulls Island of the Cape Romain National Wildlife Refuge in South Carolina. Bulls Island became one of three island propagation sites that allowed the Recovery Program to develop restoration techniques.

During 1984, Alligator River National Wildlife Refuge (ARNWR) was established on the Albemarle Peninsula of northeastern North Carolina (NENC) when the Prudential Insurance Company donated approximately 480 km² (48,000 ha) of land to the federal government (USFWS 1989). This area was identified as the future reintroduction site for red wolves because the refuge contained suitable prey for red wolves, coyotes were absent on the landscape, no livestock were present, and the presence of humans was low. In 1987, the USFWS released eight captive-born red wolves (four male-female pairs) onto ARNWR to begin reintroduction efforts. Initially, mortality rates were high as captive-born wolves were hit by cars, drowned, succumbed

to disease, or were attracted to townships (Phillips et al. 2003). As a result, early attempts to established red wolves on ARNWR were aggressive and resulted in the release of more than 60 red wolves from 1987 through 1994 (Phillips et al. 2003). Eventually, the NENC population transitioned from captive-born individuals to wild-born individuals and the release of captive-born adult wolves to augment the NENC population ceased. Currently, almost all red wolves in NENC are wild born. Periodically, island-born juveniles and captive-born pups fostered into wild litters are used to maintain genetic diversity and health of the wild population. By the mid-1990s, red wolves in the wild formed packs, maintained territories, and successfully bred, and the reintroduction marked the first successful reintroduction of a wolf species. It also marked the first successful attempt to reintroduce a large predator that was completely extirpated from the wild.

The USFWS initiated a second reintroduction in the Great Smoky Mountains National Park (GSMNP) of the southern Appalachians (USFWS 1990). During 1991, the initial stage of the GSMNP reintroduction was implemented to gather information on interactions of red wolves and coyotes, livestock, and humans (Lucash et al. 1998). Initial efforts appeared successful when a mated adult pair and two pups established a territory in Cades Cove of the GSMNP, so the USFWS proceeded with a full-scale reintroduction. However, most of the 37 red wolves released were unable to establish and maintain territories within the park boundaries and left for better habitat on surrounding lower-elevation agricultural land (Henry 1998). Additionally, red wolves that maintained territories on GSMNP had low pup survival as a result of Parvovirus, malnutrition, and parasites (Henry 1998). After repeated introduction attempts and low pup survival, it was determined that the red wolf population on GSMNP would have to be perpetually managed within the park and the GSMNP red wolf reintroduction was terminated in 1998. Red wolves that remained in the park were subsequently captured and relocated to ARNWR.

Although nearly 25 years have elapsed since red wolves were reintroduced into the wild, more than half of the red wolf population still exists in captivity. The captive-breeding program safeguards approximately 200 red wolves in more than 40 captive facilities around the United

States while the reintroduced red wolf population has expanded throughout the Albemarle Peninsula to about 70-80 animals in approximately 15 packs (USFWS 2013). Since 1987, the Recovery Area has expanded to accommodate the growing population from approximately 480 km^2 to approximately 6800 km^2 of federal, state, and private lands (Figure 2). Although red wolf restoration has experienced success in many ways, efforts to maintain the NENC population and to find future reintroduction sites continually face challenges. For instance, the red wolf species continues to be plagued by taxonomic controversy regarding its origin and arguments against the systematic validity of the red wolf have been used to oppose red wolf restoration (Phillips and Henry 1992; Nowak and Federoff 1998). Red wolves still remain a remnant population and experience a series of ecological threats such as hybridization with coyotes and inbreeding (Kelly et al. 1999; Stoskopf et al. 2005; USFWS 2007). Without management of coyotes in the Recovery Area, it is likely that the red wolf population would be genetically assimilated into the eastern coyote population (Kelly et al. 1999). Additionally, the small number of red wolves makes the population in NENC susceptible to genetic drift and inbreeding depression (Rabon and Waddell 2010). To prevent inbreeding and maintain genetic diversity in the wild population, captive-born and island-born individuals are periodically released into the Recovery Area. Additionally, quixotic fervor within the hunting community to suppress predators continues to hamper red wolf population growth in NENC. Increased mortality by gunshot during the hunting season has reduced the number of red wolf packs, lowered red wolf survival, and has facilitated coyote expansion into the Recovery Area (USFWS 2007).

In the progress of overcoming these challenges to restoring red wolves to the wild, there is a need to consolidate knowledge and contemplate those experiences as recovery efforts move forward. Therefore, our objective is to provide a synopsis of the challenges to restoration of the red wolf and suggest future research needed to pursue full recovery of the species.

Red Wolf Taxonomy

Currently, scientists find themselves in a contentious debate regarding the taxonomy of New World wolves and its implications on the evolution, ecology, and conservation of *Canis* species in eastern North America (Chambers et al. 2012). The origin of the red wolf is central to this debate (Nowak 1979, 2002; Wayne and Jenks 1991; Wilson et al. 2000). Although scientific synthesis has led to new insights into the evolution and ecology of New World wolves, massive loss of historic and geographic genetic data and recent genetic introgression by coyotes continues to hinder consensus on red wolf origin (Chambers et al. 2012). Despite significant voids in data to adequately characterize the historic red wolf populations in the Southeast, limited and anecdotal data does exist to indicate the existence of a large canid in the southeastern United States.

The unique presence of a southeastern wolf was noted during the 18th century (Bartram 1791; Harper 1942; Nowak 1992) and, by 1851, the red wolf was given a valid scientific name (Audubon and Bachman 1851). During the turn of the 20th century, several authors recognized structural differences between gray and red wolves and initiated revisions of the red wolf's taxonomic status (Bangs 1898; Baily 1905; Miller 1912). Eventually, Goldman (1937, 1944) described red wolves as distinct from gray wolves and coyotes based on cranial and dental characters and consigned all wolves of the Southeast to one species, *C. rufus*. By the 1960s, federal and state agencies generally assumed that viable populations of red wolves existed in the Southeast despite a great deal of confusion about the species status. McCarley's (1962) taxonomic study of red wolves concluded that red wolves had been replaced by coyotes and red wolf/coyote hybrids in most areas of eastern Texas, Arkansas, Louisiana, and Oklahoma. His work indicated that a few red wolf populations still existed in parts of Louisiana. After examining a number of *Canis* specimens from the Southeast, Paradiso (1965, 1968) and Pimlott and Joslin (1968) confirmed McCarley's (1962) findings and brought attention to what were believed to be the last surviving red wolf populations on the Gulf Coast in southeast Texas and southwest Louisiana (Carley 2000).

Nowak (Nowak 1979, 2002) investigated the taxonomy of *Canis* species of eastern North America using discriminant function analysis to evaluate the characteristics of modern and paleontological *Canis* skulls (Nowak 1979, 2002) and dentition (Nowak 2002). In doing so, he was able to differentiate gray wolves, red wolves, coyotes, and domestic dogs (*Canis familiaris*) into separate groups and postulated that red wolves evolved from a transitional form (i.e., *Canis mosbachensis*) between a wolf-like coyote ancestor and the gray wolf. Nowak (1979) found no evidence that gray wolves existed in the southeastern United States. Despite widespread occurrence of domestic dog in the Southeast, Nowak (1979) found no evidence of introgression from domestic dogs into the red wolf and coyote populations. The earliest red wolf specimens showed no statistical overlap with gray wolves, coyotes, or domestic dogs and had similar multivariate distribution as the red wolf specimens from the Pleistocene era. Specimens collected before 1930 indicated hybridization between red wolves and coyotes was uncommon where their ranges approached. However, specimens from the 1930s until the 1950s indicated hybridization with coyotes was occurring over large areas of the red wolf's southern range where coyotes were replacing red wolves. Nowak (1979, 2002) suggested that hybridization between red wolves and coyotes began at the turn of the 20th century when anthropogenic factors destroyed ecological and behavioral isolation. Despite coyote introgression into the red wolf genome during the 20th century, Nowak (2002) reported that the morphology of modern red wolves is predominately like *C. rufus* that persisted in the eastern United States 10,000 years ago.

Although it had been suggested that red wolves were the result of coyote and gray wolf hybridization (Mech 1970), the hypothesis of a hybrid origin did not receive much attention until applied molecular techniques became the primary means of evaluating red wolf taxonomy. Analyzing mitochondrial DNA (mtDNA), Wayne and Jenks (1991) evaluated the genetic integrity of red wolves in the captive-breeding program and reported no unique genetic markers in red wolves that were distinct from gray wolves and coyotes. Therefore, they concluded that the red wolf is a hybrid form derived from gray wolves and coyotes. Similar conclusions were

reached by a series of genetic papers examining red wolf mtDNA and nuclear DNA (nDNA) that accepted the premise that red wolves originated from hybridization events occurring between 250 to 13,000 years ago (Roy et al. 1996; Reich et al. 1999; vonHoldt et al. 2011). However, these conclusions have been contested in morphological (Nowak and Federoff 1996; Nowak 2002, 2003) and molecular (Bertorelle and Excoffier 1998; Wilson et al. 2000; Hedrick et al. 2002; Adams et al. 2003; Wilson et al. 2003; Kyle et al. 2006; Hailer et al. 2008; Chambers et al. 2012; Rutledge et al. 2012) studies.

Examining the origin and taxonomy of wolves in eastern Canada, Wilson et al. (2000, 2003) reported that captive red wolves and eastern wolves (*Canis lycaon*) have mtDNA control sequences more closely related with coyotes, while exhibiting unique haplotypes not found in gray wolves and coyotes. Although these mtDNA sequences don't occur in western coyotes, they cluster among western coyote populations and Wilson et al. (2000) attributed this as evidence that red wolves, eastern wolves, and coyotes share a recent common ancestor in the New World independent of gray wolves. Other studies have supported these conclusions (Wilson et al. 2003; Wheeldon et al. 2010; Chambers et al. 2012) and these results appear to reconcile early observations that red wolves and coyotes approached one another in morphology (Nowak 1979; Goldman 1937). Although the results of these studies indicate that red wolves are not of hybrid origin, Wilson et al. 2000 proposed that the red wolf and eastern wolf are genetically close enough to be considered a single species under *C. lycaon*. The disagreement among these genetic studies stems in part from differing assumptions about the nature of the coyote-like mtDNA found in eastern and red wolves. Those that support a hybrid origin interpret the coyote-like mtDNA as being from coyotes, whereas those that support the hypothesis that red wolves, eastern wolves, and coyotes share a common ancestry interpret the coyote-like mtDNA as being eastern wolf in origin and a result of incomplete lineage sorting.

Significant gaps in the historic and geographic genetic data and recent hybridization makes it difficult to sort out the evolutionary history of red wolves. As a result, the taxonomy of

North American wolves is complex and not without debate. Prior to and during European colonization of the Southeast, there appears to have been a small wolf species present and its modern equivalent may be the red wolf. It is also possible that red wolves are morphologically and genetically similar to coyotes because they fall within the species limits of the coyote clade (Chambers et al. 20012). Although the door is open for future taxonomic revision, the hybrid origin of red wolves is difficult to reconcile because gray wolves have historically been absent from the southeastern United States and, until the mid-20th century, coyotes were absent from the region for over 10,000 years (Nowak 2002). Additionally, there is no evidence of ongoing hybridization between gray wolves and coyotes that are currently sympatric (Kyle et al. 2006; Wheeldon et al. 2010; Rutledge et al. 2012). Modern hybridization among *Canis* species in the East makes it difficult to sort out the evolutionary history of red wolves. Recent and developing studies demonstrate that the taxonomy of red wolves is complex and morphological and molecular studies of fossilized wolves from the southeast are essential to settling the debate over red wolf origin.

Ecological Challenges

Red Wolf and Coyote Hybridization

Red wolves and coyotes exist as a panmictic population in NENC and hybridization provides an exceptionally tough set of problems for red wolf recovery. Understanding how red wolves interact with coyotes is an important issue which could dictate the success of the reintroduction project. During 1999, the USFWS re-evaluated the red wolf recovery effort by organizing a Population and Habitat Viability Assessment workshop (PHVA; Kelly et al. 1999). Introgression of coyote genes into the red wolf population was considered the principal threat to recovery efforts when it was discovered that hybridization could render the wild red wolf population unrecognizable within several generations (Kelly et al. 2006; Stoskopf et al. 2005). As a result, priorities were identified and the PHVA called for approaches that would prevent hybridization and promote the growth of a self-sustaining population of red wolves in NENC. An

adaptive management plan (Rabon et al. 2013) was designed during the PHVA with the intent to provide the Recovery Program flexibility to modify management schemes and scientific studies as conditions and threats to red wolf recovery change.

As history has proven, coyote populations are too resilient to state and federal eradication programs and clearing the Albemarle Peninsula of coyotes poses an overwhelming challenge. Two management techniques were developed during the PHVA to prevent hybridization. Coyotes and hybrids captured by USFWS personnel within the Recovery Area are reproductively sterilized (hereafter sterilized) and used as space holders until red wolves move in and occupy those areas. Coyotes and hybrids are taken to a local veterinary clinic in which females and males are sterilized by tubal ligation and vasectomy, respectively. This process keeps the hormonal system intact and avoids disrupting breeding and territorial behavior. Sterilized animals are fitted with mortality-sensitive radio-collars, released, and monitored for the duration of their life. This allows the Recovery Program to collect relevant information on coyote space use, habitat selection, and interaction with red wolves while suppressing coyote reproduction. In the event that a red wolf pairs with a sterilized coyote, the pair cannot produce hybrid litters. Additionally, sterilized coyotes that maintain territories keep those spaces occupied and prevent fertile coyotes from establishing breeding pairs on the landscape.

As recommended during the PHVA, the Recovery Area was divided into three management zones in which management efforts varied in intensity to minimize hybridization on the landscape (Figure 2). The ultimate management goal is to ensure that all *Canis* breeding pairs within the Recovery Area are red wolves. To implement this, Recovery Program biologists began eradicating coyotes and hybrids from Zone 1 while selectively using sterilized coyotes as space holders in Zone 2. When objectives in Zone 1 were completed, management efforts shifted west to Zone 2 in which sterilized space holders were removed to create space for red wolves. Once coyotes and hybrids were removed from Zone 1 and 2, management efforts would be undertaken in Zone 3. Implementing management goals in order of priority allowed the Recovery Program to

minimize hybridization by monitoring red wolf and coyote packs throughout the Recovery Area and replacing coyotes and hybrids with red wolves when opportunities arose.

Prior to the PHVA, the Recovery Program assumed all canids captured within the Recovery Area were wolves unless animals were unusually small and coyote-like in appearance (Stoskopf et al. 2005). Once hybridization was considered the primary threat to recovery efforts, molecular techniques were developed to identify coyotes and hybrids and quantify introgression into the red wolf population. Using microsatellite markers from the 14 founding individuals and other captive red wolves to generate allele frequencies, a pedigree of the red wolf population was developed (Miller et al. 2003; Adams 2006). Animals are now blood sampled upon capture and identified as red wolves, coyotes, or hybrids using 17 microsatellite markers. As these methods were developed, a hybridization event that occurred during 1993 between a female red wolf and a male coyote was detected (Adams 2006; USFWS 2007). Individuals in the wild population considered red wolves were then correctly identified as 2^{nd} and 3^{rd} generation backcrosses from the male hybrid offspring of the 1993 hybridization event. When it was realized that removing all red wolves with introgression would essentially extirpate the wild red wolf population, the Recovery Program opted to allow wild reproduction among red wolves to slowly breed the coyote genetics out. To accelerate purging of coyote genetics, the Recovery Program selectively culled animals they thought were not red wolves. Over time, selective management of backcrosses and minimizing hybridization has been successful in limiting coyote introgression in the wild red wolf population to less than 5% in 2006 (Adams 2006) and has continue to facilitate a decrease since then (USFWS unpublished).

Scientific research is essential to understanding hybridization and the interplay between research and management offers an interesting opportunity to examine this process over the long-term. Initial scientific inquiries after the PHVA were to establish studies to measure, monitor, and manage hybridization in the Recovery Area. In doing so, a complete reconstruction of a red wolf pedigree has been established and this most likely represents the most complete database for any

wild population. It's now understood that hybridization between red wolves and coyotes is not directional in terms of the wolves' sex and hybrids backcross with both species (Adams 2006; Rabon 2009; Bohling 2011). Furthermore, current research has identified young, inexperienced red wolves with coyote ancestry to be more likely to breed with coyotes (Bohling 2011). Despite these successes in measuring and monitoring hybridization, ecological explanations for hybridization have been lacking. In other words, little quantitative information exists on mate selection and possible reproductive barriers between red wolves and coyotes (Bohling 2006; Rabon 2009), and future research efforts should focus on discovering possible reproductive isolating mechanisms that exist between red wolves and coyotes.

Hybridization between red wolves and coyotes implies the obvious break down of reproductive barriers and the two species consort and breed with one another when situations favor opportunities to mate with congenerics. Currently, no extrinsic reproductive barriers (i.e., geographic barriers) exist between red wolves and coyotes because coyotes are ubiquitous throughout the red wolf's historic range. Hybridization occurs between the two species when a red wolf and a coyote form a breeding pair that will defend a territory together until the death or displacement of a mate. Consequently, the red wolf-coyote pair will produce hybrid offspring and maintain pack dynamics similar to gray wolves (Jordan et al. 1967; Mech 1970, 1999), red wolves (Phillips et al. 2003; Hinton and Chamberlain 2010; Sparkman et al. 2011), and coyotes (Gese et al. 1996a, 1996b; Bekoff and Gese 2003). This should be expected because monogamous breeding appears to be a phylogenetic component that operates at the family level and group living is common within *Canis* (Gittleman 1989; Geffen et al. 1996). Therefore, if an isolating mechanism exists, it's most likely to be an intrinsic isolating factor (i.e., behavior) that would prevent pair formation between red wolves and coyotes. Understanding the ecology of red wolf-coyote interactions is crucial to define species traits that serve as isolating mechanisms, describe how these traits prevent hybridization, and identify what selection forces in nature favor the maintenance of red wolves and coyotes as separate species.

If intrinsic isolating factors do exist between red wolves and coyotes, then behaviors that promote sexual isolation of individual red wolves and coyotes should be associated with phenotypes that promote divergence in behavior and genetic discontinuity between the two species. Red wolves and coyotes share the same body plan but do not overlap in body size in which red wolves are the larger species (Hinton et al. In review). As a result, body size is the primary trait that distinguishes red wolves from coyotes and it most likely facilitates differential use of resources between the two species. It is well established that body size has a major effect on inter- and intraspecific interactions of mammalian carnivore species in which competitive interactions are strongly asymmetrical with larger species displacing smaller competitors (Rosenzweig 1966, 1968; Gittleman 1985; Palomares and Caro 1999). Furthermore, body size is a key predictor of life history traits, population growth rates, density, space use, and predator-prey dynamics (Huxley 1936; McNab 1963; Gittleman 1985; Brown and Nicoletto 1991; Brown et al. 2004; White et al. 2007). It is logical that red wolves and coyotes are not exempt from the broad influences that body-size allometries have at individual-, population-, and community-level processes. Understanding how body size differences lead to differences in red wolf and coyote resource demands, demographics, diet, and space use will lead to more comprehensive understanding of red wolf-coyote interactions and identify what behaviors facilitate genetic discontinuity between the two species.

Recent research has allowed the Recovery Program to measure, monitor, and manage hybridization in NENC. However, preventing hybridization using reproductive sterilization techniques is heavy handed and a short-term strategy to jump start red wolf colonization. There are other important biological considerations to be addressed and research objectives regarding hybridization should shift in the direction of studying the relationship between phenotypic traits and hybridization. For instance, when choosing a mate, do red wolves and coyotes use a criterion of mate quality as a predictor of benefits that potential mates offer and, if so, how does choosing for mate complementarity effect partner fidelity and breeding pair stability? These types of

research objectives could associate specific traits with hybridization and breeding success and, eventually, allow biologists to detect selection processes within the red wolf and eastern coyote populations. Reproductive barriers are maintained through ecological, demographic, and developmental conditions (Mayr 1941) and understanding how sexual isolation operates is crucial to the restoration of red wolves.

Inbreeding Effects

Inbreeding can increase the risk of extinction for small populations by decreasing reproductive rates and increasing susceptibility to environmental change and disease (Charlesworth and Charlesworth 1987; Crnokrak and Roff 1999; Hedrick and Kalinowski 2000; Charlesworth and Willis 2009). A primary goal of many conservation programs is to minimize inbreeding depression, the deleterious effects of inbreeding, because of the link between increased inbreeding and loss of population viability (Lande 1988; Allendorf et al. 2010; Frankham 2010). As a small population pushed to the brink of extinction, the red wolf suffered considerable loss of genetic diversity and obviating the potential effects of inbreeding depression and further loss of genetic diversity on red wolf fitness is a conservation goal (USFWS 1989). Given inbreeding depression may occur when red wolves mate with closely related kin, and as a population founded by few individuals, managing the overall relatedness of captive and wild populations poses challenges for restoration efforts.

Captive breeding of red wolves began three decades ago to preserve the species and provide demographic security. Preservation of genetic diversity in captivity requires using a red wolf Population Analysis and Breeding and Transfer Plan to select sires and dams for artificial breeding (Waddell and Long 2010). The long-term goal is to preserve 80-90% of the genetic diversity for 150 years (USFWS 1989) and, currently, the captive red wolf population has retained 89.5% of the genetic diversity that existed in the 14 founders (USFWS 2007; Waddell and Long 2010). Although heritable defects, such as progressive retinal atrophy, malocclusion, and undescended testicles, were observed in a small number of captive red wolves, early studies

that examined juvenile survival and litter size reported no observable inbreeding depression in the red wolf captive program (Kalinowski et al. 1999; USFWS 2007; Hedrick and Fredrickson 2008). Subsequent studies found increased levels of inbreeding in the captive population were correlated with decreased litter size, but overall, inbreeding depression was minimal (Rabon and Waddell 2010). Rabon and Waddell (2010) concluded that improvements in husbandry, veterinary care, and nutrition positively contribute to pup survival and offset the negative effects of inbreeding in the captive population. However, these services are not extended to red wolves in the wild and understanding the effects of inbreeding in the wild population requires further study.

Red wolves are social carnivores in which intraspecific aggression and delayed dispersal play an important role in pack dynamics. The small size of the wild population and the high level of relatedness among individuals increase the risk for incestuous mating to occur. The influence of mate choice and inbreeding avoidance behavior on population dynamics remains poorly understood. It's been shown that dispersal is an important inbreeding avoidance behavior in other canid species that results in few inbred matings (Smith et al. 1997; Jankovic et al. 2010; Geffen et al. 2011). Similarly, Sparkman et al. (2012) found few instances of breeding between 1st degree relatives in wild red wolves and concluded that dispersal behaviors reduced the risk of inbreeding. Red wolf behaviors associated with inbreeding avoidance suggest that inbreeding has a negative effect on fitness and may influence population dynamics.

Inbreeding levels of wild red wolf populations may be high and the effect of inbreeding avoidance on hybridization with coyotes remains unknown. Inbreeding avoidance may cause red wolves to outbreed with a closely related species, such as coyotes, when inbreeding leads to severe fitness consequences. During the mid-2000s, Recovery Program biologists observed dispersing red wolves passing through territories of potentially available red wolf mates and pair-bonding with coyotes. They speculated inbreeding avoidance may influence red wolf mate choice and facilitate hybridization. The premise behind this observation is a hypothesis that assumes when red wolves cannot locate red wolf mates unrelated to them they will opt to breed with

unrelated coyotes to avoid incest (Beyer and Lucash personal communication). Therefore, understanding how inbreeding depression influences hybridization between red wolves and coyotes has become a concern for managing the wild red wolf population.

Research on the effects of inbreeding should involve both ecological and genetic analyses to investigate red wolf and coyote pair formation and how inbreeding avoidance influences hybridization and red wolf fitness. One particular area of promise is sequencing major histocompatibility complex (MHC) genes to examine red wolf kin recognition and mate choice. MHC genes were originally identified in inbred mice during skin graft experiments in which MHC molecules of the host recognized graft tissue as foreign antigens and attacked them (Snell and Higgins 1951). Since then, MHC genes have been discovered to play a critical role in cellular immune response and correlations between MHC alleles, haplotypes, or heterozygosity and pathogen resistance have been shown for a number of species (Apanius et al 1997; Sommer 2005). Given that MHC variation affects disease resistance, there may be an advantage to avoid kin and other mates with similar MHC alleles or haplotypes (Milinski 2006; Huchard et al. 2010). Studies have found MHC-dependent mate choice in both captive and wild species where individuals preferred MHC dissimilar mates (Piertney and Oliver 2006). Cooperative group living is a primary adaptive characteristic of red wolves and individuals are likely to recognize kin. How MHC variation influences kin recognition and, subsequently, inbreeding avoidance and hybridization in red wolves is unknown. Red wolves are known to have fewer MHC alleles than other wild canid populations (Hedrick et al. 2002) and future research should evaluate how MHC variation may influence mate selection, and hybridization.

Red Wolf Demographics

It's well established that variation in survival and reproduction are responsible for the dynamics of populations (Leslie 1945; Ginzburg 1986; Gotelli 2001; Watts et al. 2009; Stahler et al. 2013). Accurate estimates of survival and reproductive rates are essential for conservation programs to minimize extinction risks and promote conditions enhancing the persistence of small,

vulnerable populations (Willams et al. 2002; Norris 2004). Population viability analysis (PVA) has traditionally been used to project population trajectories into the future based on ecological and demographic parameters (Akçakaya 2000a, 2000b). The red wolf population currently exists as a small, vulnerable population with a high risk of extinction to demographic and environmental stochasticity. Understanding how the red wolf population is expected to change in response to environmental conditions is dependent on accurate estimates of vital rates and realistic population estimates from quantitative models.

A primary goal of red wolf recovery is to establish and maintain a red wolf population of 220 individuals in three disjunct populations within the species' historical range (USFWS 1989). To evaluate the red wolf population and its viability in the presence of a ubiquitous coyote population, a PVA model was developed at the PHVA to predict population trends and the effect of hybridization on red wolf persistence (Kelly et al. 1999). The 1999 PVA predicted that red wolves would increase 20% each year for about 10 years before reaching a carrying capacity limit of 140 individuals. Low mortality for wild wolves was assumed to drive the rate of population growth and, despite not reaching 220 individuals, no immediate risk of extinction was suspected given this scenario. When hybridization was incorporated into the 1999 PVA, increased loss of female red wolf breeders to coyote encroachment was predicted to suppress reproductive rates of red wolves to a level too low to offset natural and human-mediated mortality. Therefore, increasing levels of hybridization increases the risk of extinction not only through red wolf assimilation into the coyote population but, also through an inability to replace red wolves lost to mortality.

The 2007 5-year status review (hereafter 2007 Review) of red wolves indicated the NENC population had fluctuated between 80-130 individuals per year since 1999 (USFWS 2007). With an estimated carrying capacity (*K*) of 140 individuals that was reached in 2001, it was assumed that the red wolf population would continue to expand in subsequent years because red wolves occupied approximately 60% or less of the Albermarle Peninsula land area (USFWS

2007). However, the red wolf population did not expand but, rather, gradually declined to approximately 100 individuals since peaking in 2001 (see Red Wolf Recovery Program Quarterly Reports). Preliminary analysis of red wolf demographics from 1999 until 2007 indicated overall annual red wolf survival rate was 78.2% and anthropogenic sources of mortality (e.g. gunshots, trapping, and vehicle strikes) accounted for 58% of red wolf deaths (USFWS 2007). The 2007 Review reported the high proportion of red wolf deaths by anthropogenic factors was additive to other mortality sources and that red wolf fatalities resulting from gunshots remains the most problematic to red wolf persistence.

Red wolves were seven times more likely to be killed during the North Carolina white-tailed deer (*Odocoileus virginianus*) hunting season (October 15 – December 15) than during the non-hunting season (USFWS 2007; Bohling 2011). Illegal take of red wolves is believed to hamper red wolf population growth because it disrupts natural behavioral dynamics that effect demographic processes (Packer et al. 2009; Rutledge et al. 2012b). Furthermore, reduction of red wolves increases coyote presence in the Recovery Area by breaking up packs and destabilizing social dynamics, which reduces the red wolf's ability to hold and defend territories against coyotes. The breeding season for red wolves occurs during white-tailed deer and American black bear (*Ursus americanus*) hunting seasons and increased mortality rates during this time forces red wolf breeders to quickly replace lost mates. When red wolves lost mates to gunshots during the hunting seasons they were more likely to pair with coyotes or fail to replace their mates than to pair with red wolves (USFWS 2007). Evaluating the breeding records and individual histories of red wolves involved in hybridization events, Bohling (2011) found most hybridization events occurred after red wolves lost mates to gunshots and suggested that social structure and stability play a critical role in preventing hybridization. Similarly, Rutledge et al. (2012b) found intense harvest of eastern wolves around Algonquin Provincial Park (APP) during the 1960s to have exacerbated hybridization with coyotes. Therefore, it is prudent for red wolf conservation that managers better understand how high mortality caused by illegal killing of red wolves during the

hunting season may disrupt social structures, influence population dynamics, and promote hybridization with coyotes.

The PHVA warned that human-caused mortality that is additive would facilitate hybridization and increase the risk of extinction for red wolves. Therefore, research on red wolf demographics should focus on elucidating mechanisms that influence persistence of wolves on the landscape. This requires use of the Recovery Program's long-term monitoring data of the NENC red wolf population. Long-term monitoring involves annual trapping of red wolves during the fall to radio-tag juvenile and adult red wolves and inspection of dens during the spring to count and transponder pups (Rabon et al. 2013). These efforts allow the Recovery Program to identify individual red wolves at birth and monitor them until death to collect baseline data on survival and reproduction. Demographic parameters such as survival and population size can be estimated from capture-recapture data (Nichols et al. 1994; Burnham et al. 1995; Ivan et al. 2013) and research efforts should incorporate red wolf monitoring data to develop accurate parameters. Research objectives should estimate annual rates of population change and age-specific survival and reproductive rates of the red wolf population. Additionally, effects of natural and anthropogenic sources of mortality on red wolf persistence should be examined to understand how environmental conditions affect population dynamics over the short- and long-term. This type of research would provide accurate estimates of population parameters for PVAs and assist in developing a valuable framework to evaluate important ecological questions related to red wolf population dynamics.

Conclusions

Created in the wake of new societal values, the Red Wolf Recovery Program was tasked by the USFWS with the responsibility of restoring red wolves within their historic range. Along the road to saving the red wolf from extinction, the Recovery Program extirpated the species from the wild to prevent its genetic assimilation into the expanding coyote population. The Recovery Program established a captive-breeding program, and despite starting with 14 founders, grew a

captive population of red wolves used for future reintroductions into the wild. During fall of 1987, the red wolf became the first carnivore completely extirpated from the wild to be successfully reintroduced back into its historic range. Today, the Recovery Program manages the only wild population of red wolves on the Albemarle Peninsula of North Carolina. However one views the merits of this effort to restore red wolves, it is a story with challenges and one worth contemplation.

Disagreements about the nature of coyote-like DNA found in red wolves have created controversy in red wolf taxonomy and conservation. The initial discovery of coyote-like haplotypes in red wolves spurred conclusions that the species originated through modern hybridization between gray wolves and coyotes (Wayne and Jenks 1991; Roy et al. 1996). As a result, academic debates during the 1990s focused on the role of modern hybridization in red wolves and its implications for red wolf conservation (Gittleman and Pimm 1991; Nowak 1992; Wayne and Gittleman 1995; Nowak and Federoff 1998). However, later research reported the coyote-like DNA found in red wolves indicated a shared ancestry with eastern wolves and coyotes, and concluded that all three species evolved in a New World canid lineage independent of gray wolves (Wilson et al. 2000; Wheeldon et al 2010; Chambers et al. 2012). Predictably, the academic debate has begun shifting towards resolving whether eastern and red wolves are conspecific (Murray and Waits 2007; Kyle et al. 2008; Wheeldon et al. 2010; Chambers et al. 2012). Taxonomy is fluid because species evolve and competing concepts over species statuses are not uncommon. In the case of the red wolf, the lack of historic and geographic specimens coupled with modern hybridization between red wolves and coyotes facilitate conflicting conclusions with regards to the species origin. Therefore, it's realistic to expect scientific debate over the taxonomic status of red wolves and, as future studies provide new information, revisions to competing hypotheses regarding species origin should be expected.

Any discussion of red wolf recovery must occur against the backdrop of current ecological and anthropogenic challenges. Although hybridization, inbreeding, and demographics

were discussed separately earlier, these three issues are intrinsically related because they are influenced by the presence and management of coyotes. Therefore, these issues are complex and controversial causing management plans to promote recovery efforts to be more difficult than planned. Prior to the mid-1990s, coyotes were rare but increasing in NENC and Recovery Program biologists anticipated eventual colonization of the Peninsula by coyotes. The use of sterilized coyotes as space holders allowed the Recovery Program to saturate the Recovery Area with territories of red wolf packs and sterile coyote pairs. During the early 2000s, most coyotes captured, sterilized, and released with radio-collars failed to establish territories or pair with a space holder. In other words, the Recovery Program effectively saturated the Peninsula with canid territories and coyotes dispersing into the Recovery Area failed to find available space or mates and eventually left. However, legislation (NCGS § 113 273) passed by the NC General Assembly allowing owners of fox pens to buy live coyotes from licensed trappers and hunt them within their fox pens (NCWRC 2013) may negatively affect these efforts by disrupting red wolf packs and sterilized coyote space holders. Fox pens are enclosures averaging 250 ha in which gray foxes (*Urocyon cinereoargenteus*), red foxes (*Vulpes vulpes*), and coyotes are hunted with hound dogs for sport in approximately 20 states (Davidson et al. 1992; Baker 1993; Lee et al. 1993). Fox pen operations create legal and illegal markets for the importation and release of coyotes for hunting opportunities, and those markets may supplement local coyote populations through accidental or intentional releases of coyotes into the wild. The number of coyotes trapped in the Recovery Area increased each year after legal trafficking of live coyotes was permitted in 2003 (USFWS unpublished data). Although the number of red wolves captured and hunted in fox pens is unknown, disappearance and illegal take of red wolves has increased since the passage of the law. Increased efforts by trappers to capture coyotes and increased vigilance of deer hunters to shoot coyotes have stagnated red wolf population growth by breaking up red wolf packs and removing sterilized coyote space holders from the landscape through accidental and purposeful killing of red wolves and sterilized coyotes (USFWS unpublished data).

Evident by the widespread persistence and range expansion of coyotes, current policies to control their populations are ineffective and have failed to significantly reduce coyote populations. Laws promoting trafficking and nighttime hunting of coyotes increase the chances that red wolves will be accidentally or purposefully killed by hunters, and attempts to remove these hunting laws are constrained by organized hunting and trapping groups. Increased killing of red wolves by predator-control programs during the early 20th century facilitated the decline of red wolves and promoted their hybridization with expanding coyotes. Recent research showed intense harvest of eastern wolves also facilitated hybridization with coyotes by disrupting the population's social structure (Rutledge et al. 2012b). Today, increased killing of red wolves by humans appears to be disrupting red wolf packs and facilitating hybridization with coyotes (Bohling 2011). Increased relatedness of red wolves through discriminant killing opportunities will eventually lead to inbreeding depression in the wild population. Use of MHC genes to evaluate red wolf mate choice could lead to insights of how red wolves respond reproductively to anthropogenic changes and how MHC variation affects resistance to potential diseases that can be introduced through trafficking coyotes. Therefore, controlling hybridization and inbreeding requires understanding how anthropogenic sources of mortality facilitate conditions favorable to hybridization.

Increased mortality rates of red wolves and coyotes promote high turn-over rates of territories and erode the effectiveness of sterilization methods. Despite this, continued use of sterilization and efforts to increase the number of red wolves on the landscape will likely fail to prevent hybridization if reproductive barriers do not exist in the first place (Fredrickson and Hedrick 2006). Key to developing effective management that prevents the hybridization of sympatric red wolf and coyote populations is to identify unique traits of both species that promote sexual isolation. Within the Recovery Area, some individual red wolves and sterile coyotes appear to always prefer conspecifics as mates while others show random preferences, and assortative mating within both populations may indicate an intrinsic reproductive barrier. In the

hybridization section of this paper, we discussed evaluating the effects of body size on mate complementarity between red wolves and coyotes because body size is the most characteristically distinct trait between the two species. Life history traits (i.e., rates of individuals growth, reproduction, and mortality), population-level processes (i.e., abundance and space use), and community-level interactions (i.e., predator-prey dynamics and interspecific interactions) are known to correlate with body-size allometries regardless of taxonomic status (LaBarbera 1989; Brown et al. 1993, 2004; Capellini et al. 2010). Therefore, there are compelling reasons to study how phenotypes facilitate the outcomes of red wolf-coyote interactions because phenotypes are the direct interface between the two species. Selection acts directly on phenotypes with genetic change occurring as an indirect consequence and phenotypes have ecological effects on population dynamics and community structure (Agrawal 2001; Schluter 2001; Price et al. 2003; Kingsolver and Pfennig 2008; Siepielski et al. 2009; Crispo et al. 2010). If certain phenotypes serve as reproductive barriers between red wolves and coyotes, management can manipulate selection to achieve desired demographic effects and reduce hybridization.

A major impediment to red wolf restoration is the limited knowledge about traits that facilitate behavioral and ecological differences between red wolves and coyotes. This is critical to red wolf restoration because expanding our knowledge about mechanisms that facilitate stable and reproductively isolated red wolf populations will allow us to recognize responses of red wolves to changing environments. This knowledge guides research to make accurate inferences and predictions about the future and promotes implementation of appropriate management. The reality of incomplete reproductive isolation may present challenges to red wolf restoration but evolution is ongoing and management efforts should promote conditions that allow for the gradual evolution of reproductive barriers. Although much work remains to be done, information and experiences gained from more than 25 years of restoration efforts have made crucial contributions to the future of the red wolf. They also allow us to formulate areas of investigation that are of direct relevance to the restoration of red wolves.

Acknowledgements

We thank the Red Wolf Recovery Program, specifically R. Bartel, A. Beyer, C. Lucash, F. Mauney, M. Morse, and R. Nordsven for their support. We also thank K. Brzeski for constructive comments on the manuscript. The findings and conclusions in this article are those of the authors and do not necessarily represent the views of the U.S. Fish and Wildlife Service.

CHAPTER 3

MORPHOMETRICS OF *CANIS* TAXA IN EASTERN NORTH CAROLINA

Hinton, J.W. and M.J. Chamberlain. 2014. Submitted to *Journal of Mammalogy*, 10/24/13

Abstract

We describe the external morphological characters of red wolves, coyotes, and their hybrids from North Carolina and assess if morphology could be an accurate discriminator among the 3 canid taxa. We used body measurements from 171 red wolves (*Canis rufus*), 134 coyotes (*Canis latrans*), and 47 hybrids in a polytomous logistic regression analysis to assess if they could be used to identify canids as red wolves, coyotes, or hybrids. Polytomous logistic regression analysis of 7 morphometric variables was able to correctly allocate 86% of canids to their a priori taxa groups. Using Akaike's information criterion, we judged hind foot length, weight, width of head, and tail length as variables to best separate taxa. Among the 3 sympatric *Canis* taxa in eastern North Carolina, red wolves are clearly the larger canid with hybrids intermediate to coyotes and red wolves in body size. Our results suggest that red wolves represent a unique *Canis* phenotype in the southeastern United States.

Introduction

Recent advances in science and technology have promoted molecular genetics as the primary tool for inferring the evolutionary and demographic past of North American wolves. In particular, the role of hybridization has become a predominant and contentious issue in the evolution and conservation of wolf populations in eastern North America. For example, the use of molecular markers bolstered the possible role coyotes (*Canis latrans*) played in the ancestry of wolves in Eastern North America (Chambers et al. 2012; Wayne and Jenks 1991; Wilson et al. 2000). Despite leading to controversies surrounding the taxonomy of New World wolves, genetic markers have proven invaluable for conservation efforts by providing new insights into the evolution and ecology of *Canis* species (Chambers et al. 2012). Nevertheless, morphology is a fundamental component of biology (MacLoed 2004; Nelson 1989) and phylogenetic analysis is not possible without some method of describing the morphological variation between individuals, populations, and species (MacLeod and Forey 2004). Therefore, a complete synthesis of *Canis* species in eastern North America that leads to successful conservation requires studies from

multiple disciplines involving ecological, evolutionary, molecular, and morphological analyses (Rutledge et al. 2012).

The Red Wolf Recovery Program (Recovery Program) of the United States Fish and Wildlife Service (USFWS) oversees the recovery of endangered red wolves (*Canis rufus*) and it currently manages the only wild population of red wolves on the Albemarle Peninsula in eastern North Carolina (Hinton et al. 2013). Since its inception during 1973, the Recovery Program has considered hybridization between red wolves and coyotes to be a primary threat to red wolf recovery efforts because hybridization can render the wild red wolf population unrecognizable within several generations (Kelly et al. 1999; Rabon et al. 2013; USFWS 1989). During the initial stages of red wolf recovery efforts, morphometric data were used to identify individual red wolves captured from hybrid swarms in eastern Texas and western Louisiana, and these individuals were later used as founders for the captive and eastern North Carolina populations (USFWS 1989). Additionally, the use of morphometric measurements alluded to issues of hybridization and coyote introgression into red wolf genetics before modern molecular approaches were developed (Nowak 1979). Therefore, morphometric data provide another method to differentiate among red wolves, coyotes, and red wolf/coyote hybrids (hereafter hybrids) that is essential to determine whether hybridization is occurring. Red wolves and coyotes are sympatric in eastern North Carolina and developing morphometric profiles for red wolves, coyotes, and hybrids in this region is necessary to develop practical approaches to address hybridization and enhance conservation.

An assessment of morphometric data for *Canis* taxa in eastern North Carolina can improve important areas necessary for red wolf recovery efforts. First, it allows tests to determine if morphometric measurements can be used to discriminate among red wolves, coyotes, and hybrids in the absence of molecular markers. If successful, this will permit an evaluation of which measurements are most useful to discriminate among the 3 *Canis* taxa. Such data can be extended to ecological studies to determine the limits of potential resource use and the relative efficiency of

red wolves and coyotes to exploit resources within those limits (Wainwright 1996). Second, assessing morphometric measurements will allow the description of phenotypes of the 3 *Canis* taxa. Nowak (2002) observed the morphology of modern red wolves to be consistent with fossilized remains of small wolves in the eastern United States dating back to the Pleistocene. If this is true, regardless of the modern red wolf's evolutionary origins, the eastern North Carolina population may represent a *Canis* phenotype unique to the southeastern United States. Here we provide a systematic analysis of morphometric measurements currently collected by Recovery Program biologists from red wolves, coyotes, and hybrids and assess their reliability to describe and discriminate among the 3 taxa.

Study Area

The Red Wolf Recovery Area (Recovery Area) was established on the Albemarle Peninsula in northeastern North Carolina during 1987. The area included 5 counties (Beaufort, Dare, Hyde, Tyrrell, and Washington) and consisted of approximately 6800 km^2 of federal, state, and private lands (Figure 1). The Albemarle Peninsula was comprised of an intensively farmed agricultural-hardwood bottomland matrix in which approximately 30% of the landscape was driven by agricultural activity.

Methods

Red wolves, coyotes, and hybrids used in this study were captured by the Recovery Program during annual trapping within the designated Recovery Area from 1987 until 2011 (Rabon et al. 2013). Canids were captured using padded foot-hold traps (Victor no.3 Softcatch, Lititz, Pennsylvania, USA) and were sexed, measured, weighed, and aged by tooth wear (Gier 1968), and a blood sample was collected for genetic analysis. Ages of most red wolves were known and tooth wear estimates mostly applied to coyotes and hybrids (Rabon et al. 2013). For this study, only animals captured between the months of November through March were used. This ensured that all pups used in the analysis were at or near full potential body size for the taxa. We aged individuals > 2 years old as adults, < 2 but > 1 years old as juveniles, and > 6 months

but < 12 months old as pups. Microsatellite markers and other genetic information from the 14 founding individuals and other predefined red wolves were used to generate allele frequencies to reconstruct the pedigree of the red wolf population. Individuals used in this study were genotyped at 17 microsatellites and genetic analyses of blood samples followed the methods outlined in Adams (2006), Bohling et al. (2013), and Miller et al. (2003). Individuals were assigned to a species or hybrid group using the methods developed by Miller et al. (2003) to specifically identify red wolves, coyotes, and hybrids. During our study, these were the molecular methods used by the United States Fish and Wildlife Service for monitoring red wolf genetic ancestry (Bohling et al. 2013).

Morphometric measurements were taken from live animals and measurements were followed as closely to standard anatomical reference points as possible. Body traits measured included body weight, ear length (edge of the external auditory canal to the tip of the ear), tail length (tip of the fleshy part of the tail to the tail base), body length (anterior tip of the nose pad to the tail base), hind foot length (hock to the tip of the digital pads), shoulder height (tip of the scapula to the tip of the digital pads), front and hind paw width (width across the cushiony pads at the widest points), front and hind paw length (base of the metacarpal pad to the tip of the digital pads), length of head (edge of the premaxillary to the most posterior point of the occipital bone), and width of head (widest points across the zygomata). All animals measured were later identified as red wolves, coyotes, and hybrids by the Recovery Program using molecular methods.

We analyzed measurements of canids using univariate and multivariate statistical methods in Program R, version 3.0.2 (R Development Core Team 2013). We present statistics of measurements as the mean ± standard error. To evaluate similarities between pairs of measurements, we used a correlation analysis. Individuals were included in the analysis only once to maintain independence. To remove redundancy, we used only one measurement from a set of strongly correlated measurements to represent that taxon in further analysis.

We used analysis of variance (ANOVA) and *t*-tests to evaluate differences of measurements among and within taxa groups. We then used measurements in a polytomous logistic regression analysis to assess the reliability of morphometrics to identify canid taxa. Polytomous logistical regression is a logical extension of binary logistic regression that allows more than 2 categories of the dependent variable (Hosmer and Lemeshow 2000). The ability of the polytomous logistical regression to identify red wolves, coyotes, and hybrids using morphometric measurements was revealed as the percentage of individuals correctly reallocated to each taxon. The number of misclassified individuals indicated the degree of overlap between the groups. We used the Akaike information criterion (AIC) to compare models of morphometric measurements by calculating the AIC_c for each model and using ΔAIC_c and Akaike weights (*w*i) to select the measurements which best delineated different canid categories (Burnham and Anderson 2002). We performed polytomous logistical regression and model selection using the polytomous and AIC functions from the polytomous and MuIN packages for Program R.

Sample sizes among measurements varied because it was not always possible to measure every variable for each individual. Only individual canids with all measurements were included in the polytomous logistical regression analysis. We used a Kolmogorov-Smirnov one-sample test for each measurement to determine whether measurements for the subset of individuals used in the polytomous logistical regression analysis were biased when compared to the larger sample from which they were drawn.

Results

From 1987 to 2011, 951 canids were captured and measured. These included 528 red wolves (56%), 264 coyotes (28%), and 159 hybrids (17%) that were genetically identified. Measurements differed among red wolves, coyotes, and hybrids (Table 1) and hybrids were intermediate to red wolves and coyotes in all morphometric measurements.

The correlation coefficients of the measurements in the original dataset were strongly correlated with one another ($r = 0.75 – 0.90$). To reduce the number of variables, we used only 7

univariate estimates (body weight, ear length, tail length, body weight, hind foot length, shoulder height, and width of head) to characterize overall size because this subset most completely represented the various aspects of canid anatomy needed for analysis. Among red wolves all 7 measurement means increased ($F_{2, 453} \geq 6.79$, $P < 0.001$) with age. Additionally, all 7 measurement means were greater ($t_{528} \geq 6.07$, $P < 0.001$) for males than females. Among coyotes, weight, ear length, body length, hind foot length, shoulder height, and width of head were greater ($t_{264} \geq 2.98$, $P \leq 0.003$) for males than females, but there was no difference in tail length ($t_{264} = 1.60$, $P = 0.11$). Ear length and tail length ($F_{2, 159} \leq 1.72$, $P \geq 0.181$) did not differ among ages, but weight, body length, hind foot length, shoulder height, and width of head ($F_{2, 163} \geq 5.61$, $P \leq 0.004$) increased with age. Among hybrids, tail length and body length ($t_{159} \leq 1.78$, $P \geq 0.077$) did not differ between males and females, whereas weight, ear length, hind foot length, shoulder height, and width of head were larger for males than females ($t_{159} \geq 2.06$, $P \leq 0.041$). Weight, tail length, and shoulder height ($F_{2, 56} \leq 4.77$, $P \geq 0.012$) increased with age, but ear length, body length, hind foot length, and width of head ($F_{2, 56} = 2.95$, $P = 0.060$) did not differ with age.

Included in the polytomous logistical regression analysis were 352 (171 red wolves, 134 coyotes, and 47 hybrids) canids for which all 7 measurements were completed. The subset used in the polytomous logistical regression analysis was not biased when compared to the larger samples of red wolves ($D = 0.10$, $P = 0.094$), coyotes ($D = 0.06$, $P = 0.925$), and hybrids ($D = 0.2$, $P = 0.110$). The polytomous logistical regression model correctly classified 86% of the canids. Coyotes and red wolves were correctly classified 99% and 98% of the time, respectively. Hybrids were correctly classified 13% of the time. Hybrids were more likely to be misclassified as coyotes than red wolves (61% vs. 35%).

When red wolves were separated as pups (> 6 but < 12 months old) and non-pups (adults and juveniles), all non-pups were correctly identified as red wolves and only 2 pups (1.8%) were misclassified as a coyote and a hybrid (Table 2). Only 2 coyotes (1.5%) were misclassified as red wolf pups and none were misclassified as hybrids. Most hybrids were misclassified as coyotes

(53%) and red wolf pups (30%). Hybrids were 29% more likely to be misclassified as red wolf pups than non-pups. This is likely because as red wolf pups, born in the spring, overlap in body size with hybrids during summer and autumn as they approach adult body sizes in the winter.

The most useful measurements for separating red wolves, coyotes, and hybrids were hind foot length, weight, width of head, and tail length (Table 3). Hind foot length was the single most useful measurement. Our findings (Tables 4) suggest a reliable threshold that canids with hind foot lengths > 21.5cm, weights > 21.5kg, width of heads > 10.5cm, and tail lengths > 35cm were most likely to be red wolves. Coyotes typically had hind foot lengths < 19.5cm, weights < 19.5kg, width of heads < 10.5cm, and tail lengths < 35cm. Hybrid values for these 4 measurements would most likely overlap the minimum values for red wolves and maximum values for coyotes.

Discussion

Our results show that body size measurements of red wolves and coyotes are distinct from one another with hybrids representing an ambiguous intermediate size. Using measurements of hind foot length, body weight, width of head, and tail length in a polytomous logistic regression analysis, we were able to correctly classify 86% of 352 canids into their correct taxa category with moderately high (80% to 90%) accuracy. Red wolves and coyotes were correctly classified 98% and 99%, respectfully. On the other hand, hybrids were more difficult to re-assign and only 13% were correctly classified. Hybrids were more likely to be misclassified as either coyotes or red wolf pups. Despite the issue of morphological ambiguity, Recovery Program biologists still correctly classify canids as hybrids prior to genetic confirmation by identifying the morphological ambiguity and breeding status of hybrids. In other words, canids intermediate in size to red wolves and coyotes that have fully developed and active reproductive systems (e.g., males with enlarged testicles and females in estrus) are obviously adult hybrids, whereas those with underdeveloped and inactive reproductive systems are considered red wolf pups and confirmed with genetic analysis.

Of the 153 hybrids measured, only 2% (3 adult males) attained measurements above the minimum threshold values used by the Recovery Program to assign canids as red wolves. Nevertheless, the minimum values for red wolves reported in this study were estimated from the smallest adult females. Adult male red wolves are significantly larger than the minimum threshold reported. Interestingly, 20 of the 25 largest hybrids were captured and measured during 1998 through 2001. Since 2001, hybrids have been more coyote-like in their morphology and rarely exceed 20 kg in body weight. Coyotes did not fully colonize the Albemarle Peninsula until the mid-2000s (USFWS 2007), so hybrids prior to this period may have been more red wolf-like because backcrosses were occurring within the smaller red wolf population. Once introgression was identified and management actions were used to reduce hybridization during the early 2000s (Hinton et al. 2013, Kelly et al. 1999, Rabon et al. 2013), hybrid backcrosses began to occur more often within the larger coyote population.

The Recovery Program uses sterilization of coyotes and hybrids as the primary management tool to prevent coyote introgression into the red wolf genome (Hinton et al. 2013, Rabon et al. 2013). After capture, sterilized canids are released back into the Recovery Area fitted with mortality-sensitive radio-collars and monitored for the duration of their life. In the event that a red wolf pairs with a sterilized canid, the pair cannot produce hybrid litters. Although molecular markers ultimately confirm the taxa of canids captured, Recovery Program biologists routinely use morphometric measurements to pre-screen, process, and re-release individual canids into the wild before receiving genetic confirmation. Morphometric measurements are used to reduce holding times because this lowers the risk that captured canids would lose breeding mates and territories because of absence. Therefore, quick identification during the canid breeding season allows Recovery Program biologists to minimize disruptions to canid packs with excessive holding times while waiting for genetic confirmation. The accuracy of using morphometric measurements we observed confirms that morphological measurements could be used to pre-screen canids for management decisions, while awaiting genetic confirmation. Ultimately, genetic

assessments are necessary to effectively monitor, measure, and manage coyote introgression in the red wolf population.

Regardless of the ambiguity of hybrid measurements, our findings concerning morphometric measurements of red wolves and coyotes are consistent with the results of Nowak (1979, 2002) who demonstrated little to no overlap in red wolf and coyote cranial and dental measurements. Throughout North America, average coyote weights reported in studies rarely exceed 18 kg (Bekoff and Gese 2003; Leopold and Chamberlain 2001; Way 2007). Additionally, our date indicates that F1 and F2 hybrids are incapable of reaching body sizes of adult red wolves. This suggests that the red wolf represents a unique *Canis* phenotype in the southeastern United States. Differences in body size measurements are highly suggestive of differences in ecological requirements, as this is particularly true for carnivores regarding diet (Carbone et al. 2007; Donadio and Buskirk 2006; Gittleman 1985), space use (Gittleman and Harvey 1982; Gompper and Gittleman 1991), and interspecific interactions (Donadio and Buskirk 2006; Palomares and Caro 1999; Rosenzweig 1966). The general relationship between morphology and ecology is well known (Arnold 1983; Hutchinson 1959; Kishida et al. 2010; Wainwright 1996), but effects of body size on the relative ability of red wolves and coyotes to successively hunt prey, acquire mates, and defend territories is not well known.

Among the 3 sympatric *Canis* taxa in eastern North Carolina, red wolves are clearly the larger canid with hybrids intermediate to coyotes and red wolves in body size. Although this is a commonly held opinion, there is no significant literature comparing the morphometrics of red wolves, coyotes, and hyrbrids. Nowak (1979, 2002) assessed measurements from skulls of prehistoric and 20th century red wolves, gray wolves (*Canis lupus*), and coyote specimens and concluded red wolves to be a species intermediate in size to gray wolves and coyotes. USFWS (1989) reported only minimum measurements used to distinguish male and female red wolves from non-red wolf canids in southeastern Texas and southwestern Louisiana during the 1970s. The 1999 Population Habitat and Viability Assessment for red wolves stated the need to develop

a morphological profile for red wolves, coyotes, and hybrids for quick identification in the field (Kelly et al. 1999). Therefore, this study represents the first morphometric comparison of sympatric red wolves, coyotes, and their hybrids. Our analysis has shown morphometrics to be valuable in exploring morphological variation among closely related and sympatric *Canis* taxa. Further examination of morphological characters between red wolves and coyotes could detect patterns of phenotypic discreteness that may highlight opportunities for analysis of traits that may have genetic, evolutionary, and ecological importance. Therefore, we recommend examining the effects of morphology on red wolf and coyote ecology and interactions that may facilitate hybridization between the 2 species.

Acknowledgements

This research was funded by the Red Wolf Recovery Program, Warnell School of Forestry and Natural Resources at the University of Georgia, and the United States Fish and Wildlife Service. The data for this study were acquired from the Red Wolf Recovery Program. We appreciate support of the Red Wolf Recovery Program, specifically R. Bartel, A. Beyer, C. Lucash, F. Mauney, M. Morse, R. Nordsven, and D. Rabon. We also thank R. Nowak, D. Cobb, R. Powell, and 2 anonymous reviewers for their constructive comments. The findings and conclusions in this article are those of the authors and do not necessarily represent the views of the US Fish and Wildlife Service.

CHAPTER 4

FACTORS AFFECTING DIETS OF RED WOLVES AND COYOTES

Hinton, J.W., M.J. Chamberlain, J.L. Gittleman, A.K. Ashley, J.A. Dellinger, J. McVey. To be submitted to the *Journal of Zoology*.

Abstract

Foraging behaviors of red wolves and coyotes are complex and their ability to form congeneric breeding pairs and hybridize adds additional difficulties into understanding factors affecting prey selection. We assessed factors affecting prey selection of red wolf packs, coyote pairs, and congeneric pairs form by red wolves and coyotes and found that all three had similar and overlapping diets. Nevertheless, we detected differential use of prey; red wolf packs consumed more white-tailed deer, fur bearers, and pig than coyote and congeneric pairs. Coyotes that formed pairs with red wolves had 10% more whited-tailed deer in their diet than conspecifics that paired with coyotes. Contrary to many studies on coyote diet in the southeastern United States, we found coyotes in northeastern North Carolina to be largely carnivorous with a narrow dietary breadth. We found breeder weight, pack size, age, white-tailed deer density, and season to be important factors influencing the diet of red wolf packs. Breeder weight and season were important factors influencing diets of coyote pairs, whereas season and white-tailed deer density influenced diets of congeneric pairs. Although prey selection was largely similar among the three groups, differences in diet among different breeding pairs were associated with body size. Larger individuals within and among different breeding pairs consumed more white-tailed deer, and less rabbits and small mammals. Therefore, partitioning of food resources by red wolves and coyotes in northeastern North Carolina is mostly via differences in quantity of similar prey rather than differences in types of prey exploited. We suggest that similarities in energetic demand of individual red wolves and coyotes that approach each other in body size may partially contribute to successful congeneric pairing and hybridization through similar use of prey.

Introduction

Understanding relationships between organisms and their food resources is a central goal in ecology, and describing mechanisms that influence foraging behavior can assist management and conservation of wildlife. In particular, diets of carnivores have always interested ecologists because predation is an essential ecological process that structures communities and influences

ecosystem productivity (Hairston *et al*., 1960; Schmitz *et al*., 2000; Ripple & Bescheta, 2004; Fortin *et al*., 2005). Foraging behavior of carnivores is a fundamental component of their ecology and evolution because it is directly related to behavior, morphology, and physiology (Christiansen & Wroe, 2007; Van Valkenburgh, 2007). A thorough understanding of a carnivore's dietary needs requires identifying primary food resources and describing what factors influence variation in the consumption of those resources. Thereafter, ecologists can use that information to understand how foraging behavior affects life history traits and population processes that will ultimately influence community- and ecosystem-level processes.

Traits affecting foraging behavior are similar between closely related and similarly sized species of Carnivora. This is particularly true for Canidae in which members of this family share similar body plans and monogamous breeding behaviors (Finarelli, 2007; Finarelli, 2008). Recently diverged taxa within Canidae tend to be ecologically similar because there is a direct link between their evolutionary relatedness and the ecological processes that determine their distribution and abundance (Johnson *et al*., 1996). Despite understanding characteristics unique to members of modern Canidae and how those traits influence foraging behaviors (Van Valkenburgh *et al*., 2004; Andersson, 2005; Slater *et al*., 2009), we still know little about factors affecting prey selection of two sympatric *Canis* species in the southeastern United States. Determining what these factors are and how they influence prey selection of red wolves (*Canis rufus*) and coyotes (*Canis latrans*) is essential for enhancing red wolf conservation, understanding mechanisms facilitating coyote expansion into the Southeast, and identifying key components of *Canis* foraging ecology.

Although a common predator of the Southeast prior to European settlement, government-supported eradication campaigns reduced red wolves to a remnant population of approximately 100 individuals by mid-20th century (USFWS, 1989; Hinton *et al*., 2013). As red wolves were eradicated, coyotes expanded east into Arkansas, Louisiana, and other southwestern regions of the red wolf's historic range (McCarley, 1962; Paradiso & Nowak, 1972). With rapidly declining

red wolf populations and extensive hybridization with the expanding coyote population, the United States Fish and Wildlife Service (USFWS) removed the last remaining red wolves from eastern Texas and western Louisiana and later reintroduced their progeny into northeastern North Carolina during the late 20th-century to begin red wolf restoration efforts (USFWS, 1989). Today, red wolves exist as a remnant population of approximately 100 individuals whereas coyotes have become ubiquitous throughout the red wolf's historic range posing a serious ecological threat because of their ability to hybridize with red wolves (Hinton *et al*., 2013).

Red wolves and coyotes share similar canid body shapes with red wolves being the larger of the two species. The effects of body size on red wolf and coyote interactions are currently unknown (Hinton *et al*., 2013). Body size represents a key morphological trait that separates red wolves from coyotes and it may affect differential use of prey between the species. Red wolves, weighing 7-18 kg heavier than the largest coyotes (Chapter 3), should feed at higher trophic levels than coyotes because body size has been shown to predict carnivore interactions with prey (LaBarbera, 1989; Gittleman, 1985; Donadio & Buskirk, 2006). The ability of both species to form congeneric breeding pairs raises an interesting question regarding how differences in body size between congeneric mates determine the efficiency with which those mates acquire and use food resources. Both species face energetic constraints that affect many aspects of their ecology, and small differences in body size between individual red wolves and coyotes may allow for successful formation of congeneric pairs because the effects on the breeder's ability to transfer energy from homeostasis to reproductive efforts is negligible.

Understanding dietary needs of red wolves and coyotes is a primary step to improving management of both species and minimizing hybridization. Our objective was to describe the diets of red wolves and coyotes by identifying the remains of prey found in red wolf and coyote scat. We used several variables (i.e., body weight, social structure, age, etc.) that have not traditionally been used in analyses of scat remains to account for variation in diet. Furthermore, this study is the first to assess dietary behaviors of congeneric canid breeding units that are the

source of hybridization. To accomplish this, we monitored over 35 canid packs and pairs over more than 6,000 km^2. As a result, this study represents the most comprehensive assessment of canid diet in the eastern United States. Assessing red wolf diet and factors influencing its variation will allow us to understand the red wolf's ecological role in the Southeast. Additionally, diets of eastern coyotes have lain at the heart of the species' impact on eastern ecosystems and the need to determine the ecological role of eastern coyotes goes beyond the scope of red wolf conservation.

Study Area

The study was conducted in the Red Wolf Recovery Area (hereafter Recovery Area) on the Albemarle Peninsula of northeastern North Carolina (Beaufort, Dare, Hyde, Tyrrell, and Washington counties). The Recovery Area consisted of approximately 6,800 km² of federal, state, and private lands. The Albemarle Peninsula is an intensively farmed agricultural-hardwood bottomland forest matrix in which approximately 45% of the landscape was driven by agricultural and commercial timber activities. Corn, cotton, soybean, and winter wheat were the primary agricultural crops and comprise approximately 30% of the land cover. Managed pine (*Pinus* spp) plantations comprise approximately 15% of the land cover. The remaining 55% of land cover types were pocosin (15%), bottomland hardwood forests (15%), saltwater marsh (5%), open water (10%), and other land cover types (10%). Potential mammalian prey of red wolves and coyotes in the Recovery Area were white-tailed deer (*Odocoileus virginianus*), raccoon (*Procyon lotor*), eastern cotton-tail rabbit (*Sylvilagus floridanus*), marsh rabbit (*Sylvilagus palustris*), feral pig (*Sus scrofa*), nutria (*Myocastor coypus*), muskrat (*Ondatra zibethicus*), hispid cotton rat (*Sigmodon hispidus*), white-footed mouse (*Peromyscus leucopus*), deer mouse (*Peromyscus maniculatus*), house mouse (*Mus musculus*), eastern harvest mouse (*Reithrodontomys humulis*), voles (*Microtus* spp), and shrews (*Blarina* spp). Primary carnivores sympatric with red wolves and coyotes were gray foxes (*Urocyon cineroargenteus*), red foxes (*Vulpes vulpes*), feral dogs (*Canis lupus familiaris*), bobcats (*Lynx rufus*), and black bears (*Ursus americanus*).

Methods

Red wolves and coyotes were captured within the Recovery Area during annual trapping efforts conducted by the United States Fish and Wildlife Service Red Wolf Recovery Program (hereafter Recovery Program). Red wolves and coyotes were sexed, measured, weighed, aged by tooth wear (Gier, 1968), and blood sampled for genetic identification. The Recovery Program categorizes red wolves and coyotes > 2 years old as adults, < 2 but > 1 year old as juveniles, and < 1 year old as pups. Coyotes captured within the Recovery Area by USFWS personnel were reproductively sterilized (hereafter sterilized) and used as space holders until red wolves moved in and occupied those areas (Hinton *et al*., 2013; Rabon *et al*., 2013). Coyotes were taken to a local veterinary clinic for surgical sterilization where males and females were sterilized by vasectomy and tubal ligation, respectively. This process kept hormonal systems intact and avoided disrupting breeding and territorial behavior. Once red wolves and coyotes were fully processed, individuals were fitted with radio-collars, released, and then monitored by the Recovery Program during weekly telemetry flights. Monitoring efforts allowed the Recovery Program to identify red wolf and coyote space use on the landscape.

Territories of red wolf packs, coyote pairs, and red wolf-coyote pairs (hereafter congeneric pairs) were surveyed at least once a month for scat from 2009 until 2011 (Dellinger *et al*., 2011a; McVey *et al*., 2013). Paved, gravel, and dirt roads were surveyed by foot, all-terrain vehicles, and trucks. We also opportunistically collected defecations from red wolves and coyotes captured during annual trapping. Scats collected were bagged, dated, marked with a unique identification number, and stored in a freezer for later dissection and analysis. We identified scats by physical appearance, including size (Dellinger *et al*., 2011b), and the presence of tracks or other predator sign in the immediate area around the scat. Approximately 40% of the scats were identified to species and individual animals using fecal DNA genotyping (Dellinger *et al*., 2011a; McVey *et al*., 2013). We assigned scats collected within known territories to red wolf packs,

coyote pairs, or congeneric pairs but excluded those that could not be associated with known pairs and packs.

We examined scats identified to red wolf packs, coyote pairs, and congeneric pairs for prey remains. Individual scats were placed in nylon panty hose and then secured in small, nylon mesh bags with water-proof labels for washing. Scats were soaked in water for 24 hours before being transferred to a washing machine and washed on the regular cycle with detergent 3 times to separate hair and bone fragments from fecal matter. We allowed scats to air dry for 72 hours prior to examining scat contents. Once dried, prey remains for each scat was analyzed for species composition. We identified the undigested food items microscopically and macroscopically by comparing to reference collections and identification manuals (Moore *et al*., 1997; Debelica & Theis, 2009). We assigned prey remains in scats to one of 5 categories: white-tailed deer (hereafter deer), rabbits (eastern cotton-tail and marsh rabbit), small mammals (mice, rats, shrews, and voles), fur bearer (muskrat, nutria, and raccoon), pig, and other food items (bird, insect, fruit, and anthropogenic material). We excluded prey items that comprised < 5% of prey found in scat from the analysis. Following identification of prey remains in scats, we estimated the percent of occurrence (PO) for each prey item using the common visual estimation of PO (Dellinger *et al*., 2011a; McVey *et al*., 2013).

Red wolf packs, coyote pairs, and congeneric pairs are the only 3 types of *Canis* breeding units monitored by the Recovery Program in northeastern North Carolina. Red wolf packs were comprised of a breeding pair along with juveniles and pups from previous litters. Some red wolves monitored for this study were newly formed breeding pairs and did not have juveniles or pups. Coyote pairs did not have juveniles and pups because at least 1 of the 2 breeders was sterilized as a management technique to suppress coyote reproduction. Congeneric pairs were comprised of a red wolf and a coyote and did not have juveniles and pups because the coyote in the pair was sterilized to prevent hybridization. Therefore, our sampling units were red wolf packs, coyote pairs, and congeneric pairs. We used breeder weight (combined weight of both

breeders), breeder age (mean age of both breeders), pack size (# of individuals in pack), deer density (# deer harvested by hunters/km^2), and season (summer and winter) as explanatory variables to account for changes in dietary composition for red wolf packs. However, because coyote pairs and mixed pairs did not have juveniles and pups, we could not include pack size as explanatory variables to account for variation in diet.

We included a measurement of deer abundance as a variable because deer are known to be an important food resource for red wolves (Dellinger *et al*., 2011a, McVey *et al*., 2013) and there is a growing concern that coyotes are negatively affecting deer populations across the Southeast (Kilgo *et al*., 2012). We used county-level hunter harvest data collected by the North Carolina Wildlife Resources Commission as measures of deer abundance in the Recovery Area. Estimates of deer harvests were divided into 3 categories, which likely corresponded with deer population sizes for the 5 counties (Beaufort, Dare, Hyde, Tyrrell, and Washington) in the Recovery Area. Our categorization resulted in areas of low (< 0.75 deer harvested/km^2), medium (0.75 – 1.5 deer harvested/km^2), and high (> 1.5 deer harvested/km^2) deer densities. Although these harvest reports do not reflect true deer densities, these categories do provide a benchmark by which to judge the effect of deer abundance on red wolf and coyote diets. To further aid in univariate comparisons, we pooled scat into 2 seasons (summer and winter) for comparison of prey selection between seasons by breeding pairs. We also collapsed pack size into 2 categories: packs of 4 or fewer individuals (hereafter smaller packs) and packs with 5 or more individuals (hereafter larger packs).

We analyzed the effects of explanatory variables on diet using univariate and multivariate statistical methods in R Statistical Environment, version 2.14.2 (R Development Core Team, 2012). We used analysis of variances (ANOVAs), Tukey tests for multiple comparisons, and *t*-tests to determine if the percentage of prey items consumed differed with respect to breeder weight, breeder age, pack size, deer density, and season. We then developed generalized linear models (GLMs) to model the percentage of a prey category for each sampling unit as a linear

function of the explanatory variables. Changes in coefficient estimates of GLMs represent the change in percent prey consumption following a one-unit change in the explanatory variables. We assessed models using a stepwise procedure by calculating Akaike information criterion (AIC_c) for each model to select which variables best explained diet by selecting the most parsimonious model with the highest weight and rank relative to the entire set of models under consideration (Burnham & Anderson, 2002). With the exception of season, all measurements were continuous data. The GLM analysis was conducted using arcsine-square root transformation to percentage data to correct for non-constant error variance.

Results

From 2009-2011, we collected and analyzed 1754 scats from 13 red wolf packs, 17 coyote pairs, and 8 congeneric pairs. Red wolf packs, coyote pairs, and congeneric pairs accounted for 55.4%, 31.6%, and 13% of the scat, respectively. Breeders of red wolf packs had the heaviest combined weights followed by those in congeneric pairs and coyote pairs and average breeder age was older for red wolves than coyotes and congeneric pairs (Table 1).

Red wolf packs, coyote pairs, and congeneric pairs differentially used deer, rabbits, small mammals, fur bearers, and pigs ($F_{2, 1754} \geq 6.77$, $P < 0.001$); deer and rabbits comprised most prey items found in scat (Table 2). No difference was detected in use of other food items ($F_{2, 1754} = 2.21$, $P = 0.110$). Coyote pairs consumed less deer and more rabbits than red wolf packs and congeneric pairs (Table 2). Coyotes consumed more small mammals than red wolves, but consumption of small mammals by congeneric pairs did not differ from coyote pairs or red wolf packs. Red wolf packs consumed more fur bearers and pig than coyote pairs and congeneric pairs.

Red wolf packs consumed more deer and pig in areas of medium deer density than areas of low and high density ($F_{2,968} \geq 6.43$, $P < 0.001$). Red wolf packs consumed more rabbits in areas of high deer density than in areas of low and medium density ($F_{2,968} = 33.40$, $P < 0.001$). Red wolf consumption of small mammals, fur bearers, and other food items were greater in areas of low deer density than areas of medium and high deer density ($F_{2,968} \geq 8.01$, $P < 0.001$). We only

compare diet between medium and high deer density areas for coyote pairs and congeneric pairs because they were absent in counties with low deer density (Table 3). We detected no difference in coyote consumption of white-tailed deer, rabbit, small mammals and pig between medium and high deer density ($t_{552} \leq 0.86$, $P \geq 0.392$). We did find that coyotes in areas of medium deer density consumed more fur bearers and other food items than in areas of high deer density ($t_{552} \geq 2.00$, $P \leq 0.046$). We detected no difference in consumption of any prey species by congeneric pairs between medium and high deer densities ($t_{227} \leq 1.77$, $P \geq 0.079$).

Older red wolf breeders consumed more rabbits and pig than younger breeders, whereas younger red wolf breeders' consumed more deer, small mammals, and other food items ($t_{969} \geq 2.47$, $P \leq 0.014$) than older breeders (Table 4). No differences were observed in the consumption of fur bearers by older and younger red wolf breeders ($t_{969} = 1.47$, $P = 0.142$). Younger coyote breeders consumed less deer and more rabbits than older breeders ($t_{552} \geq 2.49$, $P \leq 0.014$). No differences were observed between older and younger coyote breeders in their consumption of small mammals, fur bearers, pig and other food items ($t_{552} \leq 1.32$, $P \geq 0.188$). Older breeders in congeneric pairs consumed more small mammals ($t_{227} = 2.22$, $P = 0.027$) than younger breeders. No differences were observed between older and younger breeders in congeneric pairs of their consumption of deer, rabbits, fur bearer, pig, and other food items ($t_{227} \leq 1.83$, $P \geq 0.065$).

No seasonal differences were detected in consumption of deer, small mammals, and other food items ($t_{969} \leq 0.70$, $P \geq 0.484$) by red wolves. Red wolves consumed less fur bearers and pigs and more rabbits during winter than summer (Table 5; $t_{969} \geq 2.24$, $P \leq 0.025$). Coyote pairs consumed more deer and less rabbits during winter than summer ($t_{552} \geq 3.38$, $P \leq 0.001$). No seasonal differences were detected in coyote consumption of small mammals, fur bearers, pig, and other food items ($t_{552} \leq 1.57$, $P \geq 0.060$). Congeneric pairs consumed more deer and less other food items ($t_{227} \geq 2.01$, $P \leq 0.046$) during summer than winter. No seasonal differences were detected in the consumption of rabbits, small mammals, fur bearers, and pig by congeneric pairs ($t_{227} \leq 1.93$, $P \geq 0.060$). Also, smaller red wolf packs consumed more deer than larger packs

whereas larger packs consumed more rabbit, small mammals, fur bearers, pig, and other food items (Figure 1; $t_{969} \geq 2.63$, $P \leq 0.009$).

The most important factors for explaining variation of deer in red wolf diet was breeder weight and pack size (Table 6). Consumption of rabbits of was best explained by breeder age and deer density. All factors were important in explaining red wolf consumption of small mammals and pig. Red wolf consumption of fur bearer was best explained by summer and weight and other food items were influenced by deer density and season. Coyote consumption of deer and rabbits were best explained by weight and season (Table 7). Age, weight, deer density, and season best explained coyote consumption of small mammals and deer density best explained consumption of other food items. Season best explained consumption of deer and other food items by congeneric pairs (Table 8). Deer density, season, and age influenced consumption of rabbits and deer density and season influenced use of small mammals. Consumption of fur bearers and pig by coyote pairs and congeneric pairs was negligible and therefore not modeled.

Discussion

Little is known about the historic diets of red wolves throughout the Southeast because red wolf natural history and ecology was never well-documented. Previous diet assessments of remnant, declining red wolf populations in salt marsh and coastal habitats of Texas and Louisiana during the mid-20th century indicated red wolf diet consisted of nutria, rabbits, and cotton rats (Paradiso & Nowak, 1972; Shaw, 1975). Recent studies conducted after red wolves were reintroduced into NENC indicated greater use of deer and rabbits than the source population (Phillips *et al*., 2003; Dillenger *et al*., 2011a; McVey et al., 2013). Conversely, coyote diet has been studied extensively throughout North America in which they have been labeled as generalists or opportunistic foragers (Henderson, 1930; Korschgen, 1957; Prugh, 2005; Chamberlain & Leopold, 1999; Schecengost *et al*., 2008). Our results demonstrate that red wolves and coyotes in northeastern North Carolina have a strong carnivorous diet and consume primarily mammalian prey, such as deer, rabbits, and small mammals.

Management activities to sterilize coyotes within the Recovery Area influence factors affecting coyote interactions with prey by preventing coyote and congeneric packs from forming packs. For instance, pack size was an important factor influencing red wolf diet in which the diet of packs of fewer than 4 individuals contained greater amounts of deer and less small mammal prey than packs of 4 or more individuals. The negative relationship between pack size and food acquisition has been observed in gray wolves (Nudds, 1978; Thurber & Peterson, 1993; Schmidt & Mech, 1997; MacNulty *et al*., 2011) and our data suggest that red wolves are constrained by similar group dynamics. Although we couldn't assess effects of pack size on coyote diet, we can only speculate that the diets of coyote and congeneric pairs would be similarly constrained by group living dynamics that affect cooperation and conflict within their packs as they increase in size.

Pack size likely caused variation in red wolf diet by effecting pack hunting efficiency and energetic gains acquired from kills. Recently, MacNulty *et al*. (2011) examined hunting efficiency of gray wolf packs and proposed the free-riding hypothesis in which pack members can decrease hunting efficiency by superficially cooperating in hunts to gain access to kills. Although our study was not designed to assess hunting efficiency of red wolves, deer consumption peaked with smaller red wolf packs and that may indicate greater hunting efficiencies at smaller group sizes. It is difficult for our study to discern whether pack hunting efficiency was truly affected by pack size because larger wolf packs had greater percentages of rabbits, fur bearers, pig, and other food items in their diet to compensate for the decrease in use of deer. If hunting efficiency remained the same between small and large red wolf packs, it is likely that deer comprised a lower percentage of the diets of larger packs because kills had to be divided and shared among more individuals. This would cause larger red wolf packs to broaden their diet to include other prey to supplement energetic loses from sharing their deer kills with offspring. Whether large packs experience lower hunting efficiencies or reduce energetic profits from kills through sharing, it is likely that increasing red wolf density within territories has a negative effect on

foraging that may eventually facilitate fragmentation of packs through parent-offspring conflicts over food acquisition (Gese *et al*., 1996).

Canis species lack adaptations for prey control (i.e., grappling abilities) and increased body weight likely improves their killing ability by allowing individuals to more effectively hold down large prey while other pack members deliver repeated bites to the abdomen and hindquarters. Dentition is also a primary trait used to subdue prey and substantial, prolonged bite forces that are necessary for handling large prey put considerable stress on teeth (Van Valkenburgh, 1991; Slater *et al*., 2009). MacNulty *et al*. (2009a) observed that the ability of gray wolves in Yellowstone National Park to kill ungulates improved with increased body size. Also, hunting performance of gray wolves was observed to decrease with age because of physiological deterioration caused by senescence (MacNulty *et al*., 2009b). Similarly, we found body weight and age of red wolf breeders to influence pack diet. Although age was not an important variable predicting red wolf consumption of deer, its positive correlation with consumption of smaller-sized prey indicates that older breeders depended more on rabbits and small mammals for food than did younger breeders. As individuals age, canines and incisors are eventually worn down and fractured because of repetitive use and it's not unusual for red wolves > 4 years of age to have substantially worn and damaged teeth (USFWS, *unpublished data*). As a result, we suspect that deterioration to dentition through aging was a primary reason older breeders relied on smaller-sized prey.

As observed with red wolf packs, larger coyote pairs consumed more deer than smaller conspecifics. Coyote pairs also consumed more deer during winter than summer and our findings are contrary to many studies conducted on coyote diet in the southeastern United States (Chamberlain & Leopold, 1999; Schrecengost *et al*., 2008; Kilgo *et al*., 2012). These studies have indicated that coyote predation of deer occurs primarily on fawns during summer and coyote consumption of deer during winter is a result of scavenging of hunter dump sites or deer crippled or un-recovered by hunters (Chamberlain & Leopold, 1999; Thornton *et al*., 2004; Schrecengost

et al., 2008). We do not believe that scavenging explains increased use of deer during winter because the positive relationship between coyote consumption of deer and coyote body weight implies that body size is an important trait for coyotes to acquire deer in their diet through predation, whereas scavenging is opportunistic and should not be affected by body size. Coyotes in the western United States have been observed hunting and killing white-tailed deer (Patterson & Messier, 2000; Lingle & Pellis, 2002), mule deer (*Odocoileus hemionus*; Bowyer, 1987; Lingle & Pellis, 2002), elk (*Cervus elaphus*; Gese & Grothe, 1995), bighorn sheep (*Ovis Canadensis*; Bleich, 1999), pronghorn (*Antilocapra americana*; Keller *et al*. 2013) and other large prey. Therefore, it is reasonable to assume that coyotes in the southeastern United States are capable of killing deer outside of the fawning season.

The average coyote lifespan in this study was statistically lower than red wolves by almost 2.5 years because many coyotes were removed from the landscape for management reasons related to red wolf recovery or opportunistically by hunters and trappers (Hinton, *unpublished data*). Therefore, it is difficult to insinuate whether the effects of age on coyote and congeneric pair food habits were related to physiological deterioration or experience. Older coyote breeders consumed more white-tailed deer, but this consumption is probably a result of a few coyote breeders approaching their peak performance age of 3-4 years old. If natural senescence had been more common with coyotes in our study area, we believe that age would have had a similar effect on coyote and congeneric pair food habits as it did on red wolf packs.

Although congeneric pairs typically weighed 20-40% more than coyote pairs and consumed 10% more deer, breeder weight was not useful in explaining variation in use of deer in the diets of congeneric pairs. This discrepancy is likely a result of management actions that remove coyotes from congeneric pairs to make resident red wolves available to dispersing red wolves during the breeding season. Therefore, most congeneric pairs form during late winter or early spring when management actions shift to monitoring red wolf denning behavior. Solitary red wolves acquiring a coyote mate likely increase hunting efficiency during spring and summer

but, when they lose their coyote mate to management action prior to the breeding season, they hunt solitarily until they find a new mate.

A 15-20 kg threshold was proposed in which carnivores weighing above that threshold would have to switch to larger vertebrate prey that approach their body weight because of higher energetic demands and constraints related their body size (Carbone *et al*., 1999; Carbone *et al*., 2007). Coyotes in northeastern North Carolina approach the 15-20 kg threshold and the smallest red wolves are above it. How these pairs adjust energy budgets associated with changes in breeder body mass and hunting efficiency is unknown. Differences in body size between red wolves and coyotes will affect energy requirements and capacities for searching for and processing prey which, in turn, may affect how they perceive the distribution, abundance, and profitability of prey on the landscape. Therefore, the formation of congeneric pairs and the stability of those pairs to successfully raise hybrid litters may be related to how similar individuals are in their energy demands. Partitioning of food resources by red wolves and coyotes in northeastern North Carolina is mostly via differences in the quantity of similar prey exploited and via differences in types of prey used. This is probably a result of greater energetic demands placed on red wolves from their larger body size to rely more on deer, rabbits, and fur bearers and indicates that the diets of red wolves and coyotes conform to the predictions from existing theory on foraging behavior in which relative body size appear to be important factors governing the overlap of resources and intensity of competition (Rosenzweig, 1966; Gittleman, 1985; Carbone *et al*., 2007). Different use of prey, habitat, and space use by red wolves and coyotes resulting from differences in body sizes may serve as a reproductive barrier by preventing congeneric pairing. Therefore, we hypothesize that hybridization rates between red wolves and coyotes increase as both populations approach each other in body size. Our ability to identify key traits and understand how they facilitate reproductive barriers is crucial for red wolf recovery.

CHAPTER 5

SPACE USE AND HABITAT SELECTION BY RESIDENT AND TRANSIENT COYOTES

Hinton, J.W., M.J. Chamberlain, and F.T. van Manen. To be submitted to the *Journal of Animal Ecology*.

Abstract

Little information exists on coyote spatial ecology in the southeastern United States and the few studies conducted have been conducted at small scales (e.g., ≤ 500 km2). Studies on coyote ecology in the Southeast have typically been conducted at small scales (e.g., ≤ 500 km²) and often provide conflicting insights regarding coyote ecology. Therefore, studies of coyote spatial ecology at broader geographic areas (e.g., ≥ 2,500 km2) may provide relevant insights as to how coyote populations adjust to various ecological circumstances on the landscape. During 2009-2011, we studied coyote space use and habitat selection on the Albemarle Peninsula (>6,000 km^2) of northeastern North Carolina using GPS radio-collars. We quantified home range sizes and 2nd- and 3rd-order habitat selection for resident and transient coyotes to describe space use patterns in response to a dynamic agricultural landscape. We observed an upper limit on coyote home-range sizes to be approximately 50 km² and suggest body size constraints may limit the amount of finite space coyote groups can maintain as a territory. We also observed preferences for agricultural habitats over forested habitats by resident and transient coyotes, and resident coyotes pushed transients into marginal forest habitats. Coyotes had exhibited avoidance of roads during diurnal hours despite exhibiting preferences for them during nocturnal hours. Overall, loss of cover resulting from harvest of agricultural crops facilitated strong shifts to using forested areas for cover by resident coyotes during fall and winter. Consequently, use of forested areas by resident coyotes forced transient coyotes to rely more on road and edge habitats during fall and winter.

Introduction

Coyote colonization of eastern North America has generated much interest from ecologists and the general public (Gompper 2002; Levy 2012) because it occurred in several waves (Parker 1995; Nowak 2002; Bozarth et al. 2011), resulting in noticeable changes in phenotype (i.e., body size and pelt color; Thurber and Peterson 1991; Way 2007) and hybridization with remnant wolf populations (Kays et al. 2010; Wheeldon et al. 2010). Presence

in eastern North America during the Pleistocene indicates that coyotes have history of range expansions and contractions that can be attributed to the emergence and loss of other *Canis* competitors on the landscape (Nowak 2002) and changes in climate (Koblmüller et al. 2012). Although successful colonization has been attributed to the coyote's generalist behaviors, phenotypic plasticity, and ability to hybridize with remnant wolf populations, developing a conceptual framework for understanding coyote range expansion remains contentious (Thurber and Peterson 1991; Lariviére and Créte 1993; Kays et al. 2010; Wheeldon et al. 2010).

Coyote colonization of the southeastern United States has received more attention in recent years, but little information exists on large scale spatial and temporal patterns of landscape use by coyotes in the region. Studies on coyote ecology in the Southeast have typically been conducted at small extents (e.g., $\leq$ 500 km²) and often provide conflicting insights. Fine-scale studies are problematic because they fail to capture broad scale variations in coyote ecology and landscape structure that can be used to explain why coyotes have become established throughout the Southeast. Aspects of coyote spatial ecology that influence variation in size and habitat composition of home ranges have important consequences for processes such as population growth and regulation because differential use of space and habitats allows access to important prey species and reduces risks of mortality, both of which affect survival and reproduction. Therefore, studying the placement, size, and habitat composition of coyote home ranges over broad geographic areas (e.g., $\geq$ 2,500 km^2) will provide relevant insights as to how coyote populations adjust regionally varying ecological conditions.

In particular, the effects of eastern forested and agricultural landscapes on coyote movements and space use in the Southeast are not well known. While it has been suggested that eastern forested landscapes represent marginal habitat for coyotes (Tremblay et al. 1998; Crête et al. 2001; Richer et al. 2002), other studies have suggested that eastern forests are suitable habitat (Kays et al. 2008). Although these studies were conducted in the Northeast, many regions of the Southeast are characterized by large agriculture-forested mosaics similar to areas colonized by

coyotes in the Northeast and generalities can be drawn by comparing studies conducted in different regions. For instance, coyote home-range sizes typically vary between 2.5 – 70 km^2 (Bekoff and Gese 2003; Leopold and Chamberlain 2001). Although variability can be attributed to adjustments of space use patterns to local environmental conditions, a central tendency of coyote space use is driven by their metabolic needs, which is known to vary with body mass (McNab 1963; Gompper and Gittleman 1991). Along with body size, locomotor mode is known to be a key parameter for explaining large scale patterns in carnivores (Van Valkenburgh 1999). Coyotes are cursorial carnivores that evolved in the extensive grassland region of central North America. Dense forested areas may make pursuit hunting, and therefore resource acquisition, more difficult for coyotes. On the other hand, agricultural fields and early successional habitats may be analogous to the open, expansive habitats to which coyotes are adapted, and may provide ideal habitat for population centers. Therefore, understanding coyote distributional patterns in response to habitat heterogeneity is fundamental to develop a full understanding of how this species successfully colonized eastern North America.

Coyotes are sympatric with red wolves in northeastern North Carolina and both species are managed and monitored by the United States Fish and Wildlife Service (USFWS) Red Wolf Recovery Program (Recovery Program) on the Albemarle Peninsula of northeastern North Carolina (Hinton et al. 2013; Rabon et al. 2013). Red wolves show strong preferences for agricultural fields over the surrounding forested areas (Chadwick et al. 2010, Hinton and Chamberlain 2010, Dellinger et al. 2013) and very high frequency (VHF) radio-telemetry data indicates that coyotes exhibit similar habitat preferences (USFWS *unpublished*). It is suspected that coastal bottomland forests and wetlands are unsuitable habitat to red wolves and coyotes in northeastern North Carolina because dense understories and periodic inundation hinder or prevent movements. On the other hand, agricultural croplands may provide suitable habitat because they are dry, treeless environments with no understory structure to hinder movements and foraging efforts. Although the effect of roads on coyote movements remains unknown, previous gray wolf

(James and Stuart-Smith 2000; Whittington et al. 2005) and red wolf (Dellinger et al. 2013) studies suggested that secondary, low-use roads provided some benefit to wolves by increasing foraging efficiency and lowering movement costs. Coyotes are known to have higher tolerance to human presence than wolves (Grinder and Krausman 2001; Atwood et al. 2004; Way et al. 2004; Gehrt et al. 2009) and studies have documented coyote use of roads in heavily populated urban areas (Tigas et al. 2002; Way 2009; Gehrt et al. 2011; Hinton et al. 2012). This trait may allow them to exploit primary (paved) and secondary (unpaved) roads as travel corridors through barriers (i.e., rivers) and unsuitable habitats regardless of human density.

With *a priori* assumptions that forested areas in northeastern North Carolina represent poor habitat for coyotes, we monitored resident and transient coyotes fitted with global positioning system (GPS) radio-collars to assess ways in which coyotes move, interact, and use several primary habitats on the Albemarle Peninsula. During summer, we expected coyotes to avoid forested areas and increase their use of row crops (i.e., corn, soybean, and winter wheat) because crops provide adequate cover with little understory to impede movements. We also expected coyotes to increase their use of forested areas for cover during winter because crops were harvested and forests provided the only cover during that time of year. Transient coyotes are individuals that have not established residency and display nomadic movement with no fidelity for any one area; they also may display different space use patterns than resident coyotes that maintain home ranges (Gese et al. 1988, Kamler and Gipson 2000; Hinton et al. 2012). Previous work observed localized space use patterns lasting between 2-8 weeks that were analogous to patterns of home range use (Hinton et al. 2012). These space use patterns of transients were called biding areas and studying them may provide important insights into how coyotes move through the landscape searching for unoccupied areas and/or mates to establish residency. This study represents the first broad scaled study (> 5000 km^2) of resident and transient coyotes in the southeastern United States.

Study Area

Our study was conducted on the Albemarle Peninsula in the northeastern region of North Carolina (Figure 1). The study area was approximately 6000 km^2 of federal, state, and private lands comprised of a row-crop agricultural-bottomland matrix with little change in elevation (0-50m). Agricultural crops (i.e., corn, cotton, soybean, and winter wheat) and managed pine (*Pinus* spp) comprised approximately 30% and 15% of the land cover, respectively (Figure 1). Other prominent land cover types were coastal bottomland forests and pocosin (35%), herbaceous wetlands and saltwater marshes (5%), open water (5%), and other minor land cover types (10%). The climate was typical of the mid-Atlantic: 4 full seasons, nearly equal in length, with an annual precipitation averaging between 122-132 cm. Summer climate was typically hot and humid with temperatures ranging from 27°C to over 38°C and winters were relatively cool with temperatures ranging between -4°C to 7°C.

Methods

We captured coyotes using padded foot-hold traps (Victor no.3 Softcatch, Lititz, Pennsylvania, USA) from October through May during 2009-2011. Coyotes were sexed, measured, weighed, aged by tooth wear (Gier, 1968), and a blood sample was collected. We categorized coyotes as > 2 years old as adults, < 2 but > 1 year old as juveniles, and < 1 year old as pups. Coyotes on the Albemarle Peninsula were reproductively sterilized by the USFWS to prevent introgression into the red wolf population (Hinton et al. 2013; Rabon et al. 2013). Coyotes were taken to a local veterinary clinic for surgical sterilization where males and females were reproductively sterilized by vasectomy and tubal ligation, respectively. This process kept hormonal systems intact to avoid disrupting breeding and territorial behavior (Seidler and Gese 2012). Prior to release at the original capture sites, we fitted coyotes with a mortality-sensitive GPS radio-collar (Lotek 3300s, Newmarket, Ontario, Canada) scheduled to record a location every 4 hours (0:00, 04:00, 08:00, etc.) throughout the year. Animal handling methods were

approved by the Louisiana State University Agricultural Center Institutional Animal Care and Use Committee (Protocol Number AE2009-19).

To reflect the anthropogenic effects of agriculture on the landscape, we divided year into 2 6-month seasons based on agricultural activity: planting/growing (1 March – 31 August) and harvest/fallow (1 September – 28 February). We also separated coyote locations for each season into diurnal and nocturnal categories based monthly photoperiods. We estimated space use of resident and transient coyotes by fitting dynamic Brownian bridge movement models (dBBMMs) to the time-specific location data to estimate the probability of use along the full movement track of each coyote (Kranstauber and Smolla 2013) using the R package moveud (Collier 2013) in the R statistical environment (R Core Team 2013). We chose window sizes based on the temporal resolution of each track and our *a priori* assumptions of the time scale of major behavioral shifts (Byrne et al. 2014). For resident coyotes, 95% and 50% contour intervals were considered home ranges and core areas, respectively. For transient coyotes, 95% and 50% contour intervals were considered transient range and biding areas (Hinton et al. 2012), respectively. We used *t*-tests to examine changes in home range and space use sizes between seasons.

Predominant habitat types were estimated from a digitalized landscape map of vegetative communities developed by the North Carolina Gap Analysis Project (McKerrow et al. 2006). We collapsed the vegetative communities estimated by McKerrow et al. (2006) into 7 general habitat types with 30m resolution. For the habitat selection analysis, we divided the landscape into agriculture, coastal bottomland forest, pine forest, open water, upland forest, urban, and wetland. Because roads may serve as corridors for coyote movements, we included road as the 8th habitat type by superimposing a linear feature layer with a 30m buffer around roads onto the final habitat raster map with 30m resolution.

We used analysis of variances (ANOVAs) and *t*-tests to determine if the percentage of habitat composition of home ranges and transient ranges differed between each other and between seasons. We also developed generalized linear models (GLMs) to examine the effects of coyote

body weight and age, white-tailed deer abundance, and habitat composition on coyote home-range size. We used county-level harvest data collected by the North Carolina Wildlife Resources Commission as a measure of deer abundance in the study area. Although harvest reports do not reflect true white-tailed deer densities, hunter harvest/km^2 does provide a benchmark by which to judge the effect of white-tailed deer abundance on coyote home-range size. Habitat composition of home ranges were calculated as % agricultural, % forest (coastal bottomland and pine), and % road. We assessed models using a stepwise procedure by calculating Akaike's information criterion for small sample sizes (AIC_c) for each model to select which variables best explained home-range size.

We compared habitat selection of coyotes at two scales: population (2^{nd}-order) and individual (3^{rd}-order). Habitats were converted into continuous variables by quantifying percent of habitat cover for each 30m cell using a moving window with a 150m radius in FRAGSTATS (McGarigal et al. 2012). We also quantified edge density and patch richness across the study area because coyotes are known to forage along edges (Tigas et al. 2002). Information from raster maps were extracted to coyote locations and home ranges using ArcGIS 10.1 (Environmental Systems Research Institute Inc., Redlands, California). We used resource-selection functions (RSFs) to examine the effect of habitat type on where coyotes established home ranges on the landscape (2^{nd}-order selection of resources; Johnson 1980) and examine the effect of habitat type on how coyotes use their home ranges (3^{rd}-order selection of resources; Johnson 1980) following Manly et al. (2002). We assumed seasonal and photoperiod variation in habitat use by residents and transients and, therefore, developed RSFs for residents and transients by season and photoperiod for 3^{rd}-order selection. We used a binomial approach to estimate resource-selection functions by comparing characteristics of known (used) locations to random (available) locations (Manly et al. 2002). We used logistic regression and AIC_c to form RSFs that identified habitats important to individual coyotes. We evaluated the relative importance of coefficients associated with the habitat types by examining Akaike weights (w_i) after adding each of these covariates to a

core model set (e.g., higher w_i and lower AIC_c suggested model improvement; Burnham and Anderson 2002). We also evaluated the predictive performances of the most parsimonious core models using the *k*-fold cross validation method (Boyce et al. 2002; Johnson et al. 2006). The cross-validation method performs *k* iterations of training and validation in which a different fold of the data is held out for validation while the remaining $k - 1$ folds are used for learning. For cross-validation, we used 10 folds ($k = 10$) to estimate performance of RSF models.

Results

During 2009-2011, we monitored 28 coyotes fitted with GPS radio-collars. We monitored 22 (79%) resident and 6 (21%) transient coyotes and 8 (29%) coyotes were transients prior to becoming residents. Mean weight and age of coyotes monitored were 14.0 kg ± 0.4 and 2.5 yrs ± 0.2, respectively, in which weights and age of residents were greater than transients (Table 1; $t_{26} \geq 2.23$, $P \leq 0.034$). Home ranges and core areas of residents did not differ between seasons (Table 2; $t_{45} \leq 0.024$, $P \geq 0.800$) and home ranges ranged from 13.4 km² to 47.3 km². We also detected no seasonal difference of transient ranges and biding areas (Table 1; $t_{17} \leq 1.86$, $P \geq 0.080$) and transient areas ranged from 64.5 km² to 633.4 km². Home range size was best explained by the percentage of agricultural fields, white-tailed deer density, and forested areas in which home range size decreased with increasing percentage of agricultural fields ($r^2 = 0.30$, $P = 0.007$) and deer density ($r^2 = 0.40$, $P = 0.001$), but increased with increasing percentage of forests ($r^2 = 0.33$, $P = 0.004$).

Home ranges and core areas were comprised mostly of agricultural fields, coastal bottomland and pine forest, and roads (Figure 2; $F_{6, 161} = 36.69$, $P < 0.001$). Pine and upland forest, urban, road, and wetland composition between home ranges and core areas did not differ ($t_{46} \leq 1.31$, $P \geq 0.195$) but home ranges typically consisted of more coastal bottomland forest and less agricultural fields than did core areas ($t_{46} \geq 2.39$, $P \geq 0.022$). Similarly, transient ranges and biding areas were comprised mostly of agricultural fields, coastal bottomland and pine forests, and roads (Figure 2; $F_{6, 161} = 60.23$, $P < 0.001$). We found no differences in habitat composition

between transient ranges and biding areas ($t_{28} \leq 1.67$, $P \geq 0.105$). Home ranges consisted of more pine forests and roads and less wetlands than transient ranges ($t_{103} \geq 2.07$, $P \leq 0.022$), whereas all other habitat types were similar ($t_{103} \leq 1.06$, $P \geq 0.293$). Core areas consisted of more pine forests and less coastal bottomland forests and wetlands than biding areas ($t_{103} \geq 2.30$, $P \leq 0.024$), whereas all other habitat types were similar ($t_{103} \leq 0.96$, $P \geq 0.337$). We detected no seasonal differences between habitat types of home ranges and core areas ($t_{45} \leq 1.25$, $P \geq 0.219$) and transient ranges and biding areas ($t_{17} \leq 1.27$, $P \geq 0.220$).

We excluded wetland, upland forest, and urban habitats from our models because their occurrence in home ranges and transient ranges were negligible. Therefore, we only included edge density, patch richness, and agriculture, pine forest, coastal bottomland forest, and road habitats in our model. Only 1 covariate (edge density) was not retained in the top-ranked model for 2nd-order selection by residents (Table 2) whereas all 6 covariates were retained for transients (Tables 3). Roads, coastal bottomland forests, and patch richness were better predictors of transient occurrence than residents at the landscape level (Table 4). Agriculture, pine forest, and road habitats were retained in all top-ranked models for 3rd-order selection by residents (Table 2). Residents appeared to favor agricultural fields and pine forests during both seasons and photoperiods, whereas roads were avoided during day but used at night (Figures 4&5; Table 4). Coastal bottomland forest, pine forest, and patch richness were retained in all top-ranked models for 3rd-order selection by transients (Table 3). Coastal bottomland and pine forests were used by transients more during the growing season than harvest season, whereas patch rich areas were preferred during both seasons and photoperiods (Figures 6&7; Table 4). Similar to residents, transients used roads more at night than during day.

Discussion

The broad front of coyote expansion throughout North America is a result of dynamic space-use patterns by coyotes that permit them to move across and persist in a variety of environments. In particular, coyote populations consist of resident and transient individuals

(Andelt et al. 1985, Gese et al. 1988, Kamler and Gipson 2000). Similar to other studies (Gese et al. 1988, Windberg and Knowlton 1988, Chamberlain et al. 2000), our results indicate that approximately 70% of coyotes in northeastern North Carolina are likely residents whereas the remaining 30% are transients.

Home-range sizes of coyotes did not vary between seasons despite an average 35% reduction in winter cover within home ranges resulting from crop harvest (Figure 2). This indicates that coyotes may not adjust home range size to immediate demand, but rather potential demand. In other words, coyotes most likely learn changes in the environment prior to establishing residency so that space acquired for home ranges is adequate to accommodate seasonal fluctuations in resource needs. Home ranges did not exceed 50 km^2 indicating that coyotes may have an upper limit to the amount of space they can effectively exploit and defend. Coyotes must be able to defend a finite area and handle the distribution of prey while maintaining a consumption rate below resource renewal to assure long-term maintenance of their home ranges. Our mean home-range sizes are typical of those reported in other studies (see Table 22.4 in Bekoff and Gese 2003 & Table 21 in Leopold and Chamberlain 2001) and similarity among studies indicates that there is a central tendency in coyote space use that is likely constrained by the effects of body size (McNab 1963; Swihart et al. 1988; LaBarbera 1989). Although we found habitat type and white-tailed deer density to have a stronger effect on variation of home-range size than did body size, it is important to note that body size is an endogenous factor resulting from evolutionary forces that reduce variability, whereas exogenous factors such as habitat and resource density would influence variation around a central tendency in coyote space use. Effects of body size on space use patterns are well established and they should be routinely tested and reported in studies of coyote spatial use regardless of statistical significance. Coyotes exhibit phenotypic variation by regions (Thurber and Peterson 1991; Way 2007) and reporting such information allows ecologists to accurately draw conclusions regarding the effects of habitat and physiology on coyote space use.

Territorial behavior in coyotes assures ideal reproductive possibilities to residents holding space (Gaston 1978). Although this prevents transients from reproducing, transiency is likely an important trait that allows populations to reconstruct themselves rapidly after suffering drastic and extensive mortality. This may be particularly important for coyote populations to persist where they are heavily exploited. Despite their wide-ranging space use patterns, many transients exhibited localized movements that were analogous to home ranges and we referred to them as biding areas (Hinton et al. 2012). Seven of the 8 (88%) residents that were transients established home ranges in or nearby their biding areas. We suggest this behavior may prove beneficial to coyote populations and should be examined in future studies because it increases survivorship of transients via familiarity of areas they roam, allows transients to assess potential areas prior to establishing home ranges, and, when opportunities arise, they can replace residents upon death.

Effects of agriculture and forest habitat on coyote space use in northeastern North Carolina are similar to those reported in other studies in the Northeast and indicate general preferences for open, treeless environments by coyotes (Crête et al. 2002, Gosselink et al. 2003, Van Deelen and Gooselink 2006). The general compositional pattern in coyote home ranges were high percentages of agricultural fields in the interior (i.e., core areas) with forest edges increasing in outer fringes. The forest cover coyotes favored in our study were pine plantations. During harvest season, coyotes typically loafed in forest habitats within 50-300m of edges adjacent to agricultural fields and roads. As winter wheat reached heights of approximately 0.5 meters during the growing season, coyotes abandoned forest habitats to loaf in wheat fields when available and then shifted to corn later in the season as wheat was harvested (Hinton, *personal observation*). Home range size decreased as agricultural fields became the predominant habitat type and vice versa for forested habitats. For example, the home range of a female coyote with the smallest home-range size (13.4 km^2) consisted of approximately 40% and 30% agricultural and forested habitat, respectively. Of her 1987 GPS locations, approximately 87% of them occurred in agricultural fields. On the other hand, the home range of a female coyote with the largest home-

range size (47.3 km^2) consisted of approximately 10% and 70% agricultural and forested habitat, respectively. Of her 2296 GPS locations, approximately 35% of them were in agricultural fields.

Although transients displayed similar attraction to habitat types as residents, residents occupied ideal habitats and most likely push transients into marginal habitats. Resource-selection models were useful in teasing out this effect and demonstrated where patterns of habitat use diverged from those of residents. Models of 2^{nd}-order selection indicated that coastal bottomland forest, roads, and edges were more important to transients than residents. Transients were typically pushed into forested areas and frequent use of roads and edges was likely to reduce the energetic costs of nomadic movements in these highly structured habitats. Conversely, models of 3^{rd}-order selection indicated 2 temporal changes in habitat use by residents that are related to foraging and security. First, they avoided roads during diurnal hours despite relying on them during nocturnal hours when they were foraging and defending their home ranges. This behavior is likely a way to avoid contact with humans, which will occur more during diurnal hours. Second, residents avoided coastal bottomland forest during the growing season and increased use of them during the harvest season, specifically during diurnal hours. Residents ceased use of coastal bottomland forests during nocturnal hours and the diurnal use by residents suggests coastal bottomland forests were used for security. Transient use of roads during nocturnal hours is likely for similar reasons as residents. Nevertheless, their habitat use patterns deviated significantly from residents during the harvest season. Agricultural fields had little influence on transient habitat use and transients avoided forested areas while depending more on roads and edge habitats for foraging and security. Most agricultural fields are barren after harvest and likely provide little foraging or security benefit to transients. Avoidance of forest habitats by transients during the harvest season is likely a result of increased use of these habitats by residents. In other words, shifts in the use of habitats by residents as a result of landscape-wide agricultural activities created significant shifts in habitat use by transients.

Coyote populations appear adept at exploiting human modified landscapes, specifically road networks, because linear features facilitate travel while providing foraging opportunities. Although transients were documented using coastal bottomland forests, we suspect those locations were more associated with the road network than the actual forested habitat (Figure 7). Roads may provide benefits to coyotes through efficient movements that improve foraging and territorial defense (i.e., scent marking) and may allow resident coyotes to detect human presence and assess predictable patterns of human activities to increase security. While facilitating transient movements on the landscape, roads may also guide coyotes into suitable habitats modified by humans such as agricultural fields. Interestingly, road networks through unsuitable forest habitat may decrease intraspecific strife by reducing or masking transient movements through territories of residents.

Coyotes colonized eastern North America in several waves occurring at different periods of the 20th century (Nowak 2002; Bozarth et al. 2011). Although it is well documented that coyotes began colonizing Arkansas, Louisiana, Mississippi, and Alabama during the mid-20th century after the extirpation of red wolves (McCarley 1962; Nowak 2002), there has been no parsimonious explanation of how coyotes have colonized the remainder of the Southeast. Large-scaled construction of the Interstate Highway system facilitated significant changes to the physical landscape of the United States during the 1960s, 1970s, and 1980s as a result of the Federal Highway Act of 1956 (Lewis 2013). Additionally, the Watershed Protection and Flood Prevention Act of 1954 encouraged land drainage and wetland destruction that resulted in significant loss of bottomland forests in the Southeast (Harris and Gosselink 1990, Dahl and Allord 1996). Several studies, including this one, have found eastern forests to be relatively poor habitat for coyotes (Tremblay et al. 1998; Crête et al. 2001; Richer et al. 2002) and that coyotes are capable of exploiting human altered landscapes and road networks (Tigas et al. 2002; Way 2009; Gehrt et al. 2011; Hinton et al. 2012). Therefore, we propose that, in concomitant with the extirpation of red wolves, large-scale changes to the landscape through development of extensive

road networks, agriculture, and residential areas during the 1960s-1980s allowed for the eventual colonization of the Southeast by coyotes by the turn of the 21st century.

CHAPTER 6

SPACE USE AND HABITAT SELECTION BY RED WOLVES

Hinton, J.W., M.J. Chamberlain, J.L. Gittleman, and F.T. van Manen. To be submitted to *Animal Conservation*.

Abstract

A general lack of knowledge regarding the ecology of our most imperiled carnivores continues to hamper recovery efforts. This is particularly true for red wolves because they were completely extirpated before any ecological profile was developed to assist recovery efforts. Therefore, reintroduction efforts were conducted with little-to-no knowledge of the species ecology. In this study, we radio-collared 34 red wolves in northeastern North Carolina to identify patterns of space use and habitat selection for resident and transient red wolves. Red wolf home range size scales positively with body weight and energetic requirements may influence variation in home range more than vegetation cover. Overall, red wolves prefer open, treeless agricultural fields over the forested habitats in the Recovery Area. Although transients display similar attraction to habitat types as residents do, resource-selection models are useful in defining differences in habitat selection between transients and resident red wolves. Specifically, transients are more likely to use forest cover and rely on road networks for travel. Reduced use of forest habitats and reliance on road networks indicates the importance of open habitats for red wolves. We suggest, prior to European settlement, fire regimes created by Native Americans and natural processes that maintained grasslands and open woodlands may have influenced red wolf abundance and distribution. We also suggest that the use of control burns to create early successional habitats and reduce forest understory may be beneficial to red wolf recovery via creating more suitable habitat.

Introduction

Carnivore reintroductions are extremely difficult and typically result in failure (Reading & Clark 1996; Breitenmoser *et al*. 2001; Gittleman and Gompper 2001). This is because the persistence of large carnivore populations is dependent on specific ecological requirements (i.e., expansive areas, access to large prey, and low mortality rates) that are difficult to achieve. Our general lack of knowledge regarding those requirements hinders conservation strategies because recovery efforts are conducted in the presence of factors responsible for global declines in large

carnivores (Breitenmoser *et al*. 2001; Hayward *et al.* 2007). As a result, recovery of large carnivores remains a primary challenge to conservation biologists because area-size requirements, negative public perception, and government-supported campaigns designed to protect livestock and hunting industries continue to hamper recovery of large carnivores in the United States (Kellert *et al*. 1996; Ripple *et al.* 2014). In particular, the conservation of red wolves (*Canis rufus*) has been exceptionally difficult because of their vulnerability to extinction via human-caused mortality and hybridization with coyotes (*Canis latrans*; Hinton *et al*.2013).

Indigenous to the United States, red wolves were completely extirpated from their historic range by 1980 and later reintroduced into northeastern North Carolina in 1987 (USFWS 1989). Although the North Carolina reintroduction has been successful, a lesser well known reintroduction attempt from 1991 until 1998 in Great Smoky Mountains National Park failed because red wolves were unable to maintain territories within park boundaries and the population suffered from low pup survivorship (Henry 1998). Similarly, red wolves in northeastern North Carolina preferred agricultural habitats of private lands over forested habitats provided by federal lands. To address this constraint, the Red Wolf Recovery Program (Recovery Program) developed management strategies to include private lands and non-federal stakeholders that allows for the expansion and management of the red wolf population on private, non-federal lands (Rabon *et al*. 2013). As a result, red wolves persist in an agricultural-bottomland forest landscape that is a mosaic of private and public lands. Recovery Program biologists are therefore faced with potential issues of predicting how the red wolf population will organize itself on the landscape as it increases, anticipate logistic and social constraints (i.e., conflicts with landowners and hunters), and understanding red wolf-coyote interactions. Therefore, studying the size and placement of red wolf home-ranges on the landscape will not only allow us to describe red wolf space use and habitat selection, but it will also allow us to identify landscape characteristics that are favorable to red wolf recovery. Additionally, space use patterns can provide information regarding where red wolves forage, disperse, and interact with coyotes.

Initial research conducted on remnant red wolf populations failed to develop an ecological profile of the species because biologists were constrained by the necessity to locate small pockets of declining populations, develop techniques to distinguish red wolves from coyotes and red wolf/coyote hybrids, and to establish a captive breeding program (McCarely 1962; Shaw 1975; Carley 2000). Although the Recovery Program has monitored and maintained a wild population in northeastern North Carolina for over 2 decades, a general lack of ecological knowledge still hinders developing practical approaches to address issues of hybridization, inbreeding, and stunted demographic trends (Hinton *et al*. 2013). Understanding patterns of red wolf space use and habitat selection is a first step towards identifying key processes responsible for red wolf persistence. Previous studies of red wolf space use and habitat selection reported home ranges that varied between 10-150 km^2 (Phillips *et al*. 2003; Chadwick *et al*. 2010) with strong preferences for agricultural habitats (Chadwick *et al.* 2010; Hinton & Chamberlain 2010; Dellinger e*t al*. 2013); however, these studies lacked testable hypotheses to explain variation observed in red wolf spatial ecology. For instance, home-range size is widely measured to study the relationship between the distribution of animals and their ecological resources and consistent statistical patterns observed in home-range sizes of carnivores are largely influenced by body size (Harestad &Bunnell 1979; Gompper & Gittleman 1991). As a large carnivore (> 20 kg), body size is a critical factor influencing red wolf prey selection (Chapter 3) and it is likely to influence spacing patterns observed in red wolves. Furthermore, *Canis* species are known to rely on open habitats and linear corridors because their locomotor habits are favored in these habitats (Van Valkenburgh 1985; Andersson 2004; McKenzie *et al*. 2012). Aligning empirical data of space use within a larger theoretical framework is essential for identifying key traits and ecological requirements of red wolves that will assist in developing conservation strategies to overcome challenges to recovery efforts.

We monitored resident and transient red wolves fitted with global positioning system (GPS) radio-collars to assess red wolf spatial ecology in northeastern North Carolina. Here we

assess the ways in which red wolves interact and use several primary habitats. We also assess if body weight influences variation observed in red wolf home ranges. Although transient individuals are known to exist in gray wolf (*Canis lupus*) and coyote populations (Thurber & Peterson 1993; Berger & Gese 2007), their general relevance to *Canis* ecology are rarely understood and have never been investigated in red wolves. Transients are nomadic individuals that have not established residency and show little-to-no fidelity for one area (Berger & Gese 2007; Hinton *et al*. 2012). We examined space use and habitat selection patterns of transients and compared them to residents. Using our analyses, we extrapolate reasons for the red wolf's decline after European colonization of North America and offer suggestions for improving red wolf recovery.

Study Area

Our study was conducted on the Albemarle Peninsula in the northeastern region of North Carolina (Figure 1). The study area was approximately 6000 km^2 of federal, state, and private lands and is hereafter referred to as The Red Wolf Recovery Area (Recovery Area). The Recovery Area was comprised of a row-crop agricultural-bottomland matrix in which agricultural crops (i.e., corn, cotton, soybean, and winter wheat) made up approximately 30% of the vegetative cover (Figure 1). Managed pine (*Pinus* spp) comprised approximately 15% of the land cover. Other prominent land cover types were coastal bottomland forests and pocosin (35%), herbaceous wetlands and saltwater marshes (5%), open water (5%), and other minor land cover types (10%). Changes in elevation were minor (0-50m) and the climate was typical of the mid-Atlantic: 4 full seasons, nearly equal in length, with annual precipitation averaging between 122-132 cm. Summer climate was typically hot and humid with temperatures ranging from 27°C to over 38°C and winters were relatively cool with temperatures ranging between -4°C to 7°C.

Methods

We captured red wolves using padded foot-hold traps (Victor no.3 Softcatch, Lititz, Pennsylvania, USA) from October through May during 2007-2011. Red wolves were sexed,

measured, and weighed. Ages and genetic confirmation of captured red wolves were known if individuals were carrying a subcutaneous passive integrated transponder (PIT) tags inserted into pups during annual surveys of suspected red wolf dens (Beck *et al*. 2009; Rabon *et al.* 2013). Individuals without PIT tags were aged by tooth wear (Gier 1968) and a blood sample was taken.

We categorized wolves > 2 years old as adults, < 2 but > 1 year old as juveniles, and < 1 year old as pups. Prior to release at the original capture sites, we fitted red wolves with a mortality-sensitive GPS radio-collars (Lotek 4400S, Newmarket, Ontario, Canada) scheduled to record a location every 5 hours on a scheduled to rotate around the 24-hour clock throughout the year. Animal handling methods were approved by the Louisiana State University Agricultural Center Institutional Animal Care and Use Committee (Protocol Number AE2009-19).

To examine the anthropogenic effects of agriculture on the landscape, we divided year into 2 6-month seasons based on agricultural activity: planting/growing (1 March – 31 August) and harvest/fallow (1 September – 28 February). Locations were further separated into diurnal and nocturnal categories based on monthly photoperiods. We estimated space use of resident and transient red wolves by fitting dynamic Brownian bridge movement models (dBBMMs) to the time-specific location data to estimate the probability of use along the full movement track of each red wolf (Kranstauber & Smolla 2013) using the R package moveud (Collier 2013) in the R statistical environment (R Core Team 2013). We chose window sizes based on the temporal resolution of each track and our *a priori* assumptions of the time scale of major behavioral shifts (Byrne *et al*. 2014). For residents, 95% and 50% contour intervals were considered home ranges and core areas, respectively. For transients, 95% and 50% contour intervals were considered transient range and biding areas (Hinton *et al*. 2012), respectively. We used *t*-tests to examine changes in home range and space use sizes between seasons.

Predominant habitat types were estimated from a digitalized landscape map of vegetative communities developed by the North Carolina Gap Analysis Project (McKerrow *et al*. 2006). We collapsed the vegetative communities estimated by McKerrow *et al*. (2006) into 7 general habitat

types with 30m resolution. For the habitat selection analysis, we divided the landscape into agriculture, coastal bottomland forest, pine forest, open water, upland forest, urban, and wetland. Because roads may serve as corridors for red wolf movements (Dellinger *et al*. 2013), we included road as the 8th habitat type by superimposing a linear feature layer with a 30m buffer around roads onto the final habitat raster map with 30m resolution.

We used analysis of variances (ANOVAs) and *t*-tests to determine if the percentage of habitat composition of home ranges and transient ranges differed between each other and between seasons. We also developed generalized linear models (GLMs) to examine the effects of body weight and age, pack size, white-tailed deer abundance, and habitat composition on red wolf home-range size. We used county-level harvest data collected by the North Carolina Wildlife Resources Commission as measures of deer abundance in the study area. Although harvest reports do not reflect true white-tailed deer densities, hunter harvest/km^2 do provide a benchmark by which to judge the effect of white-tailed deer abundance on red wolf home-range size. Habitat composition of home ranges was calculated as the percentages of the 8 habitat types. We assessed models using a stepwise procedure by calculating Akaike's information criterion for small sample sizes (AIC_c) for each model to select which variables best explained home-range size.

We compared habitat selection of red wolves at 2 scales: population (2nd-order) and individual (3rd-order). Habitats were converted into continuous variables by quantifying percent of habitat cover for each 30m cell using a moving window with a 150m radius in FRAGSTATS (McGarigal *et al*. 2012). We also quantified edge density and patch richness across the study area because we suspected red wolves of foraging along edges. Information from raster maps were extracted to red wolf locations and home ranges using ArcGIS 10.1 (Environmental Systems Research Institute Inc., Redlands, California). We used resource-selection functions (RSFs) to examine the effect of habitat type on where red wolves established home ranges on the landscape (2nd-order selection of resources; Johnson 1980) and examine the effect of habitat type on how they use their home ranges (3rd-order selection of resources; Johnson 1980) following Manly *et*

al. (2002). We assumed seasonal and photoperiod variation in habitat use by residents and transients and, therefore, developed RSFs for residents and transients by season and photoperiod for 3rd-order selection. We used a binomial approach to estimate resource-selection functions by comparing characteristics of known (used) locations to random (available) locations (Manly *et al*. 2002). We used logistic regression and AIC_c to form RSFs that identified habitats important to individual red wolves and evaluated the relative importance of coefficients associated with the habitat types by examining Akaike weights (w_i) after adding each of these covariates to a core model set (e.g., higher w_i and lower AIC_c suggested model improvement; Burnham and Anderson 2002). We also evaluated the predictive performances of the most parsimonious core models using the *k*-fold cross validation method (Boyce et al. 2002; Johnson et al. 2006). The cross-validation method performs *k* iterations of training and validation in which a different fold of the data is held out for validation while remaining $k - 1$ folds are used for learning. For cross-validation, we used 10 folds ($k = 10$) to estimate performance of RSF models.

Results

During 2007-2011, we monitored 34 red wolves fitted with GPS radio-collars. Of those red wolves, 30 (88%) were residents and 11 (32%) were transients with 7 (63%) of the residents being transients prior to establishing home ranges. Mean weight and age of red wolves monitored were 27.1 kg ± 0.4 and 3.1 yrs ± 0.2, respectively, in which weights and age of residents did not differ from transients (Table 1; $t_{43} \leq 1.41$, $P \geq 0.017$). Home ranges and core areas of residents did not differ between seasons (Table 1; $t_{65} \leq 0.46$, $P \geq 0.657$) and home ranges ranged from 25.4 km² to 183.0 km². We also detected no seasonal difference of transient ranges and biding areas (Table 1; $t_{12} \leq 0.16$, $P \geq 0.878$) and transient areas ranged from 125.1 km² to 709.9 km². Home-range size scaled positively with body weight (Figure 2; $r^2=0.37$, $P = 0.002$), occurred in the top 5 models (Table 2), and best explained the variation observed in red wolf home-range size.

Home ranges and core areas were comprised mostly of agricultural fields, coastal bottomland and pine forest, and roads (Figure 3; $F_{6, 231} = 111.98$, $P < 0.001$). Pine and upland

forest, urban, and road composition of home ranges and core areas did not differ ($t_{66} \leq 1.78$, $P \geq 0.084$) but home ranges typically consisted of more coastal bottomland forest and wetland habitat and less agricultural habitat than did core areas ($t_{66} \geq 2.31$, $P \leq 0.024$). Similarly, transient ranges and biding areas comprised mostly of agricultural fields, coastal bottomland and pine forests, and roads (Figure 3; $F_{6, 70} = 25.15$, $P < 0.001$). With the exception of roads ($t_{22} \leq 3.29$, $P = 0.004$), we found no differences in habitat composition between transient ranges and biding areas ($t_{22} \leq 1.40$, $P \geq 0.176$). Home ranges consisted of more roads and less wetland habitat than transient ranges ($t_{43} \geq 2.11$, $P \leq 0.043$), whereas all other habitat types were similar ($t_{43} \leq 1.64$, $P \geq 0.109$). Core areas consisted of more agricultural habitat and less coastal bottomland forest and wetland habitats than biding areas ($t_{43} \geq 2.04$, $P \leq 0.047$), whereas all other habitat types were similar ($t_{43} \leq 0.55$, $P \geq 0.586$). We detected no seasonal differences between habitat types within home ranges ($t_{65} \leq 1.21$, $P \geq 0.230$). Core areas consisted of more agricultural habitat and less coastal bottomland forest and wetland habitat during the growing season ($t_{65} \geq 2.21$, $P \leq 0.031$), whereas all other habitat types did not differ between seasons ($t_{65} \leq 1.17$, $P \geq 0.268$). We detected no seasonal differences between habitat types within transient ranges and biding areas ($t_{12} \leq 1.39$, $P \geq 0.188$).

We excluded wetland, upland forest, and urban habitats from our models because their occurrence in home ranges and transient ranges was little. Therefore, we only included edge density, agriculture, pine forest, coastal bottomland forest, and road habitats in our model. All 5 covariates were retained in the top-ranked model for 2nd-order selection by residents (Table 3), whereas only 1 covariate (edge density) was not retained for transients (Table 4). Agriculture and pine forest habitats were retained in all top-ranked models for 3rd-order selection by residents (Table 3). Residents appeared to favor agricultural fields and pine forests during all seasons and photoperiods (Figures 4 & 5; Table 5). Agriculture and road habitats were retained in all top-ranked models for 3rd-order selection by transients (Table 4). Coastal bottomland and pine forests

were used by transients more during the harvest season than growing season, whereas agriculture and road habitats were preferred during both seasons and photoperiods (Figures 6 & 7; Table 5).

Discussion

In general, measurements of home ranges have proven useful in understanding spacing patterns of carnivore populations and comparative studies have demonstrated that carnivore home-range size scales positively with body size (Gittleman and Harvey 1982; Gompper and Gittleman 1991). Given the red wolf's intermediate body size between gray wolves and coyotes, it's not surprising that our mean home-range sizes fall between those estimated for gray wolves (see Table 6.3 in Fuller *et al*. 2003) and coyotes (see Table 22.4 in Bekoff & Gese 2003) in North America. Our findings appear similar to those observed in comparative studies of home ranges, and suggest that body weight is a primary driver of red wolf space use with larger individuals generally maintaining larger home ranges than smaller individuals. Results of our simple model, using red wolf body weight, pack size, white-tailed deer density, and % agricultural cover , indicated that body weight alone best explained variation in home-range size. This is not surprising because we should expect the energetic requirements of red wolves and the distribution of their food resources to influence the size of home ranges. Although deviations from the regression slope can be attributed to differences in diet, we found no effect of white-tailed deer density on red wolf home-range size. We suspect that our density estimate was too crude and, because white-tailed deer only comprise approximately 40-50% of red wolf diet (Dellinger *et al*. 2011; McVey *et al*. 2012; Chapter 4), a measurement of overall prey productivity might better serve as a variable for prey.

Home-range sizes of red wolves did not vary between seasons despite the loss of agricultural cover resulting from crop harvest during the fall. The size and placement red wolf home-ranges are likely driven by energetic demands and home ranges are large enough to handle seasonal changes in food resources. Although most red wolf home-ranges (50%) fell within the 45-80 km^2 range, 25% of the red wolves maintained home ranges > 85 km^2 and < 185 km^2. Long-

term maintenance of home ranges requires red wolves to defend a finite area and consume resources at a rate low enough to allow prey populations to persist. Therefore, we suggest that 175 km^2 may be an upper limit in which red wolves can efficiently maintain and defend a home range due to body size constraints.

The general compositional pattern in red wolf home ranges were high percentages of agricultural fields in the interior (i.e., core areas) with forest edges increasing in the outer areas. Red wolf home ranges typically had more coastal bottomland forest habitat than pine forest, but this was a result of most pine plantations residing in the western portion of the Recovery Area where red wolf packs are the fewest. Similar to behaviors observed by coyotes in the Recovery Area (Chapter 5), red wolves typically loafed in forest habitats within 50-300m of edges adjacent to agricultural fields during the harvest season. As crop cover reaches heights of approximately 0.5 meters during the growing season, red wolves abandon early successional and forest habitats to loaf under crop cover. Red wolf packs typically abandon their dens and day beds in early successional and forested habitats 4-6 weeks after whelping pups to center their activities, including pup rearing, in corn fields (Hinton & Chamberlain 2010).

Transient individuals lack mates because of their nomadic behaviors and do not contribute reproductively to the population. Despite this, transiency may be an important life history trait for red wolves because they facilitate metapopulation dynamics (Hanski 1998), replace residents upon death, and may allow populations to reconstruct themselves after suffering drastic mortality event. Transient red wolves displayed localized movements similar to those observed by coyotes in northeastern North Carolina (Hinton et al. 2012). These movements were analogous to home ranges and we referred to them as biding areas (Hinton et al. 2012). Seven of the 11 (63%) transients established residency near their biding areas. We suggest this behavior allows red wolves to assess resource availability and become familiar with areas before establishing residency.

Overall, red wolves prefer the open, treeless agricultural fields over the forested habitats in the Recovery Area. For instance, 52% of approximately 55,000 GPS locations recorded were in agricultural fields, whereas 30% were in forested habitats. Although transients displayed similar attraction to habitat types as residents did, resource-selection models were useful in identifying differences in habitat selection between transients and resident red wolves. Models of 2nd-order selection indicated that agricultural fields, forested habitats, and roads were important to transients and residents; however, transients relied more on roads than did residents. Increased use of roads by transients indicates that they likely travel more and forage less than residents and roads reduce energetic costs of movements. Models of 3rd-order selection indicated that residents and transients had temporal changes in habitat use. During the growing season, residents loafed in agricultural fields near roads during the day but included some moderate use of forested habitats adjacent to roads at night, whereas transients decreased their use of forested habitats at night to increase their use of roads and edges in agricultural fields. During the harvest season, residents used agricultural fields and forested habitats near roads and decreased their use of roads and forested habitats at night to forage in the agricultural fields. Similarly, transients used agricultural fields and forest habitat during the day, but relied mostly on roads and agricultural fields during the night. Despite low use of forested habitats, red wolves do benefit from the surrounding forests because those habitats provide security during the fall and winter when agricultural fields are barren after harvest. Similar to coyotes, red wolves take advantage of road networks and other linear features to reduce costs associated with travel and increase foraging opportunities. In fact, red wolf use of forested habitats is mostly associated with the use of roads (Dellinger *et al*. 2013).

The red wolf's low-to-moderate use of forested habitats and preference for agricultural fields indicates that red wolves most likely occupied grassland and early successional habitats preying mostly on white-tailed deer and rabbits (*Sylvilagus* spp.) prior to European settlement. Forested habitats may have offered marginal habitat that was used by dispersing and transient individuals to maintain metapopulation dynamics. Prior to European settlement, fire was

widespread and frequent throughout the eastern United States in which Native Americans used fire for forest clearance and maintenance to promote growth of hard mast trees and browse for game species (Delcourt & Delcourt 2004; Nowacki & Abrams 2008). Red wolves likely exploited the mosaic of grasslands, savannas, and open woodlands maintained by natural and Native American fire-regimes. As Europeans colonized the eastern United States, Native American populations were greatly reduced and land-use practices shifted to an agricultural-grazing system. This system created significant shifts in vegetation composition and structure from grasslands, savannas, and open woodlands to closed-canopy forests with dense understories (Nowacki & Abrams 2008) that would have disrupted red wolf metapopulaton dynamics by impeding movements and creating isolated pockets of red wolf populations. Therefore, we suggest that red wolf populations first became isolated through the conversion of open habitats to closed-canopy forests. The extirpation of white-tailed deer likely lowered red wolf recruitment while increased conflict with European and American settlers disrupted pack dynamics and increased mortality rates. Together these factors eventually led to the complete extirpation of red wolves by the mid-20th century. As coyotes began colonizing the eastern United States, hybridization became a primary conservation challenge to red wolf recovery (Kelly *et al*. 1999; Hinton *et al*. 2013).

Nowak (2002) noted that the modern red wolf morphology still shows continuity with fossilized remains of small wolves in the eastern United States dating back to the Pleistocene. Therefore, the morphology of modern red wolves may not have been significantly altered from modern hybridization with coyotes. Results of this study indicate that body size is a primary trait influencing red wolf space use and it is likely that modern red wolves maintain a body size adapted to a vastly more open landscape that existed prior to European settlement of North America. Therefore, it is likely that red wolf populations will require extensive areas of open, early successional habitat with high prey productivity to support red wolf packs and facilitate the movement of dispersers and transients. Currently, red wolves use approximately 50-60% of the Recovery Area and current management strategies may need to use controlled burns to create

early successional habitat and reduce forest understory, thereby increasing the amount of suitable forest habitat available to red wolves. Understanding how red wolf populations structure themselves on the landscape is critical for making accurate inferences and promoting processes and conditions that will not only allow for the gradual expansion of red wolf populations, but permit red wolves to gradually adapt to modern landscapes.

CHAPTER 7

BODY SIZE AS A REPRODUCTIVE BARRIER IN *CANIS*: A HYPOTHESIS

Hinton, J.W., J.L. Gittleman, and M.J. Chamberlain. 2014. To be submitted to *Science*.

Abstract

Anthropogenic exploitation of natural resources has a ubiquitous presence across the globe, resulting in the elimination of geographic and biological barriers that prevented secondary contact between closely related, allopatric taxa. This is particularly problematic for endangered carnivores because they can be genetically assimilated into the more common sister species' population. Hybridization has become the primary challenge for red wolf recovery and conservation. Red wolves and coyotes exist as a panmictic population in northeastern North Carolina and hybridization occurs when individuals form congeneric breeding pairs. We hypothesize that differences in individual body size between red wolves and coyotes can serve as a reproductive barrier by promoting differential use of space and resources. Our results indicated that home-range size and consumption of white-tailed deer scaled positively with red wolf and coyote body weight. Additionally, red wolves in congeneric breeding pairs were smaller than red wolves in conspecific breeding pairs. Therefore, we suggest that body size differences between red wolves and coyotes serve as a reproductive barrier.

Introduction

Globally, carnivore species have been extirpated from most of their historic ranges and exist as remnant populations as a result of excessive killing and habitat alteration by humans. Although societal beliefs have resulted in profound changes to how carnivores are perceived, successful recovery and conservation of carnivores remains one of the most difficult ecological challenges facing our society today. What makes this challenge so difficult to overcome is that conservation efforts must be carried out in the presence of factors responsible for the global declines of carnivores (Breitenmoser *et al*. 2001; Hayward *et al*. 2007). Furthermore, anthropogenic exploitation of natural resources has a ubiquitous presence across the globe, resulting in the elimination of geographic and biological barriers that prevented secondary contact between closely related, allopatric taxa. This is particularly problematic for endangered carnivores because they can be genetically assimilated into the more common sister species

population. As a result, hybridization has become a primary conservation challenge for some carnivore species.

In particular, wolves have been extirpated from much of their historic ranges in North America by government-supported eradication campaigns to protect livestock and hunting industries. With the passage of the Endangered Species Act of 1973, several reintroductions of gray (*Canis lupus*) and red (*Canis rufus*) wolves occurred in the United States during the late 20th century. During this same time period, coyotes (*Canis latrans*) expanded their range throughout North America and are currently ubiquitous throughout the United States. Although gray wolves are reproductively isolated from coyotes (Pilgrim *et al*. 1998; Wheeldon *et al*. 2010), ongoing hybridization with coyotes has created unique conservation challenges for eastern wolves (*Canis lycaon*) in eastern Canada and red wolves in the southeastern United States (Chambers et al. 2012; Rutledge et al. 2012; Hinton et al. 2013). Despite suggestions for a more holistic approach to examining *Canis* evolution by using ecology, natural history, and the fossil record in concomitant with genetic analyses (Rutledge *et al*. 2012), research has focused *Canis* taxonomy with little effort to identify traits responsible for reproductive isolation among *Canis* species. Even in the presence of modern hybridization with coyotes by eastern and red wolves, morphological and genetic differences among the populations indicate past isolation and, therefore, the existence of isolating mechanisms. Although the literature pertaining to reproductive isolation and speciation is voluminous, its integration into carnivore conservation has been lacking despite the increasing threat hybridization now plays in the conservation of imperiled species (Rhymer and Simberloff 1996; Simberloff 1996; Genovart 2009; Ellstrand et al. 2010).

Red wolves and coyotes exist as a panmictic population in northeastern North Carolina and the Red Wolf Recovery Program (Recovery Program) intensively manages hybridization via reproductive sterilization of coyotes within the designated Red Wolf Recovery Area (Hinton et al. 2013). Although this technique ensures that hybridization does not occur when red wolves form

breeding pairs with sterilized coyotes, continued use of sterilization and efforts to increase the number of red wolves on the landscape will likely fail to prevent hybridization if reproductive barriers do not exist (Fredrickson and Hedrick 2006). Nevertheless, assortative mating may exist within both populations as some individual red wolves and sterile coyotes appear to always prefer to pair with conspecifics after the loss of a mate, whereas others show random preferences (USFWS unpublished data). A central characteristic of *Canis* is monogamous breeding which manifests in pair-bonding behavior and group living (Gittleman 1989; Geffen et al. 1996). As a result, sexual isolation between red wolves and coyotes likely occurs when both species are incapable of forming congeneric pairs to maintain breeding territories.

Red wolves and coyotes exhibit similarity in morphology and ecology, in which red wolves are the larger species (Chapter 3). Additionally, red wolves and coyotes exhibit similar use of prey and habitat selection and differences in resource use are associated with body size (Chapters 4, 5, and 6). These studies have shown red wolves to rely on larger prey than coyotes and require larger home ranges to fulfill their energetic requirements. This is not surprising given that body size is a major phenotypic trait that commonly differentiates co-occurring species (LaBarbera 1989) and co-occurring guilds of species frequently demonstrate greater morphological disparity than expected by chance (Dayan and Simberloff 2005; Davies *et al*. 2007). Long-term maintenance of monogamous breeding units by *Canis* likely requires similar and synchronized use of space and resources within each breeding pair. Differences in body size between red wolves and coyotes will affect energy requirements and capacities for searching for and processing prey which, in turn, may affect how they perceive the distribution, abundance, and profitability of prey on the landscape. Red wolves typically weigh about 10 kg or more than coyotes and the ability of congeneric pairs to adjust energy budgets associated with breeder body mass, hunting efficiency, and spatial requirements is likely key to maintaining breeding territories and, subsequently, successful hybridization. Therefore, the formation of congeneric pairs and the

stability of those pairs to successfully raise hybrid litters may be related to how similar individuals are in their energy demands via similarity in body size.

The functional significance of body size and *Canis* hybridization is unclear and the relationship between the two is worth examination. We hypothesize that as red wolves and coyotes approach each other in body size, they can complement each other as possible mates whereas larger red wolves and smaller coyotes are incapable of maintaining breeding pairs because of differences in resource needs. We use the interactions of red wolves and coyotes to predict that body size serves as a reproductive barrier for *Canis*.

Methods and Analysis

Our data are derived from red wolves, coyotes, and their breeding pairs monitored in North Carolina by the United States Fish and Wildlife Service. We attained data on known *Canis* breeding pairs during the duration of earlier studies specifically focused on red wolf and coyote morphology, diet, and space use in northeastern North Carolina (Hinton and Chamberlain 2014; Hinton *et al*. 2014a,b,c,). Methods used for estimating body weight, diet, home-range size, and habitat composition of home ranges were consistent in all studies.

Variables

1. Body weight: weight (kg) recorded from individual red wolves and coyotes prior to being released back into the wild (Chapter 3).

2. Breeding pair weight: combined weight (kg) of breeding pairs for coyote pairs, congeneric pairs, and red wolf packs (Chapter 4).

3. Home-range size: the total area (km^2) used by an individual or breeding unit as estimated in Chapters 5 and 6.

4. Percent of white-tailed deer in diet: the average percent (%) of occurrence in the diet as observed in Chapter 4.

5. Percent of rabbit in diet: the average percent (%) of occurrence in diet as observed in Chapter 4.

6. Percent of forest: percent (%) forest composition of home ranges as observed in Chapters 5 and 6.

7. Percent of agriculture: percent (%) agricultural composition of home ranges as observed in Chapters 5 and 6.

We used analysis of variance (ANOVAs) and *t*-tests to test for differences among breeding units and between red wolves and coyotes. We used simple linear regression to examine the effects of body weight and combined breeder weight on diet, home-range size, and habitat of red wolves and coyotes. We obtain the best-fitting lines between individual weight variables and ecological variables to calculate regression coefficients (r) and levels of significance.

Results

Red wolf packs had substantially larger home-range sizes than coyote and congeneric pairs (Figure 1; $F_{2,45} = 14.78$, $P < 0.001$), whereas no difference was detected in coyote and congeneric home-range sizes. We also detected no difference in habitat use among the breeding units ($F_{2, 45} \leq 0.94$, $P \geq 0.397$). We detected differential use in white-tailed deer and rabbits among the breeding units ($F_{2, 32} \geq 7.04$, $P \leq 0.002$). We found body weight of individual *Canis* positively influenced home-range size (Figure 3; $r^2 = 0.44$, $P < 0.001$) as did combined breeder weight (Figure 3; $r^2 = 0.34$, $P < 0.001$). Consumption of white-tailed deer was positively influenced by combined breeder weight (Figure 4; $r^2 = 0.38$, $P < 0.001$), whereas consumption of rabbit was negatively influenced (Figure 5; $r^2 = 0.28$, $P < 0.001$). No difference was detected in coyote body weight between breeding pairs ($t_{43} = 0.25$, $P = 0.802$). Overall, body weight of red wolves in conspecific pairs was greater than those in congeneric pairs ($t_{72} = 2.43$, $P = 0.017$). We found no difference between body weight of male red wolves in conspecific and congeneric pairs ($t_{40} = 1.22$, $P =$

0.23), whereas female red wolves in conspecific pairs were greater than those in congeneric pairs ($t_{30} = 3.09$, $P = 0.005$).

Discussion

The association between body size and spatial and feeding ecology in carnivores is well documented (Gittleman and Harvey 1982; Gittleman 1985; Gompper and Gittleman 1991; Carbone *et al*. 1999) and our results indicate that body size provides an important indicator of red wolf and coyote diet and space use patterns. Home-range size and use of white-tailed deer scaled positively with red wolf and coyote body weight. This pattern is associated with energetic requirements and foraging strategy because large carnivores have relatively high metabolic rates and increased ranging behavior would be required to fulfill greater energetic needs (Carbone *et al*. 1999; Carbone *et al.* 2007). Furthermore, we found that red wolves that formed congeneric breeding pairs with coyotes were, on average, smaller than red wolves in conspecific breeding pairs. It appears that this trend is largely driven by female red wolves, which are the smaller of the two red wolf sexes (Chapter 3). Small red wolves may approach similar ecological requirements to those of coyotes because of their smaller body size, and this may allow them to form and maintain breeding pairs with coyotes via similar spatial and feeding needs.

Coyote home-ranges in northeastern North Carolina did not exceed 50 km^2 indicating that energetic costs may limit the maximum size of coyote home ranges (Chapter 5). In this study, we observed home-range sizes of congeneric pairs to be under 50 km^2 and statistically similar to those of coyotes, whereas most red wolf home-ranges exceeded this threshold. Although coyote body weight had no effect on coyote home-range size (Chapter 5), it was the primary trait influencing variation in red wolf home-ranges (Chapter 6). Additionally, 41% of coyote pairs monitored in our study had diets in which white-tailed deer comprised < 25%, whereas white-tailed deer comprised > 30% of the diet for all red wolf packs monitored. For both coyotes and red wolves, body weight was the most important factor influencing consumption of white-tailed deer (Chapter 4). Less use of space and white-tailed deer by coyotes suggest that they impose

energetic constraints on congeneric pairs and are likely responsible for smaller home-range sizes and less reliance on white-tailed deer by congeneric pairs when compared to red wolf packs.

Intrinsic reproductive barriers are traits that prevent gene flow between populations of closely related taxa and facilitate speciation via ecological divergence (Mayr 1941; Schluter 2000; Coyne and Orr 2004; Pfennig and Pfennig 2010). As previous allopatric species, geography and habitat may have served as the primary reproductive barrier between red wolves and coyotes, but the inability to form monogamous breeding pairs likely serves as the primary barrier to gene flow between red wolves and coyotes during secondary contact. Phylogenetic relatedness and phenotypic similarities permit red wolves and coyotes to compete with each other for mating opportunities and conflict between consorting individuals may be a fundamental phenomenon preventing hybridization. Our study indicates that larger red wolves generally avoid consorting with coyotes and size-assortative mating may arise largely as a result of ecological differences resulting from divergence in body size. Conflict may arise between consorting red wolves and coyotes during energetically stressful situations, such as foraging and defending territories, that prevents successful pair formation. As red wolves and coyotes approach each other in body size, these conflicts may be reduced allowing for long-term maintenance of congeneric breeding pairs through similar use of space use and prey.

Our results highlight the need to better understand factors affecting hybridization in *Canis*, such as body size. As seen in comparative studies of carnivores, our results indicate that body size influences home-range size and prey selection of red wolves and coyotes. Morphological disparity between red wolves and coyotes likely promotes reproductive isolation and ecological divergence through energetic constraints. We believe that the key to understanding how body size affects interactions, and subsequently hybridization, between closely related *Canis* is to understand how energetic requirements scale with *Canis* body size and its effect on *Canis* ecology. For example, it has been observed that gray wolves and coyotes are reproductively isolated where populations are sympatric despite having the potential to hybridize (Pilgrim *et al*.

1998; Wheeldon *et al*. 2010). On the other hand, eastern wolves, which are intermediate in body size to gray wolves and coyotes, are capable of hybridizing with both species and are believed to serve as a conduit for genetic material between gray wolves and coyotes (Rutledge *et al*. 2010). Currently, it is unknown whether innate preferences or environmental conditions are responsible for reproductive barriers observed in eastern wolves (Benson *et al*. 2012), but it is believed that prey selection (Rutledge *et al*. 2010) and territorial aggression (Benson *et al*. 2013) play a role in reducing hybridization. Nevertheless, our findings are consistent with invariant trends observed in comparative studies which suggest that our hypothesis is biologically plausible. Our hypothesis is based on allometric relationships and represents a useful predictive framework to understand patterns of interactions and hybridization among *Canis* species. We also suggest more sophisticated comparisons using different methods and evidence are needed to fully evaluate this hypothesis.

CHAPTER 8

CONCLUSIONS

Understanding how red wolves interact with coyotes is an important issue which could dictate the success of recovery efforts. It also presents an opportunity to explore mechanisms that facilitate ecological divergence and reproductive isolation between *Canis* species. There has been limited examination of potential reproductive barriers between sympatric *Canis*, partly due to the difficulty in monitoring the interactions of large carnivores. Recent studies have suggested several possible mechanisms responsible for slowing hybridization rates between *Canis* such as differences in prey selection (Rutledge et al. 2010), stability in social structure (Bohling 2011), and aggressive interactions related with territoriality (Benson et al. 2013). Noting that monogamous breeding and group living as a central characteristic of *Canis*, we hypothesized that difference in body size between interacting *Canis* species prevents congeneric breeding-pair formation via disparity in diet and spatial needs. In other words, long-term maintenance of monogamous breeding units by *Canis* likely requires similar and synchronized use of space and resources within each breeding pair and this is likely to happen when individuals are similar in body size.

This dissertation found 4 important components of red wolf and coyote ecology that demonstrate the biological plausibility that body size disparity can serve as a reproductive barrier. First, we demonstrated that red wolves are substantially larger than coyotes with hybrids intermediate to both coyotes and red wolves in body size. In fact, red wolves attain a body size that is not achieved by coyotes or hybrids. Therefore, good concordance was found between morphometric variables and the molecular methods accepted by the United States Fish and Wildlife Service for monitoring red wolf genetic ancestry.

Second, we found red wolves and coyotes to have similar and overlapping diets. Nevertheless, consumption of white-tailed deer positively scaled with body weight in which red wolves consumed more deer than did coyotes. Interestingly, our results of coyote diet are contrary to many studies conducted in the southeastern United States because we found coyotes in northeastern North Carolina to be largely carnivorous with a narrow dietary breadth. Partitioning of food resources by red wolves and coyotes is mostly via differences in quantity of similar prey rather than differences in types of prey exploited. This suggests foraging ecology of red wolves and coyotes become similar as they approach each other in body size.

Third, we found body size to have an effect on red wolf and coyote space use. Home-range size in red wolves scaled positively with body weight in which larger red wolves generally require more space than smaller red wolves. Although body size did not influence coyote space use, coyote home ranges did not exceed 50 km^2 indicating that coyotes cannot maintain large home ranges. This constraint of coyote space use is likely a result of their smaller body size because approximately 75% of red wolf home ranges were > 40 km^2. We also found red wolves and coyotes preferred open, treeless agricultural fields over the forested habitats in northeastern North Carolina. Red wolf and coyotes centered their home ranges in open, agricultural habitats and the primary difference in spatial ecology was size of their home ranges which was influenced by body size.

Fourth, we found that red wolves that formed congeneric breeding pairs with coyotes were, on average, smaller than red wolves in conspecific breeding pairs. It appears that this trend is largely driven by female red wolves, which are the smaller of the two red wolf sexes. Small red wolves may approach similar ecological requirements to those of coyotes because of their smaller body size, and this may allow them to form and maintain breeding pairs with coyotes via similar spatial and feeding needs. For instance, we observed home-range sizes of congeneric pairs to be under 50 km^2 and statistically similar to those of coyotes, whereas most red wolf home-ranges exceeded this threshold. For both coyotes and red wolves, body weight was the most important

factor influencing consumption of white-tailed deer. Less use of space and white-tailed deer by coyotes suggest that they impose energetic constraints on congeneric pairs and are likely responsible for smaller home-range sizes and less reliance on white-tailed deer by congeneric pairs when compared to red wolf packs.

In conclusion, we suspect morphological disparity between red wolves and coyotes likely promotes reproductive isolation and ecological divergence through energetic constraints. We believe that the key to understanding how body size affects interactions, and subsequently hybridization, between closely related *Canis* is to understand how energetic requirements scale with *Canis* body size and its effect on *Canis* ecology. Our findings are consistent with invariant trends observed in comparative studies that home-range size and prey size scale positively with carnivore body size and this suggests that our hypothesis is biologically plausible.

Protocol for fecal sample collection for hormone analysis

Duration: 1 year, can start anytime of the year
Frequency: 3 time/week
Protocol:

1. For animal housed in groups, one day prior to sample collection day, feed individual with food item (e.g. meat ball) mixed with some type of marker, e.g. food coloring (Baker's paste food color), glitters (Sulyn Ind. Inc., Coral Springs, Flato), etc. to identify an individual's sample.
2. Collect fresh sample (approximately 50 g [~ golf ball size]) and place into a plastic baggie.
3. Using a permanent maker please write the animal's studbook number, sex, date sample was collected, and institution on each baggie.
4. Keep the samples in -20C until shipped to SCBI
5. To ship samples please put the samples in a Styrofoam-lined box with dry ice (see label below). Samples should be sent early in the week (Mon. – Wed.) to avoid weekend delivery. Please put "red wolf" as the reference on shipping label.

Louisiana Draft Plan

In order to be able to make more informed decisions regarding the canid population and possible existence of red wolves in Louisiana we propose the following as very preliminary steps:

Short Term

- If possible, a good initial step would be for the Sabine NWR to pre-bait areas where there appears to be active canid use with road kill or something similar, and place remote sensing cameras. That would both serve to prime the areas pre-baited for trapping shortly after and give a visual of what visits those areas. Additionally, if hair snares could be placed at those pre-bait sites and other canid use areas, it would provide a lower effort/lower need for training way of obtaining samples for genetic testing. I believe Emily has the equipment and perhaps the protocol that was used previously. All hair samples should be sent to the appropriate lab for analysis. Would likely collect a lot of non-target hair samples.

- The preferred trapping window for the health and safety of the canids, and to not disrupt breeding would be during the winter months (December, January and February), in line with trapping in the NENC NEP. Trapping past February is not recommended due to affecting breeding season, subsequent denning, birth, and then heat issues. If local Sabine NWR staff, Wildlife Services, State of Louisiana personnel, university researchers or private trappers are authorized, available, trained and equipped to safely and effectively conduct canid capture operations they could potentially start trapping in January. If not, in February, two staff from the Eastern NC ES Sub-office's Red Wolf Recovery Program could drive down to Sabine NWR and in coordination with Refuge staff conduct canid capture operations throughout the appropriate habitats of the refuge. Trapping window should be a minimum of two weeks, if not longer.

- All canids captured will have the capture location GPS'd, full measurements taken (e.g. body length, skull, weight, etc.), blood drawn, vaccinated (?) and be photographed. All capture and handling operations conducted by Red Wolf Recovery Program personnel would be in accordance with the SOPs utilized in the NENC NEP. Coordination with Refuge staff will determine the appropriate steps if non-canids are captured. For example, if the animal should be released immediately or if they would like them processed for other purposes.

- Blood samples will be sent directly to the University of Idaho for genetic testing.

- All animals would be released at or in close proximity to where they are captured as soon as they are able to be released.

- All, or a sampling of animals, that fall within the accepted morphological measurements of red wolves should be radio collared before release for the purposes of tracking their movements to determine general habitat use and home range (e.g., how much of their movement is on the refuge) and to more easily facilitate recapture should it become desire. Radio collars and frequencies to be used would need to be coordinated with Sabine NWR, university researchers and or the State of Louisiana.

- Collared canids should be monitored for general location and mortality from the air or ground preferably at least once a week to get a sense for their movements.

Long Term

- Need for additional research to determine the structure of the canid population in Louisiana and Texas.

- Research could be guided by the SCBI research work group established at this past summer's red wolf workshop and focus on a broader effort to characterize the genetic, morphological and behavioral composition of the canid population in Louisiana and Texas. Their role would hopefully be to help guide a study plan that would provide the needed scientific foundation upon which to base decisions regarding these canid populations and their management.

- Recent publications regarding potential red wolves in Louisiana and Texas provide a valuable starting point and include recommendations for additional field work and analysis to determine what is present in those areas. Including how to deal with the "ghost alleles".

- Information collected this winter would help inform research needs and provide some additional of "baseline" information.

Discussion

- January is good month to trap, but if it is to be done by the red wolf staff, it would be better suited to trap in Louisiana in February to account for management needs here in the NENC NEP.

- There is a need to recognize that samples being tested for both of the published papers that give percentages of red wolf are only comparing the specimen genetics to the know genetics of the 14 founder red wolves. Consequently, such as Heppenheimer et al. (2018) suggest, alleles that may be representative of red wolf genetics not accounted for by the founders, but present on the landscape today, will not be accounted for in the genetic results from the University of Idaho lab that indicate what percent red wolf an individual canid is.

- As discussed, although we currently use 87.5% red wolf genes within the NENC NEP as the cut off for a red wolf, that may not be the appropriate percentage for such a determination in Louisiana, particularly in light of it not accounting for unknown red wolf genetics.

- Need to begin to have discussions with the States of Louisiana and Texas regarding these canid populations and the possibility of it being determined that red wolves are present as fully endangered species with no current provision for take.

Coyote Depredation Permit

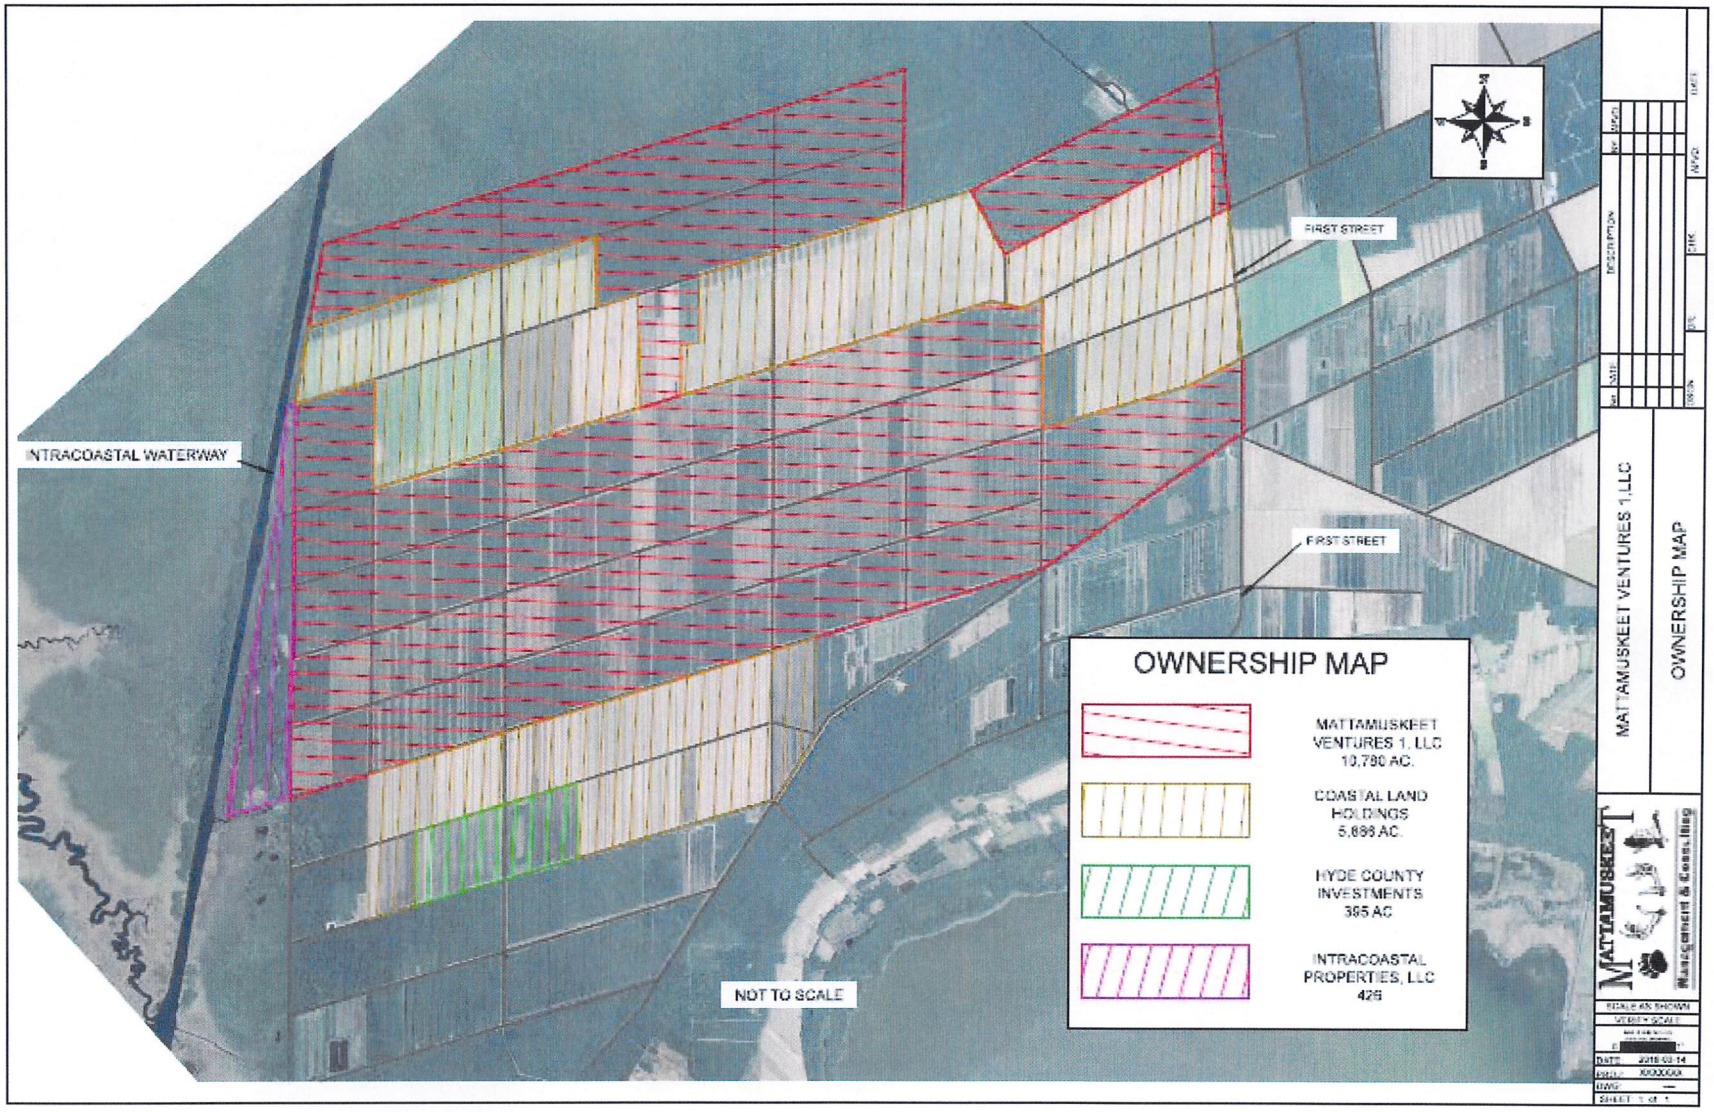
PERMIT NUMBER
N/A

EFFECTIVE	EXPIRES
04/01/2018	5/30/2018
COUNTY See Text Below	**DISTRICT** See Text Below



CONDITIONS AND AUTHORIZATIONS:

The above permittee and other individuals under written contract and under the supervision of the permittee are authorized to trap coyotes on the properties identified in **Attachment A** subject to the following conditions:

- Permit is valid for properties identified in **Attachment A**.
- This permit does not authorize access to any property, public or private.
- All individuals exercising the authority granted by this permit shall carry a copy of this permit and a letter of authorization from the permittee listed above while conducting trapping activities.
- Traps must be labeled as required by G.S. 113-291.6. Traps must be checked daily and any animals caught therein must be removed. All non-target wildlife must be released immediately onsite; however, any red wolf captured must be reported immediately to the Wildlife Resources Commission (WRC) at 800-662-7137 or the U.S. Fish and Wildlife Service to determine disposition of the red wolf.
- Coyotes being removed for depredation under this permit may only be trapped using legal foothold traps and the Collarum type trap as defined in G.S. 113-291.6. The reporting forms required for the use of Collarum type traps may be found at http://www.ncwildlife.org/Trapping/Laws-Safety. Collared animals must be reported immediately to the WRC at 800-662-7137 before final disposition is determined. All coyotes euthanized shall be disposed of in a sanitary manner. All collars from euthanized coyotes must be returned to the WRC.
- Permit holder must report the removal of coyotes to the WRC at 800-662-7137 or online at www.ncalvin.org/ckr/ckrmain.aspx within 24 hours of taking possession of each individual coyote. Each report must include the date; time; location; if the animal had a collar; and measurements of hind foot length and tail length taken from the carcass. Instructions for recording these measurements are enclosed and can be found at www.ncwildlife.org/Portals/0/License/Documents/Canid-Cooperator-Program-Instructions.pdf.
- A hair sample with follicle from each euthanized coyote must be submitted to WRC, Wildlife Management Division, 1722 Mail Service Center, Raleigh, NC 27699-1722.
- A report of all animals captured under this permit, date of capture, and their disposition is required within fifteen (15) days after the expiration of this permit.

This permit/license is nontransferable and expires at midnight on the above specified expiration date.

ATTACHMENT A

STATE: North Carolina

GRANT TITLE: W79-Wildlife Management

PROJECT TITLE: Pilot Study – Using Fine Scale GPS Technology to Research Sympatric Canid Population Dynamics (Job 2.0?)

A. Problem and Need

The coyote (*Canis latrans*) is now abundant throughout the 100 counties in North Carolina (NC), and is managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plain region of NC (Hinton et al. 2012, Murray et al. 2014). In recent years as coyotes have increased their population, some have begun to make use of the Outer Banks region.

The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of captive-bred red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). This population increased until 2008 and peaked at around 130 individuals (Group Solutions, Inc. 2016), short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013). The AP has an estimated carrying capacity of 140-150 wolves (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). The exact number of red wolves is not known, but USFWS staff report a population estimate of 45-60 individuals with eight mortalities to date in 2016 (https://www.fws.gov/redwolf/index.html August 2016). Hybridization with coyotes and inbreeding depression are suspected factors that have affected red wolf population growth and viability since the inception of the Red Wolf Recovery Program (RWRP), while vehicular and gunshot mortality are known factors (Hinton et al. 2013). Because of hybridization between red wolves and coyotes, the AP supports a continuum of sympatric canids, hereafter referred to as "sympatric canids."

As part of a recent program review, the USFWS halted many aspects of the RWRP in 2015 and discontinued the coyote sterilization program, potentially affecting the spatial

Draft - Confidential

distribution and population dynamics of sympatric canids. Telemetry data from coyotes on the AP suggests that about 70% of coyotes are residents (i.e., those that defend set territories) while the other 30% are transients, with most being dispersing juveniles (Hinton et al. 2015). Transient coyotes do not defend set territories. Coyotes can travel long distances and become transient even as adults, especially when they lose their mate. Recently described as using "compensatory immigration," coyotes opportunistically fill spatial resource gaps by periodic transiency; when spots come open, individuals that do not yet have permanent territories and have been roaming in the area, are able to inhabit the new openings (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with other canids and humans, especially when they are utilizing of anthropogenic resources.

Though a rural area, human land uses occupy a significant portion of space on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011). Concerns about fear of attacks on humans and domestic pets, the effects of sympatric canids on white-tailed deer and other game populations, and homeowner property damage comprise many of the conflict calls regarding sympatric canids on the AP (Responsive Management, forthcoming data). Wildlife managers in this region frequently receive requests for information on canid management (C. Turner, personal communication, 2016).

The changes in state and federal canid management rules have resulted in confusion regarding residents' rights and options for management of property damage by sympatric canids. As a result, some citizens are unsure of the legal and most effective methods for canid conflict management. Adding to management complexity is the need to manage canids for conservation purposes, such as reducing predation on at-risk ground nesting species or reducing hybridization of sympatric canids.

In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of sympatric canids on the AP. A USFWS and NCWRC joint memorandum documented detailed action items for the joint management of sympatric canids on the AP, including specific research objectives which this proposal seeks to address (Attachment 2). As sympatric canids on the AP increase in number, monitoring their

Draft - Confidential

movements, particularly in relation to individuals of differing ancestry, could provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about sympatric canid populations and conflict management. Collection of finer temporal scale location data would help to manage interactions of sympatric canids with humans, as well as to support development of dynamic stochastic population models.

B. Objectives (after December 1, 2016-November 30, 2018)

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners.

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

At the end of this two-year pilot study, we will deliver an observational summary detailing the use of the GPS and sensor technology for spatial and population dynamics research on sympatric canids on the AP.

C. Expected Results and Benefits

As part of a pilot study, we will monitor the status of collared individuals by using a finer scale assessment of space and habitat use than previous studies. Earlier research focused on many of the same objectives we suggest investigating here, but during a time of intense, active

Draft - Confidential

management. Specific management techniques are no longer being carried out and dynamics between sympatric canids are expected to have changed substantially. The uncertainty regarding current dynamics presents a need for additional research in order to inform actions for the management of sympatric canids. Information gained from research may impact management rules and landowner's abilities to manage canids in some areas. Additionally, GPS technology has improved since earlier research was conducted allowing for more temporally detailed data collection and more nuanced analyses. Understanding how sympatric canids collectively use resources in areas of human-dominated landscapes will allow wildlife managers to tailor management options to local conditions. On the AP, row crop agriculture and hunting represent the primary and secondary land uses, respectively. Row crop agriculture is a significant nutrient resource on the landscape and, as opportunists, canids take advantage of such resources when they are available. Non-consumptive wildlife-driven tourism persists in all seasons and wildlife watching is a main draw for tourists in this area. For many tourists, the opportunity to see or hear large carnivores is the sole attraction for traveling to the AP. Information from this study will be provided to local constituents to establish a knowledge base regarding how sympatric canids use resources on private lands. Management and guidance could serve to prevent or minimize conflict while maximizing positive wildlife interaction opportunities for constituents. Development of a common understanding between wildlife managers and landowners based upon factual information is paramount for collaboratively achieving successful management of sympatric canids. The data collected in this pilot study is the foundation upon which this understanding and future management actions will be built.

The current level of hybridization between sympatric canids on the AP will be characterized using DNA gathered during this study. Body size exists as a continuum between coyotes and red wolves and has been documented as the most important factor for successful interspecific breeding pairs of these canids (Hinton 2014). Though both species have been found to use resources in similar manners, red wolves generally have more expansive home ranges and therefore may not use local resources as intensively as coyotes, depending on body size. Obtaining individual identification of study animals will allow managers, armed with spatial information, to infer how and why individuals in the canid species continuum exploit

Draft - Confidential

anthropogenic resources considering their life history traits.

In conjunction with prior research, data collected will contribute to knowledge on sympatric canid population dynamics on the AP. Estimating population size will allow managers to monitor population trends of sympatric canids and to examine the long and short-term impacts of different management strategies on their populations. While it is unknown whether sample size will allow for population estimation, obtaining population estimates for coyotes would provide wildlife managers with baseline data, when paired with annual mortality estimates, for monitoring changes in population abundance over time. Information on changes in abundance, reproductive dynamics, and habitat use could impact management strategies to influence long-term conservation outcomes. Results of this pilot study will allow managers to determine if future work will be necessary, what amount of effort will be required to achieve each objective, and whether or not population estimates will be an attainable goal.

D. Approach

The official Red Wolf Recovery Area (RWRA) covers approximately 6,900 square kilometers within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014). However, the USFWS has proposed the RWRA be constricted to the ARNWR and the Dare County Bombing Range in Dare county by the end of 2017. Due to these proposed RWRA changes, this study proposes to capture and radio-collar 25 sympatric canids within Dare, Hyde, and Tyrrell counties (hereafter referred to as “study area”); those counties being within and directly adjacent to the proposed new RWRA. The thematic subheadings below provide detailed descriptions of the approaches required for achieving the pilot study objectives.

Sampling Efforts

Trained NCWRC personnel will conduct live trapping of sympatric canids, with assistance from the USFWS RWRP biologists, and trained, experienced local trappers. NCWRC and USFWS wildlife personnel will select local trappers based on their past performance in trapping sympatric canids, but may also select trappers from the NCWRC coyote trappers list. NCWRC staff will train contracted trappers on specific trapping procedures before every trapping

Draft - Confidential

season. The project lead will supervise and coordinate all trapping activities including locations for installation and the operation of trap lines and handling of captured animals. Simultaneous personal trapping activities by contracted trappers will not be permitted while performing contracted trapping services, as specified in the draft service contract (Attachment 4).

Trapping efforts will follow a spatial capture-recapture (SCR) framework with a systematic targeted sampling design, focusing on areas that contain resources previously found to be used by sympatric canids (e.g. edge, agricultural fields, secondary roads, etc.) (Harris et al. 2013, Ivan et al. 2013), while attempting to sample a diversity of habitat types. This effort will allow us to increase the probability of detection of sympatric canids on the landscape (Tom 2012). While it is important to sample a wide range of habitats, the most important requirement for SCR is the number of collared individuals; this requirement provides flexibility in the other requirements for field sampling as needed (K. Pacifici, personal communication, 2016). We will initially focus trapping in areas of known red wolf packs, as advised by RWRP.

Trapping will take place during the breeding season when the likelihood of capturing females in the later stages of gestation or whelping females will be low. Capture efforts will be conducted from soon after 1 December 2017 – February 2018 and December 2018 – February 2019. Captured sympatric canids will be surrendered to NCWRC or the USFWS at capture sites. Trapping should occur on both public and private lands to obtain sampling coverage of the study area. Ideally, all federal and state lands would be accessible for trap and release (hereafter referred to as "capture") of sympatric canids, but it is most important to be able to trap and release on Alligator River NWR and the Dare County Bombing Range as those encompass the newly proposed RWRP recovery area and comprise the majority of land area for Dare county. Unlike Dare county, there are ample private lands that surround Pocosin Lakes NWR and Lake Mattamuskeet NWR in both Tyrrell and Hyde counties that may be utilized to effectively sample individuals who may use those federal lands, should they be excluded from capture activities. Capture on federal lands may require USFWS take permits and proposed activities may be subject to a compatibility assessment (P. Benjamin, personal communication, 2016). Scientific collection activities that take place on private lands will require agreements outlining conditions mutually decided by NCWRC and landowners (Attachment 3).

Draft - Confidential

To increase probability of detection of sympatric canids, the accessible study area will be partitioned by a grid, the cell size of which will based on the average annual home range size of resident coyotes previously reported for the AP, approximately 23 km^2 (Hinton et al. 2015). As a system of sampling, trap lines will be referred here as "traps," and the number of trap sets (i.e. the actual trapping device) and number of each trap set size may vary between traps as necessary. Sampling will be standardized within each grid cell by use of equal number of traps per cell, on average 3 per cell, each at an approximate length of 10 km (Andelt and Gipson 1979, Way et al. 2004).

Target canids will be captured by using Softcatch #3 Coyote 4x4 (Oneida Victor Inc. Ltd., P.O. Box 32398, Euclid, Ohio 44132, Hinton 2014, Schemnitz 1994), the EZ Grip #7 (Livestock Protection Company, P.O. Box 725, Alpine, Texas 79831, Frame and Meier 2007), or equivalent. Various lures and baits will be used to increase trapping efficiency (Frederick et al. 1989, Shipley 2012). Traps will be laid on the Monday of each week and will be opened at the time of deployment. Traps will be checked once daily at dawn, to reduce potential stress to trapped individuals and will not be operated on days where the temperature is expected to reach or exceed 80° F (R. Nordsven, personal communication, 2016) or during times of predicted inclement weather (e.g. snow, hail, high wind, etc., Sikes et al. 2011). To standardize effort and remain logistically realistic, traps should be open for three trap nights in a row before being removed. Trap sets that have been closed due to non-target bycatch or other circumstances may be reopened and all traps should be re-baited and lured as appropriate.

Trap set locations will be marked by NCWRC or USFWS personnel using handheld GPS units (Garmin GPSMAP 64S, 1200 E. 151st St., Olathe, KS 66062-3426) and given a sequential identification number. Traps will also be given an identification number and trap set points will be documented in ArcMap 10.4. Trappers will keep detailed records on trap set operation, non-target species trapped, and other relevant details. Non-target species will be released from traps after an in-field assessment of injuries, if any, and animals with life threatening injuries will be euthanized by the trap operator. Targeted recapture of collared canids will occur annually during the same months, to replace GPS collar batteries and drop-off collar release units in field. Trapping effort will be quantified (trap nights), the effective sample area will be

Draft - Confidential

estimated, the encounter (detection) probability will be estimated using a Gaussian detection model (Amundson et al. 2014), and an estimate of density for coyotes will be calculated using a modified Huggins closed-capture estimator in program MARK, if sample size allows (Harris et al. 2013, Ivan et al. 2013).

Animal Handling

Handling of canids will follow American Society of Mammalogists (ASM) guidelines (Sikes et al. 2011) and will be performed at the capture site. Chemical immobilization agents may be used depending on the number of field staff during processing (i.e., three or more staff required during non-chemical immobilizations, Craft 2007, M. Morse, personal communication, 2016).

Chemical Immobilization

Unless adequate numbers of personnel are available to safely employ mechanical restraint techniques, target animals will be anesthetized with the chemical immobilization agent BAM (Wildlife Pharmaceuticals, Inc., Windsor, CO 80550). BAM, a combination of Butorphanol tartrate, Azaperone tartrate and Medetomidine HCl., will be delivered by intramuscular injection by syringe pole to the hip. Dosage for canids is based on field trails performed by Wildlife Pharmaceuticals (Wildlife Pharmaceuticals, Inc. 2016) and the recommended dose for coyotes is 0.2CC and red wolves is 0.3CC, with adjunct doses of 0.1-0.2CC delivered if initial dosages do not cause induction (S. Kirschner, personal communication, 2017). Induction times for coyotes and wolves ranged from 5 to 10 minutes after initial and/or adjunct dosages (Wildlife Pharmaceuticals, Inc. 2016). After field handling is concluded the anesthesia will be reversed using two reversal agents, Atipamezole and Naltrexone, at double the CC of Atipamezole to BAM that was delivered (including adjunct doses, if given) and 0.5CC of Naltrexone. Recovery time from the reversal agents ranged from 10 to 25 minutes during field trails (Wildlife Pharmaceuticals, Inc. 2016). Field personnel will observe animals for signs of adverse effects for up to 30 minutes after reversal agents are delivered.

Mechanical Immobilization

Unlike other carnivore families, the submissive behavioral response of canids to

Draft - Confidential

perceived dominance reduces the need to use immobilization agents. Appropriate mechanical restraint techniques can reduce handling time of animals, allowing animals to reintegrate into social groups more quickly, subsequently reducing overall stress to the individual (Powell and Proulx 2003). Target canids will be mechanically restrained with a restraint pole, until two muzzles can be placed around the snout. While pinned with the restraint pole by one person, a second person will restrain the set of legs not in the trap against the ground and a third person will release the foot from the trap. This set of legs will then be restrained by the 3rd person as the restraint pole is removed. Once the restraint pole is removed the person restraining the front legs will also then restrain the head. The first person will then move forward with processing the captured animal.

Each animal will be placed on a towel or blanket to provide thermal protection from the ground, with eyes covered and lubricated with eye ointment; temperature will be monitored with a rectal thermometer. Overheating occurs at approximately 104-105°F for canids (AZA Canid TAG 2012) and the animal handling crew will monitor temperature at 5-minute intervals; if a temperature reading reaches 104°F, corrective actions will be taken and temperature will be monitored at 1-minute intervals. Should overheating occur, the individual will be removed from insulation to expedite the natural evaporative cooling process. During days that approach 80°F in temperature, measures will be taken to reduce heat stress, such as: wetting the animal with water, application of a cold pack to the groin area between the back legs, application of rubbing alcohol to foot pads, or immediate release (AZA Canid TAG 2012). If the injured individual is suspected to be a red wolf, based on morphometrics, USFWS staff will be contacted for a decision. In the event that trap caused injuries are determined to be life threatening through use of a trap injury score assessment (Frame and Meier 2007) the individual will be euthanized. In the event that NCWRC personnel cannot be present, trained USFWS personnel may collar and measure captured target animals and will provide data sheets to NCWRC staff. Target animals will not be vaccinated or otherwise treated for diseases, regardless of the presence of disease symptoms.

Non-target animals will be released on site. Captured domestic dogs will be immediately released from the trap set following an injury score assessment and only if no life-threatening

Draft - Confidential

injuries are present. If a domestic dog has sustained life threatening injuries and owner identification information is present on the dog, then the animal will be held in either a transportable kennel, or at a dog pen on a state game land that is equipped with such facilities, until the owner can retrieve the dog. The costs associated with injuries sustained to the dog will be the responsibility of the animals' owner. Law enforcement may be requested to help communicate with the animal's owner. If the animal does not have an identifiable owner and has incurred substantial life threatening injuries (i.e. compound fracture), the dog will be euthanized on site. Target animals showing signs of disease symptoms such as circling behavior, head tilt, muscle twitches, convulsions with jaw chewing movements and salivation ("chewing gum fits"), disorientation, incoordination, staggering caused by paralysis of the hind legs, seizures, and partial or complete paralysis will be euthanized and tested according to protocol set forth by the agency veterinarian, in order to determine if there may be a public health issue (M. Palamar, personal communication, 2016). USFWS will be contacted in cases of suspected red wolves. Staff involved in animal handling duties will have the pre-exposure rabies vaccination series completed prior to field work inception and will maintain rabies titer records through properly licensed medical services providers.

If staff is bitten and skin is broken by an animal while performing handling duties, they will be advised to immediately visit a local hospital or clinic for evaluation by healthcare professionals. The field coordinator will immediately notify supervisory staff and an injury report and workers' compensation claim will be opened for the incident. The animal will be euthanized and the head will be sent to the state lab for rabies testing; the body may be sent to the Southeastern Cooperative Wildlife Disease Study (SCWDS) laboratory for additional disease investigation.

Capture Processing and Marking

During canid handling, NCWRC personnel will record age class, sex, weight, total body length, head width, ear length, and tail length, visually assess ectoparasite load, look for and disinfect with betadine or iodine as needed any minor trap caused injuries, and affix GPS collars (Knick 1990, Sikes et al. 2011). All captured canids will be fitted with appropriately-sized GPS collars in the field based on morphometrics previously indicated as reliable thresholds for

Draft - Confidential

species categorization: hind foot length, weight, width of head, and tail length (Hinton 2014); analysis of DNA samples collected during trapping efforts will help to assign captured canids to position along the species continuum post release. Age of individuals will be estimated based on physical characteristics, including weight and tooth replacement (Knick 1990, Hinton 2014, Gier 1968), and captured canids will be aged into one of three classes: > 2 years old as adults, < 2 but > 1 year old as juveniles, and > 6 months but < 12 months old as pups (Hinton 2014). Reproductive status will be determined based on estimated age class and presence of gonadal descent during the breeding season for males and the presence of nipple swelling or previous suckling for females (Hutson and Racey 2004, Magee 2008, Mengel 1971).

Captured individuals will be ear marked using a button tag (model 410, Ketchum Mfg. Co. [or equivalent], PO Box 10, 11 Town Shed Road, Lake Luzerne, NY 12846) placed along the middle of the ear where they are most protected from loss, with a pin-type applicator (485sa Pow-R-ceps plier, Ketchum Mfg. Co. [or equivalent]) (Silvy 2012). The puncture site will be treated with an antiseptic to deter infections. Each sympatric canid will also be marked with an individually-numbered, glass-encapsulated, passive integrated transponder (PIT model HPT12, 12.5 mm, 134.2 kHz, Biomark, Inc., 703 South Americana Blvd., Suite 150, Boise, ID; Gannon et al. 2007), using a syringe-type implanter and replaceable needle (model MK10 [implanter], model N125 [needle], Biomark, Inc.). Successful PIT placement will be verified with a mini portable reader (model GPR Plus, Biomark, Inc.). The implantation site will be prepared by swabbing with 70% alcohol (Mrozek et al. 1995) and a sterilized new needle will be used for each injection. The standard implantation site for transponders is subcutaneously on the dorsal midline of the back, cranial to the shoulder blades (Ingwersen 2000).

A skin biopsy will be taken from all captured target canids by puncturing the pinna of the ear with a biopsy punch in the same location where the ear tag will be placed (Palamar 2014). The biopsied area will be disinfected with alcohol after sampling. The skin biopsy will be placed in a labeled (ID, date, and sample type) cryogenic tube filled with 95% ethanol as buffer and then stored in a freezer until sent out to a lab for genetic analysis (Palamar 2014, Tom 2012). A selection of hairs with the root bulla attached will be pulled from the belly and placed in paper envelopes (Janecka et al. 2007). Hair samples will serve as back up to tissue samples

Draft - Confidential

for genetic testing. All samples will be sent to the Laboratory for Ecological, Evolutionary and Conservation Genetics, at University of Idaho (875 Perimeter Drive, MS 1136, Moscow, ID 83844) for genotyping to determine species as well as individual identification, hybridization presence, and parentage analysis following previously developed protocols (Adams et al. 2007, Hinton 2014, Miller et al. 2003). The appropriate genetic analyses that examine the coyote-hybrid-wolf species continuum will be performed.

Blood will be collected from all juvenile and adult target canids by venipuncture of the brachial or jugular veins using a 22-28-gauge needle (M. Palamar, NCWRC veterinarian, personal communication, 2016). As per NCWRC veterinarian recommendations, approximately 12 ml of blood will be collected for each animal for possible future testing for diseases of importance to sympatric canid species as well as the humans and domestic animals that they may come into contact with. A minimum of two 6 ml lavender top tube (for whole blood with EDTA) will be filled. Samples should be refrigerated at all times; a cooler with ice will suffice while in the field. Samples should be sent to the NCWRC within 48 hours or frozen for later shipping. Skin scrapes will be collected from animals presenting signs compatible with sarcoptic mange (lesions) for possible future diagnostic purposes. Lesions will be scraped until blood is drawn; the scrapings will be placed onto a slide and covered with a piece of clear tape for later visual confirmation.

Should overheating occur, processing will be performed in the following prioritization order and the first five items will need to be completed before releasing any individuals: 1) trap injury evaluation, 2) collaring, 3) DNA (skin biopsy) sample collection, 4) morphometrics, 5) aging, 6) PIT tagging, 7) weight, 8) ear tagging, 9) reproductive status, 10) ectoparasite evaluation, 11) blood collection, and 12) skin scrape collection.

Collaring

Vertex Plus GPS Collars will be attached to 25 sympatric canids captured on the study area, 10 of which will be equipped with proximity sensors (Vectronic Aerospace GmbH, Carl-Scheele-Str. 12, 12489 Berlin, Germany). Project staff will pilot test proximity sensor technology for utility in analysis of spatial and temporal community dynamics. Proximity sensors trigger increased GPS location acquisition during those time intervals when two collared individuals

Draft - Confidential

come within a set distance from each other (http://www.vectronic-aerospace.com/wildlife-monitoring/sensors/uhf-id-tags, accessed August 2016).

To avoid instances of collar induced strangulation, only adult (>2 years old) male and female individuals will receive collars (Hinton 2014). ASM guidelines recommends a collar weight of <5-10% of a canids bodyweight, we will observe these guidelines (Sikes et al. 2011). Sympatric canids not releasable at a capture site will not be collared and will not become study animals.

GPS radio-collars will have both VHF and GPS Iridium locational systems as well as store-on-board capabilities. Radio-collar units will be programmed to record GPS coordinates once every 1.75 hours producing approximately 13 locations per day while cycling through the 24-hour time cycle. These settings will allow for a GPS battery life of 300 to 552 days, averaging 431 days. The VHF beacon will be in operation from 0800 – 1600 hours daily. GPS locations will be sent via satellite once per day and each transmission with contain 12 locations. The use of an integrated drop off firing mechanism should allow the collars to drop off within a maximum of approximately 548 days after deployment. The drop off schedule once set cannot be changed. The drop off firing mechanism is wired to a battery unit independent of the collar battery, therefore should the collar battery become depleted, the drop off mechanism will not be affected (C. Akakpo, Vectronic Aerospace GmbH, personal communication, 2016). Unless a collared individual is recaptured before the collar battery dies, the drop off mechanism will fire at the scheduled time frame post collar deployment.

Observation of sympatric canid habitat use and movements will occur through GPS data obtained with combination GPS/VHF radio-collars. VHF relies on triangulation, the process of estimating the location of a transmitter by using two or more compass bearings obtained by using directional antennas at known locations remote from the transmitter's position (White and Garrott 1990), whereas GPS uses a satellite based system to obtain location coordinates. There have been many published studies where one or both of these methods were used, with mixed success for determining various aspects of carnivore ecology throughout the United States (Hinton et al. 2012, Schrecengost et al. 2009, Sparkman et al. 2012). While GPS technology has developed rapidly in recent history, the real time functional advantage of VHF

Draft - Confidential

cannot be disregarded. When GPS technology falters or malfunctions, VHF can serve as replacement for data collection in addition to its use in real time monitoring of study animals. Canids will be minimally monitored for mortality approximately every 30 days by using VHF aerial telemetry techniques (Whitehouse and Steven 1977) as there may be a delay in satellite transmission of GPS location data due to weather, season, and animal behavior. Transient canids and individuals from breeding pairs that have lost a mate, have been found to use much larger areas versus paired residents, potentially increasing the opportunity for losing track of these individuals when GPS technology reaches its functional capacity or experiences malfunction. VHF data may also provide locations of canids in cover too dense for GPS units to function. Use of VHF telemetry techniques for data collection may be expanded as necessary for project needs.

Spatial Data Analyses

Both minimum convex polygon (MCP) and adaptive kernel (AK) home ranges (95%) and core use areas (50% and 25%) (Seaman and Powell 1996, Seaman et al. 1999) will be calculated from GPS data by using BIOTAS (Ecological Software Solutions LLC, 2016) and Geospatial Modelling Environment (Spatial Ecology, LLC, 2016) for ArcGIS 10.2.2 (Environmental Systems Research Institute, 2016) (Benson et al. 2006, Riley 2006, Tucker et al. 2008, Hinton 2014) for comparison to older studies. These estimations can also be calculated using VHF data, provided data minimum requirements are met. Spatial distribution in relation to habitat will also be estimated by dynamic Brownian bridge movement models as described by Hinton (2014) with R statistical software (R Core Team 2016) using the moveud package with habitat covariates important to each species (Bryne et al. 2014, Collier 2013, Kranstauber and Smolla 2013, C. Proctor, personal communication, 2016). Additionally, recent research into how canids shift their ranges will also be investigated for populations on the AP (Morin and Kelly, in review). Spatial overlap and co-occurrence will be assessed using methods described by Shipley (2012). Habitat and cover types will be estimated from digitized maps created by the SEGAP (Hinton 2014) or ortho files, as available (Shipley 2012). Percent composition of habitat and cover types within home ranges and core areas as well as edge density will be quantified (Shipley 2012). Habitat selection and cover type use effects on spatial distribution will be estimated at both the population (2nd order) and individual (3rd order) spatial scales using resource selection functions

Draft - Confidential

(Johnson et al. 2006, Manly et al. 2002, Shipley 2012). Effects of seasonality and time of day activity will also be explored. The spatial and temporal patterns of space use by sympatric canids will be studied using data generated from the interaction GPS collar sensors, particularly distance between individuals and duration of proximity.

Den Monitoring

Project staff will attempt to locate den sites for sympatric canids to get pup counts, morphometric measurements, age estimates, and skin biopsies. Project staff will also attempt to monitor pup survival during the pup rearing season by using remote cameras placed around the den site (Harrison and Gilbert 1985, Parks 1979, Way et al. 2001). Pups will be weighed, measured, and PIT tagged during May and June of each year when they become active but are still den-obligated (Gier 1968). We will investigate the use of remote camera traps for monitoring den behavior with a two-camera array around the den (H. Garbe, personal communication, 2016, Kays and Slauson 2008). This method has been successfully used to monitor kit fox pup survival (Kluever et al. 2013). Because coyotes have been found to be sensitive to den site disturbance, there is a general lack of data in the literature regarding this approach for monitoring pup survival. Approaching an experimental methodology systematically will be important for determining which methods are effective and which are not. As a starting point for testing this methodology, remote cameras will be placed two to five meters from main den entrances and set to take photos using a passive infrared sensor trigger (a beam that when broken by movement through it, triggers the camera to take a series of photos) with a time restriction between photo intervals to limit the number of photos taken and maximize the space on the memory card for the time period between camera checks (Kluever et al. 2013). Cameras will be checked six days after deployment and will be redeployed (i.e. new batteries and memory card, if required); cameras will remain at each den site until radio-collar data indicates the den site has been moved (Kluever et al. 2013). Cameras will be not be redeployed to a new coyote den site during a season if that breeding pair has already moved the den once due to the disturbance of camera presence/deployment.

Draft - Confidential

Mortalities

If a collared animal dies during the project, the carcass will be sent to SCWDS for necropsy. Red wolves will be sent to the SCWDS laboratory for necropsy, unless it is determined to be a law enforcement case. In potential law enforcement cases, the NCWRC Division of Wildlife Management Chief and USFWS Ecological Services Raleigh Field Office Field Supervisor will be contacted and requested to contact the appropriate law enforcement personnel, immediately after determining the need for law enforcement involvement. The carcass and all relevant information will then be turned over to law enforcement; the GPS-collar will be removed and genetic samples will be taken from the individual prior to release to law enforcement.

E. Project Personnel

Andrea Shipley has worked for the North Carolina Wildlife Resources Commission as a Canid Biologist since February 2016. Prior to that, she worked as a Wildlife Biologist for a non-profit located in northeastern Nevada as well as in several different field biologist oriented positions. Andrea has a background in carnivore and spatial ecology, having earned her MS in Biological Sciences from Eastern Kentucky University and BS in Biological Sciences from Rutgers University; Andrea will act as project lead and coordinator.

Brandon Sherrill has worked for the North Carolina Wildlife Resources Commission as a Mammalogist since December 2013. Prior to that, he worked as an educator at the North Carolina Museum of Natural Sciences and as a regional wildlife biologist for the South Carolina Department of Natural Resources. Brandon earned a BS and MS in Fisheries, Wildlife, and Conservation Biology from North Carolina State University; Brandon will act as project supervisor.

Krishna Pacifici, Research Assistant Professor at NCSU, will be the quantitative analysis collaborator on the project. Krishna's background and experience in quantitative ecology makes him well suited to consult and assist with advanced statistical analyses of spatial data.

Lisette Waits, Department Head and Distinguished Professor at the University of Idaho, will be the DNA analysis collaborator for the project, responsible for all DNA related sample processing and subsequent analyses.

Draft - Confidential

F. Schedule and Estimated Costs

The project will run from soon after December 1, 2017 through June 30, 2020. The estimated timeline for major tasks is as follows:

Year 1: Initiate field work soon after December 1, 2017 with assistance from 1-2 field technicians; 1 technician will be required for trapping and den monitoring efforts. Data collection will begin immediately after collar deployment and data will be managed by Andrea Shipley throughout the life of the project. Data analysis will be initiated after den monitoring season concludes, with guidance and assistance from Krishna Pacifici at North Carolina State University (NCSU). Report, manuscript and presentation production will be initiated concurrently with data analysis.

Year 2: Continue field work and data collection with assistance from 1-2 field technicians. Continue data analysis with guidance and assistance from Krishna Pacifici at NCSU. Continue and finalize report and manuscript production, and presentation at professional working groups and/or meetings.

GPS technology allows researchers to collect locational data at fine spatial and temporal scales through the deployment of collar units on wildlife study subjects. In this project, we propose to study a sample of sympatric canid populations with GPS radio-collars, in order to investigate the population parameters outlined in previous sections as well as species interactions. The purchase and use of this technology is critical to meeting the research objectives set forth in this document as well as in the document included in Attachment 1.

While GPS technology has evolved over the past 20 years, the cost of technology has plateaued. Upfront cost per unit remains relatively high, however project savings occurs at the back end when compared to older telemetry technology such as very high frequency (VHF)

Draft - Confidential

which require intensive labor to collect data at similar spatial and temporal scales. Pilot testing the proximity sensor enabled GPS-collars will allow investigation of the utility of this relatively new tool for community dynamics analysis by providing an increased locational data acquisition when individuals come within a set distance, or closer, from each other. Additionally, these sensors record the identities of the interacting individuals and the duration of their interactions. Using a trigger to temporarily switch GPS fix schedules will enable us to collect very fine scale data while conserving battery life, achieving project objectives in an efficient manner. Exploring the efficaciousness of this technology has the potential to positively impact future research projects requiring use of GPS-collars for data collection.

Aerial tracking will provide regular study animal surveillance useful to investigate cases of mortality, collar malfunction, or satellite data transmission delays, which can vary seasonally. In some situations, ground tracking could prove less expensive than aerial tracking. However, ground telemetry techniques require more than one biologist working in tandem to acquire accurate location estimates. This often translates to increased labor to collect data, particularly in large study areas. Aerial tracking will provide a more efficient and cost-effective method for surveilling study subjects in this large study area, requiring only one biologist and a contracted pilot. NCWRC personnel will perform aerial tracking along with the NCWRC pilot at a minimum frequency of every 30 days.

Use of local trappers to assist with sampling efforts provides several benefits. Local trappers have established, long-term relationships with private land owners, thereby providing access to private lands that might be otherwise difficult to secure. This will enable project biologists to obtain a representative sample of sympatric canids in the study area, as well as to operate more trap lines concurrently. This is particularly important when using a SCR sample design, as it will have direct implications on the resulting analyses and inferences.

As part of collaboration efforts, the project will contract the services of Krishna Pacifici, Research Assistant Professor in the Applied Ecology department at NCSU. Krishna's expertise is in quantitative ecology; consultation and assistance services provided will allow project biologists to make appropriate statistically relevant inferences from collected data.

Draft - Confidential

DNA analysis will be contracted to Lisette Wait's lab at the University of Idaho. Lisette's team at The Laboratory for Ecological, Evolutionary and Conservation Genetics has previous experience in analyzing red wolf and coyote hybrid molecular samples and has the most comprehensive DNA methodology for this sympatric canid species continuum in the nation. This expertise will facilitate expedient species identification on collared study animals besides landscape level population dynamics analysis.

	Commission	In-kind	Total
a. Personnel	$ 7,200.00	$ -	$ 7,200.00

I. Glossary

Abundance: Species abundance is the number of individuals per species, and relative abundance refers to the evenness of distribution of individuals among species in a community.

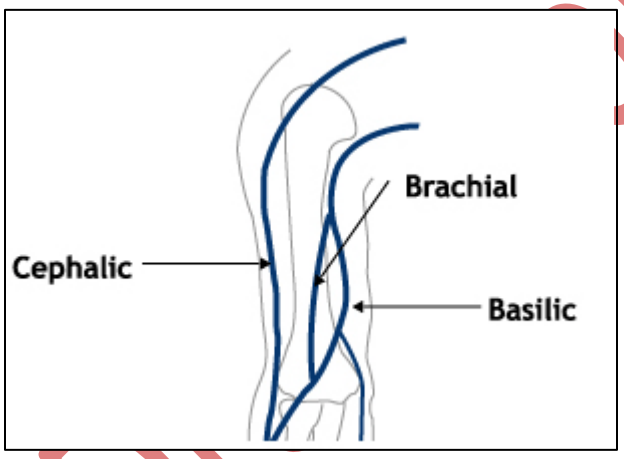
Adaptive kernel (AK): A probabilistic home range estimator based on the distribution and density of locations that has been collected over a period of time.

Adverse reactions: In pharmacology, any unexpected or dangerous reaction to a drug.

Aerial: Existing, happening, or operating in the air.

Annually: Once a year; every year.

Anthropogenic: Caused or influenced by humans.



Apex: Having no natural predators in its ecosystem.

Ataxia: The loss of full control of bodily movements.

Beacon: A radio beacon whose purpose is the investigation of the propagation of radio signals.

Biopsy: The removal for diagnostic study of a piece of tissue from a living body.

Brachial vein: One of a pair of veins accompanying the brachial artery and uniting with each other and with the basilic vein to form the axillary vein.

Breeding pair: A pair of animals which cooperate over time to produce offspring with some form of a bond between the individuals.

Carrying capacity: The maximum population size of the species that the environment can sustain indefinitely, given the food, habitat, water, and other necessities available in the environment.

Compensatory immigration: Individuals emigrating from areas with lower mortality to those with higher mortality; filling a deficiency of individuals in a population experiencing higher mortality. The increase in size or activity of one part of an organism or organ that makes up for the loss or dysfunction of another.

Composition: The combining of distinct parts or elements to form a whole.

Confidential

Co-occurrence: Refers to observation of the spatial overlap between two (or more) different individuals over a period of time.

Coordinates: Any of the scales or magnitudes that serve to define the position of a point.

Core use areas: An area within a home range exhibited by a dense concentration of location points; commonly estimated at 50% of the location data points.

Covariates: A variable that is possibly predictive of the outcome under study.

Cranial: Pertaining to the cranium or to the anterior (in animals) or superior (in humans) end of the body.

Cryogenic: Very low temperatures, e.g. -80^{o}C.

Den-obligated: Restricted to a particular condition of life, in this case restricted to a den site.

Density: A measure of the number of organisms that make up a population in a defined area.

Deployment: To organize and send out (people or things) to be used for a particular purpose.

Depredation: The act of preying upon.

Depressed respiration: A decrease in the ability to exhale and inhale; respiration that has a rate below 12 breaths per minute or that fails to provide full ventilation and perfusion of the lungs.

Diagnostic: The process of determining by examination the nature and circumstances of a diseased condition.

Disorientation: Loss of one's sense of direction, position, or relationship with one's surroundings.

Distribution: The manner in which a biological taxon is spatially arranged.

DNA: (deoxyribonucleic acid) is a type of macromolecule known as a nucleic acid. It is shaped like a twisted double helix and is composed of long strands of alternating sugars and phosphate groups, along with nitrogenous bases (adenine, thymine, guanine and cytosine).

Dorsal: Situated on or toward the upper side of the body, equivalent to the back, or posterior, in humans; situated on or toward the posterior plane in humans or toward the upper plane in quadrupeds.

Duration: A continuous period of time.

Dynamic Brownian bridge movement models: Incorporates temporal and behavioral characteristics of movement paths into estimation of home range.

Ectoparasite: a parasite that lives on the outside of its host rather than within the hosts body; e.g. fleas and lice.

Effective trap area: Calculated by buffering each trap site by half the mean maximum distance traveled, each of these boundaries are dissolved, creating a measurable area.

Efficacious: Producing or capable of producing a desired effect.

Draft- Confidential

Efficient: Accomplishment of or ability to accomplish a job with a minimum expenditure of time and effort.

Euthanize: The act of putting to death painlessly or allowing to die, as by withholding extreme medical measures, a person or animal suffering from an incurable, especially a painful, disease or condition.

Expedient: Suitable for achieving a particular end in a given circumstance.

Evaporative cooling: reduction in temperature resulting from the evaporation of a liquid, which removes latent heat from the surface from which evaporation takes place.

Facilitate: Make an action or process easy or easier.

Genotyping: Investigate the genetic constitution of (an individual organism).

Gonadal descent: The act or process of descending from a higher to a lower location; testicular descent occurs during the breeding season annually.

GPS: Global Positioning System, is a radio navigation system that allows land, sea, and airborne users to determine their exact location, velocity, and time 24 hours a day, in all weather conditions, anywhere in the world.

Home range: an area over which an animal or group of animals regularly travels in search of food or mates, and that may overlap with those of neighboring animals or groups of the same species.

Hybridization: The result of mixing, through sexual reproduction, two animals or plants of different breeds, varieties, species or genera.

Immobilization agent: An active force or substance capable of producing an effect.

Implantation: To put or fix firmly.

Inbreeding depression: The reduced biological fitness in a given population as a result of inbreeding, or breeding of related individuals.

Inception: The establishment or starting point of an institution or activity.

Interspecific: Existing or occurring between different species.

Iridium: A satellite constellation providing voice and data coverage to satellite phones, pagers and integrated transceivers over the Earth's entire surface.

Jugular vein: Any of several large veins in the neck, carrying blood from the head and face.

Lacerations: A deep cut or tear in skin or flesh.

Locational: A position or site occupied or available for occupancy or marked by some distinguishing feature.

Malfunction: Fail to operate in the normal or usual manner

Methodology: A system of methods used in a particular area of study or activity.

Midline: A median line or plane of bilateral symmetry, especially that of the body.

Draft - Confidential

Minimum convex polygon (MCP): Completely enclose all data points by connecting the outer locations in such a way as to create a convex polygon.

Molecular samples: Genetic samples that may be used for investigation of genetic constitution of an individual.

Morphometrics: The process of measuring the external shape and dimensions of landforms, living organisms, or other objects.

Mortality: The state of being subject to death.

Non-target bycatch: Animals caught by accident that are not the target species being sought.

Parameters: A numerical or other measurable factor forming one of a set that defines a system or sets the conditions of its operation.

Parentage: The origin of something; the state or relation of a parent.

Passive integrated transponder: A microchip implant is an identifying integrated circuit placed under the skin of an animal.

Pinna: The external part of the ear in humans and other mammals; the auricle.

Plateaued: A period or state of little or no growth or decline.

Population dynamics: The branch of life sciences that studies the size and age composition of populations as dynamic systems, and the biological and environmental processes driving them (such as birth and death rates, and by immigration and emigration).

Population growth: The increase in the number of individuals in a population.

Population size: A group of organisms of the same species that live in the same area.

Population status:

Population trend: Changes over time and can include changes in ranging behavior and distribution, biogeography and life-history.

Population viability: The process that determines the probability that a population will go extinct within a given number of years.

Proximity: Nearness in space, time, or relationship.

Quantified: Express or measure the quantity of.

Quantitative: Relating to, measuring, or measured by the quantity of something rather than its quality.

Radio-telemetry: The use of radio waves for transmitting information from a distant instrument to a device that indicates or records the measurements.

Recumbency: The state of leaning, resting, or reclining.

Reintegrate: Restore (elements regarded as disparate) to unity.

Draft - Confidential

Remnant: A small remaining quantity of something.

Reproductive status: Relating to or effecting reproduction.

Spatial: Relating to, occupying, or having the character of space.

Spatial capture-recapture: A method commonly used in ecology to estimate an animal population's size. A portion of the population is captured, marked, and released. Marked animals are either recaptured or are tracked, each tracking location being considered a recapture.

Species Continuum: An aggregate of species capable of interbreeding, resulting in fertile hybrid offspring whose genetic composition may represent a varying array of phenotypes and genotypes from the parental species, at which the extreme ends of the spectrum are distinct.

Standardize: Cause (something) to conform to a standard.

Statistically relevant inferences: the process of deducing properties of an underlying distribution by analysis of data. Inferential statistical analysis infers properties about a population: this includes testing hypotheses and deriving estimates.

Stochastic population models: Ecological population modeling is concerned with the changes in population size and age distribution within a population as a consequence of interactions of organisms with the physical environment, with individuals of their own species, and with organisms of other species; stochasticity possesses some inherent randomness. In stochastic population models, the same set of parameter values and initial conditions will lead to an ensemble of different out puts.

Strangulation: The condition in which circulation of blood to a part of the body is cut off by constriction.

Stratifying: Form or arrange into strata, one of a number of portions or divisions likened to layers or levels.

Surveillance: Continuous observation of a place, person, group, or ongoing activity in order to gather information.

Survival: A living or continuing longer than, or beyond the existence of, another person, thing, or event.

Sympatric: Occurring within the same geographical area; overlapping in distribution.

Tachycardia: A heart rate that exceeds the normal resting rate. In general, a resting heart rate over 100 beats per minute is accepted as tachycardia in human adults.

Telemetry: See radio-telemetry.

Temporal: Of or relating to time.

Tooth replacement: The process of development of two successive sets of teeth, initially the deciduous set and consecutively the permanent set.

Transmitter: A set of equipment used to generate and transmit electromagnetic waves carrying messages or signals, especially those of radio or television.

Transponder: A device for receiving a radio signal and automatically transmitting a different signal.

Draft - Confidential

Vaccinate: Treat with a vaccine to produce immunity against a disease; inoculate.

Venipuncture: The puncture of a vein as part of a medical procedure, typically to withdraw a blood sample or for an intravenous injection.

VHF: Very high frequency is the ITU designation for the range of radio frequency electromagnetic waves (radio waves) from 30 MHz to 300 MHz, with corresponding wavelengths of ten to one meters.

II. State/Agency:

North Carolina / North Carolina Wildlife Resources Commission

III. Station Name:

FWS Raleigh Ecological Services Office

IV. Description of Proposed Action (attach additional pages as needed):

Conduct research project entitled "**Coyotes of the Albemarle: Spatial Ecology, Resource Selection, Demographics, and Interactions with a Sympatric Canid**"

The coyote (*Canis latrans*) is now abundant throughout the 100 counties in North Carolina (NC), where they are managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plains region of NC (Hinton et al. 2012, Murray et al. 2014).

Recently described as using "compensatory immigration," coyotes are able to opportunistically fill spatial resource gaps by periodic transiency (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with humans and other canids, especially while taking advantage of anthropogenic resources. Though a rural area, human land uses predominate on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011).

In 1968, individuals from a remnant population of red wolves were removed from Texas and Louisiana and a captive breeding program was initiated. The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). The red wolf population increased until 2008 and peaked at around 208 individuals (USFWS Red Wolf Recovery Program 2007), a few animals short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013), with an estimated carrying capacity of 140-150 for the AP (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). Red wolves presently inhabit an approximately 6900 square kilometer recovery area within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014).
Accurate up-to-date estimates of the population are unavailable, but USFWS staff report a population size of 45-60 individuals with three mortalities in 2016 (https://www.fws.gov/redwolf/index.html July 2016). Hybridization with coyotes, inbreeding depression, and gunshot mortality have all been suspected issues that have affected the population growth and viability since the inception of the Red Wolf Recovery Program (RWRP) (Hinton et al. 2013). In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of red wolves and other canids on the AP. A USFWS memorandum documented detailed action items for the joint management of canids on the AP, including specific research objectives which this proposal seeks to address (Attachment 1).

As coyotes on the AP increase in number, monitoring coyote movements, particularly in relation to red wolves, will provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about coyote population management. Collection of finer temporal scale location data will help to manage interactions of both canid species with humans, as well as to support development of dynamic stochastic population models.

Coyote and red wolves will be live trapped by cooperating NCWRC and USFWS staff, and private trappers using double coil size 3 foothold traps, during the breeding season (Nov-Feb for coyote, Jan-Feb for red wolves) in the tri-county area of Dare, Hyde and Tyrrell. Morphological measurements, incidents of injury, occurrence of ectoparasites, age classification, and reproductive status will be determined; blood and tissue samples will be taken for genetic analysis. All captured individuals that meet the age classification and weight requirements will be collared with GPS collar units. All captured and collared individuals will be released at the capture site. The objectives listed below will be achieved by obtaining measurements, samples and information from the captured, collared, and tracked individuals over the course of three years using GPS location data.

862

863

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners.

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

V. Pertinent Species and Habitat:

A. Include species/habitat: See section VI

B. Complete the following table:

SPECIES/CRITICAL HABITAT	STATUS[1]
Canis rufus	T

[1]STATUS: E = endangered, T = threatened, PE = proposed endangered, PT =proposed threatened, CH = critical habitat, PC = proposed critical habitat, C = candidate species

VI. Location:

A. Statewide

Albemarle Peninsula (see web address www.ncwildlife.org)

B. Section, township, and range (or latitude and longitude):

Dare, Hyde, Tyrrell counties

C. Distance (miles) and direction to nearest town:

As stated above

D. Species/habitat occurrence:

Canis rufus

VII. Determination of Effects:

A. Explanation of effects of the action on species and critical habitats in item V. B. (attach additional pages as needed):

SPECIES/CRITICAL HABITAT	IMPACTS TO SPECIES/CRITICAL HABITAT
Canis rufus	Trap induced injury is possible

B. Explanation of actions to be implemented to reduce adverse effects:

SPECIES/CRITICAL HABITAT	ACTIONS TO MITIGATE/MINIMIZE IMPACTS
Canis rufus	Use of appropriate trap types, daily trap checks, treatment of minor injuries, trapping season limitations and limitations on environmental conditions for trap operation

VIII. Effect Determination and Response Requested:

Species/ Critical Habitat	Determination[1]			Response[1] Requested
	NE	NA	AA	
Canis rufus		X		Concurrence

[1] Determination/Response Requested:

NE = No Effect. This determination is appropriate when the proposed action will not directly, indirectly, or cumulatively impact, either positively or negatively, any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested is optional but a "Concurrence" is recommended for a complete Administrative Record.

NA = Not Likely To Adversely Affect. The determination is appropriate when the proposed action is not likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat or there may be beneficial effects to these resources. Response Requested is a "Concurrence".

AA = Likely To Adversely Affect. This determination is appropriate when the proposed action is likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested for listed species is "Formal Consultation". Response Requested for proposed or candidate species is "Conference".

Attachment 2: Joint Memorandum

MEMORANDUM

November 20, 2013

TO: All Interested Parties

FROM: "for" Cynthia K. Dohner, Director, Southeast Region, U.S. Fish and Wildlife Service
Gordon S. Myers, Executive Director, N.C. Wildlife Resources Commission

SUBJECT: Collaborative Conservation of Red Wolves and Other Canids on North Carolina's Albemarle Peninsula

---

Recovery of the federally-listed red wolf has been a priority for the U.S. Fish and Wildlife Service (FWS) for more than 20 years and is focused in North Carolina on the Albemarle Peninsula (AP; i.e., Hyde, Tyrrell, Washington, Beaufort, and Dare counties). Comprehensive stakeholder involvement and collaboration with other management agencies is critical to successful recovery of any at-risk species. The North Carolina Wildlife Resources Commission (WRC) is a key collaborator in this regard, as it has jurisdiction over all state-trust wildlife resources in N.C.

Since 2009, the FWS and WRC have worked to broaden our collaboration in the conservation and management of all canid species (including red wolves) on the AP. As these efforts have solidified, specific actions have been jointly identified by our two agencies that will improve conservation outcomes. These actions are categorized into five areas; collaboration, research, outreach, regulatory, and enforcement. Specific action items are outlined and prioritized within each of these categories in Attachment A.

This memo establishes the FWS's and WRC's commitment to initiate, or to continue, the efforts outlined in Attachment A. The common goal in this effort is to establish clear expectations and accountability for collaboration regarding the action items on Attachment A, thus resulting in enhanced and seamless canid conservation and management on the AP. This approach provides the best opportunity to achieve recovery goals for red wolves, while at the same time managing other canids to balance biological variables with social expectations. The dynamics of these canid species are complex and offer unique opportunities for innovation. Appropriate staff from each agency is hereby tasked with immediately developing a timeline to implement these actions. Through this commitment, we will continue to advance our collective conservation goals.

875

Attachment A

Action Items for Collaborative Conservation of Canids on North Carolina's Albemarle Peninsula (AP)
(*Note: Action Items are prioritized within category.*)

Collaboration

1. The N.C. Wildlife Resources Commission (WRC) and U.S. Fish and Wildlife Service (FWS) will formalize in writing the collaborative management of canids on the AP. This agreement should:
    a. include a clear mission statement, goals, objectives, and implementation strategies (ask and answer the "Why?");
    b. set a goal to define success regarding canid management on the AP;
    c. espouse a philosophy of canid management operating within the context of a three-legged stool (i.e., federal and state governments and stakeholders);
    d. as available, commit funding and staffing resources for field personnel to contribute to the conservation of the red wolf and management of coyotes;
    e. as available, commit funding to conduct research pertinent to canid management on the AP;
    f. establish polices and goals for developing a collaborative genetic archive for AP canids, a data sharing portal accessible by staff in both agencies, and reciprocal sharing of all historical data (including phenotypic and genotypic data and literature) of the red wolf;
    g. establish a foundation for developing and implementing an adaptive approach to canid management on private lands on the AP;
    h. initiate development of a collaborative canid research program;
    i. describe plans to conduct the next five year Red Wolf Program review;
    j. outline options for holding annual workshops with federal and state enforcement staff;
    k. outline plans to hold semi-annual coordination meetings regarding canid management on the AP; and
    l. develop milestones for future development of a management plan for all canids in the AP.

2. The FWS will initiate a review of the current Red Wolf Recovery Plan to determine if the state-of-our-knowledge or field conditions have changed such as to warrant its revision. Review and comments from the WRC will be considered in this evaluation.

3. The WRC, with support and participation of the FWS, will establish a "Canid Forum" (similar to that established for manatees in Florida) to facilitate communication and discussion regarding canid management and citizen science opportunities on the AP.

876

877

Attachment A

Research

1. The FWS and WRC will provide funding and logistical support for research identified by the Red Wolf Recovery Implementation Team, Red Wolf Program staff, other FWS staff, or the WRC that promote the conservation and recovery of the red wolf and other canids on the AP. Studies could include:
    a. tests of the "placeholder theory" on the AP, including behavior of sympatric canids,
    b. determining carrying capacity of canids on the AP,
    c. determining genetic profiles of canid species on the AP,
    d. evaluating predator-prey dynamics,
    e. studies of canid habitat use,
    f. epidemiology of diseases impacting canids on the AP,
    g. development of stochastic simulation models of sympatric canid population dynamics and habitat use, and
    h. canid dispersal dynamics

2. The FWS and WRC will conduct jointly-supported research to determine the attitudes and opinions of N.C. private landowners and other citizens concerning canids on the AP (i.e., human dimensions studies).

Outreach

1. The FWS and WRC will collaborate with other partners to design and implement broad-based outreach and marketing programs with clear goals, objectives, strategies, and measurable outcomes, including development of consistent agency messages and educating the public about canids on the AP.

Regulatory

1. The FWS and WRC will initiate a review and, if needed, subsequent rule-making to clarify concepts or rectify conflicts in current federal or state rules (including the current 10(J) rule).

2. The WRC will review and evaluate statutory requirements for listing red wolves as state threatened in the five AP counties.

3. As data demonstrating a relationship between coyote hunting and red wolf mortality become available, the FWS and WRC will evaluate, and if appropriate implement, adaptive approaches to regulate of take of coyotes that may result in incidental take of red wolves.

4. The WRC will evaluate the status, management, and regulation of Controlled Fox Hunting Preserves.

878

879

Attachment A

5. The WRC will develop BMPs (due care provisions) for coyote hunting, trapping, and live sale.

6. The WRC will compile, compare, and contrast canid hunting and trapping regulations and programs in other states, including, but not limited to, other states with other species of wolves.

Enforcement

1. The FWS and WRC will develop coordination strategies to improve enforcement of federal regulations protecting red wolves.

I, the cooperator or cooperator's representative, have been informed of the methods and the manner in which research devices will be used, and of the possible hazards associated with their use. I understand that NCWRC, (to include its officers, employees and agents) will: exercise reasonable precautions to safeguard all persons to prevent injury to target and non-target animals; guard against the mishandling of control devices and materials; and exercise due caution and proper judgment in all scientific collection operations. I understand that NCWRC may collect Global Positioning System (GPS) coordinates at the project site as part of component or activity tracking or as wildlife disease monitoring or research data. I, the undersigned cooperator, do hereby give my consent and concurrence to NCWRC, its employees, and its agents, to use, upon lands owned, leased, or otherwise controlled by me, and identified by this document, the following methods and devices (an attachment of additional devices and/or methods may be attached):

Statement of agreement: The landowner, cooperator, or representative, as listed above hereby give permission to NCWRC to perform trap and release of the species listed for scientific collection purposes. In consideration of these understandings, I, the cooperator or cooperator's representative, agree to: assume responsibility for injury to my property under my control, when said injury is not the result of negligence on the part of NCWRC (it's officers, employees, and agents); assist in maintaining such warning signs as NCWRC may place for the purpose of notifying persons entering onto such lands of the possible hazards associated with scientific measures in use thereon; and to give adequate warning of these possible hazards to persons I authorize to enter onto such lands. Further, I, the cooperator or cooperator's representative, agree not to concurrently use or allow to be used upon lands covered by this agreement, any canid depredation efforts during the scientific collection time period.

Attachment 4: Trapper Service Contract

Contract in development.

Draft - Confidential

Denton Wildlife Services
Mattamuskeet Ventures Coyote Management Plan

Mattamuskeet Ventures hired Denton Wildlife Services to trap and remove coyote from their property. Denton Wildlife Services hired Terry Marsh with Carolina Predator Control.
I ran 11 trail cameras before we started trapping, and during our time there. Two weeks before and two while we were there for a total of 4 weeks. The best we could tell there was less than 10 canines on MMV properties. I am sure there are more but we trapped, did track counts, scat, and ran cameras. That was the best number we could come up with.

Of the canines I got pictures of, there was one pair of collard wolves, one single wolf with a collar in generally the same area as the pair. There was one other single collard wolf on the other side of the property. That made four USFWS collard wolves.

There was also one collared canine that appeared to be a normal size coyote wearing a FWS collar. I think it might have been one of the sterilized coyotes.
I also have a picture of NCWRC collared coyote. It had an uncollared mate. The mate was a normal size coyote.
I gave Mike Morris with USFWS a copy of all collard canines that had USFWS collars and a Map of their locations. Mike gave us two holding cages and a chip scanner in case we caught a Red Wolf or a collared animal.

I will include a USB with pictures and videos with the required collected information when I turn it into Andrea Shipley.

In the areas where I was picking up just wolf pictures off the trail cameras and their track sign on a regular basis we did not set traps. We thought it would be best to not catch a collared wolf.

In the area where we caught two wolves last year, both were collared and released back on the property.
I was told last year by the USFWS that after testing both were Red wolves. This year we were told by the USFWS that the blood work came back as 75% wolf. USFWS told us if we caught one of those canines they would remove the collars and put the animal down. The USFWS now considers a pure Red Wolf at **92% and higher.**
In this same area where we caught the two 75% canines, we caught two more this trip (Oct/18) that looked identical to the 75% canines we caught in April.
We met with Mike Morris (USFWS) and were told by Mike they were coyotes. Both were females.

We only kept 3 canines, two females and one male. Of those, we collected DNA Hair samples, hock and tail measurements and a lower canine for aging. We also recorded GPS coordinates for each capture site. Since April we have removed 17 canines from

the property. Two were returned, the two that were thought to be wolves. Nine were females with only one being bred.
On incidentals we caught 7 raccoon, 3 opossums, and two bobcats. All were released unharmed except for one opossum and one raccoon that were killed by bear. We had 14 traps set off by deer and 23 by bear. We did catch and hold two bear that were big enough to pull free and a third one in the 250 lb range, a sow we had to release.

I have asked Andrea, when she gets the DNA results from the canines samples I turned in, in April, I would like to get a copy of the results. Also I would like the same information with the ages on the samples I turned in from Oct/18.

Thanks
David
Denton Wildlife services

Page 2; 51: Maybe a short discussion on specifically what types of property damage is being referred to here? There are very few livestock operations on the AP, so depredation rates on livestock is relatively low. Wolves have been involved in very few depredation incidents over the years, and I'm not sure what other types of property damage sympatric canids would potentially cause? Most of the complaints we receive tend to be simple presence of canids on private property or a perceived reduction in observed game populations, which of course are not property.

Page 2; 54-55: Has there been any research done to analyze direct predation of canids on at risk ground nesting species as compared to potential benefits of canids through the control of other known nest predators?

Page 2; 57-59: In addition to collaborative research, the joint memorandum also instructs NCWRC to "review and evaluate statutory requirements for listing red wolves as state threatened in the five AP counties", to "evaluate, and if appropriate implement, adaptive approaches to regulate the take of coyotes that may result in incidental take of red wolves", and to "evaluate the status, management, and regulation of Controlled Fox Hunting Preserves". Just out of curiosity, what is the current status of these regulatory directives?

Page 3; 86-89: As part of the justification for this research the proposal states "Earlier research focused on many of the same objectives we suggest investigating here, but during a time of intense, active management. Specific management techniques are no longer being carried out and dynamics between sympatric canids are expected to have changed substantially."

I would contend that management and the resulting dynamics on ARNWR, and Milltail particularly, have not changed whatsoever. This pack recently had similar GPS-collar based data gathered by DOT a few years ago, and I don't feel much if anything would be gained by replicating this research. We should continue to use our own VHF radio collars on the Milltail pack as the battery life lasts much longer and we can continue to monitor them as we always have and not have to subject them to the frequent trapping for recapture and subsequent handling and processing outlined by this proposal. The joint memorandum from 2013 states that any research conducted should "promote the conservation and recovery of the red wolf and other canids on the AP." In the case of the Milltail pack especially, I think the potential risks far outweigh any potential benefits gained.

Page 4; 102-103: What information will be passed to whom specifically? I'm not sure it would be in the best interest of red wolf recovery if location information were to fall into the wrong hands.

Page 5; 132-136: This may be based on a false assumption as it is my understanding that the "federal lands only" alternative was not supposed to be our proposed alternative without first going through the NEPA process, which we are doing now. We don't yet know what the proposed alternative is going to be.

Page 6; 157: If "the most important requirement for SCR is the number of collared individuals" as stated, there is no need to initially focus trapping efforts in areas of known red wolf packs. Coyotes tend to utilize smaller home ranges than do wolves, and therefore would likely populate a particular area in higher numbers than wolves. In that sense, a greater number of collared animals may well be achieved outside of areas of known red wolf packs as long as trapping was conducted in productive habitat. Also, the premise of this proposed research is to target sympatric canids and not specifically target either species. It therefore seems contradictory and biased to initially target known red wolf packs through trapping efforts. I would suggest instead focusing on areas that known wolf packs have occupied in the past but now, due to mortality and lack of management over the last few years, the pack no longer exists, leaving an area of unknown species composition (Mattamuskeet Ventures and Texas Plantation

Gamelands are good examples). This would assist not only with the proposed research, but would provide an additional programmatic benefit of learning the species composition in current zones of ignorance. Targeting areas with known red wolf packs does not provide the additional benefit of learning species composition of an area (it is already known), and replicates data collection that has already been done. As stated above, I have concerns about targeting areas of known wolf packs, and feel the risks outweigh the potential benefits, especially since there are so few (only 3 known breeding pairs) left on the A.P. We don't need to further jeopardize them.

Page 6; 159-161: We typically wait until January to trap areas with potential red wolf puppies present in order to allow them to grow, minimizing risk of trap injury. Also, February is breeding season for wolves, and it is not a good idea to disrupt known red wolf pairs at this time, especially with the ever-present risk of injury that trapping inherently presents.

Page 6; 162-173: Releases should occur as close as possible to where the animal is trapped to avoid altering behavior and to avoid unnecessary risk to the animal attempting to get back home. This has been a recurring issue the last two or three years as the WRC has insisted that captured animals be released on ARNWR regardless of where they were captured. There is no reason these releases can't happen on state lands and private property (with landowner permission), in addition to federal lands. Refuge compatibility could obviously be another issue. Also, the statement "it is most important to be able to trap and release on Alligator River NWR and the Dare County Bombing Range as those encompass the newly proposed RWRP recovery area" is based on an inaccurate premise as we have not selected a preferred alternative yet so we have no official proposed recovery area.

Page 7; 182: Are traps staked or are drags used? Both can work but appropriate equipment must be used to avoid stakes being pulled out of the ground, which often leads to the death of the captured animal. Make sure appropriate shock springs and swivels are used as well to minimize injury potential.

Page 7; 187-190: Traps should also be covered or rendered inoperable during a hard freeze. A leg-hold trap cuts off blood circulation to the foot and can lead to frozen tissue during a hard freeze. This can lead to amputated toes and even feet.

Page 8; 215-219: We already have a protocol in place for chemical immobilization of red wolves developed by NCSU Vet school. We have used it for decades now on wolves and coyotes and there is no need to change it. Also, a syringe pole is not necessary. Simply restrain the head with a noose pole and inject with a regular syringe.

Page 9; 250-254: USFWS needs to be notified any time a red wolf is captured, injured or not, and should make the decision as to whether injuries are sufficient to euthanize the animal.

Page 9; 256-257: Red wolves absolutely should be vaccinated upon capture and treated for any diseases or illnesses present. I would recommend vaccinating coyotes before release as well. Remember the stipulation for collaborative research in the 2013 joint memorandum, that research identified should "promote the conservation and recovery of the red wolf and other canids on the AP." The wild red wolf population is far too small to be taking any unnecessary risks.

Page 10; 276-282: These animals do not automatically need to be euthanized, especially red wolves. The proposed research protocol already requires that any potential handler be vaccinated for rabies. Also, any previously captured wolf or coyote in the A.P. has been previously vaccinated for rabies and other canid diseases. Animals can be quarantined for a period of time but euthanasia is not necessary.

Page 11; 298-310: Why are ear tags necessary? I would think a GPS collar that emits a VHF signal plus a PIT tag would be sufficient for identification. Also, we should use Trovan PIT tags to remain consistent

with the ones already deployed on the A.P. Speaking of which, it would make more sense to use a radio-collar frequency range consistent with what is already deployed on the A.P. Not having the right set of gear or having to constantly switch between two separate sets of gear will prove to be problematic .

Page 11; 311-315: Skin biopsies are also not necessary. Genetic information can be collected from blood samples and sent to Lisette as proposed, and as we have always done. There is a protocol already in place for this.

Page 12; 332-335: Animals showing signs of mange should be held and treated for mange before release to avoid spreading it to surrounding canid population, particularly red wolves. Again, conservation of the species needs to be priority number one.

Page 12; 336-340: In the event of overheating, priority must be cooling/ensuring survival of the animal. After that assess any injuries, radio-collar, draw blood.

Page 13; 354-355: In regards to the VHF signal, we really need to be using the 164-165 mHz frequency range already being used for canids on the A.P. While regular GPS locations may be sufficient for research purposes, there is often a need for RWRP personnel to be able to track canids in real time (depredations and other complaints, reports of injuries, den locations, telemetry flights, etc.) It is not practical to carry two separate sets of telemetry gear at all times (especially when thick vegetation or when walking long distances), or to gear aircraft with two sets of antennas, or to constantly have to switch between two sets of gear when time is a factor. There are many field-based scenarios where utilizing two sets of gear would be problematic at best. Previous researchers (including the ones cited in this proposal) utilizing VHF or GPS collars on canids for data collection within the red wolf recovery area have always used frequencies consistent with ours to help alleviate these problems.

Page 13; 358: I would set the VHF beacon to operate beyond 1600 hours daily. You occasionally run into situations (depredations or complaints for example) that require the need to track animals in real time beyond 1600 hours. Ours are set on 12 hour rotations – 0700 to 1900 (0800 to 2000 during daylight savings).

Page 14; 378: A flight every 30 days is not going to be enough to determine cause of mortality should the GPS function fail. We already fly roughly 50 times a year to monitor red wolves, I'm not sure an additional 12 is going to benefit anything.

Page 15; 411-412: We already do den work on red wolves. The dens should not be disturbed more than once so any data collected must be in conjunction with USFWS. With fewer than 25 red wolves currently known to exist in the wild, the survival of each and every pup is vital, so no unnecessary risks will be taken. Time spent at the den must be minimal to minimize the disturbance. Skin biopsies are not necessary. We collect a blood sample for genetics and that should suffice. I'm not sure if morphometric measurements are necessary but if done it must be completed quickly. PIT tags are implanted for future identification. We use Trovan and would prefer to keep this consistent with the canids already on the A.P.

Page 15; 413-432: Cameras at a red wolf den site are a bad idea. We have attempted the use of them a couple of times in the past. One time it caused a visible disturbance when the adults returned, and the other time it resulted in puppy deaths when the female would not re-enter the den. Again, each and every red wolf pup is vital. If attempts want to be made to experiment with cameras at den sites, use them at coyote dens but not wolf dens, at least until more is known about potential disturbance (2 to 5 meters is likely too close). Another issue with these cameras is that wolves, and likely coyotes as well, will typically move the pups to a new den site very soon after a disturbance. In the type of habitat found

on the A.P., den sites are usually located in vegetation so thick cameras may be ineffective, and any human visit to the site is going to cause an unavoidable disturbance.

Page 16; 435: Red wolf carcasses go to the lab in Madison, WI as they always have. LE cases go to Asheland, OR. Coyotes can go to SCWDS.

Page 16; 436-442: We notify LE after every red wolf mortality. They decide if it will become an LE case and if they need to take possession of the animal. LE also probably won't allow genetic samples to be taken from animals they need to take possession of for evidence.

Aside from the specific concerns addressed above, I am also concerned by the overall scope of this proposal. If this proposal were carried out as written, it would effectively hand control and management of the red wolf program at the field level to the WRC. WRC plans to collar 25 "sympatric canids", and initially target known red wolf packs with their trapping efforts. There are only 23 known red wolves currently on the A.P. If they were to successfully radio-collar the majority of those wolves with collars emitting their own frequency range, it would severely limit our ability to monitor and manage this population. They also propose doing their own den work, using their own labs for necropsies, using separate protocols for data collection, etc. All this is concerning on two fronts. First, it is our (USFWS) legal mandate to manage and recover this federally listed species on the landscape. We do not turn over management to a state agency until the species is recovered to the point where federal protections are no longer needed. Second, the WRC has made it clear that their objective is to eradicate this species from the state of North Carolina. Turning monitoring and field management over to the WRC likely would not bode well for the recovery of this species.

I would prefer to see a research proposal more limited in scope with a clearer objective, and to use equipment and protocols consistent with equipment and protocols already in place on the A.P. Target animals in current zones of ignorance (which is now the majority of the A.P.) instead of targeting known wolf packs. While I think it is preferable in theory for the two agencies to collaboratively conserve and manage red wolves and other canids on the A.P., it is problematic when their respective objectives are polar opposites of one another. It is quite clear now, after exhaustive and repetitive reviews on the taxonomy and historical range of the red wolf, that the best available science indicates that this is indeed a valid listable species native to northeast NC. If the two agencies are to realistically work towards the conservation and management of canids on the A.P., the WRC needs to, at minimum, rescind their resolution requesting that red wolves be removed from the state of NC and declared extinct in the wild, and move towards listing the red wolf as a state listed threatened species. Then, in addition to collaborative research, we can explore joint regulatory efforts to reduce anthropogenic causes of red wolf mortality on the A.P. Until then I am not comfortable handing over this level of monitoring and management of red wolves on the A.P. to WRC.

Page 2; 51: Maybe a short discussion on specifically what types of property damage is being referred to here? There are very few livestock operations on the AP, so depredation rates on livestock is relatively low. Wolves have been involved in very few depredation incidents over the years, and I'm not sure what other types of property damage sympatric canids would potentially cause? Most of the complaints we receive tend to be simple presence of canids on private property or a perceived reduction in observed game populations, which of course are not property.

Page 2; 54-55: Has there been any research done to analyze direct predation of canids on at risk ground nesting species as compared to potential benefits of canids through the control of other known nest predators?

Page 2; 57-59: In addition to collaborative research, the joint memorandum also instructs NCWRC to "review and evaluate statutory requirements for listing red wolves as state threatened in the five AP counties", to "evaluate, and if appropriate implement, adaptive approaches to regulate the take of coyotes that may result in incidental take of red wolves", and to "evaluate the status, management, and regulation of Controlled Fox Hunting Preserves". Just out of curiosity, what is the current status of these regulatory directives?

Page 3; 86-89: As part of the justification for this research the proposal states "Earlier research focused on many of the same objectives we suggest investigating here, but during a time of intense, active management. Specific management techniques are no longer being carried out and dynamics between sympatric canids are expected to have changed substantially."

Should specify what dynamics are expected to have changed. I would contend that management and the resulting dynamics on ARNWR, and Milltail particularly, have not changed significantly at all. This pack recently had similar GPS-collar based data gathered by DOT a few years ago, and I don't feel much if anything would be gained by replicating this research. We should continue to use our own VHF radio collars on the Milltail pack as the battery life lasts much longer and we can continue to monitor them as we always have, and not have to subject them to the frequent trapping for recapture and subsequent handling and processing outlined by this proposal. The joint memorandum from 2013 states that any research conducted should "promote the conservation and recovery of the red wolf and other canids on the AP." In the case of the Milltail pack especially, I think the potential risks far outweigh any potential benefits gained.

Page 4; 102-103: What information will be passed to whom specifically? I'm not sure it would be in the best interest of red wolf recovery if location information were to fall into the wrong hands.

Page 5; 132-136: This may be based on a false assumption as it is my understanding that the "federal lands only" alternative was not supposed to be our proposed alternative without first going through the NEPA process, which we are doing now. We don't yet know what the proposed alternative is going to be.

Page 6; 157: If "the most important requirement for SCR is the number of collared individuals" as stated, there is no need to initially focus trapping efforts in areas of known red wolf packs. Coyotes tend to utilize smaller home ranges than do wolves, and therefore would likely populate a particular area in higher numbers than wolves. In that sense, a greater number of collared animals may well be achieved outside of areas of known red wolf packs as long as trapping was conducted in productive habitat. Also, the premise of this proposed research is to target sympatric canids and not specifically target either species. It therefore seems contradictory and biased to initially target known red wolf packs through trapping efforts. I would suggest instead focusing on areas that known wolf packs have occupied in the past but now, due to mortality and lack of management over the last few years, the pack no longer

exists, leaving an area of unknown species composition (Mattamuskeet Ventures and Texas Plantation Gamelands are good examples). This would assist not only with the proposed research, but would provide an additional programmatic benefit of learning the species composition in current zones of ignorance. Targeting areas with known red wolf packs does not provide the additional benefit of learning species composition of an area (it is already known), and replicates data collection that has already been done. As stated above, I have concerns about targeting areas of known wolf packs, and feel the risks outweigh the potential benefits, especially since there are so few (only 3 known breeding pairs) left on the A.P. We don't need to further jeopardize them.

Page 6; 159-161: We typically wait until January to trap areas with potential red wolf puppies present in order to allow them to grow, minimizing risk of trap injury. Also, February is breeding season for wolves, and it is not a good idea to disrupt known red wolf pairs at this time, especially with the ever-present risk of injury that trapping inherently presents.

Page 6; 162-173: Releases should occur as close as possible to where the animal is trapped to avoid altering behavior and to avoid unnecessary risk to the animal attempting to get back home. This has been a recurring issue the last two or three years as the WRC has insisted that captured animals be released on ARNWR regardless of where they were captured. These releases need to happen at or near the capture site, even if that land is state owned or private property (with landowner permission), in addition to federal lands. Refuge compatibility could obviously be another issue. Also, the statement "it is most important to be able to trap and release on Alligator River NWR and the Dare County Bombing Range as those encompass the newly proposed RWRP recovery area" is based on an inaccurate premise as we have not selected a preferred alternative yet so we have no official proposed recovery area.

Page 7; 182: Are traps staked or are drags used? Both can work but appropriate equipment must be used to avoid stakes being pulled out of the ground, which often leads to the death of the captured animal. Make sure appropriate shock springs and swivels are used as well to minimize injury potential. An additional thought – make sure all trappers have secure kennels to place animals in while waiting for processing to occur. It is best to remove a captured animal from a trap as soon as possible to minimize potential injury, overheating, and escape, so have the trappers place the animals in a secure kennel right away. You'd be surprised at some of the flimsy wire cages some of them carry for this purpose. Others have used duct tape on the legs and muzzle – obviously not a good idea. Have a protocol in place for this.

Page 7; 187-190: Traps should also be covered or rendered inoperable during a hard freeze. A leg-hold trap cuts off blood circulation to the foot and can lead to frozen tissue during a hard freeze. This can lead to amputated toes and even feet.

Page 8; 215-219: We already have a protocol in place for chemical immobilization of red wolves developed by NCSU Vet school. We have used it for decades now on wolves and coyotes and there is no need to change it. Also, a syringe pole is not necessary. Simply restrain the head with a noose pole and inject with a regular syringe.

Page 9; 250-254: USFWS needs to be notified any time a red wolf is captured, injured or not, and should make the decision as to whether injuries are sufficient to euthanize the animal.

Page 9; 256-257: Red wolves absolutely should be vaccinated upon capture and treated for any diseases or illnesses present. I would recommend vaccinating coyotes before release as well. Remember the stipulation for collaborative research in the 2013 joint memorandum, that research identified should "promote the conservation and recovery of the red wolf and other canids on the AP." The wild red wolf population is far too small to be taking any unnecessary risks.

Page 10; 276-282: These animals do not automatically need to be euthanized, especially red wolves. The proposed research protocol already requires that any potential handler be vaccinated for rabies. Also, any previously captured wolf or coyote on the A.P. has already been vaccinated for rabies and other canid diseases. Animals can be quarantined for a period of time but euthanasia is not necessary.

Page 11; 298-310: Why are ear tags necessary? I would think a GPS collar that emits a VHF signal plus a PIT tag would be sufficient for identification. Also, we should use Trovan PIT tags to remain consistent with the ones already deployed on the A.P. Speaking of which, it would make more sense to use a radio-collar frequency range consistent with what is already deployed on the A.P. Not having the right set of gear when needed, or having to constantly switch between two separate sets of gear will prove to be problematic .

Page 11; 311-315: Skin biopsies are also not necessary. Genetic information can be collected from blood samples and sent to Lisette as proposed, and as we have always done. There is a protocol already in place for this.

Page 12; 332-335: Animals showing signs of mange should be held and treated for mange before release to avoid spreading it to surrounding canid population, particularly red wolves. Again, conservation of the species needs to be priority number one.

Page 12; 336-340: In the event of overheating, priority must be cooling/ensuring survival of the animal. After that assess any injuries, radio-collar, draw blood. Then weights, measurements, etc.

Page 13; 354-355: In regards to the VHF signal, we really need to continue using the 164-165 mHz frequency range already being used for canids on the A.P. While regular GPS locations may be sufficient for research purposes, there is often a need for RWRP personnel to be able to track canids in real time (depredations and other complaints, reports of injuries, den locations, telemetry flights, etc.) It is not practical to carry two separate sets of telemetry gear at all times (especially when thick vegetation or when walking long distances), or to gear aircraft with two sets of antennas, or to constantly have to switch between two sets of gear when time is a factor. There are many field-based scenarios where utilizing two sets of gear would be problematic at best. Previous researchers (including the ones cited in this proposal) utilizing VHF or GPS collars on canids for data collection within the red wolf recovery area have always used frequencies consistent with ours to help alleviate these problems.

Page 13; 358: I would set the VHF beacon to operate beyond 1600 hours daily. You occasionally run into situations (depredations or complaints for example) that require the need to track animals in real time beyond 1600 hours. Ours are set on 12 hour rotations – 0700 to 1900 (0800 to 2000 during daylight savings).

Page 14; 378: A flight every 30 days is not going to be enough to determine cause of mortality should the GPS function fail. We already fly roughly 50 times a year to monitor red wolves, I'm not sure an additional 12 is going to benefit anything.

Page 15; 411-412: We already do den work on red wolves. The dens should not be disturbed more than once so any data collected must be in conjunction with USFWS. Then, in addition to collaborative research, we can explore joint regulatory efforts to reduce anthropogenic causes of red wolf mortality, take steps to minimize hybridization and control the coyote population as necessary, and collaboratively manage and recover red wolves on the A.P. Until then I am not comfortable handing over this level of monitoring and management of red wolves on the A.P. to WRC.

STATE: North Carolina

GRANT TITLE: W79-Wildlife Management

PROJECT TITLE: Pilot Study – Using Fine Scale GPS Technology to Research Sympatric Canid Population Dynamics (Job 2.0?)

A. Problem and Need

The coyote (*Canis latrans*) is now abundant throughout the 100 counties in North Carolina (NC), and is managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plain region of NC (Hinton et al. 2012, Murray et al. 2014). In recent years as coyotes have increased their population, some have begun to make use of the Outer Banks region.

The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of captive-bred red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). This population increased until 2008 and peaked at around 130 individuals (Group Solutions, Inc. 2016), short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013). The AP has an estimated carrying capacity of 140-150 wolves (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). The exact number of red wolves is not known, but USFWS staff report a population estimate of 45-60 individuals with eight mortalities to date in 2016 (https://www.fws.gov/redwolf/index.html August 2016). Hybridization with coyotes and inbreeding depression are suspected factors that have affected red wolf population growth and viability since the inception of the Red Wolf Recovery Program (RWRP), while vehicular and gunshot mortality are known factors (Hinton et al. 2013). Because of hybridization between red wolves and coyotes, the AP supports a continuum of sympatric canids, hereafter referred to as "sympatric canids."

As part of a recent program review, the USFWS halted many aspects of the RWRP in 2015 and discontinued the coyote sterilization program, potentially affecting the spatial

Commented [OSE1]: Citation! How abundant?

Commented [JM2]: Morse - The 220 animals in the wild was to be a total population number devided into 2-3 mainland sites.

Commented [JM3]: Morse - The actual estimate for carrying capacity in the NEP is more like 175 animals.

Commented [OSE4]: This information is obviously out of date and invalid.

Commented [OSE5]: Hybridization has not been an issue since the beginning of the program as there were no coyotes out here in the beginning.

Commented [JM6]: Morse - Gunshot mortality is known to be the number one and most critical factor affecting population growth.

Commented [JM7]: Morse - The coyote sterilization program needs to be part of the NCWRC research proposal. (Deal breaker)

Draft - Confidential

distribution and population dynamics of sympatric canids. Telemetry data from coyotes on the AP suggests that about 70% of coyotes are residents (i.e., those that defend set territories) while the other 30% are transients, with most being dispersing juveniles (Hinton et al. 2015). Transient coyotes do not defend set territories. Coyotes can travel long distances and become transient even as adults, especially when they lose their mate. Recently described as using "compensatory immigration," coyotes opportunistically fill spatial resource gaps by periodic transiency; when spots come open, individuals that do not yet have permanent territories and have been roaming in the area, are able to inhabit the new openings (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with other canids and humans, especially when they are utilizing of anthropogenic resources.

Though a rural area, human land uses occupy a significant portion of space on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011). Concerns about fear of attacks on humans and domestic pets, the effects of sympatric canids on white-tailed deer and other game populations, and homeowner property damage comprise many of the conflict calls regarding sympatric canids on the AP (Responsive Management, forthcoming data). Wildlife managers in this region frequently receive requests for information on canid management (C. Turner, personal communication, 2016).

The changes in state and federal canid management rules have resulted in confusion regarding residents' rights and options for management of property damage by sympatric canids. As a result, some citizens are unsure of the legal and most effective methods for canid conflict management. Adding to management complexity is the need to manage canids for conservation purposes, such as reducing predation on at-risk ground nesting species or reducing hybridization of sympatric canids.

In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of sympatric canids on the AP. A USFWS and NCWRC joint memorandum documented detailed action items for the joint management of sympatric canids on the AP, including specific research objectives which this proposal seeks to address (Attachment 2). As sympatric canids on the AP increase in number, monitoring their

Commented [JM8]: Morse - Need to see the forthcoming data to comment on it. No predator/prey relationship studies have been conducted in the NEP for red wolves or coyotes and whitetail deer or any other game species. This should be part of the study proposal.

Commented [JM9]: Morse - Need information on information request to FWS by Chris Turner. Not sure of any to date.

Commented [JM10]: Morse - The current law/reg. is clear: it is legal to take or harass a red wolf in defense of human life or to protect pets and livestock.

Commented [JM11]: See Ryan's comment.

Commented [OSE12]: Does this mean that they are going to trap at Pea Island or any other state and federal land that occurs in Dare county that's not on the peninsula?

Commented [JM13]: Morse - Need examples of at-risk, ground nesting species to be able to comment adequately.

Commented [JM14]: See Ryan's comment.

Commented [JM15]: See Ryan's comment.

Commented [JM16]: Does not acknowledge dramatic decrease of red wolves because of lumping as sympatric canids.

Commented [OSE17]: As stated on page one "the AP supports a continuum of sympatric canids" this means coyotes, hybrids and wolves. I guarantee that wolf numbers are declining while others on the continuum are increasing; thus making this statement false. It implies that all variations are increasing.

This sentiment is explained more clearly on page 33 paragraph 3. They refer to coyotes and wolves separately.

Draft - Confidential

movements, particularly in relation to individuals of differing ancestry, could provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about sympatric canid populations and conflict management. Collection of finer temporal scale location data would help to manage interactions of sympatric canids with humans, as well as to support development of dynamic stochastic population models.

B. Objectives (after December 1, 2016-November 30, 2018)

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners.

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

At the end of this two-year pilot study, we will deliver an observational summary detailing the use of the GPS and sensor technology for spatial and population dynamics research on sympatric canids on the AP.

C. Expected Results and Benefits

As part of a pilot study, we will monitor the status of collared individuals by using a finer scale assessment of space and habitat use than previous studies. Earlier research focused on many of the same objectives we suggest investigating here, but during a time of intense, active

Commented [OSE18]: Don't see how this would work, unless they are talking about human dimensions.

Commented [JM19]: Morse - Need description on how this data will help manage interactions of sympatric canids with humans.

Commented [JM20]: Objectives talk about GPS'd animals but don't take into account any data from the existing 23 radio-collared red wolves and 29 collared coyotes.

Commented [OSE21]: Is this list a weighted list? I would hate to think that this was the objective with the highest priority.

Commented [JM22]: Morse - This testing should be conducted with coyotes, not wolves until performance levels are confirmed. Coyotes should be sterilized to assist with gaining private landowner permissions.

Commented [JM23]: Morse - There is currently no area on ARNWR where this level of wolf/coyote interaction occurs. Where will this investigation be conducted?

Commented [OSE24]: Why do they need location data for number of animals and age?

Commented [JM25]: Morse -The number and age of wolf offspring in breeding groups is already known using conventional VHF data collection and USFWS den work.

Commented [OSE26]: As stated later in this proposal no target animals will be treated for disease. Not treating wolves for visible or known disease is contrary to the recovery program, whether that be for recovery in the wild or increasing numbers in captivity. By continuing treating any wolves we would be compromising the validity of any conclusions from the data. Additionally, are they talking about actual source locations, as in disease originating locus, or causes of mortality?

Commented [JM27]: Morse - FWS already conducts ~100 telemetry flight/year to access red wolf and radio-collared coyote mortality sources.

Commented [JM28]: Morse - Need description of how this will happen and what data is to be shared with private landowners.

Commented [OSE29]: How do they propose to accomplish this? Which specific conflicts? How does knowing exact location help?

Commented [JM30]: Morse - This needs to be a separate and ongoing project conducted with ASU or a different university.

Commented [OSE31]: Their section 7 attachment state 3 years. Granted they state they will be tracking over the course of 3 years. Did they mean 2 years of trapping with a ...

Draft Confidential

management. Specific management techniques are no longer being carried out and dynamics between sympatric canids are expected to have changed substantially. The uncertainty regarding current dynamics presents a need for additional research in order to inform actions for the management of sympatric canids. Information gained from research may impact management rules and landowner's abilities to manage canids in some areas. Additionally, GPS technology has improved since earlier research was conducted allowing for more temporally detailed data collection and more nuanced analyses. Understanding how sympatric canids collectively use resources in areas of human-dominated landscapes will allow wildlife managers to tailor management options to local conditions. On the AP, row crop agriculture and hunting represent the primary and secondary land uses, respectively. Row crop agriculture is a significant nutrient resource on the landscape and, as opportunists, canids take advantage of such resources when they are available. Non-consumptive wildlife-driven tourism persists in all seasons and wildlife watching is a main draw for tourists in this area. For many tourists, the opportunity to see or hear large carnivores is the sole attraction for traveling to the AP. Information from this study will be provided to local constituents to establish a knowledge base regarding how sympatric canids use resources on private lands. Management and guidance could serve to prevent or minimize conflict while maximizing positive wildlife interaction opportunities for constituents. Development of a common understanding between wildlife managers and landowners based upon factual information is paramount for collaboratively achieving successful management of sympatric canids. The data collected in this pilot study is the foundation upon which this understanding and future management actions will be built.

The current level of hybridization between sympatric canids on the AP will be characterized using DNA gathered during this study. Body size exists as a continuum between coyotes and red wolves and has been documented as the most important factor for successful interspecific breeding pairs of these canids (Hinton 2014). Though both species have been found to use resources in similar manners, red wolves generally have more expansive home ranges and therefore may not use local resources as intensively as coyotes, depending on body size. Obtaining individual identification of study animals will allow managers, armed with spatial information, to infer how and why individuals in the canid species continuum exploit

Commented [JM32]: Morse - Do not rule out the possibility of more intense, active management techniques as described in the RW adaptive management plan.

Commented [JM33]: See Ryan's comment.

Commented [OSE34]: I would like to see a citation for everything in this sentence. Additionally, how do they take advantage of the resources? Are they eating part of it? Primary hunting area?

Commented [JM35]: Morse -What does this mean?

Commented [JM36]: See Ryan's comment.

Commented [OSE37]: Who are these local constituents? One of the main results that I can think of is that landowner requests for wolf removal will increase. Wasteful spending of federal and state money on removal efforts of coyotes, just like the failed removal effort of a coyote in 2016.

Commented [OSE38]: Is a wolf breeding with a hybrid considered hybridization?

Draft - Confidential

anthropogenic resources considering their life history traits.

In conjunction with prior research, data collected will contribute to knowledge on sympatric canid population dynamics on the AP. Estimating population size will allow managers to monitor population trends of sympatric canids and to examine the long and short-term impacts of different management strategies on their populations. While it is unknown whether sample size will allow for population estimation, obtaining population estimates for coyotes would provide wildlife managers with baseline data, when paired with annual mortality estimates, for monitoring changes in population abundance over time. Information on changes in abundance, reproductive dynamics, and habitat use could impact management strategies to influence long-term conservation outcomes. Results of this pilot study will allow managers to determine if future work will be necessary, what amount of effort will be required to achieve each objective, and whether or not population estimates will be an attainable goal.

D. Approach

The official Red Wolf Recovery Area (RWRA) covers approximately 6,900 square kilometers within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014). However, the USFWS has proposed the RWRA be constricted to the ARNWR and the Dare County Bombing Range in Dare county by the end of 2017. Due to these proposed RWRA changes, this study proposes to capture and radio-collar 25 sympatric canids within Dare, Hyde, and Tyrrell counties (hereafter referred to as "study area"); those counties being within and directly adjacent to the proposed new RWRA. The thematic subheadings below provide detailed descriptions of the approaches required for achieving the pilot study objectives.

Sampling Efforts

Trained NCWRC personnel will conduct live trapping of sympatric canids, with assistance from the USFWS RWRP biologists, and trained, experienced local trappers. NCWRC and USFWS wildlife personnel will select local trappers based on their past performance in trapping sympatric canids, but may also select trappers from the NCWRC coyote trappers list. NCWRC staff will train contracted trappers on specific trapping procedures before every trapping

Commented [OSE39]: What? They are opportunistic animals and will use any resources that they are able to, or is there something in the literature that states that coyote and wolves don't use anthropogenic resources. They even stated earlier that canids take advantage of row crops which would imply anthropogenic resources are an integral part of their life history. They are implying that the use of anthropogenic resources is abnormal behavior.

Commented [JM40]: Morse - This aspect of a coyote population size estimate would best be done in an area with no other sympatric canids.

Commented [JM41]: I don't believe technically a "recovery area" has been delineated, just an NEP boundary.

Commented [JM42]: See Ryan's comment.

Commented [OSE43]: Are we really going to let them trap on the refuge?? Needless to say this would hand over significant control of the program over to the State. I would dare say an illegal hand over at this point.

Loss of control 1.

Draft - Confidential

season. The project lead will supervise and coordinate all trapping activities including locations for installation and the operation of trap lines and handling of captured animals. Simultaneous personal trapping activities by contracted trappers will not be permitted while performing contracted trapping services, as specified in the draft service contract (Attachment 4).

Trapping efforts will follow a spatial capture-recapture (SCR) framework with a systematic targeted sampling design, focusing on areas that contain resources previously found to be used by sympatric canids (e.g. edge, agricultural fields, secondary roads, etc.) (Harris et al. 2013, Ivan et al. 2013), while attempting to sample a diversity of habitat types. This effort will allow us to increase the probability of detection of sympatric canids on the landscape (Tom 2012). While it is important to sample a wide range of habitats, the most important requirement for SCR is the number of collared individuals; this requirement provides flexibility in the other requirements for field sampling as needed (K. Pacifici, personal communication, 2016). We will initially focus trapping in areas of known red wolf packs, as advised by RWRP.

Trapping will take place during the breeding season when the likelihood of capturing females in the later stages of gestation or whelping females will be low. Capture efforts will be conducted from soon after 1 December 2017 – February 2018 and December 2018 – February 2019. Captured sympatric canids will be surrendered to NCWRC or the USFWS at capture sites. Trapping should occur on both public and private lands to obtain sampling coverage of the study area. Ideally, all federal and state lands would be accessible for trap and release (hereafter referred to as "capture") of sympatric canids, but it is most important to be able to trap and release on Alligator River NWR and the Dare County Bombing Range as those encompass the newly proposed RWRP recovery area and comprise the majority of land area for Dare county. Unlike Dare county, there are ample private lands that surround Pocosin Lakes NWR and Lake Mattamuskeet NWR in both Tyrrell and Hyde counties that may be utilized to effectively sample individuals who may use those federal lands, should they be excluded from capture activities. Capture on federal lands may require USFWS take permits and proposed activities may be subject to a compatibility assessment (P. Benjamin, personal communication, 2016). Scientific collection activities that take place on private lands will require agreements outlining conditions mutually decided by NCWRC and landowners (Attachment 3).

Commented [OSE44]: Another level of lost control.

Loss of control 2

Commented [OSE45]: Trap shy animals will be difficult to recapture, thus biasing their results.

Commented [OSE46]: There are only two known wolf packs left in their proposed study area.

Commented [JM47]: See Ryan's comment.

Commented [OSE48]: Breeding disruption is a possibility. Higher chance of trapping too many animals too young, as per their protocol, to collar.

In the Section 7 attachment they specifically state that coyote trapping will commence in Nov and end in Feb, while wolf trapping will start in Dec and end in Feb.

Commented [JM49]: Morse - Not for red wolves (deal breaker).

Commented [JM50]: See Ryan's comment.

Commented [JM51]: See Ryan's comment.

Commented [JM52]: Is it appropriate for NCWRC personnel and contract trappers to be trapping on the Refuge vice highly trained and experienced FWS personnel?

Commented [OSE53]: This sentence is a little vague. Do they mean that will have the opportunity to trap private land if the public land is excluded?

Commented [OSE54]: Compatibility assessment?. If this study goes through, it would effectively give the State full control of the wild population. At the bare minimum this would constitute a 10j rule change.

Where is the assessment?

Draft - Confidential

To increase probability of detection of sympatric canids, the accessible study area will be partitioned by a grid, the cell size of which will based on the average annual home range size of resident coyotes previously reported for the AP, approximately 23 km^2 (Hinton et al. 2015). As a system of sampling, trap lines will be referred here as "traps," and the number of trap sets (i.e. the actual trapping device) and number of each trap set size may vary between traps as necessary. Sampling will be standardized within each grid cell by use of equal number of traps per cell, on average 3 per cell, each at an approximate length of 10 km (Andelt and Gipson 1979, Way et al. 2004).

Target canids will be captured by using Softcatch #3 Coyote 4x4 (Oneida Victor Inc. Ltd., P.O. Box 32398, Euclid, Ohio 44132, Hinton 2014, Schemnitz 1994), the EZ Grip #7 (Livestock Protection Company, P.O. Box 725, Alpine, Texas 79831, Frame and Meier 2007), or equivalent. Various lures and baits will be used to increase trapping efficiency (Frederick et al. 1989, Shipley 2012). Traps will be laid on the Monday of each week and will be opened at the time of deployment. Traps will be checked once daily at dawn, to reduce potential stress to trapped individuals and will not be operated on days where the temperature is expected to reach or exceed 80° F (R. Nordsven, personal communication, 2016) or during times of predicted inclement weather (e.g. snow, hail, high wind, etc., Sikes et al. 2011). To standardize effort and remain logistically realistic, traps should be open for three trap nights in a row before being removed. Trap sets that have been closed due to non-target bycatch or other circumstances may be reopened and all traps should be re-baited and lured as appropriate.

Trap set locations will be marked by NCWRC or USFWS personnel using handheld GPS units (Garmin GPSMAP 64S, 1200 E. 151st St., Olathe, KS 66062-3426) and given a sequential identification number. Traps will also be given an identification number and trap set points will be documented in ArcMap 10.4. Trappers will keep detailed records on trap set operation, non-target species trapped, and other relevant details. Non-target species will be released from traps after an in-field assessment of injuries, if any, and animals with life threatening injuries will be euthanized by the trap operator. Targeted recapture of collared canids will occur annually during the same months, to replace GPS collar batteries and drop-off collar release units in field. Trapping effort will be quantified (trap nights), the effective sample area will be

Commented [JM55]: See Ryan's comment.

Commented [JM56]: See Ryan's comment.

Commented [OSE57]: What about freezing or below freezing temps. This concern might be covered by their inclement weather statement. The temperature range should be spelled out and private trappers would have to be explicitly told not to trap.

Commented [OSE58]: Why only 3 nights

Commented [OSE59]: Loss of control 3. Implied.

Commented [OSE60]: Good luck capturing trap shy animals. Additionally wont this interfere with subsequent trapping years of the study, or are they planning on not trapping for new animals in the same locations the following year.

Draft - Confidential

estimated, the encounter (detection) probability will be estimated using a Gaussian detection model (Amundson et al. 2014), and an estimate of density for coyotes will be calculated using a modified Huggins closed-capture estimator in program MARK, if sample size allows (Harris et al. 2013, Ivan et al. 2013).

Animal Handling

Handling of canids will follow American Society of Mammalogists (ASM) guidelines (Sikes et al. 2011) and will be performed at the capture site. Chemical immobilization agents may be used depending on the number of field staff during processing (i.e., three or more staff required during non-chemical immobilizations, Craft 2007, M. Morse, personal communication, 2016).

Chemical Immobilization

Unless adequate numbers of personnel are available to safely employ mechanical restraint techniques, target animals will be anesthetized with the chemical immobilization agent BAM (Wildlife Pharmaceuticals, Inc., Windsor, CO 80550). BAM, a combination of Butorphanol tartrate, Azaperone tartrate and Medetomidine HCl., will be delivered by intramuscular injection by syringe pole to the hip. Dosage for canids is based on field trails performed by Wildlife Pharmaceuticals (Wildlife Pharmaceuticals, Inc. 2016) and the recommended dose for coyotes is 0.2CC and red wolves is 0.3CC, with adjunct doses of 0.1-0.2CC delivered if initial dosages do not cause induction (S. Kirschner, personal communication, 2017). Induction times for coyotes and wolves ranged from 5 to 10 minutes after initial and/or adjunct dosages (Wildlife Pharmaceuticals, Inc. 2016). After field handling is concluded the anesthesia will be reversed using two reversal agents, Atipamezole and Naltrexone, at double the CC of Atipamezole to BAM that was delivered (including adjunct doses, if given) and 0.5CC of Naltrexone. Recovery time from the reversal agents ranged from 10 to 25 minutes during field trails (Wildlife Pharmaceuticals, Inc. 2016). Field personnel will observe animals for signs of adverse effects for up to 30 minutes after reversal agents are delivered.

Mechanical Immobilization

Unlike other carnivore families, the submissive behavioral response of canids to

Commented [OSE61]: Why is the sample area going to be estimated when they stated earlier that they were going to grid out accessible areas?

Commented [OSE62]: This probability is comprised of two factors. 1) Availability "which is the probability that an animal is present in the survey area and signaling its presence to the observer" and 2) Perceptibility "which is the probability that an animal available for detection (e.g., a bird sings) is detected by the observer" This is taken directly form the Amundson paper. I understand how the collars will help with determining availability, but I am curious how they will determine perceptibility. Is the perceptibility tied to the number of traps or ear tags?

Commented [OSE63]: Are they talking about immobilization while the animal is in the trap or are they talking about after the animal is out of the trap? Lots of possible implications when dealing with contract trappers if it is the former. What about total animal process time vs checking trap lines.

Commented [JM64]: Morse - Wolves will be turned over to FWS for processing and radio-collaring at the RWEC (Columbia, NC) with support from NCWRC biologists. (deal breaker).

Commented [JM65]: Morse - Two biologists and one note taker (if available). If not, two biologists can do the processing with no problems.

Commented [JM66]: Morse - We have a better, cleaner and safer chemical immobilization protocol developed specifically for red wolves by the NCSU Vet School. Butorphanol @ 0.4mg/kg w/ Dexmedetomide @ 0.04mg/kg
Antagonist: Naloxone @ 0.02mg/kg w/ atipamizole @ 0.2mg/kg

Commented [JM67]: See Ryan's comment.

Draft - Confidential

perceived dominance reduces the need to use immobilization agents. Appropriate mechanical restraint techniques can reduce handling time of animals, allowing animals to reintegrate into social groups more quickly, subsequently reducing overall stress to the individual (Powell and Proulx 2003). Target canids will be mechanically restrained with a restraint pole, until two muzzles can be placed around the snout. While pinned with the restraint pole by one person, a second person will restrain the set of legs not in the trap against the ground and a third person will release the foot from the trap. This set of legs will then be restrained by the 3rd person as the restraint pole is removed. Once the restraint pole is removed the person restraining the front legs will also then restrain the head. The first person will then move forward with processing the captured animal.

Each animal will be placed on a towel or blanket to provide thermal protection from the ground, with eyes covered and lubricated with eye ointment; temperature will be monitored with a rectal thermometer. Overheating occurs at approximately 104-105°F for canids (AZA Canid TAG 2012) and the animal handling crew will monitor temperature at 5-minute intervals; if a temperature reading reaches 104°F, corrective actions will be taken and temperature will be monitored at 1-minute intervals. Should overheating occur, the individual will be removed from insulation to expedite the natural evaporative cooling process. During days that approach 80°F in temperature, measures will be taken to reduce heat stress, such as: wetting the animal with water, application of a cold pack to the groin area between the back legs, application of rubbing alcohol to foot pads, or immediate release (AZA Canid TAG 2012). If the injured individual is suspected to be a red wolf, based on morphometrics, USFWS staff will be contacted for a decision. In the event that trap caused injuries are determined to be life threatening through use of a trap injury score assessment (Frame and Meier 2007) the individual will be euthanized. In the event that NCWRC personnel cannot be present, trained USFWS personnel may collar and measure captured target animals and will provide data sheets to NCWRC staff. Target animals will not be vaccinated or otherwise treated for diseases, regardless of the presence of disease symptoms.

Non-target animals will be released on site. Captured domestic dogs will be immediately released from the trap set following an injury score assessment and only if no life-threatening

Draft - Confidential

Commented [OSE68]: This is not always a guarantee that the animal is a wolf or not

Commented [OSE69]: Loss of control 4. Implied.

Commented [JM70]: See Ryan's comment.

Commented [OSE71]: FWS will be "allowed" to do this?! This statement plus several others would seem to indicate a takeover of the red wolf program by the NCWRC.

Loss of control 5. Implied.

Commented [JM72]: This seems like an unnecessary statement, as FWS personnel have the authority to handle red wolves.

Commented [JM73]: Why would we not vaccinate the capture animals, especially red wolves given the high value of each individual within a population so low?

Commented [OSE74]: Not treating wolves for visible or known disease is contrary to the recovery program, whether that be for recovery in the wild or increasing numbers in captivity. These wolves would be integral for population increase in the wild or for the "SSP meta-population"

Commented [JM75]: See Ryan's comment.

injuries are present. If a domestic dog has sustained life threatening injuries and owner identification information is present on the dog, then the animal will be held in either a transportable kennel, or at a dog pen on a state game land that is equipped with such facilities, until the owner can retrieve the dog. The costs associated with injuries sustained to the dog will be the responsibility of the animals' owner. Law enforcement may be requested to help communicate with the animal's owner. If the animal does not have an identifiable owner and has incurred substantial life threatening injuries (i.e. compound fracture), the dog will be euthanized on site. Target animals showing signs of disease symptoms such as circling behavior, head tilt, muscle twitches, convulsions with jaw chewing movements and salivation ("chewing gum fits"), disorientation, incoordination, staggering caused by paralysis of the hind legs, seizures, and partial or complete paralysis will be euthanized and tested according to protocol set forth by the agency veterinarian, in order to determine if there may be a public health issue (M. Palamar, personal communication, 2016). USFWS will be contacted in cases of suspected red wolves. Staff involved in animal handling duties will have the pre-exposure rabies vaccination series completed prior to field work inception and will maintain rabies titer records through properly licensed medical services providers.

If staff is bitten and skin is broken by an animal while performing handling duties, they will be advised to immediately visit a local hospital or clinic for evaluation by healthcare professionals. The field coordinator will immediately notify supervisory staff and an injury report and workers' compensation claim will be opened for the incident. The animal will be euthanized and the head will be sent to the state lab for rabies testing; the body may be sent to the Southeastern Cooperative Wildlife Disease Study (SCWDS) laboratory for additional disease investigation.

Capture Processing and Marking

During canid handling, NCWRC personnel will record age class, sex, weight, total body length, head width, ear length, and tail length, visually assess ectoparasite load, look for and disinfect with betadine or iodine as needed any minor trap caused injuries, and affix GPS collars (Knick 1990, Sikes et al. 2011). All captured canids will be fitted with appropriately-sized GPS collars in the field based on morphometrics previously indicated as reliable thresholds for

Commented [OSE76]: Loss of control 6. Implied.

Commented [OSE77]: Do they not have facilities to hold the animal for observation? They are going to unilaterally euthanize a wolf??

Commented [JM78]: I disagree that staff being bitten during a capture should result in a red wolf being euthanized, particularly if that animal is displaying no signs of disease. We can't afford to lose any more individuals in such a low population. And no euthanasia of a red wolf should occur without FWS involvement in the decision making process.

Commented [JM79]: See Ryan's comment.

Commented [OSE80]: This whole section gives state complete control of the program. Additionally are they going to remove our collars and put their own on?

Commented [OSE81]: Loss of control 7. Implied.

Draft - Confidential

species categorization: hind foot length, weight, width of head, and tail length (Hinton 2014); analysis of DNA samples collected during trapping efforts will help to assign captured canids to position along the species continuum post release. Age of individuals will be estimated based on physical characteristics, including weight and tooth replacement (Knick 1990, Hinton 2014, Gier 1968), and captured canids will be aged into one of three classes: > 2 years old as adults, < 2 but > 1 year old as juveniles, and > 6 months but < 12 months old as pups (Hinton 2014). Reproductive status will be determined based on estimated age class and presence of gonadal descent during the breeding season for males and the presence of nipple swelling or previous suckling for females (Hutson and Racey 2004, Magee 2008, Mengel 1971).

Captured individuals will be ear marked using a button tag (model 410, Ketchum Mfg. Co. [or equivalent], PO Box 10, 11 Town Shed Road, Lake Luzerne, NY 12846) placed along the middle of the ear where they are most protected from loss, with a pin-type applicator (485sa Pow-R-ceps plier, Ketchum Mfg. Co. [or equivalent]) (Silvy 2012). The puncture site will be treated with an antiseptic to deter infections. Each sympatric canid will also be marked with an individually-numbered, glass-encapsulated, passive integrated transponder (PIT model HPT12, 12.5 mm, 134.2 kHz, Biomark, Inc., 703 South Americana Blvd., Suite 150, Boise, ID; Gannon et al. 2007), using a syringe-type implanter and replaceable needle (model MK10 [implanter], model N125 [needle], Biomark, Inc.). Successful PIT placement will be verified with a mini portable reader (model GPR Plus, Biomark, Inc.). The implantation site will be prepared by swabbing with 70% alcohol (Mrozek et al. 1995) and a sterilized new needle will be used for each injection. The standard implantation site for transponders is subcutaneously on the dorsal midline of the back, cranial to the shoulder blades (Ingwersen 2000).

A skin biopsy will be taken from all captured target canids by puncturing the pinna of the ear with a biopsy punch in the same location where the ear tag will be placed (Palamar 2014). The biopsied area will be disinfected with alcohol after sampling. The skin biopsy will be placed in a labeled (ID, date, and sample type) cryogenic tube filled with 95% ethanol as buffer and then stored in a freezer until sent out to a lab for genetic analysis (Palamar 2014, Tom 2012). A selection of hairs with the root bulla attached will be pulled from the belly and placed in paper envelopes (Janecka et al. 2007). Hair samples will serve as back up to tissue samples

Commented [OSE82]: What is the point of this if they are going to have a collar on them. Would this be used for mark/recapture purposes for any animal in excess of the 25 collars? Or is this for continued identification after the collars fall off. Collars falling off of wolves does us no good for continued tracking after the study.

I have conflicting thoughts on this. Makes it easier to identify while in a trap prior to release but makes it easier for someone to see and shoot the animal. Alternatively it could stop someone from shooting and thus biasing mortality results.

Commented [JM83]: Morse - Why - no need. the ear tags are not needed and are a constant source of infection and irritation. In addition, when we,ve used them in the past - the animals tear them out.

Commented [OSE84]: Are we going to give them our tags or will they use their own. Either way is a loss of control of the program.

Commented [JM85]: Morse - Continue to use PIT tags by Trovan to keep consistency with animals already deployed.

Commented [JM86]: Concerns over PIT tag not being compatible with our reader

Commented [JM87]: See Ryan's comment.

Commented [OSE88]: What is the point of this and how does it help them achieve any of their stated goals? Are they proposing to make a hole in the ear first using this method and then place the tag in the hole?

Commented [JM89]: Morse - genetic analysis can be done with blood serum.

Commented [JM90]: See Ryan's comment.

Commented [OSE91]: Not opposed to this but again, why? Can they get more info from this than from blood samples? They are proposing 3 separate DNA samples.

Draft - Confidential

for genetic testing. All samples will be sent to the Laboratory for Ecological, Evolutionary and Conservation Genetics, at University of Idaho (875 Perimeter Drive, MS 1136, Moscow, ID 83844) for genotyping to determine species as well as individual identification, hybridization presence, and parentage analysis following previously developed protocols (Adams et al. 2007, Hinton 2014, Miller et al. 2003). The appropriate genetic analyses that examine the coyote-hybrid-wolf species continuum will be performed.

Blood will be collected from all juvenile and adult target canids by venipuncture of the brachial or jugular veins using a 22-28-gauge needle (M. Palamar, NCWRC veterinarian, personal communication, 2016). As per NCWRC veterinarian recommendations, approximately 12 ml of blood will be collected for each animal for possible future testing for diseases of importance to sympatric canid species as well as the humans and domestic animals that they may come into contact with. A minimum of two 6 ml lavender top tube (for whole blood with EDTA) will be filled. Samples should be refrigerated at all times; a cooler with ice will suffice while in the field. Samples should be sent to the NCWRC within 48 hours or frozen for later shipping. Skin scrapes will be collected from animals presenting signs compatible with sarcoptic mange (lesions) for possible future diagnostic purposes. Lesions will be scraped until blood is drawn; the scrapings will be placed onto a slide and covered with a piece of clear tape for later visual confirmation.

Should overheating occur, processing will be performed in the following prioritization order and the first five items will need to be completed before releasing any individuals: 1) trap injury evaluation, 2) collaring, 3) DNA (skin biopsy) sample collection, 4) morphometrics, 5) aging, 6) PIT tagging, 7) weight, 8) ear tagging, 9) reproductive status, 10) ectoparasite evaluation, 11) blood collection, and 12) skin scrape collection.

Collaring

Vertex Plus GPS Collars will be attached to 25 sympatric canids captured on the study area, 10 of which will be equipped with proximity sensors (Vectronic Aerospace GmbH, Carl-Scheele-Str. 12, 12489 Berlin, Germany). Project staff will pilot test proximity sensor technology for utility in analysis of spatial and temporal community dynamics. Proximity sensors trigger increased GPS location acquisition during those time intervals when two collared individuals

Commented [JM92]: Morse - Pull one red top tube to spin for serum collection. Why 2 - 6 mm purple top tubes (isn't 1 enough)? Also, FWS is going to need to maintain additional blood samples for database.

Commented [JM93]: See Ryan's comment.

Commented [JM94]: Morse - define overheating temp. range and cooling procedures. In the event of overheating, the first thing to do is to immediately cool the animal. Collar then blood draw (omit the rest).

Commented [OSE95]: Given our concerns over many aspects of tissue collection, I feel that this list should be revisited.

Commented [JM96]: See Ryan's comment.

Draft Confidential

come within a set distance from each other (http://www.vectronic-aerospace.com/wildlife-monitoring/sensors/uhf-id-tags, accessed August 2016).

To avoid instances of collar induced strangulation, only adult (>2 years old) male and female individuals will receive collars (Hinton 2014). ASM guidelines recommends a collar weight of <5-10% of a canids bodyweight, we will observe these guidelines (Sikes et al. 2011). Sympatric canids not releasable at a capture site will not be collared and will not become study animals.

GPS radio-collars will have both VHF and GPS Iridium locational systems as well as store-on-board capabilities. Radio-collar units will be programmed to record GPS coordinates once every 1.75 hours producing approximately 13 locations per day while cycling through the 24-hour time cycle. These settings will allow for a GPS battery life of 300 to 552 days, averaging 431 days. The VHF beacon will be in operation from 0800 – 1600 hours daily. GPS locations will be sent via satellite once per day and each transmission with contain 12 locations. The use of an integrated drop off firing mechanism should allow the collars to drop off within a maximum of approximately 548 days after deployment. The drop off schedule once set cannot be changed. The drop off firing mechanism is wired to a battery unit independent of the collar battery, therefore should the collar battery become depleted, the drop off mechanism will not be affected (C. Akakpo, Vectronic Aerospace GmbH, personal communication, 2016). Unless a collared individual is recaptured before the collar battery dies, the drop off mechanism will fire at the scheduled time frame post collar deployment.

Observation of sympatric canid habitat use and movements will occur through GPS data obtained with combination GPS/VHF radio-collars. VHF relies on triangulation, the process of estimating the location of a transmitter by using two or more compass bearings obtained by using directional antennas at known locations remote from the transmitter's position (White and Garrott 1990), whereas GPS uses a satellite based system to obtain location coordinates. There have been many published studies where one or both of these methods were used, with mixed success for determining various aspects of carnivore ecology throughout the United States (Hinton et al. 2012, Schrecengost et al. 2009, Sparkman et al. 2012). While GPS technology has developed rapidly in recent history, the real time functional advantage of VHF

Commented [JM97]: So in theory they could catch a one year old red wolf and by their protocol they would not collar it because it is less than 2 and they would release it without a collar. So basically the effort to trap a red wolf and the potential for injury has already occurred, but we do not take advantage of that by placing a collar on it to be able to monitor as much of the population as possible. Doesn't make sense.

Commented [OSE98]: I have a feeling that there is going to be many animals that fall into this category especially considering the prevalent landowner attitude towards carnivores in general and coyotes specifically. Additionally this constitutes a double standard in regards to releasing animals. We have landowner authorization in many cases but the State still will not allow us to use those lands for release, but are they going to allow themselves to do that? Also I feel that they should have all landowner agreements in place and the study/trapping areas well defined prior to any trapping effort. I have serious doubts that they can get this in place prior to Dec 1st.

Commented [JM99]: Needs clarification. Are they trying to say that if a landowner won't let them release a captured canid on their property then they won't collar it and release it? The context of the paragraph doesn't jive with that.

Commented [OSE100]: What frequency range?

Commented [JM101]: See Ryan's comment.

Commented [JM102]: See Ryan's comment.

Commented [JM103]: Morse -What happens to ability to monitor animals with no collars?

Draft - Confidential

cannot be disregarded. When GPS technology falters or malfunctions, VHF can serve as replacement for data collection in addition to its use in real time monitoring of study animals. Canids will be minimally monitored for mortality approximately every 30 days by using VHF aerial telemetry techniques (Whitehouse and Steven 1977) as there may be a delay in satellite transmission of GPS location data due to weather, season, and animal behavior. Transient canids and individuals from breeding pairs that have lost a mate, have been found to use much larger areas versus paired residents, potentially increasing the opportunity for losing track of these individuals when GPS technology reaches its functional capacity or experiences malfunction. VHF data may also provide locations of canids in cover too dense for GPS units to function. Use of VHF telemetry techniques for data collection may be expanded as necessary for project needs.

Commented [OSE104]: Can the GPS collars transmit through water? If not and you have an animal that tumbles into water right after mortality you've lost data.

Commented [JM105]: See Ryan's comment.

Commented [JM106]: They are proposing monitoring for dead canids every 30 days. For any collared red wolf, we would like to add those frequencies to our flights so they can be monitored much more frequently. Which is another reason the frequencies of their collars should be in the same range as the existing collars.

Spatial Data Analyses

Both minimum convex polygon (MCP) and adaptive kernel (AK) home ranges (95%) and core use areas (50% and 25%) (Seaman and Powell 1996, Seaman et al. 1999) will be calculated from GPS data by using BIOTAS (Ecological Software Solutions LLC, 2016) and Geospatial Modelling Environment (Spatial Ecology, LLC, 2016) for ArcGIS 10.2.2 (Environmental Systems Research Institute, 2016) (Benson et al. 2006, Riley 2006, Tucker et al. 2008, Hinton 2014) for comparison to older studies. These estimations can also be calculated using VHF data, provided data minimum requirements are met. Spatial distribution in relation to habitat will also be estimated by dynamic Brownian bridge movement models as described by Hinton (2014) with R statistical software (R Core Team 2016) using the moveud package with habitat covariates important to each species (Bryne et al. 2014, Collier 2013, Kranstauber and Smolla 2013, C. Proctor, personal communication, 2016). Additionally, recent research into how canids shift their ranges will also be investigated for populations on the AP (Morin and Kelly, in review). Spatial overlap and co-occurrence will be assessed using methods described by Shipley (2012). Habitat and cover types will be estimated from digitized maps created by the SEGAP (Hinton 2014) or ortho files, as available (Shipley 2012). Percent composition of habitat and cover types within home ranges and core areas as well as edge density will be quantified (Shipley 2012). Habitat selection and cover type use effects on spatial distribution will be estimated at both the population (2nd order) and individual (3rd order) spatial scales using resource selection functions

Draft - Confidential

(Johnson et al. 2006, Manly et al. 2002, Shipley 2012). Effects of seasonality and time of day activity will also be explored. The spatial and temporal patterns of space use by sympatric canids will be studied using data generated from the interaction GPS collar sensors, particularly distance between individuals and duration of proximity.

Den Monitoring

Project staff will attempt to locate den sites for sympatric canids to get pup counts, morphometric measurements, age estimates, and skin biopsies. Project staff will also attempt to monitor pup survival during the pup rearing season by using remote cameras placed around the den site (Harrison and Gilbert 1985, Parks 1979, Way et al. 2001). Pups will be weighed, measured, and PIT tagged during May and June of each year when they become active but are still den-obligated (Gier 1968). We will investigate the use of remote camera traps for monitoring den behavior with a two-camera array around the den (H. Garbe, personal communication, 2016, Kays and Slauson 2008). This method has been successfully used to monitor kit fox pup survival (Kluever et al. 2013). Because coyotes have been found to be sensitive to den site disturbance, there is a general lack of data in the literature regarding this approach for monitoring pup survival. Approaching an experimental methodology systematically will be important for determining which methods are effective and which are not. As a starting point for testing this methodology, remote cameras will be placed two to five meters from main den entrances and set to take photos using a passive infrared sensor trigger (a beam that when broken by movement through it, triggers the camera to take a series of photos) with a time restriction between photo intervals to limit the number of photos taken and maximize the space on the memory card for the time period between camera checks (Kluever et al. 2013). Cameras will be checked six days after deployment and will be redeployed (i.e. new batteries and memory card, if required); cameras will remain at each den site until radio-collar data indicates the den site has been moved (Kluever et al. 2013). Cameras will be not be redeployed to a new coyote den site during a season if that breeding pair has already moved the den once due to the disturbance of camera presence/deployment.

Commented [OSE107]: No mention USFWS personnel in conjunction with this phrase.

Loss of control 8. Implied in conjunction with Project Personnel section.

Commented [JM108]: Morse – A minimum number of biologists will attend a den (2-3).

Commented [JM109]: See Ryan's comment.

Commented [OSE110]: No need for biopsies. Again, why do they need this? We already draw blood.

Commented [JM111]: Morse – No skin biopsies on pups.

Commented [JM112]: Morse – No. Best if not at all. Cameras set no closer than 7 m. to den entrance

Commented [OSE113]: Getting this close to dens in order to set up the cameras will cause high enough disturbance that the mother will move the pups or will abandon the pups all together. Even if by some miracle they were not moved or abandoned after first deployment, good luck with that not occurring after your first 6 day revisit. Looking at the Kluever paper I noticed 2 major differences between the Kluever study and this one.

The first is terrain. The Kluever study was conducted in the Great Basin in NE Utah. The area as described in the paper is very open and lacks dense vegetation. Lines of site were not an issue. Often times canid dens in SE will be located in dense vegetation. Not to say that this issue cannot be overcome, but it may be impractical to deploy cameras effectively, or site modification, i.e. clearing out veg, could be enough to cause den abandonment or den relocation.

The second issue is animal behavior is quite different. Kluever et al. were observing kit foxes. Camera deployment was done in the afternoons when the foxes were underground in their dens. The foxes most likely had no clue that the researchers were ever there. In fact the authors attributed the lack of den abandonment to this probable factor. There would never be a time where a pack would not be aware of, or disturbed by camera deployment here in NC.

Commented [JM114]: Morse - 6 days is too often to disturb a den

Commented [JM115]: See Ryan's comment.

Draft-Confidential

Mortalities

If a collared animal dies during the project, the carcass will be sent to SCWDS for necropsy. Red wolves will be sent to the SCWDS laboratory for necropsy, unless it is determined to be a law enforcement case. In potential law enforcement cases, the NCWRC Division of Wildlife Management Chief and USFWS Ecological Services Raleigh Field Office Field Supervisor will be contacted and requested to contact the appropriate law enforcement personnel, immediately after determining the need for law enforcement involvement. The carcass and all relevant information will then be turned over to law enforcement; the GPS-collar will be removed and genetic samples will be taken from the individual prior to release to law enforcement.

Commented [JM116]: Morse - Coyotes will be sent to SCWDS

Commented [JM117]: See Ryan's comment.

Commented [JM118]: Morse - Red Wolf Carcasses will be sent of the National Wildlife Health Lab in Madison, WI.

Commented [OSE119]: We have our own facility for this. This would be another point of lost control.

Loss of control 9.

Commented [OSE120]: Why? Just contact LE and then inform the Chief and Field Supervisor

Commented [JM121]: See Ryan's comment.

E. Project Personnel

Andrea Shipley has worked for the North Carolina Wildlife Resources Commission as a Canid Biologist since February 2016. Prior to that, she worked as a Wildlife Biologist for a non-profit located in northeastern Nevada as well as in several different field biologist oriented positions. Andrea has a background in carnivore and spatial ecology, having earned her MS in Biological Sciences from Eastern Kentucky University and BS in Biological Sciences from Rutgers University; Andrea will act as project lead and coordinator.

Brandon Sherrill has worked for the North Carolina Wildlife Resources Commission as a Mammalogist since December 2013. Prior to that, he worked as an educator at the North Carolina Museum of Natural Sciences and as a regional wildlife biologist for the South Carolina Department of Natural Resources. Brandon earned a BS and MS in Fisheries, Wildlife, and Conservation Biology from North Carolina State University; Brandon will act as project supervisor.

Krishna Pacifici, Research Assistant Professor at NCSU, will be the quantitative analysis collaborator on the project. Krishna's background and experience in quantitative ecology makes him well suited to consult and assist with advanced statistical analyses of spatial data.

Lisette Waits, Department Head and Distinguished Professor at the University of Idaho, will be the DNA analysis collaborator for the project, responsible for all DNA related sample processing and subsequent analyses.

Draft - Confidential

F. Schedule and Estimated Costs

The project will run from soon after December 1, 2017 through June 30, 2020. The estimated timeline for major tasks is as follows:

Year 1: Initiate field work soon after December 1, 2017 with assistance from 1-2 field technicians; 1 technician will be required for trapping and den monitoring efforts. Data collection will begin immediately after collar deployment and data will be managed by Andrea Shipley throughout the life of the project. Data analysis will be initiated after den monitoring season concludes, with guidance and assistance from Krishna Pacifici at North Carolina State University (NCSU). Report, manuscript and presentation production will be initiated concurrently with data analysis.

Year 2: Continue field work and data collection with assistance from 1-2 field technicians. Continue data analysis with guidance and assistance from Krishna Pacifici at NCSU. Continue and finalize report and manuscript production, and presentation at professional working groups and/or meetings.

Commented [OSE122]: Where are these techs coming from? Are we going to be paying for them?

Commented [OSE123]: Will we have any access to these data or only receive what the State is willing to give us? How will these data be used? Will the state cherry pick data and use it as a claim that the wolf is not a species?

Loss of control 10.

Commented [OSE124]: Where is year 3; as stated in their section 7 attachment?

GPS technology allows researchers to collect locational data at fine spatial and temporal scales through the deployment of collar units on wildlife study subjects. In this project, we propose to study a sample of sympatric canid populations with GPS radio-collars, in order to investigate the population parameters outlined in previous sections as well as species interactions. The purchase and use of this technology is critical to meeting the research objectives set forth in this document as well as in the document included in Attachment 1.

While GPS technology has evolved over the past 20 years, the cost of technology has plateaued. Upfront cost per unit remains relatively high, however project savings occurs at the back end when compared to older telemetry technology such as very high frequency (VHF)

Draft - Confidential

which require intensive labor to collect data at similar spatial and temporal scales. Pilot testing the proximity sensor enabled GPS-collars will allow investigation of the utility of this relatively new tool for community dynamics analysis by providing an increased locational data acquisition when individuals come within a set distance, or closer, from each other. Additionally, these sensors record the identities of the interacting individuals and the duration of their interactions. Using a trigger to temporarily switch GPS fix schedules will enable us to collect very fine scale data while conserving battery life, achieving project objectives in an efficient manner. Exploring the efficaciousness of this technology has the potential to positively impact future research projects requiring use of GPS-collars for data collection.

Aerial tracking will provide regular study animal surveillance useful to investigate cases of mortality, collar malfunction, or satellite data transmission delays, which can vary seasonally. In some situations, ground tracking could prove less expensive than aerial tracking. However, ground telemetry techniques require more than one biologist working in tandem to acquire accurate location estimates. This often translates to increased labor to collect data, particularly in large study areas. Aerial tracking will provide a more efficient and cost-effective method for surveilling study subjects in this large study area, requiring only one biologist and a contracted pilot. NCWRC personnel will perform aerial tracking along with the NCWRC pilot at a minimum frequency of every 30 days.

Use of local trappers to assist with sampling efforts provides several benefits. Local trappers have established, long-term relationships with private land owners, thereby providing access to private lands that might be otherwise difficult to secure. This will enable project biologists to obtain a representative sample of sympatric canids in the study area, as well as to operate more trap lines concurrently. This is particularly important when using a SCR sample design, as it will have direct implications on the resulting analyses and inferences.

As part of collaboration efforts, the project will contract the services of Krishna Pacifici, Research Assistant Professor in the Applied Ecology department at NCSU. Krishna's expertise is in quantitative ecology; consultation and assistance services provided will allow project biologists to make appropriate statistically relevant inferences from collected data.

Commented [JM125]: Morse - why the need for 12 more flights if using GPS collars for location/mortality?

Commented [OSE126]: Access does not necessarily denote cooperation. A land owner may say it's okay to trap but nay not agree to releasing the animal back on to the property.

Draft - Confidential

DNA analysis will be contracted to Lisette Wait's lab at the University of Idaho. Lisette's team at The Laboratory for Ecological, Evolutionary and Conservation Genetics has previous experience in analyzing red wolf and coyote hybrid molecular samples and has the most comprehensive DNA methodology for this sympatric canid species continuum in the nation. This expertise will facilitate expedient species identification on collared study animals besides landscape level population dynamics analysis.

	Commission	In-kind	Total
a. Personnel	$ 7,200.00	$ -	$ 7,200.00
b. Fringe Benefits	$ -	$ -	$ -
c. Travel	$ 30,000.00	$ -	$ 30,000.00
d. Equipment	$ 54,000.00	$ -	$ 54,000.00
e. Supplies	$ 61,500.00	$ -	$ 61,500.00
f. Contractual	$315,590.00	$ -	$315,590.00

I. Glossary

Abundance: Species abundance is the number of individuals per species, and relative abundance refers to the evenness of distribution of individuals among species in a community.

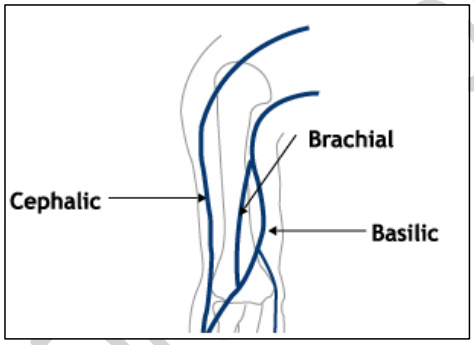
Adaptive kernel (AK): A probabilistic home range estimator based on the distribution and density of locations that has been collected over a period of time.

Adverse reactions: In pharmacology, any unexpected or dangerous reaction to a drug.

Aerial: Existing, happening, or operating in the air.

Annually: Once a year; every year.

Anthropogenic: Caused or influenced by humans.



Apex: Having no natural predators in its ecosystem.

Ataxia: The loss of full control of bodily movements.

Beacon: A radio beacon whose purpose is the investigation of the propagation of radio signals.

Biopsy: The removal for diagnostic study of a piece of tissue from a living body.

Brachial vein: One of a pair of veins accompanying the brachial artery and uniting with each other and with the basilic vein to form the axillary vein.

Breeding pair: A pair of animals which cooperate over time to produce offspring with some form of a bond between the individuals.

Carrying capacity: The maximum population size of the species that the environment can sustain indefinitely, given the food, habitat, water, and other necessities available in the environment.

Compensatory immigration: Individuals emigrating from areas with lower mortality to those with higher mortality; filling a deficiency of individuals in a population experiencing higher mortality. The increase in size or activity of one part of an organism or organ that makes up for the loss or dysfunction of another.

Composition: The combining of distinct parts or elements to form a whole.

Confidential

Co-occurrence: Refers to observation of the spatial overlap between two (or more) different individuals over a period of time.

Coordinates: Any of the scales or magnitudes that serve to define the position of a point.

Core use areas: An area within a home range exhibited by a dense concentration of location points; commonly estimated at 50% of the location data points.

Covariates: A variable that is possibly predictive of the outcome under study.

Cranial: Pertaining to the cranium or to the anterior (in animals) or superior (in humans) end of the body.

Cryogenic: Very low temperatures, e.g. -80ºC.

Den-obligated: Restricted to a particular condition of life, in this case restricted to a den site.

Density: A measure of the number of organisms that make up a population in a defined area.

Deployment: To organize and send out (people or things) to be used for a particular purpose.

Depredation: The act of preying upon.

Depressed respiration: A decrease in the ability to exhale and inhale; respiration that has a rate below 12 breaths per minute or that fails to provide full ventilation and perfusion of the lungs.

Diagnostic: The process of determining by examination the nature and circumstances of a diseased condition.

Disorientation: Loss of one's sense of direction, position, or relationship with one's surroundings.

Distribution: The manner in which a biological taxon is spatially arranged.

DNA: (deoxyribonucleic acid) is a type of macromolecule known as a nucleic acid. It is shaped like a twisted double helix and is composed of long strands of alternating sugars and phosphate groups, along with nitrogenous bases (adenine, thymine, guanine and cytosine).

Dorsal: Situated on or toward the upper side of the body, equivalent to the back, or posterior, in humans; situated on or toward the posterior plane in humans or toward the upper plane in quadrupeds.

Duration: A continuous period of time.

Dynamic Brownian bridge movement models: Incorporates temporal and behavioral characteristics of movement paths into estimation of home range.

Ectoparasite: a parasite that lives on the outside of its host rather than within the hosts body; e.g. fleas and lice.

Effective trap area: Calculated by buffering each trap site by half the mean maximum distance traveled, each of these boundaries are dissolved, creating a measurable area.

Efficacious: Producing or capable of producing a desired effect.

Draft - Confidential

Efficient: Accomplishment of or ability to accomplish a job with a minimum expenditure of time and effort.

Euthanize: The act of putting to death painlessly or allowing to die, as by withholding extreme medical measures, a person or animal suffering from an incurable, especially a painful, disease or condition.

Expedient: Suitable for achieving a particular end in a given circumstance.

Evaporative cooling: reduction in temperature resulting from the evaporation of a liquid, which removes latent heat from the surface from which evaporation takes place.

Facilitate: Make an action or process easy or easier.

Genotyping: Investigate the genetic constitution of (an individual organism).

Gonadal descent: The act or process of descending from a higher to a lower location; testicular descent occurs during the breeding season annually.

GPS: Global Positioning System, is a radio navigation system that allows land, sea, and airborne users to determine their exact location, velocity, and time 24 hours a day, in all weather conditions, anywhere in the world.

Home range: an area over which an animal or group of animals regularly travels in search of food or mates, and that may overlap with those of neighboring animals or groups of the same species.

Hybridization: The result of mixing, through sexual reproduction, two animals or plants of different breeds, varieties, species or genera.

Immobilization agent: An active force or substance capable of producing an effect.

Implantation: To put or fix firmly.

Inbreeding depression: The reduced biological fitness in a given population as a result of inbreeding, or breeding of related individuals.

Inception: The establishment or starting point of an institution or activity.

Interspecific: Existing or occurring between different species.

Iridium: A satellite constellation providing voice and data coverage to satellite phones, pagers and integrated transceivers over the Earth's entire surface.

Jugular vein: Any of several large veins in the neck, carrying blood from the head and face.

Lacerations: A deep cut or tear in skin or flesh.

Locational: A position or site occupied or available for occupancy or marked by some distinguishing feature.

Malfunction: Fail to operate in the normal or usual manner

Methodology: A system of methods used in a particular area of study or activity.

Midline: A median line or plane of bilateral symmetry, especially that of the body.

Draft - Confidential

Minimum convex polygon (MCP): Completely enclose all data points by connecting the outer locations in such a way as to create a convex polygon.

Molecular samples: Genetic samples that may be used for investigation of genetic constitution of an individual.

Morphometrics: The process of measuring the external shape and dimensions of landforms, living organisms, or other objects.

Mortality: The state of being subject to death.

Non-target bycatch: Animals caught by accident that are not the target species being sought.

Parameters: A numerical or other measurable factor forming one of a set that defines a system or sets the conditions of its operation.

Parentage: The origin of something; the state or relation of a parent.

Passive integrated transponder: A microchip implant is an identifying integrated circuit placed under the skin of an animal.

Pinna: The external part of the ear in humans and other mammals; the auricle.

Plateaued: A period or state of little or no growth or decline.

Population dynamics: The branch of life sciences that studies the size and age composition of populations as dynamic systems, and the biological and environmental processes driving them (such as birth and death rates, and by immigration and emigration).

Population growth: The increase in the number of individuals in a population.

Population size: A group of organisms of the same species that live in the same area.

Population status:

Population trend: Changes over time and can include changes in ranging behavior and distribution, biogeography and life-history.

Population viability: The process that determines the probability that a population will go extinct within a given number of years.

Proximity: Nearness in space, time, or relationship.

Quantified: Express or measure the quantity of.

Quantitative: Relating to, measuring, or measured by the quantity of something rather than its quality.

Radio-telemetry: The use of radio waves for transmitting information from a distant instrument to a device that indicates or records the measurements.

Recumbency: The state of leaning, resting, or reclining.

Reintegrate: Restore (elements regarded as disparate) to unity.

Draft - Confidential

Remnant: A small remaining quantity of something.

Reproductive status: Relating to or effecting reproduction.

Spatial: Relating to, occupying, or having the character of space.

Spatial capture-recapture: A method commonly used in ecology to estimate an animal population's size. A portion of the population is captured, marked, and released. Marked animals are either recaptured or are tracked, each tracking location being considered a recapture.

Species Continuum: An aggregate of species capable of interbreeding, resulting in fertile hybrid offspring whose genetic composition may represent a varying array of phenotypes and genotypes from the parental species, at which the extreme ends of the spectrum are distinct.

Standardize: Cause (something) to conform to a standard.

Statistically relevant inferences: the process of deducing properties of an underlying distribution by analysis of data. Inferential statistical analysis infers properties about a population: this includes testing hypotheses and deriving estimates.

Stochastic population models: Ecological population modeling is concerned with the changes in population size and age distribution within a population as a consequence of interactions of organisms with the physical environment, with individuals of their own species, and with organisms of other species; stochasticity possesses some inherent randomness. In stochastic population models, the same set of parameter values and initial conditions will lead to an ensemble of different out puts.

Strangulation: The condition in which circulation of blood to a part of the body is cut off by constriction.

Stratifying: Form or arrange into strata, one of a number of portions or divisions likened to layers or levels.

Surveillance: Continuous observation of a place, person, group, or ongoing activity in order to gather information.

Survival: A living or continuing longer than, or beyond the existence of, another person, thing, or event.

Sympatric: Occurring within the same geographical area; overlapping in distribution.

Tachycardia: A heart rate that exceeds the normal resting rate. In general, a resting heart rate over 100 beats per minute is accepted as tachycardia in human adults.

Telemetry: See radio-telemetry.

Temporal: Of or relating to time.

Tooth replacement: The process of development of two successive sets of teeth, initially the deciduous set and consecutively the permanent set.

Transmitter: A set of equipment used to generate and transmit electromagnetic waves carrying messages or signals, especially those of radio or television.

Transponder: A device for receiving a radio signal and automatically transmitting a different signal.

Draft - Confidential

Vaccinate: Treat with a vaccine to produce immunity against a disease; inoculate.

Venipuncture: The puncture of a vein as part of a medical procedure, typically to withdraw a blood sample or for an intravenous injection.

VHF: Very high frequency is the ITU designation for the range of radio frequency electromagnetic waves (radio waves) from 30 MHz to 300 MHz, with corresponding wavelengths of ten to one meters.

II. State/Agency:

NORTH CAROLINA / NORTH CAROLINA WILDLIFE RESOURCES COMMISSION

III. Station Name:

FWS RALEIGH ECOLOGICAL SERVICES OFFICE

IV. Description of Proposed Action (attach additional pages as needed):

Conduct research project entitled "**Coyotes of the Albemarle: Spatial Ecology, Resource Selection, Demographics, and Interactions with a Sympatric Canid"**

The coyote (*Canis latrans*) is now abundant throughout the 100 counties in North Carolina (NC), where they are managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plains region of NC (Hinton et al. 2012, Murray et al. 2014).

Recently described as using "compensatory immigration," coyotes are able to opportunistically fill spatial resource gaps by periodic transiency (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with humans and other canids, especially while taking advantage of anthropogenic resources. Though a rural area, human land uses predominate on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011).

In 1968, individuals from a remnant population of red wolves were removed from Texas and Louisiana and a captive breeding program was initiated. The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). The red wolf population increased until 2008 and peaked at around 208 individuals (USFWS Red Wolf Recovery Program 2007), a few animals short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013), with an estimated carrying capacity of 140-150 for the AP (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). Red wolves presently inhabit an approximately 6900 square kilometer recovery area within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014).
Accurate up-to-date estimates of the population are unavailable, but USFWS staff report a population size of 45-60 individuals with three mortalities in 2016 (https://www.fws.gov/redwolf/index.html July 2016). Hybridization with coyotes, inbreeding depression, and gunshot mortality have all been suspected issues that have affected the population growth and viability since the inception of the Red Wolf Recovery Program (RWRP) (Hinton et al. 2013). In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of red wolves and other canids on the AP. A USFWS memorandum documented detailed action items for the joint management of canids on the AP, including specific research objectives which this proposal seeks to address (Attachment 1).

As coyotes on the AP increase in number, monitoring coyote movements, particularly in relation to red wolves, will provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about coyote population management. Collection of finer temporal scale location data will help to manage interactions of both canid species with humans, as well as to support development of dynamic stochastic population models.

Coyote and red wolves will be live trapped by cooperating NCWRC and USFWS staff, and private trappers using double coil size 3 foothold traps, during the breeding season (Nov-Feb for coyote, Jan-Feb for red wolves) in the tri-county area of Dare, Hyde and Tyrrell. Morphological measurements, incidents of injury, occurrence of ectoparasites, age classification, and reproductive status will be determined; blood and tissue samples will be taken for genetic analysis. All captured individuals that meet the age classification and weight requirements will be collared with GPS collar units. All captured and collared individuals will be released at the capture site. The objectives listed below will be achieved by obtaining measurements, samples and information from the captured, collared, and tracked individuals over the course of three years using GPS location data.

862
863

Commented [JM130]: Morse - 11 mortalities in 2016 (insert current pop. estimate

Not trapping during breeding season (February).
No tissue samples from live wolves.
Will coyotes be sterilized?

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners.

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

V. Pertinent Species and Habitat:

A. Include species/habitat: See section VI

B. Complete the following table:

SPECIES/CRITICAL HABITAT	STATUS[1]
Canis rufus	T

[1]STATUS: E = endangered, T = threatened, PE = proposed endangered, PT =proposed threatened, CH = critical habitat, PC = proposed critical habitat, C = candidate species

VI. Location:

A. Statewide

Albemarle Peninsula (see web address www.ncwildlife.org)

B. Section, township, and range (or latitude and longitude):

Dare, Hyde, Tyrrell counties

C. Distance (miles) and direction to nearest town:

As stated above

D. Species/habitat occurrence:

Canis rufus

VII. Determination of Effects:

A. Explanation of effects of the action on species and critical habitats in item V. B. (attach additional pages as needed):

SPECIES/CRITICAL HABITAT	IMPACTS TO SPECIES/CRITICAL HABITAT
Canis rufus	Trap induced injury is possible

B. Explanation of actions to be implemented to reduce adverse effects:

SPECIES/CRITICAL HABITAT	ACTIONS TO MITIGATE/MINIMIZE IMPACTS
Canis rufus	Use of appropriate trap types, daily trap checks, treatment of minor injuries, trapping season limitations and limitations on environmental conditions for trap operation

Commented [JM131]: Morse – VI B. Include Washington and Beaufort Counties

Section VII. B. Include early morning trap checks.

VIII. Effect Determination and Response Requested:

Species/ Critical Habitat	Determination[1]			Response[1] Requested
	NE	NA	AA	
Canis rufus		X		Concurrence

[1] Determination/Response Requested:

NE = No Effect. This determination is appropriate when the proposed action will not directly, indirectly, or cumulatively impact, either positively or negatively, any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested is optional but a "Concurrence" is recommended for a complete Administrative Record.

NA = Not Likely To Adversely Affect. The determination is appropriate when the proposed action is not likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat or there may be beneficial effects to these resources. Response Requested is a "Concurrence".

AA = Likely To Adversely Affect. This determination is appropriate when the proposed action is likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested for listed species is "Formal Consultation". Response Requested for proposed or candidate species is "Conference".

Attachment 2: Joint Memorandum

MEMORANDUM

November 20, 2013

TO: All Interested Parties

FROM: "for"
Cynthia K. Dohner, Director, Southeast Region, U.S. Fish and Wildlife Service
Gordon S. Myers, Executive Director, N.C. Wildlife Resources Commission

SUBJECT: Collaborative Conservation of Red Wolves and Other Canids on North Carolina's Albemarle Peninsula

---

Recovery of the federally-listed red wolf has been a priority for the U.S. Fish and Wildlife Service (FWS) for more than 20 years and is focused in North Carolina on the Albemarle Peninsula (AP; i.e., Hyde, Tyrrell, Washington, Beaufort, and Dare counties). Comprehensive stakeholder involvement and collaboration with other management agencies is critical to successful recovery of any at-risk species. The North Carolina Wildlife Resources Commission (WRC) is a key collaborator in this regard, as it has jurisdiction over all state-trust wildlife resources in N.C.

Since 2009, the FWS and WRC have worked to broaden our collaboration in the conservation and management of all canid species (including red wolves) on the AP. As these efforts have solidified, specific actions have been jointly identified by our two agencies that will improve conservation outcomes. These actions are categorized into five areas; collaboration, research, outreach, regulatory, and enforcement. Specific action items are outlined and prioritized within each of these categories in Attachment A.

This memo establishes the FWS's and WRC's commitment to initiate, or to continue, the efforts outlined in Attachment A. The common goal in this effort is to establish clear expectations and accountability for collaboration regarding the action items on Attachment A, thus resulting in enhanced and seamless canid conservation and management on the AP. This approach provides the best opportunity to achieve recovery goals for red wolves, while at the same time managing other canids to balance biological variables with social expectations. The dynamics of these canid species are complex and offer unique opportunities for innovation. Appropriate staff from each agency is hereby tasked with immediately developing a timeline to implement these actions. Through this commitment, we will continue to advance our collective conservation goals.

875

Attachment A

Action Items for Collaborative Conservation of Canids on North Carolina's Albemarle Peninsula (AP)
(*Note: Action Items are prioritized within category.*)

Collaboration

1. The N.C. Wildlife Resources Commission (WRC) and U.S. Fish and Wildlife Service (FWS) will formalize in writing the collaborative management of canids on the AP. This agreement should:
    a. include a clear mission statement, goals, objectives, and implementation strategies (ask and answer the "Why?");
    b. set a goal to define success regarding canid management on the AP;
    c. espouse a philosophy of canid management operating within the context of a three-legged stool (i.e., federal and state governments and stakeholders);
    d. as available, commit funding and staffing resources for field personnel to contribute to the conservation of the red wolf and management of coyotes;
    e. as available, commit funding to conduct research pertinent to canid management on the AP;
    f. establish polices and goals for developing a collaborative genetic archive for AP canids, a data sharing portal accessible by staff in both agencies, and reciprocal sharing of all historical data (including phenotypic and genotypic data and literature) of the red wolf;
    g. establish a foundation for developing and implementing an adaptive approach to canid management on private lands on the AP;
    h. initiate development of a collaborative canid research program;
    i. describe plans to conduct the next five year Red Wolf Program review;
    j. outline options for holding annual workshops with federal and state enforcement staff;
    k. outline plans to hold semi-annual coordination meetings regarding canid management on the AP; and
    l. develop milestones for future development of a management plan for all canids in the AP.

2. The FWS will initiate a review of the current Red Wolf Recovery Plan to determine if the state-of-our-knowledge or field conditions have changed such as to warrant its revision. Review and comments from the WRC will be considered in this evaluation.

3. The WRC, with support and participation of the FWS, will establish a "Canid Forum" (similar to that established for manatees in Florida) to facilitate communication and discussion regarding canid management and citizen science opportunities on the AP.

876

877

Attachment A

Research

1. The FWS and WRC will provide funding and logistical support for research identified by the Red Wolf Recovery Implementation Team, Red Wolf Program staff, other FWS staff, or the WRC that promote the conservation and recovery of the red wolf and other canids on the AP. Studies could include:
    a. tests of the "placeholder theory" on the AP, including behavior of sympatric canids,
    b. determining carrying capacity of canids on the AP,
    c. determining genetic profiles of canid species on the AP,
    d. evaluating predator-prey dynamics,
    e. studies of canid habitat use,
    f. epidemiology of diseases impacting canids on the AP,
    g. development of stochastic simulation models of sympatric canid population dynamics and habitat use, and
    h. canid dispersal dynamics

2. The FWS and WRC will conduct jointly-supported research to determine the attitudes and opinions of N.C. private landowners and other citizens concerning canids on the AP (i.e., human dimensions studies).

Outreach

1. The FWS and WRC will collaborate with other partners to design and implement broad-based outreach and marketing programs with clear goals, objectives, strategies, and measurable outcomes, including development of consistent agency messages and educating the public about canids on the AP.

Regulatory

1. The FWS and WRC will initiate a review and, if needed, subsequent rule-making to clarify concepts or rectify conflicts in current federal or state rules (including the current 10(J) rule).

2. The WRC will review and evaluate statutory requirements for listing red wolves as state threatened in the five AP counties.

3. As data demonstrating a relationship between coyote hunting and red wolf mortality become available, the FWS and WRC will evaluate, and if appropriate implement, adaptive approaches to regulate of take of coyotes that may result in incidental take of red wolves.

4. The WRC will evaluate the status, management, and regulation of Controlled Fox Hunting Preserves.

878

879

5. The WRC will develop BMPs (due care provisions) for coyote hunting, trapping, and live sale.

6. The WRC will compile, compare, and contrast canid hunting and trapping regulations and programs in other states, including, but not limited to, other states with other species of wolves.

Enforcement

1. The FWS and WRC will develop coordination strategies to improve enforcement of federal regulations protecting red wolves.

I, the cooperator or cooperator's representative, have been informed of the methods and the manner in which research devices will be used, and of the possible hazards associated with their use. I understand that NCWRC, (to include its officers, employees and agents) will: exercise reasonable precautions to safeguard all persons to prevent injury to target and non-target animals; guard against the mishandling of control devices and materials; and exercise due caution and proper judgment in all scientific collection operations. I understand that NCWRC may collect Global Positioning System (GPS) coordinates at the project site as part of component or activity tracking or as wildlife disease monitoring or research data. I, the undersigned cooperator, do hereby give my consent and concurrence to NCWRC, its employees, and its agents, to use, upon lands owned, leased, or otherwise controlled by me, and identified by this document, the following methods and devices (an attachment of additional devices and/or methods may be attached):

Statement of agreement: The landowner, cooperator, or representative, as listed above hereby give permission to NCWRC to perform trap and release of the species listed for scientific collection purposes. In consideration of these understandings, I, the cooperator or cooperator's representative, agree to: assume responsibility for injury to my property under my control, when said injury is not the result of negligence on the part of NCWRC (it's officers, employees, and agents); assist in maintaining such warning signs as NCWRC may place for the purpose of notifying persons entering onto such lands of the possible hazards associated with scientific measures in use thereon; and to give adequate warning of these possible hazards to persons I authorize to enter onto such lands. Further, I, the cooperator or cooperator's representative, agree not to concurrently use or allow to be used upon lands covered by this agreement, any canid depredation efforts during the scientific collection time period.

STATE: North Carolina

GRANT TITLE: W79-Wildlife Management

PROJECT TITLE: Pilot Study – Using Fine Scale GPS Technology to Research Sympatric Canid Population Dynamics (Job 2.0?)

A. Problem and Need

The coyote (*Canis latrans*) is now abundant throughout the 100 counties in North Carolina (NC), and is managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plain region of NC (Hinton et al. 2012, Murray et al. 2014). In recent years as coyotes have increased their population, some have begun to make use of the Outer Banks region.

The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of captive-bred red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). This population increased until 2008 and peaked at around 130 individuals (Group Solutions, Inc. 2016), short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013). The AP has an estimated carrying capacity of 140-150 wolves (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). The exact number of red wolves is not known, but USFWS staff report a population estimate of 45-60 individuals with eight mortalities to date in 2016 (https://www.fws.gov/redwolf/index.html August 2016). Hybridization with coyotes and inbreeding depression are suspected factors that have affected red wolf population growth and viability since the inception of the Red Wolf Recovery Program (RWRP), while vehicular and gunshot mortality are known factors (Hinton et al. 2013). Because of hybridization between red wolves and coyotes, the AP supports a continuum of sympatric canids, hereafter referred to as "sympatric canids."

As part of a recent program review, the USFWS halted many aspects of the RWRP in 2015 and discontinued the coyote sterilization program, potentially affecting the spatial

Commented [OSE1]: Citation! How abundant?

Commented [JM2]: Morse - The 220 animals in the wild was to be a total population number devided into 2-3 mainland sites.

Commented [JM3]: Morse - The actual estimate for carrying capacity in the NEP is more like 175 animals.

Commented [OSE4]: This information is obviously out of date and invalid.

Commented [OSE5]: Hybridization has not been an issue since the beginning of the program as there were no coyotes out here in the beginning.

Commented [JM6]: Morse - Gunshot mortality is known to be the number one and most critical factor affecting population growth.

Commented [JM7]: Morse - The coyote sterilization program needs to be part of the NCWRC research proposal. (Deal breaker)

Draft - Confidential

distribution and population dynamics of sympatric canids. Telemetry data from coyotes on the AP suggests that about 70% of coyotes are residents (i.e., those that defend set territories) while the other 30% are transients, with most being dispersing juveniles (Hinton et al. 2015). Transient coyotes do not defend set territories. Coyotes can travel long distances and become transient even as adults, especially when they lose their mate. Recently described as using "compensatory immigration," coyotes opportunistically fill spatial resource gaps by periodic transiency; when spots come open, individuals that do not yet have permanent territories and have been roaming in the area, are able to inhabit the new openings (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with other canids and humans, especially when they are utilizing of anthropogenic resources.

Though a rural area, human land uses occupy a significant portion of space on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011). Concerns about fear of attacks on humans and domestic pets, the effects of sympatric canids on white-tailed deer and other game populations, and homeowner property damage comprise many of the conflict calls regarding sympatric canids on the AP (Responsive Management, forthcoming data). Wildlife managers in this region frequently receive requests for information on canid management (C. Turner, personal communication, 2016).

The changes in state and federal canid management rules have resulted in confusion regarding residents' rights and options for management of property damage by sympatric canids. As a result, some citizens are unsure of the legal and most effective methods for canid conflict management. Adding to management complexity is the need to manage canids for conservation purposes, such as reducing predation on at-risk ground nesting species or reducing hybridization of sympatric canids.

In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of sympatric canids on the AP. A USFWS and NCWRC joint memorandum documented detailed action items for the joint management of sympatric canids on the AP, including specific research objectives which this proposal seeks to address (Attachment 2). As sympatric canids on the AP increase in number, monitoring their

Commented [JM8]: Morse - Need to see the forthcoming data to comment on it. No predator/prey relationship studies have been conducted in the NEP for red wolves or coyotes and whitetail deer or any other game species. This should be part of the study proposal.

Commented [JM9]: Morse - Need information on information request to FWS by Chris Turner. Not sure of any to date.

Commented [JM10]: Morse - The current law/reg. is clear: it is legal to take or harass a red wolf in defense of human life or to protect pets and livestock.

Commented [JM11]: See Ryan's comment.

Commented [OSE12]: Does this mean that they are going to trap at Pea Island or any other state and federal land that occurs in Dare county that's not on the peninsula?

Commented [JM13]: Morse - Need examples of at-risk, ground nesting species to be able to comment adequately.

Commented [JM14]: See Ryan's comment.

Commented [JM15]: See Ryan's comment.

Commented [JM16]: Does not acknowledge dramatic decrease of red wolves because of lumping as sympatric canids.

Commented [OSE17]: As stated on page one "the AP supports a continuum of sympatric canids" this means coyotes, hybrids and wolves. I guarantee that wolf numbers are declining while others on the continuum are increasing; thus making this statement false. It implies that all variations are increasing.

This sentiment is explained more clearly on page 33 paragraph 3. They refer to coyotes and wolves separately.

Draft - Confidential

movements, particularly in relation to individuals of differing ancestry, could provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about sympatric canid populations and conflict management. Collection of finer temporal scale location data would help to manage interactions of sympatric canids with humans, as well as to support development of dynamic stochastic population models.

B. Objectives (after December 1, 2016-November 30, 2018)

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners.

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

At the end of this two-year pilot study, we will deliver an observational summary detailing the use of the GPS and sensor technology for spatial and population dynamics research on sympatric canids on the AP.

C. Expected Results and Benefits

As part of a pilot study, we will monitor the status of collared individuals by using a finer scale assessment of space and habitat use than previous studies. Earlier research focused on many of the same objectives we suggest investigating here, but during a time of intense, active

Commented [OSE18]: Don't see how this would work, unless they are talking about human dimensions.

Commented [JM19]: Morse - Need description on how this data will help manage interactions of sympatric canids with humans.

Commented [JM20]: Objectives talk about GPS'd animals but don't take into account any data from the existing 23 radio-collared red wolves and 29 collared coyotes.

Commented [OSE21]: Is this list a weighted list? I would hate to think that this was the objective with the highest priority.

Commented [JM22]: Morse - This testing should be conducted with coyotes, not wolves until performance levels are confirmed. Coyotes should be sterilized to assist with gaining private landowner permissions.

Commented [JM23]: Morse - There is currently no area on ARNWR where this level of wolf/coyote interaction occurs. Where will this investigation be conducted?

Commented [OSE24]: Why do they need location data for number of animals and age?

Commented [JM25]: Morse -The number and age of wolf offspring in breeding groups is already known using conventional VHF data collection and USFWS den work.

Commented [OSE26]: As stated later in this proposal no target animals will be treated for disease. Not treating wolves for visible or known disease is contrary to the recovery program, whether that be for recovery in the wild or increasing numbers in captivity. By continuing treating any wolves we would be compromising the validity of any conclusions from the data. Additionally, are they talking about actual source locations, as in disease originating locus, or causes of mortality?

Commented [JM27]: Morse - FWS already conducts ~100 telemetry flight/year to access red wolf and radio-collared coyote mortality sources.

Commented [JM28]: Morse - Need description of how this will happen and what data is to be shared with private landowners.

Commented [OSE29]: How do they propose to accomplish this? Which specific conflicts? How does knowing exact location help?

Commented [JM30]: Morse - This needs to be a separate and ongoing project conducted with ASU or a different university.

Commented [OSE31]: Their section 7 attachment state 3 years. Granted they state they will be tracking over the course of 3 years. Did they mean 2 years of trapping with a ...

Draft Confidential

management. Specific management techniques are no longer being carried out and dynamics between sympatric canids are expected to have changed substantially. The uncertainty regarding current dynamics presents a need for additional research in order to inform actions for the management of sympatric canids. Information gained from research may impact management rules and landowner's abilities to manage canids in some areas. Additionally, GPS technology has improved since earlier research was conducted allowing for more temporally detailed data collection and more nuanced analyses. Understanding how sympatric canids collectively use resources in areas of human-dominated landscapes will allow wildlife managers to tailor management options to local conditions. On the AP, row crop agriculture and hunting represent the primary and secondary land uses, respectively. Row crop agriculture is a significant nutrient resource on the landscape and, as opportunists, canids take advantage of such resources when they are available. Non-consumptive wildlife-driven tourism persists in all seasons and wildlife watching is a main draw for tourists in this area. For many tourists, the opportunity to see or hear large carnivores is the sole attraction for traveling to the AP. Information from this study will be provided to local constituents to establish a knowledge base regarding how sympatric canids use resources on private lands. Management and guidance could serve to prevent or minimize conflict while maximizing positive wildlife interaction opportunities for constituents. Development of a common understanding between wildlife managers and landowners based upon factual information is paramount for collaboratively achieving successful management of sympatric canids. The data collected in this pilot study is the foundation upon which this understanding and future management actions will be built.

The current level of hybridization between sympatric canids on the AP will be characterized using DNA gathered during this study. Body size exists as a continuum between coyotes and red wolves and has been documented as the most important factor for successful interspecific breeding pairs of these canids (Hinton 2014). Though both species have been found to use resources in similar manners, red wolves generally have more expansive home ranges and therefore may not use local resources as intensively as coyotes, depending on body size. Obtaining individual identification of study animals will allow managers, armed with spatial information, to infer how and why individuals in the canid species continuum exploit

Commented [JM32]: Morse - Do not rule out the possibility of more intense, active management techniques as described in the RW adaptive management plan.

Commented [JM33]: See Ryan's comment.

Commented [OSE34]: I would like to see a citation for everything in this sentence. Additionally, how do they take advantage of the resources? Are they eating part of it? Primary hunting area?

Commented [JM35]: Morse -What does this mean?

Commented [JM36]: See Ryan's comment.

Commented [OSE37]: Who are these local constituents? One of the main results that I can think of is that landowner requests for wolf removal will increase. Wasteful spending of federal and state money on removal efforts of coyotes, just like the failed removal effort of a coyote in 2016.

Commented [OSE38]: Is a wolf breeding with a hybrid considered hybridization?

Draft - Confidential

anthropogenic resources considering their life history traits.

In conjunction with prior research, data collected will contribute to knowledge on sympatric canid population dynamics on the AP. Estimating population size will allow managers to monitor population trends of sympatric canids and to examine the long and short-term impacts of different management strategies on their populations. While it is unknown whether sample size will allow for population estimation, obtaining population estimates for coyotes would provide wildlife managers with baseline data, when paired with annual mortality estimates, for monitoring changes in population abundance over time. Information on changes in abundance, reproductive dynamics, and habitat use could impact management strategies to influence long-term conservation outcomes. Results of this pilot study will allow managers to determine if future work will be necessary, what amount of effort will be required to achieve each objective, and whether or not population estimates will be an attainable goal.

D. Approach

The official Red Wolf Recovery Area (RWRA) covers approximately 6,900 square kilometers within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014). However, the USFWS has proposed the RWRA be constricted to the ARNWR and the Dare County Bombing Range in Dare county by the end of 2017. Due to these proposed RWRA changes, this study proposes to capture and radio-collar 25 sympatric canids within Dare, Hyde, and Tyrrell counties (hereafter referred to as "study area"); those counties being within and directly adjacent to the proposed new RWRA. The thematic subheadings below provide detailed descriptions of the approaches required for achieving the pilot study objectives.

Sampling Efforts

Trained NCWRC personnel will conduct live trapping of sympatric canids, with assistance from the USFWS RWRP biologists, and trained, experienced local trappers. NCWRC and USFWS wildlife personnel will select local trappers based on their past performance in trapping sympatric canids, but may also select trappers from the NCWRC coyote trappers list. NCWRC staff will train contracted trappers on specific trapping procedures before every trapping

Commented [OSE39]: What? They are opportunistic animals and will use any resources that they are able to, or is there something in the literature that states that coyote and wolves don't use anthropogenic resources. They even stated earlier that canids take advantage of row crops which would imply anthropogenic resources are an integral part of their life history. They are implying that the use of anthropogenic resources is abnormal behavior.

Commented [JM40]: Morse - This aspect of a coyote population size estimate would best be done in an area with no other sympatric canids.

Commented [JM41]: I don't believe technically a "recovery area" has been delineated, just an NEP boundary.

Commented [JM42]: See Ryan's comment.

Commented [OSE43]: Are we really going to let them trap on the refuge?? Needless to say this would hand over significant control of the program over to the State. I would dare say an illegal hand over at this point.

Loss of control 1.

Draft - Confidential

season. The project lead will supervise and coordinate all trapping activities including locations for installation and the operation of trap lines and handling of captured animals. Simultaneous personal trapping activities by contracted trappers will not be permitted while performing contracted trapping services, as specified in the draft service contract (Attachment 4).

Trapping efforts will follow a spatial capture-recapture (SCR) framework with a systematic targeted sampling design, focusing on areas that contain resources previously found to be used by sympatric canids (e.g. edge, agricultural fields, secondary roads, etc.) (Harris et al. 2013, Ivan et al. 2013), while attempting to sample a diversity of habitat types. This effort will allow us to increase the probability of detection of sympatric canids on the landscape (Tom 2012). While it is important to sample a wide range of habitats, the most important requirement for SCR is the number of collared individuals; this requirement provides flexibility in the other requirements for field sampling as needed (K. Pacifici, personal communication, 2016). We will initially focus trapping in areas of known red wolf packs, as advised by RWRP.

Trapping will take place during the breeding season when the likelihood of capturing females in the later stages of gestation or whelping females will be low. Capture efforts will be conducted from soon after 1 December 2017 – February 2018 and December 2018 – February 2019. Captured sympatric canids will be surrendered to NCWRC or the USFWS at capture sites. Trapping should occur on both public and private lands to obtain sampling coverage of the study area. Ideally, all federal and state lands would be accessible for trap and release (hereafter referred to as "capture") of sympatric canids, but it is most important to be able to trap and release on Alligator River NWR and the Dare County Bombing Range as those encompass the newly proposed RWRP recovery area and comprise the majority of land area for Dare county. Unlike Dare county, there are ample private lands that surround Pocosin Lakes NWR and Lake Mattamuskeet NWR in both Tyrrell and Hyde counties that may be utilized to effectively sample individuals who may use those federal lands, should they be excluded from capture activities. Capture on federal lands may require USFWS take permits and proposed activities may be subject to a compatibility assessment (P. Benjamin, personal communication, 2016). Scientific collection activities that take place on private lands will require agreements outlining conditions mutually decided by NCWRC and landowners (Attachment 3).

Commented [OSE44]: Another level of lost control.

Loss of control 2

Commented [OSE45]: Trap shy animals will be difficult to recapture, thus biasing their results.

Commented [OSE46]: There are only two known wolf packs left in their proposed study area.

Commented [JM47]: See Ryan's comment.

Commented [OSE48]: Breeding disruption is a possibility. Higher chance of trapping too many animals too young, as per their protocol, to collar.

In the Section 7 attachment they specifically state that coyote trapping will commence in Nov and end in Feb, while wolf trapping will start in Dec and end in Feb.

Commented [JM49]: Morse - Not for red wolves (deal breaker).

Commented [JM50]: See Ryan's comment.

Commented [JM51]: See Ryan's comment.

Commented [JM52]: Is it appropriate for NCWRC personnel and contract trappers to be trapping on the Refuge vice highly trained and experienced FWS personnel?

Commented [OSE53]: This sentence is a little vague. Do they mean that will have the opportunity to trap private land if the public land is excluded?

Commented [OSE54]: Compatibility assessment?. If this study goes through, it would effectively give the State full control of the wild population. At the bare minimum this would constitute a 10j rule change.

Where is the assessment?

Draft - Confidential

To increase probability of detection of sympatric canids, the accessible study area will be partitioned by a grid, the cell size of which will based on the average annual home range size of resident coyotes previously reported for the AP, approximately 23 km^2 (Hinton et al. 2015). As a system of sampling, trap lines will be referred here as "traps," and the number of trap sets (i.e. the actual trapping device) and number of each trap set size may vary between traps as necessary. Sampling will be standardized within each grid cell by use of equal number of traps per cell, on average 3 per cell, each at an approximate length of 10 km (Andelt and Gipson 1979, Way et al. 2004).

Target canids will be captured by using Softcatch #3 Coyote 4x4 (Oneida Victor Inc. Ltd., P.O. Box 32398, Euclid, Ohio 44132, Hinton 2014, Schemnitz 1994), the EZ Grip #7 (Livestock Protection Company, P.O. Box 725, Alpine, Texas 79831, Frame and Meier 2007), or equivalent. Various lures and baits will be used to increase trapping efficiency (Frederick et al. 1989, Shipley 2012). Traps will be laid on the Monday of each week and will be opened at the time of deployment. Traps will be checked once daily at dawn, to reduce potential stress to trapped individuals and will not be operated on days where the temperature is expected to reach or exceed 80° F (R. Nordsven, personal communication, 2016) or during times of predicted inclement weather (e.g. snow, hail, high wind, etc., Sikes et al. 2011). To standardize effort and remain logistically realistic, traps should be open for three trap nights in a row before being removed. Trap sets that have been closed due to non-target bycatch or other circumstances may be reopened and all traps should be re-baited and lured as appropriate.

Trap set locations will be marked by NCWRC or USFWS personnel using handheld GPS units (Garmin GPSMAP 64S, 1200 E. 151st St., Olathe, KS 66062-3426) and given a sequential identification number. Traps will also be given an identification number and trap set points will be documented in ArcMap 10.4. Trappers will keep detailed records on trap set operation, non-target species trapped, and other relevant details. Non-target species will be released from traps after an in-field assessment of injuries, if any, and animals with life threatening injuries will be euthanized by the trap operator. Targeted recapture of collared canids will occur annually during the same months, to replace GPS collar batteries and drop-off collar release units in field. Trapping effort will be quantified (trap nights), the effective sample area will be

Commented [JM55]: See Ryan's comment.

Commented [JM56]: See Ryan's comment.

Commented [OSE57]: What about freezing or below freezing temps. This concern might be covered by their inclement weather statement. The temperature range should be spelled out and private trappers would have to be explicitly told not to trap.

Commented [OSE58]: Why only 3 nights

Commented [OSE59]: Loss of control 3. Implied.

Commented [OSE60]: Good luck capturing trap shy animals. Additionally wont this interfere with subsequent trapping years of the study, or are they planning on not trapping for new animals in the same locations the following year.

Draft - Confidential

estimated, the encounter (detection) probability will be estimated using a Gaussian detection model (Amundson et al. 2014), and an estimate of density for coyotes will be calculated using a modified Huggins closed-capture estimator in program MARK, if sample size allows (Harris et al. 2013, Ivan et al. 2013).

Animal Handling

Handling of canids will follow American Society of Mammalogists (ASM) guidelines (Sikes et al. 2011) and will be performed at the capture site. Chemical immobilization agents may be used depending on the number of field staff during processing (i.e., three or more staff required during non-chemical immobilizations, Craft 2007, M. Morse, personal communication, 2016).

Chemical Immobilization

Unless adequate numbers of personnel are available to safely employ mechanical restraint techniques, target animals will be anesthetized with the chemical immobilization agent BAM (Wildlife Pharmaceuticals, Inc., Windsor, CO 80550). BAM, a combination of Butorphanol tartrate, Azaperone tartrate and Medetomidine HCl., will be delivered by intramuscular injection by syringe pole to the hip. Dosage for canids is based on field trails performed by Wildlife Pharmaceuticals (Wildlife Pharmaceuticals, Inc. 2016) and the recommended dose for coyotes is 0.2CC and red wolves is 0.3CC, with adjunct doses of 0.1-0.2CC delivered if initial dosages do not cause induction (S. Kirschner, personal communication, 2017). Induction times for coyotes and wolves ranged from 5 to 10 minutes after initial and/or adjunct dosages (Wildlife Pharmaceuticals, Inc. 2016). After field handling is concluded the anesthesia will be reversed using two reversal agents, Atipamezole and Naltrexone, at double the CC of Atipamezole to BAM that was delivered (including adjunct doses, if given) and 0.5CC of Naltrexone. Recovery time from the reversal agents ranged from 10 to 25 minutes during field trails (Wildlife Pharmaceuticals, Inc. 2016). Field personnel will observe animals for signs of adverse effects for up to 30 minutes after reversal agents are delivered.

Mechanical Immobilization

Unlike other carnivore families, the submissive behavioral response of canids to

Commented [OSE61]: Why is the sample area going to be estimated when they stated earlier that they were going to grid out accessible areas?

Commented [OSE62]: This probability is comprised of two factors. 1) Availability "which is the probability that an animal is present in the survey area and signaling its presence to the observer" and 2) Perceptibility "which is the probability that an animal available for detection (e.g., a bird sings) is detected by the observer" This is taken directly form the Amundson paper. I understand how the collars will help with determining availability, but I am curious how they will determine perceptibility. Is the perceptibility tied to the number of traps or ear tags?

Commented [OSE63]: Are they talking about immobilization while the animal is in the trap or are they talking about after the animal is out of the trap? Lots of possible implications when dealing with contract trappers if it is the former. What about total animal process time vs checking trap lines.

Commented [JM64]: Morse - Wolves will be turned over to FWS for processing and radio-collaring at the RWEC (Columbia, NC) with support from NCWRC biologists. (deal breaker).

Commented [JM65]: Morse - Two biologists and one note taker (if available). If not, two biologists can do the processing with no problems.

Commented [JM66]: Morse - We have a better, cleaner and safer chemical immobilization protocol developed specifically for red wolves by the NCSU Vet School. Butorphanol @ 0.4mg/kg w/ Dexmedetomide @ 0.04mg/kg
Antagonist: Naloxone @ 0.02mg/kg w/ atipamizole @ 0.2mg/kg

Commented [JM67]: See Ryan's comment.

Draft - Confidential

perceived dominance reduces the need to use immobilization agents. Appropriate mechanical restraint techniques can reduce handling time of animals, allowing animals to reintegrate into social groups more quickly, subsequently reducing overall stress to the individual (Powell and Proulx 2003). Target canids will be mechanically restrained with a restraint pole, until two muzzles can be placed around the snout. While pinned with the restraint pole by one person, a second person will restrain the set of legs not in the trap against the ground and a third person will release the foot from the trap. This set of legs will then be restrained by the 3rd person as the restraint pole is removed. Once the restraint pole is removed the person restraining the front legs will also then restrain the head. The first person will then move forward with processing the captured animal.

Each animal will be placed on a towel or blanket to provide thermal protection from the ground, with eyes covered and lubricated with eye ointment; temperature will be monitored with a rectal thermometer. Overheating occurs at approximately 104-105°F for canids (AZA Canid TAG 2012) and the animal handling crew will monitor temperature at 5-minute intervals; if a temperature reading reaches 104°F, corrective actions will be taken and temperature will be monitored at 1-minute intervals. Should overheating occur, the individual will be removed from insulation to expedite the natural evaporative cooling process. During days that approach 80°F in temperature, measures will be taken to reduce heat stress, such as: wetting the animal with water, application of a cold pack to the groin area between the back legs, application of rubbing alcohol to foot pads, or immediate release (AZA Canid TAG 2012). If the injured individual is suspected to be a red wolf, based on morphometrics, USFWS staff will be contacted for a decision. In the event that trap caused injuries are determined to be life threatening through use of a trap injury score assessment (Frame and Meier 2007) the individual will be euthanized. In the event that NCWRC personnel cannot be present, trained USFWS personnel may collar and measure captured target animals and will provide data sheets to NCWRC staff. Target animals will not be vaccinated or otherwise treated for diseases, regardless of the presence of disease symptoms.

Non-target animals will be released on site. Captured domestic dogs will be immediately released from the trap set following an injury score assessment and only if no life-threatening

Draft - Confidential

Commented [OSE68]: This is not always a guarantee that the animal is a wolf or not

Commented [OSE69]: Loss of control 4. Implied.

Commented [JM70]: See Ryan's comment.

Commented [OSE71]: FWS will be "allowed" to do this?! This statement plus several others would seem to indicate a takeover of the red wolf program by the NCWRC.

Loss of control 5. Implied.

Commented [JM72]: This seems like an unnecessary statement, as FWS personnel have the authority to handle red wolves.

Commented [JM73]: Why would we not vaccinate the capture animals, especially red wolves given the high value of each individual within a population so low?

Commented [OSE74]: Not treating wolves for visible or known disease is contrary to the recovery program, whether that be for recovery in the wild or increasing numbers in captivity. These wolves would be integral for population increase in the wild or for the "SSP meta-population"

Commented [JM75]: See Ryan's comment.

injuries are present. If a domestic dog has sustained life threatening injuries and owner identification information is present on the dog, then the animal will be held in either a transportable kennel, or at a dog pen on a state game land that is equipped with such facilities, until the owner can retrieve the dog. The costs associated with injuries sustained to the dog will be the responsibility of the animals' owner. Law enforcement may be requested to help communicate with the animal's owner. If the animal does not have an identifiable owner and has incurred substantial life threatening injuries (i.e. compound fracture), the dog will be euthanized on site. Target animals showing signs of disease symptoms such as circling behavior, head tilt, muscle twitches, convulsions with jaw chewing movements and salivation ("chewing gum fits"), disorientation, incoordination, staggering caused by paralysis of the hind legs, seizures, and partial or complete paralysis will be euthanized and tested according to protocol set forth by the agency veterinarian, in order to determine if there may be a public health issue (M. Palamar, personal communication, 2016). USFWS will be contacted in cases of suspected red wolves. Staff involved in animal handling duties will have the pre-exposure rabies vaccination series completed prior to field work inception and will maintain rabies titer records through properly licensed medical services providers.

If staff is bitten and skin is broken by an animal while performing handling duties, they will be advised to immediately visit a local hospital or clinic for evaluation by healthcare professionals. The field coordinator will immediately notify supervisory staff and an injury report and workers' compensation claim will be opened for the incident. The animal will be euthanized and the head will be sent to the state lab for rabies testing; the body may be sent to the Southeastern Cooperative Wildlife Disease Study (SCWDS) laboratory for additional disease investigation.

Capture Processing and Marking

During canid handling, NCWRC personnel will record age class, sex, weight, total body length, head width, ear length, and tail length, visually assess ectoparasite load, look for and disinfect with betadine or iodine as needed any minor trap caused injuries, and affix GPS collars (Knick 1990, Sikes et al. 2011). All captured canids will be fitted with appropriately-sized GPS collars in the field based on morphometrics previously indicated as reliable thresholds for

Commented [OSE76]: Loss of control 6. Implied.

Commented [OSE77]: Do they not have facilities to hold the animal for observation? They are going to unilaterally euthanize a wolf??

Commented [JM78]: I disagree that staff being bitten during a capture should result in a red wolf being euthanized, particularly if that animal is displaying no signs of disease. We can't afford to lose any more individuals in such a low population. And no euthanasia of a red wolf should occur without FWS involvement in the decision making process.

Commented [JM79]: See Ryan's comment.

Commented [OSE80]: This whole section gives state complete control of the program. Additionally are they going to remove our collars and put their own on?

Commented [OSE81]: Loss of control 7. Implied.

Draft - Confidential

species categorization: hind foot length, weight, width of head, and tail length (Hinton 2014); analysis of DNA samples collected during trapping efforts will help to assign captured canids to position along the species continuum post release. Age of individuals will be estimated based on physical characteristics, including weight and tooth replacement (Knick 1990, Hinton 2014, Gier 1968), and captured canids will be aged into one of three classes: > 2 years old as adults, < 2 but > 1 year old as juveniles, and > 6 months but < 12 months old as pups (Hinton 2014). Reproductive status will be determined based on estimated age class and presence of gonadal descent during the breeding season for males and the presence of nipple swelling or previous suckling for females (Hutson and Racey 2004, Magee 2008, Mengel 1971).

Captured individuals will be ear marked using a button tag (model 410, Ketchum Mfg. Co. [or equivalent], PO Box 10, 11 Town Shed Road, Lake Luzerne, NY 12846) placed along the middle of the ear where they are most protected from loss, with a pin-type applicator (485sa Pow-R-ceps plier, Ketchum Mfg. Co. [or equivalent]) (Silvy 2012). The puncture site will be treated with an antiseptic to deter infections. Each sympatric canid will also be marked with an individually-numbered, glass-encapsulated, passive integrated transponder (PIT model HPT12, 12.5 mm, 134.2 kHz, Biomark, Inc., 703 South Americana Blvd., Suite 150, Boise, ID; Gannon et al. 2007), using a syringe-type implanter and replaceable needle (model MK10 [implanter], model N125 [needle], Biomark, Inc.). Successful PIT placement will be verified with a mini portable reader (model GPR Plus, Biomark, Inc.). The implantation site will be prepared by swabbing with 70% alcohol (Mrozek et al. 1995) and a sterilized new needle will be used for each injection. The standard implantation site for transponders is subcutaneously on the dorsal midline of the back, cranial to the shoulder blades (Ingwersen 2000).

A skin biopsy will be taken from all captured target canids by puncturing the pinna of the ear with a biopsy punch in the same location where the ear tag will be placed (Palamar 2014). The biopsied area will be disinfected with alcohol after sampling. The skin biopsy will be placed in a labeled (ID, date, and sample type) cryogenic tube filled with 95% ethanol as buffer and then stored in a freezer until sent out to a lab for genetic analysis (Palamar 2014, Tom 2012). A selection of hairs with the root bulla attached will be pulled from the belly and placed in paper envelopes (Janecka et al. 2007). Hair samples will serve as back up to tissue samples

Commented [OSE82]: What is the point of this if they are going to have a collar on them. Would this be used for mark/recapture purposes for any animal in excess of the 25 collars? Or is this for continued identification after the collars fall off. Collars falling off of wolves does us no good for continued tracking after the study.

I have conflicting thoughts on this. Makes it easier to identify while in a trap prior to release but makes it easier for someone to see and shoot the animal. Alternatively it could stop someone from shooting and thus biasing mortality results.

Commented [JM83]: Morse - Why - no need. the ear tags are not needed and are a constant source of infection and irritation. In addition, when we,ve used them in the past - the animals tear them out.

Commented [OSE84]: Are we going to give them our tags or will they use their own. Either way is a loss of control of the program.

Commented [JM85]: Morse - Continue to use PIT tags by Trovan to keep consistency with animals already deployed.

Commented [JM86]: Concerns over PIT tag not being compatible with our reader

Commented [JM87]: See Ryan's comment.

Commented [OSE88]: What is the point of this and how does it help them achieve any of their stated goals? Are they proposing to make a hole in the ear first using this method and then place the tag in the hole?

Commented [JM89]: Morse - genetic analysis can be done with blood serum.

Commented [JM90]: See Ryan's comment.

Commented [OSE91]: Not opposed to this but again, why? Can they get more info from this than from blood samples? They are proposing 3 separate DNA samples.

Draft - Confidential

for genetic testing. All samples will be sent to the Laboratory for Ecological, Evolutionary and Conservation Genetics, at University of Idaho (875 Perimeter Drive, MS 1136, Moscow, ID 83844) for genotyping to determine species as well as individual identification, hybridization presence, and parentage analysis following previously developed protocols (Adams et al. 2007, Hinton 2014, Miller et al. 2003). The appropriate genetic analyses that examine the coyote-hybrid-wolf species continuum will be performed.

Blood will be collected from all juvenile and adult target canids by venipuncture of the brachial or jugular veins using a 22-28-gauge needle (M. Palamar, NCWRC veterinarian, personal communication, 2016). As per NCWRC veterinarian recommendations, approximately 12 ml of blood will be collected for each animal for possible future testing for diseases of importance to sympatric canid species as well as the humans and domestic animals that they may come into contact with. A minimum of two 6 ml lavender top tube (for whole blood with EDTA) will be filled. Samples should be refrigerated at all times; a cooler with ice will suffice while in the field. Samples should be sent to the NCWRC within 48 hours or frozen for later shipping. Skin scrapes will be collected from animals presenting signs compatible with sarcoptic mange (lesions) for possible future diagnostic purposes. Lesions will be scraped until blood is drawn; the scrapings will be placed onto a slide and covered with a piece of clear tape for later visual confirmation.

Should overheating occur, processing will be performed in the following prioritization order and the first five items will need to be completed before releasing any individuals: 1) trap injury evaluation, 2) collaring, 3) DNA (skin biopsy) sample collection, 4) morphometrics, 5) aging, 6) PIT tagging, 7) weight, 8) ear tagging, 9) reproductive status, 10) ectoparasite evaluation, 11) blood collection, and 12) skin scrape collection.

Collaring

Vertex Plus GPS Collars will be attached to 25 sympatric canids captured on the study area, 10 of which will be equipped with proximity sensors (Vectronic Aerospace GmbH, Carl-Scheele-Str. 12, 12489 Berlin, Germany). Project staff will pilot test proximity sensor technology for utility in analysis of spatial and temporal community dynamics. Proximity sensors trigger increased GPS location acquisition during those time intervals when two collared individuals

Commented [JM92]: Morse - Pull one red top tube to spin for serum collection. Why 2 - 6 mm purple top tubes (isn't 1 enough)? Also, FWS is going to need to maintain additional blood samples for database.

Commented [JM93]: See Ryan's comment.

Commented [JM94]: Morse - define overheating temp. range and cooling procedures. In the event of overheating, the first thing to do is to immediately cool the animal. Collar then blood draw (omit the rest).

Commented [OSE95]: Given our concerns over many aspects of tissue collection, I feel that this list should be revisited.

Commented [JM96]: See Ryan's comment.

Draft Confidential

come within a set distance from each other (http://www.vectronic-aerospace.com/wildlife-monitoring/sensors/uhf-id-tags, accessed August 2016).

To avoid instances of collar induced strangulation, only adult (>2 years old) male and female individuals will receive collars (Hinton 2014). ASM guidelines recommends a collar weight of <5-10% of a canids bodyweight, we will observe these guidelines (Sikes et al. 2011). Sympatric canids not releasable at a capture site will not be collared and will not become study animals.

GPS radio-collars will have both VHF and GPS Iridium locational systems as well as store-on-board capabilities. Radio-collar units will be programmed to record GPS coordinates once every 1.75 hours producing approximately 13 locations per day while cycling through the 24-hour time cycle. These settings will allow for a GPS battery life of 300 to 552 days, averaging 431 days. The VHF beacon will be in operation from 0800 – 1600 hours daily. GPS locations will be sent via satellite once per day and each transmission with contain 12 locations. The use of an integrated drop off firing mechanism should allow the collars to drop off within a maximum of approximately 548 days after deployment. The drop off schedule once set cannot be changed. The drop off firing mechanism is wired to a battery unit independent of the collar battery, therefore should the collar battery become depleted, the drop off mechanism will not be affected (C. Akakpo, Vectronic Aerospace GmbH, personal communication, 2016). Unless a collared individual is recaptured before the collar battery dies, the drop off mechanism will fire at the scheduled time frame post collar deployment.

Observation of sympatric canid habitat use and movements will occur through GPS data obtained with combination GPS/VHF radio-collars. VHF relies on triangulation, the process of estimating the location of a transmitter by using two or more compass bearings obtained by using directional antennas at known locations remote from the transmitter's position (White and Garrott 1990), whereas GPS uses a satellite based system to obtain location coordinates. There have been many published studies where one or both of these methods were used, with mixed success for determining various aspects of carnivore ecology throughout the United States (Hinton et al. 2012, Schrecengost et al. 2009, Sparkman et al. 2012). While GPS technology has developed rapidly in recent history, the real time functional advantage of VHF

Commented [JM97]: So in theory they could catch a one year old red wolf and by their protocol they would not collar it because it is less than 2 and they would release it without a collar. So basically the effort to trap a red wolf and the potential for injury has already occurred, but we do not take advantage of that by placing a collar on it to be able to monitor as much of the population as possible. Doesn't make sense.

Commented [OSE98]: I have a feeling that there is going to be many animals that fall into this category especially considering the prevalent landowner attitude towards carnivores in general and coyotes specifically. Additionally this constitutes a double standard in regards to releasing animals. We have landowner authorization in many cases but the State still will not allow us to use those lands for release, but are they going to allow themselves to do that? Also I feel that they should have all landowner agreements in place and the study/trapping areas well defined prior to any trapping effort. I have serious doubts that they can get this in place prior to Dec 1st.

Commented [JM99]: Needs clarification. Are they trying to say that if a landowner won't let them release a captured canid on their property then they won't collar it and release it? The context of the paragraph doesn't jive with that.

Commented [OSE100]: What frequency range?

Commented [JM101]: See Ryan's comment.

Commented [JM102]: See Ryan's comment.

Commented [JM103]: Morse -What happens to ability to monitor animals with no collars?

Draft - Confidential

cannot be disregarded. When GPS technology falters or malfunctions, VHF can serve as replacement for data collection in addition to its use in real time monitoring of study animals. Canids will be minimally monitored for mortality approximately every 30 days by using VHF aerial telemetry techniques (Whitehouse and Steven 1977) as there may be a delay in satellite transmission of GPS location data due to weather, season, and animal behavior. Transient canids and individuals from breeding pairs that have lost a mate, have been found to use much larger areas versus paired residents, potentially increasing the opportunity for losing track of these individuals when GPS technology reaches its functional capacity or experiences malfunction. VHF data may also provide locations of canids in cover too dense for GPS units to function. Use of VHF telemetry techniques for data collection may be expanded as necessary for project needs.

Commented [OSE104]: Can the GPS collars transmit through water? If not and you have an animal that tumbles into water right after mortality you've lost data.

Commented [JM105]: See Ryan's comment.

Commented [JM106]: They are proposing monitoring for dead canids every 30 days. For any collared red wolf, we would like to add those frequencies to our flights so they can be monitored much more frequently. Which is another reason the frequencies of their collars should be in the same range as the existing collars.

Spatial Data Analyses

Both minimum convex polygon (MCP) and adaptive kernel (AK) home ranges (95%) and core use areas (50% and 25%) (Seaman and Powell 1996, Seaman et al. 1999) will be calculated from GPS data by using BIOTAS (Ecological Software Solutions LLC, 2016) and Geospatial Modelling Environment (Spatial Ecology, LLC, 2016) for ArcGIS 10.2.2 (Environmental Systems Research Institute, 2016) (Benson et al. 2006, Riley 2006, Tucker et al. 2008, Hinton 2014) for comparison to older studies. These estimations can also be calculated using VHF data, provided data minimum requirements are met. Spatial distribution in relation to habitat will also be estimated by dynamic Brownian bridge movement models as described by Hinton (2014) with R statistical software (R Core Team 2016) using the moveud package with habitat covariates important to each species (Bryne et al. 2014, Collier 2013, Kranstauber and Smolla 2013, C. Proctor, personal communication, 2016). Additionally, recent research into how canids shift their ranges will also be investigated for populations on the AP (Morin and Kelly, in review). Spatial overlap and co-occurrence will be assessed using methods described by Shipley (2012). Habitat and cover types will be estimated from digitized maps created by the SEGAP (Hinton 2014) or ortho files, as available (Shipley 2012). Percent composition of habitat and cover types within home ranges and core areas as well as edge density will be quantified (Shipley 2012). Habitat selection and cover type use effects on spatial distribution will be estimated at both the population (2nd order) and individual (3rd order) spatial scales using resource selection functions

Draft - Confidential

(Johnson et al. 2006, Manly et al. 2002, Shipley 2012). Effects of seasonality and time of day activity will also be explored. The spatial and temporal patterns of space use by sympatric canids will be studied using data generated from the interaction GPS collar sensors, particularly distance between individuals and duration of proximity.

Den Monitoring

Project staff will attempt to locate den sites for sympatric canids to get pup counts, morphometric measurements, age estimates, and skin biopsies. Project staff will also attempt to monitor pup survival during the pup rearing season by using remote cameras placed around the den site (Harrison and Gilbert 1985, Parks 1979, Way et al. 2001). Pups will be weighed, measured, and PIT tagged during May and June of each year when they become active but are still den-obligated (Gier 1968). We will investigate the use of remote camera traps for monitoring den behavior with a two-camera array around the den (H. Garbe, personal communication, 2016, Kays and Slauson 2008). This method has been successfully used to monitor kit fox pup survival (Kluever et al. 2013). Because coyotes have been found to be sensitive to den site disturbance, there is a general lack of data in the literature regarding this approach for monitoring pup survival. Approaching an experimental methodology systematically will be important for determining which methods are effective and which are not. As a starting point for testing this methodology, remote cameras will be placed two to five meters from main den entrances and set to take photos using a passive infrared sensor trigger (a beam that when broken by movement through it, triggers the camera to take a series of photos) with a time restriction between photo intervals to limit the number of photos taken and maximize the space on the memory card for the time period between camera checks (Kluever et al. 2013). Cameras will be checked six days after deployment and will be redeployed (i.e. new batteries and memory card, if required); cameras will remain at each den site until radio-collar data indicates the den site has been moved (Kluever et al. 2013). Cameras will be not be redeployed to a new coyote den site during a season if that breeding pair has already moved the den once due to the disturbance of camera presence/deployment.

Commented [OSE107]: No mention USFWS personnel in conjunction with this phrase.

Loss of control 8. Implied in conjunction with Project Personnel section.

Commented [JM108]: Morse – A minimum number of biologists will attend a den (2-3).

Commented [JM109]: See Ryan's comment.

Commented [OSE110]: No need for biopsies. Again, why do they need this? We already draw blood.

Commented [JM111]: Morse – No skin biopsies on pups.

Commented [JM112]: Morse – No. Best if not at all. Cameras set no closer than 7 m. to den entrance

Commented [OSE113]: Getting this close to dens in order to set up the cameras will cause high enough disturbance that the mother will move the pups or will abandon the pups all together. Even if by some miracle they were not moved or abandoned after first deployment, good luck with that not occurring after your first 6 day revisit. Looking at the Kluever paper I noticed 2 major differences between the Kluever study and this one.

The first is terrain. The Kluever study was conducted in the Great Basin in NE Utah. The area as described in the paper is very open and lacks dense vegetation. Lines of site were not an issue. Often times canid dens in SE will be located in dense vegetation. Not to say that this issue cannot be overcome, but it may be impractical to deploy cameras effectively, or site modification, i.e. clearing out veg, could be enough to cause den abandonment or den relocation.

The second issue is animal behavior is quite different. Kluever et al. were observing kit foxes. Camera deployment was done in the afternoons when the foxes were underground in their dens. The foxes most likely had no clue that the researchers were ever there. In fact the authors attributed the lack of den abandonment to this probable factor. There would never be a time where a pack would not be aware of, or disturbed by camera deployment here in NC.

Commented [JM114]: Morse - 6 days is too often to disturb a den

Commented [JM115]: See Ryan's comment.

Draft-Confidential

Mortalities

If a collared animal dies during the project, the carcass will be sent to SCWDS for necropsy. Red wolves will be sent to the SCWDS laboratory for necropsy, unless it is determined to be a law enforcement case. In potential law enforcement cases, the NCWRC Division of Wildlife Management Chief and USFWS Ecological Services Raleigh Field Office Field Supervisor will be contacted and requested to contact the appropriate law enforcement personnel, immediately after determining the need for law enforcement involvement. The carcass and all relevant information will then be turned over to law enforcement; the GPS-collar will be removed and genetic samples will be taken from the individual prior to release to law enforcement.

Commented [JM116]: Morse - Coyotes will be sent to SCWDS

Commented [JM117]: See Ryan's comment.

Commented [JM118]: Morse - Red Wolf Carcasses will be sent of the National Wildlife Health Lab in Madison, WI.

Commented [OSE119]: We have our own facility for this. This would be another point of lost control.

Loss of control 9.

Commented [OSE120]: Why? Just contact LE and then inform the Chief and Field Supervisor

Commented [JM121]: See Ryan's comment.

E. Project Personnel

Andrea Shipley has worked for the North Carolina Wildlife Resources Commission as a Canid Biologist since February 2016. Prior to that, she worked as a Wildlife Biologist for a non-profit located in northeastern Nevada as well as in several different field biologist oriented positions. Andrea has a background in carnivore and spatial ecology, having earned her MS in Biological Sciences from Eastern Kentucky University and BS in Biological Sciences from Rutgers University; Andrea will act as project lead and coordinator.

Brandon Sherrill has worked for the North Carolina Wildlife Resources Commission as a Mammalogist since December 2013. Prior to that, he worked as an educator at the North Carolina Museum of Natural Sciences and as a regional wildlife biologist for the South Carolina Department of Natural Resources. Brandon earned a BS and MS in Fisheries, Wildlife, and Conservation Biology from North Carolina State University; Brandon will act as project supervisor.

Krishna Pacifici, Research Assistant Professor at NCSU, will be the quantitative analysis collaborator on the project. Krishna's background and experience in quantitative ecology makes him well suited to consult and assist with advanced statistical analyses of spatial data.

Lisette Waits, Department Head and Distinguished Professor at the University of Idaho, will be the DNA analysis collaborator for the project, responsible for all DNA related sample processing and subsequent analyses.

Draft - Confidential

F. Schedule and Estimated Costs

The project will run from soon after December 1, 2017 through June 30, 2020. The estimated timeline for major tasks is as follows:

Year 1: Initiate field work soon after December 1, 2017 with assistance from 1-2 field technicians; 1 technician will be required for trapping and den monitoring efforts. Data collection will begin immediately after collar deployment and data will be managed by Andrea Shipley throughout the life of the project. Data analysis will be initiated after den monitoring season concludes, with guidance and assistance from Krishna Pacifici at North Carolina State University (NCSU). Report, manuscript and presentation production will be initiated concurrently with data analysis.

Year 2: Continue field work and data collection with assistance from 1-2 field technicians. Continue data analysis with guidance and assistance from Krishna Pacifici at NCSU. Continue and finalize report and manuscript production, and presentation at professional working groups and/or meetings.

Commented [OSE122]: Where are these techs coming from? Are we going to be paying for them?

Commented [OSE123]: Will we have any access to these data or only receive what the State is willing to give us? How will these data be used? Will the state cherry pick data and use it as a claim that the wolf is not a species?

Loss of control 10.

Commented [OSE124]: Where is year 3; as stated in their section 7 attachment?

GPS technology allows researchers to collect locational data at fine spatial and temporal scales through the deployment of collar units on wildlife study subjects. In this project, we propose to study a sample of sympatric canid populations with GPS radio-collars, in order to investigate the population parameters outlined in previous sections as well as species interactions. The purchase and use of this technology is critical to meeting the research objectives set forth in this document as well as in the document included in Attachment 1.

While GPS technology has evolved over the past 20 years, the cost of technology has plateaued. Upfront cost per unit remains relatively high, however project savings occurs at the back end when compared to older telemetry technology such as very high frequency (VHF)

Draft - Confidential

which require intensive labor to collect data at similar spatial and temporal scales. Pilot testing the proximity sensor enabled GPS-collars will allow investigation of the utility of this relatively new tool for community dynamics analysis by providing an increased locational data acquisition when individuals come within a set distance, or closer, from each other. Additionally, these sensors record the identities of the interacting individuals and the duration of their interactions. Using a trigger to temporarily switch GPS fix schedules will enable us to collect very fine scale data while conserving battery life, achieving project objectives in an efficient manner. Exploring the efficaciousness of this technology has the potential to positively impact future research projects requiring use of GPS-collars for data collection.

Aerial tracking will provide regular study animal surveillance useful to investigate cases of mortality, collar malfunction, or satellite data transmission delays, which can vary seasonally. In some situations, ground tracking could prove less expensive than aerial tracking. However, ground telemetry techniques require more than one biologist working in tandem to acquire accurate location estimates. This often translates to increased labor to collect data, particularly in large study areas. Aerial tracking will provide a more efficient and cost-effective method for surveilling study subjects in this large study area, requiring only one biologist and a contracted pilot. NCWRC personnel will perform aerial tracking along with the NCWRC pilot at a minimum frequency of every 30 days.

Use of local trappers to assist with sampling efforts provides several benefits. Local trappers have established, long-term relationships with private land owners, thereby providing access to private lands that might be otherwise difficult to secure. This will enable project biologists to obtain a representative sample of sympatric canids in the study area, as well as to operate more trap lines concurrently. This is particularly important when using a SCR sample design, as it will have direct implications on the resulting analyses and inferences.

As part of collaboration efforts, the project will contract the services of Krishna Pacifici, Research Assistant Professor in the Applied Ecology department at NCSU. Krishna's expertise is in quantitative ecology; consultation and assistance services provided will allow project biologists to make appropriate statistically relevant inferences from collected data.

Commented [JM125]: Morse - why the need for 12 more flights if using GPS collars for location/mortality?

Commented [OSE126]: Access does not necessarily denote cooperation. A land owner may say it's okay to trap but nay not agree to releasing the animal back on to the property.

Draft - Confidential

DNA analysis will be contracted to Lisette Wait's lab at the University of Idaho. Lisette's team at The Laboratory for Ecological, Evolutionary and Conservation Genetics has previous experience in analyzing red wolf and coyote hybrid molecular samples and has the most comprehensive DNA methodology for this sympatric canid species continuum in the nation. This expertise will facilitate expedient species identification on collared study animals besides landscape level population dynamics analysis.

	Commission	In-kind	Total
a. Personnel	$ 7,200.00	$ -	$ 7,200.00
b. Fringe Benefits	$ -	$ -	$ -
c. Travel	$ 30,000.00	$ -	$ 30,000.00
d. Equipment	$ 54,000.00	$ -	$ 54,000.00
e. Supplies	$ 61,500.00	$ -	$ 61,500.00

I. Glossary

Abundance: Species abundance is the number of individuals per species, and relative abundance refers to the evenness of distribution of individuals among species in a community.

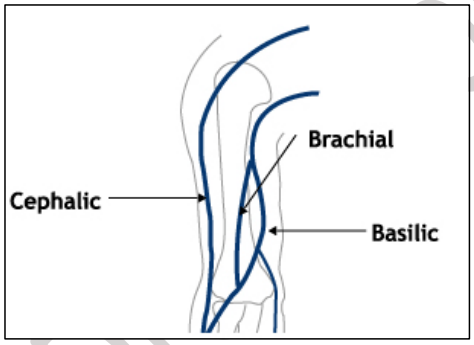
Adaptive kernel (AK): A probabilistic home range estimator based on the distribution and density of locations that has been collected over a period of time.

Adverse reactions: In pharmacology, any unexpected or dangerous reaction to a drug.

Aerial: Existing, happening, or operating in the air.

Annually: Once a year; every year.

Anthropogenic: Caused or influenced by humans.



Apex: Having no natural predators in its ecosystem.

Ataxia: The loss of full control of bodily movements.

Beacon: A radio beacon whose purpose is the investigation of the propagation of radio signals.

Biopsy: The removal for diagnostic study of a piece of tissue from a living body.

Brachial vein: One of a pair of veins accompanying the brachial artery and uniting with each other and with the basilic vein to form the axillary vein.

Breeding pair: A pair of animals which cooperate over time to produce offspring with some form of a bond between the individuals.

Carrying capacity: The maximum population size of the species that the environment can sustain indefinitely, given the food, habitat, water, and other necessities available in the environment.

Compensatory immigration: Individuals emigrating from areas with lower mortality to those with higher mortality; filling a deficiency of individuals in a population experiencing higher mortality. The increase in size or activity of one part of an organism or organ that makes up for the loss or dysfunction of another.

Composition: The combining of distinct parts or elements to form a whole.

Confidential

Co-occurrence: Refers to observation of the spatial overlap between two (or more) different individuals over a period of time.

Coordinates: Any of the scales or magnitudes that serve to define the position of a point.

Core use areas: An area within a home range exhibited by a dense concentration of location points; commonly estimated at 50% of the location data points.

Covariates: A variable that is possibly predictive of the outcome under study.

Cranial: Pertaining to the cranium or to the anterior (in animals) or superior (in humans) end of the body.

Cryogenic: Very low temperatures, e.g. -80ºC.

Den-obligated: Restricted to a particular condition of life, in this case restricted to a den site.

Density: A measure of the number of organisms that make up a population in a defined area.

Deployment: To organize and send out (people or things) to be used for a particular purpose.

Depredation: The act of preying upon.

Depressed respiration: A decrease in the ability to exhale and inhale; respiration that has a rate below 12 breaths per minute or that fails to provide full ventilation and perfusion of the lungs.

Diagnostic: The process of determining by examination the nature and circumstances of a diseased condition.

Disorientation: Loss of one's sense of direction, position, or relationship with one's surroundings.

Distribution: The manner in which a biological taxon is spatially arranged.

DNA: (deoxyribonucleic acid) is a type of macromolecule known as a nucleic acid. It is shaped like a twisted double helix and is composed of long strands of alternating sugars and phosphate groups, along with nitrogenous bases (adenine, thymine, guanine and cytosine).

Dorsal: Situated on or toward the upper side of the body, equivalent to the back, or posterior, in humans; situated on or toward the posterior plane in humans or toward the upper plane in quadrupeds.

Duration: A continuous period of time.

Dynamic Brownian bridge movement models: Incorporates temporal and behavioral characteristics of movement paths into estimation of home range.

Ectoparasite: a parasite that lives on the outside of its host rather than within the hosts body; e.g. fleas and lice.

Effective trap area: Calculated by buffering each trap site by half the mean maximum distance traveled, each of these boundaries are dissolved, creating a measurable area.

Efficacious: Producing or capable of producing a desired effect.

Draft - Confidential

Efficient: Accomplishment of or ability to accomplish a job with a minimum expenditure of time and effort.

Euthanize: The act of putting to death painlessly or allowing to die, as by withholding extreme medical measures, a person or animal suffering from an incurable, especially a painful, disease or condition.

Expedient: Suitable for achieving a particular end in a given circumstance.

Evaporative cooling: reduction in temperature resulting from the evaporation of a liquid, which removes latent heat from the surface from which evaporation takes place.

Facilitate: Make an action or process easy or easier.

Genotyping: Investigate the genetic constitution of (an individual organism).

Gonadal descent: The act or process of descending from a higher to a lower location; testicular descent occurs during the breeding season annually.

GPS: Global Positioning System, is a radio navigation system that allows land, sea, and airborne users to determine their exact location, velocity, and time 24 hours a day, in all weather conditions, anywhere in the world.

Home range: an area over which an animal or group of animals regularly travels in search of food or mates, and that may overlap with those of neighboring animals or groups of the same species.

Hybridization: The result of mixing, through sexual reproduction, two animals or plants of different breeds, varieties, species or genera.

Immobilization agent: An active force or substance capable of producing an effect.

Implantation: To put or fix firmly.

Inbreeding depression: The reduced biological fitness in a given population as a result of inbreeding, or breeding of related individuals.

Inception: The establishment or starting point of an institution or activity.

Interspecific: Existing or occurring between different species.

Iridium: A satellite constellation providing voice and data coverage to satellite phones, pagers and integrated transceivers over the Earth's entire surface.

Jugular vein: Any of several large veins in the neck, carrying blood from the head and face.

Lacerations: A deep cut or tear in skin or flesh.

Locational: A position or site occupied or available for occupancy or marked by some distinguishing feature.

Malfunction: Fail to operate in the normal or usual manner

Methodology: A system of methods used in a particular area of study or activity.

Midline: A median line or plane of bilateral symmetry, especially that of the body.

Draft - Confidential

Minimum convex polygon (MCP): Completely enclose all data points by connecting the outer locations in such a way as to create a convex polygon.

Molecular samples: Genetic samples that may be used for investigation of genetic constitution of an individual.

Morphometrics: The process of measuring the external shape and dimensions of landforms, living organisms, or other objects.

Mortality: The state of being subject to death.

Non-target bycatch: Animals caught by accident that are not the target species being sought.

Parameters: A numerical or other measurable factor forming one of a set that defines a system or sets the conditions of its operation.

Parentage: The origin of something; the state or relation of a parent.

Passive integrated transponder: A microchip implant is an identifying integrated circuit placed under the skin of an animal.

Pinna: The external part of the ear in humans and other mammals; the auricle.

Plateaued: A period or state of little or no growth or decline.

Population dynamics: The branch of life sciences that studies the size and age composition of populations as dynamic systems, and the biological and environmental processes driving them (such as birth and death rates, and by immigration and emigration).

Population growth: The increase in the number of individuals in a population.

Population size: A group of organisms of the same species that live in the same area.

Population status:

Population trend: Changes over time and can include changes in ranging behavior and distribution, biogeography and life-history.

Population viability: The process that determines the probability that a population will go extinct within a given number of years.

Proximity: Nearness in space, time, or relationship.

Quantified: Express or measure the quantity of.

Quantitative: Relating to, measuring, or measured by the quantity of something rather than its quality.

Radio-telemetry: The use of radio waves for transmitting information from a distant instrument to a device that indicates or records the measurements.

Recumbency: The state of leaning, resting, or reclining.

Reintegrate: Restore (elements regarded as disparate) to unity.

Draft - Confidential

Remnant: A small remaining quantity of something.

Reproductive status: Relating to or effecting reproduction.

Spatial: Relating to, occupying, or having the character of space.

Spatial capture-recapture: A method commonly used in ecology to estimate an animal population's size. A portion of the population is captured, marked, and released. Marked animals are either recaptured or are tracked, each tracking location being considered a recapture.

Species Continuum: An aggregate of species capable of interbreeding, resulting in fertile hybrid offspring whose genetic composition may represent a varying array of phenotypes and genotypes from the parental species, at which the extreme ends of the spectrum are distinct.

Standardize: Cause (something) to conform to a standard.

Statistically relevant inferences: the process of deducing properties of an underlying distribution by analysis of data. Inferential statistical analysis infers properties about a population: this includes testing hypotheses and deriving estimates.

Stochastic population models: Ecological population modeling is concerned with the changes in population size and age distribution within a population as a consequence of interactions of organisms with the physical environment, with individuals of their own species, and with organisms of other species; stochasticity possesses some inherent randomness. In stochastic population models, the same set of parameter values and initial conditions will lead to an ensemble of different out puts.

Strangulation: The condition in which circulation of blood to a part of the body is cut off by constriction.

Stratifying: Form or arrange into strata, one of a number of portions or divisions likened to layers or levels.

Surveillance: Continuous observation of a place, person, group, or ongoing activity in order to gather information.

Survival: A living or continuing longer than, or beyond the existence of, another person, thing, or event.

Sympatric: Occurring within the same geographical area; overlapping in distribution.

Tachycardia: A heart rate that exceeds the normal resting rate. In general, a resting heart rate over 100 beats per minute is accepted as tachycardia in human adults.

Telemetry: See radio-telemetry.

Temporal: Of or relating to time.

Tooth replacement: The process of development of two successive sets of teeth, initially the deciduous set and consecutively the permanent set.

Transmitter: A set of equipment used to generate and transmit electromagnetic waves carrying messages or signals, especially those of radio or television.

Transponder: A device for receiving a radio signal and automatically transmitting a different signal.

Draft - Confidential

Vaccinate: Treat with a vaccine to produce immunity against a disease; inoculate.

Venipuncture: The puncture of a vein as part of a medical procedure, typically to withdraw a blood sample or for an intravenous injection.

VHF: Very high frequency is the ITU designation for the range of radio frequency electromagnetic waves (radio waves) from 30 MHz to 300 MHz, with corresponding wavelengths of ten to one meters.

II. State/Agency:

NORTH CAROLINA / NORTH CAROLINA WILDLIFE RESOURCES COMMISSION

III. Station Name:

FWS RALEIGH ECOLOGICAL SERVICES OFFICE

IV. Description of Proposed Action (attach additional pages as needed):

Conduct research project entitled "**Coyotes of the Albemarle: Spatial Ecology, Resource Selection, Demographics, and Interactions with a Sympatric Canid"**

The coyote (*Canis latrans*) is now abundant throughout the 100 counties in North Carolina (NC), where they are managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plains region of NC (Hinton et al. 2012, Murray et al. 2014).

Recently described as using "compensatory immigration," coyotes are able to opportunistically fill spatial resource gaps by periodic transiency (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with humans and other canids, especially while taking advantage of anthropogenic resources. Though a rural area, human land uses predominate on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011).

In 1968, individuals from a remnant population of red wolves were removed from Texas and Louisiana and a captive breeding program was initiated. The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). The red wolf population increased until 2008 and peaked at around 208 individuals (USFWS Red Wolf Recovery Program 2007), a few animals short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013), with an estimated carrying capacity of 140-150 for the AP (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). Red wolves presently inhabit an approximately 6900 square kilometer recovery area within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014).
Accurate up-to-date estimates of the population are unavailable, but USFWS staff report a population size of 45-60 individuals with three mortalities in 2016 (https://www.fws.gov/redwolf/index.html July 2016). Hybridization with coyotes, inbreeding depression, and gunshot mortality have all been suspected issues that have affected the population growth and viability since the inception of the Red Wolf Recovery Program (RWRP) (Hinton et al. 2013). In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of red wolves and other canids on the AP. A USFWS memorandum documented detailed action items for the joint management of canids on the AP, including specific research objectives which this proposal seeks to address (Attachment 1).

As coyotes on the AP increase in number, monitoring coyote movements, particularly in relation to red wolves, will provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about coyote population management. Collection of finer temporal scale location data will help to manage interactions of both canid species with humans, as well as to support development of dynamic stochastic population models.

Coyote and red wolves will be live trapped by cooperating NCWRC and USFWS staff, and private trappers using double coil size 3 foothold traps, during the breeding season (Nov-Feb for coyote, Jan-Feb for red wolves) in the tri-county area of Dare, Hyde and Tyrrell. Morphological measurements, incidents of injury, occurrence of ectoparasites, age classification, and reproductive status will be determined; blood and tissue samples will be taken for genetic analysis. All captured individuals that meet the age classification and weight requirements will be collared with GPS collar units. All captured and collared individuals will be released at the capture site. The objectives listed below will be achieved by obtaining measurements, samples and information from the captured, collared, and tracked individuals over the course of three years using GPS location data.

862
863

Commented [JM130]: Morse - 11 mortalities in 2016 (insert current pop. estimate

Not trapping during breeding season (February).
No tissue samples from live wolves.
Will coyotes be sterilized?

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners.

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

V. Pertinent Species and Habitat:

A. Include species/habitat: See section VI

B. Complete the following table:

SPECIES/CRITICAL HABITAT	STATUS[1]
Canis rufus	T

[1]STATUS: E = endangered, T = threatened, PE = proposed endangered, PT =proposed threatened, CH = critical habitat, PC = proposed critical habitat, C = candidate species

VI. Location:

A. Statewide

Albemarle Peninsula (see web address www.ncwildlife.org)

B. Section, township, and range (or latitude and longitude):

Dare, Hyde, Tyrrell counties

C. Distance (miles) and direction to nearest town:

As stated above

D. Species/habitat occurrence:

Canis rufus

VII. Determination of Effects:

A. Explanation of effects of the action on species and critical habitats in item V. B. (attach additional pages as needed):

SPECIES/CRITICAL HABITAT	IMPACTS TO SPECIES/CRITICAL HABITAT
Canis rufus	Trap induced injury is possible

B. Explanation of actions to be implemented to reduce adverse effects:

SPECIES/CRITICAL HABITAT	ACTIONS TO MITIGATE/MINIMIZE IMPACTS
Canis rufus	Use of appropriate trap types, daily trap checks, treatment of minor injuries, trapping season limitations and limitations on environmental conditions for trap operation

Commented [JM131]: Morse – VI B. Include Washington and Beaufort Counties

Section VII. B. Include early morning trap checks.

VIII. Effect Determination and Response Requested:

Species/ Critical Habitat	Determination[1]			Response[1] Requested
	NE	NA	AA	
Canis rufus		X		Concurrence

[1] Determination/Response Requested:

NE = No Effect. This determination is appropriate when the proposed action will not directly, indirectly, or cumulatively impact, either positively or negatively, any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested is optional but a "Concurrence" is recommended for a complete Administrative Record.

NA = Not Likely To Adversely Affect. The determination is appropriate when the proposed action is not likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat or there may be beneficial effects to these resources. Response Requested is a "Concurrence".

AA = Likely To Adversely Affect. This determination is appropriate when the proposed action is likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested for listed species is "Formal Consultation". Response Requested for proposed or candidate species is "Conference".

Attachment 2: Joint Memorandum

MEMORANDUM

November 20, 2013

TO: All Interested Parties

FROM: "for"
Cynthia K. Dohner, Director, Southeast Region, U.S. Fish and Wildlife Service
Gordon S. Myers, Executive Director, N.C. Wildlife Resources Commission

SUBJECT: Collaborative Conservation of Red Wolves and Other Canids on North Carolina's Albemarle Peninsula

---

Recovery of the federally-listed red wolf has been a priority for the U.S. Fish and Wildlife Service (FWS) for more than 20 years and is focused in North Carolina on the Albemarle Peninsula (AP; i.e., Hyde, Tyrrell, Washington, Beaufort, and Dare counties). Comprehensive stakeholder involvement and collaboration with other management agencies is critical to successful recovery of any at-risk species. The North Carolina Wildlife Resources Commission (WRC) is a key collaborator in this regard, as it has jurisdiction over all state-trust wildlife resources in N.C.

Since 2009, the FWS and WRC have worked to broaden our collaboration in the conservation and management of all canid species (including red wolves) on the AP. As these efforts have solidified, specific actions have been jointly identified by our two agencies that will improve conservation outcomes. These actions are categorized into five areas; collaboration, research, outreach, regulatory, and enforcement. Specific action items are outlined and prioritized within each of these categories in Attachment A.

This memo establishes the FWS's and WRC's commitment to initiate, or to continue, the efforts outlined in Attachment A. The common goal in this effort is to establish clear expectations and accountability for collaboration regarding the action items on Attachment A, thus resulting in enhanced and seamless canid conservation and management on the AP. This approach provides the best opportunity to achieve recovery goals for red wolves, while at the same time managing other canids to balance biological variables with social expectations. The dynamics of these canid species are complex and offer unique opportunities for innovation. Appropriate staff from each agency is hereby tasked with immediately developing a timeline to implement these actions. Through this commitment, we will continue to advance our collective conservation goals.

875

Attachment A

Action Items for Collaborative Conservation of Canids on North Carolina's Albemarle Peninsula (AP)
(*Note: Action Items are prioritized within category.*)

Collaboration

1. The N.C. Wildlife Resources Commission (WRC) and U.S. Fish and Wildlife Service (FWS) will formalize in writing the collaborative management of canids on the AP. This agreement should:
    a. include a clear mission statement, goals, objectives, and implementation strategies (ask and answer the "Why?");
    b. set a goal to define success regarding canid management on the AP;
    c. espouse a philosophy of canid management operating within the context of a three-legged stool (i.e., federal and state governments and stakeholders);
    d. as available, commit funding and staffing resources for field personnel to contribute to the conservation of the red wolf and management of coyotes;
    e. as available, commit funding to conduct research pertinent to canid management on the AP;
    f. establish polices and goals for developing a collaborative genetic archive for AP canids, a data sharing portal accessible by staff in both agencies, and reciprocal sharing of all historical data (including phenotypic and genotypic data and literature) of the red wolf;
    g. establish a foundation for developing and implementing an adaptive approach to canid management on private lands on the AP;
    h. initiate development of a collaborative canid research program;
    i. describe plans to conduct the next five year Red Wolf Program review;
    j. outline options for holding annual workshops with federal and state enforcement staff;
    k. outline plans to hold semi-annual coordination meetings regarding canid management on the AP; and
    l. develop milestones for future development of a management plan for all canids in the AP.

2. The FWS will initiate a review of the current Red Wolf Recovery Plan to determine if the state-of-our-knowledge or field conditions have changed such as to warrant its revision. Review and comments from the WRC will be considered in this evaluation.

3. The WRC, with support and participation of the FWS, will establish a "Canid Forum" (similar to that established for manatees in Florida) to facilitate communication and discussion regarding canid management and citizen science opportunities on the AP.

876

877

Attachment A

Research

1. The FWS and WRC will provide funding and logistical support for research identified by the Red Wolf Recovery Implementation Team, Red Wolf Program staff, other FWS staff, or the WRC that promote the conservation and recovery of the red wolf and other canids on the AP. Studies could include:
    a. tests of the "placeholder theory" on the AP, including behavior of sympatric canids,
    b. determining carrying capacity of canids on the AP,
    c. determining genetic profiles of canid species on the AP,
    d. evaluating predator-prey dynamics,
    e. studies of canid habitat use,
    f. epidemiology of diseases impacting canids on the AP,
    g. development of stochastic simulation models of sympatric canid population dynamics and habitat use, and
    h. canid dispersal dynamics

2. The FWS and WRC will conduct jointly-supported research to determine the attitudes and opinions of N.C. private landowners and other citizens concerning canids on the AP (i.e., human dimensions studies).

Outreach

1. The FWS and WRC will collaborate with other partners to design and implement broad-based outreach and marketing programs with clear goals, objectives, strategies, and measurable outcomes, including development of consistent agency messages and educating the public about canids on the AP.

Regulatory

1. The FWS and WRC will initiate a review and, if needed, subsequent rule-making to clarify concepts or rectify conflicts in current federal or state rules (including the current 10(J) rule).

2. The WRC will review and evaluate statutory requirements for listing red wolves as state threatened in the five AP counties.

3. As data demonstrating a relationship between coyote hunting and red wolf mortality become available, the FWS and WRC will evaluate, and if appropriate implement, adaptive approaches to regulate of take of coyotes that may result in incidental take of red wolves.

4. The WRC will evaluate the status, management, and regulation of Controlled Fox Hunting Preserves.

878

879

5. The WRC will develop BMPs (due care provisions) for coyote hunting, trapping, and live sale.

6. The WRC will compile, compare, and contrast canid hunting and trapping regulations and programs in other states, including, but not limited to, other states with other species of wolves.

Enforcement

1. The FWS and WRC will develop coordination strategies to improve enforcement of federal regulations protecting red wolves.

I, the cooperator or cooperator's representative, have been informed of the methods and the manner in which research devices will be used, and of the possible hazards associated with their use. I understand that NCWRC, (to include its officers, employees and agents) will: exercise reasonable precautions to safeguard all persons to prevent injury to target and non-target animals; guard against the mishandling of control devices and materials; and exercise due caution and proper judgment in all scientific collection operations. I understand that NCWRC may collect Global Positioning System (GPS) coordinates at the project site as part of component or activity tracking or as wildlife disease monitoring or research data. I, the undersigned cooperator, do hereby give my consent and concurrence to NCWRC, its employees, and its agents, to use, upon lands owned, leased, or otherwise controlled by me, and identified by this document, the following methods and devices (an attachment of additional devices and/or methods may be attached):

Statement of agreement: The landowner, cooperator, or representative, as listed above hereby give permission to NCWRC to perform trap and release of the species listed for scientific collection purposes. In consideration of these understandings, I, the cooperator or cooperator's representative, agree to: assume responsibility for injury to my property under my control, when said injury is not the result of negligence on the part of NCWRC (it's officers, employees, and agents); assist in maintaining such warning signs as NCWRC may place for the purpose of notifying persons entering onto such lands of the possible hazards associated with scientific measures in use thereon; and to give adequate warning of these possible hazards to persons I authorize to enter onto such lands. Further, I, the cooperator or cooperator's representative, agree not to concurrently use or allow to be used upon lands covered by this agreement, any canid depredation efforts during the scientific collection time period.

STATE: North Carolina

GRANT TITLE: W79-Wildlife Management

PROJECT TITLE: Pilot Study – Using Fine Scale GPS Technology to Research Sympatric Canid Population Dynamics (Job 2.0?)

A. Problem and Need

The coyote (*Canis latrans*) is now abundant throughout the 100 counties in North Carolina (NC), and is managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plain region of NC (Hinton et al. 2012, Murray et al. 2014). In recent years as coyotes have increased their population, some have begun to make use of the Outer Banks region.

The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of captive-bred red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). This population increased until 2008 and peaked at around 130 individuals (Group Solutions, Inc. 2016), short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013). The AP has an estimated carrying capacity of 140-150 wolves (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). The exact number of red wolves is not known, but USFWS staff report a population estimate of 45-60 individuals with eight mortalities to date in 2016 (https://www.fws.gov/redwolf/index.html August 2016). Hybridization with coyotes and inbreeding depression are suspected factors that have affected red wolf population growth and viability since the inception of the Red Wolf Recovery Program (RWRP), while vehicular and gunshot mortality are known factors (Hinton et al. 2013). Because of hybridization between red wolves and coyotes, the AP supports a continuum of sympatric canids, hereafter referred to as "sympatric canids."

As part of a recent program review, the USFWS halted many aspects of the RWRP in 2015 and discontinued the coyote sterilization program, potentially affecting the spatial

Commented [OSE1]: Citation! How abundant?

Commented [OSE2]: This information is obviously out of date and invalid.

Commented [OSE3]: Hybridization has not been an issue since the beginning of the program as there were no coyotes out here in the beginning.

Draft - Confidential

distribution and population dynamics of sympatric canids. Telemetry data from coyotes on the AP suggests that about 70% of coyotes are residents (i.e., those that defend set territories) while the other 30% are transients, with most being dispersing juveniles (Hinton et al. 2015). Transient coyotes do not defend set territories. Coyotes can travel long distances and become transient even as adults, especially when they lose their mate. Recently described as using "compensatory immigration," coyotes opportunistically fill spatial resource gaps by periodic transiency; when spots come open, individuals that do not yet have permanent territories and have been roaming in the area, are able to inhabit the new openings (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with other canids and humans, especially when they are utilizing of anthropogenic resources.

Though a rural area, human land uses occupy a significant portion of space on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011). Concerns about fear of attacks on humans and domestic pets, the effects of sympatric canids on white-tailed deer and other game populations, and homeowner property damage comprise many of the conflict calls regarding sympatric canids on the AP (Responsive Management, forthcoming data). Wildlife managers in this region frequently receive requests for information on canid management (C. Turner, personal communication, 2016).

The changes in state and federal canid management rules have resulted in confusion regarding residents' rights and options for management of property damage by sympatric canids. As a result, some citizens are unsure of the legal and most effective methods for canid conflict management. Adding to management complexity is the need to manage canids for conservation purposes, such as reducing predation on at-risk ground nesting species or reducing hybridization of sympatric canids.

In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of sympatric canids on the AP. A USFWS and NCWRC joint memorandum documented detailed action items for the joint management of sympatric canids on the AP, including specific research objectives which this proposal seeks to address (Attachment 2). As sympatric canids on the AP increase in number, monitoring their

Commented [OSE4]: Does this mean that they are going to trap at Pea Island or any other state and federal land that occurs in Dare county that's not on the peninsula?

Commented [OSE5]: As stated on page one "the AP supports a continuum of sympatric canids" this means coyotes, hybrids and wolves. I guarantee that wolf numbers are declining while others on the continuum are increasing; thus making this statement false. It implies that all variations are increasing.

This sentiment is explained more clearly on page 33 paragraph 3. They refer to coyotes and wolves separately.

Draft - Confidential

movements, particularly in relation to individuals of differing ancestry, could provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about sympatric canid populations and conflict management. Collection of finer temporal scale location data would help to manage interactions of sympatric canids with humans, as well as to support development of dynamic stochastic population models.

Commented [OSE6]: Don't see how this would work, unless they are talking about human dimensions.

B. Objectives (after December 1, 2016-November 30, 2018)

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Commented [OSE7]: Is this list a weighted list? I would hate to think that this was the objective with the highest priority.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Commented [OSE8]: Why do they need location data for number of animals and age?

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Commented [OSE9]: As stated later in this proposal no target animals will be treated for disease. Not treating wolves for visible or known disease is contrary to the recovery program, whether that be for recovery in the wild or increasing numbers in captivity. By continuing treating any wolves we would be compromising the validity of any conclusions from the data. Additionally, are they talking about actual source locations, as in disease originating locus, or causes of mortality?

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners.

Commented [OSE10]: How do they propose to accomplish this? Which specific conflicts? How does knowing exact location help?

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

At the end of this two-year pilot study, we will deliver an observational summary detailing the use of the GPS and sensor technology for spatial and population dynamics research on sympatric canids on the AP.

Commented [OSE11]: Their section 7 attachment state 3 years. Granted they state they will be tracking over the course of 3 years. Did they mean 2 years of trapping with an additional year of tracking so that all animals have a minimum of 2 years of tracking?

C. Expected Results and Benefits

As part of a pilot study, we will monitor the status of collared individuals by using a finer scale assessment of space and habitat use than previous studies. Earlier research focused on many of the same objectives we suggest investigating here, but during a time of intense, active

Draft, Confidential

management. Specific management techniques are no longer being carried out and dynamics between sympatric canids are expected to have changed substantially. The uncertainty regarding current dynamics presents a need for additional research in order to inform actions for the management of sympatric canids. Information gained from research may impact management rules and landowner's abilities to manage canids in some areas. Additionally, GPS technology has improved since earlier research was conducted allowing for more temporally detailed data collection and more nuanced analyses. Understanding how sympatric canids collectively use resources in areas of human-dominated landscapes will allow wildlife managers to tailor management options to local conditions. On the AP, row crop agriculture and hunting represent the primary and secondary land uses, respectively. Row crop agriculture is a significant nutrient resource on the landscape and, as opportunists, canids take advantage of such resources when they are available. Non-consumptive wildlife-driven tourism persists in all seasons and wildlife watching is a main draw for tourists in this area. For many tourists, the opportunity to see or hear large carnivores is the sole attraction for traveling to the AP. Information from this study will be provided to local constituents to establish a knowledge base regarding how sympatric canids use resources on private lands. Management and guidance could serve to prevent or minimize conflict while maximizing positive wildlife interaction opportunities for constituents. Development of a common understanding between wildlife managers and landowners based upon factual information is paramount for collaboratively achieving successful management of sympatric canids. The data collected in this pilot study is the foundation upon which this understanding and future management actions will be built.

The current level of hybridization between sympatric canids on the AP will be characterized using DNA gathered during this study. Body size exists as a continuum between coyotes and red wolves and has been documented as the most important factor for successful interspecific breeding pairs of these canids (Hinton 2014). Though both species have been found to use resources in similar manners, red wolves generally have more expansive home ranges and therefore may not use local resources as intensively as coyotes, depending on body size. Obtaining individual identification of study animals will allow managers, armed with spatial information, to infer how and why individuals in the canid species continuum exploit

Commented [OSE12]: I would like to see a citation for everything in this sentence. Additionally, how do they take advantage of the resources? Are they eating part of it? Primary hunting area?

Commented [OSE13]: Who are these local constituents? One of the main results that I can think of is that landowner requests for wolf removal will increase. Wasteful spending of federal and state money on removal efforts of coyotes, just like the failed removal effort of a coyote in 2016.

Commented [OSE14]: Is a wolf breeding with a hybrid considered hybridization?

Draft - Confidential

anthropogenic resources considering their life history traits.

In conjunction with prior research, data collected will contribute to knowledge on sympatric canid population dynamics on the AP. Estimating population size will allow managers to monitor population trends of sympatric canids and to examine the long and short-term impacts of different management strategies on their populations. While it is unknown whether sample size will allow for population estimation, obtaining population estimates for coyotes would provide wildlife managers with baseline data, when paired with annual mortality estimates, for monitoring changes in population abundance over time. Information on changes in abundance, reproductive dynamics, and habitat use could impact management strategies to influence long-term conservation outcomes. Results of this pilot study will allow managers to determine if future work will be necessary, what amount of effort will be required to achieve each objective, and whether or not population estimates will be an attainable goal.

D. Approach

The official Red Wolf Recovery Area (RWRA) covers approximately 6,900 square kilometers within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014). However, the USFWS has proposed the RWRA be constricted to the ARNWR and the Dare County Bombing Range in Dare county by the end of 2017. Due to these proposed RWRA changes, this study proposes to capture and radio-collar 25 sympatric canids within Dare, Hyde, and Tyrrell counties (hereafter referred to as "study area"); those counties being within and directly adjacent to the proposed new RWRA. The thematic subheadings below provide detailed descriptions of the approaches required for achieving the pilot study objectives.

Sampling Efforts

Trained NCWRC personnel will conduct live trapping of sympatric canids, with assistance from the USFWS RWRP biologists, and trained, experienced local trappers. NCWRC and USFWS wildlife personnel will select local trappers based on their past performance in trapping sympatric canids, but may also select trappers from the NCWRC coyote trappers list. NCWRC staff will train contracted trappers on specific trapping procedures before every trapping

Commented [OSE15]: What? They are opportunistic animals and will use any resources that they are able to, or is there something in the literature that states that coyote and wolves don't use anthropogenic resources. They even stated earlier that canids take advantage of row crops which would imply anthropogenic resources are an integral part of their life history. They are implying that the use of anthropogenic resources is abnormal behavior.

Commented [OSE16]: Are we really going to let them trap on the refuge?? Needless to say this would hand over significant control of the program over to the State. I would dare say an illegal hand over at this point.

Loss of control 1.

Draft - Confidential

season. The project lead will supervise and coordinate all trapping activities including locations for installation and the operation of trap lines and handling of captured animals. Simultaneous personal trapping activities by contracted trappers will not be permitted while performing contracted trapping services, as specified in the draft service contract (Attachment 4).

Trapping efforts will follow a spatial capture-recapture (SCR) framework with a systematic targeted sampling design, focusing on areas that contain resources previously found to be used by sympatric canids (e.g. edge, agricultural fields, secondary roads, etc.) (Harris et al. 2013, Ivan et al. 2013), while attempting to sample a diversity of habitat types. This effort will allow us to increase the probability of detection of sympatric canids on the landscape (Tom 2012). While it is important to sample a wide range of habitats, the most important requirement for SCR is the number of collared individuals; this requirement provides flexibility in the other requirements for field sampling as needed (K. Pacifici, personal communication, 2016). We will initially focus trapping in areas of known red wolf packs, as advised by RWRP.

Trapping will take place during the breeding season when the likelihood of capturing females in the later stages of gestation or whelping females will be low. Capture efforts will be conducted from soon after 1 December 2017 – February 2018 and December 2018 – February 2019. Captured sympatric canids will be surrendered to NCWRC or the USFWS at capture sites. Trapping should occur on both public and private lands to obtain sampling coverage of the study area. Ideally, all federal and state lands would be accessible for trap and release (hereafter referred to as "capture") of sympatric canids, but it is most important to be able to trap and release on Alligator River NWR and the Dare County Bombing Range as those encompass the newly proposed RWRP recovery area and comprise the majority of land area for Dare county. Unlike Dare county, there are ample private lands that surround Pocosin Lakes NWR and Lake Mattamuskeet NWR in both Tyrrell and Hyde counties that may be utilized to effectively sample individuals who may use those federal lands, should they be excluded from capture activities. Capture on federal lands may require USFWS take permits and proposed activities may be subject to a compatibility assessment (P. Benjamin, personal communication, 2016). Scientific collection activities that take place on private lands will require agreements outlining conditions mutually decided by NCWRC and landowners (Attachment 3).

Commented [OSE17]: Another level of lost control.

Loss of control 2

Commented [OSE18]: Trap shy animals will be difficult to recapture, thus biasing their results.

Commented [OSE19]: There are only two known wolf packs left in their proposed study area.

Commented [OSE20]: Breeding disruption is a possibility. Higher chance of trapping too many animals too young, as per their protocol, to collar.

In the Section 7 attachment they specifically state that coyote trapping will commence in Nov and end in Feb, while wolf trapping will start in Dec and end in Feb.

Commented [OSE21]: This sentence is a little vague. Do they mean that will have the opportunity to trap private land if the public land is excluded?

Commented [OSE22]: Compatibility assessment my ass. If this study goes through, it would effectively give the State full control of the wild population. At the bare minimum this would constitute a 10j rule change.

Where is the assessment?

Draft - Confidential

To increase probability of detection of sympatric canids, the accessible study area will be partitioned by a grid, the cell size of which will based on the average annual home range size of resident coyotes previously reported for the AP, approximately 23 km^2 (Hinton et al. 2015). As a system of sampling, trap lines will be referred here as "traps," and the number of trap sets (i.e. the actual trapping device) and number of each trap set size may vary between traps as necessary. Sampling will be standardized within each grid cell by use of equal number of traps per cell, on average 3 per cell, each at an approximate length of 10 km (Andelt and Gipson 1979, Way et al. 2004).

Target canids will be captured by using Softcatch #3 Coyote 4x4 (Oneida Victor Inc. Ltd., P.O. Box 32398, Euclid, Ohio 44132, Hinton 2014, Schemnitz 1994), the EZ Grip #7 (Livestock Protection Company, P.O. Box 725, Alpine, Texas 79831, Frame and Meier 2007), or equivalent. Various lures and baits will be used to increase trapping efficiency (Frederick et al. 1989, Shipley 2012). Traps will be laid on the Monday of each week and will be opened at the time of deployment. Traps will be checked once daily at dawn, to reduce potential stress to trapped individuals and will not be operated on days where the temperature is expected to reach or exceed 80° F (R. Nordsven, personal communication, 2016) or during times of predicted inclement weather (e.g. snow, hail, high wind, etc., Sikes et al. 2011). To standardize effort and remain logistically realistic, traps should be open for three trap nights in a row before being removed. Trap sets that have been closed due to non-target bycatch or other circumstances may be reopened and all traps should be re-baited and lured as appropriate.

Trap set locations will be marked by NCWRC or USFWS personnel using handheld GPS units (Garmin GPSMAP 64S, 1200 E. 151st St., Olathe, KS 66062-3426) and given a sequential identification number. Traps will also be given an identification number and trap set points will be documented in ArcMap 10.4. Trappers will keep detailed records on trap set operation, non-target species trapped, and other relevant details. Non-target species will be released from traps after an in-field assessment of injuries, if any, and animals with life threatening injuries will be euthanized by the trap operator. Targeted recapture of collared canids will occur annually during the same months, to replace GPS collar batteries and drop-off collar release units in field. Trapping effort will be quantified (trap nights), the effective sample area will be

Commented [OSE23]: What about freezing or below freezing temps. This concern might be covered by their inclement weather statement. The temperature range should be spelled out and private trappers would have to be explicitly told not to trap.

Commented [OSE24]: Why only 3 nights

Commented [OSE25]: Loss of control 3. Implied.

Commented [OSE26]: Good luck capturing trap shy animals. Additionally wont this interfere with subsequent trapping years of the study, or are they planning on not trapping for new animals in the same locations the following year.

Draft - Confidential

estimated, the encounter (detection) probability will be estimated using a Gaussian detection model (Amundson et al. 2014), and an estimate of density for coyotes will be calculated using a modified Huggins closed-capture estimator in program MARK, if sample size allows (Harris et al. 2013, Ivan et al. 2013).

Animal Handling

Handling of canids will follow American Society of Mammalogists (ASM) guidelines (Sikes et al. 2011) and will be performed at the capture site. Chemical immobilization agents may be used depending on the number of field staff during processing (i.e., three or more staff required during non-chemical immobilizations, Craft 2007, M. Morse, personal communication, 2016).

Chemical Immobilization

Unless adequate numbers of personnel are available to safely employ mechanical restraint techniques, target animals will be anesthetized with the chemical immobilization agent BAM (Wildlife Pharmaceuticals, Inc., Windsor, CO 80550). BAM, a combination of Butorphanol tartrate, Azaperone tartrate and Medetomidine HCl., will be delivered by intramuscular injection by syringe pole to the hip. Dosage for canids is based on field trails performed by Wildlife Pharmaceuticals (Wildlife Pharmaceuticals, Inc. 2016) and the recommended dose for coyotes is 0.2CC and red wolves is 0.3CC, with adjunct doses of 0.1-0.2CC delivered if initial dosages do not cause induction (S. Kirschner, personal communication, 2017). Induction times for coyotes and wolves ranged from 5 to 10 minutes after initial and/or adjunct dosages (Wildlife Pharmaceuticals, Inc. 2016). After field handling is concluded the anesthesia will be reversed using two reversal agents, Atipamezole and Naltrexone, at double the CC of Atipamezole to BAM that was delivered (including adjunct doses, if given) and 0.5CC of Naltrexone. Recovery time from the reversal agents ranged from 10 to 25 minutes during field trails (Wildlife Pharmaceuticals, Inc. 2016). Field personnel will observe animals for signs of adverse effects for up to 30 minutes after reversal agents are delivered.

Mechanical Immobilization

Unlike other carnivore families, the submissive behavioral response of canids to

Commented [OSE27]: Why is the sample area going to be estimated when they stated earlier that they were going to grid out accessible areas?

Commented [OSE28]: This probability is comprised of two factors. 1) Availability "which is the probability that an animal is present in the survey area and signaling its presence to the observer" and 2) Perceptibility "which is the probability that an animal available for detection (e.g., a bird sings) is detected by the observer" This is taken directly form the Amundson paper. I understand how the collars will help with determining availability, but I am curious how they will determine perceptibility. Is the perceptibility tied to the number of traps or ear tags?

Commented [OSE29]: Are they talking about immobilization while the animal is in the trap or are they talking about after the animal is out of the trap? Lots of possible implications when dealing with contract trappers if it is the former. What about total animal process time vs checking trap lines.

Draft - Confidential

perceived dominance reduces the need to use immobilization agents. Appropriate mechanical restraint techniques can reduce handling time of animals, allowing animals to reintegrate into social groups more quickly, subsequently reducing overall stress to the individual (Powell and Proulx 2003). Target canids will be mechanically restrained with a restraint pole, until two muzzles can be placed around the snout. While pinned with the restraint pole by one person, a second person will restrain the set of legs not in the trap against the ground and a third person will release the foot from the trap. This set of legs will then be restrained by the 3rd person as the restraint pole is removed. Once the restraint pole is removed the person restraining the front legs will also then restrain the head. The first person will then move forward with processing the captured animal.

Each animal will be placed on a towel or blanket to provide thermal protection from the ground, with eyes covered and lubricated with eye ointment; temperature will be monitored with a rectal thermometer. Overheating occurs at approximately 104-105°F for canids (AZA Canid TAG 2012) and the animal handling crew will monitor temperature at 5-minute intervals; if a temperature reading reaches 104°F, corrective actions will be taken and temperature will be monitored at 1-minute intervals. Should overheating occur, the individual will be removed from insulation to expedite the natural evaporative cooling process. During days that approach 80°F in temperature, measures will be taken to reduce heat stress, such as: wetting the animal with water, application of a cold pack to the groin area between the back legs, application of rubbing alcohol to foot pads, or immediate release (AZA Canid TAG 2012). If the injured individual is suspected to be a red wolf, based on morphometrics, USFWS staff will be contacted for a decision. In the event that trap caused injuries are determined to be life threatening through use of a trap injury score assessment (Frame and Meier 2007) the individual will be euthanized. In the event that NCWRC personnel cannot be present, trained USFWS personnel may collar and measure captured target animals and will provide data sheets to NCWRC staff. Target animals will not be vaccinated or otherwise treated for diseases, regardless of the presence of disease symptoms.

Non-target animals will be released on site. Captured domestic dogs will be immediately released from the trap set following an injury score assessment and only if no life-threatening

Commented [OSE30]: This is not always a guarantee that the animal is a wolf or not

Commented [OSE31]: Loss of control 4. Implied.

Commented [OSE32]: I'll be allowed to do this?! Do not do me any favors. I am not your lackey NCWRC! This statement plus several others would seem to indicate a total takeover of the red wolf program by the NCWRC.

Loss of control 5. Implied.

Commented [OSE33]: Not treating wolves for visible or known disease is contrary to the recovery program, whether that be for recovery in the wild or increasing numbers in captivity. These wolves would be integral for population increase in the wild or for the "SSP meta-population"

Draft - Confidential

injuries are present. If a domestic dog has sustained life threatening injuries and owner identification information is present on the dog, then the animal will be held in either a transportable kennel, or at a dog pen on a state game land that is equipped with such facilities, until the owner can retrieve the dog. The costs associated with injuries sustained to the dog will be the responsibility of the animals' owner. Law enforcement may be requested to help communicate with the animal's owner. If the animal does not have an identifiable owner and has incurred substantial life threatening injuries (i.e. compound fracture), the dog will be euthanized on site. Target animals showing signs of disease symptoms such as circling behavior, head tilt, muscle twitches, convulsions with jaw chewing movements and salivation ("chewing gum fits"), disorientation, incoordination, staggering caused by paralysis of the hind legs, seizures, and partial or complete paralysis will be euthanized and tested according to protocol set forth by the agency veterinarian, in order to determine if there may be a public health issue (M. Palamar, personal communication, 2016). USFWS will be contacted in cases of suspected red wolves. Staff involved in animal handling duties will have the pre-exposure rabies vaccination series completed prior to field work inception and will maintain rabies titer records through properly licensed medical services providers.

If staff is bitten and skin is broken by an animal while performing handling duties, they will be advised to immediately visit a local hospital or clinic for evaluation by healthcare professionals. The field coordinator will immediately notify supervisory staff and an injury report and workers' compensation claim will be opened for the incident. The animal will be euthanized and the head will be sent to the state lab for rabies testing; the body may be sent to the Southeastern Cooperative Wildlife Disease Study (SCWDS) laboratory for additional disease investigation.

Capture Processing and Marking

During canid handling, NCWRC personnel will record age class, sex, weight, total body length, head width, ear length, and tail length, visually assess ectoparasite load, look for and disinfect with betadine or iodine as needed any minor trap caused injuries, and affix GPS collars (Knick 1990, Sikes et al. 2011). All captured canids will be fitted with appropriately-sized GPS collars in the field based on morphometrics previously indicated as reliable thresholds for

Commented [OSE34]: Loss of control 6. Implied.

Commented [OSE35]: Do they not have facilities to hold the animal for observation? They are going to unilaterally euthanize a wolf??

Commented [OSE36]: This whole section gives state complete control of the program. Additionally are they going to remove our collars and put their own on?

Commented [OSE37]: Loss of control 7. Implied.

Draft - Confidential

species categorization: hind foot length, weight, width of head, and tail length (Hinton 2014); analysis of DNA samples collected during trapping efforts will help to assign captured canids to position along the species continuum post release. Age of individuals will be estimated based on physical characteristics, including weight and tooth replacement (Knick 1990, Hinton 2014, Gier 1968), and captured canids will be aged into one of three classes: > 2 years old as adults, < 2 but > 1 year old as juveniles, and > 6 months but < 12 months old as pups (Hinton 2014). Reproductive status will be determined based on estimated age class and presence of gonadal descent during the breeding season for males and the presence of nipple swelling or previous suckling for females (Hutson and Racey 2004, Magee 2008, Mengel 1971).

Captured individuals will be ear marked using a button tag (model 410, Ketchum Mfg. Co. [or equivalent], PO Box 10, 11 Town Shed Road, Lake Luzerne, NY 12846) placed along the middle of the ear where they are most protected from loss, with a pin-type applicator (485sa Pow-R-ceps plier, Ketchum Mfg. Co. [or equivalent]) (Silvy 2012). The puncture site will be treated with an antiseptic to deter infections. Each sympatric canid will also be marked with an individually-numbered, glass-encapsulated, passive integrated transponder (PIT model HPT12, 12.5 mm, 134.2 kHz, Biomark, Inc., 703 South Americana Blvd., Suite 150, Boise, ID; Gannon et al. 2007), using a syringe-type implanter and replaceable needle (model MK10 [implanter], model N125 [needle], Biomark, Inc.). Successful PIT placement will be verified with a mini portable reader (model GPR Plus, Biomark, Inc.). The implantation site will be prepared by swabbing with 70% alcohol (Mrozek et al. 1995) and a sterilized new needle will be used for each injection. The standard implantation site for transponders is subcutaneously on the dorsal midline of the back, cranial to the shoulder blades (Ingwersen 2000).

A skin biopsy will be taken from all captured target canids by puncturing the pinna of the ear with a biopsy punch in the same location where the ear tag will be placed (Palamar 2014). The biopsied area will be disinfected with alcohol after sampling. The skin biopsy will be placed in a labeled (ID, date, and sample type) cryogenic tube filled with 95% ethanol as buffer and then stored in a freezer until sent out to a lab for genetic analysis (Palamar 2014, Tom 2012). A selection of hairs with the root bulla attached will be pulled from the belly and placed in paper envelopes (Janecka et al. 2007). Hair samples will serve as back up to tissue samples

Commented [OSE38]: What is the point of this if they are going to have a collar on them. Would this be used for mark/recapture purposes for any animal in excess of the 25 collars? Or is this for continued identification after the collars fall off. Collars falling off of wolves does us no good for continued tracking after the study.

I have conflicting thoughts on this. Makes it easier to identify while in a trap prior to release but makes it easier for someone to see and shoot the animal. Alternatively it could stop someone from shooting and thus biasing mortality results.

Commented [OSE39]: Are we going to give them our tags or will they use their own. Either way is a loss of control of the program.

Commented [OSE40]: What is the point of this and how does it help them achieve any of their stated goals? Are they proposing to make a hole in the ear first using this method and then place the tag in the hole?

Commented [OSE41]: Not opposed to this but again, why? Can they get more info from this than from blood samples? They are proposing 3 separate DNA samples.

Draft - Confidential

for genetic testing. All samples will be sent to the Laboratory for Ecological, Evolutionary and Conservation Genetics, at University of Idaho (875 Perimeter Drive, MS 1136, Moscow, ID 83844) for genotyping to determine species as well as individual identification, hybridization presence, and parentage analysis following previously developed protocols (Adams et al. 2007, Hinton 2014, Miller et al. 2003). The appropriate genetic analyses that examine the coyote-hybrid-wolf species continuum will be performed.

Blood will be collected from all juvenile and adult target canids by venipuncture of the brachial or jugular veins using a 22-28-gauge needle (M. Palamar, NCWRC veterinarian, personal communication, 2016). As per NCWRC veterinarian recommendations, approximately 12 ml of blood will be collected for each animal for possible future testing for diseases of importance to sympatric canid species as well as the humans and domestic animals that they may come into contact with. A minimum of two 6 ml lavender top tube (for whole blood with EDTA) will be filled. Samples should be refrigerated at all times; a cooler with ice will suffice while in the field. Samples should be sent to the NCWRC within 48 hours or frozen for later shipping. Skin scrapes will be collected from animals presenting signs compatible with sarcoptic mange (lesions) for possible future diagnostic purposes. Lesions will be scraped until blood is drawn; the scrapings will be placed onto a slide and covered with a piece of clear tape for later visual confirmation.

Should overheating occur, processing will be performed in the following prioritization order and the first five items will need to be completed before releasing any individuals: 1) trap injury evaluation, 2) collaring, 3) DNA (skin biopsy) sample collection, 4) morphometrics, 5) aging, 6) PIT tagging, 7) weight, 8) ear tagging, 9) reproductive status, 10) ectoparasite evaluation, 11) blood collection, and 12) skin scrape collection.

Commented [OSE42]: Given our concerns over many aspects of tissue collection, I feel that this list should be revisited.

Collaring

Vertex Plus GPS Collars will be attached to 25 sympatric canids captured on the study area, 10 of which will be equipped with proximity sensors (Vectronic Aerospace GmbH, Carl-Scheele-Str. 12, 12489 Berlin, Germany). Project staff will pilot test proximity sensor technology for utility in analysis of spatial and temporal community dynamics. Proximity sensors trigger increased GPS location acquisition during those time intervals when two collared individuals

Draft Confidential

come within a set distance from each other (http://www.vectronic-aerospace.com/wildlife-monitoring/sensors/uhf-id-tags, accessed August 2016).

To avoid instances of collar induced strangulation, only adult (>2 years old) male and female individuals will receive collars (Hinton 2014). ASM guidelines recommends a collar weight of <5-10% of a canids bodyweight, we will observe these guidelines (Sikes et al. 2011). Sympatric canids not releasable at a capture site will not be collared and will not become study animals.

GPS radio-collars will have both VHF and GPS Iridium locational systems as well as store-on-board capabilities. Radio-collar units will be programmed to record GPS coordinates once every 1.75 hours producing approximately 13 locations per day while cycling through the 24-hour time cycle. These settings will allow for a GPS battery life of 300 to 552 days, averaging 431 days. The VHF beacon will be in operation from 0800 – 1600 hours daily. GPS locations will be sent via satellite once per day and each transmission with contain 12 locations. The use of an integrated drop off firing mechanism should allow the collars to drop off within a maximum of approximately 548 days after deployment. The drop off schedule once set cannot be changed. The drop off firing mechanism is wired to a battery unit independent of the collar battery, therefore should the collar battery become depleted, the drop off mechanism will not be affected (C. Akakpo, Vectronic Aerospace GmbH, personal communication, 2016). Unless a collared individual is recaptured before the collar battery dies, the drop off mechanism will fire at the scheduled time frame post collar deployment.

Observation of sympatric canid habitat use and movements will occur through GPS data obtained with combination GPS/VHF radio-collars. VHF relies on triangulation, the process of estimating the location of a transmitter by using two or more compass bearings obtained by using directional antennas at known locations remote from the transmitter's position (White and Garrott 1990), whereas GPS uses a satellite based system to obtain location coordinates. There have been many published studies where one or both of these methods were used, with mixed success for determining various aspects of carnivore ecology throughout the United States (Hinton et al. 2012, Schrecengost et al. 2009, Sparkman et al. 2012). While GPS technology has developed rapidly in recent history, the real time functional advantage of VHF

Commented [OSE43]: I have a feeling that there is going to be many animals that fall into this category especially considering the prevalent landowner attitude towards carnivores in general and coyotes specifically. Additionally this constitutes a double standard in regards to releasing animals. We have landowner authorization in many cases but the State still will not allow us to use those lands for release, but it's okay for the State to do as they please? Also I feel that they should have all landowner agreements in place and the study/trapping areas well defined prior to any trapping effort. I have serious doubts that they can get this in place prior to Dec 1st.

Commented [OSE44]: What frequency range?

Draft - Confidential

cannot be disregarded. When GPS technology falters or malfunctions, VHF can serve as replacement for data collection in addition to its use in real time monitoring of study animals. Canids will be minimally monitored for mortality approximately every 30 days by using VHF aerial telemetry techniques (Whitehouse and Steven 1977) as there may be a delay in satellite transmission of GPS location data due to weather, season, and animal behavior. Transient canids and individuals from breeding pairs that have lost a mate, have been found to use much larger areas versus paired residents, potentially increasing the opportunity for losing track of these individuals when GPS technology reaches its functional capacity or experiences malfunction. VHF data may also provide locations of canids in cover too dense for GPS units to function. Use of VHF telemetry techniques for data collection may be expanded as necessary for project needs.

Commented [OSE45]: Can the GPS collars transmit through water? If not and you have an animal that tumbles into water right after mortality you've lost data.

Spatial Data Analyses

Both minimum convex polygon (MCP) and adaptive kernel (AK) home ranges (95%) and core use areas (50% and 25%) (Seaman and Powell 1996, Seaman et al. 1999) will be calculated from GPS data by using BIOTAS (Ecological Software Solutions LLC, 2016) and Geospatial Modelling Environment (Spatial Ecology, LLC, 2016) for ArcGIS 10.2.2 (Environmental Systems Research Institute, 2016) (Benson et al. 2006, Riley 2006, Tucker et al. 2008, Hinton 2014) for comparison to older studies. These estimations can also be calculated using VHF data, provided data minimum requirements are met. Spatial distribution in relation to habitat will also be estimated by dynamic Brownian bridge movement models as described by Hinton (2014) with R statistical software (R Core Team 2016) using the moveud package with habitat covariates important to each species (Bryne et al. 2014, Collier 2013, Kranstauber and Smolla 2013, C. Proctor, personal communication, 2016). Additionally, recent research into how canids shift their ranges will also be investigated for populations on the AP (Morin and Kelly, in review). Spatial overlap and co-occurrence will be assessed using methods described by Shipley (2012). Habitat and cover types will be estimated from digitized maps created by the SEGAP (Hinton 2014) or ortho files, as available (Shipley 2012). Percent composition of habitat and cover types within home ranges and core areas as well as edge density will be quantified (Shipley 2012). Habitat selection and cover type use effects on spatial distribution will be estimated at both the population (2nd order) and individual (3rd order) spatial scales using resource selection functions

Draft - Confidential

(Johnson et al. 2006, Manly et al. 2002, Shipley 2012). Effects of seasonality and time of day activity will also be explored. The spatial and temporal patterns of space use by sympatric canids will be studied using data generated from the interaction GPS collar sensors, particularly distance between individuals and duration of proximity.

Den Monitoring

Project staff will attempt to locate den sites for sympatric canids to get pup counts, morphometric measurements, age estimates, and skin biopsies. Project staff will also attempt to monitor pup survival during the pup rearing season by using remote cameras placed around the den site (Harrison and Gilbert 1985, Parks 1979, Way et al. 2001). Pups will be weighed, measured, and PIT tagged during May and June of each year when they become active but are still den-obligated (Gier 1968). We will investigate the use of remote camera traps for monitoring den behavior with a two-camera array around the den (H. Garbe, personal communication, 2016, Kays and Slauson 2008). This method has been successfully used to monitor kit fox pup survival (Kluever et al. 2013). Because coyotes have been found to be sensitive to den site disturbance, there is a general lack of data in the literature regarding this approach for monitoring pup survival. Approaching an experimental methodology systematically will be important for determining which methods are effective and which are not. As a starting point for testing this methodology, remote cameras will be placed two to five meters from main den entrances and set to take photos using a passive infrared sensor trigger (a beam that when broken by movement through it, triggers the camera to take a series of photos) with a time restriction between photo intervals to limit the number of photos taken and maximize the space on the memory card for the time period between camera checks (Kluever et al. 2013). Cameras will be checked six days after deployment and will be redeployed (i.e. new batteries and memory card, if required); cameras will remain at each den site until radio-collar data indicates the den site has been moved (Kluever et al. 2013). Cameras will be not be redeployed to a new coyote den site during a season if that breeding pair has already moved the den once due to the disturbance of camera presence/deployment.

Commented [OSE46]: No mention USFWS personnel in conjunction with this phrase.

Loss of control 8. Implied in conjunction with Project Personnel section.

Commented [OSE47]: No need for biopsies. Again, why do they need this? We already draw blood.

Commented [OSE48]: Getting this close to dens in order to set up the cameras will cause high enough disturbance that the mother will move the pups or will abandon the pups all together. Even if by some miracle they were not moved or abandoned after first deployment, good luck with that not occurring after your first 6 day revisit. Looking at the Kluever paper I noticed 2 major differences between the Kluever study and this one.

The first is terrain. The Kluever study was conducted in the Great Basin in NE Utah. The area as described in the paper is very open and lacks dense vegetation. Lines of site were not an issue. Often times canid dens in SE will be located in dense vegetation. Not to say that this issue cannot be overcome, but it may be impractical to deploy cameras effectively, or site modification, i.e. clearing out veg, could be enough to cause den abandonment or den relocation.

The second issue is animal behavior is quite different. Kluever et al. were observing kit foxes. Camera deployment was done in the afternoons when the foxes were underground in their dens. The foxes most likely had no clue that the researchers were ever there. In fact the authors attributed the lack of den abandonment to this probable factor. There would never be a time where a pack would not be aware of, or disturbed by camera deployment here in NC.

Draft - Confidential

Mortalities

If a collared animal dies during the project, the carcass will be sent to SCWDS for necropsy. Red wolves will be sent to the SCWDS laboratory for necropsy, unless it is determined to be a law enforcement case. In potential law enforcement cases, the NCWRC Division of Wildlife Management Chief and USFWS Ecological Services Raleigh Field Office Field Supervisor will be contacted and requested to contact the appropriate law enforcement personnel, immediately after determining the need for law enforcement involvement. The carcass and all relevant information will then be turned over to law enforcement; the GPS-collar will be removed and genetic samples will be taken from the individual prior to release to law enforcement.

Commented [OSE49]: We have our own facility for this. This would be another point of lost control.

Loss of control 9.

Commented [OSE50]: Why? Just contact LE and then inform the Chief and Field Supervisor

E. Project Personnel

Andrea Shipley has worked for the North Carolina Wildlife Resources Commission as a Canid Biologist since February 2016. Prior to that, she worked as a Wildlife Biologist for a non-profit located in northeastern Nevada as well as in several different field biologist oriented positions. Andrea has a background in carnivore and spatial ecology, having earned her MS in Biological Sciences from Eastern Kentucky University and BS in Biological Sciences from Rutgers University; Andrea will act as project lead and coordinator.

Brandon Sherrill has worked for the North Carolina Wildlife Resources Commission as a Mammalogist since December 2013. Prior to that, he worked as an educator at the North Carolina Museum of Natural Sciences and as a regional wildlife biologist for the South Carolina Department of Natural Resources. Brandon earned a BS and MS in Fisheries, Wildlife, and Conservation Biology from North Carolina State University; Brandon will act as project supervisor.

Krishna Pacifici, Research Assistant Professor at NCSU, will be the quantitative analysis collaborator on the project. Krishna's background and experience in quantitative ecology makes him well suited to consult and assist with advanced statistical analyses of spatial data.

Lisette Waits, Department Head and Distinguished Professor at the University of Idaho, will be the DNA analysis collaborator for the project, responsible for all DNA related sample processing and subsequent analyses.

Draft - Confidential

F. Schedule and Estimated Costs

The project will run from soon after December 1, 2017 through June 30, 2020. The estimated timeline for major tasks is as follows:

Year 1: Initiate field work soon after December 1, 2017 with assistance from 1-2 field technicians; 1 technician will be required for trapping and den monitoring efforts. Data collection will begin immediately after collar deployment and data will be managed by Andrea Shipley throughout the life of the project. Data analysis will be initiated after den monitoring season concludes, with guidance and assistance from Krishna Pacifici at North Carolina State University (NCSU). Report, manuscript and presentation production will be initiated concurrently with data analysis.

Year 2: Continue field work and data collection with assistance from 1-2 field technicians. Continue data analysis with guidance and assistance from Krishna Pacifici at NCSU. Continue and finalize report and manuscript production, and presentation at professional working groups and/or meetings.

GPS technology allows researchers to collect locational data at fine spatial and temporal scales through the deployment of collar units on wildlife study subjects. In this project, we propose to study a sample of sympatric canid populations with GPS radio-collars, in order to investigate the population parameters outlined in previous sections as well as species interactions. The purchase and use of this technology is critical to meeting the research objectives set forth in this document as well as in the document included in Attachment 1.

While GPS technology has evolved over the past 20 years, the cost of technology has plateaued. Upfront cost per unit remains relatively high, however project savings occurs at the back end when compared to older telemetry technology such as very high frequency (VHF)

Commented [OSE51]: Where are these techs coming from? Are we going to be paying for them?

Commented [OSE52]: Will we have any access to these data or only receive what the State is willing to give us? How will these data be used? Will the state cherry pick data and use it as a claim that the wolf is not a species?

Loss of control 10.

Commented [OSE53]: Where is year 3; as stated in their section 7 attachment?

Draft - Confidential

which require intensive labor to collect data at similar spatial and temporal scales. Pilot testing the proximity sensor enabled GPS-collars will allow investigation of the utility of this relatively new tool for community dynamics analysis by providing an increased locational data acquisition when individuals come within a set distance, or closer, from each other. Additionally, these sensors record the identities of the interacting individuals and the duration of their interactions. Using a trigger to temporarily switch GPS fix schedules will enable us to collect very fine scale data while conserving battery life, achieving project objectives in an efficient manner. Exploring the efficaciousness of this technology has the potential to positively impact future research projects requiring use of GPS-collars for data collection.

Aerial tracking will provide regular study animal surveillance useful to investigate cases of mortality, collar malfunction, or satellite data transmission delays, which can vary seasonally. In some situations, ground tracking could prove less expensive than aerial tracking. However, ground telemetry techniques require more than one biologist working in tandem to acquire accurate location estimates. This often translates to increased labor to collect data, particularly in large study areas. Aerial tracking will provide a more efficient and cost-effective method for surveilling study subjects in this large study area, requiring only one biologist and a contracted pilot. NCWRC personnel will perform aerial tracking along with the NCWRC pilot at a minimum frequency of every 30 days.

Use of local trappers to assist with sampling efforts provides several benefits. Local trappers have established, long-term relationships with private land owners, thereby providing access to private lands that might be otherwise difficult to secure. This will enable project biologists to obtain a representative sample of sympatric canids in the study area, as well as to operate more trap lines concurrently. This is particularly important when using a SCR sample design, as it will have direct implications on the resulting analyses and inferences.

Commented [OSE54]: Access does not necessarily denote cooperation. A land owner may say it's okay to trap but nay not agree to releasing the animal back on to the property.

As part of collaboration efforts, the project will contract the services of Krishna Pacifici, Research Assistant Professor in the Applied Ecology department at NCSU. Krishna's expertise is in quantitative ecology; consultation and assistance services provided will allow project biologists to make appropriate statistically relevant inferences from collected data.

Draft - Confidential

DNA analysis will be contracted to Lisette Wait's lab at the University of Idaho. Lisette's team at The Laboratory for Ecological, Evolutionary and Conservation Genetics has previous experience in analyzing red wolf and coyote hybrid molecular samples and has the most comprehensive DNA methodology for this sympatric canid species continuum in the nation. This expertise will facilitate expedient species identification on collared study animals besides landscape level population dynamics analysis.

	Commission	In-kind	Total
a. Personnel	$ 7,200.00	$ -	$ 7,200.00
b. Fringe Benefits	$ -	$ -	$ -
c. Travel	$ 30,000.00	$ -	$ 30,000.00
d. Equipment	$ 54,000.00	$ -	$ 54,000.00
e. Supplies	$ 61,500.00	$ -	$ 61,500.00
f. Contractual	$315,590.00	$ -	$315,590.00
g. Construction	$ -	$ -	$ -

I. Glossary

Abundance: Species abundance is the number of individuals per species, and relative abundance refers to the evenness of distribution of individuals among species in a community.

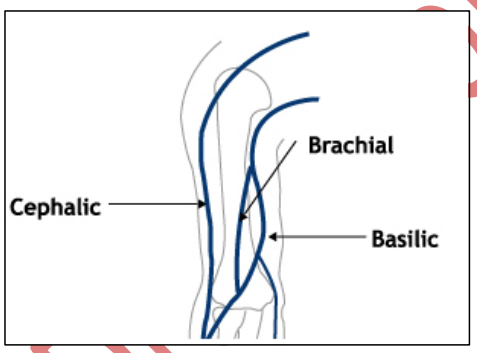
Adaptive kernel (AK): A probabilistic home range estimator based on the distribution and density of locations that has been collected over a period of time.

Adverse reactions: In pharmacology, any unexpected or dangerous reaction to a drug.

Aerial: Existing, happening, or operating in the air.

Annually: Once a year; every year.

Anthropogenic: Caused or influenced by humans.



Apex: Having no natural predators in its ecosystem.

Ataxia: The loss of full control of bodily movements.

Beacon: A radio beacon whose purpose is the investigation of the propagation of radio signals.

Biopsy: The removal for diagnostic study of a piece of tissue from a living body.

Brachial vein: One of a pair of veins accompanying the brachial artery and uniting with each other and with the basilic vein to form the axillary vein.

Breeding pair: A pair of animals which cooperate over time to produce offspring with some form of a bond between the individuals.

Carrying capacity: The maximum population size of the species that the environment can sustain indefinitely, given the food, habitat, water, and other necessities available in the environment.

Compensatory immigration: Individuals emigrating from areas with lower mortality to those with higher mortality; filling a deficiency of individuals in a population experiencing higher mortality. The increase in size or activity of one part of an organism or organ that makes up for the loss or dysfunction of another.

Composition: The combining of distinct parts or elements to form a whole.

Confidential

Co-occurrence: Refers to observation of the spatial overlap between two (or more) different individuals over a period of time.

Coordinates: Any of the scales or magnitudes that serve to define the position of a point.

Core use areas: An area within a home range exhibited by a dense concentration of location points; commonly estimated at 50% of the location data points.

Covariates: A variable that is possibly predictive of the outcome under study.

Cranial: Pertaining to the cranium or to the anterior (in animals) or superior (in humans) end of the body.

Cryogenic: Very low temperatures, e.g. -80°C.

Den-obligated: Restricted to a particular condition of life, in this case restricted to a den site.

Density: A measure of the number of organisms that make up a population in a defined area.

Deployment: To organize and send out (people or things) to be used for a particular purpose.

Depredation: The act of preying upon.

Depressed respiration: A decrease in the ability to exhale and inhale; respiration that has a rate below 12 breaths per minute or that fails to provide full ventilation and perfusion of the lungs.

Diagnostic: The process of determining by examination the nature and circumstances of a diseased condition.

Disorientation: Loss of one's sense of direction, position, or relationship with one's surroundings.

Distribution: The manner in which a biological taxon is spatially arranged.

DNA: (deoxyribonucleic acid) is a type of macromolecule known as a nucleic acid. It is shaped like a twisted double helix and is composed of long strands of alternating sugars and phosphate groups, along with nitrogenous bases (adenine, thymine, guanine and cytosine).

Dorsal: Situated on or toward the upper side of the body, equivalent to the back, or posterior, in humans; situated on or toward the posterior plane in humans or toward the upper plane in quadrupeds.

Duration: A continuous period of time.

Dynamic Brownian bridge movement models: Incorporates temporal and behavioral characteristics of movement paths into estimation of home range.

Ectoparasite: a parasite that lives on the outside of its host rather than within the hosts body; e.g. fleas and lice.

Effective trap area: Calculated by buffering each trap site by half the mean maximum distance traveled, each of these boundaries are dissolved, creating a measurable area.

Efficacious: Producing or capable of producing a desired effect.

Draft - Confidential

Efficient: Accomplishment of or ability to accomplish a job with a minimum expenditure of time and effort.

Euthanize: The act of putting to death painlessly or allowing to die, as by withholding extreme medical measures, a person or animal suffering from an incurable, especially a painful, disease or condition.

Expedient: Suitable for achieving a particular end in a given circumstance.

Evaporative cooling: reduction in temperature resulting from the evaporation of a liquid, which removes latent heat from the surface from which evaporation takes place.

Facilitate: Make an action or process easy or easier.

Genotyping: Investigate the genetic constitution of (an individual organism).

Gonadal descent: The act or process of descending from a higher to a lower location; testicular descent occurs during the breeding season annually.

GPS: Global Positioning System, is a radio navigation system that allows land, sea, and airborne users to determine their exact location, velocity, and time 24 hours a day, in all weather conditions, anywhere in the world.

Home range: an area over which an animal or group of animals regularly travels in search of food or mates, and that may overlap with those of neighboring animals or groups of the same species.

Hybridization: The result of mixing, through sexual reproduction, two animals or plants of different breeds, varieties, species or genera.

Immobilization agent: An active force or substance capable of producing an effect.

Implantation: To put or fix firmly.

Inbreeding depression: The reduced biological fitness in a given population as a result of inbreeding, or breeding of related individuals.

Inception: The establishment or starting point of an institution or activity.

Interspecific: Existing or occurring between different species.

Iridium: A satellite constellation providing voice and data coverage to satellite phones, pagers and integrated transceivers over the Earth's entire surface.

Jugular vein: Any of several large veins in the neck, carrying blood from the head and face.

Lacerations: A deep cut or tear in skin or flesh.

Locational: A position or site occupied or available for occupancy or marked by some distinguishing feature.

Malfunction: Fail to operate in the normal or usual manner

Methodology: A system of methods used in a particular area of study or activity.

Midline: A median line or plane of bilateral symmetry, especially that of the body.

Draft - Confidential

Minimum convex polygon (MCP): Completely enclose all data points by connecting the outer locations in such a way as to create a convex polygon.

Molecular samples: Genetic samples that may be used for investigation of genetic constitution of an individual.

Morphometrics: The process of measuring the external shape and dimensions of landforms, living organisms, or other objects.

Mortality: The state of being subject to death.

Non-target bycatch: Animals caught by accident that are not the target species being sought.

Parameters: A numerical or other measurable factor forming one of a set that defines a system or sets the conditions of its operation.

Parentage: The origin of something; the state or relation of a parent.

Passive integrated transponder: A microchip implant is an identifying integrated circuit placed under the skin of an animal.

Pinna: The external part of the ear in humans and other mammals; the auricle.

Plateaued: A period or state of little or no growth or decline.

Population dynamics: The branch of life sciences that studies the size and age composition of populations as dynamic systems, and the biological and environmental processes driving them (such as birth and death rates, and by immigration and emigration).

Population growth: The increase in the number of individuals in a population.

Population size: A group of organisms of the same species that live in the same area.

Population status:

Population trend: Changes over time and can include changes in ranging behavior and distribution, biogeography and life-history.

Population viability: The process that determines the probability that a population will go extinct within a given number of years.

Proximity: Nearness in space, time, or relationship.

Quantified: Express or measure the quantity of.

Quantitative: Relating to, measuring, or measured by the quantity of something rather than its quality.

Radio-telemetry: The use of radio waves for transmitting information from a distant instrument to a device that indicates or records the measurements.

Recumbency: The state of leaning, resting, or reclining.

Reintegrate: Restore (elements regarded as disparate) to unity.

Draft - Confidential

Remnant: A small remaining quantity of something.

Reproductive status: Relating to or effecting reproduction.

Spatial: Relating to, occupying, or having the character of space.

Spatial capture-recapture: A method commonly used in ecology to estimate an animal population's size. A portion of the population is captured, marked, and released. Marked animals are either recaptured or are tracked, each tracking location being considered a recapture.

Species Continuum: An aggregate of species capable of interbreeding, resulting in fertile hybrid offspring whose genetic composition may represent a varying array of phenotypes and genotypes from the parental species, at which the extreme ends of the spectrum are distinct.

Standardize: Cause (something) to conform to a standard.

Statistically relevant inferences: the process of deducing properties of an underlying distribution by analysis of data. Inferential statistical analysis infers properties about a population: this includes testing hypotheses and deriving estimates.

Stochastic population models: Ecological population modeling is concerned with the changes in population size and age distribution within a population as a consequence of interactions of organisms with the physical environment, with individuals of their own species, and with organisms of other species; stochasticity possesses some inherent randomness. In stochastic population models, the same set of parameter values and initial conditions will lead to an ensemble of different out puts.

Strangulation: The condition in which circulation of blood to a part of the body is cut off by constriction.

Stratifying: Form or arrange into strata, one of a number of portions or divisions likened to layers or levels.

Surveillance: Continuous observation of a place, person, group, or ongoing activity in order to gather information.

Survival: A living or continuing longer than, or beyond the existence of, another person, thing, or event.

Sympatric: Occurring within the same geographical area; overlapping in distribution.

Tachycardia: A heart rate that exceeds the normal resting rate. In general, a resting heart rate over 100 beats per minute is accepted as tachycardia in human adults.

Telemetry: See radio-telemetry.

Temporal: Of or relating to time.

Tooth replacement: The process of development of two successive sets of teeth, initially the deciduous set and consecutively the permanent set.

Transmitter: A set of equipment used to generate and transmit electromagnetic waves carrying messages or signals, especially those of radio or television.

Transponder: A device for receiving a radio signal and automatically transmitting a different signal.

Draft - Confidential

Vaccinate: Treat with a vaccine to produce immunity against a disease; inoculate.

Venipuncture: The puncture of a vein as part of a medical procedure, typically to withdraw a blood sample or for an intravenous injection.

VHF: Very high frequency is the ITU designation for the range of radio frequency electromagnetic waves (radio waves) from 30 MHz to 300 MHz, with corresponding wavelengths of ten to one meters.

II. State/Agency:

NORTH CAROLINA / NORTH CAROLINA WILDLIFE RESOURCES COMMISSION

III. Station Name:

FWS RALEIGH ECOLOGICAL SERVICES OFFICE

IV. Description of Proposed Action (attach additional pages as needed):

Conduct research project entitled "**Coyotes of the Albemarle: Spatial Ecology, Resource Selection, Demographics, and Interactions with a Sympatric Canid"**

The coyote (*Canis latrans*) is now abundant throughout the 100 counties in North Carolina (NC), where they are managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plains region of NC (Hinton et al. 2012, Murray et al. 2014).

Recently described as using "compensatory immigration," coyotes are able to opportunistically fill spatial resource gaps by periodic transiency (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with humans and other canids, especially while taking advantage of anthropogenic resources. Though a rural area, human land uses predominate on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011).

In 1968, individuals from a remnant population of red wolves were removed from Texas and Louisiana and a captive breeding program was initiated. The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). The red wolf population increased until 2008 and peaked at around 208 individuals (USFWS Red Wolf Recovery Program 2007), a few animals short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013), with an estimated carrying capacity of 140-150 for the AP (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). Red wolves presently inhabit an approximately 6900 square kilometer recovery area within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014).
Accurate up-to-date estimates of the population are unavailable, but USFWS staff report a population size of 45-60 individuals with three mortalities in 2016 (https://www.fws.gov/redwolf/index.html July 2016). Hybridization with coyotes, inbreeding depression, and gunshot mortality have all been suspected issues that have affected the population growth and viability since the inception of the Red Wolf Recovery Program (RWRP) (Hinton et al. 2013). In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of red wolves and other canids on the AP. A USFWS memorandum documented detailed action items for the joint management of canids on the AP, including specific research objectives which this proposal seeks to address (Attachment 1).

As coyotes on the AP increase in number, monitoring coyote movements, particularly in relation to red wolves, will provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about coyote population management. Collection of finer temporal scale location data will help to manage interactions of both canid species with humans, as well as to support development of dynamic stochastic population models.

Coyote and red wolves will be live trapped by cooperating NCWRC and USFWS staff, and private trappers using double coil size 3 foothold traps, during the breeding season (Nov-Feb for coyote, Jan-Feb for red wolves) in the tri-county area of Dare, Hyde and Tyrrell. Morphological measurements, incidents of injury, occurrence of ectoparasites, age classification, and reproductive status will be determined; blood and tissue samples will be taken for genetic analysis. All captured individuals that meet the age classification and weight requirements will be collared with GPS collar units. All captured and collared individuals will be released at the capture site. The objectives listed below will be achieved by obtaining measurements, samples and information from the captured, collared, and tracked individuals over the course of three years using GPS location data.

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners.

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

V. Pertinent Species and Habitat:

A. Include species/habitat: See section VI

B. Complete the following table:

SPECIES/CRITICAL HABITAT	STATUS[1]
Canis rufus	T

[1]STATUS: E = endangered, T = threatened, PE = proposed endangered, PT =proposed threatened, CH = critical habitat, PC = proposed critical habitat, C = candidate species

VI. Location:

A. Statewide

Albemarle Peninsula (see web address www.ncwildlife.org)

B. Section, township, and range (or latitude and longitude):

Dare, Hyde, Tyrrell counties

C. Distance (miles) and direction to nearest town:

As stated above

D. Species/habitat occurrence:

Canis rufus

VII. Determination of Effects:

A. Explanation of effects of the action on species and critical habitats in item V. B. (attach additional pages as needed):

SPECIES/CRITICAL HABITAT	IMPACTS TO SPECIES/CRITICAL HABITAT
Canis rufus	Trap induced injury is possible

B. Explanation of actions to be implemented to reduce adverse effects:

SPECIES/CRITICAL HABITAT	ACTIONS TO MITIGATE/MINIMIZE IMPACTS
Canis rufus	Use of appropriate trap types, daily trap checks, treatment of minor injuries, trapping season limitations and limitations on environmental conditions for trap operation

VIII. Effect Determination and Response Requested:

Species/ Critical Habitat	Determination[1]			Response[1] Requested
	NE	NA	AA	
Canis rufus		X		Concurrence

[1] Determination/Response Requested:

NE = No Effect. This determination is appropriate when the proposed action will not directly, indirectly, or cumulatively impact, either positively or negatively, any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested is optional but a "Concurrence" is recommended for a complete Administrative Record.

NA = Not Likely To Adversely Affect. The determination is appropriate when the proposed action is not likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat or there may be beneficial effects to these resources. Response Requested is a "Concurrence".

AA = Likely To Adversely Affect. This determination is appropriate when the proposed action is likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested for listed species is "Formal Consultation". Response Requested for proposed or candidate species is "Conference".

Attachment 2: Joint Memorandum

MEMORANDUM

November 20, 2013

TO: All Interested Parties

FROM: "for"
Cynthia K. Dohner, Director, Southeast Region, U.S. Fish and Wildlife Service
Gordon S. Myers, Executive Director, N.C. Wildlife Resources Commission

SUBJECT: Collaborative Conservation of Red Wolves and Other Canids on North Carolina's Albemarle Peninsula

---

Recovery of the federally-listed red wolf has been a priority for the U.S. Fish and Wildlife Service (FWS) for more than 20 years and is focused in North Carolina on the Albemarle Peninsula (AP; i.e., Hyde, Tyrrell, Washington, Beaufort, and Dare counties). Comprehensive stakeholder involvement and collaboration with other management agencies is critical to successful recovery of any at-risk species. The North Carolina Wildlife Resources Commission (WRC) is a key collaborator in this regard, as it has jurisdiction over all state-trust wildlife resources in N.C.

Since 2009, the FWS and WRC have worked to broaden our collaboration in the conservation and management of all canid species (including red wolves) on the AP. As these efforts have solidified, specific actions have been jointly identified by our two agencies that will improve conservation outcomes. These actions are categorized into five areas; collaboration, research, outreach, regulatory, and enforcement. Specific action items are outlined and prioritized within each of these categories in Attachment A.

This memo establishes the FWS's and WRC's commitment to initiate, or to continue, the efforts outlined in Attachment A. The common goal in this effort is to establish clear expectations and accountability for collaboration regarding the action items on Attachment A, thus resulting in enhanced and seamless canid conservation and management on the AP. This approach provides the best opportunity to achieve recovery goals for red wolves, while at the same time managing other canids to balance biological variables with social expectations. The dynamics of these canid species are complex and offer unique opportunities for innovation. Appropriate staff from each agency is hereby tasked with immediately developing a timeline to implement these actions. Through this commitment, we will continue to advance our collective conservation goals.

875

Attachment A

Action Items for Collaborative Conservation of Canids on North Carolina's Albemarle Peninsula (AP)
(*Note: Action Items are prioritized within category.*)

Collaboration

1. The N.C. Wildlife Resources Commission (WRC) and U.S. Fish and Wildlife Service (FWS) will formalize in writing the collaborative management of canids on the AP. This agreement should:
    a. include a clear mission statement, goals, objectives, and implementation strategies (ask and answer the "Why?");
    b. set a goal to define success regarding canid management on the AP;
    c. espouse a philosophy of canid management operating within the context of a three-legged stool (i.e., federal and state governments and stakeholders);
    d. as available, commit funding and staffing resources for field personnel to contribute to the conservation of the red wolf and management of coyotes;
    e. as available, commit funding to conduct research pertinent to canid management on the AP;
    f. establish polices and goals for developing a collaborative genetic archive for AP canids, a data sharing portal accessible by staff in both agencies, and reciprocal sharing of all historical data (including phenotypic and genotypic data and literature) of the red wolf;
    g. establish a foundation for developing and implementing an adaptive approach to canid management on private lands on the AP;
    h. initiate development of a collaborative canid research program;
    i. describe plans to conduct the next five year Red Wolf Program review;
    j. outline options for holding annual workshops with federal and state enforcement staff;
    k. outline plans to hold semi-annual coordination meetings regarding canid management on the AP; and
    l. develop milestones for future development of a management plan for all canids in the AP.

2. The FWS will initiate a review of the current Red Wolf Recovery Plan to determine if the state-of-our-knowledge or field conditions have changed such as to warrant its revision. Review and comments from the WRC will be considered in this evaluation.

3. The WRC, with support and participation of the FWS, will establish a "Canid Forum" (similar to that established for manatees in Florida) to facilitate communication and discussion regarding canid management and citizen science opportunities on the AP.

876

877

Attachment A

Research

1. The FWS and WRC will provide funding and logistical support for research identified by the Red Wolf Recovery Implementation Team, Red Wolf Program staff, other FWS staff, or the WRC that promote the conservation and recovery of the red wolf and other canids on the AP. Studies could include:
    a. tests of the "placeholder theory" on the AP, including behavior of sympatric canids,
    b. determining carrying capacity of canids on the AP,
    c. determining genetic profiles of canid species on the AP,
    d. evaluating predator-prey dynamics,
    e. studies of canid habitat use,
    f. epidemiology of diseases impacting canids on the AP,
    g. development of stochastic simulation models of sympatric canid population dynamics and habitat use, and
    h. canid dispersal dynamics

2. The FWS and WRC will conduct jointly-supported research to determine the attitudes and opinions of N.C. private landowners and other citizens concerning canids on the AP (i.e., human dimensions studies).

Outreach

1. The FWS and WRC will collaborate with other partners to design and implement broad-based outreach and marketing programs with clear goals, objectives, strategies, and measurable outcomes, including development of consistent agency messages and educating the public about canids on the AP.

Regulatory

1. The FWS and WRC will initiate a review and, if needed, subsequent rule-making to clarify concepts or rectify conflicts in current federal or state rules (including the current 10(J) rule).

2. The WRC will review and evaluate statutory requirements for listing red wolves as state threatened in the five AP counties.

3. As data demonstrating a relationship between coyote hunting and red wolf mortality become available, the FWS and WRC will evaluate, and if appropriate implement, adaptive approaches to regulate of take of coyotes that may result in incidental take of red wolves.

4. The WRC will evaluate the status, management, and regulation of Controlled Fox Hunting Preserves.

878

879

5. The WRC will develop BMPs (due care provisions) for coyote hunting, trapping, and live sale.

6. The WRC will compile, compare, and contrast canid hunting and trapping regulations and programs in other states, including, but not limited to, other states with other species of wolves.

Enforcement

1. The FWS and WRC will develop coordination strategies to improve enforcement of federal regulations protecting red wolves.

I, the cooperator or cooperator's representative, have been informed of the methods and the manner in which research devices will be used, and of the possible hazards associated with their use. I understand that NCWRC, (to include its officers, employees and agents) will: exercise reasonable precautions to safeguard all persons to prevent injury to target and non-target animals; guard against the mishandling of control devices and materials; and exercise due caution and proper judgment in all scientific collection operations. I understand that NCWRC may collect Global Positioning System (GPS) coordinates at the project site as part of component or activity tracking or as wildlife disease monitoring or research data. I, the undersigned cooperator, do hereby give my consent and concurrence to NCWRC, its employees, and its agents, to use, upon lands owned, leased, or otherwise controlled by me, and identified by this document, the following methods and devices (an attachment of additional devices and/or methods may be attached):

Statement of agreement: The landowner, cooperator, or representative, as listed above hereby give permission to NCWRC to perform trap and release of the species listed for scientific collection purposes. In consideration of these understandings, I, the cooperator or cooperator's representative, agree to: assume responsibility for injury to my property under my control, when said injury is not the result of negligence on the part of NCWRC (it's officers, employees, and agents); assist in maintaining such warning signs as NCWRC may place for the purpose of notifying persons entering onto such lands of the possible hazards associated with scientific measures in use thereon; and to give adequate warning of these possible hazards to persons I authorize to enter onto such lands. Further, I, the cooperator or cooperator's representative, agree not to concurrently use or allow to be used upon lands covered by this agreement, any canid depredation efforts during the scientific collection time period.

From the Field: Implementing recovery of the red wolf—integrating research scientists and managers

Michael K. Stoskopf, Karen Beck, Bud B. Fazio, Todd K. Fuller, Eric M. Gese, Brian T. Kelly, Frederick F. Knowlton, Dennis L. Murray, William Waddell, and Lisette Waits

Abstract The United States Fish and Wildlife Service (USFWS) developed guidelines for the composition and role of endangered species recovery implementation teams, but few teams have been established and their success has not been evaluated. Using the recovery program of the red wolf (*Canis rufus*) as a model, we describe the genesis, function, and success of the Red Wolf Recovery Implementation Team (RWRIT) in helping guide the establishment of a viable red wolf population in eastern North Carolina. In operation since 1999, the RWRIT meets bi-annually to review USFWS progress and provide recommendations aimed at maximizing success of species recovery. The team is comprised of 8 research scientists from disciplines including population genetics, canid ecology, population ecology, veterinary medicine, and captive management. Representation from each of these disciplines is deemed necessary for proper evaluation of recovery progress and assessment of future needs. Meeting attendance by the USFWS field management team ensures both proper reporting of past progress and future implementation of management recommendations. Over time, RWRIT members have assumed specific assignments for data analyses, further contributing to the recovery effort. Through the combined efforts of the USFWS field team and the RWRIT, the threat of introgression of coyote (*Canis latrans*) genes into the red wolf population has been substantially curtailed within the recovery area, and red wolf numbers and range have increased. The RWRIT serves as an example of a recovery implementation team that is successfully incorporating the principles of adaptive management and whose template could be adapted to other endangered species.

Key words adaptive management, *Canis rufus*, endangered species, implementation, recovery, red wolf

Recovery of any endangered species is influenced by a range of political, economic, social, as well as biological issues (Tear et al. 1993, Scott et al. 1995, Lundquist et al. 2002). Reconciling disparate concerns and perspectives into a cohesive program requires planning and decision-making processes that consider conflicting interests of various stakeholders. However, for a recovery program to succeed, it is equally critical that professionals tasked with the responsibility for managing endangered species be able to move forward with timely decisions based on practical management needs and scientific knowledge (Westrum 1994). The United States Fish and Wildlife Service (USFWS) red wolf (*Canis rufus*) recovery program is an example of a program faced with complex issues, where man-

agement successes have been strengthened and accelerated by integrating active adaptive management with careful and timely scientific inquiry. This paper describes how this integration is being achieved via a designated "recovery implementation team."

The red wolf is an endangered species that once roamed an extensive range including the southeastern United States, and possibly the entire woodlands of eastern North America (Wilson et al. 2000, Nowak 2002, Grewal et al. 2004). Although listed as endangered in 1967 (USFWS, 1967), population decline and apparent hybridization with coyotes (*Canis latrans*) were recognized in the early 1960s (McCarley 1962, McCarley and Carley 1979). The remaining red wolves were removed from the wild in the mid- to late 1970s with the goals of establishing a captive breeding program and eventually restoring captive-bred animals to portions of their historical range (U.S. Fish and Wildlife Service [USFWS] 1989). In 1987 the first red wolves were released in easternmost North Carolina (Figure 1) with the plan to establish a viable population (Parker 1987). The reintroduction efforts faced a myriad of social, political, and biological issues as the Red Wolf Recovery Plan (USFWS 1989) was implemented (Henry and Lucash 2000, Phillips et al. 2003).

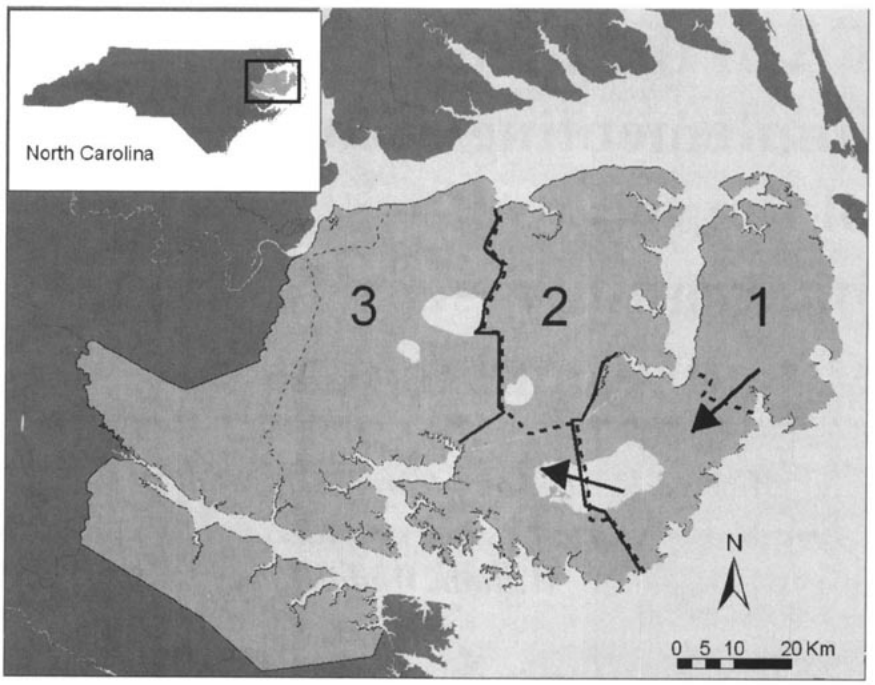

Figure 1. Changes in management zone boundaries within the Red Wolf Recovery Area of eastern North Carolina, as made in accordance with Red Wolf Adaptive Management Plans. The boundaries of the original management Zones 1, 2, and 3 (dashed lines) were first established in April 2000. In March 2002, as red wolf recovery proceeded, boundaries in the southern parts of the zones were moved west (solid lines); part of Zone 2 became Zone 1, while part of Zone 3 became Zone 2 (arrows). In August 2003 some management aspects of canids (i.e., sterilization vs. euthanasia) captured in the eastern half of Zone 3 (thin dotted line) began to follow guidelines applied to Zone 2.

Although the reintroduction area was initially considered uninhabited by coyotes, by the mid-1990s it was apparent coyotes had infiltrated the area and hybridization with red wolves was recurring (Phillips et al. 2003). Due primarily to the renewed hybrid threat and termination of the reintroduction of red wolves into Great Smoky Mountains National Park (Henry 1998), the USFWS decided it needed to re-evaluate its red wolf recovery effort in light of what had been learned over the previous decade. A key step in this review process involved a Population and Habitat Viability Assessment (PHVA) organized by the USFWS in 1999 and facilitated by the Conservation Breeding Specialists Group of the World Conservation Union, Species Survival Commission (IUCN SSC) (Kelly et al. 1999). The diverse assemblage of attendees, representing a variety of expertise and interests, agreed that introgression of coyote genes into the red wolf population was the principal threat to recovery success (Kelly et al. 1999). The group also recognized this issue required urgent attention before hybridization became so pervasive as to virtually ensure the genetic swamping of the only extant free-ranging population of red wolves. However, 2 views of how to address the hybrid threat emerged from the PHVA; one believed research was integral to addressing the problem, and the other expressed concern that research efforts would distract from the primary goal of maintaining the only free-ranging population of red wolves in the world. A consensus agreement was reached on this debate and resulted in an overarch-

ing workshop statement, including:

> "...our primary recovery focus must be protecting and promoting the growth of a self-sustaining, non-hybridizing population of red wolves in the wild and sustaining an active captive component. Actions to be taken will use an adaptive management approach that will not compromise the ability to achieve this goal." (USFWS 1999:52)

This level of agreement among the diverse participants of the PHVA set the stage for designing an adaptive management plan (*cf.* Lancia et al. 1996) that would reduce the threat of wolf-coyote hybridization. This plan (Kelly 2000) diverged from conventional endangered species management because it involved an incremental process tailored to modify field protocols according to past success in eliminating the threat of hybridization. Specifically, it required the release area to be segregated into several defined management zones, each managed to provide an integrated optimization of risk reduction within the resource limitations available to the project (Figure 1). As nonwolf canids were removed from given zones and replaced with red wolves, management options could be adapted by modifying zone boundaries or adjusting specific management protocols.

Adoption of this plan, requiring frequent re-evaluation of data and attendant management adjustments, spawned close interactions between USFWS field biologists and scientists with backgrounds relevant to the work being undertaken. A Red Wolf Recovery Implementation Team (RWRIT) was formed to advise USFWS as they implemented the adaptive management plan; this team was created pursuant to Section 4(f)(2) of the amended Endangered Species Act (ESA), which authorizes the Secretary of the Interior to procure the services of appropriate public and private agencies, institutions, and other qualified persons to help implement endangered species recovery plans. Other USFWS-designated species-specific implementation teams, as opposed to planning teams, have been formed (e.g., black-footed ferret [*Mustela nigripes*], northern right whale [*Eubalaena glacialis*], Okaloosa darter [*Etheostoma okaloosae*], and southern sea otter [*Enhydra lutris*]; USFWS files), but they are rare and no formal description of one's workings or success has yet been documented.

Recovery implementation team composition

Selection of the RWRIT scientists and their leadership was important to the success of implementing and evaluating the adaptive management plan. The PHVA helped the USFWS identify individuals with the combined expertise and personality considered important in a functional RWRIT. The PHVA also provided insight to the breadth of expertise needed over the long term. This expertise included such diverse fields as systematics, genetics, population modeling, health management, and canid biology, behavior, ecology, and management. Social scientists were not required in this case because those issues were, and continue to be, successfully dealt with by the USFWS field management team in conjunction with non-governmental organizations (Henry and Lucash 2000). Direct experience with the red wolf was not a requisite criterion for RWRIT membership. In fact, due to the long and controversial scientific history of the red wolf, some team members were sought for their naiveté of red wolves to minimize preconceived notions regarding the problems the adaptive management plan addressed. Thus, a mixture of experienced and young research scientists with strong records of scientific productivity and interpersonal skills was selected. Each member of the RWRIT had to be willing to use a data-driven approach to decision-making while remaining open to challenges of interpretation. Each member also had to be willing to accept group decisions as well as devote considerable personal time toward solving issues associated with the red wolf program.

The RWRIT needed to be large enough to provide the scientific diversity needed to assess the broad range of critical issues, but small enough to support close working relationships among members and result in productive meetings (Clark and Westrum 1989). A basic philosophy was that if the RWRIT needed expertise from individuals or disciplines outside the RWRIT to address specific issues, guest scientists would be invited to participate in the appropriate meetings. Initially, a goal of 8 members and 4 alternates was considered. Interactions of the group and reliability of participation in early meetings were used to identify the core members of the RWRIT. Since then, the size and composition of the RWRIT (8 members, no alternates) has worked well, sustaining effective decision-making with absences at meetings being rare. The leader of

the RWRIT needed to moderate meetings efficiently while allowing for creative interactions among RWRIT members. To ensure this, a senior scientist at a local university was selected due to his demonstrated scientific and leadership skills.

Experienced and stable field team

The USFWS field team involved in the day-to-day operation and management of the red wolf recovery program was key to the success of the RWRIT. The field team attended all RWRIT meetings as nonvoting members and provided the necessary data and expertise for the meetings to progress effectively. This distinction between the teams initially caused some anxiety, but this subsided once roles had been fully elucidated. The field team is remarkably stable and has worked cohesively on the red wolf project for many years (Phillips et al. 2003). Scientists of the RWRIT recognize the field team as the most experienced red wolf biologists and essential for successful functioning of the RWRIT itself. In turn, the field team's willingness to listen to and implement recommendations made by the RWRIT has been a critical factor in the success of the program. Open communications between the 2 teams keeps RWRIT scientists aware of the implementation of recommendations and fosters respect for the dedication of the field team.

Getting started

The first meeting of the RWRIT was important in establishing the tenor of group interactions and future functioning. Subsequent meetings would focus on examining data related to specific questions within an established agenda, but the first meeting focused on developing operating procedures for decisions as well as the types of data and data formats the team preferred for review and evaluation. This was a step that helped acquaint members of the team and recognize proper working protocols. It also ensured that all members of the team had a common understanding of the Red Wolf Adaptive Management Plan (RWAMP).

The charge of the RWRIT was established a priori by the Team Leader of the Red Wolf Recovery Program (i.e., "Red Wolf Program Leader"). This task was defined specifically as reviewing progress on the RWAMP and recommending changes to the plan based on data provided by the USFWS. As the team gained experience, this charge evolved to include recommendations for data relevant to answering specific questions important to the field team in the day-to-day management of the wild red wolf population. The 2 charges were closely related, frequently blended, seldom distinct, fundamental to the Adaptive Management Paradigm (Walters 1986), and are the responsibilities that drive efforts of RWRIT members. From the beginning, per the ESA, RWRIT recommendations were strictly advisory, with decisions for implementation being at the discretion of the USFWS.

Ground rules established in the first meeting have rarely been adjusted. Some established the mechanics of operations. For example, it was decided a minimum of 6 RWRIT members would be required as a quorum for a functional meeting. Failure to achieve quorum would trigger an evaluation by the RWRIT Leader and the Red Wolf Program Leader to assess whether the RWRIT remained an appropriate mechanism. To date this has not been necessary due to continued strong and enthusiastic attendance.

Other rules provided guidance for RWRIT interactions. To reduce stifling potentially meritorious but perhaps unconventional ideas, the team adopted a basic rule indicating that speakers must present alternative solutions when challenging or negating a proposed idea or approach. Ideas would be withdrawn from consideration only after careful efforts to refine them failed to produce workable solutions. To the fullest extent possible, data would be used to support all positions.

Other procedural mechanisms established in the first meeting have had a beneficial effect on RWRIT operations. For example, tentative dates, times, and location of future meetings are established jointly early in the agenda of each meeting. In addition, the agenda of the next meeting is established near the completion of the current session, which probably produces a more dynamic agenda than a call just before the meeting. Opportunities to add agenda items at any time remain, but the draft of the agenda appears in the final minutes; serving as a reminder for participants as they prepare for the coming meeting.

An important activity reserved for the end of each meeting is an exercise in prioritizing "action items", which are further classified as either "tasks" (expected to be accomplished within the time frame of the meeting or between meetings); "projects" (longer duration activities); or "manuscripts" (the drafting of information for publication).

Individual RWRIT members are recognized as responsible for addressing each item. With many issues to consider and an active agenda, many more action items are identified than can typically be accomplished with the resources available. The action items established throughout the meeting and recognized as "projects" are assembled in a descriptive list and as a final exercise, each member of the RWRIT assigns a priority level to each item and the mean rating is computed. This rating is offered to the Red Wolf Program Leader as a recommendation for activities to pursue or fund. At the first meeting, a pattern was established where RWRIT members worked to identify key management questions and to focus scientific inquiry in areas of need with constant reference to the adaptive management plan. Assets are identified and resource limitations discussed so recommendations have a reasonable likelihood of implementation. Short proposals outlining the objective of projects and the team member(s) involved in the work are distributed to the RWRIT via the team's webpage. The webpage also includes team member contact information, minutes of meetings (see below), data sets, reports, press releases, publications, project descriptions, manuscripts in progress, and upcoming meeting agendas and related materials such as reports and summaries.

Since 2000 the RWRIT has met bi-annually, which is sufficient to respond in a timely manner to questions from the field and to strengthen collegial bonds among members. This schedule also allows sufficient time for the field team to implement recommendations and to document their progress and for RWRIT members to work independently on action items. Other factors affecting meeting schedules include a need to make recommendations ahead of budget deadlines and to accommodate schedules of the individual RWRIT members and the field team. The current pattern of meetings includes 1 meeting in March prior to the denning season and a second in October prior to intensive trapping efforts.

Staying flexible

Any group with dynamic tasks needs a mechanism for adjusting the nature of the group as it matures and as tasks change (Clark and Reading 1994). The concept of alternate members soon was abandoned because of the strong attendance by RWRIT members and because it reduced inefficiencies associated with updating new attendees. The ability to invite experts in areas not represented on the RWRIT provides a mechanism to maintain flexibility and adaptability. Periodic review of expertise needed for specific tasks and projects of the RWRIT keeps the issue of change before the team. In addition, there exists ample opportunity to discuss candidly both the pros and cons of the teams' efforts, either formally at the end of each meeting or informally during meals or after hours. The RWRIT Leader needs to recognize dissenting views and address contentious issues promptly and effectively. The fact that for most meetings the entire RWRIT was communally housed in rented accommodations further ensured the establishment of favorable personal relationships benefiting RWRIT interactions and discussion.

Complete minutes of RWRIT deliberations provide documentation of the team's discussions and recommendations. An iterative process of editing minutes is used by the RWRIT, ensuring important information developed at each meeting is recorded accurately and in language deemed appropriate by the participants. Notes are converted into a draft each evening and individualized, and printed copies are distributed to attendees the following morning for editing. All drafts are synthesized into the penultimate draft for further comment, which is followed by a final draft distributed electronically shortly after completion of the meeting. The RWRIT members have a week to return any corrections, after which the final minutes are completed and distributed electronically. The deliberations of the RWRIT are considered privileged communication, and all meeting participants are asked to limit discussions of information received at the meetings to individuals within their respective research groups. This policy allows RWRIT members access to sensitive and preliminary data and provides more freedom of discussion without concerns about inappropriate disclosure. Distribution of the minutes beyond the RWRIT is at the discretion of the Red Wolf Program Leader.

How well does it work?

The test of any system is how well it functions to meet the goals and objectives of the program it serves. In the 4 years since the first formal meeting of the RWRIT, key challenges to implementing the plan developed at the PHVA have been identified and strategies have been devised to provide practi-

cal solutions and evaluate success of recovery efforts. Perhaps more importantly, all RWRIT members and the entire red wolf field team have become close colleagues who look forward to each meeting. We enjoy the frank and open exchange of ideas, the ability to quickly address both practical and theoretical problems and make changes in management practices, and the successes in the field that result from the collaboration. The details of these changes and successes are the basis of several scientific papers, some already published or in press and others currently in preparation, but a brief summary is warranted.

Prior to 1998 all canids captured in the red wolf recovery area were assumed to be wolves unless they were so small as to be considered coyotes, if they were black, or if they looked part dog. If there was some indication that a single female wolf was consorting with a coyote or dog, pups she produced were removed (A. Beyer, USFWS, personal communication). Thus, the basic challenge of rapidly and confidently identifying animals as red wolves versus hybrids or coyotes, especially young animals, was identified early as a key concern of the PHVA and the field team. The RWRIT served as catalyst for developing an enhanced and improved genomic testing protocol by expanding the ability to assess alleles at 19 loci (Miller et al. 2003). A priority placed on obtaining genomic assessments of the entire group of founders in the captive breeding program, as well for coyotes in the vicinity of the wolf release zones, greatly improved the confidence in the genomic data now available. Genetic analyses were integrated with pedigree and morphometric data to develop decision trees for all captured animals (Table 1). Extension of the DNA analysis capabilities to fecal samples increased the potential for assessing presence of red wolves, as well as undesired non-red wolves, in the field samples without the need of capturing and handling animals (Adams et al. 2003). Additional research efforts were directed at using this technology for assessing red wolf population size (J. R. Adams and L. P. Waits, University of Idaho, unpublished data).

To evaluate progress of the adaptive management plan, RWRIT scientists wanted detailed and current descriptions of animal locations, their genotypes, and canid inventory efforts in relation to geographic areas. A coordinated Geographic Information System (GIS) database system is now used at all RWRIT meetings to examine recovery progress. This is steadily approaching the goal of a real-time data view as data entry and validation challenges are addressed and data summaries are refined. These tools help identify areas where data are insufficient to define the status of canids and help develop strategies to eliminate so-called "areas of ignorance" by concentrating efforts in areas needing more attention. In addition, they have lead to improved ground telemetry efforts and more efficient use of resources and personnel.

Modeling effects of coyote genomic intrusion, using more refined data sets and newer models than available at the PHVA, provided RWRIT scien-

Table 1. Decision path for genetic results of red wolves (RW) captured in the experimental population area in northeastern North Carolina, applied in fall of 2003 (explanation of genetic result classifications given in Miller et al. 2003). Decision parameters listed in the following priority: Genetic testing; Pedigree; Morphology; Mate.

	Capture location[a]	
Decision parameter	Zone 1	Zone 2
1. Genetic test: 100% RW (pedigree 100% RW)	Release	Release
1. Genetic test: 100% RW but cannot exclude 75% RW hypothesis	Consider pedigree (go to 2)	
2. Pedigree is 100% to 87.5% RW	Release	Release
2. Pedigree is 87% to 75% RW or unknown	Consider morphology (go to 3)	
3. Morphologically "hybrid-like"	Euthanize	Sterilize
3. Morphologically "RW-like"	Consider mate (go to 4)	
4. Mate is ≥75% RW	Release	Release
4. Mate is <75% RW or uncertain	Euthanize	Sterilize 1 mate
1. Genetic Test: 75% RW or 75% RW but cannot exclude 50% RW hypothesis	Consider pedigree (go to 5)	
5. Pedigree is <75% RW	Euthanize	Sterilize
5. Pedigree is ≥75% RW or unknown	Consider morphology (go to 3)	

[a] See Figure 1.

tists new insights into impacts of genomic intrusion (e.g., Miller et al. 2003). This allowed for key insights to establishing acceptable risks defined in the decision trees. This also assisted in the making of informed recommendations for modifying approaches to the various management zones for red wolf recovery. Recently, the RWRIT initiated an effort to conduct detailed analyses of home range, spatial interactions, habitat use, and demographic attributes of all radiomonitored red wolves since 1986, with the objective of developing a population viability model to help guide future management and recovery actions. Den management techniques via implementation of early genomic sampling and use of cross-fostering of wild-caught and captive bred pups into wild litters have been developed (cf. Kitchen and Knowlton, *in press).* Methodology also has been enhanced to conduct surgical procedures to support the use of hormonally intact but sterile hybrids and coyotes to serve as sterile buffers (i.e., temporary territory placeholders that discourage establishment of new, intact nonwolves) in peripheral management zones (Figure 1).

The net result of such activities has led to an increase in the area occupied by red wolves, total number of red wolves, and number of red wolf social units, as well as a major decrease in the total area where the status of canids, in general, is unknown (B. B. Fazio, USFWS, unpublished data). Such changes in these metrics were identified in the RWAMP as key indicators of the successful management of wolf-coyote hybridization. Importantly, coyotes or hybrids have essentially been eliminated from fully half of the red wolf recovery area. To date, genetic intrusion into the red wolf population has been largely controlled, albeit through aggressive intervention.

The effective functioning of the RWRIT has ensured that issues identified at the PHVA as described in the RWAMP have been, or are being, successfully addressed by USFWS. And as should be expected, the original red wolf adaptive management plan is now revised to include 5 years of evolving adaptive management (Fazio et al. 2004). The approach taken by the RWRIT represents a good example of successful application of the Adaptive Resource Management paradigm and is likewise consistent with, and respectful of, concerns raised by the participants at the PHVA that the primary goal of conserving the only free-ranging population of red wolves not be overshadowed by the desire to conduct research. Indeed, the USFWS recently highlighted the efforts of the Red Wolf Recovery Program in a videotape on how the use of sound science is key to meeting its mission.

We believe the recent tangible success in red wolf recovery is a direct result of conducting the PHVA, crafting a RWAMP, establishing the RWRIT, and the cooperation and close interaction between the RWRIT and the USFWS field team directly tasked with red wolf recovery. Endangered species recovery should involve a strong linkage between scientific investigation under the rubric of adaptive management and the appropriate blend of social, political, and economic issues (Clark et al. 1994). In light of the mixed past success in recovering endangered species in the United States (Crouse et al. 2002, Gerber and Hatch 2002), we believe, based on the success of the RWRIT, that recovery implementation teams can serve as an effective vehicle for helping guide recovery programs and actions.

Acknowledgments. The authors thank the USFWS and the Morris Animal Foundation for financial support of activities reported in this manuscript and the red wolf field team for its excellent efforts and cooperation with the RWRIT.

The collaborators on this paper have a variety of academic degrees, work experiences, and publications in a wide selection of fields and disciplines and have studied species from A to Z. They include (seated, from left to right) ***Karen Beck*** (ecological epidemiologist), ***Buddy Fazio*** (fiscal conservationist), ***Todd Fuller*** (quasi-experimental theoriologist), ***Eric Gese*** (investigative carnivologist), and ***Brian Kelly*** (politico-ecologist), and (standing, left to right) ***Fred Knowlton*** (historical canidilist), ***Dennis Murray*** (taxon-free numero-ecologist), ***Michael Stoskopf*** (conservation metabonomist), ***Will Waddell*** (ex-situ zoologist), and ***Lisette Waits*** (pan-molecular faecologist).

CHARTER

For the

Albemarle Peninsula Collaborative Canid Conservation Team

I. Mission

The mission of the Albemarle Peninsula Collaborative Canid Conservation Team (APCCC) is to *promote science based conservation and management of all wild canids, including the red wolf, on the Albemarle Peninsula while considering ecological variables and striving to meet social expectations.*

II. Executive Committee

The work of the APCCC will be overseen by an Executive Committee comprised of the North Carolina Wildlife Resources Commission (NCWRC) Executive Director and the U.S. Fish and Wildlife Service (USFWS) Assistant Southeast Regional Director for Ecological Services. The Executive Committee's responsibility is to ensure that the APCCC is meeting the expectations identified in the November 20, 2013, memorandum establishing the APCCC (Exhibit A). The Executive Committee appoints members to the Steering Committee and approves Steering Committee work products.

III. Steering Committee

Activities of the APCCC will be guided by the Steering Committee. The primary responsibility of the Steering Committee will be to provide the necessary resources and guidance to accomplish the APCCC Mission. The Steering Committee will establish, as needed, sub-committees of the Steering Committee and/or Working Groups comprised of members of the Steering Committee and other stakeholders, charged with developing various products that will comprise a comprehensive conservation strategy for Albemarle Peninsula canids. Members of the Steering Committee will serve as a managing body for the Working Groups, resolve impasses in consensus within the Working Groups, and approve all final Working Group and sub-committee plans and products.

IV. Membership

Members of the Steering Committee include:

- Dr. David Cobb, Wildlife Chief, NCWRC;
- Dr. Maria Palamar, Wildlife Veterinarian, NCWRC;
- Brandon Sherrill, Mammalogist, NCWRC;
- Dr. David Rabon, Red Wolf Program Coordinator, USFWS;
- Art Beyer, Red Wolf Field Coordinator, USFWS;
- Pete Benjamin, Raleigh Ecological Services Field Office Supervisor, USFWS.

V. Responsibilities of Members

A. Attendance. Members of the Steering Committee agree to attend all meetings.

B. Preparation for Meetings. Members of the Steering Committee agree to read appropriate material and arrive prepared to work.

C. Representation. Members represent their individual organization's positions to the Steering Committee. Members also represent the Steering Committee's position to their associated organizations.

D. Members agree to support the mission of the APCCC.

VI. Decision Process and Internal Organization

Use of Consensus: The Steering Committee will operate by consensus. Steering Committee decisions will be made only with concurrence of all members represented at the meeting. No member can be outvoted.

Failure to Reach Consensus: If the Steering Committee fails to reach consensus on an issue, the issue will be presented to the Executive Committee for resolution. This will occur only after the Steering Committee members have agreed that consensus cannot be reached (i.e., there is consensus on the lack of consensus).

Officers: A Chair shall be selected annually from the members of the Steering Committee at the first meeting of each calendar year. Members will serve as Chair for a one-year term. A Vice Chair shall also be selected annually to function in the absence of the Chair. When the Chair's term ends, the Vice Chair will become the new Chair and a new Vice-Chair will be selected.

Subcommittees: The Steering Committee may establish subcommittees to address specific issues as needed. Subcommittees may consult individuals with technical skills and information pertinent to the issue at hand. Subcommittees are not authorized to make decisions for the Steering Committee unless the Steering Committee explicitly grants such authorization. Subcommittee findings will be forwarded to the Steering Committee Chair.

Working Groups: The Steering Committee may establish Working Groups comprised of APCCC members and non-member stakeholders to address specific issues, as needed. Working Groups are not authorized to make decisions for the Steering Committee. Working Group findings will be forwarded to the Steering Committee Chair.

Agendas: Prior to each scheduled meeting, a draft meeting agenda will be developed by the Steering Committee Chair for distribution to committee members for review and approval.

Meeting Summaries: The Steering Committee Chair will distribute a draft meeting summary to all Steering Committee members for review prior to the next regular meeting. The summary will include attendance record, a summary of actions taken at the meeting, and other information pertaining to the deliberations.

Schedule: The Steering Committee will meet as needed or at least quarterly each year.

VII. Rules of Order:

A. Ground rules: Members of the Steering Committee (and all Subcommittees) agree to participate constructively in all meetings. Ground rules for constructive interaction include:

1. Treat all members with courtesy and respect.
2. Speak one at a time.
3. Listen carefully.
4. Be clear and concise in your comments.
5. Stick to the agenda; avoid off-target discussions.
6. Be prepared to take part; be an active participant.
7. Be candid; it's ok to disagree.
8. Ask relevant questions.
9. Focus on the problem, not finding fault.
10. Separate interests from positions.
11. Don't bring hidden agendas.
12. Meetings adjourn on schedule or can be extended in duration by consensus.

These ground rules may be amended at any meeting. These ground rules will be provided to all subcommittees.

B. Enforcement of Ground Rules: Ground rules will be monitored and enforced by Steering Committee members and/or the Chair.

VII: Responsibilities of the Chair

The primary task of the Chair is to guide the meetings of the Steering Committee, Sub-committees, and Working Groups within the framework of the charter. These responsibilities may include managing the meeting agenda, encouraging participation, helping the Steering Committee stay on task, and helping the Steering Committee reach consensus.

VIII. Changes to the Organizational Protocol

Changes to this charter can be made at any scheduled meeting of the Steering Committee through a consensus procedure.

FWS/R4/ES

Mr. Gordon Myers
Executive Director
Wildlife Resources Commission
1701 Mail Service Center
Raleigh, North Carolina 27699-1701

Dear Mr. Myers:

Thank you for your June 2, 2014, letter responding to the U.S. Fish and Wildlife Service's (Service) request for renewal of a permit from the North Carolina Wildlife Resources Commission (Commission) to trap, sterilize, and release coyotes in the five-county red wolf recovery area on North Carolina's Albemarle Peninsula. At the same time, you expressed concerns about our current management strategies and requested a program evaluation to determine whether the red wolf non-essential, experimental population (NEP) should be continued in eastern North Carolina.

The red wolf became one of the earliest federally protected species with its listing as endangered under the Endangered Species Act (ESA) on March 11, 1967. The initial phase of recovery for the red wolf involved capturing all remaining wild red wolves in Southeastern Texas and the establishment of a captive population. This action became a landmark effort in conservation and has saved this wolf from the brink of extinction. The red wolf breeding program evolved into one of the most successful captive-breeding efforts in the United States and now includes close to 200 red wolves located at 43 facilities, of which greater than 90% are independently funded conservation programs.

In 1986, the Service moved ahead with the establishment of the NEP on federal lands at Alligator River National Wildlife Refuge and Dare County Bombing Range. Efforts to establish a red wolf NEP succeeded to the point where in 1995 the Service expanded the NEP to include Pocosin Lakes National Wildlife Refuge. At this stage of the Red Wolf Recovery Program, the Service had over 310,000 acres of federal lands able to support a maximum population of approximately 45 to 55 animals of all age classes. The established recovery goal calls for a total of 220 red wolves in three separate self-sustaining populations. The NEP in eastern North Carolina is just one. A second attempt to establish a red wolf NEP was started in western North Carolina in 1991. This project ended in 1998. The locations for the other two populations have not been identified.

The Service met its population goal for the Albemarle Peninsula in the late 1990s. This significant accomplishment was a first-of-its-kind for a canid species protected under the ESA. The Service continued to manage the red wolf population to a point where it expanded on federally managed and private lands and currently is estimated to be between 90 and 110 red wolves in the NEP's five-county area. Even with this accomplishment, the red wolf in the NEP continues to face challenges, including hybridization and gunshot mortality.

Hybridization with coyotes was identified as a significant threat to the species when the Service decided to remove it from the wild in the 1970s. Now, with the expansion of coyotes across North Carolina and into formerly unoccupied habitats in the Albemarle Peninsula, hybridization must be addressed. Since 1999, the Service has trapped, sterilized and released coyotes as a tool to manage hybridization. Under our November 2013 joint memorandum, our two agencies agreed to evaluate the placeholder theory as the underlying principle for canid management in the Albemarle Peninsula. However, we acknowledge that our renewed permit to trap coyotes in the five-county area will no longer allow for sterilization and release of trapped coyotes but rather require that they be humanely euthanized. We will fully comply with your permit requirements regarding coyote trapping.

The Service fully supports appropriate management tools for canids, including hunting. We have concerns about night hunting as stated in our April 16, 2012 letter and also have concerns about the increase in red wolf gunshot mortality since 2004 in the five-county recovery area. We welcome continued conversations on the November 2013 joint memorandum which is designed, in part, to balance coyote control and red wolf recovery, as well as manage non-natural mortality (e.g., vehicular strikes).

We support protecting private landowners, who through mistaken identity and without intent to take a red wolf, from prosecution under Section 9 of the ESA. The Service clarified this position in the Federal Register in April 1995, specifically finding that it is appropriate to modify the language of the special red wolf rule by limiting the Section 9 prohibition on private lands only to intentional and willful taking of red wolves.

Lastly, the Service agrees it is time to conduct a program evaluation of the red wolf recovery efforts in the Albemarle Peninsula of eastern North Carolina. We are committed to perform this evaluation together with the state as was outlined in our November 2013 agreement. In fact, we have already begun that process. This evaluation will consider the program's history and its results as well as the perspectives of all stakeholder groups including private landowners, local, state and federal agencies, and conservation partners. We also want to ensure that the evaluation addresses your concerns regarding habitat management on federal lands and the Service's implementation of legislated provisions to protect the interests of private landowners. The Service will conduct this evaluation in close coordination with the Commission. We expect to develop a scope of work for this evaluation by the end of June. To that end, I have asked Leopoldo Miranda, Assistant Regional Director of Ecological Services, to coordinate with you on the scope and logistics of this program evaluation.

The Service remains committed to continuing the collaborative approach to canid management on the Albemarle Peninsula espoused in the memorandum we jointly signed in November 2013. That agreement builds on a strong collaboration over the past five years by setting commitments to re-evaluate science, identify research needs, and establish a broad partnership. While these issues are complex, we believe our collective commitment to this strong partnership will serve us well as we identify solutions that meet our mutual conservation objectives moving forward.

Again, thank you for your work on these issues. We will be following up with you in the days ahead. In the meantime, please let me know if you have any questions or need additional information.

Sincerely yours,

Cynthia K. Dohner

ABSTRACT

Understanding the mechanisms that govern interspecific hybridization is vital to mitigating its impacts on endangered species. Research suggests that behavioral mechanisms such as mate choice and social disruption can regulate the rate at which hybridizing species interbreed. We investigated hybridization events between endangered red wolves (*Canis rufus*) and coyotes (*Canis latrans*) in eastern North Carolina to evaluate potential factors that may promote hybridization between these species. Specifically, we examined spatial location, breeding experience, breeder origin (captive vs wild), breeder ancestry (pure vs hybrid), and past history of the animal. There were over four times (126 vs 30) as many red wolf litters as hybrid litters over a 13 year time period. Over half of the hybridization events followed the disruption of a stable breeding pair of red wolves due to mortality of one or both breeders. Of these 69% were due to anthropogenic causes, primarily gunshot mortality prior to the red wolf breeding season. Both male and female red wolves interbred with coyotes, although a majority (90%) of the events we observed involved females. Wolves that produced hybrid litters tended to be young, first-time breeders with slightly higher levels of coyote ancestry. Only 16% of the hybrid litters were produced in the inner core of the red wolf recovery area. Our results suggest that disruption of stable breeding pairs of red wolves facilitates hybridization, jeopardizing future recovery of the red wolf. They also indicate the importance of behavioral forces, especially social stability, in regulating hybridization.

1. Introduction

Human activity has the potential to disrupt dynamics between hybridizing species, which can cause hybridization and introgression to emerge as conservation threats (Rhymer and Simberloff, 1996; Allendorf et al., 2001). As with any conservation problem, developing solutions requires recognizing the mechanisms that influence the process. For hybridization, that requires understanding the mechanisms that cause previously reproductively isolated species to interbreed. Species introductions (Rhymer and Simberloff, 1996; Stigall, 2010), habitat destruction and ecological homogenization (Seehausen et al., 2008; Crispo et al., 2011), and the spread of domesticated species (Likre et al., 2010; Champagnon et al., 2012) have been implicated as processes that may facilitate these shifts.

Still, these forces primarily influence whether hybridizing species come into contact, not necessarily whether individuals will interbreed. There is increasing recognition that behavioral processes such as mate choice (Pfennig, 2007; Reyer, 2008; Svedin et al., 2008; Gilman and Behm, 2011; Robbins et al., 2014), interspecific competition (Wolf et al., 2001; Krosby and Rohwer, 2010; Sacks et al., 2011), and Allee effects (Lode et al., 2005) can influence the rate of hybridization. The potential for behavioral forces to moderate hybridization and introgression may be a critical factor that would influence conservation schemes.

Understanding the mechanisms that govern interspecific mating is vital to recovery of species threatened by hybridization, especially the critically endangered red wolf (*Canis rufus*) in eastern North Carolina. Historically red wolves were distributed across eastern North America, but overharvest, habitat destruction, and hybridization with coyotes (*Canis latrans*) led to extinction in the wild by 1980 (Paradiso and Nowak, 1972; Nowak, 2002; USFWS, 1990). Beginning in 1987, captive red wolves were reintroduced into eastern North Carolina and today a population of about 80–100 individuals occupies the 600 000 hectare Albemarle Peninsula (Phillips and Parker, 1988; Phillips et al., 2003; Bartel and Rabon, 2013).

At the same time, coyotes expanded their range into North Carolina (Hill et al., 1987) and in 1993 the first hybridization event between a reintroduced red wolf and a coyote was detected (Phillips et al., 2003). A subsequent population viability analysis

suggested that hybridization was the greatest threat to red wolf recovery (Kelly et al., 1999). This led to the development of an aggressive adaptive management plan by the US Fish and Wildlife Service (USFWS) and the Red Wolf Recovery Implementation Team (RWRIT, Stoskopf et al., 2005) to limit hybridization and introgression. The genetic composition of the population is managed by an active monitoring program combined with genetic testing to remove hybrid individuals from the landscape (Stoskopf et al., 2005; USFWS, 2007; Bartel and Rabon, 2013).

Such aggressive practices have been implemented based on the hypothesis that a small red wolf population would be genetically swamped by coyotes without human intervention (Kelly et al., 1999). This is predicated on the assumption that when sympatric, red wolves and coyotes will breed indiscriminately. However, this assumption has not been tested empirically. Fredrickson and Hedrick (2006) modeled red wolf viability and found that positive assortative mating and aggressive interactions between the species were the most important factors in maintaining population viability. They developed hypothetical values for those parameters because empirical estimates did not exist. USFWS field biologists have observed red wolves displacing and occasionally killing coyotes and hybrids (USFWS, 2007). Otherwise, there is little understanding of how mate choice and social structure influence interactions between these species. Given the importance of social dynamics on the ecology of mammalian carnivores, there is potential for behavioral processes such as mate choice, social structure, and competition to limit hybridization (Rutledge et al., 2010; Sacks et al., 2011; Shurtliff, 2011). Conversely, disrupting these social systems may in turn influence reproductive patterns (Brainerd et al., 2008; Borg et al., in press) and hybridization rates (Rutledge et al., 2010).

We examined breeding records and individual histories of red wolves involved in hybridization events from 2001 to 2013 to elucidate factors that facilitate interbreeding between these species. Specifically, we asked the following questions: (1) Do age, prior breeding experience, and origin of the wolf influence the likelihood of hybridization, (2) are individuals with mixed red wolf/coyote ancestry more likely to hybridize, (3) are hybridization events evenly distributed across the recovery area, and (4) are hybrid litters produced under particular scenarios or breeder histories? If breeding between these species is indiscriminate, we would expect young dispersing red wolves to be the most likely individuals to encounter and breed with a coyote. Breeding opportunities within wolf packs are often restricted to a dominant breeding pair, which forces individuals in search of mates to disperse outside the pack (Mech and Boitani, 2003; Sparkman et al., 2012). In this system dispersing would increase the likelihood of an individual encountering a coyote considering that wolf packs are known to exclude coyotes within their range (USFWS, 2007). This is similar to observations of eastern wolf (*Canis lycaon*) packs in southern Canada (Benson and Patterson, 2013). We predicted that hybridization would increase from east to west, since the western portion of the study area has the fewest wolves, least stringent management, and closest proximity to the mainland coyote population. Also, we hypothesized that individuals with mixed red wolf/coyote ancestry would be involved in more hybridization events. By examining the characteristics and history of red wolves responsible for hybridization events with coyotes, we can better understand the mechanisms that govern hybridization, aiding recovery of this species.

2. Materials and methods

2.1. Genetic monitoring

Every spring USFWS biologists track female red wolves to locate active dens that contain pups. Blood samples are collected from pups and genetic testing is conducted to assess their ancestry and place them within the red wolf pedigree (Adams, 2006; Bohling et al., 2013). Since the implementation of the adaptive management plan in 2000 monitoring of red wolf dens and genetic testing of captured canids, including pups, became standard, which improved detectability of hybridization events (Stoskopf et al., 2005; USFWS, 2007). As a result, we only considered hybridization events that have occurred since 2000 for this study. USFWS biologists possessed permits for capturing and handling red wolves that have been jointly issued by the USFWS, Association of Zoos and Aquariums Reintroduction Scientific Advisory Group, and IUCN Species Survival Commission Reintroduction Specialist Group.

Parentage for red wolf and hybrid litters was determined following the methods of Adams (2006) and Bohling et al. (2013). To summarize, each pup was genotyped at 17 microsatellite loci and assigned to red wolf parents using genetic and field data, allowing for $\leqslant 1$ mismatch for a parent pair. Based on this pedigree we were able to estimate an individual's ancestry by averaging the amount of red wolf ancestry possessed by the parents as traced through the pedigree. In the case of hybrid litters, typically only the red wolf parent was identified, although in several situations the non-red wolf parent was later captured and determined to be a parent using genetic analysis. Several hybrid litters were detected when hybrid offspring were captured as juveniles and later assigned to a red wolf parent. Three hybrid litters fit this scenario; thus, the exact size of those litters could not be determined.

2.2. Location

The adaptive management plan divided the peninsula into three zones with different management goals (Stoskopf et al., 2005) (Fig. 1). Zone 1, the easternmost portion of the peninsula, serves as the core red wolf population and coyotes and hybrids captured in this area are euthanized. In Zone 2, directly west of Zone 1, hybrid individuals are euthanized but coyotes are sterilized under the hypothesis that sterile individuals would serve as territorial placeholders that discourage undetected coyotes from dispersing into the peninsula (Bartel and Rabon, 2013). Zone 3 is the furthest west section and falls at the junction of the peninsula and the mainland. Management practices in Zone 3 vary, but many sections of this area are managed similarly to Zone 2. This entire region has been designated as the Red Wolf Experimental Population Area (RWEPA).

We classified each hybrid and red wolf litter to a Zone based upon where it was detected (Zone 1, 2, or 3) and used a χ^2-squared test of independence to evaluate the distribution of each type of litter across all three zones. As noted, some hybrids were discovered as adults. In these situations, once the red wolf parent was identified via genetic testing we assigned the location of these litters according to the home range of that red wolf during the prior breeding season.

2.3. Breeder experience

To examine the impact of breeder experience on hybridization we compared both the age and prior breeding experience of red wolves that produced hybrid and red wolf litters. For breeding experience we classified each litter according to whether it was produced by a first-time breeder or an experienced breeder. This was only performed for females since the sample size of male red wolves was low (see Section 3.1). We defined first-time breeder as any individual producing its first known litter of pups, regardless of whether it was a hybrid or red wolf litter. An individual was considered an experienced breeder once it had produced a second litter. We compared the proportion of total red wolf and hybrid litters that were born to experienced breeders using a χ^2

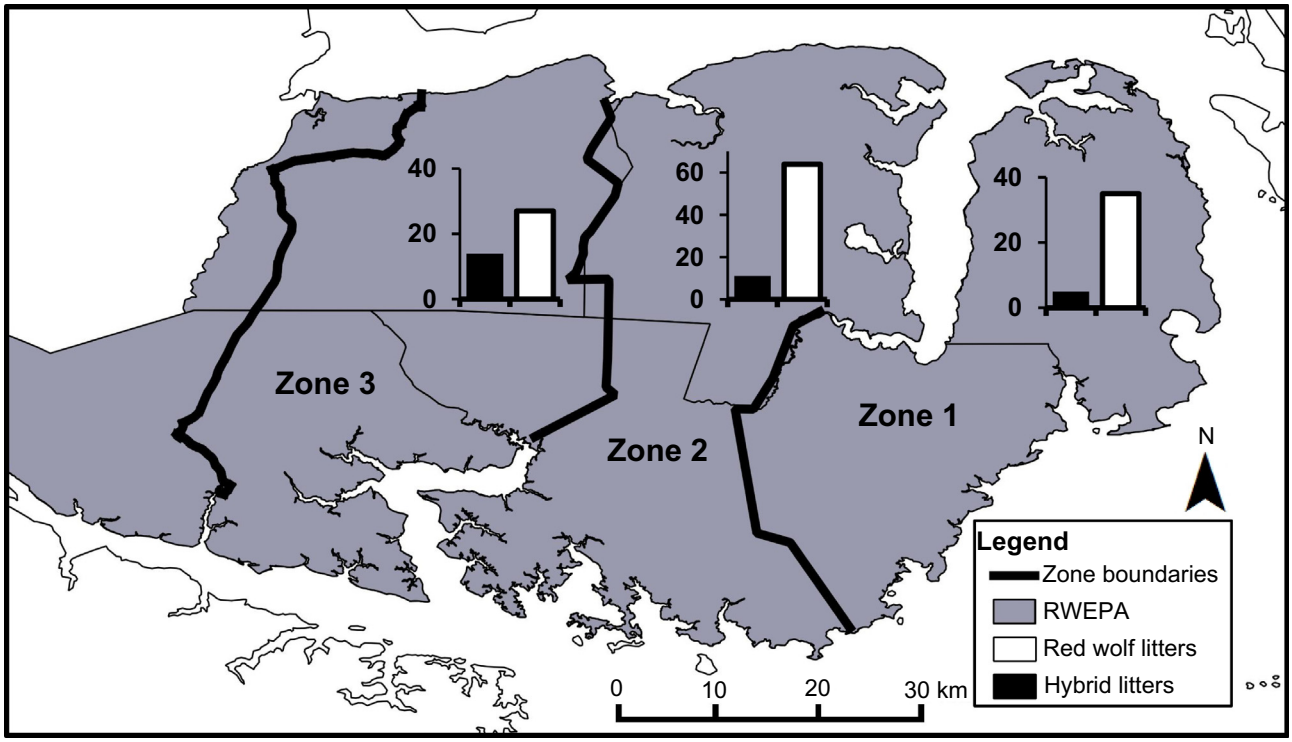

Fig. 1. Map of the Red Wolf Experimental Population Area (RWEPA) and the spatial distribution of hybrid and red wolf litters from 2001 to 2013. The thick black lines indicate the boundaries of the management zones 1, 2, and 3. The number of hybrid and red wolf litters per zone indicated by the graphs within each zone boundary. White columns represent red wolf litters, black hybrid litters.

test of independence. The effect of breeder age was measured by comparing the overall age of individuals responsible for hybridization events to the age of individuals producing red wolf litters. For three females the year of birth was unknown (Table 1).

2.4. Breeder origin

Over the past two decades the USFWS has released captive individuals and individuals raised in island-propagation programs to augment the wolf population. The island-propagation program consists of releasing captive red wolves to isolated, unoccupied barrier islands in the southeastern US so they can acclimate to the wild (Phillips et al., 2003). We hypothesized that the unfamiliarity of captive and island-raised individuals with the RWEPA would inhibit their ability to locate red wolf mates, increasing the likelihood that they would encounter and breed with a coyote. Using the pedigree we were able to determine the origin of each red wolf (wild, captive, and island-born) and whether it produced any litters. We also noted wolves produced through cross-fostering, which involves integrating recently born captive pups into wild litters to provide an input of genetic diversity (Bartel and Rabon, 2013).

2.5. Breeder ancestry

The hybridization event that occurred in 1993 between a female red wolf and male coyote resulted in introgression of coyote genetic material into the red wolf population. Two F1 hybrid males from this event bred with female red wolves and their offspring backcrossed with the red wolf population. The USFWS and RWRIT decided that any individual possessing >87.5% red wolf ancestry based on pedigree assignment would remain in the population (Stoskopf et al., 2005). A large segment of population now consists of these backcrossed individuals that have a slight amount of known coyote ancestry (87.5–98% red wolf) (Adams, 2006; Bohling et al., 2013). Our goal was to determine whether these admixed individuals had a higher propensity to hybridize than 'pure' wolves. We calculated the average ancestry of individuals involved in hybridization events using the pedigree and compared that to the ancestry of individuals producing red wolf litters using a two-tailed *t*-test. We applied an arcsin transformation to ancestry values prior to analysis.

Even though red wolves and coyotes hybridize, there are noticeable differences in morphology, behavior, and ecology between the species (Phillips and Henry, 1992; Nowak, 2002; Phillips et al., 2003; Hinton and Chamberlain, 2014). Hybrids are intermediate between the two species; thus, we predicted that a red wolf would be more likely to select a hybrid as a mate than a coyote. However, since aggressive management practices remove hybrids from the landscape, we hypothesized that the production of hybrid litters would be primarily driven by interbreeding with coyotes. Since the non-red wolf parent was identified for several hybrid litters, we evaluated the ancestry of these animals using two methods to determine if they were coyotes or individuals of mixed ancestry. First, ancestry of non-red wolf individuals was assessed using the Bayesian clustering program STRUCTURE 2.3 (Pritchard et al., 2000; Falush et al., 2003). We used four known genetic groups as training sets: coyotes ($N = 94$) from North Carolina, Virginia, and Texas; gray wolves ($N = 38$) (*Canis lupus*) from Idaho and Alaska; domestic dogs ($N = 28$); and founders of the captive red wolf population ($N = 17$). Our previous work (Bohling and Waits, 2011; Bohling et al., 2013) showed that these four groups form distinct clusters when applied to STRUCTURE in a free-clustering framework. In the STRUCTURE analysis, individuals from our four known genetic groups were assigned a POPFLAG designation of 1 and the 'Use Population Information' option was used as the ancestry model with the default parameter settings and the correlated allele frequency model. Unknown individuals were given the

[a] Identification number of the individual wolf involved in the hybridization event.
[b] F – female; M – male.
[c] Based on the red wolf pedigree.
[d] Birth location of individual.
[e] Wild-born individual from the reintroduced population in North Carolina.
[f] For these individuals the age of birth could not determined.
[g] These litters were detected after USFWS biologists captured the hybrids as juveniles and genetic testing assigned parents.
[h] Refers to the management zone that the litter was discovered.
[i] The individual that bred with the red wolf was unable to be determined for all litters.
[j] History of the location and/or red wolf prior to the production of the hybrid litters.
[k] No significant history was recorded for these individuals.
[l] The individual the red wolf had paired with had been erroneously identified as a red wolf.

POPFLAG = 0 designation, which means their genotypes were not used to estimate allele frequencies. The number of populations was set to four with a burn-in period of 100 000 reps followed by 1 000 000 MCMC repetitions.

For each genetic cluster STRUCTURE produces a probability value that an individual's genotype originated from that group. We considered an individual 'admixed' using two different criteria following Bohling and Waits (2011). If an individual had a probability of assignment $\geqslant 0.1$ for two or more species, we considered that evidence of admixture under our 'Relaxed' criterion. STRUCTURE estimates credibility intervals around each probability value. If the 90% credibility intervals for the values of two or more genetic groups did not overlap zero, we considered this strong evidence of admixture under our 'Conservative' criterion. Our reasoning was to provide two perspectives for interpreting individual ancestry (Bohling and Waits, 2011; Latch et al., 2011). A concern with comparing these results with the red wolf pedigree is that the pedigree is based on theoretical expectations of inheritance while the STRUCTURE results are based on model-estimates using genetic data. To examine if there was any bias in using ancestry estimates based on the pedigree, we compared ancestry estimates produced by both methods for all red wolves involved in hybrid and wolf reproductive events using a paired *t*-test.

Miller et al. (2003) developed a maximum-likelihood assignment test specifically for this red wolf–coyote system. This Canid Assignment Test (CAT) uses genotypes of founders of the captive red wolf population and coyotes from Texas, Virginia, and North Carolina to simulate genotypes of red wolves, coyotes, F1 and F2 hybrids, and F1 × backcrosses with each parental species. Maximum-likelihood tests are then used to estimate the probability of an individual's genotype originating from those six classes. This test is used by the USFWS in conjunction with the pedigree assignment in management decisions and we included those results for another perspective on ancestry.

2.6. Breeder history

We assessed breeder history for each red wolf involved in known hybridization events. The information we collected focused on qualitative descriptions of specific events experienced by the wolves and/or the pack they were associated with. These events were documented by USFWS biologists as they monitored individual wolves over the course of the main period of dispersal and breeding (October–March). Examples of significant events included but were not limited to dispersal, displacement, formation of a new pack, disruption of breeding pairs, and mortality of an associated breeder. In the case of mortalities, a necropsy was conducted to determine whether the cause of mortality was natural or anthropogenic.

3. Results

3.1. Location

From 2001 to 2013, 30 hybrid litters and 126 red wolf litters were documented by USFWS biologists and confirmed via genetic testing (Fig. 2). The mean number of hybrid litters per year was 2.2 ($\pm 1.4\sigma$) whereas the mean number of red wolf litters was 9.7 ($\pm 1.7\sigma$). The average number of pups were higher in hybrid litters (5.5) than red wolf litters (4.2) ($p = 0.001$). In a majority of the cases (27 of 30) a female was confirmed as the red wolf parent of a hybrid litter. A total of 23 female red wolves were involved in hybridization events; most only produced one hybrid litter. Two females were responsible for two hybrid litters each and another was responsible for three. The three male red wolves that produced hybrid litters were responsible for one each.

A majority of the hybrid litters were found in Zones 3 ($n = 14$) and 2 ($n = 11$), with the lowest number in Zone 1 ($n = 5$) (Fig. 1). Conversely, red wolf litters were more evenly distributed (Zone 1 = 35, Zone 2 = 64, Zone 3 = 27). The distribution of red wolf and hybrid litters across the zones was significantly different ($\chi^2 = 8.05$, $p = 0.02$). All red wolves that produced hybrid litters were originally born in the wild except for one female wolf that was born in the island propagation program. Most of the females responsible for red wolf litters were also wild-born ($n = 43$), but four cross-fostered and three island-born females also produced litters. Among males that produced red wolf litters, 47 were wild-born, six island-born, one captive-born, and one cross-fostered.

3.2. Breeder experience

Since a majority of the hybrid litters were produced by females, we only examined breeding age and experience for female red wolves. Among hybrid litters, 16 of 27 involved a female breeding for the first time. This was a significantly higher ($\chi^2 = 8.8$, $p = 0.003$) than the proportion of red wolves litters that involved a first-time breeding female (35 out of 120). Across all litters, the average age of female red wolves responsible for hybrid litters (4.2 years ± 1.6σ) was less than the average age of those responsible for red wolf litters (5.2 years ± 2σ; $p = 0.007$).

3.3. Breeder ancestry

There was no significance difference between the values of ancestry produced by the pedigree and STRUCTURE for individual red wolves ($p = 0.89$). Thus, we report results from the pedigree. Due to the low number of males involved in hybrid litters, we restricted comparisons to female wolves to ensure adequate sample sizes. The average red wolf ancestry of females involved in hybrid events was 0.939 while those involved in red wolf litters had an average of 0.963. Following data transformation, these values were not significantly different ($t = 2.02$, $p = 0.128$). For males, the average amount of red wolf ancestry was 0.947 for those that produced red wolf litters and 0.854 for those producing hybrid litters, but we did not test statistical significance due to low sample size.

The suspected non-red wolf parent was identified by USFWS biologists using field observations for 16 hybrid litters. Two litters involved the same non-red wolf parent: a male that had been mistakenly identified as a red wolf based on morphological examination in the field. Genotypes were obtained for 10 of these non-red wolf parents. Based on the STRUCTURE results, only three individuals appeared to be pure coyotes using the 0.9 q-value threshold (Fig. 3). Two additional individuals also appeared to be coyotes, for they had q-values of 0.81 and 0.77, respectively, for the coyote cluster and no other q-value >0.1. For these five individuals the credibility interval surrounding the q-value for only the coyote cluster did not overlap zero. Four of these individuals we classified as coyotes by the CAT; one, 30272, was classified as a coyote × F1 backcross (Table 2).

Two individuals had q-values indicative of F1 coyote–red wolf hybrids (Fig. 3). Using the red wolf pedigree, we were able to identify the red wolf and coyote parent for both of these individuals, confirming that they were F1 hybrids. Individual 30205 was the only individual for which the credibility intervals for the coyote and red wolf cluster did not overlap zero. Both individuals were classified as F1 hybrids by the CAT (Table 2). Two other individuals appeared to be F1 × red wolf backcrosses (75%), which were confirmed using the pedigree, and one (30145) produced credibility intervals for two clusters that did not overlap zero. The CAT also classified these individuals as F1 × red wolf backcrosses. One individual appeared to be a F1 coyote–dog hybrid × coyote backcross (~75% coyote, ~25% dog) using the 'Relaxed' criterion. To the CAT, which does not incorporate dog ancestry, this individual was a coyote.

3.4. Breeder history

Seven of the 30 hybrid litters had no notable previous history associated with the red wolf responsible for the litter (Table 1). Only two instances resulting in hybrid litters involved red wolves that were considered 'dispersers'. One was a female red wolf that had been displaced by a neighboring female wolf and settled with a non-red wolf mate. The other was a female that exhibited wide movement patterns during the breeding season and never paired

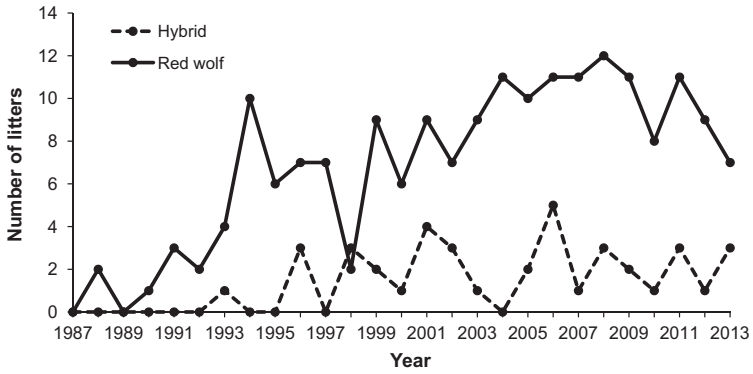

Fig. 2. Number of red wolf and hybrid litters produced each year since the reintroduction of red wolves into North Carolina. Beginning in 2000 the FWS implemented an adaptive management program to genetically monitor the population and reduce hybridization. As a result, for this study we focused solely on litters produced after 2001.

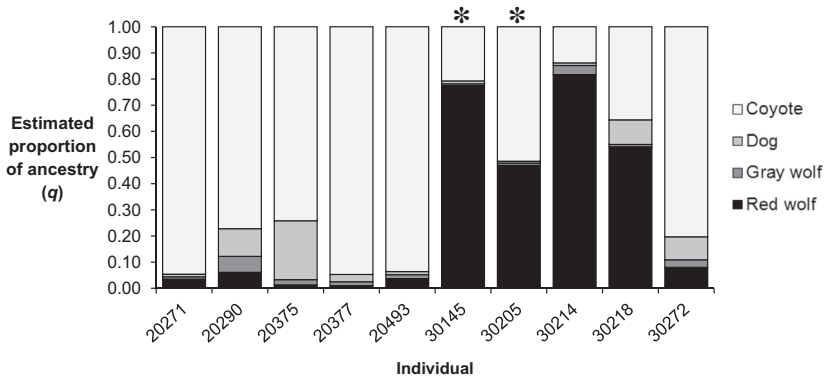

Fig. 3. STRUCTURE ancestry coefficients for the non-red wolf individuals responsible for hybridization events. Each bar represents an individual ancestry composition and each color reflects the ancestry value assigned to each species. This analysis was conducted with a dataset containing 17 polymorphic microsatellite loci. For individuals with a * above their bar plot, the STRUCTURE 90% credibility intervals did not overlap zero for two genetic groups. Individuals 30205 and 30218 were determined to be F1 coyote–red wolf hybrid using the pedigree. Individuals 30145 and 30214 were determined to be F1 × red wolf backcrosses using the pedigree.

Table 2
Results from the Canid Assignment Test (CAT) for non-red wolf individuals responsible for hybridization events. This test uses maximum-likelihood statistics to evaluate the probability of an individual belonging to six separate ancestry classes. The six classes are the two parental species (red wolf, coyote), F1 and F2 hybrid, and F1 backcrosses with each parental species. Values indicated the probability (p) that an individual's genotype can be excluded from that ancestry class. The most likely class is indicated by the term 'LMI'. Coyotes Specific Alleles (CSA) refers to number of alleles possessed by an individual that are found only in coyotes and not the founders of the red wolf population.

Individual	Most likely classification	Maximum-likelihood probability of assignment						CSA
		Red wolf	Coyote	F1	RWBC[a]	CoyBC[b]	F2

[a] Red wolf × F1 hybrid backcross.
[b] Coyote × F1 hybrid backcross.

with a male red wolf. Three hybridization events were the result of a red wolf pairing with an individual that was previously believed to be a red wolf until genetic testing revealed otherwise. The previous history of these females was unknown. All three of these cases occurred in 2002 and 2003, soon after the implementation of the new management plan and strict genetic testing. Two of these cases involved the same female red wolf and male non-red wolf.

Half of the hybrid litters (16 of 30) followed the disruption of a stable breeding pair of red wolves prior to or during the breeding season. Most of these litters ($n = 9$) followed the death of one or both members of a breeding pair of red wolves by gunshot. Another two followed the death of a red wolf breeder by either poison or a trap injury. Two hybrid litters followed the "disappearance" of a breeder, meaning the FWS has lost radio contact with a breeding member of a red wolf pack. Five hybrid litters followed the disruption of a breeding pair by natural causes. One involved a female wolf whose male partner died naturally after a foreign object punctured a lung, causing a systemic lung infection. Another occurred when a female wolf mated with a non-red wolf after both the breeders in her pack died of mange. The third case involved a female whose mate was killed by another wolf. In two other situations a female red wolf had been paired with a sterilized coyote that was subsequently displaced or killed by a red wolf from another pack; these female red wolves then mated with non-red wolves.

To summarize, excluding the seven cases with no known history, 78% (18/23) of the hybrid events followed disruption of social groups. Of these, 61% (11/18) followed anthropogenic mortality, which could be an underestimate if the two individuals that "disappeared" had a similar fate. In situations of breeder disruption either the remaining breeder ($n = 7$) or a previously unmated member of the pack ($n = 9$) interbred with a non-red wolf.

4. Discussion

Exploring individual records of hybridization events in this red wolf–coyote system provides insights into mechanisms that may regulate interactions between these two species. There are several observations we can draw from the wolves involved in these events. First, a large number (90%) of hybridization events involved female red wolves. Based on genetic data, researchers have hypothesized that introgression between wolves and coyotes predominantly occurred when male wolves bred with female coyotes (Lehman et al., 1991; Mozón et al., 2014); our findings refute that hypothesis and support the genetic results of Hailer and Leonard (2008). It also matches the predictions of Wirtz (1999) that hybridization is driven by females from the rarer species selecting heterospecific mates from the more common species.

Ultimately, it appears that hybridization events tend to follow the disruption of stable breeding pairs of wolves, frequently due to anthropogenic actions such as gunshot mortality. In this system canids begin establishing pair bonds during a period that corresponds with the onset of hunting seasons for large mammals. The elimination of red wolf breeders during the breeding season forces reproductively active red wolves to quickly locate another

mate. A higher percentage of hybrid than red wolf litters were produced by first-time female breeders, which is likely due to the low natural turnover in red wolf breeders from year to year (Sparkman et al., 2011). We hypothesize that as stable red wolf pairs dissolve a social 'release' occurs for young wolves providing them with the opportunity to breed, which echoes findings from other wolf populations (Brainerd et al., 2008). The inexperience of these animals coupled with the timing of pair dissolution during the breeding season may facilitate selection of a heterospecific mate.

Such findings correspond with those from other mammalian carnivore social systems that have demonstrated sensitivity to disruption due to human activity (Tuyttens and Macdonald, 2000; Loveridge et al., 2007; Packer et al., 2009; Wallach et al., 2009; Rutledge et al., 2010; Davidson et al., 2011; Borg et al., in press). By pooling data from multiple wolf populations across Europe and North America, Brainerd et al. (2008) found breeder loss facilitated pack dissolution and abandonment of territory. Disrupting stable social systems in canids has cascading effects on intraspecific and, as shown by this red wolf system and wolves in southeastern Canada (Rutledge et al., 2010, 2011), interspecific interactions. Management of wolves must take into account the consequences of breeding pair dissolution for these events can facilitate genetic introgression into small populations.

The disparity between the number of red wolf and hybrid litters suggests that red wolf pairings are more common than those between red wolves and coyotes, which is encouraging considering coyotes outnumber wolves in portions of the RWEPA (USFWS, 2007; Bohling, 2011; Bartel and Rabon, 2013). Such patterns are heavily influenced by human management, which impacts our interpretation of these results. Regardless, the low number of hybridization events that could be attributed to naturally dispersing individuals suggests that even when sympatric these species do not breed randomly and red wolves seek conspecific mates. This is despite the fact that the red wolf population is increasingly inbred (Brzeski et al., 2014) and genetic diversity has declined over time (Bohling et al., 2013). Inbreeding avoidance can facilitate selection of a heterospecific mate (Palmer and Edmunds, 2000; Gee, 2003). In pack-forming canids inbreeding avoidance is linked with dispersal from natal packs (Sillero-Zubiri et al., 1996; vonHoldt et al., 2008; Sparkman et al., 2012), which could facilitate hybridization if dispersing increases the probability of interacting with heterospecifics. Despite the abundance of coyotes and limited gene pool, hybridization does not appear to be fueled by dispersing red wolves, which indicates some form of assortative mating may be operating in this system.

Many of the non-red wolf parents involved in these hybridization events had mixed ancestry. With the removal of hybrids from the landscape, we expected most hybridization events to involve coyotes; these results, however, suggest that red wolves may be selecting for admixed mates over pure coyotes if available. Both traditional trapping (USFWS, 2007; Bartel and Rabon, 2013) and non-invasive genetic sampling (Adams et al., 2007; Bohling, 2011; Bohling and Waits, 2011) reveal that coyotes vastly outnumber hybrids in this landscape, yet admixed individuals were responsible for 40% of the hybridization events when the non-wolf parent was identified. In hybrid systems in which there is a morphological, behavioral, ecological, or size disparity between the parental groups suggest, hybrids can serve as a bridge between the two parental groups and facilitate introgression (Dowling and Secor, 1997; Goodman et al., 1999; Seehausen et al., 2008; Duvernell and Schaefer, 2014). If red wolves are preferentially selecting admixed mates in this landscape, then efforts to remove hybrids must remain a management priority.

Characterizing the wolves involved in hybridization events is difficult due to the circumstances that surround these events. Any observed patterns could simply be a result of a random artificial selection due to the stochastic nature of anthropogenic mortality. For example, wolves involved in hybridization events tended to have slightly higher levels of coyote ancestry. However, this was not a strong pattern and could be a random artifact. Low sample size of hybridization events relative to red wolf litters, although good for red wolf conservation, limits our ability to draw inferences. Ascertainment bias may also influence the results since the breeding habits of red wolves that are not monitored are difficult to determine. This may explain the overwhelming bias toward female red wolves producing hybrid litters: USFWS biologists monitor female wolves as they begin to localize around a den site so they can locate the pups but do not do the same for males. Questions regarding the impact of genetic ancestry, breeding experience, and sex on hybridization could be best answered with mate choice experiments.

The realization that hybridization tends to follow the disruption of stable breeding pairs is important for management of the red wolf population. There has been a dramatic increase in the amount of gunshot and overall human-caused mortality over the past decade (Bartel and Rabon, 2013). For the adaptive management plan to be successful, more effort must be placed in reducing the number of red wolves killed by gunshot to facilitate efforts to restrict hybridization. A recent agreement between the North Carolina Wildlife Resources Commission and several environmental groups to limit coyote hunting in the RWEPA is a positive step toward achieving this goal (SELC, 2014).

Interpreting the spatial distribution of hybridization events and their significance for red wolf conservation is more complex. Trapping surveys indicate that wolves and coyotes are not evenly distributed across the RWEPA (USFWS, 2007; Bartel and Rabon, 2013). Non-invasive genetic surveys suggest that over 80% of the canids in Zone 1 are red wolves, whereas coyotes composed 70% of the population in Zone 3 (Bohling, 2011). Zone 2 is close to a 50–50 split between the two species. Thus, the abundance of hybridization events in Zone 3 could be simply a result of an abundance of coyotes and the inability of wolves to locate conspecifics, which matched our initial expectations and the classic 'desperation hypothesis' (Hubbs, 1955).

The distribution of hybrid events may also be linked to human social factors and land use practices. Zone 1 is predominantly composed of protected areas under public ownership and the first reintroductions occurred in this area, meaning the USFWS has longstanding relationships with many of the landowners. Expansion of the red wolf population westward has mainly occurred on private lands. Many of these landowners did not anticipate wolf colonization of their property, which has created friction between local communities and the USFWS as was highlighted in an independent review of the red wolf program (WMI, 2014). This conflict, combined with lack of protected refuges for wolves, lack of awareness among the hunting community, and proximity to the mainland coyote population, likely facilitates breeding pair disruption and the spatial pattern of hybridization events.

The management approach taken by the USFWS places value on protecting the genetic 'purity' of the population by limiting hybridization. Such efforts hinge on the commitment to protect a species that today is populated by descendants from just a few founders. The taxonomy and ancestry of these founders has been the source of controversy and some genetic studies suggest the red wolf is a relatively recent product of hybridization between coyotes and gray wolves (Lehman et al., 1991; Roy et al., 1996; vonHoldt et al., 2011). An alternative perspective is that red wolves align closely with eastern wolves in southeastern Canada, which represent a North American-derived wolf sharing a close evolutionary relationship with coyotes (Wilson et al., 2000; Hedrick et al., 2002; Kyle et al., 2006; Rutledge et al., 2012). The debate concerning these alternative hypotheses is ongoing (vonHoldt et al., 2011;

Rutledge et al., 2012). This uncertainty has fueled debate regarding the efficacy of investing resources in the protection of a population potentially derived from hybridization (Gittleman and Pimm, 1991; O'Brien and Mayr, 1991; Jenks and Wayne, 1992; vonHoldt et al., 2011). Further complicating matters is the perception that red wolves have a high propensity to hybridize, leading some to suggest management should be lessened allowing the population to assimilate with the surrounding coyote population (Kyle et al., 2006).

Our results provide a new perspective in this debate by revealing the extent to which human factors, both positive and negative, govern hybridization dynamics in this system. The opposing forces of management designed to maintain the red wolf gene pool and human disruption eroding reproductive boundaries impact our perception of potential red wolf recovery. The current introduced population has remained morphologically (Hinton and Chamberlain, 2014) and genetically (Adams et al., 2007; Bohling et al., 2013) distinct from the resident coyote population. We must recognize that human management as a principle factor in maintaining this pattern. At this point, though, management may operate as a zero-sum game, with facilitation of red wolf reproduction counteracting the impacts of pack disruption. In this case, the infrequency and stochasticity of hybridization events and low number of hybrids across this landscape (Adams et al., 2007; Bohling, 2011; Bohling and Waits, 2011) suggest behavioral processes play a role in maintaining the distinctiveness of the red wolf population.

Research has demonstrated the importance of behavioral forces in regulating interspecific hybridization and species boundaries (Wolf et al., 2001; Pfennig, 2007; Reyer, 2008; Svedin et al., 2008; Krosby and Rohwer, 2010; Sacks et al., 2011; Robbins et al., 2014). Even in the face of introgression, boundaries between parental groups can be maintained through behavioral mechanisms. Our findings mirror those of eastern wolves around Algonquin Park in which hunting disrupted pack dynamics and facilitated coyote introgression (Rutledge et al., 2010, 2011). Following restrictions on hunting in areas surrounding the park, the social dynamics of the population were restored and introgression became less frequent. Reducing manipulation, especially pack disruption, would reveal whether red wolves are capable of maintaining their genetic profile as eastern wolves have. Decisions regarding the future of red wolf management must account for the fact that human activity can facilitate hybridization and in turn impacts our interpretation of the relationship of this species to other canids.

Acknowledgements

Funding for this project was provided by the US Fish and Wildlife Service Red Wolf Recovery Team. We thank J. Adams and members of the USFWS Red Wolf Recovery Team for providing much needed information regarding the history of these animals. A. Beyer compiled the data regarding the history of wolves involved in hybrid events. The Waits Lab and three anonymous peer reviewers provided constructive comments that greatly improved the manuscript. We declare no competing interests in the publication of this manuscript.

Mattamuskeet Ventures coyote removal records

Oct, 2018

01) Date 10/02/2018

Sex: Female

Hock measurement – 8 ¾ inches

Tail measurement – 12 ¼ inches

GPS location: N

Hair Sample: Yes

Tooth: yes

Reporting number – CKR - 00053

02) Date 10/04/2018

Sex – Male

Hock Measurement: 7 ¾

Tail measurement: 15 ½

GPS Location: N35. 34’ 42.6” – W 076. 03’ 54.3”

Hair sample - yes

Tooth: yes

Reporting number – CKR - 00054

03) 10/06/2018

Sex – Female

Hock Measurement: 8 ¼”

Tail Measurement: 14”

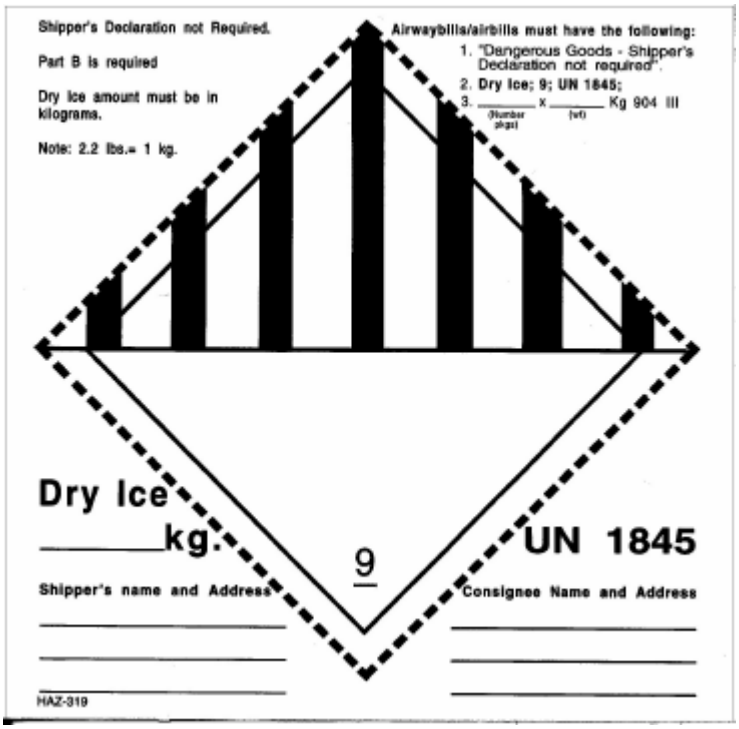
GPS Location: N 35.35.19.1 – W 76.07.12.1

Hair Sample – yes

Tooth: Yes

Reporting number – CKR - 00055

Fecal collection protocol for microbiome analysis



Frequency: 1 time in either October, November or December

Protocol

1. Collect fresh fecal sample (~50g); golf ball size) in a sterile manner within one hour of defecation
2. Place in clean ziplock bag or falcon tube.
3. Record the studbook number, sex, collection date, institution on the bag or tube. Also please write “MICROBE” on the bag or tube as well.
4. Keep samples in -20C until shipped to SCBI. Avoid using any freezers that have a freeze-thaw cycle.
5. To ship samples please put the samples in a Styrofoam-lined box with dry ice (see label below) . Samples should be sent early in the week (Mon. – Wed.) to avoid weekend delivery. Please put “red wolf” as the reference on shipping label.

   Dr. Nucharin Songsasen
   Smithsonian Conservation Biology Institute
   1500 Remount Road
   Front Royal, VA 22630
   Tel: 540-635-0030

6. Contact Morgan, mbragg2@masonlive.gmu.edu, when samples are ready to be sent out so I can give the FedEx account number.

Joe's General Comments (others in the email to Pete and in the document)

- What is their plan if they catch a red wolf that already has a collar?

- What is the actual authority of NCWRC currently to capture, process and "harass" red wolves? Are they already legally permitted to do that?

- The document contains too many assumptions of our management, particularly going into the future when that has not been determined yet.

- No euthanasia decisions should be made without FWS staff involvement.

- Concerns over active monitoring red wolf dens with cameras and repeated visits to dens.

- Concerns that it proposes that red wolf carcasses would not be sent to USFWS labs.

- Project personnel summaries do not indicate any trapping experience.

- Significant Federal funding – All Section 6?

- Why limited to just 3 of the 5 NEP counties?

- David's subsequent email concerns me regarding them not seeing Ryan or Michael involved much and believing this proposal actually "dovetails" with our work.

Ryan's Comments (notated in document)

Page 2; 51: Maybe a short discussion on specifically what types of property damage is being referred to here? There are very few livestock operations on the AP, so depredation rates on livestock is relatively low. Wolves have been involved in very few depredation incidents over the years, and I'm not sure what other types of property damage sympatric canids would potentially cause? Most of the complaints we receive tend to be simple presence of canids on private property or a perceived reduction in observed game populations, which of course are not property.

Page 2; 54-55: Has there been any research done to analyze direct predation of canids on at risk ground nesting species as compared to potential benefits of canids through the control of other known nest predators?

Page 2; 57-59: In addition to collaborative research, the joint memorandum also instructs NCWRC to "review and evaluate statutory requirements for listing red wolves as state threatened in the five AP counties", to "evaluate, and if appropriate implement, adaptive approaches to regulate the take of coyotes that may result in incidental take of red wolves", and to "evaluate the status, management, and regulation of Controlled Fox Hunting Preserves". Just out of curiosity, what is the current status of these regulatory directives?

Page 3; 86-89: As part of the justification for this research the proposal states "Earlier research focused on many of the same objectives we suggest investigating here, but during a time of intense, active

management. Specific management techniques are no longer being carried out and dynamics between sympatric canids are expected to have changed substantially."

Should specify what dynamics are expected to have changed. I would contend that management and the resulting dynamics on ARNWR, and Milltail particularly, have not changed significantly at all. This pack recently had similar GPS-collar based data gathered by DOT a few years ago, and I don't feel much if anything would be gained by replicating this research. We should continue to use our own VHF radio collars on the Milltail pack as the battery life lasts much longer and we can continue to monitor them as we always have, and not have to subject them to the frequent trapping for recapture and subsequent handling and processing outlined by this proposal. The joint memorandum from 2013 states that any research conducted should "promote the conservation and recovery of the red wolf and other canids on the AP." In the case of the Milltail pack especially, I think the potential risks far outweigh any potential benefits gained.

Page 4; 102-103: What information will be passed to whom specifically? I'm not sure it would be in the best interest of red wolf recovery if location information were to fall into the wrong hands.

Page 5; 132-136: This may be based on a false assumption as it is my understanding that the "federal lands only" alternative was not supposed to be our proposed alternative without first going through the NEPA process, which we are doing now. We don't yet know what the proposed alternative is going to be.

Page 6; 157: If "the most important requirement for SCR is the number of collared individuals" as stated, there is no need to initially focus trapping efforts in areas of known red wolf packs. Coyotes tend to utilize smaller home ranges than do wolves, and therefore would likely populate a particular area in higher numbers than wolves. In that sense, a greater number of collared animals may well be achieved outside of areas of known red wolf packs as long as trapping was conducted in productive habitat. Also, the premise of this proposed research is to target sympatric canids and not specifically target either species. It therefore seems contradictory and biased to initially target known red wolf packs through trapping efforts. I would suggest instead focusing on areas that known wolf packs have occupied in the past but now, due to mortality and lack of management over the last few years, the pack no longer exists, leaving an area of unknown species composition (Mattamuskeet Ventures and Texas Plantation Gamelands are good examples). This would assist not only with the proposed research, but would provide an additional programmatic benefit of learning the species composition in current zones of ignorance. Targeting areas with known red wolf packs does not provide the additional benefit of learning species composition of an area (it is already known), and replicates data collection that has already been done. As stated above, I have concerns about targeting areas of known wolf packs, and feel the risks outweigh the potential benefits, especially since there are so few (only 3 known breeding pairs) left on the A.P. We don't need to further jeopardize them.

Page 6; 159-161: We typically wait until January to trap areas with potential red wolf puppies present in order to allow them to grow, minimizing risk of trap injury. Also, February is breeding season for wolves, and it is not a good idea to disrupt known red wolf pairs at this time, especially with the ever-present risk of injury that trapping inherently presents.

Page 6; 162-173: Releases should occur as close as possible to where the animal is trapped to avoid altering behavior and to avoid unnecessary risk to the animal attempting to get back home. This has

been a recurring issue the last two or three years as the WRC has insisted that captured animals be released on ARNWR regardless of where they were captured. These releases need to happen at or near the capture site, even if that land is state owned or private property (with landowner permission), in addition to federal lands. Refuge compatibility could obviously be another issue. Also, the statement "it is most important to be able to trap and release on Alligator River NWR and the Dare County Bombing Range as those encompass the newly proposed RWRP recovery area" is based on an inaccurate premise as we have not selected a preferred alternative yet so we have no official proposed recovery area.

Page 7; 182: Are traps staked or are drags used? Both can work but appropriate equipment must be used to avoid stakes being pulled out of the ground, which often leads to the death of the captured animal. Make sure appropriate shock springs and swivels are used as well to minimize injury potential. An additional thought – make sure all trappers have secure kennels to place animals in while waiting for processing to occur. It is best to remove a captured animal from a trap as soon as possible to minimize potential injury, overheating, and escape, so have the trappers place the animals in a secure kennel right away. You'd be surprised at some of the flimsy wire cages some of them carry for this purpose. Others have used duct tape on the legs and muzzle – obviously not a good idea. Have a protocol in place for this.

Page 7; 187-190: Traps should also be covered or rendered inoperable during a hard freeze. A leg-hold trap cuts off blood circulation to the foot and can lead to frozen tissue during a hard freeze. This can lead to amputated toes and even feet.

Page 8; 215-219: We already have a protocol in place for chemical immobilization of red wolves developed by NCSU Vet school. We have used it for decades now on wolves and coyotes and there is no need to change it. Also, a syringe pole is not necessary. Simply restrain the head with a noose pole and inject with a regular syringe.

Page 9; 250-254: USFWS needs to be notified any time a red wolf is captured, injured or not, and should make the decision as to whether injuries are sufficient to euthanize the animal.

Page 9; 256-257: Red wolves absolutely should be vaccinated upon capture and treated for any diseases or illnesses present. I would recommend vaccinating coyotes before release as well. Remember the stipulation for collaborative research in the 2013 joint memorandum, that research identified should "promote the conservation and recovery of the red wolf and other canids on the AP." The wild red wolf population is far too small to be taking any unnecessary risks.

Page 10; 276-282: These animals do not automatically need to be euthanized, especially red wolves. The proposed research protocol already requires that any potential handler be vaccinated for rabies. Also, any previously captured wolf or coyote on the A.P. has already been vaccinated for rabies and other canid diseases. Animals can be quarantined for a period of time but euthanasia is not necessary.

Page 11; 298-310: Why are ear tags necessary? I would think a GPS collar that emits a VHF signal plus a PIT tag would be sufficient for identification. Also, we should use Trovan PIT tags to remain consistent with the ones already deployed on the A.P. Speaking of which, it would make more sense to use a radio-collar frequency range consistent with what is already deployed on the A.P. Not having the right set of gear when needed, or having to constantly switch between two separate sets of gear will prove to be problematic .

Page 11; 311-315: Skin biopsies are also not necessary. Genetic information can be collected from blood samples and sent to Lisette as proposed, and as we have always done. There is a protocol already in place for this.

Page 12; 332-335: Animals showing signs of mange should be held and treated for mange before release to avoid spreading it to surrounding canid population, particularly red wolves. Again, conservation of the species needs to be priority number one.

Page 12; 336-340: In the event of overheating, priority must be cooling/ensuring survival of the animal. After that assess any injuries, radio-collar, draw blood. Then weights, measurements, etc.

Page 13; 354-355: In regards to the VHF signal, we really need to continue using the 164-165 mHz frequency range already being used for canids on the A.P. While regular GPS locations may be sufficient for research purposes, there is often a need for RWRP personnel to be able to track canids in real time (depredations and other complaints, reports of injuries, den locations, telemetry flights, etc.) It is not practical to carry two separate sets of telemetry gear at all times (especially when thick vegetation or when walking long distances), or to gear aircraft with two sets of antennas, or to constantly have to switch between two sets of gear when time is a factor. There are many field-based scenarios where utilizing two sets of gear would be problematic at best. Previous researchers (including the ones cited in this proposal) utilizing VHF or GPS collars on canids for data collection within the red wolf recovery area have always used frequencies consistent with ours to help alleviate these problems.

Page 13; 358: I would set the VHF beacon to operate beyond 1600 hours daily. You occasionally run into situations (depredations or complaints for example) that require the need to track animals in real time beyond 1600 hours. Ours are set on 12 hour rotations – 0700 to 1900 (0800 to 2000 during daylight savings).

Page 14; 378: A flight every 30 days is not going to be enough to determine cause of mortality should the GPS function fail. We already fly between 50 and 100 times a year to monitor red wolves, I'm not sure an additional 12 is going to benefit anything.

Page 15; 411-412: We already do den work on red wolves. The dens should not be disturbed more than once so any data collected must be in conjunction with USFWS. With fewer than 25 red wolves currently known to exist in the wild, the survival of each and every pup is vital, so no unnecessary risks will be taken. Time spent at the den must be minimal to minimize the disturbance. Skin biopsies are not necessary. We collect a blood sample for genetics and that should suffice. I'm not sure if morphometric measurements are necessary but if done it must be completed quickly. PIT tags are implanted for future identification. We use Trovan and would prefer to keep this consistent with the canids already on the A.P.

Page 15; 413-432: Cameras at a red wolf den site are a bad idea. We have attempted the use of them a couple of times in the past. One time it caused a visible disturbance when the adults returned, and the other time it resulted in puppy deaths when the female would not re-enter the den. Again, each and every red wolf pup is vital. If attempts want to be made to experiment with cameras at den sites, use them at coyote dens but not wolf dens, at least until more is known about potential disturbance (2 to 5 meters is likely too close). Another issue with these cameras is that wolves, and likely coyotes as well, will typically move the pups to a new den site very soon after a disturbance. In the type of habitat found

on the A.P., den sites are usually located in vegetation so thick cameras may be ineffective, and any human visit to the site is going to cause an unavoidable disturbance.

Page 16; 435: Red wolf carcasses go to the lab in Madison, WI as they always have. LE cases go to Asheland, OR. Coyotes can go to SCWDS.

Page 16; 436-442: We notify LE after every red wolf mortality. They decide if it will become an LE case and if they need to take possession of the animal. LE also probably won't allow genetic samples to be taken from animals they need to take possession of for evidence.

Aside from the specific concerns addressed above, I am also concerned by the overall scope of this proposal. I would prefer to see a research proposal more limited in scope with a clearer objective (for example, an analysis or quantification of predator/prey relationships on the A.P. would be beneficial), and to use equipment and protocols consistent with equipment and protocols already in place on the A.P. Sympatric canids should be targeted in current zones of ignorance (which is now the majority of the A.P.) instead of targeting known wolf packs.

If this proposal were carried out as written, it would effectively hand control and management of the red wolf program at the field level to the WRC. WRC plans to collar 25 "sympatric canids", and initially target known red wolf packs with their trapping efforts. There are only 23 known red wolves currently on the A.P. If they were to successfully radio-collar the majority of those wolves with collars emitting their own frequency range, it would severely limit our ability to monitor and manage this population. They also propose doing their own den work, using their own labs for necropsies, using separate protocols for data collection, etc. All this is concerning on two fronts. First, it is our (USFWS) legal mandate to manage and recover this federally listed species on the landscape. We do not turn over management to a state agency until the species is recovered to the point where federal protections are no longer needed. Second, the WRC has made it clear that their objective is to eradicate this species from the state of North Carolina. Turning monitoring and field management over to the WRC likely would not bode well for the recovery of this species.

While I think it is preferable in theory for the two agencies to collaboratively conserve and manage red wolves and other canids on the A.P., it is problematic when their respective objectives are polar opposites of one another. It is quite clear now, after exhaustive and repetitive reviews on the taxonomy and historical range of the red wolf, that the best available science indicates that this is indeed a valid listable species native to northeast NC. If the two agencies are to realistically work towards the conservation and management of canids on the A.P., the WRC needs to, at minimum, rescind their resolution requesting that red wolves be removed from the state of NC and declared extinct in the wild, and move towards listing the red wolf as a state listed threatened species. Then, in addition to collaborative research, we can explore joint regulatory efforts to reduce anthropogenic causes of red wolf mortality, take steps to minimize hybridization and control the coyote population as necessary, and collaboratively manage and recover red wolves on the A.P. Until then I am not comfortable handing over this level of monitoring and management of red wolves on the A.P. to WRC.

Joe's General Comments (others in the email to Pete and in the document)

- What is their plan if they catch a red wolf that already has a collar?

- What is the actual authority of NCWRC currently to capture, process and "harass" red wolves? Are they already legally permitted to do that?

- The document contains too many assumptions of our management, particularly going into the future when that has not been determined yet.

- No euthanasia decisions should be made without FWS staff involvement.

- Concerns over active monitoring red wolf dens with cameras and repeated visits to dens.

- Concerns that it proposes that red wolf carcasses would not be sent to USFWS labs.

- Project personnel summaries do not indicate any trapping experience.

- Significant Federal funding – All Section 6?

- Why limited to just 3 of the 5 NEP counties?

- David's subsequent email concerns me regarding them not seeing Ryan or Michael involved much and believing this proposal actually "dovetails" with our work.

Ryan's Comments (notated in document)

Page 2; 51: Maybe a short discussion on specifically what types of property damage is being referred to here? There are very few livestock operations on the AP, so depredation rates on livestock is relatively low. Wolves have been involved in very few depredation incidents over the years, and I'm not sure what other types of property damage sympatric canids would potentially cause? Most of the complaints we receive tend to be simple presence of canids on private property or a perceived reduction in observed game populations, which of course are not property.

Page 2; 54-55: Has there been any research done to analyze direct predation of canids on at risk ground nesting species as compared to potential benefits of canids through the control of other known nest predators?

Page 2; 57-59: In addition to collaborative research, the joint memorandum also instructs NCWRC to "review and evaluate statutory requirements for listing red wolves as state threatened in the five AP counties", to "evaluate, and if appropriate implement, adaptive approaches to regulate the take of coyotes that may result in incidental take of red wolves", and to "evaluate the status, management, and regulation of Controlled Fox Hunting Preserves". Just out of curiosity, what is the current status of these regulatory directives?

Page 3; 86-89: As part of the justification for this research the proposal states "Earlier research focused on many of the same objectives we suggest investigating here, but during a time of intense, active

management. Specific management techniques are no longer being carried out and dynamics between sympatric canids are expected to have changed substantially."

Should specify what dynamics are expected to have changed. I would contend that management and the resulting dynamics on ARNWR, and Milltail particularly, have not changed significantly at all. This pack recently had similar GPS-collar based data gathered by DOT a few years ago, and I don't feel much if anything would be gained by replicating this research. We should continue to use our own VHF radio collars on the Milltail pack as the battery life lasts much longer and we can continue to monitor them as we always have, and not have to subject them to the frequent trapping for recapture and subsequent handling and processing outlined by this proposal. The joint memorandum from 2013 states that any research conducted should "promote the conservation and recovery of the red wolf and other canids on the AP." In the case of the Milltail pack especially, I think the potential risks far outweigh any potential benefits gained.

Page 4; 102-103: What information will be passed to whom specifically? I'm not sure it would be in the best interest of red wolf recovery if location information were to fall into the wrong hands.

Page 5; 132-136: This may be based on a false assumption as it is my understanding that the "federal lands only" alternative was not supposed to be our proposed alternative without first going through the NEPA process, which we are doing now. We don't yet know what the proposed alternative is going to be.

Page 6; 157: If "the most important requirement for SCR is the number of collared individuals" as stated, there is no need to initially focus trapping efforts in areas of known red wolf packs. Coyotes tend to utilize smaller home ranges than do wolves, and therefore would likely populate a particular area in higher numbers than wolves. In that sense, a greater number of collared animals may well be achieved outside of areas of known red wolf packs as long as trapping was conducted in productive habitat. Also, the premise of this proposed research is to target sympatric canids and not specifically target either species. It therefore seems contradictory and biased to initially target known red wolf packs through trapping efforts. I would suggest instead focusing on areas that known wolf packs have occupied in the past but now, due to mortality and lack of management over the last few years, the pack no longer exists, leaving an area of unknown species composition (Mattamuskeet Ventures and Texas Plantation Gamelands are good examples). This would assist not only with the proposed research, but would provide an additional programmatic benefit of learning the species composition in current zones of ignorance. Targeting areas with known red wolf packs does not provide the additional benefit of learning species composition of an area (it is already known), and replicates data collection that has already been done. As stated above, I have concerns about targeting areas of known wolf packs, and feel the risks outweigh the potential benefits, especially since there are so few (only 3 known breeding pairs) left on the A.P. We don't need to further jeopardize them.

Page 6; 159-161: We typically wait until January to trap areas with potential red wolf puppies present in order to allow them to grow, minimizing risk of trap injury. Also, February is breeding season for wolves, and it is not a good idea to disrupt known red wolf pairs at this time, especially with the ever-present risk of injury that trapping inherently presents.

Page 6; 162-173: Releases should occur as close as possible to where the animal is trapped to avoid altering behavior and to avoid unnecessary risk to the animal attempting to get back home. This has

been a recurring issue the last two or three years as the WRC has insisted that captured animals be released on ARNWR regardless of where they were captured. These releases need to happen at or near the capture site, even if that land is state owned or private property (with landowner permission), in addition to federal lands. Refuge compatibility could obviously be another issue. Also, the statement "it is most important to be able to trap and release on Alligator River NWR and the Dare County Bombing Range as those encompass the newly proposed RWRP recovery area" is based on an inaccurate premise as we have not selected a preferred alternative yet so we have no official proposed recovery area.

Page 7; 182: Are traps staked or are drags used? Both can work but appropriate equipment must be used to avoid stakes being pulled out of the ground, which often leads to the death of the captured animal. Make sure appropriate shock springs and swivels are used as well to minimize injury potential. An additional thought – make sure all trappers have secure kennels to place animals in while waiting for processing to occur. It is best to remove a captured animal from a trap as soon as possible to minimize potential injury, overheating, and escape, so have the trappers place the animals in a secure kennel right away. You'd be surprised at some of the flimsy wire cages some of them carry for this purpose. Others have used duct tape on the legs and muzzle – obviously not a good idea. Have a protocol in place for this.

Page 7; 187-190: Traps should also be covered or rendered inoperable during a hard freeze. A leg-hold trap cuts off blood circulation to the foot and can lead to frozen tissue during a hard freeze. This can lead to amputated toes and even feet.

Page 8; 215-219: We already have a protocol in place for chemical immobilization of red wolves developed by NCSU Vet school. We have used it for decades now on wolves and coyotes and there is no need to change it. Also, a syringe pole is not necessary. Simply restrain the head with a noose pole and inject with a regular syringe.

Page 9; 250-254: USFWS needs to be notified any time a red wolf is captured, injured or not, and should make the decision as to whether injuries are sufficient to euthanize the animal.

Page 9; 256-257: Red wolves absolutely should be vaccinated upon capture and treated for any diseases or illnesses present. I would recommend vaccinating coyotes before release as well. Remember the stipulation for collaborative research in the 2013 joint memorandum, that research identified should "promote the conservation and recovery of the red wolf and other canids on the AP." The wild red wolf population is far too small to be taking any unnecessary risks.

Page 10; 276-282: These animals do not automatically need to be euthanized, especially red wolves. The proposed research protocol already requires that any potential handler be vaccinated for rabies. Also, any previously captured wolf or coyote on the A.P. has already been vaccinated for rabies and other canid diseases. Animals can be quarantined for a period of time but euthanasia is not necessary.

Page 11; 298-310: Why are ear tags necessary? I would think a GPS collar that emits a VHF signal plus a PIT tag would be sufficient for identification. Also, we should use Trovan PIT tags to remain consistent with the ones already deployed on the A.P. Speaking of which, it would make more sense to use a radio-collar frequency range consistent with what is already deployed on the A.P. Not having the right set of gear when needed, or having to constantly switch between two separate sets of gear will prove to be problematic .

Page 11; 311-315: Skin biopsies are also not necessary. Genetic information can be collected from blood samples and sent to Lisette as proposed, and as we have always done. There is a protocol already in place for this.

Page 12; 332-335: Animals showing signs of mange should be held and treated for mange before release to avoid spreading it to surrounding canid population, particularly red wolves. Again, conservation of the species needs to be priority number one.

Page 12; 336-340: In the event of overheating, priority must be cooling/ensuring survival of the animal. After that assess any injuries, radio-collar, draw blood. Then weights, measurements, etc.

Page 13; 354-355: In regards to the VHF signal, we really need to continue using the 164-165 mHz frequency range already being used for canids on the A.P. While regular GPS locations may be sufficient for research purposes, there is often a need for RWRP personnel to be able to track canids in real time (depredations and other complaints, reports of injuries, den locations, telemetry flights, etc.) It is not practical to carry two separate sets of telemetry gear at all times (especially when thick vegetation or when walking long distances), or to gear aircraft with two sets of antennas, or to constantly have to switch between two sets of gear when time is a factor. There are many field-based scenarios where utilizing two sets of gear would be problematic at best. Previous researchers (including the ones cited in this proposal) utilizing VHF or GPS collars on canids for data collection within the red wolf recovery area have always used frequencies consistent with ours to help alleviate these problems.

Page 13; 358: I would set the VHF beacon to operate beyond 1600 hours daily. You occasionally run into situations (depredations or complaints for example) that require the need to track animals in real time beyond 1600 hours. Ours are set on 12 hour rotations – 0700 to 1900 (0800 to 2000 during daylight savings).

Page 14; 378: A flight every 30 days is not going to be enough to determine cause of mortality should the GPS function fail. We already fly between 50 and 100 times a year to monitor red wolves, I'm not sure an additional 12 is going to benefit anything.

Page 15; 411-412: We already do den work on red wolves. The dens should not be disturbed more than once so any data collected must be in conjunction with USFWS. 16. Abstract

We used data from 16 red wolves fitted with GPS-collars between January 2009 and April 2011 to evaluate home range size and habitat selection, road permeability, and identify significant red wolf highway crossing locations. Home range size for red wolves averaged 13.7 mi^2 with no significant difference between males and females. Although we found no significant difference in home range size among age classes, dispersers tended to have larger home ranges than adults and juveniles. Red wolf home ranges were larger during winter than during other seasons. Red wolves avoided wetter habitats such as pocosins, wetlands, and lowland forests, leaving agriculture the best predictor of red wolf presence. Red wolves also selected for the presence of agriculture/forest road systems for travel. Road permeability, calculated using GPS-collar data, was 100%, thus the current 2-lane highway does not impose a barrier effect on the red wolf population. This increases the risk of road mortality events. Using a 3281 ft. (1 km) buffer, construction north of the current US 64 in Tyrrell County has the potential to remove up to 0.16 mi^2 of red wolf habitat and 6% of the home range area used by a current red wolf pack while construction to the south will impact only 0.09 mi^2 of red wolf habitat and will not displace any current red wolf packs. East of Alligator River in Dare County, a widening of the current highway to the south has the potential to remove up to of 0.07 mi^2 of red wolf habitat and 20% of the home range used by the only existing red wolf pack in Alligator River National Wildlife Refuge if construction disturbs out to 3281 ft. (1 km) from the current road. Construction to the north of US 64 in Dare County has the potential to remove up to 0.04 mi^2 of red wolf habitat and will not overlap with any current packs, based on 95% home ranges. Through the use of GPS-collars and remote camera traps, we identified 5 important red wolf crossing locations, 4 in Tyrrell County west of Alligator River and 1 in Dare County east of Alligator River. The presence of agricultural fields, successional fields, and/or upland forests 328 to 492 ft. from the road provided the most parsimonious explanation for the location of crossing sites identified using GPS-collar locations; trail/road width provided the best explanation for the location of crossing sites identified by remote camera traps. The presence of agricultural fields, successional fields, and upland forests as well as proximity to maintained agricultural/forest roads at crossing sites corresponds to habitat selection results. Four of the 5 red wolf crossing locations we identified are suitable for crossing structures. The most western crossing site is located within the town of Colombia, NC where retro-fitting a wildlife underpass is not practical. Well maintained trails at least 26.24 ft. (8 m) in width leading to and from underpasses, which connect habitats selected for by red wolves (e.g. agriculture, successional fields, and upland forests), is suggested to optimize efficacy.

Acknowledgements

Thank you to the North Carolina Department of Transportation for providing the necessary funding to complete this project. We would like to offer a special thank you to Anne Burroughs and John Kirby, North Carolina Department of Transportation, for their guidance, input, and support throughout this project. Our gratitude is also extended to Mike Bryant, Scott Lanier, Dennis Stewart, Colleen Olfenbuttel, and the entire Red Wolf Recovery Team (David Rabon, Art Beyer, Chris Lucash, Ford Mauney, Michael Morse, and Ryan Nordsven). Their input, support, and field assistance was invaluable to the success of this project. Our appreciation is also extended to all of the field and lab technicians for their tireless efforts: Thomas Esson, J. Bernardo Mesa, Jacob Humm, David Drewett, Casey Carbaugh, Rebecca Landis, John Vanek, Jaya Kannan, Chris Haggard, Bryan Will, and Rebecca Fraenkel. This research would not have been possible without their assistance. We would like to acknowledge Justin Dellinger at Auburn University for his statistical expertise and assistance in evaluating habitat data.

Executive Summary

Information reported here is the result of a 2-year study evaluating red wolf (*Canis rufus*) habitat use and crossing patterns along US 64 from Columbia, NC east to the 64/264 intersection in Manns Harbor, NC. This report includes a problem statement and background information, evaluation of red wolf home range size and habitat selection, an analysis of probable effects to red wolf home range and habitat availability in the event of a highway widening, identification of current red wolf crossing locations, and suggestions for the location and type of crossing structures to mitigate potential adverse effects of a highway widening of US 64.

We used data from 16 red wolves fitted with GPS-collars between January 2009 and April 2011 to evaluate home range size and habitat selection. Home range size for red wolves averaged 13.7 mi^2 with no significant difference between males and females. Although we found no significant difference in home range size among age classes, dispersers tended to have larger home ranges than adults and juveniles. Red wolf home ranges were larger during winter than during other seasons. Red wolves avoided wetter habitats such as pocosins, wetlands, and lowland forests, leaving agriculture the best predictor of red wolf presence. Red wolves also selected for the presence of agriculture/forest road systems for travel.

Road permeability, calculated using GPS-collar data, was 100%, thus the current 2-lane highway does not impose a barrier effect on the red wolf population. This increases the risk of road mortality events. A decrease in the red wolf population to the west of Columbia, NC, prevented collaring of red wolves where widening to a 4-lane highway was completed. Therefore, we were not able to compare highway permeability between 2- and 4-lane highways. Using a 3281 ft. (1 km) buffer, construction north of the current US 64 in Tyrrell County has the potential to remove up to 0.16 mi^2 of red wolf habitat and 6% of the home range area used by a current red wolf pack while construction to the south will impact only 0.09 mi^2 of red wolf habitat and will not displace any current red wolf packs. East of Alligator River in Dare County, a widening of the current highway to the south has the potential to remove up to of 0.07 mi^2 of red wolf habitat and 20% of the home range used by the only existing red wolf pack in Alligator River National Wildlife Refuge if construction disturbs out to 3281 ft. (1 km) from the current road. Construction to the north of US 64 in Dare County has the potential to remove up to 0.04 mi^2 of red wolf habitat and will not overlap with any current packs, based on 95% home ranges.

Through the use of GPS-collars and remote camera traps, we identified 5 important red wolf crossing locations, 4 in Tyrrell County west of Alligator River and 1 in Dare County east of Alligator River. The presence of agricultural fields, successional fields, and/or upland forests 328 to 492 ft. from the road provided the most parsimonious explanation for the location of crossing sites identified using GPS-collar locations; trail/road width provided the best explanation for the location of crossing sites identified by remote camera traps. The presence of agricultural fields, successional fields, and upland forests as well as proximity to maintained agricultural/forest roads at crossing sites corresponds to habitat selection results.

Four of the 5 red wolf crossing locations we identified are suitable for crossing structures. The most western crossing site is located within the town of Colombia, NC where retro-fitting a wildlife underpass is not practical. Well maintained trails at least 26.24 ft. (8 m) in width leading to and from underpasses, which connect habitats selected for by red wolves (e.g. agriculture, successional fields, and upland forests), is suggested to optimize efficacy.
Detailed results and discussion are provided in the report below.

Evaluating potential effects of widening US 64 on red wolves in Washington, Tyrrell, and Dare Counties, North Carolina

Final Report

Principal Investigators:
Michael R Vaughan, PhD and Marcella J Kelly, PhD

Introduction

Roads have profound effects, both direct and indirect, on natural ecosystems (see reviews by Forman et al. 2003 and Coffin, 2007). Forman and Alexander (1998) estimated that the approximately 10.9 million hectares of public roads in the US and their related habitat loss and degradation has affected >20% of land area in the United States. In a 43-year period (1960 – 2003), the number of registered cars increased from 74 to 231 million nation-wide and the annual distance traveled by car in the US grew from approximately 720,000 to 2.8 million miles (Ouren and Watts, 2005). As transportation needs increase, a rise in the amount of habitat lost and degraded due to road construction can be expected. Indeed, the link between economic development and transportation expansion was well documented by the mid 1960's (Kansky, 1963; Taaffe et al., 1963; Haggett 1965). Such large-scale and multifaceted changes to ecosystems have many detrimental impacts on wildlife (Jackson, 1999), including direct mortality (Lalo, 1987; Harris and Scheck, 1991; Schwabe and Schuhmann, 2002), habitat destruction (Theobald et al., 1997; Angelsen and Kaimowitz, 1999), barrier effects (Forman et al, 2003), and increased human land use activities (Bjurlin and Cypher, 2003; Coffin, 2007).

There is perhaps no other human impact as transportation infrastructure whose far-reaching, cumulative effects on wildlife are so devastating and demanding of attention, yet so commonly underestimated. Direct wildlife mortality results from construction injury and vehicular collisions (Trombulak and Frissell, 2000) and has now surpassed hunting as the leading direct human cause of vetebrate mortality on land (Forman and Alexander, 1998), with an estimated 720,000 to 1.5-million deer-vehicle crashes reported annually (Conover et al., 1995; Forman et al., 2003). While the number of common species killed along roads is staggering, in most cases road mortality of wildlife does not translate into population level effect. However, road related impacts to threatened and endangered species are of particular concern. Road kill is the primary cause of mortality in Florida for Florida panthers, black bears, key deer, and crocodiles (Harris and Scheck, 1991) and accounts for a high percentage of deaths in Iberian lynx (Ferreras et al., 1992). In addition, road impacts have been found in gray wolves (Thiel, 1985; Paquet and Callaghan, 1996), desert tortoises (Boarman, 1996), and some populations of San Joaquin kit foxes (Bjurlin and Cypher, 2003). For the declining copperbelly water snake in Indiana, road mortality accounts for approximately 17% of all deaths (Roe et. al, 2006). Road mortality was the second highest cause of death for red wolves in North Carolina within the 5 county recovery zone between 1999 and 2006, accounting for 14% of mortality overall (USFWS, 2007). When broken down by age class, vehicle strikes were the leading cause of death in dispersing red

wolves, accounting for 19% of mortality (USFWS, 2007). The increasing incidence of wildlife-vehicle collisions also presents a real issue for humans, as they claim hundreds of lives, cause tens of thousands of injuries, and inflict an enormous monetary cost for medical treatment and vehicle repair each year nationwide (Forman et al., 2003). For example, in 1993 1.5 million deer-vehicle crashes were reported in the US leading to $1.1 billion in vehicle damages (Durbin, 2004). Deer-vehicle collisions have been reported to cause 29,000 human injuries and claim 211 lives (Conover et al., 1995).

Beyond direct mortality, roads can negatively affect wildlife populations by degrading habitat quality (Theobald et al., 1997; Carr et al., 2002), fragmenting habitat and populations (Oxley et al., 1974; Trombulak and Frissell, 2000; Nellermann et al., 2001), hindering gene flow (Gerlach and Musolf, 2000; Epps et al., 2005; Riley et al., 2006), skewing sex ratios (Gibbs and Steen, 2005), and limiting dispersal (Beier, 1995). Most roads exhibit a distinct trade-off between permeability and road kill (Forman and Alexander, 1998). A highly permeable road might result in a high level of wildlife/vehicular collisions, whereas an impermeable road might have few road kill events. Yet this decrease in road kill comes at the expense of habitat connectivity. As individuals lose their mobility and gene flow is reduced, portions of the population become isolated. In the event of local extinction due to some stochastic event, fragmentation can make recolonization of previously-occupied habitat impossible (Theobald et al., 1997). These affects are of particular concern in small populations. Small populations have an increased risk of extinction due to demographic stochasticity, decreased heterozygosity, genetic drift, inbreeding, and low effective population size (Caughley, 1994), all of which can be exacerbated though road construction and expansion-related barrier effects. Social organization may also be affected by spatial change leading to population instability (Krausman et al., 2004).

Low population densities and large home ranges make carnivores particularly vulnerable to the effects of habitat fragmentation by roads (Whittington et al., 2005). A highway was found to restrict gene flow in a Cleveland, Ohio coyote population and direct the movements of migrants towards urbanizing centers (Rashleigh et al., 2008). Riley et al. (2006) found that coyote and bobcat populations in southern California separated by a major freeway exhibited genetic differentiation, suggesting that the freeway is a barrier to dispersal. Even when they do not constitute an absolute physical barrier, high-use roads can lead to avoidance behavior in canids affecting their ability to move across a landscape (Kaartinen et al., 2005, Paquet and Callaghan, 1996, Whittington et al., 2004). For those that do cross, heightened territorial behavior along roadways can discourage reproductive success, again limiting gene flow (Riley et al., 2006). The degree to which a road affects canid survival is dependent on the specific situation, and sometimes no detrimental effects are observed, as is the case with a California population of San Joaquin kit foxes (Cypher et al., 2009). Some documentation exists regarding wolves in the vicinity of highways. A study tracking gray wolf dispersal in Minnesota found that wolves were willing to cross major highways to colonize areas in Wisconsin and Michigan (Mech et al., 1995). For gray wolves (*Canis lupus*), a 4-lane unfenced highway in Wisconsin seemed to not influence wolf movements (Kohn et al., 1999). In contrast, a 4-lane fenced highway in Banff National Park in Alberta, Canada, appears to hinder wolf movements (Paquet and Callaghan, 1996), although crossing structures mitigated its barrier effect to some degree (Clevenger and Waltho, 2000, 2005). In Spain, wolves whose home ranges were greater than 5 km from the highway crossed a 4-lane, fenced highway via vehicle bridges (Blanco et al., 2005), however

those living in close proximity to the highway (<5 km) crossed the highway only after severe habitat disturbance. Gray wolves in Canada and Spain seem to prefer large, open wildlife overpasses (Forman et al., 2003). In general, a large void exists in addressing factors that affect how large carnivores use passages. Major transportation corridors bisect and potentially fragment most of the major ecosystems that still support wide-ranging carnivores. Increased concerns expressed by transportation and natural resources agencies regarding mitigation planning for large carnivores highlight the need for more information and research in this area (Forman et al., 2003).

The use of wildlife crossing structures can mitigate some of the negative effects associated with highways (Forman and Alexander, 1998). The appropriate type of crossing structure to mitigate road effects varies with species (Mata et al., 2008). A study monitoring the success of multi-species highway underpasses following the highway-widening just west of this current study area found that bobcats, black bears, and foxes utilized underpasses (McCollister and van Manen, 2010), however there were no confirmed detections of coyotes or red wolves using the underpasses. Because the red wolf population of both this study and the one cited above is the only wild red wolf population, there does not exist literature on the preference of red wolves for particular crossing structures. However several studies have found that while gray wolves will use wide tunnels and underpasses (Clevenger and Waltho, 2000, Kusak et al., 2009), they prefer open overpasses (Forman et al., 2003, Kusak et al., 2009). In Banff, wolves select for taller underpasses close to town (Clevenger and Waltho, 2000). Coyotes on the other hand have been found to use underpasses of a wide variety of sizes, from pipe culverts to wide underpasses, as long as they did not connect developed areas (Ng et al., 2004). Likewise, a study in Virginia found that coyotes readily used a variety of underpasses (Donaldson, 2007). The Wildlife Crossing Structure Handbook published in 2011 by the Federal Highway Administration recommends that underpasses geared towards large mammals (deer, bears, and wolves) and high mobility medium sized mammals (coyote, fox, and likely the category red wolves would be placed) should be greater than 32 ft. in width and greater than 13 ft. in height and that overpasses be at least 50 ft. wide (Clevenger and Huijer, 2011). If designing mitigating structures solely for high mobility medium sized mammals, underpasses and culverts with a diameter of 4ft. have been effective (Clevenger and Huijer, 2011). However, it appears that the structural components of crossing structures play a larger role in determining success for ungulates (Clevenger and Waltho, 2005; Gagnon et al., 2011) while habitat connectivity plays a larger role in the successful use of crossing structures for carnivores (White and Ernst, 2004; Singleton et al., 2005; Riley et al, 2006; Kindall and van Manen, 2007).

Underpasses can function as effective crossing structures for wolves, but high variability in use indicates that consideration of social interactions, placement, construction specifications and distance between crossings is essential for success (Paquet and Callaghan, 1996). Animals do not treat all sections of a roadway indiscriminately, so crossing funnel areas and natural habitat linkages at the landscape level must be identified. White and Ernst (2004), Singleton et al. (2005), and Kindall and van Manen (2007) all stress the need to identify habitat linkages across barriers to properly place crossings. In addition, Roger and Ramp (2009) discuss the importance of species-specific habitat use data in determining roadway impacts. Thus, it is imperative not only that wildlife underpasses be constructed in areas identified as high use for crossings (Scheick and Jones, 1999), but habitat variables at crossing locations be collected as well to

model what landscape factors predict crossings. Often times it is also necessary to install exclusionary fencing in addition to a crossing structure to guide animals to the crossing point and discourage crossing at road-level (Baker, 2005).

Indeed, one study in Portugal found that fencing had a funneling effect, directing larger animals towards culverts (Ascensao and Mira, 2006). Similarly, fencing along a highway reduced elk-vehicle collisions by 97% and other wildlife-vehicle collisions by 64% in Arizona (Gagnon et al., 2010) and likely lead to a decease in white-tailed deer-vehicle collisions in North Carolina (Jones et al., 2010). A study in Germany found that fencing successfully reduced wildcat road mortality by 83% (Klar et al., 20009) and fencing along with culverts lowered wildlife-vehicle collisions by 93.5% in Paynes Prairie State Preserve (Dodd et al., 2004). Ungulate-vehicle collisions were reduced by 80% following the installation of roadside fencing in Banff National Park, Canada (Clevenger et al., 2001). Jaeger and Fahrig (2004) developed a model to look at the trade-off between reductions of road kill and increased barrier effect due to fencing installation. They found that below a certain traffic volume, the barrier effect of fencing is harmful to a population and therefore they only recommend the use of roadside fencing when traffic volume is high (e.g. high risk of road mortality) and the target species does not show behavioral avoidance of roads (Jaeger and Fahrig, 2004). Both Clevenger et al. (2001) and McCollister and van Manen (2010) found that while fencing reduced wildlife-vehicle collisions close to underpasses, wildlife-vehicle collisions increase approaching fence ends. McCollister and van Manen (2010) found that road mortality was higher in fenced highway segments as compared to unfenced segments due to the increased mortality where roadside fencing ends. Therefore, if non-continuous fencing is used, it may be necessary to modify fence ends to direct wildlife away from the highway (Clevenger et al., 2001). Ungulates are the focal species for most studies that successfully demonstrate the effectiveness of roadside fencing. Fencing may be less effective for carnivores as they often go over (e.g. black bears) or under (e.g. coyotes) fencing (Clevenger et al., 2001). Indeed, the use of fencing did not increase culvert use by bobcats in Texas (Cain et al., 2003) and actually lead to an increase in wolf road mortality in Spain (Colino-Rabinal et al., 2011). Burying roadside fencing can help to discourage some species from digging under the fence (Clevenger et al., 2001).

Clearly, an understanding of red wolf activity patterns, movements, and habitat use are all needed in the vicinity of US 64 and across the Albemarle Peninsula. This study assessed red wolf home range, habitat selection, and highway crossing patterns along the US 64 corridor with the use of GPS collars and remote cameras to determine important red wolf habitat and to identify significant red wolf highway crossing locations. In addition, this research examined which landscape attributes promote red wolf use of crossing locations to increase the success of mitigating structures.

Background Information

The North Carolina Department of Transportation (NCDOT) is planning a highway improvement project for US 64 in Tyrrell and Dare Counties North Carolina, which will extend across the full length of the Albemarle Peninsula when completed, separating the northern section of the 5 county (Washington, Tyrrell, Dare, Hyde, and Beaufort counties) red wolf recovery zone. The effects of the highway widening on red wolf recovery and conservation could

be substantial, potentially creating a barrier to movement and gene flow of red wolves and other wildlife from one side of the highway to the other. In addition, the habitat loss associated with a highway widening likely will disrupt red wolves living adjacent to the existing highway causing a shift in current home ranges. Any shifts in home ranges have the potential to affect social order. Even in the absence of a barrier effect, the project may lead to an increase in vehicle related deaths as wolves attempt to cross a wider highway with increased speed limits. In addition, there is a potential to concentrate prey and herbaceous food sources at highway edges, attracting wolves, coyotes, black bears, white-tailed deer and other wildlife, increasing the risk of vehicle collisions. Highway barrier effects, habitat loss, social disruptions, and road mortality resulting from the highway widening may culminate in reduced red wolf population viability.

Problem Need/Definition

Viable populations of wildlife depend, in part, on dispersal to maintain genetic diversity. Whether natural or man-made, barriers to dispersal are of concern to wildlife managers. For restored or recovering populations, potential barriers such as highways or large fenced areas magnify in importance because of their potential to restrict or retard growth and genetic diversity in small wildlife populations. Roads, in particular, recently received attention with respect to large carnivore population dynamics related to increased direct (vehicle collisions) and indirect (changes in behavior that affect food acquisition) mortality (Trombulak and Frissell, 2000). Forced spatial change also may affect area-wide social organization and thus population stability, and increased noise or activity levels may initially affect wildlife behavior (Krausman et al., 2004).

For the past several years the North Carolina Department of Transportation (NCDOT) has been planning a proposed project to widen US 64 from 2 to 4 lanes from Raleigh to Manteo, North Carolina. With respect to the segment of US 64 already widened and elevated between Plymouth and Columbia by 2005, preliminary data collected by the U.S. Fish and Wildlife Service indicates red wolf (*Canis rufus*) movements and gene flow, including dispersal and home range size, may already be restricted by that highway segment. Remaining sections of US 64 planned for widening are the approximate 15.5-mile section from Columbia to Alligator River, and 11.8-mile section that runs through Alligator River National Wildlife Refuge.

The nature of the US 64 widening project calls into question important ecological and regulatory considerations that, together, mean data collection is needed to assist with science-based decisions and project design. Red wolves will be involved in two federal regulatory processes pertinent to widening of US 64, namely, project consultation under Section 7 of the U.S. Endangered Species Act of 1973, and assessment of "refuge compatibility" under the National Wildlife Refuge System Improvement Act of 1997 (Public Law 105-57), along with the National Wildlife Refuge System Administration Act of 1966 (16 U.S.C. 668dd-668ee), as amended. These processes allow cooperation toward achieving a project that takes into account human safety, traffic management, and wildlife concerns that include passage, mortality, large-sized animals, and multiple wildlife refuge values. Refuge considerations include endangered species conservation, waterfowl management, wildlife habitat with associated species, hydrology, wetlands, reptiles and amphibians, public use, fire management, exotic species management, etc.

The effects of US 64 widening on red wolf recovery and conservation could be substantial. Widening US 64 may be accompanied by increased speed limits, and likely will create a barrier to movement of red wolves and other wildlife from one side of the highway to the other. Thus, it is imperative that wildlife crossing structures be constructed in areas identified as high use crossings by red wolves, bears, deer, and other species (Scheick and Jones, 1999). Completed and planned phases of the US 64 widening project extend across the full length of the Albemarle Peninsula, separating and otherwise affecting the entire northern quarter of the 5-county red wolf experimental population area.

Construction of the highway itself most likely will directly disrupt the red wolf population, along with other wildlife populations (e.g., black bear, white-tailed deer) living adjacent to the existing highway during the 1-2 year construction period. These disruptions may cause red wolves to shift out of their current home ranges or territories during the construction phase and move into areas already occupied by other red wolves, causing social disruptions and ripple effects across the Albemarle Peninsula. While the disruption due directly to construction will be short-term, effects on the red wolf population may be long lasting and even permanent. Habitat loss, social disruptions, and ripple effects, as a result of direct, indirect, and cumulative effects of a highway widening, may result in a reduction of the red wolf population, its gene flow, and gene diversity, by some unknown quantity.

Vehicle strike mortality significantly impacts the wild red wolf population on the Albemarle Peninsula in North Carolina (USFWS, 2007). Of 166 known adult red wolf loses since 1999, 23 were killed in vehicle strikes. Vehicle strikes are three times higher in non-breeder (19%) vs. breeder (6%) red wolves in the designated experimental population area. This is partly explained by single red wolves dispersing or roaming over large distances.

Studies are needed to assess how the red wolf population has utilized the area since restoration began. An examination of which landscape attributes promote red wolf use would be helpful, along with a thorough assessment of site-specific habitat availability.

More specifically, the potential problems or benefits examined for red wolves in association with US 64 widening should include the following concerns.

1. Vehicle mortality of red wolves and associated human safety.
2. Reproduction and survival.
3. Considerations of placement of underpasses or overpasses.
4. Changes in red wolf habitat, prey, home range size, dynamics, and associated landscape fragmentation.
5. Effects upon red wolf activity, movements, gene flow, dispersal, territory dynamics, social organization, pack integrity, habitat use, and land occupancy.
6. Ripple effects throughout the red wolf population, across the Albemarle Peninsula.
7. Changes in red wolf numbers pre-project, during project, and post-project.
8. Influences on eastern coyotes, a competitor and threat to red wolves.
9. Effects upon monitoring of red wolves and eastern coyotes.

It is important to understand the effect of canid activity and movements out of or into the experimental area along the expanded highway in western portions of the Albemarle Peninsula. Possible study topics include coyote/red wolf interactions and retrospective examination of adaptability of coyote/hybrids vs. red wolves in the face of significant habitat change and/or significant project construction.

Research Objectives

The objectives of this research project are to:

1. Evaluate wolf habitat use along the entire US 64 corridor from Plymouth to the US 64/264 intersection

2. Evaluate the significance of red wolf habitat changes anticipated from the proposed highway project from Columbia to the US 64/264 intersection in terms of movements, survival, reproduction, home range shifts, and social organization.

3. Identify significant red wolf crossing areas to determine where wildlife crossing structures or other design features could be placed to minimize adverse project effects on red wolves.

Study Area

The only wild population of red wolves occurs on more than 2,567 mi^2 of federal, state, and private lands in 5 counties (Beaufort, Dare, Hyde, Tyrrell, and Washington) in northeastern North Carolina (Figure 1), known as the Red Wolf Recovery Zone (RWRZ). Two of the northern counties within the RWRZ, Tyrrell and Dare Counties, were the focal point of this study because they contain the remaining 27.34 mi of US 64 to be widened. Federal lands within the study area include Pocosin Lakes National Wildlife Refuge, Alligator River National Wildlife Refuge, and a bombing range shared by the Navy and Air Force. State land consists of numerous game management properties, while private lands are primarily made-up of timber plantations, agricultural fields, and a few developed residential and commercial properties.

The most prevalent land cover types within the study area, as identified by the North Carolina Gap database (2009), are agricultural fields (~30%) planted primarily with wheat, corn, soybean, cotton, and potatoes; commercial pine plantations (~15%); pocosin (~15%); non-riverine swamp forests (~10%); and saltwater marsh or open water (~10%). Climate within the study area is characterized by 4 full seasons of nearly equal length with annual precipitation averaging 50 in. Temperatures range from a mean of 41°F in winter to 80.6°F in summer. Elevation ranges from sea level to 164 ft. (Beck et al., 2009). Carnivores that co-occur with red wolves within the study area include gray foxes (*Urocyon cineroargenteus*), red foxes (*Vulpes vulpes*), coyotes (*Canis latrans*), feral dogs (*Canis lupus familiaris*), bobcats (*Lynx rufus*), black bears (*Ursus americanus*), and various mustelids.

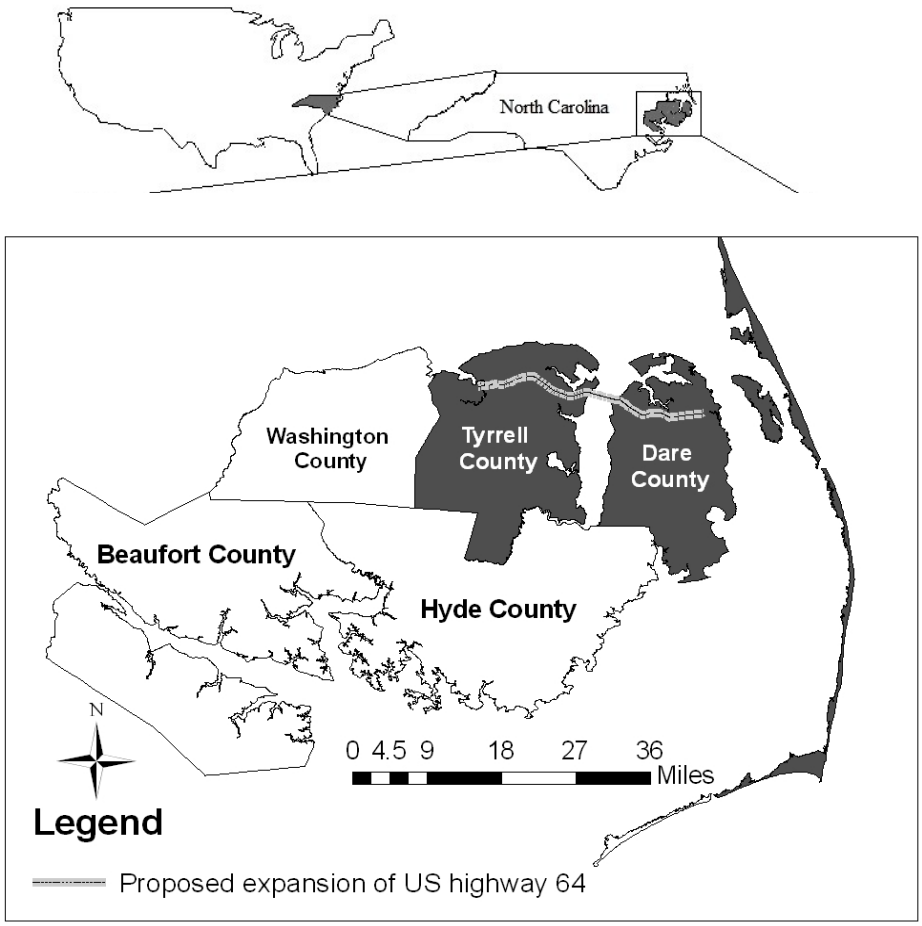

Figure 1. The study area (highlighted in gray) is located within 2 of the northern counties, Tyrrell and Dare, of the 5 county red wolf recovery zone in northeastern North Carolina. The study area focuses on the remaining 27.3 mi section of US 64, between Columbia, NC and the US 64/264 intersection, to be expanded from a 2- to 4-lane highway.

Methods

Capturing and collaring of animals*:* From January 2009 to April 2011, adult and juvenile red wolves were captured by USFWS biologists and fitted with mortality-sensitive Lotek GPS 4400S collars (Lotek Wireless, Inc., Ontario, Canada). Red wolves > 2 years old were classified as adults, < 2 years old as juveniles, and < 9 months old as pups. Pups were not fitted with GPS collars because typically they were too small to safely wear collars. Prior to deployment, GPS collars were remotely programmed to record locations every 5 hours with a nested program to collect a position every 30-minutes for a 5 hour period daily. The nested 30-minute program was scheduled to rotate around the 24-hour clock to capture detailed movements. Each collar emitted a VHF locator beacon each day from 0900 – 1200, allowing us to locate collared animals every 12 weeks on the ground and remotely download stored data.

Objective 1: Evaluate wolf habitat use along the entire US 64 corridor from Plymouth NC to the US 64/264 intersection

***Independence of animal movements*:** To address the issue of correlation of GPS location data between pack mates, we calculated home ranges (Getz et al., 2007) for all collared wolves in a single pack then associated locations for each animal with the corresponding isopleth. Next, Spearman correlation matrices were used to determine the similarity of home ranges and habitat use among all collared animals within the pack. This determined if animals within a pack should be treated separately or if habitat use, selection, and home range of one collared animal was representative of the entire pack.

***Home range analyses*:** Following the conclusion of field work, rarefaction curves of cumulative weekly home ranges were calculated on all complete data sets for each collared animal to determine the relationship between length of time collar was deployed and when size of home range stabilized (Bekoff and Mech, 1984). Starting by calculating size of home range of an animal during the first week of collar deployment, we calculated size of home range of the animal during the second week of collar deployment and so on until the complete data set for that animal was included in calculating size of home range. Ninety-five percent home range isopleths were constructed using adaptive nearest neighbor convex hull methods (Getz et al., 2007). Animals whose home ranges did not stabilize in size were excluded from subsequent analyses. Given the varying age, dominance, and sex of the animals that were collared, and that home range composition between packs with collared animals may vary; we assumed that all factors influencing stabilization of size of home range were captured sufficiently. For individuals whose home range stabilized, monthly home ranges were constructed according to Getz et al. (2007) to examine short-term and seasonal variations in home range composition and size.

Overall and monthly home ranges were overlaid onto habitat maps developed by NC GAP to determine percent composition of home ranges. Habitat types included agricultural fields, wetlands, upland forests, lowland forests, successional fields, and pocosin (areas covered with evergreen vegetation and inundated with water). We used one-way ANOVA to test for differences in overall home range size among age classes and Student's *t*-tests to test for a difference in home range size between sexes. Student's *t*-tests were also used to determine if seasonal variation in monthly home range size and composition for each habitat type were

significantly different. Following previous studies (Phillips et al., 2003; Chadwick et al., 2010; Hinton et al., 2010), we recognized a summer (April – September) and winter (October – March) season. Significance was set at $\alpha \leq 0.05$.

***Habitat use and selection analyses*:** Resource selection functions (RSFs; Manly et al., 2002) were used to examine 2nd order (home range) and 3rd order (within home range) habitat use by red wolves (Johnson, 1980). Resource selection functions were developed using use/availability data with a binomial distribution (Manly et al., 2002).

For 2nd order habitat use, we considered the entire 5 county red wolf recovery area as available habitat and all locations of each GPS-collared animal occurring within its respective 95% home range (Getz et al., 2007) as used habitat. For 3rd order habitat use, the entire 95% home range (Getz et al., 2007) was considered to be available. All locations of each animal contained within its respective 95% home range were combined to examine 2nd and 3rd order habitat use for the entire population. An equal number of random points, compared to locations, were generated within the available areas for 2nd and 3rd order habitat use, respectively. Distance to road and water, human density (people per square mile), and habitat type were determined for all used and random locations. Habitat types were the same as those for determining home range composition. After combining used and random locations for each order of habitat use, RSFs were developed for each order of habitat use which contained habitat type, distance to roads and water, human density, and all biologically meaningful interactions (habitat type by distance to roads, habitat type by human density, and distance to roads by human density). Animals were monitored for varying lengths of time, had different numbers of locations, were of different age classes, and different sexes. Therefore each animal could have potentially influenced the RSFs more or less than another animal. Thus to make sure that no animal biased the RSFs, preliminary 2nd and 3rd order RSFs were developed using a sampling with replacement method in which each animal was excluded once from calculation of a RSF while all other animals were included. For the 3rd order RSF, a random effect for animal was included in the RSFs to account for differences in habitats available to each animal. Akaike's information criterion corrected for small sample sizes (AICc) was used to choose the most parsimonious RSF from the global (all possible variables included) RSF and all possible subsets for each order of habitat use (Burnham and Anderson, 2002). Twenty-five percent of used and random locations for each order of habitat use were not used in developing all RSFs to evaluate fit of most parsimonious RSFs using cross-validation (Johnson et al., 2006). The most parsimonious RSFs that were shown to have a good fit to the data were projected in a GIS to create habitat suitability maps depicting areas of high, medium, and low quality habitat and probability of occurrence of red wolves.

AICc weights of most parsimonious 2nd and 3rd order RSFs were compared to determine whether habitat type, distance to roads and water, and density of humans were scale dependent for red wolves. The RSF with the greatest AICc weight demonstrated the scale at which the variables of interest and associated interactions influenced habitat use the most. Statistical analyses were conducted in R 2.11.1 (R Development Core Team 2010) and spatial analyses using ArcGIS 10 (ESRI® ArcMap™ 10, Copyright © 1999-2010 ESRI Inc.) and Geospatial Modeling Environment 0.5.3 (Beyer, H. L., Copyright © 2001-2010 Spatial Ecology LLC).

Objective 2: Evaluate the significance of red wolf habitat changes anticipated from the proposed highway project from Columbia NC to the US 64/264 intersection.

***Quantifying barrier effects using passage rates*:** Following Dodd et al. (2007), we quantified the barrier effects of US 64 by calculating a permeability index. A permeability index is a passage rate measuring an individuals willingness to attempt a road crossing and is calculated by using the following equation: #crossings/(#crossings + #approaches), where an approach is defined as a red wolf entering into a 164 ft. buffer zone around the highway without crossing (see Figure 2). The 164 ft. (50 m) buffer zone was determined by measuring the distance between US 64 and the boundary of the closest red wolf home range (95% MCP) to the highway. This was done to exclude movements within a home range from being counted as an approach. The permeability index ranges from 0 to 1, with 0 indicating an impermeable road and 1 indicating 100% permeability. Permeability indices were calculated for the 30-minute and 5-hour data sets separately. An overall permeability index (using total number of crosses and approaches from all study animals) for the duration of the study was calculated as well as monthly permeability indices. We used a paired t-test to compare monthly permeability indices calculated using the 30-minute and 5-hour data sets.

Using 30-minute monthly permeability indices, regression analysis was then used to determine if a relationship existed between monthly permeability indices and monthly traffic flow along the existing US 64.

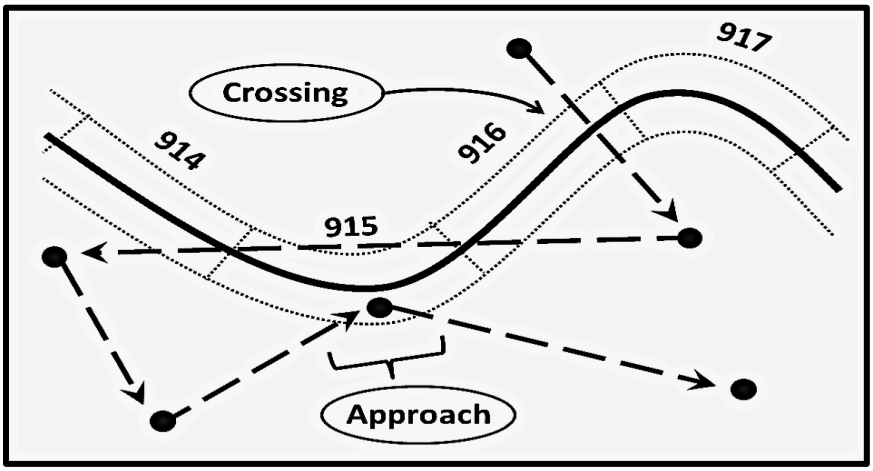

Figure 2. A **crossing** was defined as a line connecting two points on opposite sides of a road that intersects the roadway. An **approach** was defined as any excursion from a point further than 164 ft. from the road to a point within 164 ft., and then back, *without* crossing.

Assessing the effect of the highway widening on current red wolf territories: To determine the potential for the highway widening to displace current red wolf packs, buffers at ~ 164 ft. (50 m) intervals were constructed around the current US 64. The buffers were then overlaid on current red wolf home range locations and the number of home ranges intersected by each buffer was counted. Where the buffers intersected home ranges, the percent of total home range intersected was calculated. As with the home range analysis above, only one home range per pack was used when the movements among individuals of a pack were correlated.

Assessing the effect of the highway widening on important red wolf habitat: To determine the potential for the highway widening to affect important red wolf habitat, buffers around the current US 64 at ~164 ft. (50 m) intervals were overlaid on a habitat map. The area of available red wolf habitat was then calculated within each buffer zone.

Objective 3: Identify significant red wolf crossing areas to determine where wildlife crossing structures or other design features could be placed to minimize adverse project effects on wolves.

***Determining crossing locations and rates using GPS collars*:** Because of the occurrence of different collar schedules, wolf locations were sub-sampled into both 5-hour and 30-minute intervals. The following methods were used to analyze data collected for each frequency, 5-hour and 30-minute, respectively. Using ArcGIS v9.3 (ESRI® ArcMap™ 9.3, Copyright © 1999-2010 ESRI Inc.), we divided the 27.3 mi-section of US 64 into 273 segments, each 0.10 miles long. To determine road crossings, we used the Home Range Tools v9 extension for ArcGIS to calculate the travel path of each individual by connecting consecutive GPS fixes. We then overlaid the travel paths on the segmented highway layer and counted the number of crossings per highway segment for each individual. A crossing was defined as two consecutive fixes on opposite sides of the highway (see Figure 2). Crossing rates for each individual were determined by dividing the number of crossings by the number of days the collar was actively collecting data for each collection frequency sub-sample. Total crossing frequencies per segment were plotted in a histogram to identify the location of key red wolf crossing areas.

***Statistical Analysis*:** To test the hypothesis that the crossing distribution calculated using GPS collar locations was different from a random crossing distribution, an equivalent number of random line segments were drawn between the GPS locations for each red wolf. To approximate actual red wolf movement, random segment lengths were constrained to less than or equal to the maximum distance moved by a red wolf for the 30-minute and 5-hour data sets, respectively. Crossing frequencies for the random segments were calculated for each highway segment following the methods above. The distributions for the GPS crossing frequencies and the random crossing frequencies were compared using a Kolmogorov-Smirnov test (Clevenger et al., 2001). We used a t-test to test for differences in crossing rates between male and female wolves and a one –way ANOVA to test for differences in crossing rates among age classes.

Determining crossing locations using Camera Traps: Even with 30-minute locations, the GPS collars likely did not catch all red wolf crossing events. To capture additional crossing events, remote cameras were placed at canal crossings along the 27.3 mi stretch of US 64 within 328 ft. (100 m) of the roadside. Because drainage canals exist along the entire length of US 64, canal crossings serve as an access point for animals to reach the highway. We used both film and digital remote cameras triggered by laser or heat disturbance. All cameras were active 24-hours per day to maximize the number of crossings captured. Cameras were active from July 2009 to March 2011. However, the number of trap nights varied for each camera station so captures were reported per 100 trap nights. To avoid pseudoreplication, consecutive photos of an individual animal were considered a single event.

Using GPS locations, camera stations were associated with one of the 273 segments along US 64. Not all segments had camera stations. Total crossing frequencies per segment were plotted in a histogram to identify the location of key red wolf crossing areas as identified by cameras.

Evaluating habitat characteristics at crossing sites identified by GPS collar locations: Using the NC GAP habitat map, we extracted the habitat type for each of the 273 highway segments at 164 ft. (50 m) intervals starting at the road to a distance of 656 ft. (200 m) perpendicular to the segment (ArcGIS v9.3). Segments that had at least one crossing were coded with a 1 and segments without crossings were coded with a 0. Logistic regression was used to evaluate 5 *a priori* models developed using site-specific habitat type at different distance intervals and the occurrence of a red wolf crossing. The most parsimonious model was chosen using AIC corrected for small sample size (AICc) (Burnham and Anderson, 2002), with models ranked using ΔAICc.

Evaluating habitat characteristics at crossing sites identified by camera traps:
Using the NC GAP habitat map, we extracted the habitat type for each of the camera stations at 164 ft. (50 m) intervals starting at the camera sites to a distance of 656 ft. (200 m) perpendicular to US 64 (ArcGIS v9.3). In addition, the width of the access road/trail was measured at each camera station. Camera sites that captured red wolves were coded with a 1 and camera sites that did not capture red wolves were coded with a 0. Logistic regression was used to evaluate 5 *a priori* models developed using habitat variables and trail width at camera placement. The most parsimonious model was chosen using AIC corrected for small sample size (AICc) (Burnham and Anderson, 2002), with models ranked using ΔAICc.

Results

Capturing and collaring of animals: Between January 2009 and April 2011, the USFWS Red Wolf Team deployed 32 of 40 collars. Due to a decrease in red wolf population in Washington County, North Carolina, the 8 collars reserved for red wolves living in the vicinity of the previously expanded portion of US 64 could not be deployed. Thirteen of the 32 collars deployed were placed on females (8 adults, 5 juveniles) and 19 on males (8 adults, 11 juveniles). The average collar deployment was 14.8 months (range: 4 to 30 months) and average collar success in obtaining GPS locations was 86.0% (range: 63.6% to 97.5%). In total, 39, 573 successful red wolf locations were collected. We used 6 different collar schedules: 30-minute locations for 5 hours per day, 5-hour locations, 5-hour locations with the nested 30-minute schedule for 5-hours per day, 11-hour locations, 12-hour locations, and 23-hour locations (Table 1).

* RO = Rollover. A rollover schedule collects locations continuously at a set time interval without resetting at the start of each day.

Objective 1: Evaluate wolf habitat use along the entire US 64 corridor from Plymouth NC to the US 64/264 intersection

***Home range analyses*:** Movements of individuals within the same pack were highly correlated (r_s = 0.87–0.91); therefore only 1 animal per pack (chosen randomly) was used in the following analyses. After removing those individuals where multiple animals in a pack were collared, we calculated cumulative weekly home ranges for 21 of 32 animals (Figure 3). Following analysis, we removed 5 (1 juvenile, 2 dispersers, 2 adults) additional individuals from our sample due to an inadequate number of locations to capture a complete home range. Overall home range varied between 2.61 mi^2 and 38.19 mi^2 with a mean of 12.93 ± 9.50 mi^2

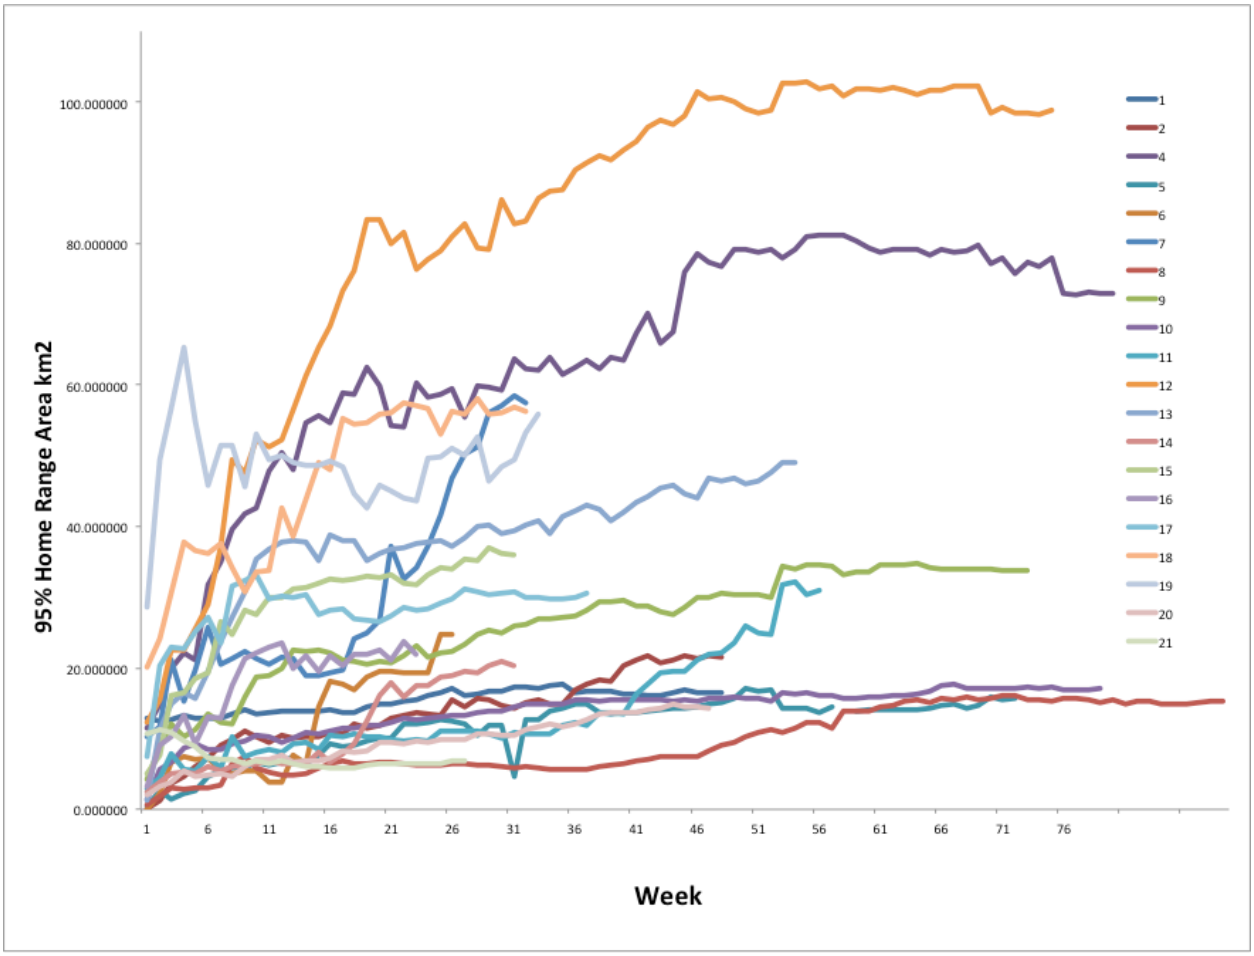

Figure 3. To determine if an adequate number of locations were obtained from each wolf to capture home range area, rarefaction curves of cumulative weekly home ranges were calculated for 21 red wolves of different age groups and sexes collared from January 2009 to April 2011. A home range is considered to be at equilibrium at the point that the home range area no longer increases and reaches a plateau (Bekoff and Mech, 1984). Home range did not reach equilibrium for 5 of the 21 wolves in our sample (6, 7, 11, 13, 14), thus they were excluded from further home range analyses. Collared red wolves were located in Tyrell, Dare, Washington, and Hyde Counties, NC.

Although home range size among age classes (F =2.71, P =0.14) and between sexes (t_{10} = 2.10, P = 0.57) did not differ significantly (Tables 2 and 3), the home range size of dispersers tended to be larger than those of juveniles or adults. Five of 8 animals that died while collared were dispersing and 2 additional dispersers were removed from further home range analyses due to inadequate data.

Table 2. Average and range of 95% home range areas for three age classes of red wolves. A local convex hull method was used to calculate home range from GPS collar locations. The home range analysis was generated from 16 red wolves collared in Washington, Tyrell, Dare, Hyde, and Beaufort Counties, NC from January 2009 to April 2011.

	Juvenile	Disperser	Adult
n	3	3	10
Average (mi^2)	9.15	21.86	15.29
Min (mi^2)	5.93	21.61	2.61
Max (mi^2)	11.95	22.21	38.19

Table 3. Average and range of 95% home range areas for male and female red wolves. A local convex hull method was used to calculate home range from GPS collar locations. The home range analysis was generated from 16 red wolves collared in Washington, Tyrell, Dare, Hyde, and Beaufort Counties, NC from January 2009 to April 2011.

	Male	Female
n	9	7
Average (mi^2)	14.54	12.11
Min (mi^2)	2.61	5.52
Max (mi^2)	38.19	22.21

Home ranges were composed primarily of agricultural fields with 95% home range isopleths on average containing 55% agricultural fields (Table 4). Summer home ranges were between 0.77 and 3.09 mi^2 smaller (t_{10} = -4.84, P < 0.01) than winter home ranges (Table 5). Average monthly home range percent composition was different between summer and winter. Red wolves increased their use of pocosin (t_{10} = -2.65, P =0.03), wetlands (t_{10} = -4.29, P < 0.01), and upland forests (t_{10} = -4.17, P < 0.01) in late winter and increased use of agricultural fields (t_{10} = 3.44, P < 0.01) in summer months (Table 6). Agricultural fields and successional fields account for over 65% of habitat composition regardless of season.

Table 4. Average composition of 95% home ranges for 16 red wolves collared in Washington, Tyrell, Dare, Hyde, and Beaufort Counties, NC from January 2009 to April 2011.

Habitat Type	Average %
Pocosin	6
Lowland Forests	6
Successional Fields	13
Upland Forests	12
Wetlands	8
Agricultural Fields	55

December	5	4	16	7	7	59

***Habitat use and selection analyses*:** We used 29,680 locations of red wolves to construct the 2nd and 3rd order resource selection functions (RSFs), respectively (Johnson, 1980). Second order RSF predicted a patchy distribution of red wolves across the 5-county red wolf recovery area (Figure 4). Third order RSF predicted a relatively equal probability of habitat use by red wolves across a given home range (Figure 5). RSFs calculated for each individual wolf included the same variables as the most parsimonious 2nd and 3rd order RSFs. Thus, despite the fact that collars were deployed on wolves of all ages and both sexes over a range of collar deployment periods (2009, 2010, and 2011) and deployment lengths (4 to 30 months), no one animal was considered to bias the RSFs in a unique way different from other animals. The most parsimonious 2nd order RSF contained: habitat type, distance to roads and water, human density, an interaction between distance to road and habitat type, and an interaction between human density and habitat type (Table 7). The AICc weight of the most parsimonious 2nd order RSF was 0.98. The next most parsimonious RSF included an interaction between human density and distance to road, and had a ΔAICc of 8 and an AICc weight of 0.02. Agricultural fields were more likely to be used than all other habitat types. Likelihood of habitat use by red wolves decreased as human density increased, distance to road increased, and distance to water sources (e.g. steams and ponds) decreased. As distance to road increased, lowland forest, pocosin, and wetland habitats were disproportionately less likely to be used by red wolves than other habitat

types. As human density increased, upland forests and wetlands were more likely to be used by red wolves than other habitat types.

The most parsimonious 3rd order RSF contained: 5 habitat types, distance to roads, and distance to water sources (e.g. steams and ponds) (Table 8). The AICc weight of the most parsimonious 3rd order RSF was 0.75. The next most parsimonious RSF included habitat type, distance to water, and human density, and had a ΔAICc of 2 and an AICc weight of 0.25. Again, agricultural fields were more likely to be used than all other habitat types. Likelihood of habitat use by red wolves decreased as distance to roads and water increased.

To test the validity of our selected 2nd and 3rd order RSF models, we overlaid 9,893 red wolf locations withheld from the initial analysis on the resulting probability maps (Figures 4 and 5). The GPS-collar locations (observed) overlapped areas identified as high probability of red wolf occurrence (expected) for both 2nd ($t_1 = 0.79$, $P > 0.05$) and 3rd order ($t_1 = 1.06$, $P > 0.05$) RSFs.

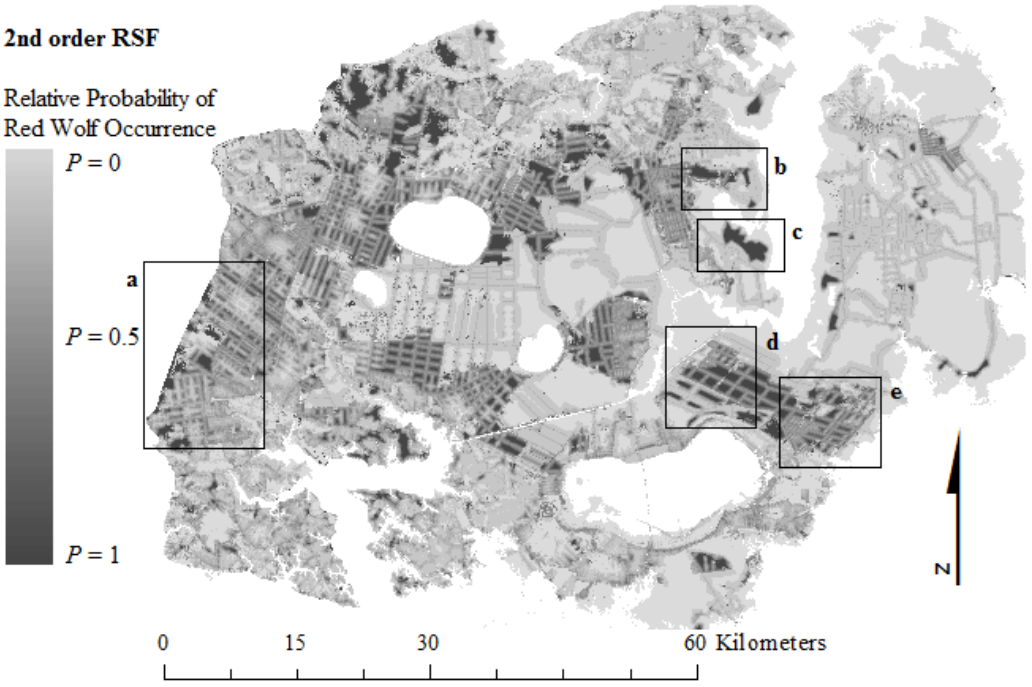

Figure 4. Relative probability of occurrence of red wolves (*Canis rufus*) across Washington, Tyrrell, Dare, Hyde, and Beaufort Counties, North Carolina with respect to 2nd order habitat use, 2009-2011. a) Relative location of packs no longer in existence but identified as habitat with high relative probability of occurrence of red wolves; b-e) Relative location of packs not represented in our dataset but in existence at the time of this study.

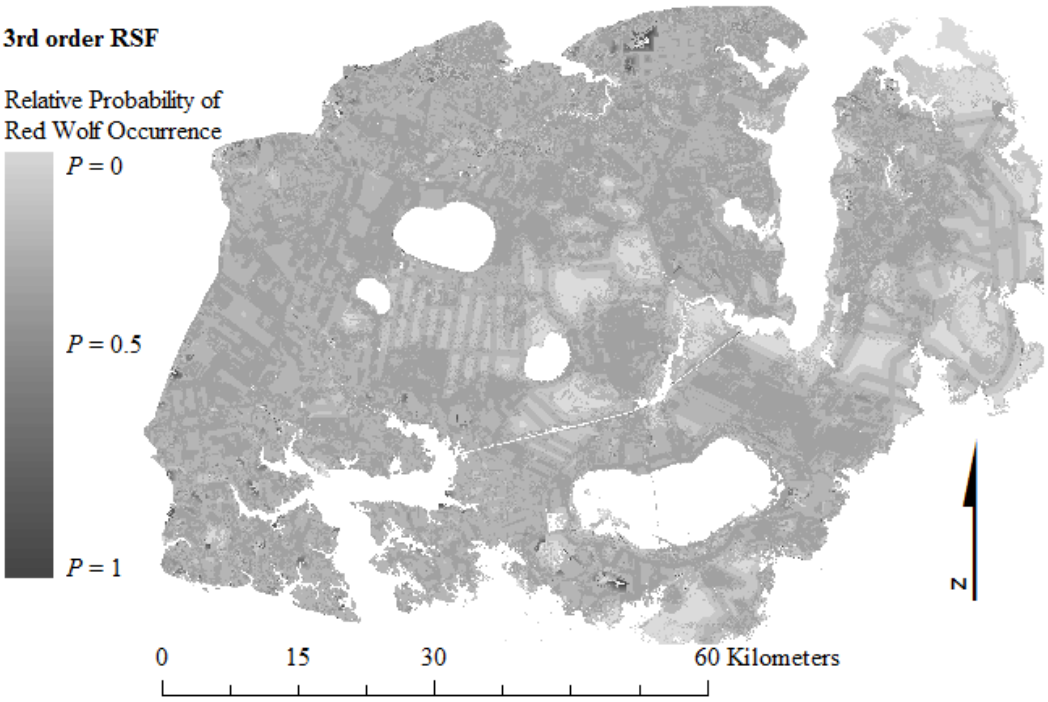

Figure 5. Relative probability of occurrence of red wolves (*Canis rufus*) across Washington, Tyrrell, Dare, Hyde, and Beaufort Counties, North Carolina with respect to 3rd order habitat use, 2009-2011.

Table 7. Most parsimonious 2nd order RSF, according to AICc, for habitat use of red wolves in Washington, Tyrrell, Dare, Hyde, and Beaufort Counties, North Carolina from 2009-2011.

Objective 2: Evaluate the significance of red wolf habitat changes anticipated from the proposed highway project from Columbia to the US 64/264 intersection.

***Quantifying barrier effects using passage rates*:** Though 3 times as many crossings were recorded using the 30-minute collar schedule compared to the 5-hour schedule, the overall permeability for US 64 calculated from both collar schedules was approximately 100% (Table 9). No difference in monthly permeability index was found between the 30-minute and 5-hour collar scheduled ($t_{10} = 0.045$, $P = 0.48$). No relationship ($F=0.021$, $P=0.89$, $r^2=1.0$) was found between monthly permeability and monthly traffic flow (Figure 6).

Table 9. Permeability index for US 64 between Columbia, NC and the US 64/264 intersection in Manns Harbor, NC. The permeability index was calculated by dividing the number of highway crossings by (the number of highway crossings + the number of approaches). Road crossings were determined using red wolf GPS-collar locations collected between January 2009 and April 2011. A permeability index of 1 represents a highly permeable road while an index of zero indicates impermeability.

Collar Schedule	No. of Wolves	No. of Crossings	No. of Approaches	Permeability Index
5-hour	6	25	0	1.00
30-minute	8	76	1	0.99

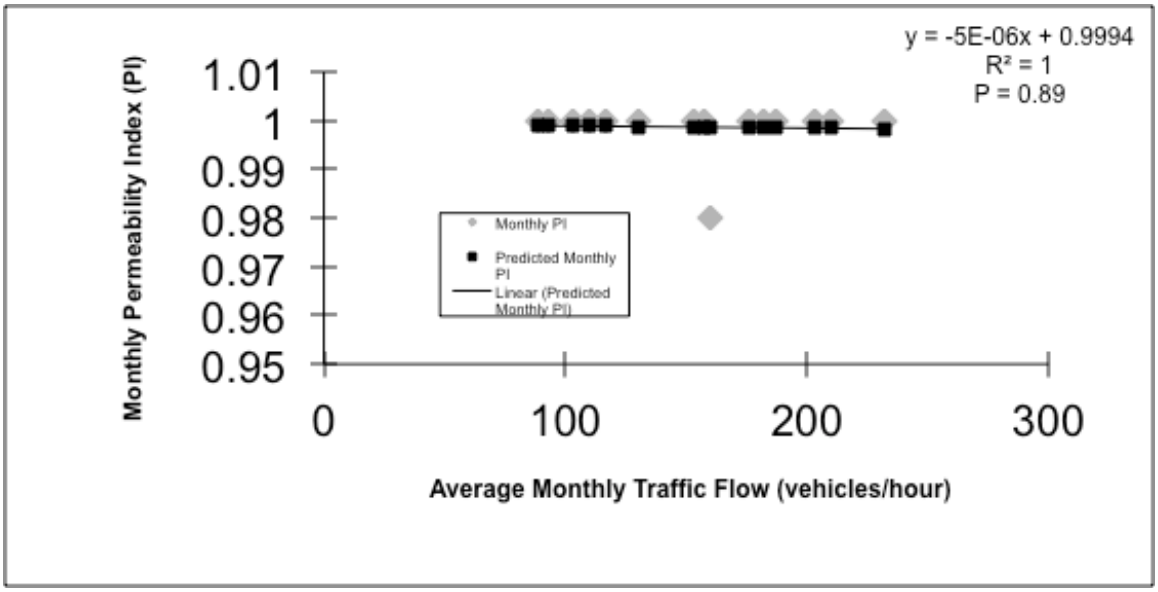

Figure 6. Regression analyzing the relationship between monthly permeability index and average monthly traffic flow rates (vehicles/hour). The monthly permeability index was calculated using GPS-collar data on the 5-hour schedule from 6 red wolves between March 2009 and May 2010 in Tyrrell and Dare Counties, NC.

Assessing the effect of the highway widening on current red wolf territories: Buffers around US 64 to a distance of 3281 ft. (1000 m) in 164 ft. (50 m) increments overlaid on a map displaying current red wolf home ranges showed that 2 red wolf packs would be directly affected by a highway widening. One pack is located north of the current 2-lane highway in Tyrrell County and the second is south of the highway in Dare County, the only existing pack in Alligator River National Wildlife Refuge. The proportion of home range to be affected in Tyrell County ranges between 0.11% and 6.63% (Table 10) and is located between 820 ft. (250 m) and 3218 ft. (1000 m) from the existing highway just east of Columbia, NC where the previously widened portion of US 64 narrows to a 2-lane highway (Figure 7). In Dare County, the proportion of home range that would be affected ranges between 0.01% and 20.31% (Table 11) and is located south of US 64 between River Rd. and Bear Rd. on Alligator River National Wildlife Refuge (Figure 8).

Assessing the effect of the highway widening on important red wolf habitat: Important red wolf habitat is defined as, following the results of the resource selection function analysis in objective 1, agricultural fields, successional fields, and upland forests. Buffers at 164 ft. (50 m) increments extending out to a distance of 3281 ft. (1 km) from US 64 overlaid on the NC GAP habitat map revealed that construction to the north of the current US 64 in Tyrrell County would remove more red wolf habitat than construction to the south. The opposite was found in Dare County, with more red wolf habitat at risk south of the current US 64 than north (Figures 9 and 10). If highway construction were to disturb the entire area between the existing US 64 and the 3281 ft. (1 km) buffer, a total of 0.16 mi^2 of red wolf habitat will be removed north of the highway vs. 0.09 mi^2 south of the highway in Tyrrell County. For Dare County, 0.04 mi^2 would be removed north of the highway vs. 0.07 mi^2 south of the highway if construction were disturb the whole area between the existing US 64 and the 3281 ft. (1 km) buffer.

Table 10. The proportion of a red wolf pack home range that will be directly affected by highway construction in Tyrell County between 820 ft. and 3218 ft. from the existing highway. The red wolf pack is located north of US 64 east of Columbia, NC where the previously widened portion of US 64 narrows to a 2-lane highway.

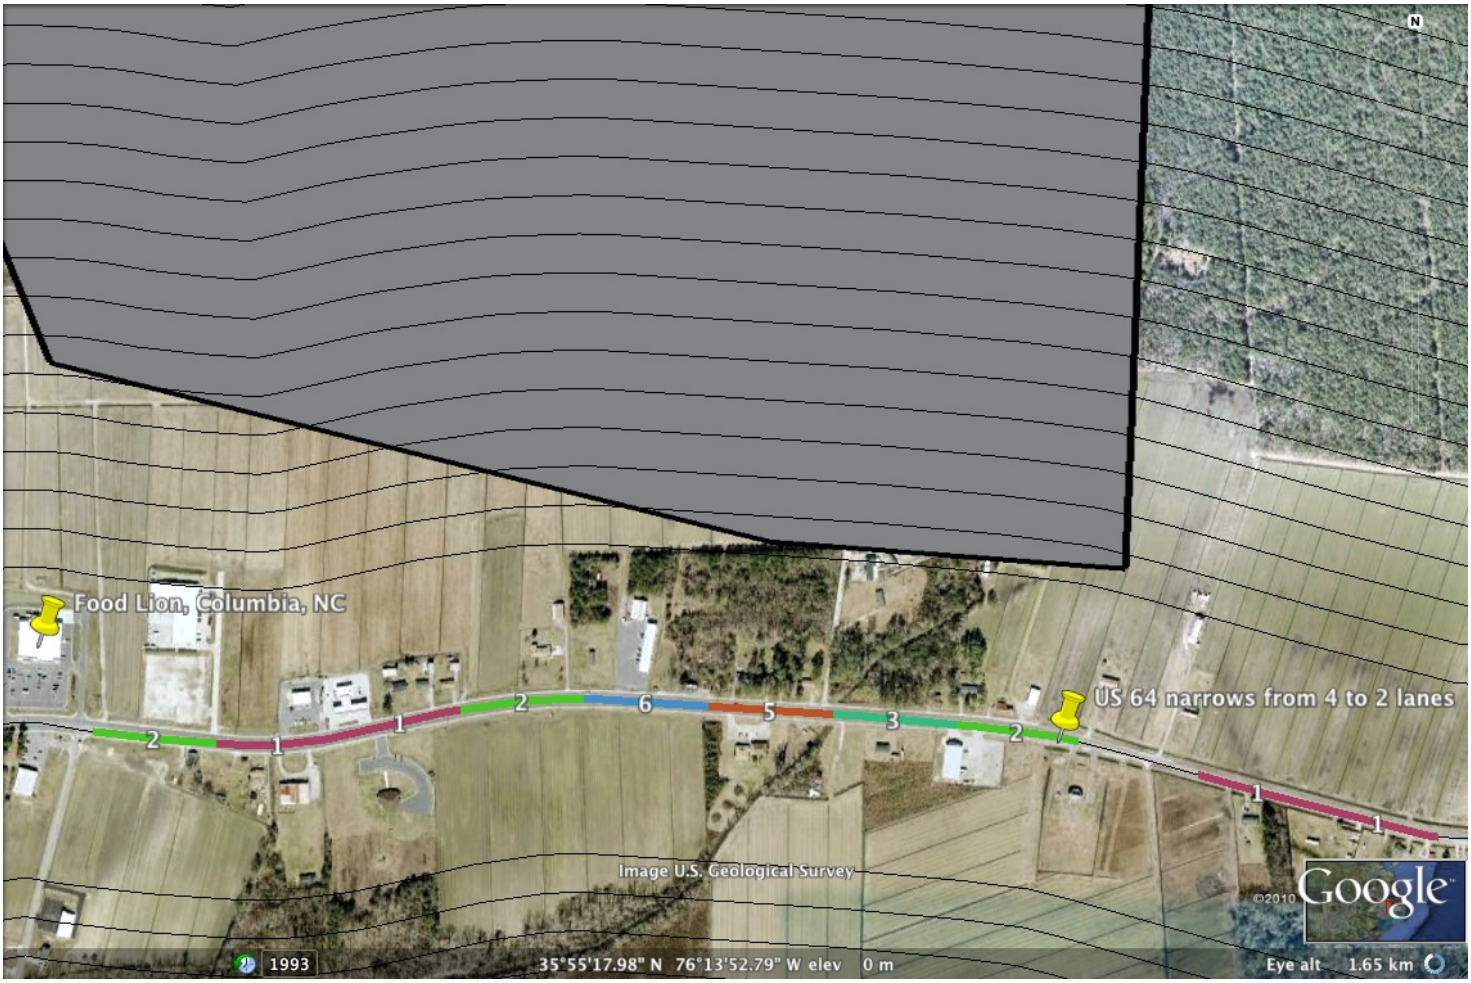

Figure 7. Location of the Tyrrell County red wolf pack home range with potential to be directly affected by highway construction. The home range extends to within 820 ft. from the existing highway where 4-lanes merge into 2-lanes just east of Columbia, NC. The highway buffer lines above (black lines) start at 820 ft. from US 64 and end at 3281 ft. in 164 ft. increments. If highway construction were to disturb the area between 820 ft. to 3281 ft. from the existing highway, 6.63% of this pack's home range would be removed. The numbers along US 64 indicate the number of red wolf highway crossings per 0.10 mi. segment captured using GPS-collar data collected between January 2009 and April 2011.

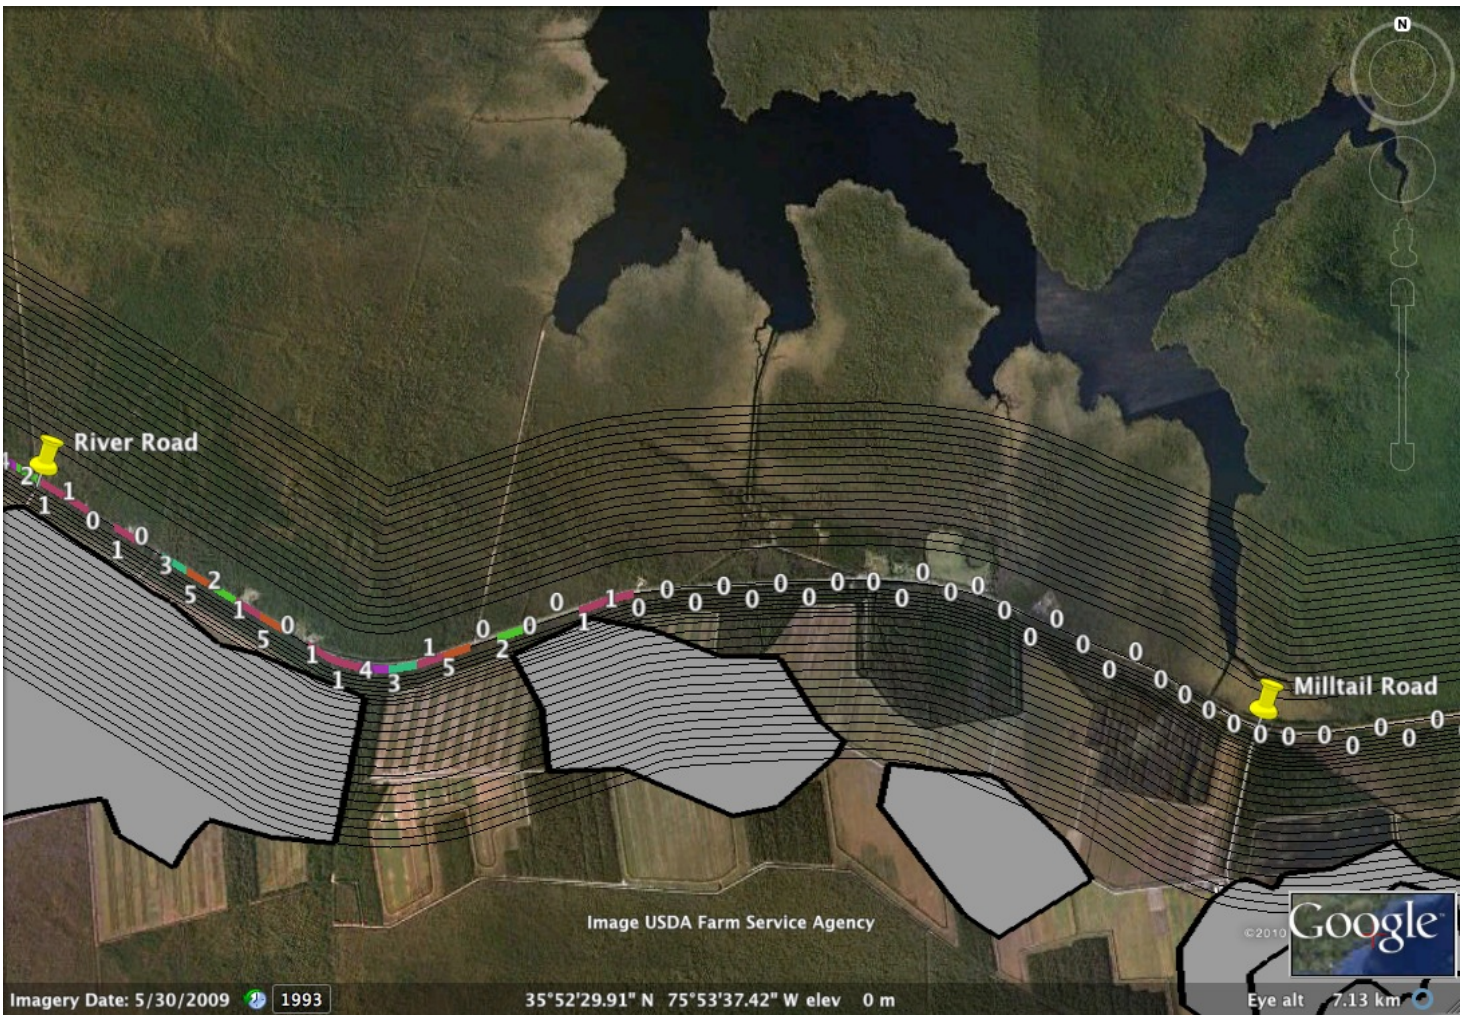

Figure 8. Location of the Dare County red wolf pack home range with potential to be directly affected by highway construction. The home range extends to within 264 ft. just south of the existing highway between River Rd. and Bear Rd. (east of Milltail Rd – not pictured) on Alligator River National Wildlife Refuge. This is the only red wolf pack on the refuge. The highway buffer lines above (black lines) start at 264 ft. from US 64 and end at 3281 ft. in 164 ft. increments. If highway construction were to disturb the area between 264 ft. to 3281 ft. from the existing highway, 20.31% of this pack's home range would be removed. The numbers along US 64 indicate the number of red wolf highway crossings per 0.10 mi. segment captured using GPS-collar data collected between January 2009 and April 2011.

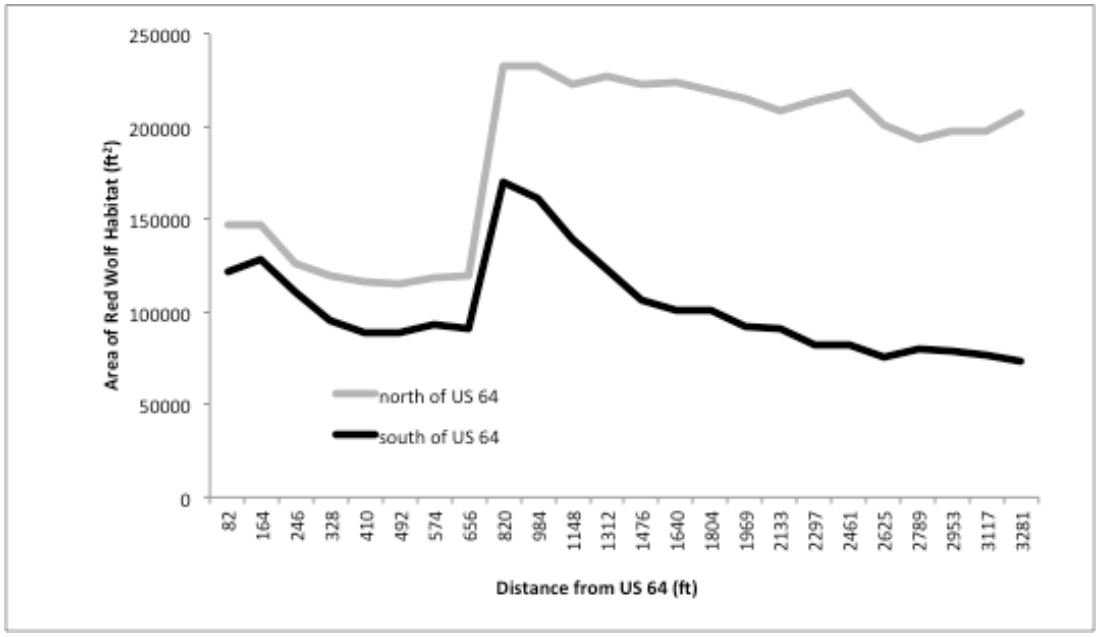

Figure 9. The area of important red wolf habitat per 164 ft. buffer for Tyrrell County, NC. Important red wolf habitat for eastern North Carolina includes agricultural land, upland forests, and early successional fields.

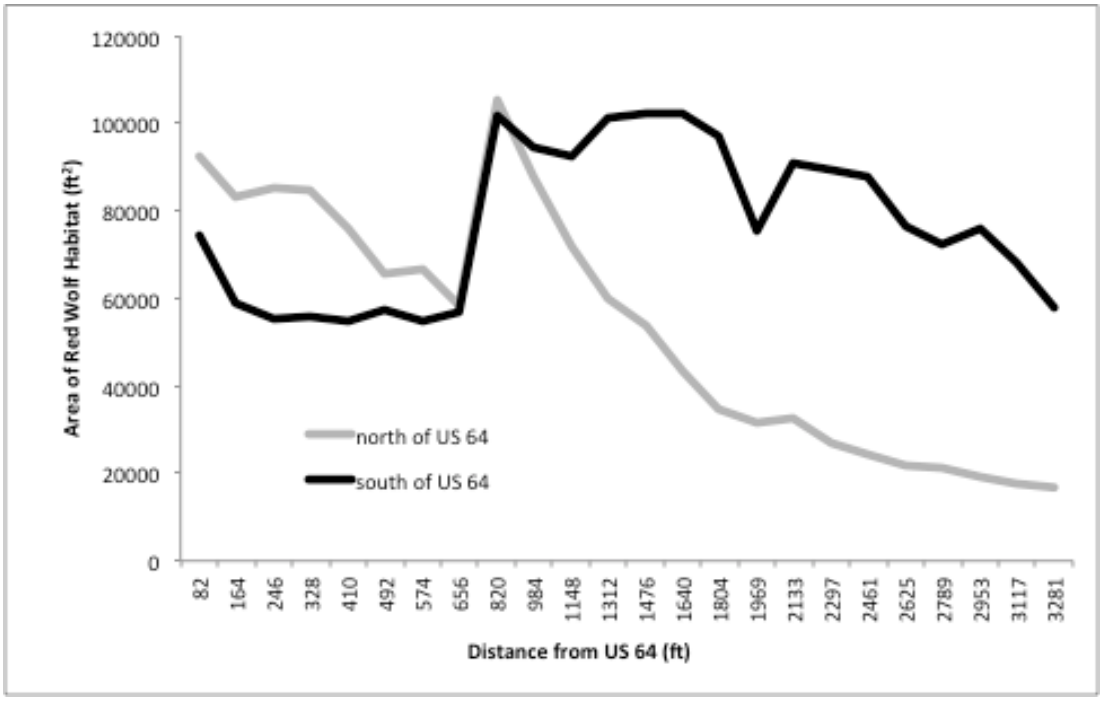

Figure 10. The area of important red wolf habitat per 164 ft. buffer for Dare County, NC. Important red wolf habitat for eastern North Carolina includes agricultural land, upland forests, and early successional fields.

Objective 3: Identify significant red wolf crossing areas to determine where wildlife crossing structures or other design features could be placed to minimize adverse project effects on wolves.

***Determining crossing locations and rates using GPS collars*:** Six wolves on the 5-hour schedule (3 M: 3 F) and 8 on the 30-minute schedule (4 M: 4 F), with 3 wolves that started on the 5-hour and were switched to the 30-minute schedule, displayed crossing activity around US 64 out of a total of 32 collars. Only wolves with home ranges along US 64 crossed the highway. Wolves on the 5-hour schedule crossed between 2 and 9 times while wolves on the 30-minute crossed between 2 and 20 times. Five wolves (1 M: 4 F) on the 30-minute schedule, subsampled every 5-hours for a paired t-test, crossed 53 (30-minute) and 19 times (5-hour), respectively (*P=0.030),* showing that the 30-minute schedule captured nearly 3 times the road crossings as compared to the 5-hour rollover.

An additional 5-hour wolf, (8-year-old female #1880; Figure 11), crossed the highway 266 times. On reviewing the distribution of her points, which extended about 11 miles along the highway, it was determined that US 64 bisected the core of her home range (Figure 12). Additionally, her movements in a narrow band surrounding the road increased the likelihood of "false crossings," where the line connecting consecutive points on either side of the highway did not necessarily represent the true crossing location. For these reasons, and because 1880 represented an unusual circumstance that heavily skewed the rest of the data, this wolf was considered an outlier and removed from all further analysis of US 64 GPS-collar data.

Figure 11. Photo of wolf #1880 (adult female) obtained by camera trap along US 64 in Tyrrell County, North Carolina in July 2009.

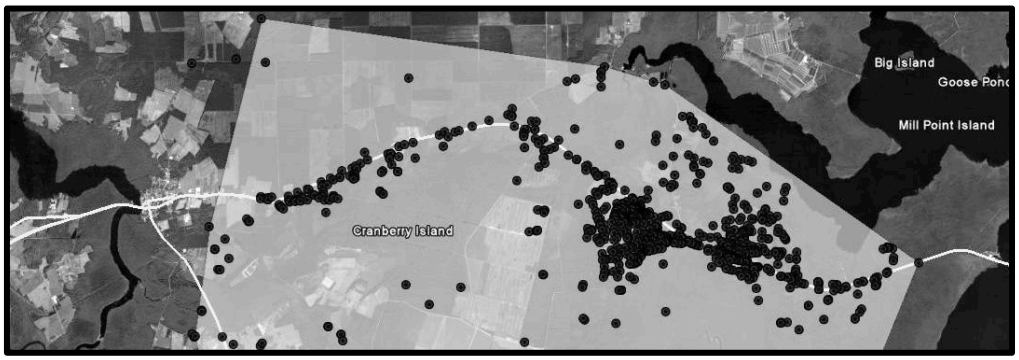

Figure 12. GPS-collar locations collected between April 2009 and November 2009 of wolf #1880 along US 64, Tyrrell County, North Carolina within its 95% MCP home range.

Although observed red wolf crossings and randomly generated crossings were both normally distributed, observed red wolf crossings occurred at a significantly lower frequency (*t=1.196, P=0.03*) and were bimodal as compared to the random crossings (Figure 13). Data from both the 5-hour and 30-minute schedules pointed to 2-crossing locations (Figures 14 and 15, respectively), 1 east of Alligator River in Dare County between miles 8 and 10 and 1 to the west in Tyrrell County centered on mile 28. However, the 30-minute data were more tightly concentrated and obvious. The two clusters of crossings identified by the GPS-collar data (Figure 16) coincided with where home ranges approached US 64.

Using the 30-minute collar data, red wolf highway crossing rates did not differ by wolf age (*F=5.14*, *P* = 0.13, *n = 13*; 3 juveniles, 3 dispersers, 7 adults) or sex (*t=0.32, P* = 0.76; *n = 13*; 7 males, 6 females).

Determining crossing locations using Camera Traps: Crossing data were collected at 39 camera stations along US 64 accumulated over 8,154 trap nights. The average and median number of trap nights per station was 204 and 160, respectively. The number of trap nights per station ranged from 35 to 617 nights. Four red wolf crossing sites were identified from camera data, 3 west of Alligator River in Tyrrell County at miles 19, 20.5 and 23 - 24 and 1 east of Alligator River in Dare County between miles 9 and 10 (Figure 17). The crossing site in Tyrrell County between miles 23 – 24 and the crossing site in Dare County between miles 9 – 10 were considered one location each due to proximity and habitat continuity.

The combined GPS and camera crossing data indicated 5 important crossing sections along US 64 between Columbia, NC and the US 64/264 intersection, 4 west of Alligator River in Tyrrell County and 1 east of Alligator River in Dare County (see Figures 17 - 19). The crossing site in Dare County identified by the cameras overlaps with the crossing site identified using GPS-collar locations, however that was not the case in Tyrrell County. The 3 crossing sites identified in Tyrrell County using cameras are from crossings made by wolf #1880, the wolf excluded from collar analyses. The crossing site in Tyrrell County identified with the GPS-collar data occurred in an area where no cameras were placed, within the town limits of Columbia, North Carolina.

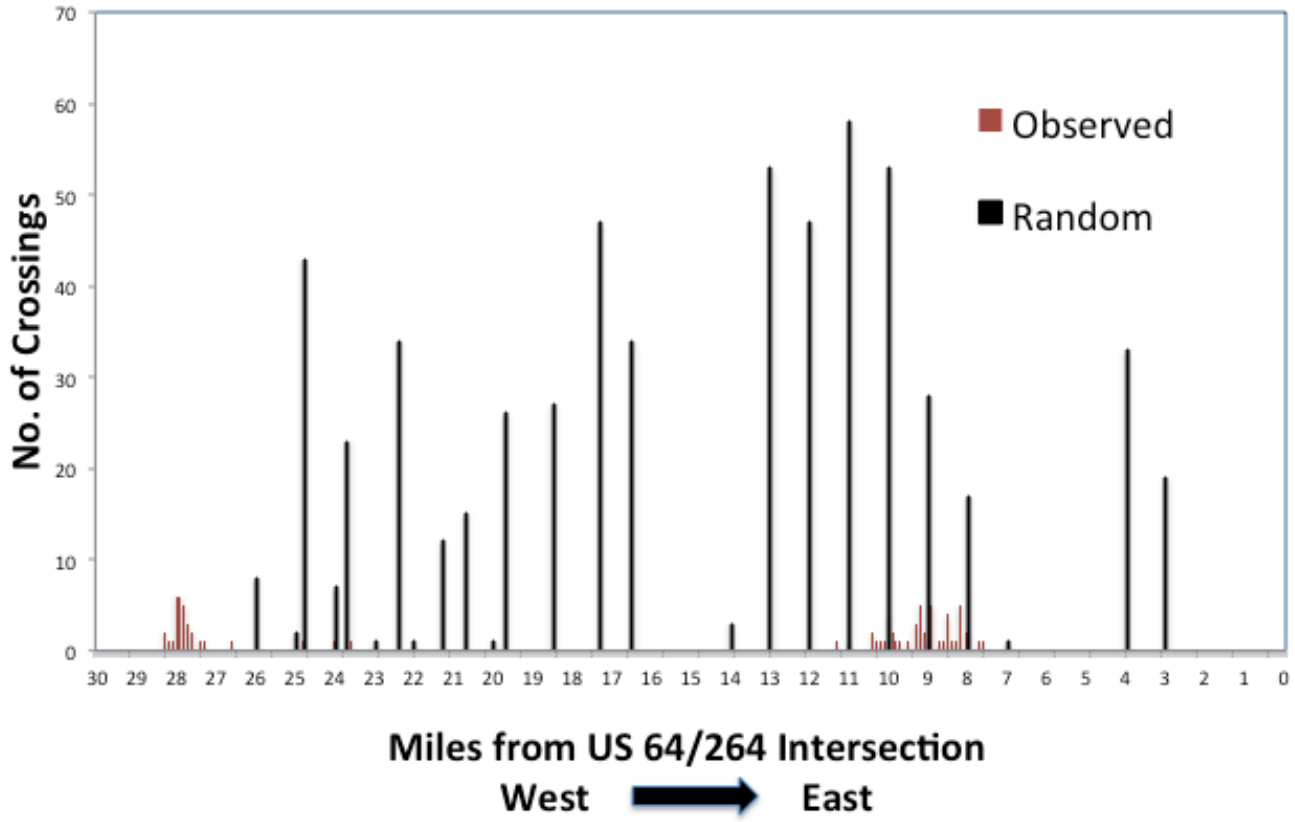

Figure 13. Observed red wolf crossings (red bars) occurred at a significantly lower frequency (*t=1.196, P=0.03*) and were bimodal as compared to the random crossings (black bars). Observed crossings are based on GPS locations taken at 30- minute intervals from red wolves in Washington, Tyrrell, Dare, Hyde, and Beaufort Counties, North Carolina collared between October 2009 and March 2011. An equivalent number of random line segments were drawn between the GPS locations for each red wolf. To approximate actual red wolf movement, random segment lengths were constrained to less than or equal to the maximum distance moved by a red wolf for the 30-minute data sets.

Determining crossing locations using historical road kill data: From May 1988 to February 2009, 58 wolves (31 M, 27 F) died as a result of vehicle collisions in the recovery zone, with an average of nearly 3 wolves per year. Twelve of these occurred on US 64. While not significant, the locations of current known road-kills appear to be generally clustered around crossing sites identified in this analysis, particularly on US 64 (Figures 18 – 19). However many of the historic road kill events highlight the location of packs no longer present.

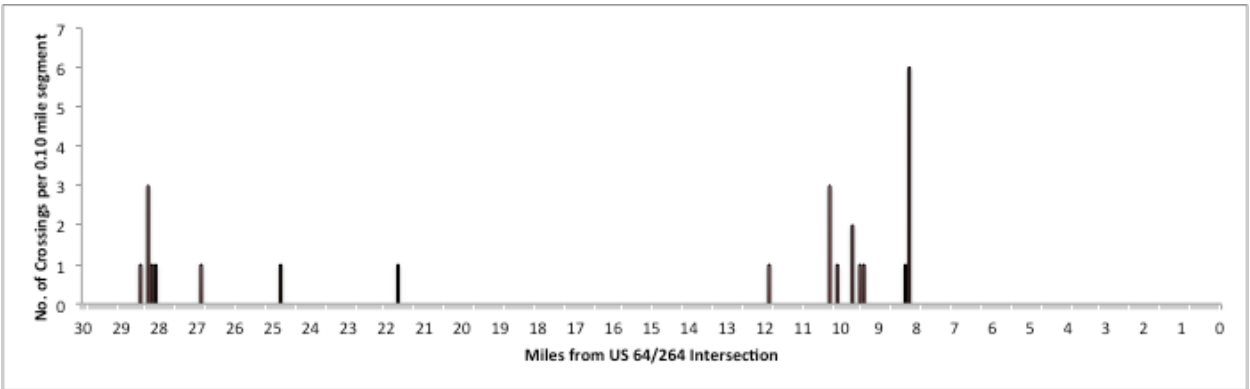

Figure 14. The number of red wolf crossings identified by GPS locations per 0.10 mile segments along US64 between Columbia, NC and the US64/US264 intersection. Crossings are based on GPS locations taken at 5- hour intervals between January 2009 and March 2011.

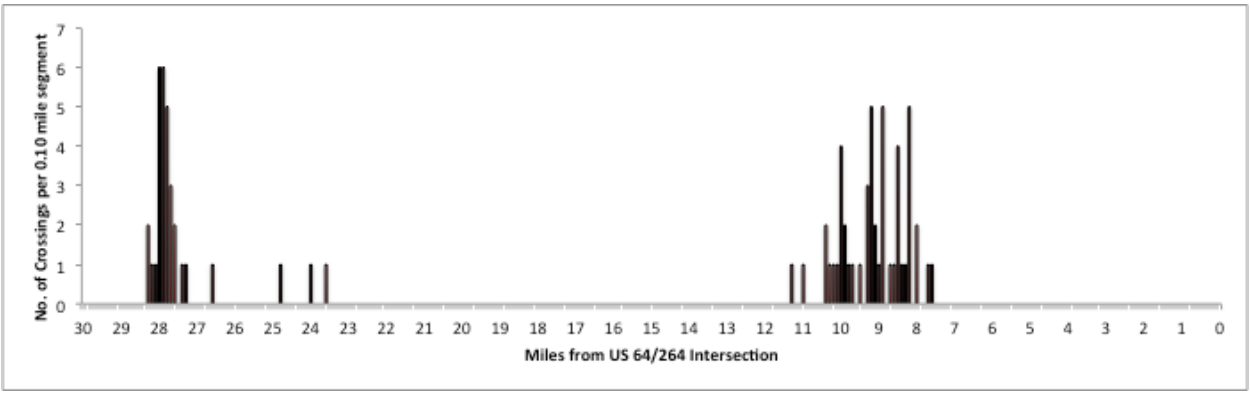

Figure 15. The number of red wolf crossings identified by GPS locations per 1 mile segments along US64 between Columbia, NC and the US64/US264 intersection. Crossings are based on GPS locations taken at 30- minute intervals between October 2009 and March 2011.

a)

b)

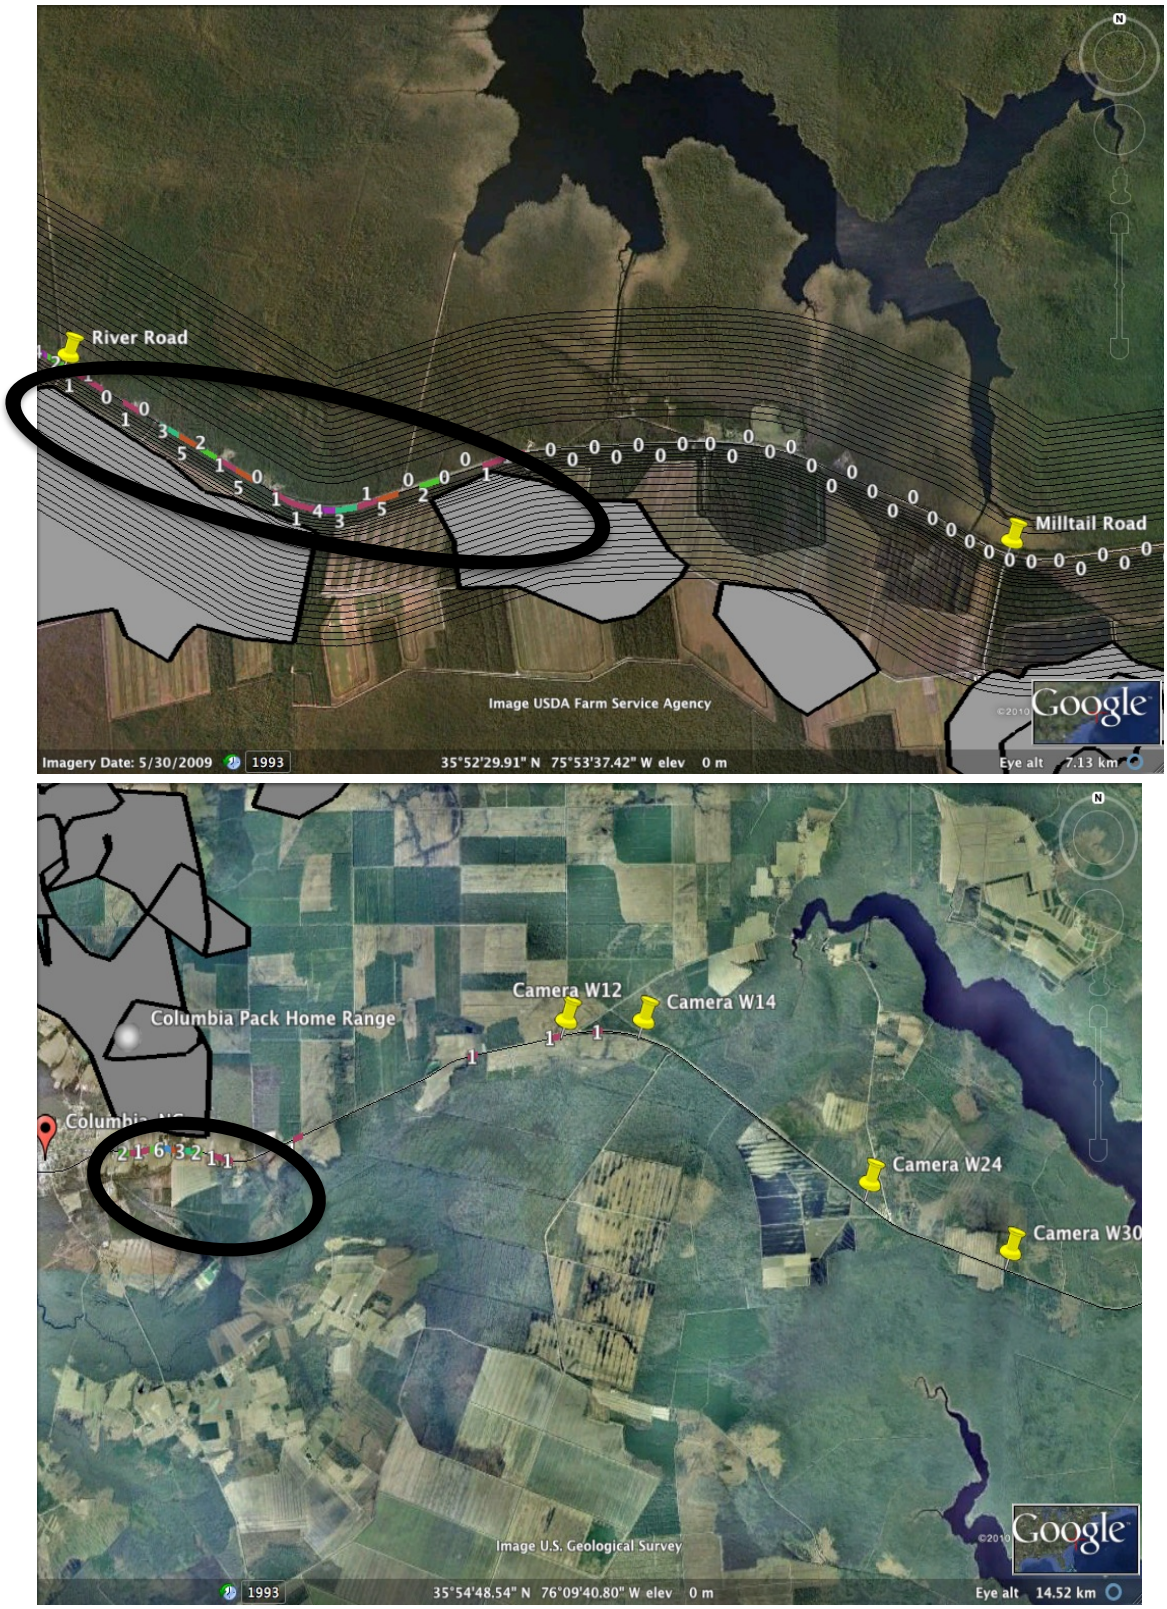

Figure 16. The two clusters of crossings identified by the GPS-collar data in both a) Dare and b) Tyrrell Counties, North Carolina coincided with the location where home ranges approached US 64. Crossings are based on GPS locations taken at 30- minute intervals between October 2009 and March 2011.

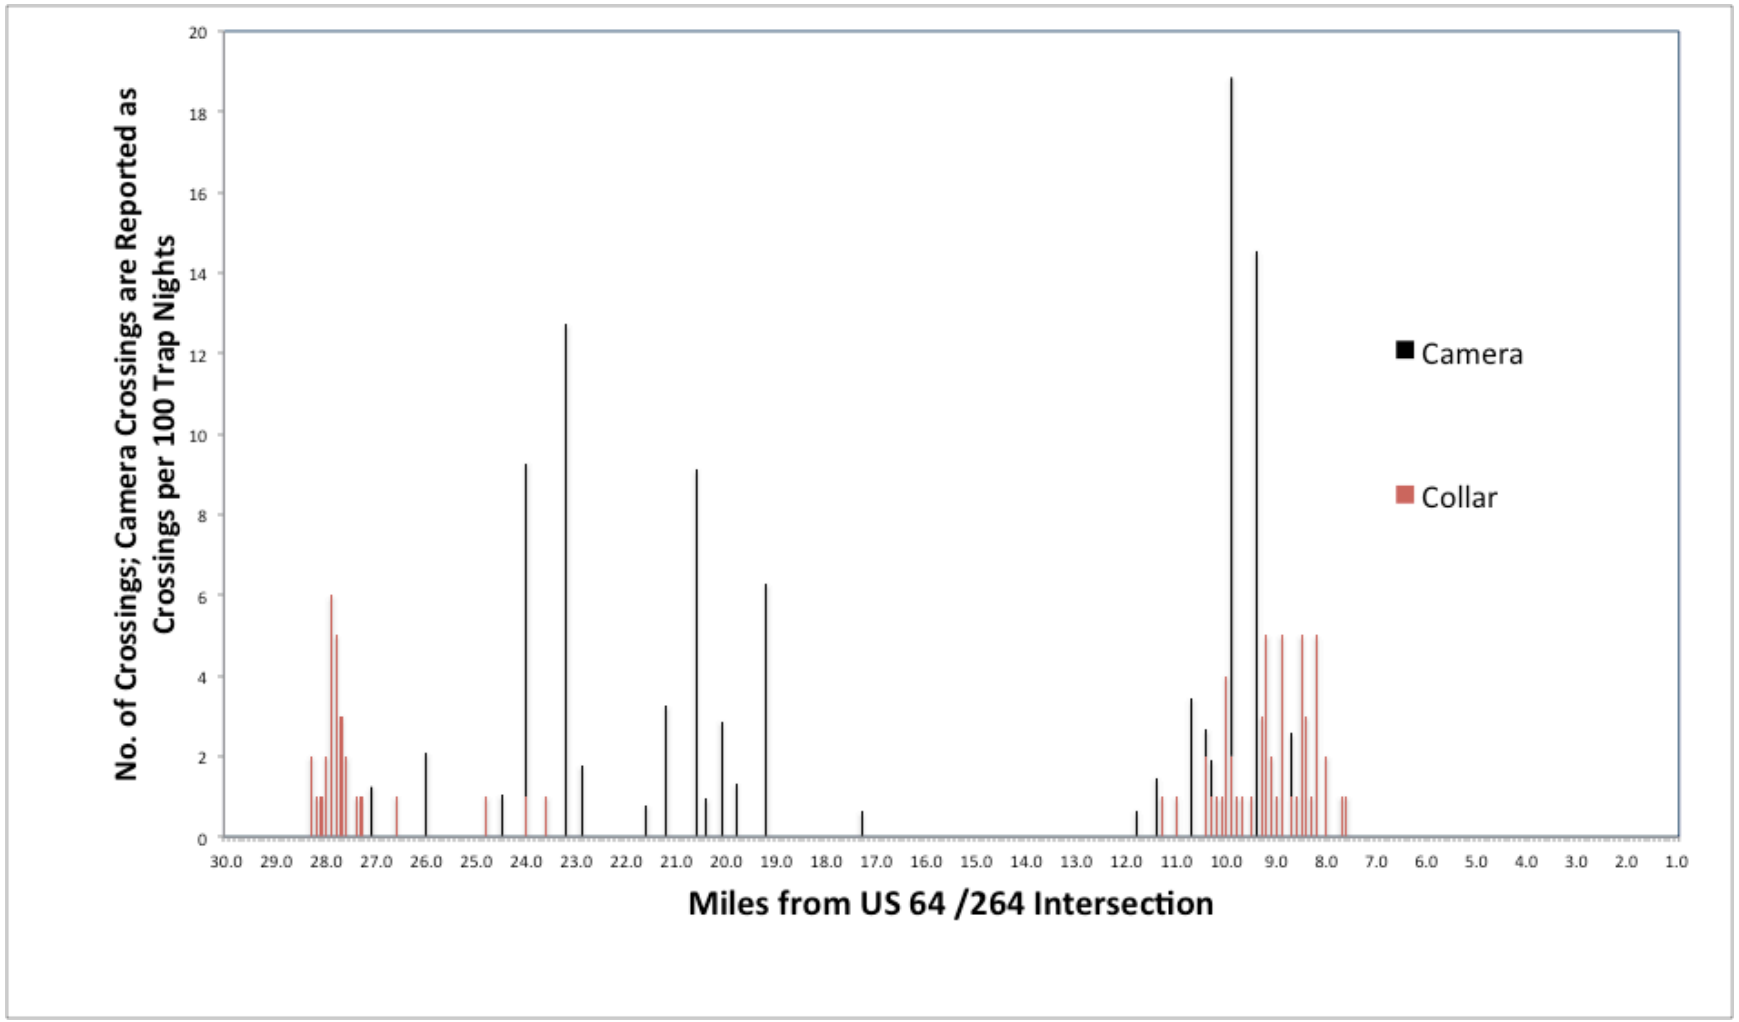

Figure 17. Combined GPS- collar (red bars) and camera (black bars) data, collected from 2009 – 2011, revealed 5 areas along US 64 currently used by red wolves as crossing sites, 4 in Tyrrell County west of Alligator River and 1 in Dare County east of Alligator River, North Carolina. Camera data are presented as number of captures per 100 trap nights. The red wolf crossing site identified by camera data in Dare County (miles 9 – 10) overlaps with the crossing identified by GPS-collar data (miles 8 – 10). However, crossing sites identified by camera data in Tyrrell County (miles 19, 20.5 and 23 – 24) do not overlap with the crossing site identified using GPS-collar data (mile 28). The crossing site in Dare County between miles 9 – 10 and the crossing site in Tyrrell County between miles 23 – 24 were considered one location each due to proximity and habitat continuity.

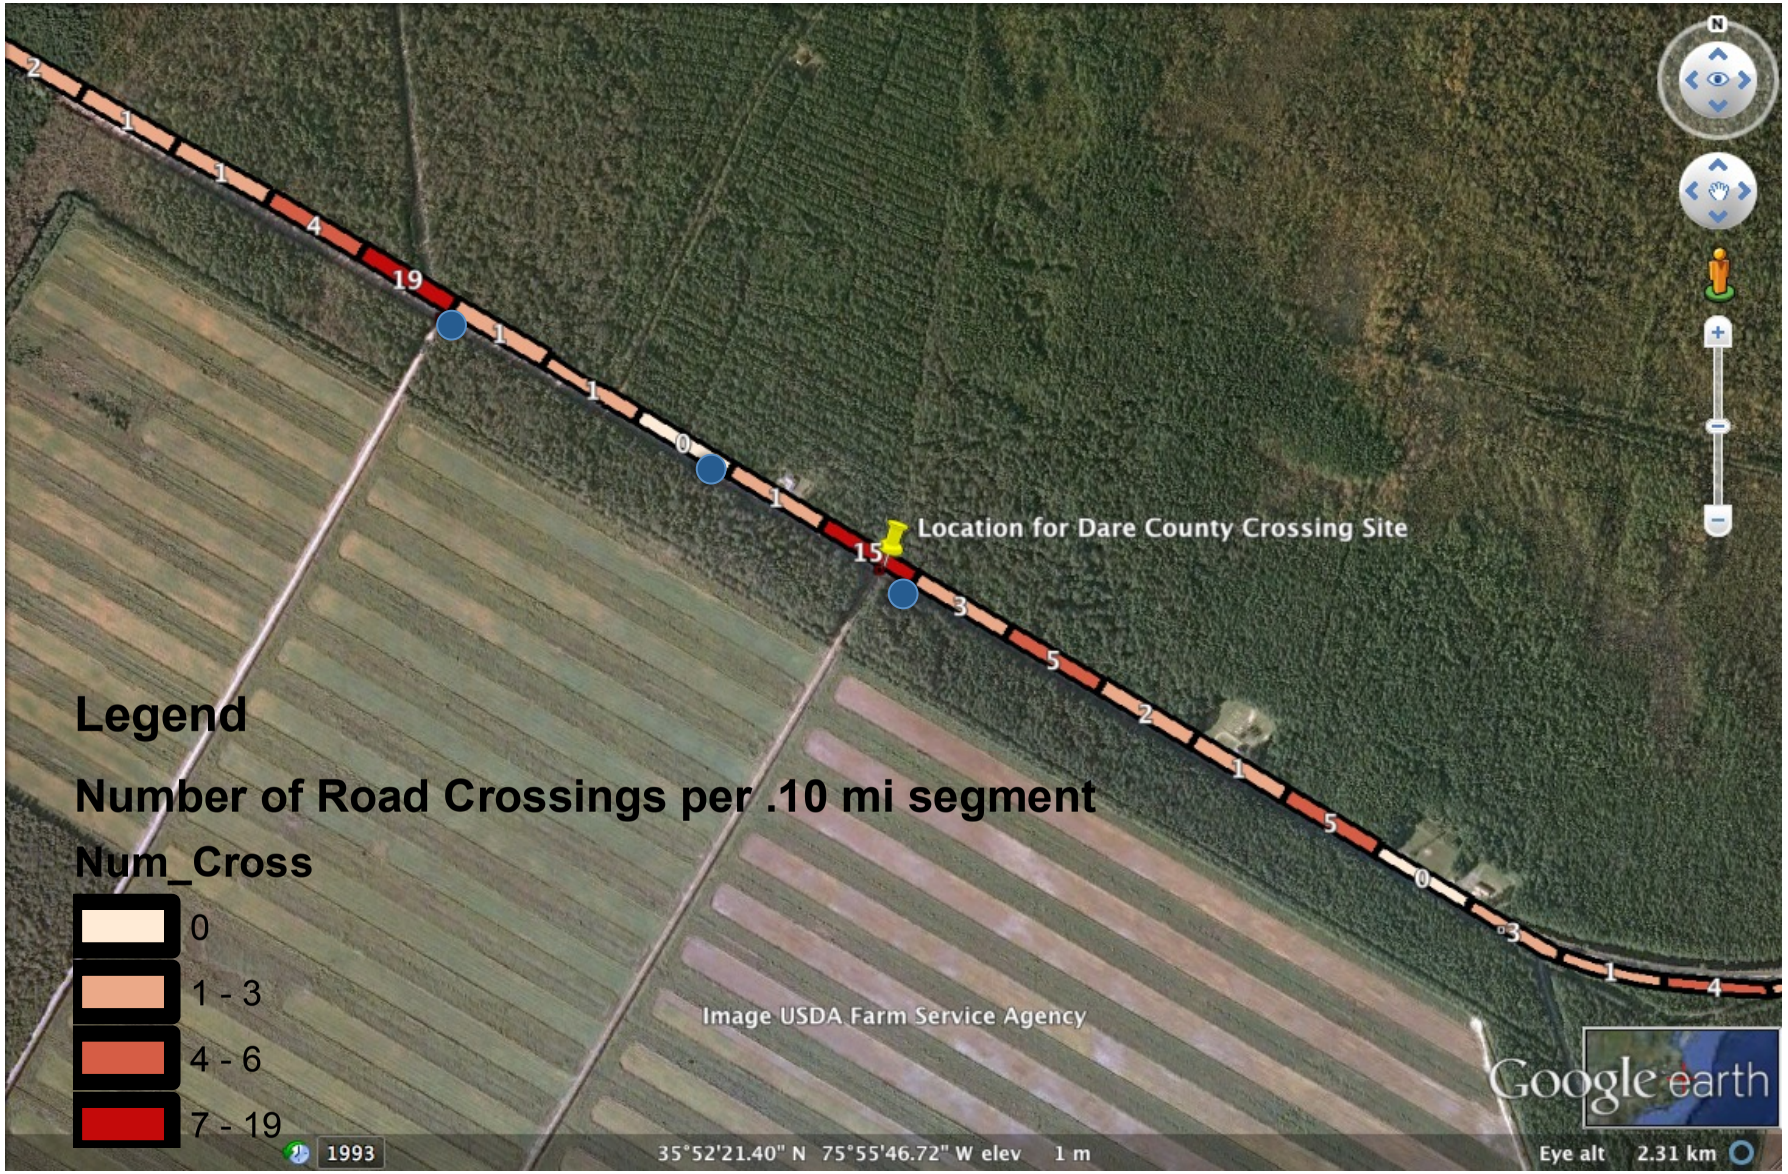

Figure 18. Map of red wolf highway crossing locations along US 64 in Dare County, NC. Crossing locations were calculated from GPS collar and remote camera data. The numbers indicate how many crossings per 0.10 mi. segment were recorded. The yellow marker shows the suggested location for a red wolf crossing structure in Dare County. The blue points indicate the location of a red wolf road mortality event.

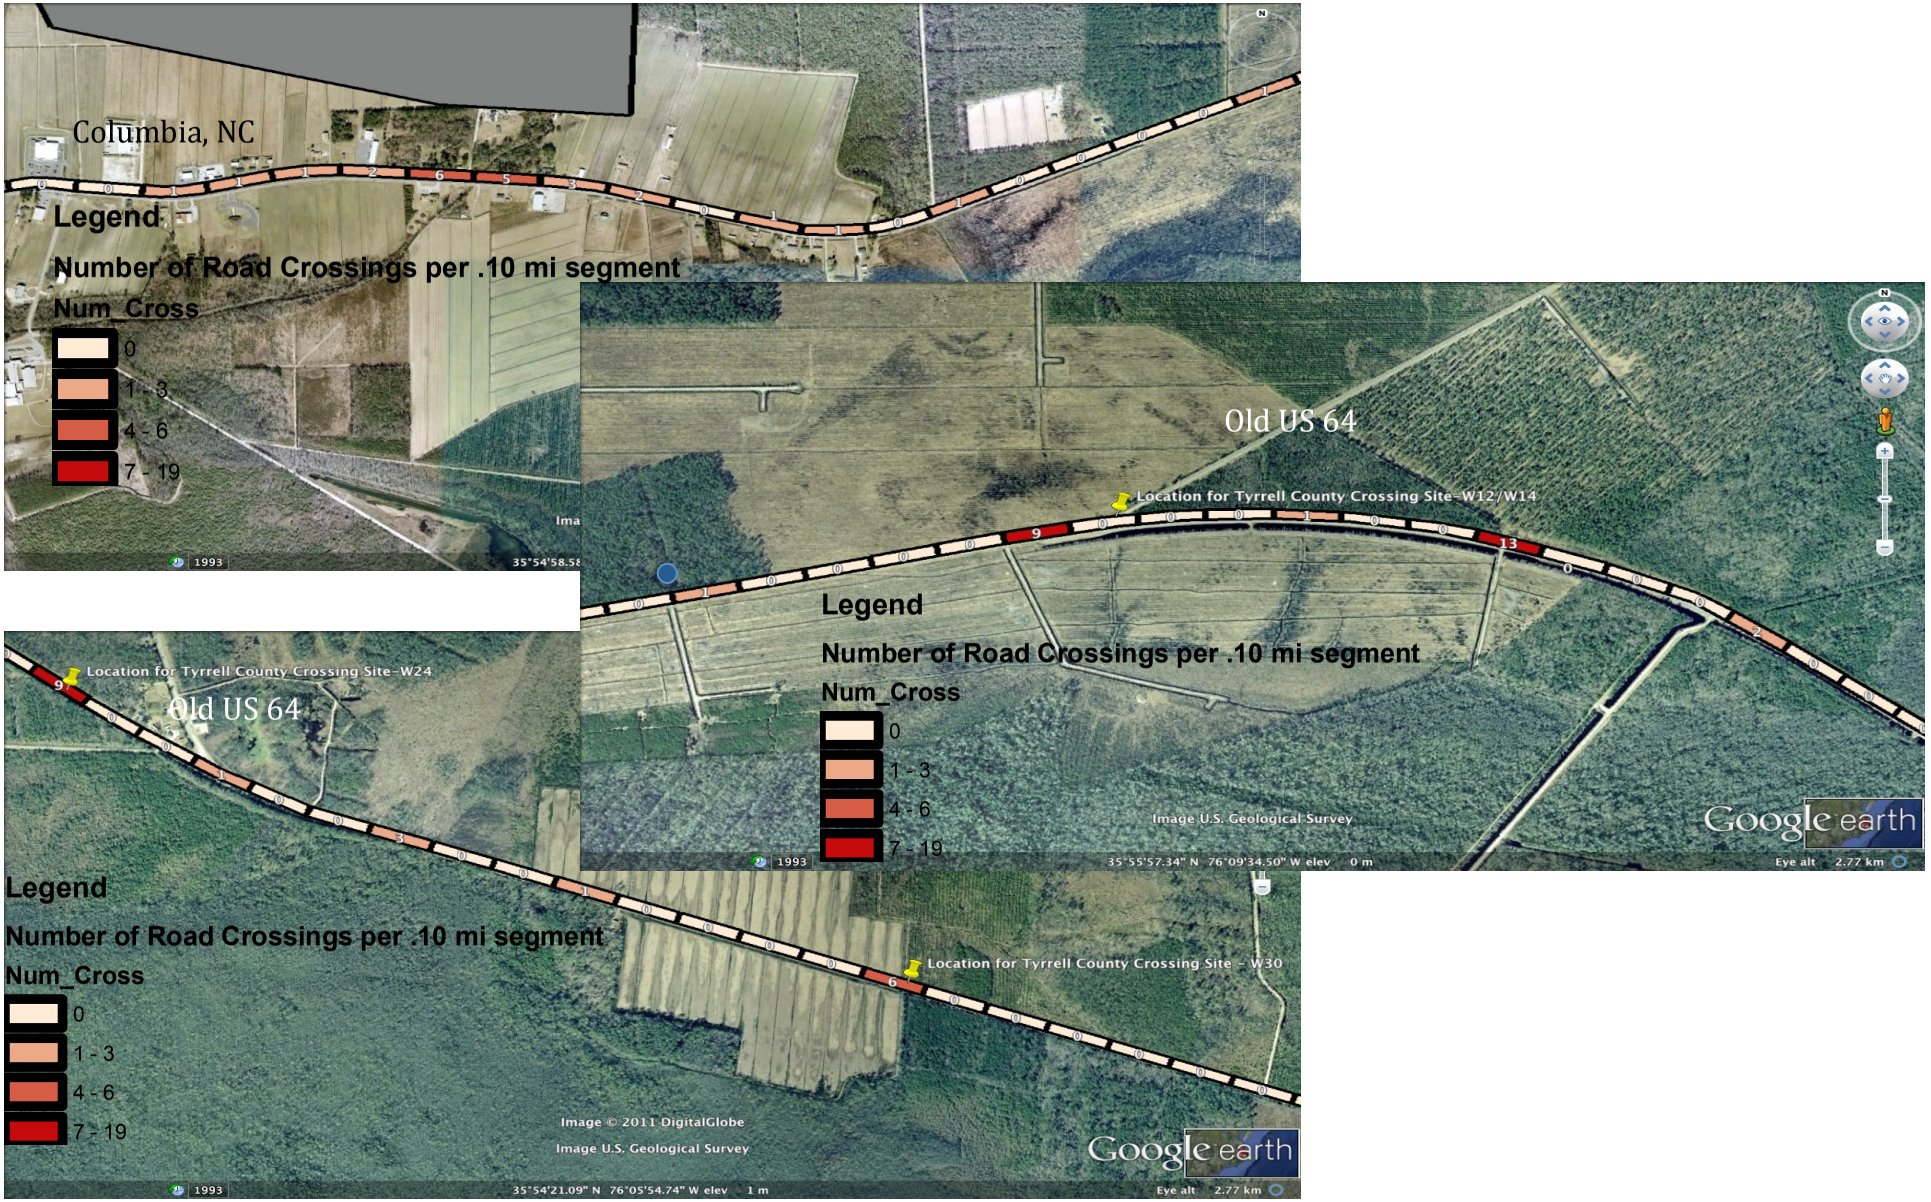

Figure 19. Map of red wolf highway crossing locations along US 64 in Tyrrell County, NC. Crossing locations were calculated from GPS collar and remote camera data. The numbers indicate how many crossings per 0.10 mi. segment were recorded. The yellow markers show the location of the 3 suggested locations for red wolf crossing structures in Tyrrell County. The blue point indicates the location of a red wolf road mortality event.

Evaluating habitat characteristics at crossing sites identified by GPS collar locations: The most parsimonious habitat model at crossing locations determined using GPS-collar data included habitat type at distances of 328 ft. and 492 ft. from the crossing site (Table 12). The AICc weight of the most parsimonious habitat model was 0.69. The second most parsimonious model included habitat type at 656 ft. from the crossing site and had a ΔAICc of 3.19 and an AICc weight of 0.07. The habitat types at distances of 328 ft. and 492 ft. from crossing locations correspond to those identified by resource selection functions for red wolves: agriculture, upland forests, and early successional fields.

Evaluating habitat characteristics at crossing sites identified by camera traps: The most parsimonious habitat model at crossing locations determined using camera trap data included width of the road/trail at the camera location (Table 13). The AICc weight of the most parsimonious habitat model was 0.89. The second most parsimonious model included road/trail width and habitat type at 164 ft. from the camera site and had a ΔAICc of 6 and an AICc weight of 0.03. The trail widths (which ranged from 1.64 ft. to 65.6 ft.) at camera trap locations with recorded red wolf crossings were 26.24 ft. or wider.

Table 12. Most parsimonious habitat model for red wolf crossing sites in Tyrrell and Dare Counties, NC identified using GPS-collar data collected between January 2009 and April 2011.

Model	AICc	ΔAICc
Habitat 329 ft from US 64 + Habitat 492 ft from US 64	42.99	0.00

Discussion

Objective 1: Evaluate wolf habitat use along the entire US 64 corridor from Plymouth NC to the US 64/264 intersection

Understanding of basic species survival needs is required before completing any wildlife management plan. This study used data from 16 wolves from 16 different packs to estimate home range size and habitat selection of red wolves (*Canis rufus*) in eastern North Carolina. The home range sizes we calculated (2.61 mi^2 – 38.19 mi^2) were smaller than those reported in 2 earlier studies that followed 3-red wolf packs each (Phillips et al., 2003: 13.40 mi^2 - 78.10 mi^2; Chadwick et al., 2010: 31.51 mi^2 - 57.72 mi^2). However, if the red wolf pack with the largest home range size in the Phillips et al. (2003) study is excluded, the home ranges for the remaining 2 packs fall within the range of our findings (13.40 mi^2 - 30.00 mi^2). In addition, Phillips et al. (2003) used minimum convex polygons to determine home range size where as we used α-NNCH, a more conservative method of home range estimation (Getz et al., 2007), which could account for the discrepancy in home range sizes between the two studies. Chadwick et al. (2010) tracked males 2 – 3-years in age, two of which were brothers, and therefore may have been dispersing individuals. Though not significantly different, our study showed that dispersing animals tended to have larger home ranges than adults or juveniles, which could account for the differences in home range size between our study and the one completed by Chadwick et al. (2010). Small sample size likely accounts for no significant difference in home range size among age classes. Seven dispersers were eliminated from this study, 5 due to death and 2 because of inadequate data. Summer (June – September) home range size (4.84 mi^2 – 5.73 mi^2) averaged for all 16 packs over 2-years (2009 and 2010) corresponded to summer home ranges reported (1.34 mi^2 – 4.72 mi^2) for one red wolf pack monitored during the summer of 2005 (Hinton et al., 2010). We did not look at the influence of pack size on home range size, as previous research suggests that a relationship does not exist between pack size and home range size in gray wolves (Jedrzejewski et al., 2007).

Similar to Phillips et al. (2003) and Chadwick et al. (2010), our study revealed that home range size varied with season, being smaller during summer months and larger in winter with monthly home range size peaking in January. Smaller home ranges in summer are likely due to the presence of pups (Phillips et al. 2003; Chadwick et al., 2010). Mating, den preparation and whelping for red wolves typically occurs between February and April (C. Lucash, per. comm.), which coincides with the reduction of monthly home range sizes. This study found that monthly home range continually reduced in size starting in February and continued until reaching the smallest size in April. Monthly home ranges remained small until September when they started a steady increase that peaked in January. Jedrzejewski et al. (2001) showed home range size and movement patterns of gray wolf (*Canis lupus*) packs were also influenced by reproductive cycles.

Habitat and prey availability also may influence seasonal fluctuations in home range size. We found that habitat in the home ranges was primarily composed of agricultural fields

year round. However, the percentage of agriculture within home ranges was highest in summer and lowest in winter. Increased use of agricultural fields in summer could be due to increased food resources available to prey species of red wolves such as white-tailed deer. A recent study found that red wolves readily prey on adult white-tailed deer (*Odocoileus virginianus*) and fawns during summer months (Dellinger et al., *In Press*). Growth of crops in agricultural fields in summer could help concentrate prey (Vercauteren and Hygnstrom, 1998). Additionally, the birth of fawns in early summer could provide a source of prey that is easier to catch, thus allowing red wolf packs to gather adequate food in a smaller area. Variation in home range size due to prey availability also has been shown in gray wolves (Ballard et al., 1987).

A decrease in percentage of agricultural fields making up home ranges in winter may be related to the harvesting of crops. Harvesting eliminates food resources available to prey and eliminates potential cover for red wolves. This study found an increase in non-agricultural habitats, such as upland forests, pocosins, and wetlands, during the fall and winter months (Table 6). Chadwick et al. (2010) noted that increased use of non-agricultural habitats corresponded to the harvesting of row crops between September and November and with the onset of the hunting season. Although this study showed that red wolves typically selected against non-agricultural habitats, cover types such as early successional fields, upland forests, and pocosins could be providing essential cover for red wolves after crop harvesting. Also, red wolves tend to prefer cover types with denser ground vegetation for den sites (Phillips et al., 2003), thus leading to a switch in habitat use during late winter and spring months.

Another important habitat finding is the selection for areas closer to roads. Most roads in the red wolf recovery zone are unpaved gravel or dirt roads used for agricultural purposes (C. Lucash pers. comm.). Red wolves likely used the road network as travel corridors, which could allow for packs to persist in areas where habitats are highly interspersed and large parcels of quality habitats are few.

Conclusion: White and Ernst (2004), Singleton et al. (2005), and Kindall and van Manen (2007) all stress the need to identify habitat linkages across barriers to properly place crossings. Thus, it is imperative not only that wildlife underpasses are constructed in areas identified as high use for crossings (Scheick and Jones, 1999), but also that crossings are placed in a manner that connects habitat being selected by the species of concern. This study suggests that red wolf crossing structures should connect agricultural landscapes that are interspersed with upland forests, successional fields and pocosins. In addition, avoiding the aforementioned cover types during construction will minimize direct impacts to the red wolf population.

Objective 2: Evaluate the significance of red wolf habitat changes anticipated from the proposed highway project from Columbia NC to the US 64/264 intersection.

This was the first study to employ the use of a permeability index to a non-seasonal migrating species. This provided a challenge in determining what could be considered a

road “approach”, as we had to be careful not to include normal movements within a home range as an approach. The resulting buffer width of 164 ft., which is similar to the buffer width suggested for gray wolves (Paquet and Callaghan, 1996), illustrates the willingness of red wolves to establish home ranges in close proximity to the current 2-lane highway. The resulting permeability indices calculated for the 2-lane section of US 64 using both 5-hour and 30-minute data were 1.0 and 0.99, respectively. This suggests that the current 2-lane highway is not discouraging the red wolf population from attempting to cross US 64. However, it is important to note that only 14 of the 32 collared red wolves crossed a highway within the 5-county recovery zone, and 8 of those only crossed either once or during dispersal. Just 6 wolves from 3 packs crossed a highway regularly, and all 3 packs had home ranges that were adjacent to or straddled US 64.

The original goal was to compare permeability indices between the previously widened 4-lane section of US 64 in Washington County to the permeability index for the 2–lane section. However, a decrease in and near disappearance of the red wolf population to the west of Columbia, NC, prevented the collaring of red wolves where the widening to a 4-lane highway already was completed.

Although the current 2-lane highway is not discouraging wolves from attempting to cross, it is important to note that most roads exhibit a distinct trade-off between permeability and road kill (Forman and Alexander, 1998). A highly permeable road might result in a high level of wildlife/vehicular collisions, whereas an impermeable road might have few road kill events. Yet this decrease in road kill comes at the expense of habitat connectivity. This trade-off indeed holds true for US 64. Though the 2-lane portion of US 64 may not be hindering attempts to cross, road mortality is the second leading cause of death among red wolves accounting for 14% of mortalities (USFWS, 2007).

Permeability was expected to behave inversely to traffic flow, decreasing during the busy summer months and increasing during the winter. However, due to the high permeability of the highway, no such relationship existed. In addition, time of day may play an instrumental role in the event that crossing times (typically at night) do not coincide with peak traffic hours (midday). Such a pattern could be determined by separating traffic flow and permeability data by time. It should also be noted that while traffic fluctuates heavily on US 64 between summer and winter, the highway experiences relatively low traffic volume (maximum 250 vehicles per hour during the peak season) in comparison to other highways in the vicinity of the Outer Banks outside of the study area (~791 vehicles per hour; Currituck Development Group, 2011). The Federal Highway Administration reports that relatively few animals avoid crossing the road at traffic volumes below 2,500 cars per day and, that while road avoidance increases at moderate volumes (2,500 – 10,000 cars per day), it is not until traffic volume surpasses 10,000 cars per day that a large portion of animals will avoid highway crossing attempts (Clevenger and Huijer et al., 2011). The average daily traffic volume for the study site is 1,995 cars per day with a peak of 6,500 cars per day in July, placing the focal section of US 64 in the low to moderate traffic flow category as defined by the Federal Highway Administration.

Construction north of the current US 64 in Tyrrell County has the potential to remove a maximum of 0.16 mi^2 of red wolf habitat and 6% of the home range area used by a current red wolf pack while construction to the south will directly impact only 0.09 mi^2 of red wolf habitat and will not displace any current red wolf packs. East of Alligator River in Dare County, a widening of the current highway to the south has the potential to lead to a loss of 0.07 mi^2 of red wolf habitat and 20% the home range used by the only existing red wolf pack in Alligator River National Wildlife Refuge. Construction to the north of US 64 in Dare County will only remove up to 0.04 mi^2 of red wolf habitat and will not overlap with any current packs. Therefore, limiting construction to the south of the existing US 64 in Tyrrell County and north of the highway in Dare County will avoid direct effects to the current red wolf population.

We highlight that these results quantify only direct effects on current wolf home ranges. Road construction can have many indirect effects through changing hydrology; air, water, noise, and light pollution levels; wind flow; humidity; temperature; vulnerability to invasive species; and habitat continuity (Forman et al., 2003; Coffin, 2007). These indirect effects of the construction can disrupt red wolves living adjacent to the existing highway causing a shift in current home ranges. Any shift in home ranges has the potential to affect social order, mating, and ability to locate prey. At this time we are not able to quantify these effects, but these potential indirect effects may be measured in the "during-" and "post-" construction phases of the project.

Conclusion: Road permeability, calculated using GPS-collar data, was 100%, thus the current 2-lane highway does not discourage the red wolf population from attempting to cross US 64. This does, however, increase the risk of road mortality events. A decrease in the red wolf population to the west of Columbia, NC, prevented collaring of red wolves where widening to a 4-lane highway was completed. Therefore, we were not able to compare highway permeability between 2- and 4-lane highways. To avoid any direct effects to the current red wolf population, highway construction should be limited to the south of the existing US 64 in Tyrrell County and north of the highway in Dare County. Potential indirect effects of highway widening activities were not quantified, as they could not be quantified using GPS or camera data. It is important to note that indirect effects can negatively effect the red wolf population.

Objective 3: Identify significant red wolf crossing areas to determine where wildlife crossing structures or other design features could be placed to minimize adverse project effects on wolves.

Movement patterns obtained through tracking of GPS locations and remote camera traps clearly demonstrate that red wolves crossed US 64 and two other highways in the red wolf recovery zone, with some frequency. This implies there is potential for one of two outcomes of widening the road from 2 to 4 lanes: (1) either increased traffic or the increased width itself may increase road mortality, or (2) these factors may decrease road permeability. The degree to which these threats are deemed relevant and serious will have a significant bearing on NC DOT's planning and execution of the construction project.

The distribution of GPS-collar locations and camera trap photos along US 64 revealed 5 distinct red wolf crossing sites, 4 west of Alligator River in Tyrrell County and 1 east of the river in Dare County. Though they do not overlap completely, GPS-collar data and camera trap data are in accordance for the location of the crossing site in Dare County. However, that is not the case in Tyrrell County. GPS-collar data revealed 1 crossing site in Tyrrell County, while camera trap data identified the 3 additional crossing sites. Two factors contributed to the 2-methods not overlapping in Tyrrell County. First, due to the number of false crossings, GPS-collar data from wolf #1880 was eliminated from our analysis, thus eliminating GPS-collar data along the section of US 64 coinciding with the cameras. False crossings were obtained from this wolf because US 64 bisected her home range (Figure 12). Secondly, cameras were not set up where GPS-collar data identified a crossing location in Tyrrell County due to increased risk of camera theft within the town limits of Columbia, NC.

The potential for "false crossings," which may suggest that a crossing took place in a different location from where it actually occurred, exists in the remainder of the GPS-collar data as well. However, the presence of such distinct activity clusters, particularly under the 30-minute schedule, suggests that our results captured real movement trends. Although we captured nearly 3 times as many crossing events and the data displayed tighter clustering with better defined locations using the 30-minute collar schedules, the location of crossing sites identified using GPS-collar data was generally consistent between the 2 schedules (5-hour and 30-minute).

The red wolf crossing site identified in Dare County is within the Alligator River Wildlife National Wildlife Refuge and is centered on Hickory Road. This matches the location of an important black bear crossing site (Vaughan et al., 2011), and therefore is a candidate site for the placement of a multi-species crossing structure for large wildlife. Likewise, the 3 red wolf crossing sites in Tyrrell County located via camera trap data overlap with candidate areas for large wildlife crossing structures identified in an earlier study by University of Central Florida (UCF) (Smith, 2011). The red wolf crossing site between miles 23 and 24 (cameras W12 and W14) overlaps with "Area 1" of the UCF study (Smith, 2011), which is centered on the western intersection of Old US 64 and US 64. The red wolf crossing sites at mile 20.5 (camera W24) and mile 19 (camera W30S) overlap with "Area 3"and "Area 5" of the UCF study, respectively (Smith, 2011) and are located near the eastern intersection of Old US 64 and US 64. Using the eastern intersection of Old US 64 and US 64 as a reference point, "Area 3" is 0.31 miles west of the intersection and "Area 5" is 1.16 miles east of the intersection.

The red wolf crossing site in Tyrrell County identified using GPS-collar locations is located within the town limits of Columbia, NC where US 64 narrows from 4 to 2 lanes. Placement of a crossing structure here may not be practical because of proximity to residential areas.

Crossing rates suggest that there is no difference in highway crossing behavior between sexes or among ages. As with the home range analysis, the lack of any significant difference in either sex or age class might simply be a function of low sample size, and it

is possible that a real relationship could be hidden by an interaction between the two variables, which we were unable to test for the same reason. This possibility is supported by data on road mortality, which has impacted dispersers hardest among the age classes. Although road mortality accounts for 14% of deaths for the red wolf population over all, when broken down by age class, road mortality accounts for 19% of dispersers but only 6% of breeding adults (USFWS, 2007). Low sample size and high expense per individual is a common hurdle in research involving large carnivores, as was true for this study. In addition, the status of the red wolf as critically endangered puts a major constraint on population size from which to draw a sample.

In addition to identifying the location of important red wolf crossing sites, we also investigated which habitat variables were correlated with those locations. The presence of agricultural fields, successional fields, and/or upland forests 328 ft. to 492 ft. (100 to 150 m) from the road best predicted where a red wolf chose to cross when using GPS-collar data while trail/road greater than 26.24 ft. (8 m) provided the best explanation for the location of crossing sites identified by remote camera traps. The presence of agricultural fields, successional fields, and upland forests as well as proximity to maintained agricultural/forest roads at crossing sites corresponds to habitat selection results.

Conclusion: The distribution of GPS-collar locations and camera trap photos along US 64 revealed 5 distinct red wolf crossing sites, 4 west of Alligator River in Tyrrell County and 1 east of the river in Dare County. Four of the 5 red wolf crossing locations we identified are suitable for crossing structures. The most western crossing site is located within the town of Columbia, NC where retro fitting a wildlife underpass may be impractical. All 4 crossing sites suitable for placement of a crossing structure overlap with large wildlife crossing locations identified in previous studies. The 1 red wolf crossing site located in Dare County is centered on Hickory Road and the 3 crossing sites in Tyrrell County are approximately where US Old 64 intersects with US 64. Although no significant difference in crossing behavior was found during this study, high road mortality among dispersers suggests they may cross the highway more frequently than adults or juveniles. The most parsimonious models looking at the relationship between habitat variables at 164 ft. increments from US 64 and road/trail widths measured at road access points where cameras were placed (e.g. dikes, logging roads, public property access roads) indicates that well maintained trails at least 26.24 ft. (8 m) in width leading to and from underpasses and connect habitats selected for by red wolves (e.g. agriculture, successional fields, and upland forests), will optimize efficacy.

The data presented here are reflective of the current population's behavior. In the event that wildlife crossing structures are deemed necessary, our results identify locations where crossing structures would have the greatest effect on the red wolf population. This project is only one of several examining the use of US 64 by numerous wildlife species. The results of those studies, in addition to this one, should be taken into account in determining the need for mitigation, the type of mitigation to use, and the layout that would be most compatible with all target species. The direct and indirect effects of the road widening project remain difficult to predict, yet the potential for a negative effect on the red wolf must be considered. Careful monitoring of the red wolf population

throughout and following the construction process will be crucial to ensuring red wolf survival and will aid management decisions in future road issues.

Literature Review

Red Wolves: Past, Present, and Future

Red wolves (*Canis rufus*) were originally described in 1851 by Audubon and Bachman and considered a subspecies of the gray wolf. However, red wolf heritage came under debate in the mid-1900's when Goldman suggested that all of the southeastern wolf subspecies should be combined into the distinct species of *Canis rufus*, separate from gray wolves. Many supported this decision until the advent of genetic methodologies in the 1990's. Genetic studies in the 1990's provided support for the hypothesis that red wolves evolved from a natural hybridization between gray wolves and coyotes (Wayne and Jenks 1991; Wayne 1992; Roy et al. 1994, 1996; Wayne and Gittleman 1995; Wayne et al. 1998; Reich et al. 1999). However, Wilson et al. (2000) suggested that red wolves and Algonquin wolves (*Canis lupus lycaon*) diverged from gray wolves 1.2 million years ago and then diverged from coyotes 150,000 to 300,000 years ago. Work by Hendrick et al. (2000) investigating major histocompatibility complex genetics data indicates that red wolves are more closely related to coyotes than to gray wolves, adding support to the claims made by Wilson et al. (2000).

The current stance that the red wolf is a species in its own right, separate from gray wolves, coyotes, and domestic dogs is based on mtDNA sequencing of 340 base pairs showing a unique sequence for red wolves (Adams, 2002; Adams et al., 2003). However, the debate over red wolf taxonomy is far from over. Both Wilson et al. (2000, 2003) and Kyle et al. (2006, 2007) now suggest that red wolves and Algonquin wolves are genetically similar enough to be combined into one species, the eastern wolf (*Canis lycaon*). In 2007 Murray and Waits, while acknowledging the genetic similarity between red wolves and Algonquin wolves and the plausibility that they are conspecifics, argue that combining the two species would hinder red wolf conservation efforts and the ability to secure conservation funds because red wolf extinction would become an issue of population extinction rather than species extinction. In 2008, Kyle et al. rebutted the article by Murray and Waits stating that taxonomy embracing conservation agendas rather than scientific scrutiny should be avoided. Kyle et al. (2008) go on to say that while they agree with Murray and Waits (2007) that there are instances in which genetically unique populations warrant protection, that the genetic uniqueness of the red wolf population is not supported scientifically. Red wolves and Algonquin wolves are only separated genetically by one mtDNA haplotype differing by one base pair (Wilson et al. (2000, 2003). Kyle et al. (2008) suggest that any difference between red wolves and Algonquin wolves may be an artifact of a low effective population size, a founder effect, a by-product of artificial selection, and/or because of current management strategies that remove individuals that are <80% red wolf from the breeding population (potentially removing important red wolf genes from the population). For now, the taxonomy of red wolves remains under debate.

The historical range of red wolves was originally described as occurring from south central Texas east to Florida and then north to the Ohio River (Nowak, 1979). The historical range was then extended north to Pennsylvania in 1995 (Nowak) and then north again to south central Maine in 2002 (Nowak) in support of the theory that there is one eastern wolf species. Red wolves declined initially with European colonization (USFWS, 2007). Predator control programs and habitat fragmentation in the 1960's dramatically reduced red wolf populations. By the 1970's, red wolves were reduced to remnant populations along the Texas and Louisiana coast. In 1973, the red wolf achieved endangered status with the passing of the Endangered Species Act of 1973. The United States Fish and Wildlife (USFWS) Service worked to capture the remaining wild red wolves between 1974 and 1980 to establish a captive breeding population as a last ditch effort to save the red wolf (USFWS, 2007). The USFWS successfully captured 17 individuals, 14 of which were used as founders for the captive breeding program (USFWS, 2007). As a result of capturing the remaining wild animals, red wolves were declared extinct in the wild in 1980.

Through the establishment of a captive red wolf breeding program with the Association of Zoos and Aquariums (AZA), enough red wolves were bred in captivity to attempt a reintroduction in 1987. The reintroduction began with the release of 4 breeding pairs on the Alligator River National Wildlife Refuge. By 1988, the first pups (2 litters) were born post reintroduction (USFWS, 2007). The USFWS started two additional red wolf reintroduction programs; in 1991 at the Great Smoky Mountains National Park at the Tennessee/North Carolina border and in 1993 at the Pocosin Lakes National Wildlife Refuge in North Carolina just 27 miles west of the original reintroduction site. The reintroduction in the Great Smoky Mountains did not succeed, but the reintroduced populations at Alligator River National Wildlife Refuge and the Pocosin Lakes National Wildlife Refuge continued to expand and merged to form the current, and only, red wolf population in the wild. The current red wolf recovery zone has expanded to 5 counties in North Carolina's Albemarle Peninsula (Dare, Tyrrell, Washington, Beaufort, and Hyde Counties – see current range in Figure 1) and contains between 100 and 130 red wolves forming 20 packs (USFWS, 2007). Red wolves remain listed under the Endangered Species Act of 1973 (USFWS, 2007) and are recognized by IUCN as one of the most endangered canid species in the world (IUCN, 2006). The re-introduced population is designated as non-essential experimental.

The USFWS has a population goal of 220 individuals, yet the population has fluctuated between 100 and 130 individuals over the past 12 years (USFWS, 2007). USFWS biologists with the Red Wolf Recovery team feel that the population can still expand further west allowing population growth to continue. However, non-USFWS researchers on the Red Wolf Implementation Team believe that the red wolf population may have reached carrying capacity within the recovery zone (USFWS, 2007). Models suggest that carrying capacity for red wolves within the current 5 county recovery zone is approximately 138 individuals (Murray, unpublished data). Starting in 2002, to help bolster the wild population, captive-born pups have been fostered to wild parents with similarly aged pups (USFWS). However, a better understanding of habitat requirements is needed to determine the ability of the peninsula to hold more animals.

Management of the red wolf gene pool and genetic fitness are the primary focus of the red wolf recovery and species survival plan due to a low effective population and potential founder effects. Genetic drift and inbreeding depression are of concern with small populations (Caughley, 1994). A study by Kalinowski et al. (1999) reported to find no evidence of inbreeding depression within the captive red wolf population. Long and Waddell (2006) reported that the captive population retained 89.65% of the genetic diversity of the founding captive population. Despite these results, there have been reports of physical anomalies in the captive red wolf population such as progressive retinal atrophy, malocclusion and undescended testicles (USFWS, 2007). Although a study by Miller et al. (2003) showed that only a few individuals per generation were needed to maintain sufficient genetic diversity in a grizzly bear population, further studies are needed to determine if genetic drift and inbreeding depression are impacting the wild red wolf populations.

For now, management of the reintroduced red wolf population focuses on a different genetic problem, the introgression of coyote genetics. Kelly et al. (1999) reported interbreeding between coyotes and red wolves resulting in coyote gene introgression into the wild red wolf population. As a result, an adaptive management plan was developed (Fazio et al., 2005). The plan calls for either the complete removal of coyotes and hybrids or the sterilization of hormonally intact coyotes and hybrids via vasectomy and tubal ligation, depending on the location within the recovery zone. In Zone 1 of the plan, all coyotes and hybrids are removed. In zones 2 and 3, coyotes and hybrids are sterilized and then used as territorial "place-holders" until replaced by wild red wolves. The sterilized coyotes and hybrids cannot interbreed with wild red wolves and they exclude intact coyotes or hybrids from the territory they hold. The idea is that these sterilized animals act as "place-holders" until red wolves replace them either naturally via displacement or through management actions to make room for translocation of a red wolf pair. The effectiveness of the management plan is evaluated via non-invasive genetic monitoring of canid scats (Waits 2004; Waits and Paetkau, 2005; Adams, 2006; Adams and Waits 2007). Through continued genetic monitoring, Adams noted strong evidence that a single hybridization event in 1993 resulted in most introgression of coyote genes into the red wolf population observed to date. From this evidence, Adams (2006) infers that hybridization with coyotes has had less genetic impact on the restored red wolf population than originally thought by Kelly et al. (1999), largely because backcrossing has been rare in the population.

Due to the immediate attention required to address the hybridization of red wolves and coyotes, less is known about red wolf home range, habitat, and diet requirements. Two recent studies examined red wolf home range and habitat use. The first study (Hinton and Chamberlain, 2010) used VHF collars to follow two red wolf packs during summer 2005 (July to September), one with pups and one without pups. This study found that the pack with pups had a smaller average home range size than the pack without pups, 5.74 km^2 vs. 9.55 km^2 for diurnal home range and 8.24 km^2 vs. 9.40 km^2 for nocturnal home ranges, respectively (Hinton and Chamberlain, 2010). Although it is important to note that the larger averaged home range calculated for the non-breeding pack is likely driven

by one male whose home range was 2-3 times larger than any other wolf in the study. Adults in both packs increased home range size nocturnally (1800-0559 hours) and both packs spent approximately 98% of their time in agricultural fields, defined as corn, soybean, and cotton (Hinton and Chamberlain, 2010).

The second study investigating red wolf home range and habitat use employed GPS collars to monitor 4 male wolves from 3 packs over a period ranging from 11 to 18 months (Chadwick et al., 2010). Chadwick et al. (2010) corroborated the finding that red wolf packs primarily utilize agricultural fields during summer and early fall months, with highest use of agricultural fields occurring July through September. However, they noted a seasonal switch to grass/brush and forested habitats during winter and early spring months, November to May (Chadwick et al., 2010). Though results of both studies showed similar summer habitat preferences, the home range size estimates calculated by Chadwick et al. (2010) were several magnitudes larger than those calculated by Hinton and Chamberlain (2010). Home ranges reported in Hinton et al. (2010) ranged from 3.48 km^2 to 12.24 km^2 while those calculated by Chadwick et al. (2010) ranged from 81.6 km^2 to 148.1 km^2. Both studies employed kernel density estimators to estimate home range size. Chadwick et al. (2010) did mention that they found a 40 to 63% reduction in home range size during summer months, but that places their summer home range estimates between 51.4 km^2 and 59.24 km^2, still considerably larger than those estimated by Hinton and Chamberlain (2010).

Though Hinton and Chamberlain (2010) did calculate home range size for both sexes and all age classes, they only collected point locations for a period of 3 months and the number of daily locations varied. Chadwick et al. (2010), while focusing only on nocturnal movements of males, collected point locations over a period of 11 to 18 months and were able to consistently collect 4 locations per day with the use of GPS collars. This suggests that the discrepancy in home range estimates between the two publications may be the result of Hinton and Chamberlain (2010) not collecting enough locations to accurately capture the entire home range size. Until data on all sexes and age classes collected covering the entire 24-hour period and across all seasons is made available, conclusions concerning red wolf home range and habitat requirements cannot be made.

Phillips et al. (2003) reports that the primary prey species of red wolves include: white-tailed deer, raccoon, rabbits, nutria, and other small rodents. A more recent diet assessment via scat analysis lists white-tailed deer as the primary prey item of red wolves (Dellinger et al. in review). However, packs will increase the amount of small rodents and human-sourced foods (e.g. hog pits) in their diet during periods of increased energy demands such as pup rearing (Dellinger et al., in review).

For red wolf management to move forward, the current gaps in knowledge of red wolf natural history need to be filled. Furthermore, before model building to predict the effect of a highway widening through the red wolf recovery zone starts, base knowledge of home range and habitat selection is required.

Road Ecology

Accompanying the rapid expansion of our transportation network was a growing concern over the environmental effects of roadways. The emergence of road ecology, coined by Richard T.T. Forman (1998), as a distinct discipline has brought together scientists from many disciplines (e.g. landscape ecology, wildlife biology, toxicology, hydrology, limnology, etc) and engineers to tackle the ecological challenges posed by transportation systems. For several decades now, researchers have studied the effects of roads on both the abiotic and biotic components of ecosystems. As a result, we now know that roads affect hydrology, air, water, noise, light pollution levels, wind flow, humidity, temperature, vulnerability to invasive species, and habitat continuity (Forman et al., 2003; Coffin, 2007). Such large-scale and multifaceted changes to ecosystems have many detrimental effects on wildlife (Jackson, 1999), including direct mortality (Lalo, 1987; Harris and Scheck, 1991; Schwabe and Schuhmann, 2002), habitat destruction (Theobald et al., 1997; Angelsen and Kaimowitz, 1999), barrier effects (Forman et al, 2003), and increased human land use activities (Bjurlin and Cypher, 2003; Coffin, 2007).

Before road mortality can be effectively mitigated, it is important to understand the factors that influence wildlife-vehicle collisions to occur in the first place. Jaarsma et al. (2006) modeled several road, traffic, vehicle, and species characteristics to find which had the greatest influence on the occurrence of a wildlife vehicle collision event. They found that traffic volume and the animal's traversing speed were the greatest predictors in determining a road mortality event, with higher traffic volumes and slower crossing speeds more likely to lead to a collision (Jaarsma et al., 2006). Two separate studies investigating the relationship among road kill events, body size, and diet found that carnivores were less likely to be hit along a road as compared to herbivores and omnivores (Ford and Fahrig, 2007, Barthelmess and Brooks, 2010). Those same two studies found a peaked relationship between road mortality and body size, with small (<1 kg) and large (>10 kg) body animals less like to be killed by vehicles as compared to medium (1 – 10 kg) sized animals (Ford and Fahrig, 2007, Barthelmess and Brooks, 2010). All three of the above cited articles suggest that direct mortality resulting from roads may not have a significant negative impact on carnivore populations as many carnivores are faster moving and larger bodied.

However, a study in southern Texas that looked at the influence of habitat variables on the location of bobcat road mortality events found that suitable habitat adjacent to the highway best explained the location of mortality events (Cain et al., 2003). These results were corroborated by another bobcat study in southern Illinois (Kolowski and Nielsen, 2008). Likewise, red wolves in northeastern North Carolina cross highways at locations adjacent to preferred habitat and established home ranges (Proctor, unpublished data). These results are similar to studies evaluating the use and success of highway crossing structures. The most successful wildlife crossing structures are the ones that connect preferred habitats of the targeted species (Ng et al. 2003, White and Ernst 2004, Singleton et al., 2005, Kindall and van Manen, 2007).

When vehicle strikes do occur, they account for a low percentage of mortality in

carnivores and do not translate into population level effects. Even for endangered San Joaquin kit foxes, road mortality rarely accounted for over 10% of mortality, with predators accounting for most mortality events (Bjurlin and Cypher, 2003). In a 3-year study that followed 60 radio collared kit foxes that lived in close proximity to a 2-lane paved highway, only one was lost to a vehicle strike (Cypher et al. 2009). However, prior to mitigation efforts, road mortalities did account for 49% of mortality in Florida panthers (Maehr et al., 1991). The carnivore populations with the highest reports of road kill events in the United States are black bears. In Virginia, black bears and white-tailed deer account for the most frequently recorded road kill events (Donaldson, 2007). Two studies in Florida found increased road mortality of black bears in areas of higher road density (Hostetler et al., 2009, McCown et al., 2009). These results differ from studies focusing on other carnivore populations where an increase in road density lead to increased road avoidance rather than increased mortality events (Dickson et al. 2005, Chetkiewicz and Boyce 2009). However, the studies by Ford and Fahrig (2007) and Barthelmess and Brooks (2010) did find that omnivores are more likely to be stuck by vehicles as compared to carnivores. Although black bears are classified as carnivores, their diet is omnivorous.

A barrier effect blocking access to resources, dispersal, and gene flow is the greatest impact of highways and roads on carnivore population in the United State. A study in southern California found that while cougars often made use of dirt roads, they actively avoided paved roads (Dickson et al., 2005). Similar results were found in another study with cougars negatively associated with roads, particularly during winter months (Chetkiewicz and Boyce, 2009). Riley et al. (2006) found that coyote and bobcat populations in southern California separated by a major freeway exhibited genetic differentiation, suggesting that the freeway is a barrier to dispersal. For those that do cross, heightened territorial behavior along roadways can discourage reproductive success, again limiting gene flow (Riley et al., 2006). Likewise, a study found that a highway in southern Canada is acting as a dispersal barrier for grizzly bears at the US-Canada border, as evidenced through genetic differentiation between the two populations (Proctor et al., 2005). The result is the creation of two vulnerably small populations (Proctor et al., 2005). A highway was found to restrict gene flow in a Cleveland, Ohio coyote population and direct the movements of migrants towards urbanizing centers (Rashleigh et al., 2008). Even when they do not constitute an absolute physical barrier, high-use roads can lead to avoidance behavior in canids affecting their ability to move across a landscape (Kaartinen et al., 2005, Whittington et al., 2004). The degree to which a road impacts canid survival is dependent on the specific situation, and sometimes no detrimental effects are observed, as in the case with San Joaquin kit foxes (Cypher et al., 2009).

The amount to which a road constitutes a movement barrier for black bears is dependent of the level of traffic volume (McCown et al., 2009). A study documenting the movements of two black bear populations along the same highway in Florida found that the population living in the area with lower traffic volume crossed the highway more often (McCown et al., 2009). In Maryland, black bears avoided the larger primary highways, but readily crossed all other road classes (Fecske et al., 2002). In the northern

Rockies, just under 50% of collared black bears were willing to cross a highway at least once were (Lewis et al. 2011). A study in North Carolina found that site occupancy of black bears deceased from 0.81 to 0.35 a highway in the study area was widened from 2-lanes to 4-lanes (Nicholson and van Manen 2009). For black bears, roads appear to exhibit the distinct trade-off between permeability and road kill discussed by Forman and Alexander (1998).

Though the last 10 years has documented many adverse effects of highways and roads on carnivore populations, there have been positive developments as well. Highway crossing structures have been successful at mitigating some negative impacts of highways on carnivore populations. In Texas, bobcats did make use of culverts to cross a highway when the culverts were placed adjacent to suitable habitat (Cain et al., 2003). A study in California found that a large variety of species, including reptiles, small mammals, carnivores, and mule deer use highway underpasses, even underpasses not designed specifically for wildlife (Ng et al., 2004). A study investigating wide variety of structures, including culverts, modified box-culverts, underpasses, and overpasses, found that culverts were the least used preferences between underpasses and overpasses varied with species (Mata et al., 2008). A study in Portugal found that red foxes, badgers, genet, and Egyptian mongooses used underpasses and culverts without preference (Grilo et al., 2008). However, a study of wildlife underpasses in Virginia revealed that while they were effective for foxes and coyotes, they did not find evidence of black bears utilizing highway underpasses (Donaldson, 2007). Likewise, a study monitoring the success of multi-species highway underpasses following a highway-widening project found that bobcats, black bears, and foxes utilized underpasses, but not coyotes or red wolves present in the area (McCollister and van Manen, 2010).

In all documented success of highway crossing structures, the authors noted that the successful structures connected areas of suitable habitat for the target species. The non-detection of all area carnivore species in the multi-species crossing structures may be the result of not being located in an area that contains suitable habitat for all species. Though multi-species structures may be may appear to be more cost effective initially, a lower success rate will decrease the cost effectiveness in the long run.

While the subjects above have gotten considerable coverage in the peer-reviewed literature, relatively little research has been directed at determining the placement of highway underpasses. In may be beneficial to focus future research efforts on determining the effective placement of highway crossing

Of the studies that focused on placing mitigating structures, methodologies have varied widely and range from non-invasive to the capture and handling of target species. Non-invasive techniques include the use of track/trail counts (Van Dyke et al., 1986; Rodriguez et al., 1996; Alexander and Waters, 1999; Scheick and Jones, 1999, 2000; Barnum, 2001, 2003), remote cameras (Scheick and Jones, 1999, 2000), barbed wire hair traps (Wills and Vaughan, 2005), road kill surveys (Clevenger et al., 2003b; Mazerolle, 2004; Smith et al., 2009), and GIS based modeling (Smith et al. 1998; Klein, 1999; Kobler and Adamic, 1999; Sheick and Jones, 1999, 2000; Clevenger et al., 2003a; Lloyd

et al., 2005). Non-invasive techniques are relatively inexpensive and can be effective, however all are time intensive. A constraint of track counts is the requirement of an appropriate substrate, the use of sand, or, in some areas, the presence of fresh snow. Remote camera traps provide crossing location, date, time, and work for a wide variety of species. Yet, cameras cannot cover the entire length of the highway simultaneously. Running barbed wire the length of the study area provides crossing location and, with the addition of genetics, crossing frequency on the level of the individual. Drawbacks of using barbed wire include the added cost of genetics and the limited number of mammals this technique is appropriate for. Road-kill surveys to detect crossing hotspots are an excellent method for collecting data on a wide range of species simultaneously. However rate of decay, scavenger activity, and method of survey (driving vs. walking) can affect results and must be considered in planning survey interval times. Road kill surveys may also miss animals that wander away from the collision site before dying. It has also been suggested that while road kill events do represent failed attempts to cross, they do not necessarily indicate important linkage areas. The primary weaknesses of the GIS-based techniques are data availability and data quality. GIS models are most effective when data on habitat use patterns of the subject species are well known and where the habitat is diverse and heterogeneous. A limitation of non-invasive techniques as a whole, with the exception of GIS based models, is inherent bias unless the entire length of the proposed highway construction project is covered. Many of the studies cited here established transects or plots rather than surveying the entire study area, thus missing crossing activity at sites not surveyed.

The more invasive techniques involve capturing and collaring target species in order to track movements. These techniques are especially useful when the study is focused on a particular species as opposed to a generalized group. A few studies employed the use of VHF radio collars to identify road-crossing locations and the influence of highways on animal movements (Beringer et al., 1990; Chruszcz et al., 2003; Riley et al., 2003; Dickson et al., 2005; Wray et al., 2005). Though radio telemetry is a more affordable method of telemetry, it is time intensive and often long time intervals exist between locations. Low-resolution movement data may inaccurately depict crossing sites, or miss crossings altogether. In addition, accessibility to collared animals can be limited due to terrain, road condition, and/or private property. GPS telemetry, though more expensive, allows the tracking of animal movements via satellite and reduces accessibility issues. In addition, GPS collars can be programmed to collect data in short time intervals, improving resolution. High-resolution movement data is essential for pinpointing road-crossing locations. Though GPS collars may cost more up front, they provide more accurate locations, and save money by reducing man and vehicle hours required for data collection (Rodgers et al. 1996, Mech and Barber 2002). GPS collars have successfully been used to identify road-crossings for many large mammals such as grizzly bears (Waller and Servheen, 1999, 2005), black bears (McCoy, 2005), and elk (Dodd et al., 2007).

All of the techniques described above identify cross-locations for the placement of mitigating structures, but do not measure the extent to which a road is acting as a barrier. Most studies use genetic sampling to measure whether or not a road is acting as a barrier

to gene flow in a population (Gerlach and Musolf, 2000; Epps et al., 2005; Riley et al., 2006). However, in 2007, Dodd et al. proposed the use of a permeability index to measure the barrier effect of a highway. A permeability index is a passage rate calculated by using the following equation: #crossings/(#crossings + #approaches, where an approach is defined as a red wolf entering into a 164 ft. buffer zone around the highway without crossing (see Figure 2). So far, this methodology has only been used on ungulates with seasonal migration patterns and not on species that remain in smaller defended territories.

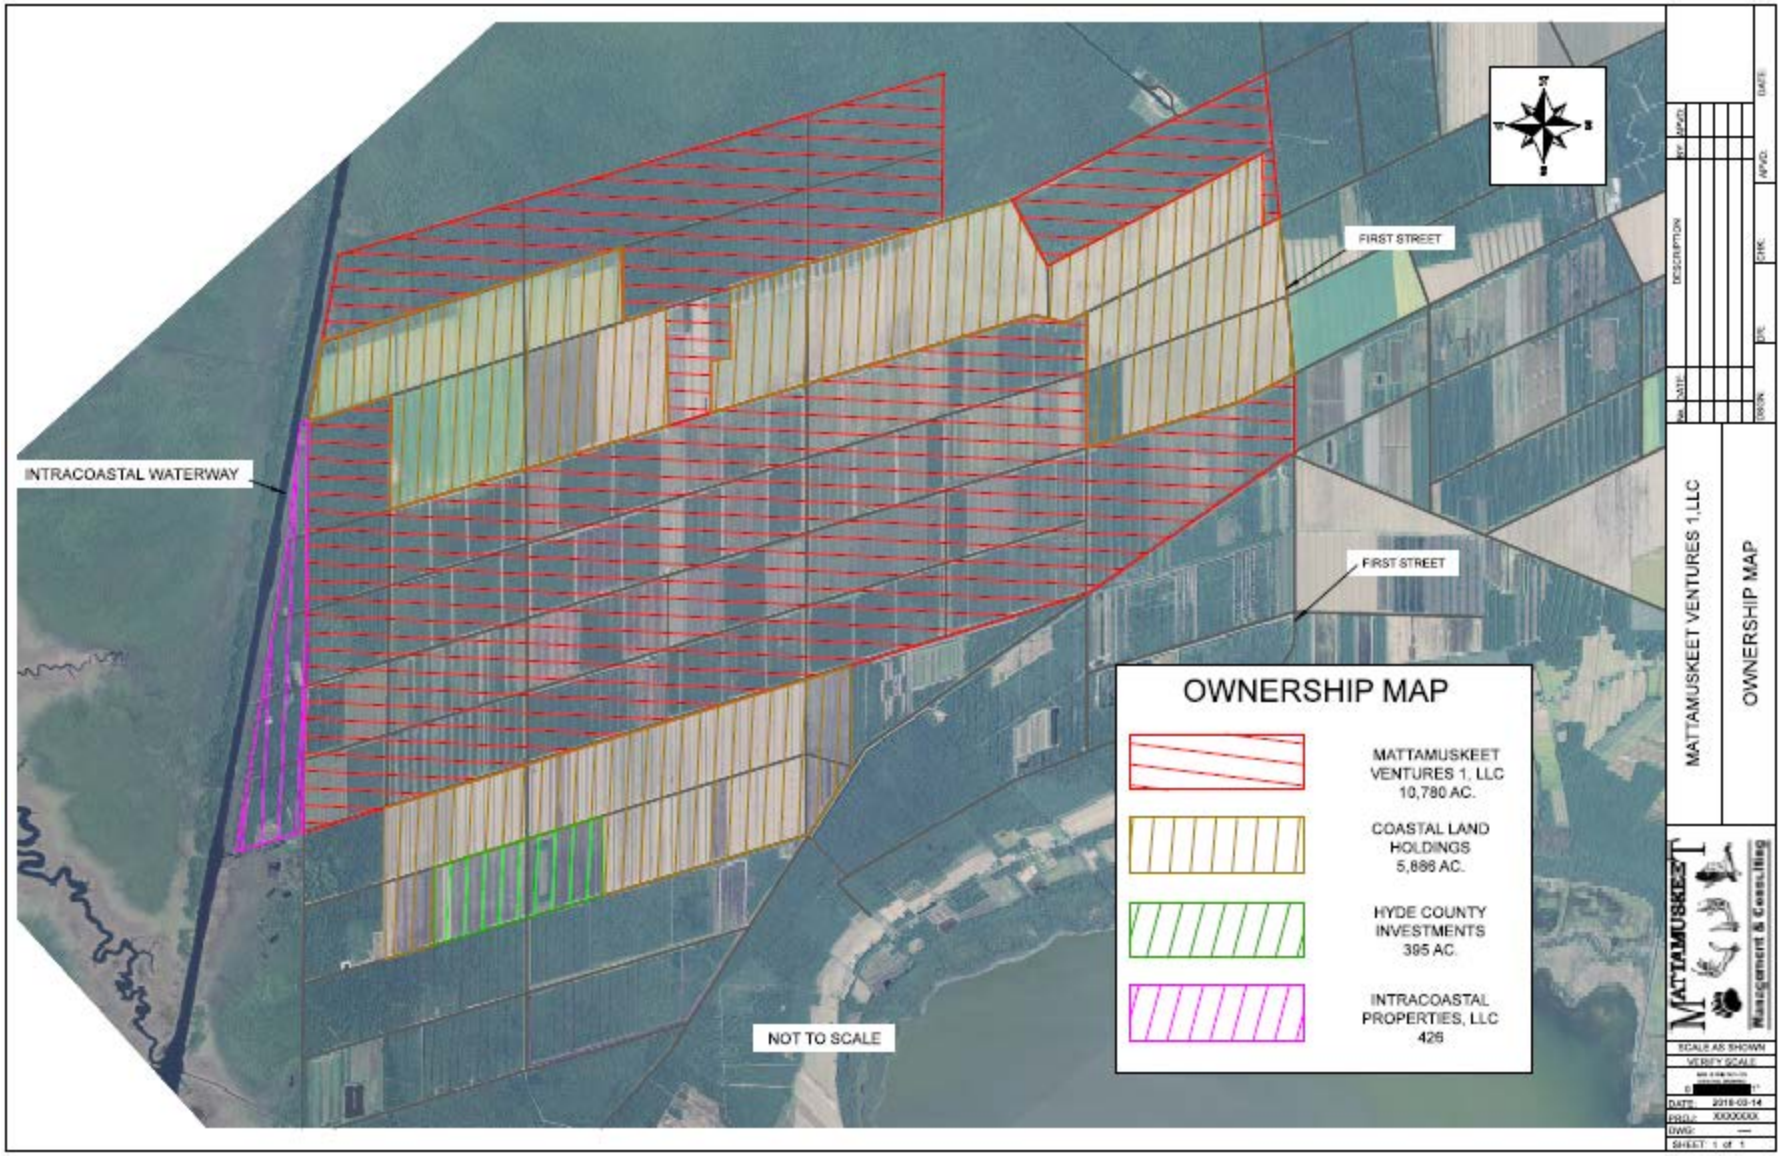
PERMITTEE/LICENSEE

Tom Harrison
[redacted]

Telephone: [redacted]

PERMIT NUMBER
DO09102018-1

EFFECTIVE	EXPIRES
10/01/2018	10/31/2018
COUNTY	**DISTRICT**
See Text Below	See Text Below



CONDITIONS AND AUTHORIZATIONS:

The above permittee and other individuals under written contract and under the supervision of the permittee are authorized to trap coyotes on the properties identified in **Attachment A** subject to the following conditions:

- Permit is valid for properties identified in **Attachment A**.
- This permit does not authorize access to any property, public or private.
- All individuals exercising the authority granted by this permit shall carry a copy of this permit and a letter of authorization from the permittee listed above while conducting trapping activities.
- Traps must be labeled as required by G.S. 113-291.6. Traps must be checked daily and any animals caught therein must be removed. All non-target wildlife must be released immediately onsite; however, any red wolf captured must be reported immediately to the Wildlife Resources Commission (WRC) at 800-662-7137 or the U.S. Fish and Wildlife Service to determine disposition of the red wolf.
- Coyotes being removed for depredation under this permit may only be trapped using legal foothold traps and the Collarum type trap as defined in G.S. 113-291.6. The reporting forms required for the use of Collarum type traps may be found at http://www.ncwildlife.org/Trapping/Laws-Safety. Collared animals must be reported immediately to the WRC at 800-662-7137 before final disposition is determined. All coyotes euthanized shall be disposed of in a sanitary manner. All collars from euthanized coyotes must be returned to the WRC.
- Permit holder must report the removal of coyotes to the WRC at 800-662-7137 or online at www.ncalvin.org/ckr/ckrmain.aspx within 24 hours of taking possession of each individual coyote. Each report must include the date; time; location; if the animal had a collar; and measurements of hind foot length and tail length taken from the carcass. Instructions for recording these measurements are enclosed and can be found at www.ncwildlife.org/Portals/0/License/Documents/Canid-Cooperator-Program-Instructions.pdf.
- A hair sample with follicle from each euthanized coyote must be submitted to WRC, Wildlife Management Division, 1722 Mail Service Center, Raleigh, NC 27699-1722.
- A report of all animals captured under this permit, date of capture, and their disposition is required within fifteen (15) days after the expiration of this permit. The report may be submitted by email to RAPSreporting@ncwildlife.org or by mail to Regulated Activity Permits Section, 1707 Mail Service Center, Raleigh, NC 27699-1707.

This permit/license is nontransferable and expires at midnight on the above specified expiration date.

ISSUED BY:	TITLE:	DATE:

ATTACHMENT A

STATE: North Carolina

GRANT TITLE: W79-Wildlife Management

PROJECT TITLE: Pilot Study – Using Fine Scale GPS Technology to Research Sympatric Canid Population Dynamics (Job 2.0?)

A. Problem and Need

The coyote (*Canis latrans*) is now abundant throughout the 100 counties in North Carolina (NC), and is managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plain region of NC (Hinton et al. 2012, Murray et al. 2014). In recent years as coyotes have increased their population, some have begun to make use of the Outer Banks region.

The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of captive-bred red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). This population increased until 2008 and peaked at around 130 individuals (Group Solutions, Inc. 2016), short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013). The AP has an estimated carrying capacity of 140-150 wolves (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). The exact number of red wolves is not known, but USFWS staff report a population estimate of 45-60 individuals with eight mortalities to date in 2016 (https://www.fws.gov/redwolf/index.html August 2016). Hybridization with coyotes and inbreeding depression are suspected factors that have affected red wolf population growth and viability since the inception of the Red Wolf Recovery Program (RWRP), while vehicular and gunshot mortality are known factors (Hinton et al. 2013). Because of hybridization between red wolves and coyotes, the AP supports a continuum of sympatric canids, hereafter referred to as "sympatric canids."

As part of a recent program review, the USFWS halted many aspects of the RWRP in 2015 and discontinued the coyote sterilization program, potentially affecting the spatial

Draft - Confidential

distribution and population dynamics of sympatric canids. Telemetry data from coyotes on the AP suggests that about 70% of coyotes are residents (i.e., those that defend set territories) while the other 30% are transients, with most being dispersing juveniles (Hinton et al. 2015). Transient coyotes do not defend set territories. Coyotes can travel long distances and become transient even as adults, especially when they lose their mate. Recently described as using "compensatory immigration," coyotes opportunistically fill spatial resource gaps by periodic transiency; when spots come open, individuals that do not yet have permanent territories and have been roaming in the area, are able to inhabit the new openings (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with other canids and humans, especially when they are utilizing of anthropogenic resources.

Though a rural area, human land uses occupy a significant portion of space on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011). Concerns about fear of attacks on humans and domestic pets, the effects of sympatric canids on white-tailed deer and other game populations, and homeowner property damage comprise many of the conflict calls regarding sympatric canids on the AP (Responsive Management, forthcoming data). Wildlife managers in this region frequently receive requests for information on canid management (C. Turner, personal communication, 2016).

The changes in state and federal canid management rules have resulted in confusion regarding residents' rights and options for management of property damage by sympatric canids. As a result, some citizens are unsure of the legal and most effective methods for canid conflict management. Adding to management complexity is the need to manage canids for conservation purposes, such as reducing predation on at-risk ground nesting species or reducing hybridization of sympatric canids.

In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of sympatric canids on the AP. A USFWS and NCWRC joint memorandum documented detailed action items for the joint management of sympatric canids on the AP, including specific research objectives which this proposal seeks to address (Attachment 2). As sympatric canids on the AP increase in number, monitoring their

Commented [BA1]: I don't understand the assumption that dynamics would change

Commented [BA2]: Data from how many current coyotes? Doubt you could make this determination from the current or past data, only on the coyotes that happened to have been collared in specific areas due to managing the wolf population

Commented [BA3]: Is there any data showing that this even takes place?

Commented [BA4]: Coyote number may be increasing – suggests a need, if any, to focus on them, not an endangered species with so few in the population and therefore at greater risk to loss from management actions.

Draft - Confidential

movements, particularly in relation to individuals of differing ancestry, could provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about sympatric canid populations and conflict management. Collection of finer temporal scale location data would help to manage interactions of sympatric canids with humans, as well as to support development of dynamic stochastic population models.

B. Objectives (after December 1, 2016-November 30, 2018)

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners.

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

At the end of this two-year pilot study, we will deliver an observational summary detailing the use of the GPS and sensor technology for spatial and population dynamics research on sympatric canids on the AP.

C. Expected Results and Benefits

As part of a pilot study, we will monitor the status of collared individuals by using a finer scale assessment of space and habitat use than previous studies. Earlier research focused on many of the same objectives we suggest investigating here, but during a time of intense, active

Commented [BA5]: This is a very vague statement – what decision are being sought out here, particulary that we don't have research and data on already, at least regarding red wolves.

Commented [BA6]: This objective should not be the basis for all the work suggested in this proposal on red wolves – too much potential risk. Test them on coyotes, or dogs.

Commented [BA7]: Has already been done – no need to reinvent the wheel, especially now. The time to do that was when there were significant numbers of both species on the ground. Can't get that now.

Commented [BA8]: Why? Of all things, this is not needed on red wolves for red wolf recovery.

Commented [BA9]: Done for red wolves. Focus on coyotes if anything.

Commented [BA10]:

Commented [BA11]: What conflicts?

Commented [BA12]: Again, how does this promote recovery of red wolves, and how would this be used for management

Draft - Confidential

management. Specific management techniques are no longer being carried out and dynamics between sympatric canids are expected to have changed substantially. The uncertainty regarding current dynamics presents a need for additional research in order to inform actions for the management of sympatric canids. Information gained from research may impact management rules and landowner's abilities to manage canids in some areas. Additionally, GPS technology has improved since earlier research was conducted allowing for more temporally detailed data collection and more nuanced analyses. Understanding how sympatric canids collectively use resources in areas of human-dominated landscapes will allow wildlife managers to tailor management options to local conditions. On the AP, row crop agriculture and hunting represent the primary and secondary land uses, respectively. Row crop agriculture is a significant nutrient resource on the landscape and, as opportunists, canids take advantage of such resources when they are available. Non-consumptive wildlife-driven tourism persists in all seasons and wildlife watching is a main draw for tourists in this area. For many tourists, the opportunity to see or hear large carnivores is the sole attraction for traveling to the AP. Information from this study will be provided to local constituents to establish a knowledge base regarding how sympatric canids use resources on private lands. Management and guidance could serve to prevent or minimize conflict while maximizing positive wildlife interaction opportunities for constituents. Development of a common understanding between wildlife managers and landowners based upon factual information is paramount for collaboratively achieving successful management of sympatric canids. The data collected in this pilot study is the foundation upon which this understanding and future management actions will be built.

The current level of hybridization between sympatric canids on the AP will be characterized using DNA gathered during this study. Body size exists as a continuum between coyotes and red wolves and has been documented as the most important factor for successful interspecific breeding pairs of these canids (Hinton 2014). Though both species have been found to use resources in similar manners, red wolves generally have more expansive home ranges and therefore may not use local resources as intensively as coyotes, depending on body size. Obtaining individual identification of study animals will allow managers, armed with spatial information, to infer how and why individuals in the canid species continuum exploit

Commented [BA13]:

Commented [BA14]: Lot of words here, but what type of management options would be considered for what resources?

Commented [BA15]: Take advantage of row crops?

Commented [BA16]: "large" – is that red wolves or coyotes, or both? Is there a suggestion of tourism based on coyote presence?

Commented [BA17]: Except that the numbers do not exist on the ground to do this, particulary on non-public lands where you would need to understand the "foundation". Takes out the need to do this refuges.

Commented [BA18]: So again, we already have this information – why risk on red wolves

Draft - Confidential

anthropogenic resources considering their life history traits.

In conjunction with prior research, data collected will contribute to knowledge on sympatric canid population dynamics on the AP. Estimating population size will allow managers to monitor population trends of sympatric canids and to examine the long and short-term impacts of different management strategies on their populations. While it is unknown whether sample size will allow for population estimation, obtaining population estimates for coyotes would provide wildlife managers with baseline data, when paired with annual mortality estimates, for monitoring changes in population abundance over time. Information on changes in abundance, reproductive dynamics, and habitat use could impact management strategies to influence long-term conservation outcomes. Results of this pilot study will allow managers to determine if future work will be necessary, what amount of effort will be required to achieve each objective, and whether or not population estimates will be an attainable goal.

Commented [BA19]: You can't do this in a 2-year study though – and are different management strategies being employed during this study and being incorporated.

D. Approach

The official Red Wolf Recovery Area (RWRA) covers approximately 6,900 square kilometers within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014). However, the USFWS has proposed the RWRA be constricted to the ARNWR and the Dare County Bombing Range in Dare county by the end of 2017. Due to these proposed RWRA changes, this study proposes to capture and radio-collar 25 sympatric canids within Dare, Hyde, and Tyrrell counties (hereafter referred to as "study area"); those counties being within and directly adjacent to the proposed new RWRA. The thematic subheadings below provide detailed descriptions of the approaches required for achieving the pilot study objectives.

Sampling Efforts

Trained NCWRC personnel will conduct live trapping of sympatric canids, with assistance from the USFWS RWRP biologists, and trained, experienced local trappers. NCWRC and USFWS wildlife personnel will select local trappers based on their past performance in trapping sympatric canids, but may also select trappers from the NCWRC coyote trappers list. NCWRC staff will train contracted trappers on specific trapping procedures before every trapping

Draft - Confidential

season. The project lead will supervise and coordinate all trapping activities including locations for installation and the operation of trap lines and handling of captured animals. Simultaneous personal trapping activities by contracted trappers will not be permitted while performing contracted trapping services, as specified in the draft service contract (Attachment 4).

Trapping efforts will follow a spatial capture-recapture (SCR) framework with a systematic targeted sampling design, focusing on areas that contain resources previously found to be used by sympatric canids (e.g. edge, agricultural fields, secondary roads, etc.) (Harris et al. 2013, Ivan et al. 2013), while attempting to sample a diversity of habitat types. This effort will allow us to increase the probability of detection of sympatric canids on the landscape (Tom 2012). While it is important to sample a wide range of habitats, the most important requirement for SCR is the number of collared individuals; this requirement provides flexibility in the other requirements for field sampling as needed (K. Pacifici, personal communication, 2016). We will initially focus trapping in areas of known red wolf packs, as advised by RWRP.

Trapping will take place during the breeding season when the likelihood of capturing females in the later stages of gestation or whelping females will be low. Capture efforts will be conducted from soon after 1 December 2017 – February 2018 and December 2018 – February 2019. Captured sympatric canids will be surrendered to NCWRC or the USFWS at capture sites. Trapping should occur on both public and private lands to obtain sampling coverage of the study area. Ideally, all federal and state lands would be accessible for trap and release (hereafter referred to as "capture") of sympatric canids, but it is most important to be able to trap and release on Alligator River NWR and the Dare County Bombing Range as those encompass the newly proposed RWRP recovery area and comprise the majority of land area for Dare county. Unlike Dare county, there are ample private lands that surround Pocosin Lakes NWR and Lake Mattamuskeet NWR in both Tyrrell and Hyde counties that may be utilized to effectively sample individuals who may use those federal lands, should they be excluded from capture activities. Capture on federal lands may require USFWS take permits and proposed activities may be subject to a compatibility assessment (P. Benjamin, personal communication, 2016). Scientific collection activities that take place on private lands will require agreements outlining conditions mutually decided by NCWRC and landowners (Attachment 3).

Commented [BA20]: Even if these areas were included, the numbers don't exist for this study. And I'll say it here, but if this is the last holdout for red wolves in the population, there isn't enough information to be gleaned from this study that in any way promotes recovery, especially on the refuge, and when the objectives are focused in large part on landowner conflicts and resources.

Draft - Confidential

To increase probability of detection of sympatric canids, the accessible study area will be partitioned by a grid, the cell size of which will based on the average annual home range size of resident coyotes previously reported for the AP, approximately 23 km^2 (Hinton et al. 2015). As a system of sampling, trap lines will be referred here as "traps," and the number of trap sets (i.e. the actual trapping device) and number of each trap set size may vary between traps as necessary. Sampling will be standardized within each grid cell by use of equal number of traps per cell, on average 3 per cell, each at an approximate length of 10 km (Andelt and Gipson 1979, Way et al. 2004).

Target canids will be captured by using Softcatch #3 Coyote 4x4 (Oneida Victor Inc. Ltd., P.O. Box 32398, Euclid, Ohio 44132, Hinton 2014, Schemnitz 1994), the EZ Grip #7 (Livestock Protection Company, P.O. Box 725, Alpine, Texas 79831, Frame and Meier 2007), or equivalent. Various lures and baits will be used to increase trapping efficiency (Frederick et al. 1989, Shipley 2012). Traps will be laid on the Monday of each week and will be opened at the time of deployment. Traps will be checked once daily at dawn, to reduce potential stress to trapped individuals and will not be operated on days where the temperature is expected to reach or exceed 80° F (R. Nordsven, personal communication, 2016) or during times of predicted inclement weather (e.g. snow, hail, high wind, etc., Sikes et al. 2011). To standardize effort and remain logistically realistic, traps should be open for three trap nights in a row before being removed. Trap sets that have been closed due to non-target bycatch or other circumstances may be reopened and all traps should be re-baited and lured as appropriate.

Trap set locations will be marked by NCWRC or USFWS personnel using handheld GPS units (Garmin GPSMAP 64S, 1200 E. 151st St., Olathe, KS 66062-3426) and given a sequential identification number. Traps will also be given an identification number and trap set points will be documented in ArcMap 10.4. Trappers will keep detailed records on trap set operation, non-target species trapped, and other relevant details. Non-target species will be released from traps after an in-field assessment of injuries, if any, and animals with life threatening injuries will be euthanized by the trap operator. Targeted recapture of collared canids will occur annually during the same months, to replace GPS collar batteries and drop-off collar release units in field. Trapping effort will be quantified (trap nights), the effective sample area will be

Draft - Confidential

estimated, the encounter (detection) probability will be estimated using a Gaussian detection model (Amundson et al. 2014), and an estimate of density for coyotes will be calculated using a modified Huggins closed-capture estimator in program MARK, if sample size allows (Harris et al. 2013, Ivan et al. 2013).

Animal Handling

Handling of canids will follow American Society of Mammalogists (ASM) guidelines (Sikes et al. 2011) and will be performed at the capture site. Chemical immobilization agents may be used depending on the number of field staff during processing (i.e., three or more staff required during non-chemical immobilizations, Craft 2007, M. Morse, personal communication, 2016).

Chemical Immobilization

Unless adequate numbers of personnel are available to safely employ mechanical restraint techniques, target animals will be anesthetized with the chemical immobilization agent BAM (Wildlife Pharmaceuticals, Inc., Windsor, CO 80550). BAM, a combination of Butorphanol tartrate, Azaperone tartrate and Medetomidine HCl., will be delivered by intramuscular injection by syringe pole to the hip. Dosage for canids is based on field trails performed by Wildlife Pharmaceuticals (Wildlife Pharmaceuticals, Inc. 2016) and the recommended dose for coyotes is 0.2CC and red wolves is 0.3CC, with adjunct doses of 0.1-0.2CC delivered if initial dosages do not cause induction (S. Kirschner, personal communication, 2017). Induction times for coyotes and wolves ranged from 5 to 10 minutes after initial and/or adjunct dosages (Wildlife Pharmaceuticals, Inc. 2016). After field handling is concluded the anesthesia will be reversed using two reversal agents, Atipamezole and Naltrexone, at double the CC of Atipamezole to BAM that was delivered (including adjunct doses, if given) and 0.5CC of Naltrexone. Recovery time from the reversal agents ranged from 10 to 25 minutes during field trails (Wildlife Pharmaceuticals, Inc. 2016). Field personnel will observe animals for signs of adverse effects for up to 30 minutes after reversal agents are delivered.

Mechanical Immobilization

Unlike other carnivore families, the submissive behavioral response of canids to

Commented [BA21]: Need to look at CFR on red wolves

Commented [BA22]: We've gone through testing on red wolves using various drug combination to find what works best – I'm not aware that this combination has been tested on red wolves? The field would not be the place to do this!

Draft - Confidential

perceived dominance reduces the need to use immobilization agents. Appropriate mechanical restraint techniques can reduce handling time of animals, allowing animals to reintegrate into social groups more quickly, subsequently reducing overall stress to the individual (Powell and Proulx 2003). Target canids will be mechanically restrained with a restraint pole, until two muzzles can be placed around the snout. While pinned with the restraint pole by one person, a second person will restrain the set of legs not in the trap against the ground and a third person will release the foot from the trap. This set of legs will then be restrained by the 3rd person as the restraint pole is removed. Once the restraint pole is removed the person restraining the front legs will also then restrain the head. The first person will then move forward with processing the captured animal.

Each animal will be placed on a towel or blanket to provide thermal protection from the ground, with eyes covered and lubricated with eye ointment; temperature will be monitored with a rectal thermometer. Overheating occurs at approximately 104-105°F for canids (AZA Canid TAG 2012) and the animal handling crew will monitor temperature at 5-minute intervals; if a temperature reading reaches 104°F, corrective actions will be taken and temperature will be monitored at 1-minute intervals. Should overheating occur, the individual will be removed from insulation to expedite the natural evaporative cooling process. During days that approach 80°F in temperature, measures will be taken to reduce heat stress, such as: wetting the animal with water, application of a cold pack to the groin area between the back legs, application of rubbing alcohol to foot pads, or immediate release (AZA Canid TAG 2012). If the injured individual is suspected to be a red wolf, based on morphometrics, USFWS staff will be contacted for a decision. In the event that trap caused injuries are determined to be life threatening through use of a trap injury score assessment (Frame and Meier 2007) the individual will be euthanized. In the event that NCWRC personnel cannot be present, trained USFWS personnel may collar and measure captured target animals and will provide data sheets to NCWRC staff. Target animals will not be vaccinated or otherwise treated for diseases, regardless of the presence of disease symptoms.

Commented [BA23]: Or tranponders, or previous genetic analysis – do not use morphometrics as the sole indicator of species.

Commented [BA24]: For red wolves, this should be the call of FWS – look at CFR

Non-target animals will be released on site. Captured domestic dogs will be immediately released from the trap set following an injury score assessment and only if no life-threatening

Draft - Confidential

injuries are present. If a domestic dog has sustained life threatening injuries and owner identification information is present on the dog, then the animal will be held in either a transportable kennel, or at a dog pen on a state game land that is equipped with such facilities, until the owner can retrieve the dog. The costs associated with injuries sustained to the dog will be the responsibility of the animals' owner. Law enforcement may be requested to help communicate with the animal's owner. If the animal does not have an identifiable owner and has incurred substantial life threatening injuries (i.e. compound fracture), the dog will be euthanized on site. Target animals showing signs of disease symptoms such as circling behavior, head tilt, muscle twitches, convulsions with jaw chewing movements and salivation ("chewing gum fits"), disorientation, incoordination, staggering caused by paralysis of the hind legs, seizures, and partial or complete paralysis will be euthanized and tested according to protocol set forth by the agency veterinarian, in order to determine if there may be a public health issue (M. Palamar, personal communication, 2016). USFWS will be contacted in cases of suspected red wolves. Staff involved in animal handling duties will have the pre-exposure rabies vaccination series completed prior to field work inception and will maintain rabies titer records through properly licensed medical services providers.

Commented [BA25]: Even if it is on their property?

Commented [BA26]: This is problematic on refuges.

Commented [BA27]: Not just contacted, but the decision needs to be FWS

If staff is bitten and skin is broken by an animal while performing handling duties, they will be advised to immediately visit a local hospital or clinic for evaluation by healthcare professionals. The field coordinator will immediately notify supervisory staff and an injury report and workers' compensation claim will be opened for the incident. The animal will be euthanized and the head will be sent to the state lab for rabies testing; the body may be sent to the Southeastern Cooperative Wildlife Disease Study (SCWDS) laboratory for additional disease investigation.

Capture Processing and Marking

During canid handling, NCWRC personnel will record age class, sex, weight, total body length, head width, ear length, and tail length, visually assess ectoparasite load, look for and disinfect with betadine or iodine as needed any minor trap caused injuries, and affix GPS collars (Knick 1990, Sikes et al. 2011). All captured canids will be fitted with appropriately-sized GPS collars in the field based on morphometrics previously indicated as reliable thresholds for

Draft - Confidential

species categorization: hind foot length, weight, width of head, and tail length (Hinton 2014); analysis of DNA samples collected during trapping efforts will help to assign captured canids to position along the species continuum post release. Age of individuals will be estimated based on physical characteristics, including weight and tooth replacement (Knick 1990, Hinton 2014, Gier 1968), and captured canids will be aged into one of three classes: > 2 years old as adults, < 2 but > 1 year old as juveniles, and > 6 months but < 12 months old as pups (Hinton 2014). Reproductive status will be determined based on estimated age class and presence of gonadal descent during the breeding season for males and the presence of nipple swelling or previous suckling for females (Hutson and Racey 2004, Magee 2008, Mengel 1971).

Captured individuals will be ear marked using a button tag (model 410, Ketchum Mfg. Co. [or equivalent], PO Box 10, 11 Town Shed Road, Lake Luzerne, NY 12846) placed along the middle of the ear where they are most protected from loss, with a pin-type applicator (485sa Pow-R-ceps plier, Ketchum Mfg. Co. [or equivalent]) (Silvy 2012). The puncture site will be treated with an antiseptic to deter infections. Each sympatric canid will also be marked with an individually-numbered, glass-encapsulated, passive integrated transponder (PIT model HPT12, 12.5 mm, 134.2 kHz, Biomark, Inc., 703 South Americana Blvd., Suite 150, Boise, ID; Gannon et al. 2007), using a syringe-type implanter and replaceable needle (model MK10 [implanter], model N125 [needle], Biomark, Inc.). Successful PIT placement will be verified with a mini portable reader (model GPR Plus, Biomark, Inc.). The implantation site will be prepared by swabbing with 70% alcohol (Mrozek et al. 1995) and a sterilized new needle will be used for each injection. The standard implantation site for transponders is subcutaneously on the dorsal midline of the back, cranial to the shoulder blades (Ingwersen 2000).

A skin biopsy will be taken from all captured target canids by puncturing the pinna of the ear with a biopsy punch in the same location where the ear tag will be placed (Palamar 2014). The biopsied area will be disinfected with alcohol after sampling. The skin biopsy will be placed in a labeled (ID, date, and sample type) cryogenic tube filled with 95% ethanol as buffer and then stored in a freezer until sent out to a lab for genetic analysis (Palamar 2014, Tom 2012). A selection of hairs with the root bulla attached will be pulled from the belly and placed in paper envelopes (Janecka et al. 2007). Hair samples will serve as back up to tissue samples

Commented [BA28]: Why? How does this fit into the study proposal? If not, no need to do it.

Draft - Confidential

for genetic testing. All samples will be sent to the Laboratory for Ecological, Evolutionary and Conservation Genetics, at University of Idaho (875 Perimeter Drive, MS 1136, Moscow, ID 83844) for genotyping to determine species as well as individual identification, hybridization presence, and parentage analysis following previously developed protocols (Adams et al. 2007, Hinton 2014, Miller et al. 2003). The appropriate genetic analyses that examine the coyote-hybrid-wolf species continuum will be performed.

Blood will be collected from all juvenile and adult target canids by venipuncture of the brachial or jugular veins using a 22-28-gauge needle (M. Palamar, NCWRC veterinarian, personal communication, 2016). As per NCWRC veterinarian recommendations, approximately 12 ml of blood will be collected for each animal for possible future testing for diseases of importance to sympatric canid species as well as the humans and domestic animals that they may come into contact with. A minimum of two 6 ml lavender top tube (for whole blood with EDTA) will be filled. Samples should be refrigerated at all times; a cooler with ice will suffice while in the field. Samples should be sent to the NCWRC within 48 hours or frozen for later shipping. Skin scrapes will be collected from animals presenting signs compatible with sarcoptic mange (lesions) for possible future diagnostic purposes. Lesions will be scraped until blood is drawn; the scrapings will be placed onto a slide and covered with a piece of clear tape for later visual confirmation.

Should overheating occur, processing will be performed in the following prioritization order and the first five items will need to be completed before releasing any individuals: 1) trap injury evaluation, 2) collaring, 3) DNA (skin biopsy) sample collection, 4) morphometrics, 5) aging, 6) PIT tagging, 7) weight, 8) ear tagging, 9) reproductive status, 10) ectoparasite evaluation, 11) blood collection, and 12) skin scrape collection.

Collaring

Vertex Plus GPS Collars will be attached to 25 sympatric canids captured on the study area, 10 of which will be equipped with proximity sensors (Vectronic Aerospace GmbH, Carl-Scheele-Str. 12, 12489 Berlin, Germany). Project staff will pilot test proximity sensor technology for utility in analysis of spatial and temporal community dynamics. Proximity sensors trigger increased GPS location acquisition during those time intervals when two collared individuals

Commented [BA29]: Why? What information is being collected and how would it be used to meet objectives?

Draft - Confidential

come within a set distance from each other (http://www.vectronic-aerospace.com/wildlife-monitoring/sensors/uhf-id-tags, accessed August 2016).

To avoid instances of collar induced strangulation, only adult (>2 years old) male and female individuals will receive collars (Hinton 2014). ASM guidelines recommends a collar weight of <5-10% of a canids bodyweight, we will observe these guidelines (Sikes et al. 2011). Sympatric canids not releasable at a capture site will not be collared and will not become study animals.

GPS radio-collars will have both VHF and GPS Iridium locational systems as well as store-on-board capabilities. Radio-collar units will be programmed to record GPS coordinates once every 1.75 hours producing approximately 13 locations per day while cycling through the 24-hour time cycle. These settings will allow for a GPS battery life of 300 to 552 days, averaging 431 days. The VHF beacon will be in operation from 0800 – 1600 hours daily. GPS locations will be sent via satellite once per day and each transmission with contain 12 locations. The use of an integrated drop off firing mechanism should allow the collars to drop off within a maximum of approximately 548 days after deployment. The drop off schedule once set cannot be changed. The drop off firing mechanism is wired to a battery unit independent of the collar battery, therefore should the collar battery become depleted, the drop off mechanism will not be affected (C. Akakpo, Vectronic Aerospace GmbH, personal communication, 2016). Unless a collared individual is recaptured before the collar battery dies, the drop off mechanism will fire at the scheduled time frame post collar deployment.

Observation of sympatric canid habitat use and movements will occur through GPS data obtained with combination GPS/VHF radio-collars. VHF relies on triangulation, the process of estimating the location of a transmitter by using two or more compass bearings obtained by using directional antennas at known locations remote from the transmitter's position (White and Garrott 1990), whereas GPS uses a satellite based system to obtain location coordinates. There have been many published studies where one or both of these methods were used, with mixed success for determining various aspects of carnivore ecology throughout the United States (Hinton et al. 2012, Schrecengost et al. 2009, Sparkman et al. 2012). While GPS technology has developed rapidly in recent history, the real time functional advantage of VHF

Commented [BA30]: How long is the battery life on the vhf beacon?

Commented [BA31]: This gets at the previous issues we had with managing a population of red wolves using an adaptive management plan but not having wolves collared for longer periods of time and losing contact, hence the inability to manage. You may gain data (though we already have what's being suggested here), but at the risk of the remaining few wolves in the population. In other words, I still don't see the rationale to even consider this proposal.

Commented [BA32]:

Commented [BA33]: Way to short – now no contact with wolves? Are you kidding?

Draft - Confidential

cannot be disregarded. When GPS technology falters or malfunctions, VHF can serve as replacement for data collection in addition to its use in real time monitoring of study animals. Canids will be minimally monitored for mortality approximately every 30 days by using VHF aerial telemetry techniques (Whitehouse and Steven 1977) as there may be a delay in satellite transmission of GPS location data due to weather, season, and animal behavior. Transient canids and individuals from breeding pairs that have lost a mate, have been found to use much larger areas versus paired residents, potentially increasing the opportunity for losing track of these individuals when GPS technology reaches its functional capacity or experiences malfunction. VHF data may also provide locations of canids in cover too dense for GPS units to function. Use of VHF telemetry techniques for data collection may be expanded as necessary for project needs.

Spatial Data Analyses

Both minimum convex polygon (MCP) and adaptive kernel (AK) home ranges (95%) and core use areas (50% and 25%) (Seaman and Powell 1996, Seaman et al. 1999) will be calculated from GPS data by using BIOTAS (Ecological Software Solutions LLC, 2016) and Geospatial Modelling Environment (Spatial Ecology, LLC, 2016) for ArcGIS 10.2.2 (Environmental Systems Research Institute, 2016) (Benson et al. 2006, Riley 2006, Tucker et al. 2008, Hinton 2014) for comparison to older studies. These estimations can also be calculated using VHF data, provided data minimum requirements are met. Spatial distribution in relation to habitat will also be estimated by dynamic Brownian bridge movement models as described by Hinton (2014) with R statistical software (R Core Team 2016) using the moveud package with habitat covariates important to each species (Bryne et al. 2014, Collier 2013, Kranstauber and Smolla 2013, C. Proctor, personal communication, 2016). Additionally, recent research into how canids shift their ranges will also be investigated for populations on the AP (Morin and Kelly, in review). Spatial overlap and co-occurrence will be assessed using methods described by Shipley (2012). Habitat and cover types will be estimated from digitized maps created by the SEGAP (Hinton 2014) or ortho files, as available (Shipley 2012). Percent composition of habitat and cover types within home ranges and core areas as well as edge density will be quantified (Shipley 2012). Habitat selection and cover type use effects on spatial distribution will be estimated at both the population (2nd order) and individual (3rd order) spatial scales using resource selection functions

Draft - Confidential

(Johnson et al. 2006, Manly et al. 2002, Shipley 2012). Effects of seasonality and time of day activity will also be explored. The spatial and temporal patterns of space use by sympatric canids will be studied using data generated from the interaction GPS collar sensors, particularly distance between individuals and duration of proximity.

Den Monitoring

Project staff will attempt to locate den sites for sympatric canids to get pup counts, morphometric measurements, age estimates, and skin biopsies. Project staff will also attempt to monitor pup survival during the pup rearing season by using remote cameras placed around the den site (Harrison and Gilbert 1985, Parks 1979, Way et al. 2001). Pups will be weighed, measured, and PIT tagged during May and June of each year when they become active but are still den-obligated (Gier 1968). We will investigate the use of remote camera traps for monitoring den behavior with a two-camera array around the den (H. Garbe, personal communication, 2016, Kays and Slauson 2008). This method has been successfully used to monitor kit fox pup survival (Kluever et al. 2013). Because coyotes have been found to be sensitive to den site disturbance, there is a general lack of data in the literature regarding this approach for monitoring pup survival. Approaching an experimental methodology systematically will be important for determining which methods are effective and which are not. As a starting point for testing this methodology, remote cameras will be placed two to five meters from main den entrances and set to take photos using a passive infrared sensor trigger (a beam that when broken by movement through it, triggers the camera to take a series of photos) with a time restriction between photo intervals to limit the number of photos taken and maximize the space on the memory card for the time period between camera checks (Kluever et al. 2013). Cameras will be checked six days after deployment and will be redeployed (i.e. new batteries and memory card, if required); cameras will remain at each den site until radio-collar data indicates the den site has been moved (Kluever et al. 2013). Cameras will be not be redeployed to a new coyote den site during a season if that breeding pair has already moved the den once due to the disturbance of camera presence/deployment.

Commented [BA34]: Based on past experience, will likely cause dam to move the den, or abandon pups

Draft - Confidential

Mortalities

If a collared animal dies during the project, the carcass will be sent to SCWDS for necropsy. Red wolves will be sent to the SCWDS laboratory for necropsy, unless it is determined to be a law enforcement case. In potential law enforcement cases, the NCWRC Division of Wildlife Management Chief and USFWS Ecological Services Raleigh Field Office Field Supervisor will be contacted and requested to contact the appropriate law enforcement personnel, immediately after determining the need for law enforcement involvement. The carcass and all relevant information will then be turned over to law enforcement; the GPS-collar will be removed and genetic samples will be taken from the individual prior to release to law enforcement.

Commented [BA35]: Not sure about this w/ES

Commented [BA36]: All mortalities have the potential to involve LE – this needs to be coordinated directly through FWS LE

Commented [BA37]:

Commented [BA38]: Was this not already done when handling initially? This sounds more like an attempt to collect material from canids not already involved in the study. ES material is owned by FWS – would need permit otherwise?

E. Project Personnel

Andrea Shipley has worked for the North Carolina Wildlife Resources Commission as a Canid Biologist since February 2016. Prior to that, she worked as a Wildlife Biologist for a non-profit located in northeastern Nevada as well as in several different field biologist oriented positions. Andrea has a background in carnivore and spatial ecology, having earned her MS in Biological Sciences from Eastern Kentucky University and BS in Biological Sciences from Rutgers University; Andrea will act as project lead and coordinator.

Brandon Sherrill has worked for the North Carolina Wildlife Resources Commission as a Mammalogist since December 2013. Prior to that, he worked as an educator at the North Carolina Museum of Natural Sciences and as a regional wildlife biologist for the South Carolina Department of Natural Resources. Brandon earned a BS and MS in Fisheries, Wildlife, and Conservation Biology from North Carolina State University; Brandon will act as project supervisor.

Krishna Pacifici, Research Assistant Professor at NCSU, will be the quantitative analysis collaborator on the project. Krishna's background and experience in quantitative ecology makes him well suited to consult and assist with advanced statistical analyses of spatial data.

Lisette Waits, Department Head and Distinguished Professor at the University of Idaho, will be the DNA analysis collaborator for the project, responsible for all DNA related sample processing and subsequent analyses.

Draft - Confidential

F. Schedule and Estimated Costs

The project will run from soon after December 1, 2017 through June 30, 2020. The estimated timeline for major tasks is as follows:

Year 1: Initiate field work soon after December 1, 2017 with assistance from 1-2 field technicians; 1 technician will be required for trapping and den monitoring efforts. Data collection will begin immediately after collar deployment and data will be managed by Andrea Shipley throughout the life of the project. Data analysis will be initiated after den monitoring season concludes, with guidance and assistance from Krishna Pacifici at North Carolina State University (NCSU). Report, manuscript and presentation production will be initiated concurrently with data analysis.

Year 2: Continue field work and data collection with assistance from 1-2 field technicians. Continue data analysis with guidance and assistance from Krishna Pacifici at NCSU. Continue and finalize report and manuscript production, and presentation at professional working groups and/or meetings.

GPS technology allows researchers to collect locational data at fine spatial and temporal scales through the deployment of collar units on wildlife study subjects. In this project, we propose to study a sample of sympatric canid populations with GPS radio-collars, in order to investigate the population parameters outlined in previous sections as well as species interactions. The purchase and use of this technology is critical to meeting the research objectives set forth in this document as well as in the document included in Attachment 1.

While GPS technology has evolved over the past 20 years, the cost of technology has plateaued. Upfront cost per unit remains relatively high, however project savings occurs at the back end when compared to older telemetry technology such as very high frequency (VHF)

Draft - Confidential

which require intensive labor to collect data at similar spatial and temporal scales. Pilot testing the proximity sensor enabled GPS-collars will allow investigation of the utility of this relatively new tool for community dynamics analysis by providing an increased locational data acquisition when individuals come within a set distance, or closer, from each other. Additionally, these sensors record the identities of the interacting individuals and the duration of their interactions. Using a trigger to temporarily switch GPS fix schedules will enable us to collect very fine scale data while conserving battery life, achieving project objectives in an efficient manner. Exploring the efficaciousness of this technology has the potential to positively impact future research projects requiring use of GPS-collars for data collection.

Aerial tracking will provide regular study animal surveillance useful to investigate cases of mortality, collar malfunction, or satellite data transmission delays, which can vary seasonally. In some situations, ground tracking could prove less expensive than aerial tracking. However, ground telemetry techniques require more than one biologist working in tandem to acquire accurate location estimates. This often translates to increased labor to collect data, particularly in large study areas. Aerial tracking will provide a more efficient and cost-effective method for surveilling study subjects in this large study area, requiring only one biologist and a contracted pilot. NCWRC personnel will perform aerial tracking along with the NCWRC pilot at a minimum frequency of every 30 days.

Use of local trappers to assist with sampling efforts provides several benefits. Local trappers have established, long-term relationships with private land owners, thereby providing access to private lands that might be otherwise difficult to secure. This will enable project biologists to obtain a representative sample of sympatric canids in the study area, as well as to operate more trap lines concurrently. This is particularly important when using a SCR sample design, as it will have direct implications on the resulting analyses and inferences.

As part of collaboration efforts, the project will contract the services of Krishna Pacifici, Research Assistant Professor in the Applied Ecology department at NCSU. Krishna's expertise is in quantitative ecology; consultation and assistance services provided will allow project biologists to make appropriate statistically relevant inferences from collected data.

Draft - Confidential

DNA analysis will be contracted to Lisette Wait's lab at the University of Idaho. Lisette's team at The Laboratory for Ecological, Evolutionary and Conservation Genetics has previous experience in analyzing red wolf and coyote hybrid molecular samples and has the most comprehensive DNA methodology for this sympatric canid species continuum in the nation. This expertise will facilitate expedient species identification on collared study animals besides landscape level population dynamics analysis.

I. Glossary

Abundance: Species abundance is the number of individuals per species, and relative abundance refers to the evenness of distribution of individuals among species in a community.

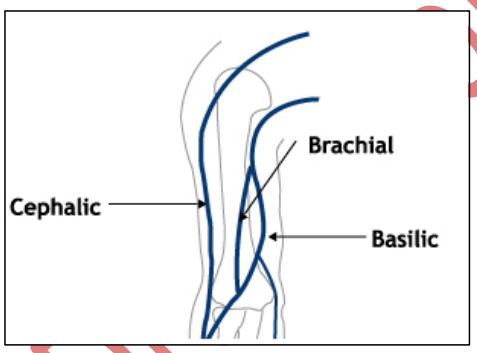
Adaptive kernel (AK): A probabilistic home range estimator based on the distribution and density of locations that has been collected over a period of time.

Adverse reactions: In pharmacology, any unexpected or dangerous reaction to a drug.

Aerial: Existing, happening, or operating in the air.

Annually: Once a year; every year.

Anthropogenic: Caused or influenced by humans.



Apex: Having no natural predators in its ecosystem.

Ataxia: The loss of full control of bodily movements.

Beacon: A radio beacon whose purpose is the investigation of the propagation of radio signals.

Biopsy: The removal for diagnostic study of a piece of tissue from a living body.

Brachial vein: One of a pair of veins accompanying the brachial artery and uniting with each other and with the basilic vein to form the axillary vein.

Breeding pair: A pair of animals which cooperate over time to produce offspring with some form of a bond between the individuals.

Carrying capacity: The maximum population size of the species that the environment can sustain indefinitely, given the food, habitat, water, and other necessities available in the environment.

Compensatory immigration: Individuals emigrating from areas with lower mortality to those with higher mortality; filling a deficiency of individuals in a population experiencing higher mortality. The increase in size or activity of one part of an organism or organ that makes up for the loss or dysfunction of another.

Composition: The combining of distinct parts or elements to form a whole.

Confidential

Co-occurrence: Refers to observation of the spatial overlap between two (or more) different individuals over a period of time.

Coordinates: Any of the scales or magnitudes that serve to define the position of a point.

Core use areas: An area within a home range exhibited by a dense concentration of location points; commonly estimated at 50% of the location data points.

Covariates: A variable that is possibly predictive of the outcome under study.

Cranial: Pertaining to the cranium or to the anterior (in animals) or superior (in humans) end of the body.

Cryogenic: Very low temperatures, e.g. -80°C.

Den-obligated: Restricted to a particular condition of life, in this case restricted to a den site.

Density: A measure of the number of organisms that make up a population in a defined area.

Deployment: To organize and send out (people or things) to be used for a particular purpose.

Depredation: The act of preying upon.

Depressed respiration: A decrease in the ability to exhale and inhale; respiration that has a rate below 12 breaths per minute or that fails to provide full ventilation and perfusion of the lungs.

Diagnostic: The process of determining by examination the nature and circumstances of a diseased condition.

Disorientation: Loss of one's sense of direction, position, or relationship with one's surroundings.

Distribution: The manner in which a biological taxon is spatially arranged.

DNA: (deoxyribonucleic acid) is a type of macromolecule known as a nucleic acid. It is shaped like a twisted double helix and is composed of long strands of alternating sugars and phosphate groups, along with nitrogenous bases (adenine, thymine, guanine and cytosine).

Dorsal: Situated on or toward the upper side of the body, equivalent to the back, or posterior, in humans; situated on or toward the posterior plane in humans or toward the upper plane in quadrupeds.

Duration: A continuous period of time.

Dynamic Brownian bridge movement models: Incorporates temporal and behavioral characteristics of movement paths into estimation of home range.

Ectoparasite: a parasite that lives on the outside of its host rather than within the hosts body; e.g. fleas and lice.

Effective trap area: Calculated by buffering each trap site by half the mean maximum distance traveled, each of these boundaries are dissolved, creating a measurable area.

Efficacious: Producing or capable of producing a desired effect.

Draft - Confidential

Efficient: Accomplishment of or ability to accomplish a job with a minimum expenditure of time and effort.

Euthanize: The act of putting to death painlessly or allowing to die, as by withholding extreme medical measures, a person or animal suffering from an incurable, especially a painful, disease or condition.

Expedient: Suitable for achieving a particular end in a given circumstance.

Evaporative cooling: reduction in temperature resulting from the evaporation of a liquid, which removes latent heat from the surface from which evaporation takes place.

Facilitate: Make an action or process easy or easier.

Genotyping: Investigate the genetic constitution of (an individual organism).

Gonadal descent: The act or process of descending from a higher to a lower location; testicular descent occurs during the breeding season annually.

GPS: Global Positioning System, is a radio navigation system that allows land, sea, and airborne users to determine their exact location, velocity, and time 24 hours a day, in all weather conditions, anywhere in the world.

Home range: an area over which an animal or group of animals regularly travels in search of food or mates, and that may overlap with those of neighboring animals or groups of the same species.

Hybridization: The result of mixing, through sexual reproduction, two animals or plants of different breeds, varieties, species or genera.

Immobilization agent: An active force or substance capable of producing an effect.

Implantation: To put or fix firmly.

Inbreeding depression: The reduced biological fitness in a given population as a result of inbreeding, or breeding of related individuals.

Inception: The establishment or starting point of an institution or activity.

Interspecific: Existing or occurring between different species.

Iridium: A satellite constellation providing voice and data coverage to satellite phones, pagers and integrated transceivers over the Earth's entire surface.

Jugular vein: Any of several large veins in the neck, carrying blood from the head and face.

Lacerations: A deep cut or tear in skin or flesh.

Locational: A position or site occupied or available for occupancy or marked by some distinguishing feature.

Malfunction: Fail to operate in the normal or usual manner

Methodology: A system of methods used in a particular area of study or activity.

Midline: A median line or plane of bilateral symmetry, especially that of the body.

Draft - Confidential

Minimum convex polygon (MCP): Completely enclose all data points by connecting the outer locations in such a way as to create a convex polygon.

Molecular samples: Genetic samples that may be used for investigation of genetic constitution of an individual.

Morphometrics: The process of measuring the external shape and dimensions of landforms, living organisms, or other objects.

Mortality: The state of being subject to death.

Non-target bycatch: Animals caught by accident that are not the target species being sought.

Parameters: A numerical or other measurable factor forming one of a set that defines a system or sets the conditions of its operation.

Parentage: The origin of something; the state or relation of a parent.

Passive integrated transponder: A microchip implant is an identifying integrated circuit placed under the skin of an animal.

Pinna: The external part of the ear in humans and other mammals; the auricle.

Plateaued: A period or state of little or no growth or decline.

Population dynamics: The branch of life sciences that studies the size and age composition of populations as dynamic systems, and the biological and environmental processes driving them (such as birth and death rates, and by immigration and emigration).

Population growth: The increase in the number of individuals in a population.

Population size: A group of organisms of the same species that live in the same area.

Population status:

Population trend: Changes over time and can include changes in ranging behavior and distribution, biogeography and life-history.

Population viability: The process that determines the probability that a population will go extinct within a given number of years.

Proximity: Nearness in space, time, or relationship.

Quantified: Express or measure the quantity of.

Quantitative: Relating to, measuring, or measured by the quantity of something rather than its quality.

Radio-telemetry: The use of radio waves for transmitting information from a distant instrument to a device that indicates or records the measurements.

Recumbency: The state of leaning, resting, or reclining.

Reintegrate: Restore (elements regarded as disparate) to unity.

Draft - Confidential

Remnant: A small remaining quantity of something.

Reproductive status: Relating to or effecting reproduction.

Spatial: Relating to, occupying, or having the character of space.

Spatial capture-recapture: A method commonly used in ecology to estimate an animal population's size. A portion of the population is captured, marked, and released. Marked animals are either recaptured or are tracked, each tracking location being considered a recapture.

Species Continuum: An aggregate of species capable of interbreeding, resulting in fertile hybrid offspring whose genetic composition may represent a varying array of phenotypes and genotypes from the parental species, at which the extreme ends of the spectrum are distinct.

Standardize: Cause (something) to conform to a standard.

Statistically relevant inferences: the process of deducing properties of an underlying distribution by analysis of data. Inferential statistical analysis infers properties about a population: this includes testing hypotheses and deriving estimates.

Stochastic population models: Ecological population modeling is concerned with the changes in population size and age distribution within a population as a consequence of interactions of organisms with the physical environment, with individuals of their own species, and with organisms of other species; stochasticity possesses some inherent randomness. In stochastic population models, the same set of parameter values and initial conditions will lead to an ensemble of different out puts.

Strangulation: The condition in which circulation of blood to a part of the body is cut off by constriction.

Stratifying: Form or arrange into strata, one of a number of portions or divisions likened to layers or levels.

Surveillance: Continuous observation of a place, person, group, or ongoing activity in order to gather information.

Survival: A living or continuing longer than, or beyond the existence of, another person, thing, or event.

Sympatric: Occurring within the same geographical area; overlapping in distribution.

Tachycardia: A heart rate that exceeds the normal resting rate. In general, a resting heart rate over 100 beats per minute is accepted as tachycardia in human adults.

Telemetry: See radio-telemetry.

Temporal: Of or relating to time.

Tooth replacement: The process of development of two successive sets of teeth, initially the deciduous set and consecutively the permanent set.

Transmitter: A set of equipment used to generate and transmit electromagnetic waves carrying messages or signals, especially those of radio or television.

Transponder: A device for receiving a radio signal and automatically transmitting a different signal.

Draft - Confidential

682 Vaccinate: Treat with a vaccine to produce immunity against a disease; inoculate.

683 Venipuncture: The puncture of a vein as part of a medical procedure, typically to withdraw a blood
684 sample or for an intravenous injection.

685 VHF: Very high frequency is the ITU designation for the range of radio frequency electromagnetic waves
686 (radio waves) from 30 MHz to 300 MHz, with corresponding wavelengths of ten to one meters.

II. State/Agency:

NORTH CAROLINA / NORTH CAROLINA WILDLIFE RESOURCES COMMISSION

III. Station Name:

FWS RALEIGH ECOLOGICAL SERVICES OFFICE

IV. Description of Proposed Action (attach additional pages as needed):

Conduct research project entitled "**Coyotes of the Albemarle: Spatial Ecology, Resource Selection, Demographics, and Interactions with a Sympatric Canid"**

The coyote (*Canis latrans*) is now abundant throughout the 100 counties in North Carolina (NC), where they are managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plains region of NC (Hinton et al. 2012, Murray et al. 2014).

Recently described as using "compensatory immigration," coyotes are able to opportunistically fill spatial resource gaps by periodic transiency (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with humans and other canids, especially while taking advantage of anthropogenic resources. Though a rural area, human land uses predominate on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011).

In 1968, individuals from a remnant population of red wolves were removed from Texas and Louisiana and a captive breeding program was initiated. The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). The red wolf population increased until 2008 and peaked at around 208 individuals (USFWS Red Wolf Recovery Program 2007), a few animals short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013), with an estimated carrying capacity of 140-150 for the AP (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). Red wolves presently inhabit an approximately 6900 square kilometer recovery area within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014).
Accurate up-to-date estimates of the population are unavailable, but USFWS staff report a population size of 45-60 individuals with three mortalities in 2016 (https://www.fws.gov/redwolf/index.html July 2016). Hybridization with coyotes, inbreeding depression, and gunshot mortality have all been suspected issues that have affected the population growth and viability since the inception of the Red Wolf Recovery Program (RWRP) (Hinton et al. 2013). In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of red wolves and other canids on the AP. A USFWS memorandum documented detailed action items for the joint management of canids on the AP, including specific research objectives which this proposal seeks to address (Attachment 1).

As coyotes on the AP increase in number, monitoring coyote movements, particularly in relation to red wolves, will provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about coyote population management. Collection of finer temporal scale location data will help to manage interactions of both canid species with humans, as well as to support development of dynamic stochastic population models.

Coyote and red wolves will be live trapped by cooperating NCWRC and USFWS staff, and private trappers using double coil size 3 foothold traps, during the breeding season (Nov-Feb for coyote, Jan-Feb for red wolves) in the tri-county area of Dare, Hyde and Tyrrell. Morphological measurements, incidents of injury, occurrence of ectoparasites, age classification, and reproductive status will be determined; blood and tissue samples will be taken for genetic analysis. All captured individuals that meet the age classification and weight requirements will be collared with GPS collar units. All captured and collared individuals will be released at the capture site. The objectives listed below will be achieved by obtaining measurements, samples and information from the captured, collared, and tracked individuals over the course of three years using GPS location data.

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners.

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

V. Pertinent Species and Habitat:

A. Include species/habitat: See section VI

B. Complete the following table:

SPECIES/CRITICAL HABITAT	STATUS[1]
Canis rufus	T

[1]STATUS: E = endangered, T = threatened, PE = proposed endangered, PT =proposed threatened, CH = critical habitat, PC = proposed critical habitat, C = candidate species

VI. Location:

A. Statewide

Albemarle Peninsula (see web address www.ncwildlife.org)

B. Section, township, and range (or latitude and longitude):

Dare, Hyde, Tyrrell counties

C. Distance (miles) and direction to nearest town:

As stated above

D. Species/habitat occurrence:

Canis rufus

VII. Determination of Effects:

A. Explanation of effects of the action on species and critical habitats in item V. B. (attach additional pages as needed):

SPECIES/CRITICAL HABITAT	IMPACTS TO SPECIES/CRITICAL HABITAT
Canis rufus	Trap induced injury is possible

B. Explanation of actions to be implemented to reduce adverse effects:

SPECIES/CRITICAL HABITAT	ACTIONS TO MITIGATE/MINIMIZE IMPACTS
Canis rufus	Use of appropriate trap types, daily trap checks, treatment of minor injuries, trapping season limitations and limitations on environmental conditions for trap operation

VIII. Effect Determination and Response Requested:

Species/ Critical Habitat	Determination[1]			Response[1] Requested
	NE	NA	AA	
Canis rufus		X		Concurrence

[1] Determination/Response Requested:

NE = No Effect. This determination is appropriate when the proposed action will not directly, indirectly, or cumulatively impact, either positively or negatively, any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested is optional but a "Concurrence" is recommended for a complete Administrative Record.

NA = Not Likely To Adversely Affect. The determination is appropriate when the proposed action is not likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat or there may be beneficial effects to these resources. Response Requested is a "Concurrence".

AA = Likely To Adversely Affect. This determination is appropriate when the proposed action is likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested for listed species is "Formal Consultation". Response Requested for proposed or candidate species is "Conference".

Attachment 2: Joint Memorandum

MEMORANDUM

November 20, 2013

TO: All Interested Parties

FROM: "for"
Cynthia K. Dohner, Director, Southeast Region, U.S. Fish and Wildlife Service
Gordon S. Myers, Executive Director, N.C. Wildlife Resources Commission

SUBJECT: Collaborative Conservation of Red Wolves and Other Canids on North Carolina's Albemarle Peninsula

---

Recovery of the federally-listed red wolf has been a priority for the U.S. Fish and Wildlife Service (FWS) for more than 20 years and is focused in North Carolina on the Albemarle Peninsula (AP; i.e., Hyde, Tyrrell, Washington, Beaufort, and Dare counties). Comprehensive stakeholder involvement and collaboration with other management agencies is critical to successful recovery of any at-risk species. The North Carolina Wildlife Resources Commission (WRC) is a key collaborator in this regard, as it has jurisdiction over all state-trust wildlife resources in N.C.

Since 2009, the FWS and WRC have worked to broaden our collaboration in the conservation and management of all canid species (including red wolves) on the AP. As these efforts have solidified, specific actions have been jointly identified by our two agencies that will improve conservation outcomes. These actions are categorized into five areas; collaboration, research, outreach, regulatory, and enforcement. Specific action items are outlined and prioritized within each of these categories in Attachment A.

This memo establishes the FWS's and WRC's commitment to initiate, or to continue, the efforts outlined in Attachment A. The common goal in this effort is to establish clear expectations and accountability for collaboration regarding the action items on Attachment A, thus resulting in enhanced and seamless canid conservation and management on the AP. This approach provides the best opportunity to achieve recovery goals for red wolves, while at the same time managing other canids to balance biological variables with social expectations. The dynamics of these canid species are complex and offer unique opportunities for innovation. Appropriate staff from each agency is hereby tasked with immediately developing a timeline to implement these actions. Through this commitment, we will continue to advance our collective conservation goals.

875

Attachment A

Action Items for Collaborative Conservation of Canids on North Carolina's Albemarle Peninsula (AP)
(*Note: Action Items are prioritized within category.*)

Collaboration

1. The N.C. Wildlife Resources Commission (WRC) and U.S. Fish and Wildlife Service (FWS) will formalize in writing the collaborative management of canids on the AP. This agreement should:
    a. include a clear mission statement, goals, objectives, and implementation strategies (ask and answer the "Why?");
    b. set a goal to define success regarding canid management on the AP;
    c. espouse a philosophy of canid management operating within the context of a three-legged stool (i.e., federal and state governments and stakeholders);
    d. as available, commit funding and staffing resources for field personnel to contribute to the conservation of the red wolf and management of coyotes;
    e. as available, commit funding to conduct research pertinent to canid management on the AP;
    f. establish polices and goals for developing a collaborative genetic archive for AP canids, a data sharing portal accessible by staff in both agencies, and reciprocal sharing of all historical data (including phenotypic and genotypic data and literature) of the red wolf;
    g. establish a foundation for developing and implementing an adaptive approach to canid management on private lands on the AP;
    h. initiate development of a collaborative canid research program;
    i. describe plans to conduct the next five year Red Wolf Program review;
    j. outline options for holding annual workshops with federal and state enforcement staff;
    k. outline plans to hold semi-annual coordination meetings regarding canid management on the AP; and
    l. develop milestones for future development of a management plan for all canids in the AP.

2. The FWS will initiate a review of the current Red Wolf Recovery Plan to determine if the state-of-our-knowledge or field conditions have changed such as to warrant its revision. Review and comments from the WRC will be considered in this evaluation.

3. The WRC, with support and participation of the FWS, will establish a "Canid Forum" (similar to that established for manatees in Florida) to facilitate communication and discussion regarding canid management and citizen science opportunities on the AP.

876

877

Attachment A

Research

1. The FWS and WRC will provide funding and logistical support for research identified by the Red Wolf Recovery Implementation Team, Red Wolf Program staff, other FWS staff, or the WRC that promote the conservation and recovery of the red wolf and other canids on the AP. Studies could include:
    a. tests of the "placeholder theory" on the AP, including behavior of sympatric canids,
    b. determining carrying capacity of canids on the AP,
    c. determining genetic profiles of canid species on the AP,
    d. evaluating predator-prey dynamics,
    e. studies of canid habitat use,
    f. epidemiology of diseases impacting canids on the AP,
    g. development of stochastic simulation models of sympatric canid population dynamics and habitat use, and
    h. canid dispersal dynamics

2. The FWS and WRC will conduct jointly-supported research to determine the attitudes and opinions of N.C. private landowners and other citizens concerning canids on the AP (i.e., human dimensions studies).

Outreach

1. The FWS and WRC will collaborate with other partners to design and implement broad-based outreach and marketing programs with clear goals, objectives, strategies, and measurable outcomes, including development of consistent agency messages and educating the public about canids on the AP.

Regulatory

1. The FWS and WRC will initiate a review and, if needed, subsequent rule-making to clarify concepts or rectify conflicts in current federal or state rules (including the current 10(J) rule).

2. The WRC will review and evaluate statutory requirements for listing red wolves as state threatened in the five AP counties.

3. As data demonstrating a relationship between coyote hunting and red wolf mortality become available, the FWS and WRC will evaluate, and if appropriate implement, adaptive approaches to regulate of take of coyotes that may result in incidental take of red wolves.

4. The WRC will evaluate the status, management, and regulation of Controlled Fox Hunting Preserves.

878

879

5. The WRC will develop BMPs (due care provisions) for coyote hunting, trapping, and live sale.

6. The WRC will compile, compare, and contrast canid hunting and trapping regulations and programs in other states, including, but not limited to, other states with other species of wolves.

Enforcement

1. The FWS and WRC will develop coordination strategies to improve enforcement of federal regulations protecting red wolves.

I, the cooperator or cooperator's representative, have been informed of the methods and the manner in which research devices will be used, and of the possible hazards associated with their use. I understand that NCWRC, (to include its officers, employees and agents) will: exercise reasonable precautions to safeguard all persons to prevent injury to target and non-target animals; guard against the mishandling of control devices and materials; and exercise due caution and proper judgment in all scientific collection operations. I understand that NCWRC may collect Global Positioning System (GPS) coordinates at the project site as part of component or activity tracking or as wildlife disease monitoring or research data. I, the undersigned cooperator, do hereby give my consent and concurrence to NCWRC, its employees, and its agents, to use, upon lands owned, leased, or otherwise controlled by me, and identified by this document, the following methods and devices (an attachment of additional devices and/or methods may be attached):

Statement of agreement: The landowner, cooperator, or representative, as listed above hereby give permission to NCWRC to perform trap and release of the species listed for scientific collection purposes. In consideration of these understandings, I, the cooperator or cooperator's representative, agree to: assume responsibility for injury to my property under my control, when said injury is not the result of negligence on the part of NCWRC (it's officers, employees, and agents); assist in maintaining such warning signs as NCWRC may place for the purpose of notifying persons entering onto such lands of the possible hazards associated with scientific measures in use thereon; and to give adequate warning of these possible hazards to persons I authorize to enter onto such lands. Further, I, the cooperator or cooperator's representative, agree not to concurrently use or allow to be used upon lands covered by this agreement, any canid depredation efforts during the scientific collection time period.

STATE: North Carolina

GRANT TITLE: W79-Wildlife Management

PROJECT TITLE: Pilot Study – Using Fine Scale GPS Technology to Research Sympatric Canid Population Dynamics (Job 2.0?)

A. Problem and Need

The coyote (*Canis latrans*) is now abundant throughout the 100 counties in North Carolina (NC), and is managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plain region of NC (Hinton et al. 2012, Murray et al. 2014). In recent years as coyotes have increased their population, some have begun to make use of the Outer Banks region.

The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of captive-bred red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). This population increased until 2008 and peaked at around 130 individuals (Group Solutions, Inc. 2016), short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013). The AP has an estimated carrying capacity of 140-150 wolves (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). The exact number of red wolves is not known, but USFWS staff report a population estimate of 45-60 individuals with eight mortalities to date in 2016 (https://www.fws.gov/redwolf/index.html August 2016). Hybridization with coyotes and inbreeding depression are suspected factors that have affected red wolf population growth and viability since the inception of the Red Wolf Recovery Program (RWRP), while vehicular and gunshot mortality are known factors (Hinton et al. 2013). Because of hybridization between red wolves and coyotes, the AP supports a continuum of sympatric canids, hereafter referred to as "sympatric canids."

As part of a recent program review, the USFWS halted many aspects of the RWRP in 2015 and discontinued the coyote sterilization program, potentially affecting the spatial

Draft - Confidential

distribution and population dynamics of sympatric canids. Telemetry data from coyotes on the AP suggests that about 70% of coyotes are residents (i.e., those that defend set territories) while the other 30% are transients, with most being dispersing juveniles (Hinton et al. 2015). Transient coyotes do not defend set territories. Coyotes can travel long distances and become transient even as adults, especially when they lose their mate. Recently described as using "compensatory immigration," coyotes opportunistically fill spatial resource gaps by periodic transiency; when spots come open, individuals that do not yet have permanent territories and have been roaming in the area, are able to inhabit the new openings (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with other canids and humans, especially when they are utilizing of anthropogenic resources.

Though a rural area, human land uses occupy a significant portion of space on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011). Concerns about fear of attacks on humans and domestic pets, the effects of sympatric canids on white-tailed deer and other game populations, and homeowner property damage comprise many of the conflict calls regarding sympatric canids on the AP (Responsive Management, forthcoming data). Wildlife managers in this region frequently receive requests for information on canid management (C. Turner, personal communication, 2016).

The changes in state and federal canid management rules have resulted in confusion regarding residents' rights and options for management of property damage by sympatric canids. As a result, some citizens are unsure of the legal and most effective methods for canid conflict management. Adding to management complexity is the need to manage canids for conservation purposes, such as reducing predation on at-risk ground nesting species or reducing hybridization of sympatric canids.

In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of sympatric canids on the AP. A USFWS and NCWRC joint memorandum documented detailed action items for the joint management of sympatric canids on the AP, including specific research objectives which this proposal seeks to address (Attachment 2). As sympatric canids on the AP increase in number, monitoring their

Commented [BA1]: I don't understand the assumption that dynamics would change

Commented [BA2]: Data from how many current coyotes? Doubt you could make this determination from the current or past data, only on the coyotes that happened to have been collared in specific areas due to managing the wolf population

Commented [BA3]: Is there any data showing that this even takes place?

Commented [BA4]: Coyote number may be increasing – suggests a need, if any, to focus on them, not an endangered species with so few in the population and therefore at greater risk to loss from management actions.

Draft - Confidential

movements, particularly in relation to individuals of differing ancestry, could provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about sympatric canid populations and conflict management. Collection of finer temporal scale location data would help to manage interactions of sympatric canids with humans, as well as to support development of dynamic stochastic population models.

B. Objectives (after December 1, 2016-November 30, 2018)

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners.

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

At the end of this two-year pilot study, we will deliver an observational summary detailing the use of the GPS and sensor technology for spatial and population dynamics research on sympatric canids on the AP.

C. Expected Results and Benefits

As part of a pilot study, we will monitor the status of collared individuals by using a finer scale assessment of space and habitat use than previous studies. Earlier research focused on many of the same objectives we suggest investigating here, but during a time of intense, active

Commented [BA5]: This is a very vague statement – what decision are being sought out here, particulary that we don't have research and data on already, at least regarding red wolves.

Commented [BA6]: This objective should not be the basis for all the work suggested in this proposal on red wolves – too much potential risk. Test them on coyotes, or dogs.

Commented [BA7]: Has already been done – no need to reinvent the wheel, especially now. The time to do that was when there were significant numbers of both species on the ground. Can't get that now.

Commented [BA8]: Why? Of all things, this is not needed on red wolves for red wolf recovery.

Commented [BA9]: Done for red wolves. Focus on coyotes if anything.

Commented [BA10]:

Commented [BA11]: What conflicts?

Commented [BA12]: Again, how does this promote recovery of red wolves, and how would this be used for management

Draft - Confidential

management. Specific management techniques are no longer being carried out and dynamics between sympatric canids are expected to have changed substantially. The uncertainty regarding current dynamics presents a need for additional research in order to inform actions for the management of sympatric canids. Information gained from research may impact management rules and landowner's abilities to manage canids in some areas. Additionally, GPS technology has improved since earlier research was conducted allowing for more temporally detailed data collection and more nuanced analyses. Understanding how sympatric canids collectively use resources in areas of human-dominated landscapes will allow wildlife managers to tailor management options to local conditions. On the AP, row crop agriculture and hunting represent the primary and secondary land uses, respectively. Row crop agriculture is a significant nutrient resource on the landscape and, as opportunists, canids take advantage of such resources when they are available. Non-consumptive wildlife-driven tourism persists in all seasons and wildlife watching is a main draw for tourists in this area. For many tourists, the opportunity to see or hear large carnivores is the sole attraction for traveling to the AP. Information from this study will be provided to local constituents to establish a knowledge base regarding how sympatric canids use resources on private lands. Management and guidance could serve to prevent or minimize conflict while maximizing positive wildlife interaction opportunities for constituents. Development of a common understanding between wildlife managers and landowners based upon factual information is paramount for collaboratively achieving successful management of sympatric canids. The data collected in this pilot study is the foundation upon which this understanding and future management actions will be built.

The current level of hybridization between sympatric canids on the AP will be characterized using DNA gathered during this study. Body size exists as a continuum between coyotes and red wolves and has been documented as the most important factor for successful interspecific breeding pairs of these canids (Hinton 2014). Though both species have been found to use resources in similar manners, red wolves generally have more expansive home ranges and therefore may not use local resources as intensively as coyotes, depending on body size. Obtaining individual identification of study animals will allow managers, armed with spatial information, to infer how and why individuals in the canid species continuum exploit

Commented [BA13]:

Commented [BA14]: Lot of words here, but what type of management options would be considered for what resources?

Commented [BA15]: Take advantage of row crops?

Commented [BA16]: "large" – is that red wolves or coyotes, or both? Is there a suggestion of tourism based on coyote presence?

Commented [BA17]: Except that the numbers do not exist on the ground to do this, particulary on non-public lands where you would need to understand the "foundation". Takes out the need to do this refuges.

Commented [BA18]: So again, we already have this information – why risk on red wolves

Draft - Confidential

anthropogenic resources considering their life history traits.

In conjunction with prior research, data collected will contribute to knowledge on sympatric canid population dynamics on the AP. Estimating population size will allow managers to monitor population trends of sympatric canids and to examine the long and short-term impacts of different management strategies on their populations. While it is unknown whether sample size will allow for population estimation, obtaining population estimates for coyotes would provide wildlife managers with baseline data, when paired with annual mortality estimates, for monitoring changes in population abundance over time. Information on changes in abundance, reproductive dynamics, and habitat use could impact management strategies to influence long-term conservation outcomes. Results of this pilot study will allow managers to determine if future work will be necessary, what amount of effort will be required to achieve each objective, and whether or not population estimates will be an attainable goal.

Commented [BA19]: You can't do this in a 2-year study though – and are different management strategies being employed during this study and being incorporated.

D. Approach

The official Red Wolf Recovery Area (RWRA) covers approximately 6,900 square kilometers within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014). However, the USFWS has proposed the RWRA be constricted to the ARNWR and the Dare County Bombing Range in Dare county by the end of 2017. Due to these proposed RWRA changes, this study proposes to capture and radio-collar 25 sympatric canids within Dare, Hyde, and Tyrrell counties (hereafter referred to as "study area"); those counties being within and directly adjacent to the proposed new RWRA. The thematic subheadings below provide detailed descriptions of the approaches required for achieving the pilot study objectives.

Sampling Efforts

Trained NCWRC personnel will conduct live trapping of sympatric canids, with assistance from the USFWS RWRP biologists, and trained, experienced local trappers. NCWRC and USFWS wildlife personnel will select local trappers based on their past performance in trapping sympatric canids, but may also select trappers from the NCWRC coyote trappers list. NCWRC staff will train contracted trappers on specific trapping procedures before every trapping

Draft - Confidential

season. The project lead will supervise and coordinate all trapping activities including locations for installation and the operation of trap lines and handling of captured animals. Simultaneous personal trapping activities by contracted trappers will not be permitted while performing contracted trapping services, as specified in the draft service contract (Attachment 4).

Trapping efforts will follow a spatial capture-recapture (SCR) framework with a systematic targeted sampling design, focusing on areas that contain resources previously found to be used by sympatric canids (e.g. edge, agricultural fields, secondary roads, etc.) (Harris et al. 2013, Ivan et al. 2013), while attempting to sample a diversity of habitat types. This effort will allow us to increase the probability of detection of sympatric canids on the landscape (Tom 2012). While it is important to sample a wide range of habitats, the most important requirement for SCR is the number of collared individuals; this requirement provides flexibility in the other requirements for field sampling as needed (K. Pacifici, personal communication, 2016). We will initially focus trapping in areas of known red wolf packs, as advised by RWRP.

Trapping will take place during the breeding season when the likelihood of capturing females in the later stages of gestation or whelping females will be low. Capture efforts will be conducted from soon after 1 December 2017 – February 2018 and December 2018 – February 2019. Captured sympatric canids will be surrendered to NCWRC or the USFWS at capture sites. Trapping should occur on both public and private lands to obtain sampling coverage of the study area. Ideally, all federal and state lands would be accessible for trap and release (hereafter referred to as "capture") of sympatric canids, but it is most important to be able to trap and release on Alligator River NWR and the Dare County Bombing Range as those encompass the newly proposed RWRP recovery area and comprise the majority of land area for Dare county. Unlike Dare county, there are ample private lands that surround Pocosin Lakes NWR and Lake Mattamuskeet NWR in both Tyrrell and Hyde counties that may be utilized to effectively sample individuals who may use those federal lands, should they be excluded from capture activities. Capture on federal lands may require USFWS take permits and proposed activities may be subject to a compatibility assessment (P. Benjamin, personal communication, 2016). Scientific collection activities that take place on private lands will require agreements outlining conditions mutually decided by NCWRC and landowners (Attachment 3).

Commented [BA20]: Even if these areas were included, the numbers don't exist for this study. And I'll say it here, but if this is the last holdout for red wolves in the population, there isn't enough information to be gleaned from this study that in any way promotes recovery, especially on the refuge, and when the objectives are focused in large part on landowner conflicts and resources.

Draft - Confidential

To increase probability of detection of sympatric canids, the accessible study area will be partitioned by a grid, the cell size of which will based on the average annual home range size of resident coyotes previously reported for the AP, approximately 23 km^2 (Hinton et al. 2015). As a system of sampling, trap lines will be referred here as "traps," and the number of trap sets (i.e. the actual trapping device) and number of each trap set size may vary between traps as necessary. Sampling will be standardized within each grid cell by use of equal number of traps per cell, on average 3 per cell, each at an approximate length of 10 km (Andelt and Gipson 1979, Way et al. 2004).

Target canids will be captured by using Softcatch #3 Coyote 4x4 (Oneida Victor Inc. Ltd., P.O. Box 32398, Euclid, Ohio 44132, Hinton 2014, Schemnitz 1994), the EZ Grip #7 (Livestock Protection Company, P.O. Box 725, Alpine, Texas 79831, Frame and Meier 2007), or equivalent. Various lures and baits will be used to increase trapping efficiency (Frederick et al. 1989, Shipley 2012). Traps will be laid on the Monday of each week and will be opened at the time of deployment. Traps will be checked once daily at dawn, to reduce potential stress to trapped individuals and will not be operated on days where the temperature is expected to reach or exceed 80° F (R. Nordsven, personal communication, 2016) or during times of predicted inclement weather (e.g. snow, hail, high wind, etc., Sikes et al. 2011). To standardize effort and remain logistically realistic, traps should be open for three trap nights in a row before being removed. Trap sets that have been closed due to non-target bycatch or other circumstances may be reopened and all traps should be re-baited and lured as appropriate.

Trap set locations will be marked by NCWRC or USFWS personnel using handheld GPS units (Garmin GPSMAP 64S, 1200 E. 151st St., Olathe, KS 66062-3426) and given a sequential identification number. Traps will also be given an identification number and trap set points will be documented in ArcMap 10.4. Trappers will keep detailed records on trap set operation, non-target species trapped, and other relevant details. Non-target species will be released from traps after an in-field assessment of injuries, if any, and animals with life threatening injuries will be euthanized by the trap operator. Targeted recapture of collared canids will occur annually during the same months, to replace GPS collar batteries and drop-off collar release units in field. Trapping effort will be quantified (trap nights), the effective sample area will be

Draft - Confidential

estimated, the encounter (detection) probability will be estimated using a Gaussian detection model (Amundson et al. 2014), and an estimate of density for coyotes will be calculated using a modified Huggins closed-capture estimator in program MARK, if sample size allows (Harris et al. 2013, Ivan et al. 2013).

Animal Handling

Handling of canids will follow American Society of Mammalogists (ASM) guidelines (Sikes et al. 2011) and will be performed at the capture site. Chemical immobilization agents may be used depending on the number of field staff during processing (i.e., three or more staff required during non-chemical immobilizations, Craft 2007, M. Morse, personal communication, 2016).

Chemical Immobilization

Unless adequate numbers of personnel are available to safely employ mechanical restraint techniques, target animals will be anesthetized with the chemical immobilization agent BAM (Wildlife Pharmaceuticals, Inc., Windsor, CO 80550). BAM, a combination of Butorphanol tartrate, Azaperone tartrate and Medetomidine HCl., will be delivered by intramuscular injection by syringe pole to the hip. Dosage for canids is based on field trails performed by Wildlife Pharmaceuticals (Wildlife Pharmaceuticals, Inc. 2016) and the recommended dose for coyotes is 0.2CC and red wolves is 0.3CC, with adjunct doses of 0.1-0.2CC delivered if initial dosages do not cause induction (S. Kirschner, personal communication, 2017). Induction times for coyotes and wolves ranged from 5 to 10 minutes after initial and/or adjunct dosages (Wildlife Pharmaceuticals, Inc. 2016). After field handling is concluded the anesthesia will be reversed using two reversal agents, Atipamezole and Naltrexone, at double the CC of Atipamezole to BAM that was delivered (including adjunct doses, if given) and 0.5CC of Naltrexone. Recovery time from the reversal agents ranged from 10 to 25 minutes during field trails (Wildlife Pharmaceuticals, Inc. 2016). Field personnel will observe animals for signs of adverse effects for up to 30 minutes after reversal agents are delivered.

Mechanical Immobilization

Unlike other carnivore families, the submissive behavioral response of canids to

Commented [BA21]: Need to look at CFR on red wolves

Commented [BA22]: We've gone through testing on red wolves using various drug combination to find what works best – I'm not aware that this combination has been tested on red wolves? The field would not be the place to do this!

Draft - Confidential

perceived dominance reduces the need to use immobilization agents. Appropriate mechanical restraint techniques can reduce handling time of animals, allowing animals to reintegrate into social groups more quickly, subsequently reducing overall stress to the individual (Powell and Proulx 2003). Target canids will be mechanically restrained with a restraint pole, until two muzzles can be placed around the snout. While pinned with the restraint pole by one person, a second person will restrain the set of legs not in the trap against the ground and a third person will release the foot from the trap. This set of legs will then be restrained by the 3rd person as the restraint pole is removed. Once the restraint pole is removed the person restraining the front legs will also then restrain the head. The first person will then move forward with processing the captured animal.

Each animal will be placed on a towel or blanket to provide thermal protection from the ground, with eyes covered and lubricated with eye ointment; temperature will be monitored with a rectal thermometer. Overheating occurs at approximately 104-105°F for canids (AZA Canid TAG 2012) and the animal handling crew will monitor temperature at 5-minute intervals; if a temperature reading reaches 104°F, corrective actions will be taken and temperature will be monitored at 1-minute intervals. Should overheating occur, the individual will be removed from insulation to expedite the natural evaporative cooling process. During days that approach 80°F in temperature, measures will be taken to reduce heat stress, such as: wetting the animal with water, application of a cold pack to the groin area between the back legs, application of rubbing alcohol to foot pads, or immediate release (AZA Canid TAG 2012). If the injured individual is suspected to be a red wolf, based on morphometrics, USFWS staff will be contacted for a decision. In the event that trap caused injuries are determined to be life threatening through use of a trap injury score assessment (Frame and Meier 2007) the individual will be euthanized. In the event that NCWRC personnel cannot be present, trained USFWS personnel may collar and measure captured target animals and will provide data sheets to NCWRC staff. Target animals will not be vaccinated or otherwise treated for diseases, regardless of the presence of disease symptoms.

Commented [BA23]: Or tranponders, or previous genetic analysis – do not use morphometrics as the sole indicator of species.

Commented [BA24]: For red wolves, this should be the call of FWS – look at CFR

Non-target animals will be released on site. Captured domestic dogs will be immediately released from the trap set following an injury score assessment and only if no life-threatening

Draft - Confidential

injuries are present. If a domestic dog has sustained life threatening injuries and owner identification information is present on the dog, then the animal will be held in either a transportable kennel, or at a dog pen on a state game land that is equipped with such facilities, until the owner can retrieve the dog. The costs associated with injuries sustained to the dog will be the responsibility of the animals' owner. Law enforcement may be requested to help communicate with the animal's owner. If the animal does not have an identifiable owner and has incurred substantial life threatening injuries (i.e. compound fracture), the dog will be euthanized on site. Target animals showing signs of disease symptoms such as circling behavior, head tilt, muscle twitches, convulsions with jaw chewing movements and salivation ("chewing gum fits"), disorientation, incoordination, staggering caused by paralysis of the hind legs, seizures, and partial or complete paralysis will be euthanized and tested according to protocol set forth by the agency veterinarian, in order to determine if there may be a public health issue (M. Palamar, personal communication, 2016). USFWS will be contacted in cases of suspected red wolves. Staff involved in animal handling duties will have the pre-exposure rabies vaccination series completed prior to field work inception and will maintain rabies titer records through properly licensed medical services providers.

Commented [BA25]: Even if it is on their property?

Commented [BA26]: This is problematic on refuges.

Commented [BA27]: Not just contacted, but the decision needs to be FWS

If staff is bitten and skin is broken by an animal while performing handling duties, they will be advised to immediately visit a local hospital or clinic for evaluation by healthcare professionals. The field coordinator will immediately notify supervisory staff and an injury report and workers' compensation claim will be opened for the incident. The animal will be euthanized and the head will be sent to the state lab for rabies testing; the body may be sent to the Southeastern Cooperative Wildlife Disease Study (SCWDS) laboratory for additional disease investigation.

Capture Processing and Marking

During canid handling, NCWRC personnel will record age class, sex, weight, total body length, head width, ear length, and tail length, visually assess ectoparasite load, look for and disinfect with betadine or iodine as needed any minor trap caused injuries, and affix GPS collars (Knick 1990, Sikes et al. 2011). All captured canids will be fitted with appropriately-sized GPS collars in the field based on morphometrics previously indicated as reliable thresholds for

Draft - Confidential

species categorization: hind foot length, weight, width of head, and tail length (Hinton 2014); analysis of DNA samples collected during trapping efforts will help to assign captured canids to position along the species continuum post release. Age of individuals will be estimated based on physical characteristics, including weight and tooth replacement (Knick 1990, Hinton 2014, Gier 1968), and captured canids will be aged into one of three classes: > 2 years old as adults, < 2 but > 1 year old as juveniles, and > 6 months but < 12 months old as pups (Hinton 2014). Reproductive status will be determined based on estimated age class and presence of gonadal descent during the breeding season for males and the presence of nipple swelling or previous suckling for females (Hutson and Racey 2004, Magee 2008, Mengel 1971).

Captured individuals will be ear marked using a button tag (model 410, Ketchum Mfg. Co. [or equivalent], PO Box 10, 11 Town Shed Road, Lake Luzerne, NY 12846) placed along the middle of the ear where they are most protected from loss, with a pin-type applicator (485sa Pow-R-ceps plier, Ketchum Mfg. Co. [or equivalent]) (Silvy 2012). The puncture site will be treated with an antiseptic to deter infections. Each sympatric canid will also be marked with an individually-numbered, glass-encapsulated, passive integrated transponder (PIT model HPT12, 12.5 mm, 134.2 kHz, Biomark, Inc., 703 South Americana Blvd., Suite 150, Boise, ID; Gannon et al. 2007), using a syringe-type implanter and replaceable needle (model MK10 [implanter], model N125 [needle], Biomark, Inc.). Successful PIT placement will be verified with a mini portable reader (model GPR Plus, Biomark, Inc.). The implantation site will be prepared by swabbing with 70% alcohol (Mrozek et al. 1995) and a sterilized new needle will be used for each injection. The standard implantation site for transponders is subcutaneously on the dorsal midline of the back, cranial to the shoulder blades (Ingwersen 2000).

A skin biopsy will be taken from all captured target canids by puncturing the pinna of the ear with a biopsy punch in the same location where the ear tag will be placed (Palamar 2014). The biopsied area will be disinfected with alcohol after sampling. The skin biopsy will be placed in a labeled (ID, date, and sample type) cryogenic tube filled with 95% ethanol as buffer and then stored in a freezer until sent out to a lab for genetic analysis (Palamar 2014, Tom 2012). A selection of hairs with the root bulla attached will be pulled from the belly and placed in paper envelopes (Janecka et al. 2007). Hair samples will serve as back up to tissue samples

Commented [BA28]: Why? How does this fit into the study proposal? If not, no need to do it.

Draft - Confidential

for genetic testing. All samples will be sent to the Laboratory for Ecological, Evolutionary and Conservation Genetics, at University of Idaho (875 Perimeter Drive, MS 1136, Moscow, ID 83844) for genotyping to determine species as well as individual identification, hybridization presence, and parentage analysis following previously developed protocols (Adams et al. 2007, Hinton 2014, Miller et al. 2003). The appropriate genetic analyses that examine the coyote-hybrid-wolf species continuum will be performed.

Blood will be collected from all juvenile and adult target canids by venipuncture of the brachial or jugular veins using a 22-28-gauge needle (M. Palamar, NCWRC veterinarian, personal communication, 2016). As per NCWRC veterinarian recommendations, approximately 12 ml of blood will be collected for each animal for possible future testing for diseases of importance to sympatric canid species as well as the humans and domestic animals that they may come into contact with. A minimum of two 6 ml lavender top tube (for whole blood with EDTA) will be filled. Samples should be refrigerated at all times; a cooler with ice will suffice while in the field. Samples should be sent to the NCWRC within 48 hours or frozen for later shipping. Skin scrapes will be collected from animals presenting signs compatible with sarcoptic mange (lesions) for possible future diagnostic purposes. Lesions will be scraped until blood is drawn; the scrapings will be placed onto a slide and covered with a piece of clear tape for later visual confirmation.

Should overheating occur, processing will be performed in the following prioritization order and the first five items will need to be completed before releasing any individuals: 1) trap injury evaluation, 2) collaring, 3) DNA (skin biopsy) sample collection, 4) morphometrics, 5) aging, 6) PIT tagging, 7) weight, 8) ear tagging, 9) reproductive status, 10) ectoparasite evaluation, 11) blood collection, and 12) skin scrape collection.

Collaring

Vertex Plus GPS Collars will be attached to 25 sympatric canids captured on the study area, 10 of which will be equipped with proximity sensors (Vectronic Aerospace GmbH, Carl-Scheele-Str. 12, 12489 Berlin, Germany). Project staff will pilot test proximity sensor technology for utility in analysis of spatial and temporal community dynamics. Proximity sensors trigger increased GPS location acquisition during those time intervals when two collared individuals

Commented [BA29]: Why? What information is being collected and how would it be used to meet objectives?

Draft - Confidential

come within a set distance from each other (http://www.vectronic-aerospace.com/wildlife-monitoring/sensors/uhf-id-tags, accessed August 2016).

To avoid instances of collar induced strangulation, only adult (>2 years old) male and female individuals will receive collars (Hinton 2014). ASM guidelines recommends a collar weight of <5-10% of a canids bodyweight, we will observe these guidelines (Sikes et al. 2011). Sympatric canids not releasable at a capture site will not be collared and will not become study animals.

GPS radio-collars will have both VHF and GPS Iridium locational systems as well as store-on-board capabilities. Radio-collar units will be programmed to record GPS coordinates once every 1.75 hours producing approximately 13 locations per day while cycling through the 24-hour time cycle. These settings will allow for a GPS battery life of 300 to 552 days, averaging 431 days. The VHF beacon will be in operation from 0800 – 1600 hours daily. GPS locations will be sent via satellite once per day and each transmission with contain 12 locations. The use of an integrated drop off firing mechanism should allow the collars to drop off within a maximum of approximately 548 days after deployment. The drop off schedule once set cannot be changed. The drop off firing mechanism is wired to a battery unit independent of the collar battery, therefore should the collar battery become depleted, the drop off mechanism will not be affected (C. Akakpo, Vectronic Aerospace GmbH, personal communication, 2016). Unless a collared individual is recaptured before the collar battery dies, the drop off mechanism will fire at the scheduled time frame post collar deployment.

Observation of sympatric canid habitat use and movements will occur through GPS data obtained with combination GPS/VHF radio-collars. VHF relies on triangulation, the process of estimating the location of a transmitter by using two or more compass bearings obtained by using directional antennas at known locations remote from the transmitter's position (White and Garrott 1990), whereas GPS uses a satellite based system to obtain location coordinates. There have been many published studies where one or both of these methods were used, with mixed success for determining various aspects of carnivore ecology throughout the United States (Hinton et al. 2012, Schrecengost et al. 2009, Sparkman et al. 2012). While GPS technology has developed rapidly in recent history, the real time functional advantage of VHF

Commented [BA30]: How long is the battery life on the vhf beacon?

Commented [BA31]: This gets at the previous issues we had with managing a population of red wolves using an adaptive management plan but not having wolves collared for longer periods of time and losing contact, hence the inability to manage. You may gain data (though we already have what's being suggested here), but at the risk of the remaining few wolves in the population. In other words, I still don't see the rationale to even consider this proposal.

Commented [BA32]:

Commented [BA33]: Way to short – now no contact with wolves? Are you kidding?

Draft - Confidential

cannot be disregarded. When GPS technology falters or malfunctions, VHF can serve as replacement for data collection in addition to its use in real time monitoring of study animals. Canids will be minimally monitored for mortality approximately every 30 days by using VHF aerial telemetry techniques (Whitehouse and Steven 1977) as there may be a delay in satellite transmission of GPS location data due to weather, season, and animal behavior. Transient canids and individuals from breeding pairs that have lost a mate, have been found to use much larger areas versus paired residents, potentially increasing the opportunity for losing track of these individuals when GPS technology reaches its functional capacity or experiences malfunction. VHF data may also provide locations of canids in cover too dense for GPS units to function. Use of VHF telemetry techniques for data collection may be expanded as necessary for project needs.

Spatial Data Analyses

Both minimum convex polygon (MCP) and adaptive kernel (AK) home ranges (95%) and core use areas (50% and 25%) (Seaman and Powell 1996, Seaman et al. 1999) will be calculated from GPS data by using BIOTAS (Ecological Software Solutions LLC, 2016) and Geospatial Modelling Environment (Spatial Ecology, LLC, 2016) for ArcGIS 10.2.2 (Environmental Systems Research Institute, 2016) (Benson et al. 2006, Riley 2006, Tucker et al. 2008, Hinton 2014) for comparison to older studies. These estimations can also be calculated using VHF data, provided data minimum requirements are met. Spatial distribution in relation to habitat will also be estimated by dynamic Brownian bridge movement models as described by Hinton (2014) with R statistical software (R Core Team 2016) using the moveud package with habitat covariates important to each species (Bryne et al. 2014, Collier 2013, Kranstauber and Smolla 2013, C. Proctor, personal communication, 2016). Additionally, recent research into how canids shift their ranges will also be investigated for populations on the AP (Morin and Kelly, in review). Spatial overlap and co-occurrence will be assessed using methods described by Shipley (2012). Habitat and cover types will be estimated from digitized maps created by the SEGAP (Hinton 2014) or ortho files, as available (Shipley 2012). Percent composition of habitat and cover types within home ranges and core areas as well as edge density will be quantified (Shipley 2012). Habitat selection and cover type use effects on spatial distribution will be estimated at both the population (2nd order) and individual (3rd order) spatial scales using resource selection functions

Draft - Confidential

(Johnson et al. 2006, Manly et al. 2002, Shipley 2012). Effects of seasonality and time of day activity will also be explored. The spatial and temporal patterns of space use by sympatric canids will be studied using data generated from the interaction GPS collar sensors, particularly distance between individuals and duration of proximity.

Den Monitoring

Project staff will attempt to locate den sites for sympatric canids to get pup counts, morphometric measurements, age estimates, and skin biopsies. Project staff will also attempt to monitor pup survival during the pup rearing season by using remote cameras placed around the den site (Harrison and Gilbert 1985, Parks 1979, Way et al. 2001). Pups will be weighed, measured, and PIT tagged during May and June of each year when they become active but are still den-obligated (Gier 1968). We will investigate the use of remote camera traps for monitoring den behavior with a two-camera array around the den (H. Garbe, personal communication, 2016, Kays and Slauson 2008). This method has been successfully used to monitor kit fox pup survival (Kluever et al. 2013). Because coyotes have been found to be sensitive to den site disturbance, there is a general lack of data in the literature regarding this approach for monitoring pup survival. Approaching an experimental methodology systematically will be important for determining which methods are effective and which are not. As a starting point for testing this methodology, remote cameras will be placed two to five meters from main den entrances and set to take photos using a passive infrared sensor trigger (a beam that when broken by movement through it, triggers the camera to take a series of photos) with a time restriction between photo intervals to limit the number of photos taken and maximize the space on the memory card for the time period between camera checks (Kluever et al. 2013). Cameras will be checked six days after deployment and will be redeployed (i.e. new batteries and memory card, if required); cameras will remain at each den site until radio-collar data indicates the den site has been moved (Kluever et al. 2013). Cameras will be not be redeployed to a new coyote den site during a season if that breeding pair has already moved the den once due to the disturbance of camera presence/deployment.

Commented [BA34]: Based on past experience, will likely cause dam to move the den, or abandon pups

Draft - Confidential

Mortalities

If a collared animal dies during the project, the carcass will be sent to SCWDS for necropsy. Red wolves will be sent to the SCWDS laboratory for necropsy, unless it is determined to be a law enforcement case. In potential law enforcement cases, the NCWRC Division of Wildlife Management Chief and USFWS Ecological Services Raleigh Field Office Field Supervisor will be contacted and requested to contact the appropriate law enforcement personnel, immediately after determining the need for law enforcement involvement. The carcass and all relevant information will then be turned over to law enforcement; the GPS-collar will be removed and genetic samples will be taken from the individual prior to release to law enforcement.

Commented [BA35]: Not sure about this w/ES

Commented [BA36]: All mortalities have the potential to involve LE – this needs to be coordinated directly through FWS LE

Commented [BA37]:

Commented [BA38]: Was this not already done when handling initially? This sounds more like an attempt to collect material from canids not already involved in the study. ES material is owned by FWS – would need permit otherwise?

E. Project Personnel

Andrea Shipley has worked for the North Carolina Wildlife Resources Commission as a Canid Biologist since February 2016. Prior to that, she worked as a Wildlife Biologist for a non-profit located in northeastern Nevada as well as in several different field biologist oriented positions. Andrea has a background in carnivore and spatial ecology, having earned her MS in Biological Sciences from Eastern Kentucky University and BS in Biological Sciences from Rutgers University; Andrea will act as project lead and coordinator.

Brandon Sherrill has worked for the North Carolina Wildlife Resources Commission as a Mammalogist since December 2013. Prior to that, he worked as an educator at the North Carolina Museum of Natural Sciences and as a regional wildlife biologist for the South Carolina Department of Natural Resources. Brandon earned a BS and MS in Fisheries, Wildlife, and Conservation Biology from North Carolina State University; Brandon will act as project supervisor.

Krishna Pacifici, Research Assistant Professor at NCSU, will be the quantitative analysis collaborator on the project. Krishna's background and experience in quantitative ecology makes him well suited to consult and assist with advanced statistical analyses of spatial data.

Lisette Waits, Department Head and Distinguished Professor at the University of Idaho, will be the DNA analysis collaborator for the project, responsible for all DNA related sample processing and subsequent analyses.

Draft - Confidential

F. Schedule and Estimated Costs

The project will run from soon after December 1, 2017 through June 30, 2020. The estimated timeline for major tasks is as follows:

Year 1: Initiate field work soon after December 1, 2017 with assistance from 1-2 field technicians; 1 technician will be required for trapping and den monitoring efforts. Data collection will begin immediately after collar deployment and data will be managed by Andrea Shipley throughout the life of the project. Data analysis will be initiated after den monitoring season concludes, with guidance and assistance from Krishna Pacifici at North Carolina State University (NCSU). Report, manuscript and presentation production will be initiated concurrently with data analysis.

Year 2: Continue field work and data collection with assistance from 1-2 field technicians. Continue data analysis with guidance and assistance from Krishna Pacifici at NCSU. Continue and finalize report and manuscript production, and presentation at professional working groups and/or meetings.

GPS technology allows researchers to collect locational data at fine spatial and temporal scales through the deployment of collar units on wildlife study subjects. In this project, we propose to study a sample of sympatric canid populations with GPS radio-collars, in order to investigate the population parameters outlined in previous sections as well as species interactions. The purchase and use of this technology is critical to meeting the research objectives set forth in this document as well as in the document included in Attachment 1.

While GPS technology has evolved over the past 20 years, the cost of technology has plateaued. Upfront cost per unit remains relatively high, however project savings occurs at the back end when compared to older telemetry technology such as very high frequency (VHF)

Draft - Confidential

which require intensive labor to collect data at similar spatial and temporal scales. Pilot testing the proximity sensor enabled GPS-collars will allow investigation of the utility of this relatively new tool for community dynamics analysis by providing an increased locational data acquisition when individuals come within a set distance, or closer, from each other. Additionally, these sensors record the identities of the interacting individuals and the duration of their interactions. Using a trigger to temporarily switch GPS fix schedules will enable us to collect very fine scale data while conserving battery life, achieving project objectives in an efficient manner. Exploring the efficaciousness of this technology has the potential to positively impact future research projects requiring use of GPS-collars for data collection.

Aerial tracking will provide regular study animal surveillance useful to investigate cases of mortality, collar malfunction, or satellite data transmission delays, which can vary seasonally. In some situations, ground tracking could prove less expensive than aerial tracking. However, ground telemetry techniques require more than one biologist working in tandem to acquire accurate location estimates. This often translates to increased labor to collect data, particularly in large study areas. Aerial tracking will provide a more efficient and cost-effective method for surveilling study subjects in this large study area, requiring only one biologist and a contracted pilot. NCWRC personnel will perform aerial tracking along with the NCWRC pilot at a minimum frequency of every 30 days.

Use of local trappers to assist with sampling efforts provides several benefits. Local trappers have established, long-term relationships with private land owners, thereby providing access to private lands that might be otherwise difficult to secure. This will enable project biologists to obtain a representative sample of sympatric canids in the study area, as well as to operate more trap lines concurrently. This is particularly important when using a SCR sample design, as it will have direct implications on the resulting analyses and inferences.

As part of collaboration efforts, the project will contract the services of Krishna Pacifici, Research Assistant Professor in the Applied Ecology department at NCSU. Krishna's expertise is in quantitative ecology; consultation and assistance services provided will allow project biologists to make appropriate statistically relevant inferences from collected data.

Draft - Confidential

DNA analysis will be contracted to Lisette Wait's lab at the University of Idaho. Lisette's team at The Laboratory for Ecological, Evolutionary and Conservation Genetics has previous experience in analyzing red wolf and coyote hybrid molecular samples and has the most comprehensive DNA methodology for this sympatric canid species continuum in the nation. This expertise will facilitate expedient species identification on collared study animals besides landscape level population dynamics analysis.

I. Glossary

Abundance: Species abundance is the number of individuals per species, and relative abundance refers to the evenness of distribution of individuals among species in a community.

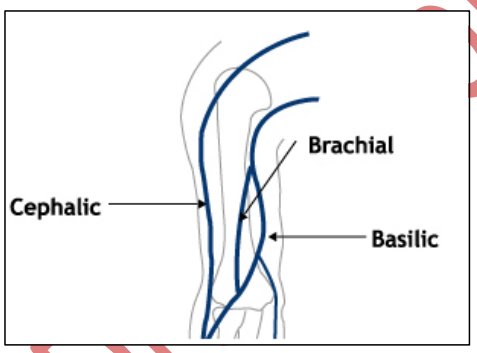
Adaptive kernel (AK): A probabilistic home range estimator based on the distribution and density of locations that has been collected over a period of time.

Adverse reactions: In pharmacology, any unexpected or dangerous reaction to a drug.

Aerial: Existing, happening, or operating in the air.

Annually: Once a year; every year.

Anthropogenic: Caused or influenced by humans.



Apex: Having no natural predators in its ecosystem.

Ataxia: The loss of full control of bodily movements.

Beacon: A radio beacon whose purpose is the investigation of the propagation of radio signals.

Biopsy: The removal for diagnostic study of a piece of tissue from a living body.

Brachial vein: One of a pair of veins accompanying the brachial artery and uniting with each other and with the basilic vein to form the axillary vein.

Breeding pair: A pair of animals which cooperate over time to produce offspring with some form of a bond between the individuals.

Carrying capacity: The maximum population size of the species that the environment can sustain indefinitely, given the food, habitat, water, and other necessities available in the environment.

Compensatory immigration: Individuals emigrating from areas with lower mortality to those with higher mortality; filling a deficiency of individuals in a population experiencing higher mortality. The increase in size or activity of one part of an organism or organ that makes up for the loss or dysfunction of another.

Composition: The combining of distinct parts or elements to form a whole.

Confidential

Co-occurrence: Refers to observation of the spatial overlap between two (or more) different individuals over a period of time.

Coordinates: Any of the scales or magnitudes that serve to define the position of a point.

Core use areas: An area within a home range exhibited by a dense concentration of location points; commonly estimated at 50% of the location data points.

Covariates: A variable that is possibly predictive of the outcome under study.

Cranial: Pertaining to the cranium or to the anterior (in animals) or superior (in humans) end of the body.

Cryogenic: Very low temperatures, e.g. -80°C.

Den-obligated: Restricted to a particular condition of life, in this case restricted to a den site.

Density: A measure of the number of organisms that make up a population in a defined area.

Deployment: To organize and send out (people or things) to be used for a particular purpose.

Depredation: The act of preying upon.

Depressed respiration: A decrease in the ability to exhale and inhale; respiration that has a rate below 12 breaths per minute or that fails to provide full ventilation and perfusion of the lungs.

Diagnostic: The process of determining by examination the nature and circumstances of a diseased condition.

Disorientation: Loss of one's sense of direction, position, or relationship with one's surroundings.

Distribution: The manner in which a biological taxon is spatially arranged.

DNA: (deoxyribonucleic acid) is a type of macromolecule known as a nucleic acid. It is shaped like a twisted double helix and is composed of long strands of alternating sugars and phosphate groups, along with nitrogenous bases (adenine, thymine, guanine and cytosine).

Dorsal: Situated on or toward the upper side of the body, equivalent to the back, or posterior, in humans; situated on or toward the posterior plane in humans or toward the upper plane in quadrupeds.

Duration: A continuous period of time.

Dynamic Brownian bridge movement models: Incorporates temporal and behavioral characteristics of movement paths into estimation of home range.

Ectoparasite: a parasite that lives on the outside of its host rather than within the hosts body; e.g. fleas and lice.

Effective trap area: Calculated by buffering each trap site by half the mean maximum distance traveled, each of these boundaries are dissolved, creating a measurable area.

Efficacious: Producing or capable of producing a desired effect.

Draft - Confidential

Efficient: Accomplishment of or ability to accomplish a job with a minimum expenditure of time and effort.

Euthanize: The act of putting to death painlessly or allowing to die, as by withholding extreme medical measures, a person or animal suffering from an incurable, especially a painful, disease or condition.

Expedient: Suitable for achieving a particular end in a given circumstance.

Evaporative cooling: reduction in temperature resulting from the evaporation of a liquid, which removes latent heat from the surface from which evaporation takes place.

Facilitate: Make an action or process easy or easier.

Genotyping: Investigate the genetic constitution of (an individual organism).

Gonadal descent: The act or process of descending from a higher to a lower location; testicular descent occurs during the breeding season annually.

GPS: Global Positioning System, is a radio navigation system that allows land, sea, and airborne users to determine their exact location, velocity, and time 24 hours a day, in all weather conditions, anywhere in the world.

Home range: an area over which an animal or group of animals regularly travels in search of food or mates, and that may overlap with those of neighboring animals or groups of the same species.

Hybridization: The result of mixing, through sexual reproduction, two animals or plants of different breeds, varieties, species or genera.

Immobilization agent: An active force or substance capable of producing an effect.

Implantation: To put or fix firmly.

Inbreeding depression: The reduced biological fitness in a given population as a result of inbreeding, or breeding of related individuals.

Inception: The establishment or starting point of an institution or activity.

Interspecific: Existing or occurring between different species.

Iridium: A satellite constellation providing voice and data coverage to satellite phones, pagers and integrated transceivers over the Earth's entire surface.

Jugular vein: Any of several large veins in the neck, carrying blood from the head and face.

Lacerations: A deep cut or tear in skin or flesh.

Locational: A position or site occupied or available for occupancy or marked by some distinguishing feature.

Malfunction: Fail to operate in the normal or usual manner

Methodology: A system of methods used in a particular area of study or activity.

Midline: A median line or plane of bilateral symmetry, especially that of the body.

Draft - Confidential

Minimum convex polygon (MCP): Completely enclose all data points by connecting the outer locations in such a way as to create a convex polygon.

Molecular samples: Genetic samples that may be used for investigation of genetic constitution of an individual.

Morphometrics: The process of measuring the external shape and dimensions of landforms, living organisms, or other objects.

Mortality: The state of being subject to death.

Non-target bycatch: Animals caught by accident that are not the target species being sought.

Parameters: A numerical or other measurable factor forming one of a set that defines a system or sets the conditions of its operation.

Parentage: The origin of something; the state or relation of a parent.

Passive integrated transponder: A microchip implant is an identifying integrated circuit placed under the skin of an animal.

Pinna: The external part of the ear in humans and other mammals; the auricle.

Plateaued: A period or state of little or no growth or decline.

Population dynamics: The branch of life sciences that studies the size and age composition of populations as dynamic systems, and the biological and environmental processes driving them (such as birth and death rates, and by immigration and emigration).

Population growth: The increase in the number of individuals in a population.

Population size: A group of organisms of the same species that live in the same area.

Population status:

Population trend: Changes over time and can include changes in ranging behavior and distribution, biogeography and life-history.

Population viability: The process that determines the probability that a population will go extinct within a given number of years.

Proximity: Nearness in space, time, or relationship.

Quantified: Express or measure the quantity of.

Quantitative: Relating to, measuring, or measured by the quantity of something rather than its quality.

Radio-telemetry: The use of radio waves for transmitting information from a distant instrument to a device that indicates or records the measurements.

Recumbency: The state of leaning, resting, or reclining.

Reintegrate: Restore (elements regarded as disparate) to unity.

Draft - Confidential

Remnant: A small remaining quantity of something.

Reproductive status: Relating to or effecting reproduction.

Spatial: Relating to, occupying, or having the character of space.

Spatial capture-recapture: A method commonly used in ecology to estimate an animal population's size. A portion of the population is captured, marked, and released. Marked animals are either recaptured or are tracked, each tracking location being considered a recapture.

Species Continuum: An aggregate of species capable of interbreeding, resulting in fertile hybrid offspring whose genetic composition may represent a varying array of phenotypes and genotypes from the parental species, at which the extreme ends of the spectrum are distinct.

Standardize: Cause (something) to conform to a standard.

Statistically relevant inferences: the process of deducing properties of an underlying distribution by analysis of data. Inferential statistical analysis infers properties about a population: this includes testing hypotheses and deriving estimates.

Stochastic population models: Ecological population modeling is concerned with the changes in population size and age distribution within a population as a consequence of interactions of organisms with the physical environment, with individuals of their own species, and with organisms of other species; stochasticity possesses some inherent randomness. In stochastic population models, the same set of parameter values and initial conditions will lead to an ensemble of different out puts.

Strangulation: The condition in which circulation of blood to a part of the body is cut off by constriction.

Stratifying: Form or arrange into strata, one of a number of portions or divisions likened to layers or levels.

Surveillance: Continuous observation of a place, person, group, or ongoing activity in order to gather information.

Survival: A living or continuing longer than, or beyond the existence of, another person, thing, or event.

Sympatric: Occurring within the same geographical area; overlapping in distribution.

Tachycardia: A heart rate that exceeds the normal resting rate. In general, a resting heart rate over 100 beats per minute is accepted as tachycardia in human adults.

Telemetry: See radio-telemetry.

Temporal: Of or relating to time.

Tooth replacement: The process of development of two successive sets of teeth, initially the deciduous set and consecutively the permanent set.

Transmitter: A set of equipment used to generate and transmit electromagnetic waves carrying messages or signals, especially those of radio or television.

Transponder: A device for receiving a radio signal and automatically transmitting a different signal.

Draft - Confidential

682 Vaccinate: Treat with a vaccine to produce immunity against a disease; inoculate.

683 Venipuncture: The puncture of a vein as part of a medical procedure, typically to withdraw a blood
684 sample or for an intravenous injection.

685 VHF: Very high frequency is the ITU designation for the range of radio frequency electromagnetic waves
686 (radio waves) from 30 MHz to 300 MHz, with corresponding wavelengths of ten to one meters.

687

NORTH CAROLINA / NORTH CAROLINA WILDLIFE RESOURCES COMMISSION

III. Station Name:

FWS RALEIGH ECOLOGICAL SERVICES OFFICE

IV. Description of Proposed Action (attach additional pages as needed):

Conduct research project entitled "**Coyotes of the Albemarle: Spatial Ecology, Resource Selection, Demographics, and Interactions with a Sympatric Canid"**

The coyote (*Canis latrans*) is now abundant throughout the 100 counties in North Carolina (NC), where they are managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plains region of NC (Hinton et al. 2012, Murray et al. 2014).

Recently described as using "compensatory immigration," coyotes are able to opportunistically fill spatial resource gaps by periodic transiency (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with humans and other canids, especially while taking advantage of anthropogenic resources. Though a rural area, human land uses predominate on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011).

In 1968, individuals from a remnant population of red wolves were removed from Texas and Louisiana and a captive breeding program was initiated. The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). The red wolf population increased until 2008 and peaked at around 208 individuals (USFWS Red Wolf Recovery Program 2007), a few animals short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013), with an estimated carrying capacity of 140-150 for the AP (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). Red wolves presently inhabit an approximately 6900 square kilometer recovery area within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014).
Accurate up-to-date estimates of the population are unavailable, but USFWS staff report a population size of 45-60 individuals with three mortalities in 2016 (https://www.fws.gov/redwolf/index.html July 2016). Hybridization with coyotes, inbreeding depression, and gunshot mortality have all been suspected issues that have affected the population growth and viability since the inception of the Red Wolf Recovery Program (RWRP) (Hinton et al. 2013). In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of red wolves and other canids on the AP. A USFWS memorandum documented detailed action items for the joint management of canids on the AP, including specific research objectives which this proposal seeks to address (Attachment 1).

As coyotes on the AP increase in number, monitoring coyote movements, particularly in relation to red wolves, will provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about coyote population management. Collection of finer temporal scale location data will help to manage interactions of both canid species with humans, as well as to support development of dynamic stochastic population models.

Coyote and red wolves will be live trapped by cooperating NCWRC and USFWS staff, and private trappers using double coil size 3 foothold traps, during the breeding season (Nov-Feb for coyote, Jan-Feb for red wolves) in the tri-county area of Dare, Hyde and Tyrrell. Morphological measurements, incidents of injury, occurrence of ectoparasites, age classification, and reproductive status will be determined; blood and tissue samples will be taken for genetic analysis. All captured individuals that meet the age classification and weight requirements will be collared with GPS collar units. All captured and collared individuals will be released at the capture site. The objectives listed below will be achieved by obtaining measurements, samples and information from the captured, collared, and tracked individuals over the course of three years using GPS location data.

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners.

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

V. Pertinent Species and Habitat:

A. Include species/habitat: See section VI

B. Complete the following table:

SPECIES/CRITICAL HABITAT	STATUS[1]
Canis rufus	T

[1]STATUS: E = endangered, T = threatened, PE = proposed endangered, PT =proposed threatened, CH = critical habitat, PC = proposed critical habitat, C = candidate species

VI. Location:

A. Statewide

Albemarle Peninsula (see web address www.ncwildlife.org)

B. Section, township, and range (or latitude and longitude):

Dare, Hyde, Tyrrell counties

C. Distance (miles) and direction to nearest town:

As stated above

D. Species/habitat occurrence:

Canis rufus

VII. Determination of Effects:

A. Explanation of effects of the action on species and critical habitats in item V. B. (attach additional pages as needed):

SPECIES/CRITICAL HABITAT	IMPACTS TO SPECIES/CRITICAL HABITAT
Canis rufus	Trap induced injury is possible

B. Explanation of actions to be implemented to reduce adverse effects:

SPECIES/CRITICAL HABITAT	ACTIONS TO MITIGATE/MINIMIZE IMPACTS
Canis rufus	Use of appropriate trap types, daily trap checks, treatment of minor injuries, trapping season limitations and limitations on environmental conditions for trap operation

VIII. Effect Determination and Response Requested:

Species/ Critical Habitat	Determination[1]			Response[1] Requested
	NE	NA	AA	
Canis rufus		X		Concurrence

[1] Determination/Response Requested:

NE = No Effect. This determination is appropriate when the proposed action will not directly, indirectly, or cumulatively impact, either positively or negatively, any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested is optional but a "Concurrence" is recommended for a complete Administrative Record.

NA = Not Likely To Adversely Affect. The determination is appropriate when the proposed action is not likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat or there may be beneficial effects to these resources. Response Requested is a "Concurrence".

AA = Likely To Adversely Affect. This determination is appropriate when the proposed action is likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested for listed species is "Formal Consultation". Response Requested for proposed or candidate species is "Conference".

Attachment 2: Joint Memorandum

MEMORANDUM

November 20, 2013

TO: All Interested Parties

FROM: "for"
Cynthia K. Dohner, Director, Southeast Region, U.S. Fish and Wildlife Service
Gordon S. Myers, Executive Director, N.C. Wildlife Resources Commission

SUBJECT: Collaborative Conservation of Red Wolves and Other Canids on North Carolina's Albemarle Peninsula

---

Recovery of the federally-listed red wolf has been a priority for the U.S. Fish and Wildlife Service (FWS) for more than 20 years and is focused in North Carolina on the Albemarle Peninsula (AP; i.e., Hyde, Tyrrell, Washington, Beaufort, and Dare counties). Comprehensive stakeholder involvement and collaboration with other management agencies is critical to successful recovery of any at-risk species. The North Carolina Wildlife Resources Commission (WRC) is a key collaborator in this regard, as it has jurisdiction over all state-trust wildlife resources in N.C.

Since 2009, the FWS and WRC have worked to broaden our collaboration in the conservation and management of all canid species (including red wolves) on the AP. As these efforts have solidified, specific actions have been jointly identified by our two agencies that will improve conservation outcomes. These actions are categorized into five areas; collaboration, research, outreach, regulatory, and enforcement. Specific action items are outlined and prioritized within each of these categories in Attachment A.

This memo establishes the FWS's and WRC's commitment to initiate, or to continue, the efforts outlined in Attachment A. The common goal in this effort is to establish clear expectations and accountability for collaboration regarding the action items on Attachment A, thus resulting in enhanced and seamless canid conservation and management on the AP. This approach provides the best opportunity to achieve recovery goals for red wolves, while at the same time managing other canids to balance biological variables with social expectations. The dynamics of these canid species are complex and offer unique opportunities for innovation. Appropriate staff from each agency is hereby tasked with immediately developing a timeline to implement these actions. Through this commitment, we will continue to advance our collective conservation goals.

875

Attachment A

Action Items for Collaborative Conservation of Canids on North Carolina's Albemarle Peninsula (AP)
(*Note: Action Items are prioritized within category.*)

Collaboration

1. The N.C. Wildlife Resources Commission (WRC) and U.S. Fish and Wildlife Service (FWS) will formalize in writing the collaborative management of canids on the AP. This agreement should:
    a. include a clear mission statement, goals, objectives, and implementation strategies (ask and answer the "Why?");
    b. set a goal to define success regarding canid management on the AP;
    c. espouse a philosophy of canid management operating within the context of a three-legged stool (i.e., federal and state governments and stakeholders);
    d. as available, commit funding and staffing resources for field personnel to contribute to the conservation of the red wolf and management of coyotes;
    e. as available, commit funding to conduct research pertinent to canid management on the AP;
    f. establish polices and goals for developing a collaborative genetic archive for AP canids, a data sharing portal accessible by staff in both agencies, and reciprocal sharing of all historical data (including phenotypic and genotypic data and literature) of the red wolf;
    g. establish a foundation for developing and implementing an adaptive approach to canid management on private lands on the AP;
    h. initiate development of a collaborative canid research program;
    i. describe plans to conduct the next five year Red Wolf Program review;
    j. outline options for holding annual workshops with federal and state enforcement staff;
    k. outline plans to hold semi-annual coordination meetings regarding canid management on the AP; and
    l. develop milestones for future development of a management plan for all canids in the AP.

2. The FWS will initiate a review of the current Red Wolf Recovery Plan to determine if the state-of-our-knowledge or field conditions have changed such as to warrant its revision. Review and comments from the WRC will be considered in this evaluation.

3. The WRC, with support and participation of the FWS, will establish a "Canid Forum" (similar to that established for manatees in Florida) to facilitate communication and discussion regarding canid management and citizen science opportunities on the AP.

876

877

Attachment A

Research

1. The FWS and WRC will provide funding and logistical support for research identified by the Red Wolf Recovery Implementation Team, Red Wolf Program staff, other FWS staff, or the WRC that promote the conservation and recovery of the red wolf and other canids on the AP. Studies could include:
    a. tests of the "placeholder theory" on the AP, including behavior of sympatric canids,
    b. determining carrying capacity of canids on the AP,
    c. determining genetic profiles of canid species on the AP,
    d. evaluating predator-prey dynamics,
    e. studies of canid habitat use,
    f. epidemiology of diseases impacting canids on the AP,
    g. development of stochastic simulation models of sympatric canid population dynamics and habitat use, and
    h. canid dispersal dynamics

2. The FWS and WRC will conduct jointly-supported research to determine the attitudes and opinions of N.C. private landowners and other citizens concerning canids on the AP (i.e., human dimensions studies).

Outreach

1. The FWS and WRC will collaborate with other partners to design and implement broad-based outreach and marketing programs with clear goals, objectives, strategies, and measurable outcomes, including development of consistent agency messages and educating the public about canids on the AP.

Regulatory

1. The FWS and WRC will initiate a review and, if needed, subsequent rule-making to clarify concepts or rectify conflicts in current federal or state rules (including the current 10(J) rule).

2. The WRC will review and evaluate statutory requirements for listing red wolves as state threatened in the five AP counties.

3. As data demonstrating a relationship between coyote hunting and red wolf mortality become available, the FWS and WRC will evaluate, and if appropriate implement, adaptive approaches to regulate of take of coyotes that may result in incidental take of red wolves.

4. The WRC will evaluate the status, management, and regulation of Controlled Fox Hunting Preserves.

878

879

5. The WRC will develop BMPs (due care provisions) for coyote hunting, trapping, and live sale.

6. The WRC will compile, compare, and contrast canid hunting and trapping regulations and programs in other states, including, but not limited to, other states with other species of wolves.

Enforcement

1. The FWS and WRC will develop coordination strategies to improve enforcement of federal regulations protecting red wolves.

I, the cooperator or cooperator's representative, have been informed of the methods and the manner in which research devices will be used, and of the possible hazards associated with their use. I understand that NCWRC, (to include its officers, employees and agents) will: exercise reasonable precautions to safeguard all persons to prevent injury to target and non-target animals; guard against the mishandling of control devices and materials; and exercise due caution and proper judgment in all scientific collection operations. I understand that NCWRC may collect Global Positioning System (GPS) coordinates at the project site as part of component or activity tracking or as wildlife disease monitoring or research data. I, the undersigned cooperator, do hereby give my consent and concurrence to NCWRC, its employees, and its agents, to use, upon lands owned, leased, or otherwise controlled by me, and identified by this document, the following methods and devices (an attachment of additional devices and/or methods may be attached):

Statement of agreement: The landowner, cooperator, or representative, as listed above hereby give permission to NCWRC to perform trap and release of the species listed for scientific collection purposes. In consideration of these understandings, I, the cooperator or cooperator's representative, agree to: assume responsibility for injury to my property under my control, when said injury is not the result of negligence on the part of NCWRC (it's officers, employees, and agents); assist in maintaining such warning signs as NCWRC may place for the purpose of notifying persons entering onto such lands of the possible hazards associated with scientific measures in use thereon; and to give adequate warning of these possible hazards to persons I authorize to enter onto such lands. Further, I, the cooperator or cooperator's representative, agree not to concurrently use or allow to be used upon lands covered by this agreement, any canid depredation efforts during the scientific collection time period.

Coyote Depredation Permit

Tele: (919) 707-0061
FAX: (919) 707-0292

North Carolina Wildlife Resources Commission
Regulated Activities Permits Section
1707 Mail Service Center
Raleigh, NC 27699-1707

AUTHORITY

STATUTES
GS 113-274

RULES
15A NCAC 10B .0106

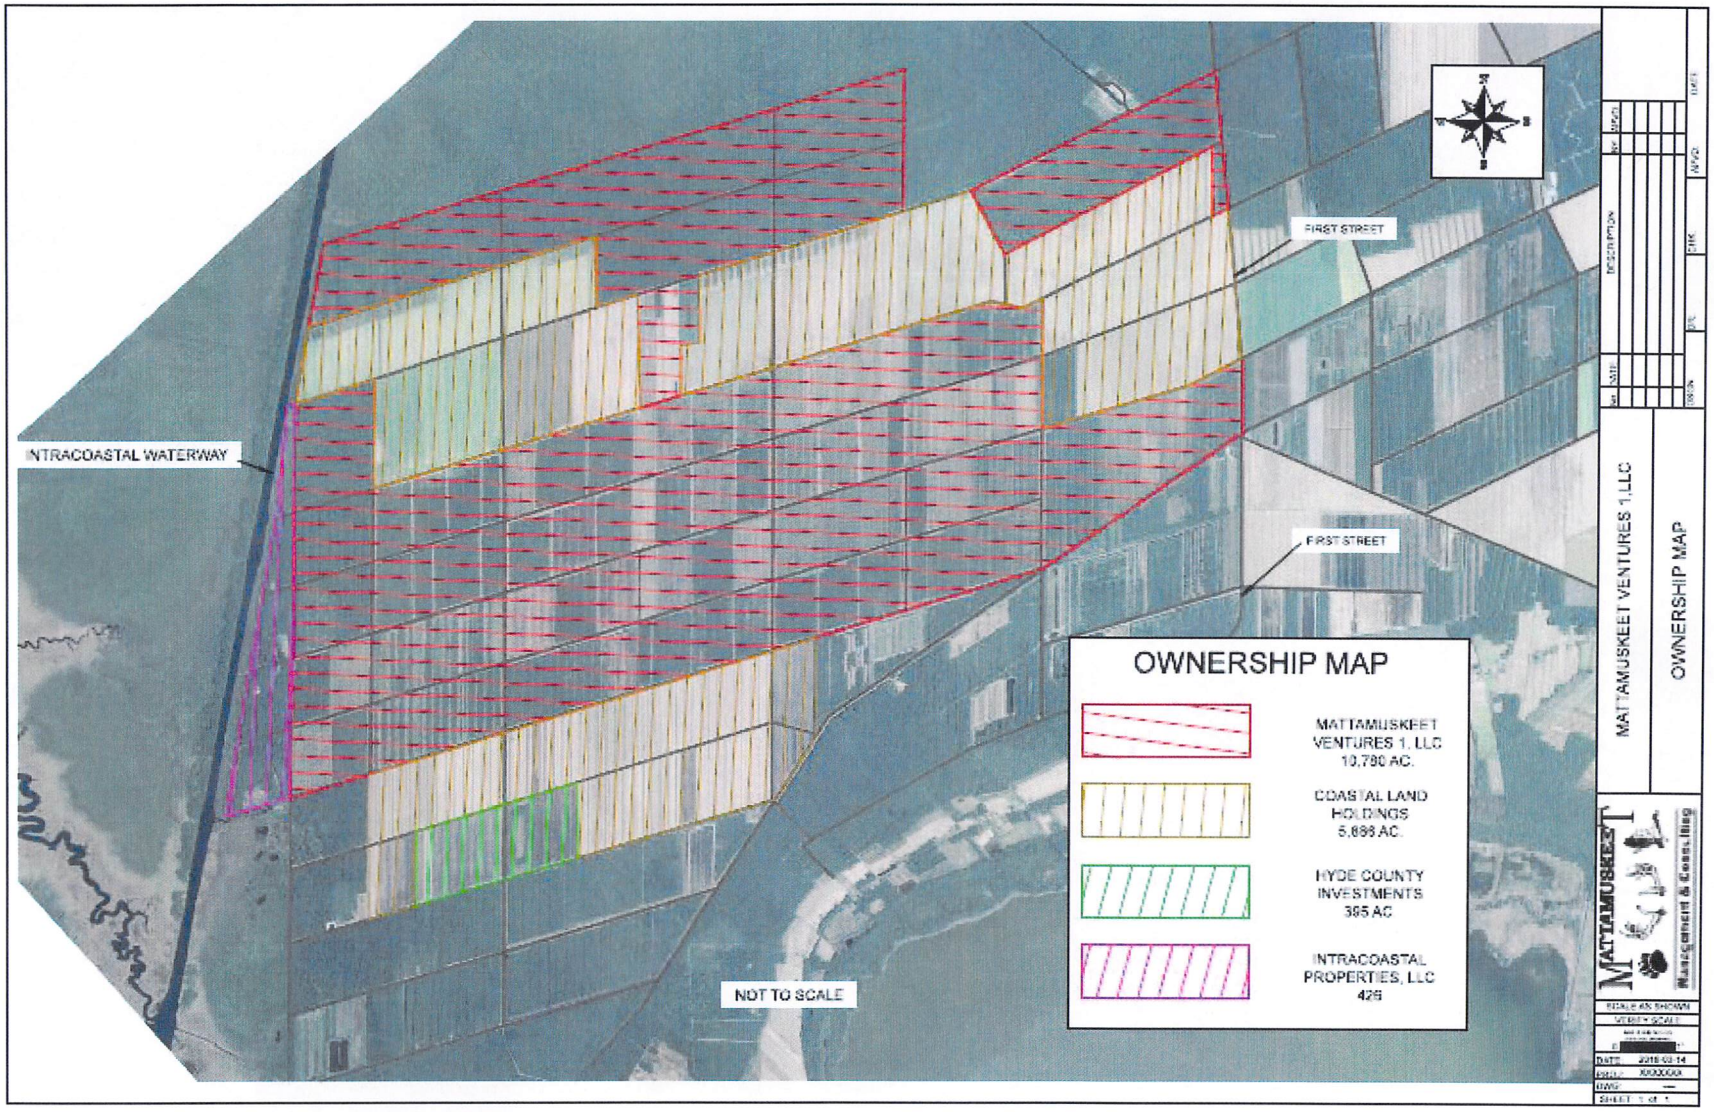
PERMITTEE/LICENSEE

Tom Harrison
[redacted]

Telephone: [redacted]

PERMIT NUMBER
N/A

EFFECTIVE	EXPIRES
04/01/2018	5/30/2018
COUNTY See Text Below	**DISTRICT** See Text Below



CONDITIONS AND AUTHORIZATIONS:

The above permittee and other individuals under written contract and under the supervision of the permittee are authorized to trap coyotes on the properties identified in **Attachment A** subject to the following conditions:

- Permit is valid for properties identified in **Attachment A**.
- This permit does not authorize access to any property, public or private.
- All individuals exercising the authority granted by this permit shall carry a copy of this permit and a letter of authorization from the permittee listed above while conducting trapping activities.
- Traps must be labeled as required by G.S. 113-291.6. Traps must be checked daily and any animals caught therein must be removed. All non-target wildlife must be released immediately onsite; however, any red wolf captured must be reported immediately to the Wildlife Resources Commission (WRC) at 800-662-7137 or the U.S. Fish and Wildlife Service to determine disposition of the red wolf.
- Coyotes being removed for depredation under this permit may only be trapped using legal foothold traps and the Collarum type trap as defined in G.S. 113-291.6. The reporting forms required for the use of Collarum type traps may be found at http://www.ncwildlife.org/Trapping/Laws-Safety. Collared animals must be reported immediately to the WRC at 800-662-7137 before final disposition is determined. All coyotes euthanized shall be disposed of in a sanitary manner. All collars from euthanized coyotes must be returned to the WRC.
- Permit holder must report the removal of coyotes to the WRC at 800-662-7137 or online at www.ncalvin.org/ckr/ckrmain.aspx within 24 hours of taking possession of each individual coyote. Each report must include the date; time; location; if the animal had a collar; and measurements of hind foot length and tail length taken from the carcass. Instructions for recording these measurements are enclosed and can be found at www.ncwildlife.org/Portals/0/License/Documents/Canid-Cooperator-Program-Instructions.pdf.
- A hair sample with follicle from each euthanized coyote must be submitted to WRC, Wildlife Management Division, 1722 Mail Service Center, Raleigh, NC 27699-1722.
- A report of all animals captured under this permit, date of capture, and their disposition is required within fifteen (15) days after the expiration of this permit.

This permit/license is nontransferable and expires at midnight on the above specified expiration date.

ATTACHMENT A

STATE: North Carolina

GRANT TITLE: W79-Wildlife Management

PROJECT TITLE: Pilot Study – Using Fine Scale GPS Technology to Research Sympatric Canid Population Dynamics (Job 2.0?)

A. Problem and Need

The coyote (*Canis latrans*) is now abundant throughout all 100 counties in North Carolina (NC), and is managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plain region of NC (Hinton et al. 2012, Murray et al. 2014). Though a rural area, human land uses occupy a significant portion of space on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011).

Telemetry data from coyotes on the AP suggests that about 70% of coyotes are residents (i.e., those that defend set territories) while the other 30% are transients, with most being dispersing juveniles (Hinton et al. 2015). Transient coyotes do not defend territories. Coyotes can travel long distances and become transient even as adults, especially when they lose their mate. Recently described as using "compensatory immigration," coyotes opportunistically fill spatial resource gaps by periodic transiency; when spots come open, individuals that do not yet have permanent territories and have been roaming in the area, are able to inhabit the new openings (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with other canids and humans, especially when they are utilizing anthropogenic resources (e.g. crops, garbage, bird seed, etc.).

The coyote is not the only medium to large-size canid inhabiting the AP. The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population (NEP) of captive-bred red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). This population increased until 2008 and peaked at around 130 individuals (Group Solutions, Inc. 2016), short of the recovery goal of 220

Draft - Confidential

individuals dispersed amongst 3 self-sustaining mainland populations in the wild (USFWS Red Wolf Recovery Program 2013, Red Wolf Recovery Program 1984). The AP has an estimated carrying capacity of 140-150 wolves (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). The exact number of red wolves is not known, but USFWS staff report a population estimate of 25-40 individuals with six recorded mortalities in 2017 (J. Madison, personal communication, 2017).

As a result, the AP now supports these sympatric canids whose recent spatial distribution overlaps, hereafter referred to as "sympatric canids." Coyotes and red wolves on the AP have a close biological relationship which developed due to one or more similar sympatric distributions in the past at other locations; an occurrence separate from current day distribution, but explanatory of the continuum of morphology and behavior that we see in sympatric canid populations on the AP. Hybridization between red wolves and coyotes and inbreeding depression are suspected factors that have affected red wolf population growth and viability since the inception of the Red Wolf Recovery Program (RWRP), while vehicular and gunshot mortality are known factors (Hinton et al. 2013, Faust et al. 2016). As part of a recent program review, the USFWS halted use of mitigating management techniques in 2015, potentially affecting the spatial distribution and population dynamics of sympatric canids.

In 2013, North Carolina Wildlife Resources Commission (NCWRC) and USFWS established a committee to oversee the collaborative management and conservation of sympatric canids on the AP. A USFWS and NCWRC joint memorandum (Memorandum) documented detailed action items for the joint management of sympatric canids on the AP, including specific research objectives which this proposal seeks to address in part (Attachment 2). The objectives outlined in the Memorandum were identified by consensus of the various USFWS and NCWRC staff as those that may "…promote the conservation and recovery of the red wolf and other canids on the AP." As sympatric canids on the AP increase in number, monitoring their movements, particularly in relation to individuals of differing ancestry, could provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about sympatric canid populations and conflict management. Collection of finer temporal scale location data could help managers in developing local strategies for

Draft - Confidential

collaborative education and outreach, prevention or resolution of negative interactions of sympatric canids with humans, as well as to support development of dynamic stochastic population models. One of the most important elements of management and conservation of sympatric canids on the AP is the involvement of stakeholders in the federal and state collaborative effort.

Concerns about fear of attacks on humans and domestic pets, the perceived effects of sympatric canids on white-tailed deer and other game populations, and homeowner property damage comprise many of the conflict calls regarding sympatric canids on the AP (Responsive Management, forthcoming data). In 2015 NCWRC established a Human-Wildlife Interaction (HWI) database to track and classify the different types of wildlife related calls the Wildlife Helpline receives. In the past 3 years wildlife managers working in the mainland AP region have received calls regarding observations (coyote and red wolf) and perceived or real threats to human, domestic pets, and livestock/chickens (coyote), and for information on how to deal with conflicts (C. Turner, personal communication, 2017).

The changes in state and federal canid management rules for the AP have resulted in confusion regarding residents' rights and options for management of property damage by canids (e.g. domestic pets, livestock, or chickens killed). As a result, some citizens are unsure of the legal and most effective methods for canid conflict management. Adding to management complexity is the need to manage canids for conservation purposes, such as reducing predation on at-risk ground nesting species (this may mean a need for higher or lower numbers of canids in an area) or reducing hybridization of listed canids. NCWRC has identified expanding education and outreach to constituents regarding coyote life history and management strategies as the most valuable tool to mitigating canid conflicts within the state (Committee of the Whole meeting, 6 December 2017). Recommended management strategies for dealing with coyote conflict promote landowner prevention responsibilities and recommend lethal tools as secondary to prevention, on a case-by-case basis, dependent on local management goals. Depredation permits, one tool for wildlife management, are not the norm for dealing with conflict issues. During the three-year period of 2015 through 2017, only six depredation permits

Draft - Confidential

for coyotes were issued for mainland AP (NCWRC depredation permit database, C. Turner, personal communication, 2017).

This pilot project seeks to lay the groundwork toward meeting many of the identified Memorandum research objectives, should additional research be pursued post-pilot. Data collected during this pilot could potentially be incorporated in analyses performed with collected data from additional targeted future prospective projects. Utilizing this pilot for initiating an understanding of the current state of hybridization between sympatric canid populations on the AP could aid USFWS staff with development of new approaches for managing hybridization in the red wolf NEP.

B. Objectives (after December 1, 2017-June 30, 2020)

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Objective 5: Use fine scale GPS data collection for developing local management strategies for preventing and mitigating canid conflicts with landowners.

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

At the end of this 2.5-year pilot study, we will deliver an observational summary detailing the efficacy of the GPS and sensor technology for spatial and population dynamics research on sympatric canids on the AP.

Draft - Confidential

C. Expected Results and Benefits

As part of a pilot study, we will monitor the status of collared individuals by using a finer scale assessment of space and habitat use than previous studies. Earlier research focused on many of the same objectives we suggest investigating here, but during a time of intense, active management. Some active management techniques are no longer being carried out, although they may be reinstated, and dynamics between sympatric canids (some breeding pairs) are expected to have changed substantially outside of the national wildlife refuge system. The uncertainty regarding current dynamics presents a need for additional research to inform actions for the management of sympatric canids, whether or not active management techniques by the red wolf program resume in the future, and whether or not the Non-essential Experimental Population (NEP) boundary ("NEP boundary") for red wolves is constricted. Information gained from research may impact management rules and landowner's abilities to manage canids in some areas. Additionally, GPS technology has improved since earlier research was conducted allowing for more temporally detailed data collection and more nuanced analyses.

Understanding how sympatric canids collectively use resources in areas of human-dominated landscapes will allow wildlife managers to tailor management options to local conditions. On the AP, row crop agriculture and hunting represent the primary and secondary land uses, respectively. Row crop agriculture is a significant nutrient resource on the landscape and, as opportunists, canids may take advantage of such resources when they are available. Non-consumptive wildlife-driven tourism persists in all seasons and wildlife watching is a main draw for tourists in this area. For many tourists, the opportunity to see or hear large carnivores is the sole attraction for traveling to the AP. Information from this study will be provided to local constituents to establish a knowledge base regarding how sympatric canids use resources on private lands. Management and guidance could serve to prevent or minimize conflict while maximizing positive wildlife interaction opportunities for constituents. Development of a common understanding between wildlife managers and landowners based upon factual information is paramount for collaboratively achieving successful management of sympatric

Draft - Confidential

canids. The data collected in this pilot study is the foundation upon which this understanding and future management actions will be built.

The current level of hybridization between sympatric canids on the AP will be characterized using DNA gathered during this study. Body size exists as a continuum between coyotes and red wolves and has been documented as the most important factor for successful interspecific breeding pairs of these canids (Hinton 2014). Though both species have been found to use resources in similar manners, red wolves generally have more expansive home ranges and therefore may not use local resources as intensively as coyotes, depending on body size. Obtaining individual characteristics of study animals will allow managers, armed with spatial information, to infer how and why individuals in the canid species continuum exploit anthropogenic resources considering their anatomical and life history traits.

In conjunction with prior research, data collected in this study will contribute to knowledge on sympatric canid population dynamics on the AP. Estimating population size will allow managers to monitor population trends of sympatric canids and to examine the long and short-term impacts of different management strategies on their populations. While it is unknown whether sample size will allow for population estimation, obtaining relative abundance estimates for coyotes would provide wildlife managers with baseline data for monitoring changes in population abundance over time when paired with annual mortality estimates. Information on changes in abundance, reproductive dynamics, and habitat use could impact management strategies to influence long-term conservation outcomes. Results of this pilot study will allow managers to determine if future work will be necessary, what amount of effort will be required to achieve each objective, and if population estimates will be an attainable goal. Furthermore, data gathered on survival rates by age class, breeding success, litter size, mortality rates by age class, and relative abundance of sympatric canids during this project could contribute toward a two-species population viability analysis (PVA) model in development by USFWS staff, expanding upon the PVA previously performed for red wolf populations (Faust et al. 2016).

The collaborative approach NCWRC seeks to take in the initiation, implementation, and finalization of this project is as equally important as the data collection itself for red wolf

Draft - Confidential

conservation and recovery. Though the two agencies have varying missions and stances regarding canid management, we believe this pilot will serve to also lay the groundwork for an ongoing, inclusive, working collaborative relationship. Overcoming the history of each agency's stances and actions will be paramount to the long-term success of respective missions and canid management goals. Cultivation and maintenance of a collaborative relationship will help to foster trust between the two agencies and with the human population that reside within the AP, a portion of which may have established suspicious and negative views of state and federal agency activities, as well as guide ongoing research directions. Crafting an understanding between the differences and similarities of the two agencies missions and goals should help clarify where each agency can add value, initiate changes, and increase collaboration within and between each agency's missions and goals. A dynamic process that should continue to be instituted well beyond the scope of this pilot project.

Exploiting locally residing NCWRC field staff for development of relationships with landowners during the implementation of the project is an imperative goal for NCWRC. Engendering trust with landowners by practicing forthrightness, upholding landowner agreements in a transparent manner, and actively working with landowners on canid conflict issues is also significant for the long-term success of canid management on the AP. Dovetailing field operations during the trapping and den monitoring seasons, in addition to addressing landowner canid conflicts in a collaborative manner that involve suspected or known red wolves, with RWRP field staff would hopefully open minds and doors of previously resistant landowners to the value of the work that we are performing while expanding the data collection value of this pilot project (see Decision Trees in Attachment 4).

D. Approach

The current NEP boundary covers approximately 6,900 square kilometers within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014). The USFWS has proposed the NEP boundary be constricted to the ARNWR and the Dare County Bombing Range in Dare county by the end of 2017; the associated National Environmental Policy Act (NEPA) process for this recommendation is ongoing (J. Madison, personal

Draft - Confidential

communication, 2017). This study proposes to capture and radio-collar 20 coyotes, and their sympatric hybrids, within Dare, Hyde, and Tyrrell counties ("study area"); those counties being comprised of and adjacent to the center of the red wolf recovery effort at ARNWR. The thematic subheadings below provide detailed descriptions of the approaches required for achieving the pilot study objectives.

Sampling Efforts

Trained NCWRC personnel will conduct live trapping of sympatric canids, with assistance from the USFWS RWRP biologists, and trained, experienced local trappers. NCWRC and USFWS wildlife personnel will select local trappers. NCWRC staff will train contracted trappers on desired trapping methods before every trapping season. The project lead will supervise and coordinate all trapping activities including locations for installation and the operation of trap lines and handling of captured animals. Simultaneous personal trapping activities by contracted trappers will not be permitted while performing contracted trapping services, as specified in the draft service contract (Attachment 4).

Trapping efforts will follow a spatial capture-recapture (SCR) framework, where subsequent location "fixes" are considered "recaptures," with a systematic targeted sampling design. We will be focusing on areas that contain resources previously found to be used by sympatric canids (e.g. edge, agricultural fields, secondary roads, etc.) (Harris et al. 2013, Ivan et al. 2013), while attempting to sample a diversity of habitat types. Due to low population numbers, we will be avoiding areas with known red wolf breeding pairs and will be coordinating with RWRP staff during the trapping season regarding dovetailing our respective programs' trapping efforts. This effort will allow us to increase the probability of detection of sympatric canids on the landscape in a balanced approach that is sensitive to issues of the NEP (Tom 2012). While it is important to sample a wide range of habitats, the most important requirement for SCR is the number of collared individuals; this requirement provides flexibility in the other requirements for field sampling as needed (K. Pacifici, personal communication, 2016). We will initially focus trapping on non-federal properties where we have been granted access.

Trapping will take place during the breeding season when the likelihood of capturing

Draft - Confidential

females in the later stages of gestation or whelping females will be low. Capture efforts will be conducted from soon after 1 December 2017 – February 2018 and December 2018 – February 2019. Captured sympatric canids will be surrendered to NCWRC or the USFWS at capture sites (please refer to the decision tree in Attachment 4). Trapping should occur on both public and private lands to obtain sampling coverage of the study area. We will focus trapping efforts on private and state game lands that are accessible for trap and release ("capture") of sympatric canids. Unlike Dare County, there are ample non-federal lands that surround Pocosin Lakes NWR and Lake Mattamuskeet NWR in both Tyrrell and Hyde counties that may be utilized upon agreement from landowners to effectively sample individuals who may use those federal lands. Management activities on federal lands by non-federal wildlife professionals are subject to compatibility assessment and some level of NEPA (P. Benjamin, personal communication, 2017). Due to the timeline for achieving approval for such activities on federal lands with respect to the timeline of this project, we will not be pursuing federal land access. Scientific collection activities that take place on non-federal lands will require agreements outlining conditions mutually decided by NCWRC and landowners/managers (Attachment 3).

Hinton and Chamberlain (2014) tested the use of morphometric measurements to differentiate between coyotes, red wolves, and their hybrids in field, prior to genetic confirmation, with an 86% success rate in differentiation, consolidating 3 age classes [pups (>6 but <12 months old), juveniles (<2 but >1 years old), and adults (>2 years old)]. While coyotes and red wolves were correctly classified 98% and 99% of the time, hybrids were only classified correctly 13% of the time and were more likely to be misclassified as coyotes (61% of the time) (Hinton 2014). Four morphological measurements which helped establish reliable thresholds for coyote and red wolf classification in field were determined by regression analysis: hind foot length, weight, width of head, and tail length. The minimum measurements for red wolves represent the small end of adult female red wolves, while adult male red wolves would have significantly greater measurement values than the minimum thresholds. Due to the overlap in body size of hybrids, Hinton and Chamberlain (2014) found that their measurement values fall between the minimum measurement values for red wolves (i.e. small female red wolves) and the maximum measurements for coyotes (e.g. large adult male coyotes). Using the

Draft - Confidential

morphological thresholds discerned in Hinton's research, we define red wolves as those individuals that inclusively meet the minimum values for the following morphological measurements: 1) hind foot length (measured from the hock to the tip of the digital pads) greater than 21.5cm, 2) weight greater than 21.5kg (47.4lb), 3) width of head greater than 10.5cm, and 4) tail length greater than 35cm, or those individuals that have been previously tagged and whom RWRP staff are able to verify their genetic testing determination. Using those same morphological measurements, we define coyotes as those individuals that fall below the maximum values as set forth by Hinton and Chamberlain (2014): 1) hind foot length less than 19.5cm, 2) weight less than 19.5kg (43lb), 3) width of head less than 10.5cm, and 4) tail length less than 35cm. Due to the range of overlap in morphological measurements of hybrids with both red wolves and coyotes, we cannot easily define what a hybrid is by method of morphological measurements. Based on Hinton's findings, it may be likely that hybrids could be classified as coyotes more often than red wolves in field. Genetic determination post processing could help reclassify red wolves and coyotes as hybrids in some cases. However, in relation to in field practices, individuals that do not inclusively fall within either the red wolf or coyote morphometric thresholds and are not tagged will be treated as of unknown canid identity. Unknown individuals will await classification based on post processing genetic analysis, but will be collared and released post process following this projects' protocol.

Target canids will be captured by using Softcatch #3 Coyote 4x4 (Oneida Victor Inc. Ltd., P.O. Box 32398, Euclid, Ohio 44132, Hinton 2014, Schemnitz 1994), the EZ Grip #7 (Livestock Protection Company, P.O. Box 725, Alpine, Texas 79831, Frame and Meier 2007), or equivalent. Stakes or drags may be implemented depending on the field conditions, the advantages and disadvantages of which will be discussed at the time of installation. Because we will be selectively trapping for adult individuals, pan tension on traps will be set to approximately 6lbs as recommended by RWRP trapping Standard Operating Procedure (SOP) 6.1 (Red Wolf Recovery Program 2017a). Various lures and baits will be used to increase trapping efficiency (Frederick et al. 1989, Shipley 2012). Traps will be laid on the Monday of each week and will be opened at the time of deployment. Traps will be checked once daily at dawn, to reduce potential stress to trapped individuals and will not be operated on days where the temperature

Draft - Confidential

is expected to reach or exceed 80° F (R. Nordsven, personal communication, 2016) or during times of predicted inclement weather or hard freeze (e.g. snow, hail, high wind, etc., Sikes et al. 2011). To standardize effort and remain logistically realistic, traps should be open for three trap nights in a row before being removed or as determined necessary based on field conditions. Trap sets that have been closed due to non-target bycatch or other circumstances may be reopened and all traps should be re-baited and lured as appropriate, given the field conditions.

Trap set locations will be marked by NCWRC or USFWS personnel using handheld GPS units (Garmin GPSMAP 64S, 1200 E. 151st St., Olathe, KS 66062-3426) and given a sequential identification number. Traps will also be given an identification number and trap set points will be documented in ArcMap 10.4. Trappers will keep detailed records on trap set operation, non-target species trapped, and other relevant details. Non-target species will be released from traps after an in-field assessment of injuries, if any, and wildlife with life threatening injuries will be euthanized by the trap operator. Trapping effort will be quantified (trap nights), the effective sample area will be estimated, the encounter (detection) probability will be estimated using a Gaussian detection model (Amundson et al. 2014), and an estimate of density for coyotes will be calculated using a modified Huggins closed-capture estimator in program MARK, if sample size allows (Harris et al. 2013, Ivan et al. 2013).

Animal Handling

Handling of canids will follow American Society of Mammalogists (ASM) guidelines (Sikes et al. 2011) and will be performed at the capture site. Chemical immobilization agents may be used depending on the number of field staff during processing (i.e., three or more staff required during non-chemical immobilizations, Craft 2007, M. Morse, personal communication, 2016). For all red wolves of known or questionable identity, RWRP staff will be involved in processing activities as determined using the decision tree (Attachment 4) on a case-by-case basis. The decision trees were developed with respect to RWRP's need for decision making in what happens to red wolves and possible red wolves as well as to address issues that may affect landowners property rights, especially in relation to the treatment of domestic canids.

Chemical Immobilization

Unless adequate numbers of personnel are available to safely employ mechanical

Draft - Confidential

restraint techniques, target animals will be anesthetized with the chemical immobilization agent BAM (Wildlife Pharmaceuticals, Inc., Windsor, CO 80550). BAM, a combination of Butorphanol tartrate, Azaperone tartrate and Medetomidine HCl., will be delivered by intramuscular injection by syringe pole or hand injection (after being restrained by a catch pole) to the muscular masses of the hind quarters. Dosage for canids is based on field trails performed by Wildlife Pharmaceuticals (Wildlife Pharmaceuticals, Inc. 2016) and the recommended dose for coyotes is 0.2CC and red wolves is 0.3CC, with adjunct doses of 0.1-0.2CC delivered if initial dosages do not cause induction (S. Kirschner, personal communication, 2017). We may also follow the RWRP SOP 1.2 for live canid immobilization for captured red wolves of known or questionable identity (Red Wolf Recovery Program 2017b). Induction times for coyotes and wolves ranged from 5 to 10 minutes after initial and/or adjunct dosages (Wildlife Pharmaceuticals, Inc. 2016). The animals will be kept with minimal disturbance until the head is down and the animal is not responding to stimuli. The animals will be placed with the neck extended to ensure proper oxygenation and with the nose at a lower level than the rest of the head to minimize the risk of aspiration. After field handling is concluded, the anesthesia will be reversed using two reversal agents, Atipamezole and Naltrexone, at double the CC of Atipamezole to BAM that was delivered (including adjunct doses, if given) and 0.5CC of Naltrexone. Recovery time from the reversal agents ranged from 10 to 25 minutes during field trails (Wildlife Pharmaceuticals, Inc. 2016). Field personnel will observe animals from an appropriate distance for signs of adverse effects after reversal agents are delivered and to ensure the safety of the recovering animal.

Mechanical Immobilization

Unlike other carnivore families, the submissive behavioral response of canids to perceived dominance reduces the need to use immobilization agents. Appropriate mechanical restraint techniques can reduce handling time of animals, allowing animals to reintegrate into social groups more quickly, subsequently reducing overall stress to the individual (Powell and Proulx 2003). Target canids will be mechanically restrained with a restraint pole, until two muzzles can be placed around the snout. While pinned with the restraint pole by one person, a second person will restrain the set of legs not in the trap against the ground and a third person

Draft - Confidential

will release the foot from the trap. This set of legs will then be restrained by the 3rd person as the restraint pole is removed. Once the restraint pole is removed the person restraining the front legs will also then restrain the head. The first person will then move forward with processing the captured animal.

Each animal will be placed on a tarp (or similar) to provide thermal protection from the ground and reduce the risk of hypothermia, with eyes covered and lubricated with eye ointment as appropriate. Respiration and heart rate will be monitored to assess stress and pain in the animal. Temperature will be monitored with a rectal thermometer. Overheating occurs at approximately 104-105°F for canids (AZA Canid TAG 2012) and the animal handling crew will monitor temperature at 5-minute intervals; if a temperature reading reaches 104°F, corrective actions will be taken and temperature will be monitored at 1-minute intervals. Should overheating occur, the individual will be removed from insulation to expedite the natural evaporative cooling process and may be released or reversed (for those under chemical immobilization) if necessary. During days that approach 80°F in temperature, measures will be taken to reduce heat stress, such as: wetting the animal with water, application of a cold pack to the groin area between the back legs, application of rubbing alcohol to foot pads, or immediate release (AZA Canid TAG 2012). If the injured individual is suspected to be a red wolf, based on morphometrics, USFWS staff will be contacted for involvement. In the event that trap caused injuries are determined to be life threatening through use of a trap injury score assessment (Frame and Meier 2007) the individual will be euthanized by an AVMA approved method; if the injured individual is suspected or known to be a red wolf, USFWS staff will be contacted for involvement. Target animals will not be vaccinated or otherwise treated for infectious disease, regardless of the presence of disease signs.

Non-target animals will be released on site. Captured domestic animals will be immediately released from the trap set, followed by an injury score assessment to determine the presence of life-threatening injuries. Captured domestic animals will be handled in an agreed upon fashion as per pre-arranged agreement with landowners or organization, or as determined by landowner consultation. If a domestic animal has sustained life threatening injuries and owner identification information is present on the animal, then the animal will be

Draft - Confidential

transported to a local veterinary facility until the owner is able to retrieve it. If a domestic animal does not have a life-threatening injury and has identifiable owner information, field personnel will treat the minor injuries and attempt to contact the owners. Field personnel may transport the animal to the owners or to a holding facility as appropriate. The costs associated with injuries sustained to the animal will be the responsibility of the animals' owner. Law enforcement may be requested to help communicate with the animal's owner. If the animal does not have an identifiable owner and has incurred substantial life threatening injuries (i.e. compound fracture), the animal will be euthanized on site by an AVMA approved method. Domestic animals that do not have identification nor life threatening injuries may be released on site as per pre-arranged agreement or landowner consultation, or may be transported to a local animal shelter as appropriate. Trapped animals showing signs of rabies (e.g. circling behavior, head tilt, muscle twitches, convulsions with jaw chewing movements and salivation ("chewing gum fits"), disorientation, incoordination, staggering caused by paralysis of the hind legs, seizures, and partial or complete paralysis) will be euthanized and tested according to protocol set forth by the agency veterinarian, to determine if there may be a public health issue (M. Palamar, personal communication, 2016). USFWS will be contacted in cases of suspected red wolves, as USFWS retains decision making authority regarding euthanasia for red wolves (see Attachment 4). Staff involved in animal handling duties will have the pre-exposure rabies vaccination series completed prior to field work inception and will maintain rabies titer records through properly licensed medical services providers.

If staff is bitten and skin is broken by an animal while performing handling duties, they will wash the wound with soap and water and will be advised to immediately visit a local hospital or clinic for evaluation by healthcare professionals and for a rabies booster and titer. The field coordinator will immediately notify supervisory staff and an injury report and workers' compensation claim will be opened for the incident and the local public health department will be notified. The animal will be euthanized and the head will be sent to the state lab for rabies testing; the body may be sent to the Southeastern Cooperative Wildlife Disease Study (SCWDS) laboratory for additional disease investigation. If the animal is suspected or known to be a red wolf, it will be returned to USFWS staff to be held for observation for an appropriate amount of

Draft - Confidential

time according to medical recommendations by the health department.

Capture Processing and Marking

During canid handling, NCWRC personnel will record age class, sex, weight, total body length, head width, ear length, and tail length, visually assess ectoparasite load, look for and disinfect as needed any minor trap caused injuries, and affix GPS collars (Knick 1990, Sikes et al. 2011). All captured canids will be fitted with appropriately-sized GPS collars in the field based on morphometrics previously indicated as reliable thresholds for species categorization: hind foot length, weight, width of head, and tail length (Hinton 2014); analysis of DNA samples collected during trapping efforts will help to assign captured canids to a position along the species continuum post release. Age of individuals will be estimated based on physical characteristics, including weight and tooth replacement (Knick 1990, Hinton 2014, Gier 1968), and captured canids will be aged into one of three classes: > 2 years old as adults, < 2 but > 1 year old as juveniles, and > 6 months but < 12 months old as pups (Hinton 2014). Reproductive status will be determined based on estimated age class and presence of gonadal descent during the breeding season for males and the presence of nipple swelling or previous suckling for females (Hutson and Racey 2004, Magee 2008, Mengel 1971).

Captured individuals will be marked with an individually-numbered, glass-encapsulated, passive integrated transponder (PIT model HPT12, 12.5 mm, 134.2 kHz, Biomark, Inc., 703 South Americana Blvd., Suite 150, Boise, ID; Gannon et al. 2007), using a syringe-type implanter and replaceable needle (model MK10 [implanter], model N125 [needle], Biomark, Inc.). Successful PIT placement will be verified with a mini portable reader (model GPR Plus, Biomark, Inc.). The implantation site will be prepared by swabbing with 70% alcohol (Mrozek et al. 1995) and a sterilized new needle will be used for each injection. The standard implantation site for transponders is subcutaneously on the dorsal midline of the back, cranial to the shoulder blades (Ingwersen 2000).

A selection of hairs with the root bulla attached will be pulled from the belly and placed in paper envelopes (Janecka et al. 2007). Hair samples will serve as back up to blood samples for genetic testing. Genetic samples will be sent to the Laboratory for Ecological, Evolutionary and Conservation Genetics, at University of Idaho (875 Perimeter Drive, MS 1136, Moscow, ID

Draft - Confidential

83844) for genotyping to determine species as well as individual identification, hybridization presence, and parentage analysis following previously developed protocols (Adams et al. 2007, Hinton 2014, Miller et al. 2003). The appropriate genetic analyses that examine the coyote-hybrid-wolf species continuum will be performed.

Blood will be collected from all juvenile and adult target canids by venipuncture of the brachial or jugular veins using a 22-28-gauge needle (M. Palamar, NCWRC veterinarian, personal communication, 2016). As per NCWRC veterinarian recommendations, approximately 12 ml of blood will be collected for each animal for possible future testing for diseases of importance to sympatric canid species as well as the humans and domestic animals that they may come into contact with. An additional 1-2 ml of blood will be collected for genetic analysis. When possible, a minimum of 6 ml of whole blood with EDTA (lavender top tube) and 6 ml of blood for serum will be filled. Samples should be refrigerated at all times; a cooler with ice will suffice while in the field. Samples should be sent to the NCWRC within 48 hours; serum samples (from whole blood) can be centrifuged and the separated serum can be frozen. Skin scrapes will be collected from animals presenting signs compatible with sarcoptic mange (lesions) for diagnostic purposes. Lesions will be scraped until blood is drawn; the scrapings will be placed onto a slide and covered with a piece of clear tape for later visual confirmation. A set of sampling guidelines will be developed for reference while performing these activities in field.

Should overheating occur, processing will be performed in the following prioritization order and the first three items will need to be completed before releasing any individuals: 1) trap injury evaluation/cooling, 2) collaring, 3) DNA (blood) sample collection, 4) PIT tagging, 5) aging, 6) morphometrics, 7) weight, 8) reproductive status, 9) ectoparasite evaluation, 10) disease (blood) collection, and 11) skin scrape collection.

Collaring

Vertex Plus GPS Collars will be attached to 20 sympatric canids captured on the study area, 10 of which will be equipped with proximity sensors (Vectronic Aerospace GmbH, Carl-Scheele-Str. 12, 12489 Berlin, Germany). Project staff will pilot test proximity sensor technology for utility in analysis of spatial and temporal community dynamics. Proximity sensors trigger increased GPS location acquisition during those time intervals when two collared individuals

Draft - Confidential

462 come within a set distance from each other (http://www.vectronic-aerospace.com/wildlife-
463 monitoring/sensors/uhf-id-tags, accessed August 2016).
464 To avoid instances of collar induced strangulation, only adult (>2 years old) male and
465 female individuals will receive collars (Hinton 2014). ASM guidelines recommends a collar
466 weight of <5-10% of a canids bodyweight, we will observe these guidelines (Sikes et al. 2011).
467 Collaring of any red wolves, known or suspected individuals, will be determined by the USFWS
468 on a case-by-case basis using the collaborative process outlined in the decision tree
469 (Attachment 4).
470 GPS radio-collars will have both VHF and GPS Iridium locational systems as well as store-
471 on-board capabilities. Radio-collar units will be programmed to record GPS coordinates once
472 every 1.75 hours producing approximately 13 locations per day while cycling through the 24-
473 hour time cycle. These settings will allow for a GPS battery life of 300 to 552 days, averaging
474 431 days. The VHF beacon will be in operation from 0800 – 1600 hours daily. GPS locations will
475 be sent via satellite once per day and each transmission with contain 12 locations. The use of an
476 integrated drop off firing mechanism should allow the collars to drop off within a maximum of
477 approximately 548 days after deployment. The drop off schedule once set cannot be changed.
478 The drop off firing mechanism is wired to a battery unit independent of the collar battery,
479 therefore should the collar battery become depleted, the drop off mechanism will not be
480 affected (C. Akakpo, Vectronic Aerospace GmbH, personal communication, 2016). Unless a
481 collared individual is recaptured before the collar battery dies, the drop off mechanism will fire
482 at the scheduled time frame post collar deployment.
483 Observation of sympatric canid habitat use and movements will occur through GPS data
484 obtained with combination GPS/VHF radio-collars. VHF relies on triangulation, the process of
485 estimating the location of a transmitter by using two or more compass bearings obtained by
486 using directional antennas at known locations remote from the transmitter's position (White
487 and Garrott 1990), whereas GPS uses a satellite based system to obtain location coordinates.
488 There have been many published studies where one or both of these methods were used, with
489 mixed success for determining various aspects of carnivore ecology throughout the United
490 States (Hinton et al. 2012, Schrecengost et al. 2009, Sparkman et al. 2012). While GPS

Draft - Confidential

technology has developed rapidly in recent history, the real time functional advantage of VHF cannot be disregarded. When GPS technology falters or malfunctions, VHF can serve as replacement for data collection in addition to its use in real time monitoring of study animals. Canids will be minimally monitored for mortality approximately every 30 days by using VHF aerial telemetry techniques (Whitehouse and Steven 1977) as there may be a delay in satellite transmission of GPS location data due to weather, season, and animal behavior. Transient canids and individuals from breeding pairs that have lost a mate, have been found to use much larger areas versus paired residents, potentially increasing the opportunity for losing track of these individuals when GPS technology reaches its functional capacity or experiences malfunction. VHF data may also provide locations of canids in cover too dense for GPS units to function. Use of VHF telemetry techniques for data collection may be expanded as necessary for project needs.

Spatial Data Analyses

Both minimum convex polygon (MCP) and adaptive kernel (AK) home ranges (95%) and core use areas (50% and 25%) (Seaman and Powell 1996, Seaman et al. 1999) will be calculated from GPS data by using BIOTAS (Ecological Software Solutions LLC, 2016) and Geospatial Modelling Environment (Spatial Ecology, LLC, 2016) for ArcGIS 10.2.2 (Environmental Systems Research Institute, 2016) (Benson et al. 2006, Riley 2006, Tucker et al. 2008, Hinton 2014) for comparison to older studies. These estimations can also be calculated using VHF data, provided data minimum requirements are met. Spatial distribution in relation to habitat will also be estimated by dynamic Brownian bridge movement models as described by Hinton (2014) with R statistical software (R Core Team 2016) using the moveud package with habitat covariates important to each species (Bryne et al. 2014, Collier 2013, Kranstauber and Smolla 2013, C. Proctor, personal communication, 2016). Additionally, recent research into how canids shift their ranges will also be investigated for populations on the AP (Morin and Kelly, in review). Spatial overlap and co-occurrence will be assessed using methods described by Shipley (2012). Habitat and cover types will be estimated from digitized maps created by the SEGAP (Hinton 2014) or ortho files, as available (Shipley 2012). Percent composition of habitat and cover types within home ranges and core areas as well as edge density will be quantified (Shipley 2012). Habitat selection and cover type use effects on spatial distribution will be estimated at both the

Draft - Confidential

population (2nd order) and individual (3rd order) spatial scales using resource selection functions (Johnson et al. 2006, Manly et al. 2002, Shipley 2012). Effects of seasonality and time of day activity will also be explored. The spatial and temporal patterns of space use by sympatric canids will be studied using data generated from the interaction GPS collar sensors, particularly distance between individuals and duration of proximity.

Den Monitoring

Project staff will attempt to locate den sites for sympatric canids to get pup counts, morphometric measurements, age estimates, and blood samples. Pups will be weighed, measured, and PIT tagged during May and June of each year when they become active but are still den-obligated (Gier 1968). USFWS will be contacted in cases of known and suspected red wolf dens following the outlined decision tree process (Attachment 4).

Project staff will also attempt to monitor coyote and hybrid canid pup survival during the pup rearing season by using remote cameras placed around the den site (Harrison and Gilbert 1985, Parks 1979, Way et al. 2001). We will investigate the use of remote camera traps for monitoring den behavior with a two-camera array around the den (H. Garbe, personal communication, 2016, Kays and Slauson 2008). This method has been successfully used to monitor kit fox pup survival (Kluever et al. 2013). Because coyotes have been found to be sensitive to den site disturbance, there is a general lack of data in the literature regarding this approach for monitoring pup survival. Approaching an experimental methodology systematically will be important for determining which methods are effective and which are not. As a starting point for testing this methodology, remote cameras will be placed two to five meters from main den entrances and set to take photos using a passive infrared sensor trigger (a beam that when broken by movement through it, triggers the camera to take a series of photos) with a time restriction between photo intervals to limit the number of photos taken and maximize the space on the memory card for the time period between camera checks (Kluever et al. 2013). Cameras will be checked six days after deployment and will be redeployed (i.e. new batteries and memory card, if required); cameras will remain at each den site until radio-collar data indicates the den site has been moved (Kluever et al. 2013). Cameras will be not be redeployed to a new coyote den site during a season if that breeding pair has already

Draft - Confidential

moved the den once due to the disturbance of camera presence/deployment. This experiment may be abandoned if success rate is low and is found to interfere with other project objectives.

Mortalities

If a collared animal dies during the project, the carcass will be sent to SCWDS for necropsy. Red wolves will be turned over to USFWS staff to be sent to the FWS Lab in Madison, WI for necropsy, unless it is determined to be a law enforcement case. In potential red wolf law enforcement cases, the NCWRC Division of Wildlife Management Chief, USFWS Ecological Services Raleigh Field Office Field Supervisor, and the RWRP office in Manteo, NC will be contacted and requested to contact the appropriate law enforcement personnel, immediately after determining the need for law enforcement involvement. The carcass and all relevant information will then be turned over to USFWS law enforcement and the carcass will be sent to the FWS Lab in Ashland, OR; the GPS-collar will be removed from the individual prior to release to law enforcement.

Data Sharing

A compilation of spatial, capture, and den monitoring data will be provided to the collaborative USFWS partners at the end of the project. Spatial, capture, and den monitoring data may be shared with RWRP staff as part of the working collaborative field work process during the implementation of the project. State agency records are subject to the Freedom Of Information Act (FOIA) and requests for information related to this project, including project data, may be shared with requestees.

E. Project Personnel

Andrea Shipley has worked for the North Carolina Wildlife Resources Commission as a Canid Biologist since February 2016. Prior to that, she worked as a Wildlife Biologist for a non-profit located in northeastern Nevada as well as in several different field biologist oriented positions. Andrea has a background in carnivore and spatial ecology, having earned her MS in Biological Sciences from Eastern Kentucky University by studying bobcat spatial dynamics and BS in Biological Sciences from Rutgers University. Her previous experience trapping mesocarnivores in the southeast make Andrea well suited to serving as project lead and coordinator.

Draft - Confidential

Krishna Pacifici, Assistant Professor at NCSU, will be the quantitative analysis collaborator on the project. Krishna's background and experience in quantitative ecology makes him well suited to consult and assist with advanced statistical analyses of spatial data.

Lisette Waits, Department Head and Distinguished Professor at the University of Idaho, will be the DNA analysis collaborator for the project, responsible for all DNA related sample processing and subsequent analyses.

Draft - Confidential

F. Schedule and Estimated Costs

The project will run from soon after December 1, 2017 through June 30, 2020. The estimated timeline for major tasks is as follows:

Year 1: Initiate field work soon after December 1, 2017 with assistance from 1-2 field technicians; 1 technician will be required for trapping and den monitoring efforts. Data collection will begin immediately after collar deployment and data will be managed by Andrea Shipley throughout the life of the project. Data analysis will be initiated after den monitoring season concludes, with guidance and assistance from Krishna Pacifici at North Carolina State University (NCSU). Report, manuscript and presentation production will be initiated concurrently with data analysis.

Year 2: Continue field work and data collection with assistance from 1-2 field technicians. Continue data analysis with guidance and assistance from Krishna Pacifici at NCSU. Continue and finalize report and manuscript production, and presentation at professional working groups and/or meetings.

Year 3 (half year): Continue data analysis with guidance and assistance from Krishna Pacifici at NCSU. Continue and finalize report and manuscript production, and presentation at professional working groups and/or meetings.

GPS technology allows researchers to collect locational data at fine spatial and temporal scales through the deployment of collar units on wildlife study subjects. In this project, we propose to study a sample of sympatric canid populations with GPS radio-collars, in order to investigate the population parameters outlined in previous sections as well as species interactions. The purchase and use of this technology is critical to meeting the research

Draft - Confidential

objectives set forth in this document as well as in the document included in Attachment 1.

While GPS technology has evolved over the past 20 years, the cost of technology has plateaued. Upfront cost per unit remains relatively high, however project savings occurs at the back end when compared to older telemetry technology such as very high frequency (VHF) which require intensive labor to collect data at similar spatial and temporal scales. Pilot testing the proximity sensor enabled GPS-collars will allow investigation of the utility of this relatively new tool for community dynamics analysis by providing an increased locational data acquisition when individuals come within a set distance, or closer, from each other. Additionally, these sensors record the identities of the interacting individuals and the duration of their interactions. Using a trigger to temporarily switch GPS fix schedules will enable us to collect very fine scale data while conserving battery life, achieving project objectives in an efficient manner. Exploring the efficaciousness of this technology has the potential to positively impact future research projects requiring use of GPS-collars for data collection.

Aerial tracking will provide regular study animal surveillance useful to investigate cases of mortality, collar malfunction, or satellite data transmission delays, which can vary seasonally. In some situations, ground tracking could prove less expensive than aerial tracking. However, ground telemetry techniques require more than one biologist working in tandem to acquire accurate location estimates. This often translates to increased labor to collect data, particularly in large study areas. Aerial tracking will provide a more efficient and cost-effective method for surveilling study subjects in this large study area, requiring only one biologist and a contracted pilot. NCWRC personnel will perform aerial tracking along with the NCWRC pilot at a minimum frequency of every 30 days.

Use of local trappers to assist with sampling efforts provides several benefits. Local trappers have established, long-term relationships with private land owners, thereby providing access to private lands that might be otherwise difficult to secure. This will enable project biologists to obtain a representative sample of sympatric canids in the study area, as well as to operate more trap lines concurrently. This is particularly important when using a SCR sample design, as it will have direct implications on the resulting analyses and inferences.

Draft - Confidential

As part of collaboration efforts, the project will contract the services of Krishna Pacifici, Assistant Professor in the Forestry and Environmental Resources department at NCSU. Krishna's expertise is in quantitative ecology; consultation and assistance services provided will allow project biologists to make appropriate statistically relevant inferences from collected data.

DNA analysis will be contracted to Lisette Wait's lab at the University of Idaho. Lisette's team at The Laboratory for Ecological, Evolutionary and Conservation Genetics has previous experience in analyzing red wolf and coyote hybrid molecular samples and has the most comprehensive DNA methodology for this sympatric canid species continuum in the nation. This expertise will facilitate expedient species identification on collared study animals besides landscape level population dynamics analysis.

I. Glossary

Abundance: Species abundance is the number of individuals per species, and relative abundance refers to the evenness of distribution of individuals among species in a community.

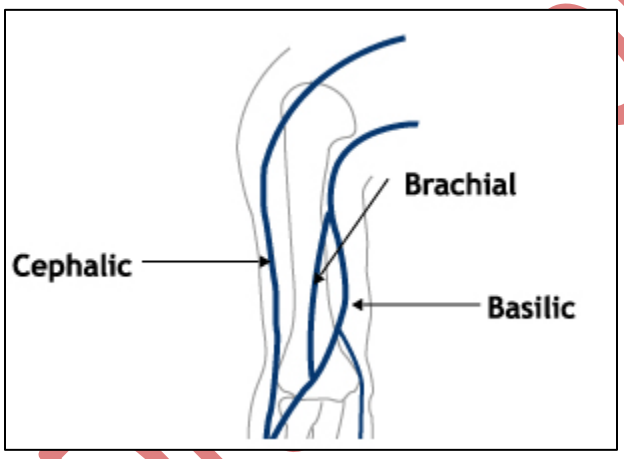
Adaptive kernel (AK): A probabilistic home range estimator based on the distribution and density of locations that has been collected over a period of time.

Adverse reactions: In pharmacology, any unexpected or dangerous reaction to a drug.

Aerial: Existing, happening, or operating in the air.

Annually: Once a year; every year.

Anthropogenic: Caused or influenced by humans.



Apex: Having no natural predators in its ecosystem.

Ataxia: The loss of full control of bodily movements.

Beacon: A radio beacon whose purpose is the investigation of the propagation of radio signals.

Biopsy: The removal for diagnostic study of a piece of tissue from a living body.

Brachial vein: One of a pair of veins accompanying the brachial artery and uniting with each other and with the basilic vein to form the axillary vein.

Breeding pair: A pair of animals which cooperate over time to produce offspring with some form of a bond between the individuals.

Carrying capacity: The maximum population size of the species that the environment can sustain indefinitely, given the food, habitat, water, and other necessities available in the environment.

Compensatory immigration: Individuals emigrating from areas with lower mortality to those with higher mortality; filling a deficiency of individuals in a population experiencing higher mortality. The increase in size or activity of one part of an organism or organ that makes up for the loss or dysfunction of another.

Composition: The combining of distinct parts or elements to form a whole.

Confidential

Co-occurrence: Refers to observation of the spatial overlap between two (or more) different individuals over a period of time.

Coordinates: Any of the scales or magnitudes that serve to define the position of a point.

Core use areas: An area within a home range exhibited by a dense concentration of location points; commonly estimated at 50% of the location data points.

Covariates: A variable that is possibly predictive of the outcome under study.

Cranial: Pertaining to the cranium or to the anterior (in animals) or superior (in humans) end of the body.

Cryogenic: Very low temperatures, e.g. -80^{o}C.

Den-obligated: Restricted to a particular condition of life, in this case restricted to a den site.

Density: A measure of the number of organisms that make up a population in a defined area.

Deployment: To organize and send out (people or things) to be used for a particular purpose.

Depredation: The act of preying upon.

Depressed respiration: A decrease in the ability to exhale and inhale; respiration that has a rate below 12 breaths per minute or that fails to provide full ventilation and perfusion of the lungs.

Diagnostic: The process of determining by examination the nature and circumstances of a diseased condition.

Disorientation: Loss of one's sense of direction, position, or relationship with one's surroundings.

Distribution: The manner in which a biological taxon is spatially arranged.

DNA: (deoxyribonucleic acid) is a type of macromolecule known as a nucleic acid. It is shaped like a twisted double helix and is composed of long strands of alternating sugars and phosphate groups, along with nitrogenous bases (adenine, thymine, guanine and cytosine).

Dorsal: Situated on or toward the upper side of the body, equivalent to the back, or posterior, in humans; situated on or toward the posterior plane in humans or toward the upper plane in quadrupeds.

Duration: A continuous period of time.

Dynamic Brownian bridge movement models: Incorporates temporal and behavioral characteristics of movement paths into estimation of home range.

Ectoparasite: a parasite that lives on the outside of its host rather than within the hosts body; e.g. fleas and lice.

Effective trap area: Calculated by buffering each trap site by half the mean maximum distance traveled, each of these boundaries are dissolved, creating a measurable area.

Efficacious: Producing or capable of producing a desired effect.

Draft- Confidential

Efficient: Accomplishment of or ability to accomplish a job with a minimum expenditure of time and effort.

Euthanize: The act of putting to death painlessly or allowing to die, as by withholding extreme medical measures, a person or animal suffering from an incurable, especially a painful, disease or condition.

Expedient: Suitable for achieving a particular end in a given circumstance.

Evaporative cooling: reduction in temperature resulting from the evaporation of a liquid, which removes latent heat from the surface from which evaporation takes place.

Facilitate: Make an action or process easy or easier.

Genotyping: Investigate the genetic constitution of (an individual organism).

Gonadal descent: The act or process of descending from a higher to a lower location; testicular descent occurs during the breeding season annually.

GPS: Global Positioning System, is a radio navigation system that allows land, sea, and airborne users to determine their exact location, velocity, and time 24 hours a day, in all weather conditions, anywhere in the world.

Home range: an area over which an animal or group of animals regularly travels in search of food or mates, and that may overlap with those of neighboring animals or groups of the same species.

Hybridization: The result of mixing, through sexual reproduction, two animals or plants of different breeds, varieties, species or genera.

Immobilization agent: An active force or substance capable of producing an effect.

Implantation: To put or fix firmly.

Inbreeding depression: The reduced biological fitness in a given population as a result of inbreeding, or breeding of related individuals.

Inception: The establishment or starting point of an institution or activity.

Interspecific: Existing or occurring between different species.

Iridium: A satellite constellation providing voice and data coverage to satellite phones, pagers and integrated transceivers over the Earth's entire surface.

Jugular vein: Any of several large veins in the neck, carrying blood from the head and face.

Lacerations: A deep cut or tear in skin or flesh.

Locational: A position or site occupied or available for occupancy or marked by some distinguishing feature.

Malfunction: Fail to operate in the normal or usual manner

Methodology: A system of methods used in a particular area of study or activity.

Midline: A median line or plane of bilateral symmetry, especially that of the body.

Draft - Confidential

Minimum convex polygon (MCP): Completely enclose all data points by connecting the outer locations in such a way as to create a convex polygon.

Molecular samples: Genetic samples that may be used for investigation of genetic constitution of an individual.

Morphometrics: The process of measuring the external shape and dimensions of landforms, living organisms, or other objects.

Mortality: The state of being subject to death.

Non-target bycatch: Animals caught by accident that are not the target species being sought.

Parameters: A numerical or other measurable factor forming one of a set that defines a system or sets the conditions of its operation.

Parentage: The origin of something; the state or relation of a parent.

Passive integrated transponder: A microchip implant is an identifying integrated circuit placed under the skin of an animal.

Pinna: The external part of the ear in humans and other mammals; the auricle.

Plateaued: A period or state of little or no growth or decline.

Population dynamics: The branch of life sciences that studies the size and age composition of populations as dynamic systems, and the biological and environmental processes driving them (such as birth and death rates, and by immigration and emigration).

Population growth: The increase in the number of individuals in a population.

Population size: A group of organisms of the same species that live in the same area.

Population status:

Population trend: Changes over time and can include changes in ranging behavior and distribution, biogeography and life-history.

Population viability: The process that determines the probability that a population will go extinct within a given number of years.

Proximity: Nearness in space, time, or relationship.

Quantified: Express or measure the quantity of.

Quantitative: Relating to, measuring, or measured by the quantity of something rather than its quality.

Radio-telemetry: The use of radio waves for transmitting information from a distant instrument to a device that indicates or records the measurements.

Recumbency: The state of leaning, resting, or reclining.

Reintegrate: Restore (elements regarded as disparate) to unity.

Draft - Confidential

Remnant: A small remaining quantity of something.

Reproductive status: Relating to or effecting reproduction.

Spatial: Relating to, occupying, or having the character of space.

Spatial capture-recapture: A method commonly used in ecology to estimate an animal population's size. A portion of the population is captured, marked, and released. Marked animals are either recaptured or are tracked, each tracking location being considered a recapture.

Species Continuum: An aggregate of species capable of interbreeding, resulting in fertile hybrid offspring whose genetic composition may represent a varying array of phenotypes and genotypes from the parental species, at which the extreme ends of the spectrum are distinct.

Standardize: Cause (something) to conform to a standard.

Statistically relevant inferences: the process of deducing properties of an underlying distribution by analysis of data. Inferential statistical analysis infers properties about a population: this includes testing hypotheses and deriving estimates.

Stochastic population models: Ecological population modeling is concerned with the changes in population size and age distribution within a population as a consequence of interactions of organisms with the physical environment, with individuals of their own species, and with organisms of other species; stochasticity possesses some inherent randomness. In stochastic population models, the same set of parameter values and initial conditions will lead to an ensemble of different out puts.

Strangulation: The condition in which circulation of blood to a part of the body is cut off by constriction.

Stratifying: Form or arrange into strata, one of a number of portions or divisions likened to layers or levels.

Surveillance: Continuous observation of a place, person, group, or ongoing activity in order to gather information.

Survival: A living or continuing longer than, or beyond the existence of, another person, thing, or event.

Sympatric: Occurring within the same geographical area; overlapping in distribution.

Tachycardia: A heart rate that exceeds the normal resting rate. In general, a resting heart rate over 100 beats per minute is accepted as tachycardia in human adults.

Telemetry: See radio-telemetry.

Temporal: Of or relating to time.

Tooth replacement: The process of development of two successive sets of teeth, initially the deciduous set and consecutively the permanent set.

Transmitter: A set of equipment used to generate and transmit electromagnetic waves carrying messages or signals, especially those of radio or television.

Transponder: A device for receiving a radio signal and automatically transmitting a different signal.

Draft - Confidential

Vaccinate: Treat with a vaccine to produce immunity against a disease; inoculate.

Venipuncture: The puncture of a vein as part of a medical procedure, typically to withdraw a blood sample or for an intravenous injection.

VHF: Very high frequency is the ITU designation for the range of radio frequency electromagnetic waves (radio waves) from 30 MHz to 300 MHz, with corresponding wavelengths of ten to one meters.

NORTH CAROLINA / NORTH CAROLINA WILDLIFE RESOURCES COMMISSION

III. Station Name:

FWS RALEIGH FIELD OFFICE, ASHEVILLE FIELD OFFICE

IV. Description of Proposed Action (attach additional pages as needed):

Conduct research project entitled "**Pilot Study – Using Fine Scale GPS Technology to Research Sympatric Canid Population Dynamics**"

This is a 2.5-year pilot research project on the efficacy of fine-scale GPS data collection and use of proximity sensors within the AP of North Carolina to improve North Carolina Wildlife Resource Commission's management of this species.

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.. *These data will be used to determine the efficacy of GPS and proximity sensor technology for collecting fine scale locational data throughout the study area.*

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference. *These data will be used to determine 1) the distribution of sympatric canids within the AP, and 2) determine habitat preferences to guide in habitat management and conflict management.*

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids. *These data will be used to determine fecundity of sympatric canids.*

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids. *These data will be used to assess sympatric canid survival.*

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners. *These data will be used to develop strategies for improved conflict management.*

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, determine parentage of individuals, and assess the level of hybridization in each individual. *These data will determine the status of the sympatric canid species on the AP. Understanding gene flow between populations and potential hybridization between sympatric canids will be important in determining management objectives for coyotes.*

992

993

V. Pertinent Species and Habitat:

A. Include species/habitat: This project

B. Complete the following table:

SPECIES/CRITICAL HABITAT	STATUS[1]
Red Wolf (*Canis rufus*)	T (on federal properties in study area)
Red Wolf (*Canis rufus*)	PT (on non-federal properties in study area)

[1]STATUS: E = endangered, T = threatened, PE = proposed endangered, PT =proposed threatened, CH = critical habitat, PC = proposed critical habitat, C = candidate species

VI. Location:

A. Statewide

Only on three counties in the Albemarle Peninsula of NC

B. Section, township, and range (or latitude and longitude):

Dare, Hyde, and Tyrrell Counties

C. Distance (miles) and direction to nearest town:

As stated above

D. Species/habitat occurrence:

The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of captive-bred red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). This population increased until 2008 and peaked at around 130 individuals (Group Solutions, Inc. 2016), short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013). The AP has an estimated carrying capacity of 140-150 wolves (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). The exact number of red wolves is not known, but USFWS staff report a population estimate of 25-40 individuals with six recorded mortalities in 2017 (J. Madison, personal communication, 2017). Though a rural area, human land uses occupy a significant portion of space on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011). Dellinger et al. (2013) found that red wolves preferentially select for agricultural fields and early successional fields versus other land cover types they have been previously found to utilize when human density is low, e.g. pocosin, wetlands, pine plantations, and

lowland forests. However, this relationship inversed as human density increased (Dellinger et al. 2013).

VII. Determination of Effects:

A. Explanation of effects of the action on species and critical habitats in item V. B. (attach additional pages as needed):

SPECIES/CRITICAL HABITAT	IMPACTS TO SPECIES/CRITICAL HABITAT
Red Wolf	Trap induced injury is possible, e.g. foot trauma, thermal regulation issues, potential predation, and capture myopathy.

B. Explanation of actions to be implemented to reduce adverse effects:

SPECIES/CRITICAL HABITAT	ACTIONS TO MITIGATE/MINIMIZE IMPACTS
Red Wolf	Use of appropriate trap types, daily trap checks in the early morning, treatment of minor injuries, trapping season timing limitations and protocols for trapping which delineate when environmental conditions become inappropriate for continued trap operation, to minimize the potential for injury/stress to canids and/or target species. USFWS employees may be involved in trapping efforts to lend expertise and veterinary services are available in Manteo, NC for treatment of any injuries or other urgent medical conditions. No trapping of red wolves during February.

VIII. Effect Determination and Response Requested:

SPECIES/	DETERMINATION[1]			RESPONSE[1]
CRITICAL HABITAT	NE	NA	AA	REQUESTED
Red Wolf		X		Concurrence

[1] DETERMINATION/RESPONSE REQUESTED:

NE = No Effect. This determination is appropriate when the proposed action will not directly, indirectly, or cumulatively impact, either positively or negatively, any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested is optional but a "Concurrence" is recommended for a complete Administrative Record.

NA = Not Likely To Adversely Affect. The determination is appropriate when the proposed action is not likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat or there may be beneficial effects to these resources. Response Requested is a "Concurrence".

AA = Likely To Adversely Affect. This determination is appropriate when the proposed action is likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested for listed species is "Formal Consultation". Response Requested for proposed or candidate species is "Conference".

Attachment 2: Joint Memorandum

MEMORANDUM

November 20, 2013

TO: All Interested Parties

FROM: "for" Cynthia K. Dohner, Director, Southeast Region, U.S. Fish and Wildlife Service
Gordon S. Myers, Executive Director, N.C. Wildlife Resources Commission

SUBJECT: Collaborative Conservation of Red Wolves and Other Canids on North Carolina's Albemarle Peninsula

---

Recovery of the federally-listed red wolf has been a priority for the U.S. Fish and Wildlife Service (FWS) for more than 20 years and is focused in North Carolina on the Albemarle Peninsula (AP; i.e., Hyde, Tyrrell, Washington, Beaufort, and Dare counties). Comprehensive stakeholder involvement and collaboration with other management agencies is critical to successful recovery of any at-risk species. The North Carolina Wildlife Resources Commission (WRC) is a key collaborator in this regard, as it has jurisdiction over all state-trust wildlife resources in N.C.

Since 2009, the FWS and WRC have worked to broaden our collaboration in the conservation and management of all canid species (including red wolves) on the AP. As these efforts have solidified, specific actions have been jointly identified by our two agencies that will improve conservation outcomes. These actions are categorized into five areas; collaboration, research, outreach, regulatory, and enforcement. Specific action items are outlined and prioritized within each of these categories in Attachment A.

This memo establishes the FWS's and WRC's commitment to initiate, or to continue, the efforts outlined in Attachment A. The common goal in this effort is to establish clear expectations and accountability for collaboration regarding the action items on Attachment A, thus resulting in enhanced and seamless canid conservation and management on the AP. This approach provides the best opportunity to achieve recovery goals for red wolves, while at the same time managing other canids to balance biological variables with social expectations. The dynamics of these canid species are complex and offer unique opportunities for innovation. Appropriate staff from each agency is hereby tasked with immediately developing a timeline to implement these actions. Through this commitment, we will continue to advance our collective conservation goals.

Attachment A

Action Items for Collaborative Conservation of Canids on North Carolina's Albemarle Peninsula (AP)
(*Note: Action Items are prioritized within category.*)

Collaboration

1. The N.C. Wildlife Resources Commission (WRC) and U.S. Fish and Wildlife Service (FWS) will formalize in writing the collaborative management of canids on the AP. This agreement should:
    a. include a clear mission statement, goals, objectives, and implementation strategies (ask and answer the "Why?");
    b. set a goal to define success regarding canid management on the AP;
    c. espouse a philosophy of canid management operating within the context of a three-legged stool (i.e., federal and state governments and stakeholders);
    d. as available, commit funding and staffing resources for field personnel to contribute to the conservation of the red wolf and management of coyotes;
    e. as available, commit funding to conduct research pertinent to canid management on the AP;
    f. establish polices and goals for developing a collaborative genetic archive for AP canids, a data sharing portal accessible by staff in both agencies, and reciprocal sharing of all historical data (including phenotypic and genotypic data and literature) of the red wolf;
    g. establish a foundation for developing and implementing an adaptive approach to canid management on private lands on the AP;
    h. initiate development of a collaborative canid research program;
    i. describe plans to conduct the next five year Red Wolf Program review;
    j. outline options for holding annual workshops with federal and state enforcement staff;
    k. outline plans to hold semi-annual coordination meetings regarding canid management on the AP; and
    l. develop milestones for future development of a management plan for all canids in the AP.

2. The FWS will initiate a review of the current Red Wolf Recovery Plan to determine if the state-of-our-knowledge or field conditions have changed such as to warrant its revision. Review and comments from the WRC will be considered in this evaluation.

3. The WRC, with support and participation of the FWS, will establish a "Canid Forum" (similar to that established for manatees in Florida) to facilitate communication and discussion regarding canid management and citizen science opportunities on the AP.

Attachment A

Research

1. The FWS and WRC will provide funding and logistical support for research identified by the Red Wolf Recovery Implementation Team, Red Wolf Program staff, other FWS staff, or the WRC that promote the conservation and recovery of the red wolf and other canids on the AP. Studies could include:
    a. tests of the "placeholder theory" on the AP, including behavior of sympatric canids,
    b. determining carrying capacity of canids on the AP,
    c. determining genetic profiles of canid species on the AP,
    d. evaluating predator-prey dynamics,
    e. studies of canid habitat use,
    f. epidemiology of diseases impacting canids on the AP,
    g. development of stochastic simulation models of sympatric canid population dynamics and habitat use, and
    h. canid dispersal dynamics

2. The FWS and WRC will conduct jointly-supported research to determine the attitudes and opinions of N.C. private landowners and other citizens concerning canids on the AP (i.e., human dimensions studies).

Outreach

1. The FWS and WRC will collaborate with other partners to design and implement broad-based outreach and marketing programs with clear goals, objectives, strategies, and measurable outcomes, including development of consistent agency messages and educating the public about canids on the AP.

Regulatory

1. The FWS and WRC will initiate a review and, if needed, subsequent rule-making to clarify concepts or rectify conflicts in current federal or state rules (including the current 10(J) rule).

2. The WRC will review and evaluate statutory requirements for listing red wolves as state threatened in the five AP counties.

3. As data demonstrating a relationship between coyote hunting and red wolf mortality become available, the FWS and WRC will evaluate, and if appropriate implement, adaptive approaches to regulate of take of coyotes that may result in incidental take of red wolves.

4. The WRC will evaluate the status, management, and regulation of Controlled Fox Hunting Preserves.

1008

1009

1010

Attachment A

5. The WRC will develop BMPs (due care provisions) for coyote hunting, trapping, and live sale.

6. The WRC will compile, compare, and contrast canid hunting and trapping regulations and programs in other states, including, but not limited to, other states with other species of wolves.

Enforcement

1. The FWS and WRC will develop coordination strategies to improve enforcement of federal regulations protecting red wolves.

I, the cooperator or cooperator's representative, have been informed of the methods and the manner in which research devices will be used, and of the possible hazards associated with their use. I understand that NCWRC, (to include its officers, employees and agents) will: exercise reasonable precautions to safeguard all persons to prevent injury to target and non-target animals; guard against the mishandling of control devices and materials; and exercise due caution and proper judgment in all scientific collection operations. I understand that NCWRC may collect Global Positioning System (GPS) coordinates at the project site as part of component or activity tracking or as wildlife disease monitoring or research data. I, the undersigned cooperator, do hereby give my consent and concurrence to NCWRC, its employees, and its agents, to use, upon lands owned, leased, or otherwise controlled by me, and identified by this document, the following methods and devices (an attachment of additional devices and/or methods may be attached):

Statement of agreement: The landowner, cooperator, or representative, as listed above hereby give permission to NCWRC to perform trap and release of the species listed for scientific collection purposes. In consideration of these understandings, I, the cooperator or cooperator's representative, agree to: assume responsibility for injury to my property under my control, when said injury is not the result of negligence on the part of NCWRC (it's officers, employees, and agents); assist in maintaining such warning signs as NCWRC may place for the purpose of notifying persons entering onto such lands of the possible hazards associated with scientific measures in use thereon; and to give adequate warning of these possible hazards to persons I authorize to enter onto such lands. Further, I, the cooperator or cooperator's representative, agree not to concurrently use or allow to be used upon lands covered by this agreement, any canid depredation efforts during the scientific collection time period.

Discussion of Collaborative Field Work Efforts

28 Nov 2017
10:00AM EST at Pocosin Lakes NWR Offices in Columbia, NC

Meeting called by: David Cobb

Attendees:

WRC - David Cobb, Kyle Briggs, Allen Boynton, Brandon Sherrill, Andrea Shipley

USFWS – Howard Phillips, Joe Madison, Art Beyer, Rebekah Martin, Michael Morse, Ryan Nordsven, Becky Harrison, Scott Lanier, Kelley Van Druten, Shaun Olson

Please read: Draft Sympatric Canid Project Proposal

Potential Topics for Discussion

Trapping coordination with FWS – dovetailing our efforts and areas to avoid

Trapping on private lands – landowner buy-in/relationship building

Trapping in the Texas Plantation area – existing landowner relationships?

Trapping on public lands: the Refuge Administration Act process

Section 7 b.e. – discuss effects of targeting RW vs. RW as bycatch

Draft sympatric canid project proposal – discuss any areas of concern

---

Project Summary:

In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of sympatric canids on the AP. A USFWS and NCWRC joint memorandum documented detailed action items for the joint management of sympatric canids on the AP, including specific research objectives which this proposal seeks to address. As sympatric canids on the AP increase in number, monitoring their movements, particularly in relation to individuals of differing ancestry, could provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about sympatric canid populations and conflict management. Collection of finer temporal scale location data would help to manage interactions of sympatric canids with humans, as well as to support development of dynamic stochastic population models. At the end of this two-year pilot study, we will deliver an observational summary detailing the use of the GPS and sensor technology for spatial and population dynamics research on sympatric canids on the AP.

Job Opportunity

Position: W/F Conservation Technician I/II

Department: North Carolina Wildlife Resources Commission (NCWRC)

Division: Wildlife Management

Salary: Commensurate with experience

Appointment Type: Temporary (3 months) – December 2018 – February 2019

Office Location: Swanquarter, NC

Area of Work: Dare, Hyde, and Tyrrell counties

Housing: Field housing provided

Description of Work:

This position is responsible for assisting with NCWRC research efforts on coyote, red wolf, and other canids on the Albemarle Peninsula of North Carolina which includes Dare, Hyde, and Tyrrell counties. This position will work closely with NCWRC staff to effectively carry-out job responsibilities. Duties will include, but are not limited to, assisting with the capture of canids, collecting morphometric data, deploying GPS and/or VHF radio-collars, and conducting radio telemetry. Field work may require use of immobilization/euthanasia drugs or other techniques to restrain, capture, and/or handle live animals. Work may include wildlife disease/mortality investigations (including field necropsies) and collection of a variety of biological samples. Office work will include submission of administrative paperwork and data entry. Field work will be conducted in a variety of relatively remote habitats, including dense forests and rural agricultural areas. This position will require work in harsh weather conditions (e.g., rain, heat, humidity, cold, etc.) and frequent exposure to a variety of potentially irritating environmental factors (e.g., ticks, biting flies, chiggers, snakes, etc.).

Knowledge, Skills, and Abilities/Competencies:

- Ability to work as part of a team, but also work independently, and effectively coordinate and prioritize work assignments
- Ability to provide clear, timely, and effective updates to supervisor
- Knowledge of the principles and techniques of wildlife management, including knowledge of wildlife habitats and species requirements
- Ability to safely capture and handle wildlife
- Ability to accurately collect and log field data

- Skilled use of computers for word processing and information management
- Knowledge and ability to use basic wildlife research tools and equipment, including GPS, telemetry gear, and capture equipment
- Ability to operate and maintain equipment and vehicles (e.g., ATV, 4WD truck, boat, etc.) used in wildlife research
- Physical stamina to work outdoors for prolonged periods of time in adverse conditions
- Ability to work a flexible schedule, with potential night and/or weekend work

Minimum Education and Experience:

Associate's or Bachelor's degree in wildlife or fisheries management, zoology or biology from an appropriately accredited institution and one year of experience in wildlife or fisheries management; or an equivalent combination of education and experience.

Preferred Qualifications: Experience trapping and handling large carnivores.

United States Fish and Wildlife Service

RED WOLF RECOVERY PROGRAM
Post Office Box 1969
Manteo, North Carolina 27954

STANDARD OPERATING PROCEDURE (SOP)

Title: Processing and immobilizing a live canid
SOP Number: 1.2
Date: 31 October 2012

Exceptions: The only permissible exceptions to the procedure described herein are those specified under an approved separate study (e.g., via NC State College of Veterinary Medicine). Otherwise, deviations from this SOP will only be permissible by having a new version approved.

Background: Wolves and other canids are routinely captured and handled in order to collect biological samples and to facilitate the monitoring of free-ranging animals. It is imperative to ensure the safety of the animals while they are immobilized and processed. It is equally as important to ensure the safety of personnel during this process.

Purpose: This SOP describes the standard protocol by which personnel of the Red Wolf Recovery Program (Program) will handle, immobilize, and process a live red wolf or other canid. Two scenarios are discussed in regard to the use of Butorphanol and Dexmedetomidine.

Important Note: ***Remember that the safety of field personnel, followed by the safety of the animal, is paramount. If attempts to stabilize an animal under sedation are not successful, sedation and processing should be abbreviated or abandoned and the sedation reversed. Be prepared to physically restrain the animal.***

Procedure: It is important that all of your capture and processing equipment be with you and in working order, and that you have a working knowledge of what you are using ***before*** you set out to capture or handle a canid. While processing the animal, record all biological information, drugs administered, and other pertinent information on a processing sheet (Appendix A). However, do not risk the health or safety of a canid or yourself by taking time to write something down.

The following steps should be followed in the order given anytime a canid is captured or handled:

SUBDUE ANIMAL

Once you arrive on site, subdue the animal as quickly as possible. Rapidly subduing the animal will minimize potential injuries, hyperthermia, and other stress-related conditions as the animal attempts to escape. If chemical immobilization will be required, draw up the immobilizing drugs and reversal drugs prior to subduing the animal (see # 2 under Chemical Immobilization - Scenario 1 below).

1. Snatch- or catch-poles are effective in subduing an animal that is restricted in movement. They provide a fair amount of safety to the handler but can be dangerous to the animal if used improperly:

    a. If they are not maintained or are worn, the cable may not release properly after it has been tightened around the animal's neck. Test the catch pole each time before it is used. Keep a good pair of wire cutters on hand in case the cable does not release.

    b. Once tightened around the animal's neck, the cable may restrict the animal's ability to breathe. If there is ***any*** reason (e.g., a panicked, open-mouth response; pawing at the mouth; gasping; lack of breathing; pale or bluish gums and tongue; or unconsciousness) to suspect that the animal's breathing is impaired **IMMEDIATELY** relax the cable. Try to place the "ball" of the snatch pole, rather than bare cable, at the level of the trachea.

    c. Damage to the neck muscles and/or vertebrae may occur if the animal is thrashing, if the pole is used to drag the animal, or if the pole is used to subdue an animal that has a wide range of movement. If these scenarios occur, use other methods described below to subdue the animal.

2. Large salmon nets are effective in subduing an animal that has a wide range of movement or when there is a high probability that the animal may escape before it can be subdued and immobilized. A netted animal often maintains control of its head and mouth, so take care when removing animals from the net, particularly if no immobilization drugs have been used.

3. A pin-stick (Y-bar) or other device to control the head or pin the animal down may be used. Pin the animal down from the back of the neck.

4. An animal should be darted only if physical restraint is impossible (refer to SOP 1.3 Darting).

IMMOBILIZATION OF ANIMAL

Once subdued, the animal should be immobilized immediately. Both ***Chemical Immobilization*** and ***Physical Restraint*** are addressed below. Individual judgment should be exercised in

determining whether physical or chemical immobilization is appropriate. Chemical immobilization should not be used (or used with extreme care) in the following situations:

1. Avoid using drugs to immobilize pregnant or lactating females.

2. Avoid using drugs on animals that you suspect for any reason to be sick. Sedation will make it more difficult for a veterinarian to diagnose any problems and could complicate medical issues. Sedation **should** be used if animals are injured but not sick. In such cases, immobilization will decrease the likelihood that the animal's injury will become worse with handling.

3. Avoid using drugs on animals that you suspect to be hypothermic (< 99º F), especially if the animal appears to be in shock. Drugs alone may lead to hypothermia and they may compound the problem if the animal is already cold.

Chemical Immobilization

Chemical immobilization is a very effective means of restraining an animal for extended periods of time, allowing a greater degree of safety for the handler and a lower level of stress for the canid during processing. ***DO NOT LEAVE A SEDATED ANIMAL UNATTENDED AT ANY TIME***. It is also very important when using chemical immobilization that you understand what the particular drugs are used for, how they work, and the dosage used. You **must** have the necessary drugs on hand for reversing immobilization and for addressing emergencies. All drugs (including emergency drugs) must be within their expiration date. ***See protocol on using drugs or vaccinations on pregnant or lactating females and pups*** (Appendix C).

Scenario 1: To provide enough sedation to immobilize an animal so that it may be removed from a trap and released or kenneled for transport to another location.

1. Estimate the animal's body weight to determine dosages for immobilization drugs. Your estimate should be within 5 lbs. on most animals. Once the animal is adequately immobilized, it should be weighed for accurate dosing of other drugs.

2. Draw up doses of immobilization drugs and reversal drug(s) and label the syringes. Immobilization drugs should be drawn into a syringe and combined before the animal is restrained or subdued. Administer Butorphanol at a dose of 0.4 mg/kg (0.18 mg/lb.) body weight and Dexmedetomidine at a dose of 0.04 mg/kg (0.018 mg/lb.) body weight, delivered intramuscular (IM) in the same syringe (see Appendix B for dosing amounts). Atipamezole, the reversal agent for Dexmedetomidine, should be drawn up at 0.2 mg/kg (0.09 mg/lb.) body weight (see Appendix B for dosing amounts). This reversal agent should be drawn up before immobilization drugs are administered. If this procedure is followed, reversal agents will be always be ready in case any complications develop.

a. Administer the initial doses of immobilization drugs as soon as possible after the animal is subdued. Note the time of administration.

b. Allow 15-20 minutes for full sedation. If the animal is extremely agitated, onset of sedation may be prolonged and extent of sedation may be lessened. It is important that all external stimuli, including noise, be minimized. Cover the animal's eyes if possible. **Do not leave the animal unattended at any time.**

c. If additional sedation is required following the 15-20 minute induction period, administer **only** Butorphanol IM at ½ the original Butorphanol dose. Note the time of this supplemental administration.

3. Once the animal is under sedation, pull the tongue out to help insure an open airway. If the airway cannot be secured this way, intubate. Use the largest endotracheal tube possible, gently inflate the cuff and secure to the top of the muzzle using gauze or similar material. Be prepared to deflate the cuff and remove the tube when you administer the reversal drugs or the animal recovers.

4. Monitor vital signs of the animal during sedation **every 5 minutes**. When assessing vital signs, it is important to look for trends in measurements, not just pinpoint values. The following vital signs should be checked and addressed if abnormal:

a. Maintain an open airway and check the respiratory rate. Normal rate is 10-30 breaths/min. Animals will likely pant if they are hyperthermic and should be allowed to do so, especially if body temperature is > 104º F. If the respiratory rate is below 8 breaths per minute, or if breathing is very shallow, the wolf should be manually stimulated. If this is ineffective in increasing respiratory rate or depth, the animal should be reversed with the calculated dose of Atipamezole as well as Naloxone at 0.02 mg/kg (0.009 mg/lb.) (see Appendix B for dosing amounts). If the animal STOPS breathing, see *Medical Emergencies* section at the end of this document.

i. Determine that the heart is beating by feeling between the ribs. Continue to monitor heart rate by feeling between the ribs or by palpating the femoral pulse. Femoral pulses should be strong. Capillary refill time (CRT) should be less than two seconds and the gums should be pink. If the animal appears to be in shock, see *Medical Emergencies* section at the end of this document. This drug combination may cause the heart rate to slow considerably. If the heart rate slows to 40 beats per minute or less, administer reversal agents (Atipamezole and Naloxone) and reassess heart

rate. Be prepared to physically restrain the animal. If the animal's heart STOPS beating, see *Medical Emergencies* section at the end of this document.

ii. Monitor body temperature. If body temperature falls below 99º F or above 104º F, implement procedures to warm or cool the animal as appropriate (See *Medical Emergencies* section at the end of this document). Consider drug reversal if attempts to stabilize the temperature are unsuccessful (particularly if the animal is cold and does not warm up). Be prepared to physically restrain the animal.

5. Once it is determined that the animal is stable, apply Paralube or similar eye lubricant to both eyes. Covering the eyes with a towel or cloth will not only protect the eyes but often keeps the animal calmer during sedation and recovery.

6. Before placing the animal into a kennel for transport, administer Atipamezole IM in order to reverse the Dexmedetomidine. **Do not transport an animal that is fully sedated**. Wait until the animal is no longer ataxic and can hold its head up before transporting. If the animal is still not alert enough for transport 10-15 minutes after Atipamezole administration, Naloxone may be administered IM in order to reverse the Butorphanol.

Scenario 2: To provide enough sedation to process an animal in the field and release the animal when completed.

Follow step 1-6 above for administering an initial dose of Butorphanol and Dexmedetomidine (see Appendix A) and additional Butorphanol if needed. ***Do not leave the animal unattended****.*

1. If additional down-time is needed or the animal is responsive to painful stimuli, administer Ketamine at a dose of 1 mg/kg (0.5 mg/lb.) IM or intravenously (IV) (see Appendix B for dosing amounts). It is best that Ketamine be administered 30-40 minutes after the initial injection of Butorphanol/Dexmedetomidine, but it may be administered earlier.

2. Monitor vital signs of the animal **every 5 minutes** (refer to # 4 under Scenario 1).

3. Prior to releasing the animal, administer Naloxone IM and Atipamezole (see Appendix B). If Ketamine was administered, wait at least 30 minutes after the **last** injection of Ketamine before reversing Butorphanol and Medetomidine. If more than two additional injections of Ketamine were given, wait at least 45 minutes after the **last** injection before reversing Butorphanol andDexmedetomidine.

4. Wait a minimum of five minutes after injection of Naloxone and Atipamezole before releasing. Many animals are fully reversed in five minutes and almost all should reverse within 10-15 minutes. The animal should show increased alertness. **Do not release the animal if it still appears sedated or uncoordinated**.

NOTE: The amount of each drug administered should be recorded on the processing sheet, along with the time of each administration, date, and animal ID number. Be sure this information is passed along to the individual responsible for tracking scheduled drugs.

Physical Restraint

Physical restraint can be effectively applied by using a muzzle and restraining all four legs with rope. **DO NOT LEAVE AN ANIMAL UNATTENDED**. An apparently subdued animal could suddenly break free and run off, possibly with a muzzle, snatch-pole, or injury.

1. Make sure the animal can breathe adequately. Continue to monitor this during the entire handling event.

2. Check for shock. Though we rarely come across it, shock is potentially life threatening to the animal. If an animal appears to be in shock, see *Medical Emergencies* section of this document. Signs of shock include:

    a. CRT > 2 seconds.

    b. Mucous membranes are pale, cold and dry.

    c. Cool extremities.

    d. Unresponsiveness or sluggish behavior.

3. Obtain a body temperature. If it is within normal range (99º F - 104º F), recheck in 5 minutes to determine if it has decreased or increased to hyper- or hypothermia. Watch for a trend and continue monitoring throughout the handling process. If body temperature is not within normal range, treat accordingly before proceeding (see Medical Emergencies below).

PROCESSING - For each point below, note the appropriate information on the processing sheet (Appendix A) as soon as possible.

1. Check the animal thoroughly for any leg fractures, dislocations, or any other medical condition requiring veterinarian care. If so, kennel it IMMEDIATELY and transport it to the veterinarian to receive treatment.

2. Note the general condition of the animal including coat quality, body fat, and tooth wear.

3. Obtain a body weight. Make sure that the rope is secure and that the animal's head will not hit the ground if the rope slips.

4. Note the ID number of the animal. This number may be found by scanning for a transponder chip, checking a radio collar, and/or looking for an old tattoo. Transponder chips may migrate under the skin, so scan the entire body. Once identification is established, one can determine which procedures need to be performed and if the animal needs to be processed.

5. If the animal has no identification or has not been processed in the past 24 months, it should be placed into a dog kennel and transported for processing.

6. Look inside the mouth for any lodged sticks or similar items. If there is anything lodged or stuck, it will need to be removed on site or by a veterinarian.

7. Administer vaccinations IM:

    a. Administer rabies vaccination if > 90 days have elapsed since the last administration.

    b. If the animal has received three 8-way vaccinations or less, repeat 8-way vaccination ONLY if it has been ≥14 days since the last administration. If the animal has received at least four vaccinations total, administer vaccine only if >90 days have elapsed.

8. Draw blood from a cephalic (foreleg) vein or saphenous (hind leg) vein. Fill one purple top EDTA tube (collect at least 2ml) and one 10 ml red/grey top serum separator tube. Label each tube with the animal's ID, if known, and the date. Store both tubes in a cooler and keep cool until the blood is processed (see SOP 1.4 Blood Handling). A heartworm test, using blood from the EDTA tube, should be performed as soon as possible to determine whether to administer Ivermectin.

9. Ivermectin may be administered for heartworm prevention **only** if the canid is heartworm negative and **only** if >30 days have elapsed since the last Ivermectin administration. Administer Ivermectin at a dose of 0.09 mg/lb. SQ.

10. Place a radio collar on the wolf at this time if applicable.

    a. Remove the magnet and test the collar to be sure it is working.

b. Record the frequency and serial number of the collar on the processing sheet.

c. If the animal is ≥ 45 lbs. place a mod-500 collar on it. If it is < 45 lbs. and ≥ 35 lbs. place a mod-400 collar on it. If it is <35 lbs. and ≥25 lbs. place a mod-315 on it.

d. Ensure the collar is secure enough that it cannot be pulled over the canid's head but loose enough so that it does not restrict breathing. With younger animals, a judgment call will need to be made in order to allow for some growth or a winter coat.

e. Tighten the collar nuts securely but DO NOT over tighten since you could break the bolts.

f. Cut off the extra belt but DO NOT cut through the antenna. Leave enough of the belt to include the last set of holes in case the collar can be adjusted later.

11. If no transponder chip was detected, inject one SQ between the shoulder blades. Palpate to make sure the chip is underneath the skin, and test it with the reader. Record the number on the processing sheet and save the label to be attached to the sheet.

12. Obtain body measurements.

13. Check the entire body for ectoparasites. Spend one minute on the body and one minute on the head. Record the type and number found on the processing sheet.

14.

15. Before releasing an animal, check the processing sheet for anything that may have been missed.

DOCUMENTATION

1. Fill out the processing sheet (Appendix A) as soon as possible.

2. Within 24 hours (ideally the same day), route the original sheet to the individual(s) responsible for entering data, or enter all data into the temporary files on the computer for proofing.

MEDICAL EMERGENCIES

Shock

Treatment for shock:

1. Administer 500-1000 ml lactated ringers IV through a catheter, and run fluids full open. If you cannot hit a vein, administer SQ. Avoid over-hydration as it could lead to fluid in the lungs. You can determine this by checking the gums or tongue for CRT and moisture. CRT will have returned to normal and the mucous membranes will be moist. Also, listen to the lungs with a stethoscope if possible. Fluid in the lungs may produce a crackling noise.

2. Administer dexamethasone sodium phosphate IV (see Appendix B for dosing amount). This can be administered through the IV line if one is established.

3. Ensure a clear airway. If the animal is unresponsive, intubate and use an Ambu bag if available, or pull the tongue out and continue to monitor breathing. If intubating, use the largest endotracheal tube possible, inflate the cuff gently and secure to the top of the muzzle with gauze or similar material.

4. Seek veterinary care for the animal ASAP. Any canid recovering from shock should be held at least overnight.

Body temperature complications

If **hyperthermic** (>104º F) or you notice a rapid increase in temperature leading to hyperthermia, cool the canid in one or more of the following ways:

1. Submersing in water is a quick way to reduce body temperature.

2. Apply water to ventral surface, especially under the legs and groin. Fan vigorously to aid in evaporation.

3. Administer lactated ringers solution IV through a catheter. This will rapidly cool temperature and is helpful in treatment or prevention of shock.

4. Apply alcohol to the foot pads and inside of the ears. If the animal is sedated, applying alcohol inside the ears could stimulate the animal.

5. Administer a cold water enema. Although effective this makes it difficult to monitor rectal temperature.

6. Administer dexamethasone IV (see Appendix B for dosing amount & Appendix C for contraindications).

If **hypothermic** (< 99º F) or you notice a rapid decrease in temperature leading to hypothermia, warm the animal using one or more of the methods below. Finish the handling event as soon as possible. Reversing an animal from sedation will allow it to produce more heat. Be sure to check for shock. If the animal is in shock, avoid warming the extremities and focus on warming the animal's core, and address the situations described for shock above. Within reason, treatment of shock supersedes treatment of low body temperature - shock needs to be treated promptly.

1. Apply heat packs under the legs against the body. Avoid warming the extremities quickly, especially when the animal is in shock.

2. Wrap the canid in a blanket/coat/etc. to conserve body heat. Rub vigorously.

3. Keep the animal inside a truck with the heater if it is immobilized. DO NOT chemically immobilize an animal in order to hold the animal in the truck.

4. If the animal is under sedation, administer reversal agents.

Respiratory Distress or Arrest

1. Check for anything obvious that may be blocking the airway, including the tongue or foreign material in the throat. Look around the mouth and nose as well as within the mouth.

2. If Medetomidine and Butorphanol were administered, administer the reversal drugs Atipamezole IV and Naloxone IV (rather than usual IM route) (see Appendix B for dosing amounts).

3. Intubate and use an Ambu bag to provide artificial respirations. If unavailable or unable to intubate, lay the canid on its side and compress the chest.

4. Administer Doxapram IV (see Appendix B for dosing amount).

Cardiac Arrest or Distress

1. If Medetomidine and Butorphanol were administered, administer Atipamezole IV and Naloxone IV (rather than usual IM route; see

Appendix B for dosing amounts).

2. Administer atropine IV or IM, only after Dexmedetomidine has been reversed (see Appendix B for dosing amount).

3. If the heart has stopped, administer Epinephrine into the heart (see Appendix B for dosing amount). If unable to hit the heart, administer IV.

DRUG DOSAGE CHART

The dose for each drug is:
Butorphanol @ 0.4 mg/kg or 0.18 mg/lb ..... Naloxone @ 0.02 mg/kg or 0.009 mg/lb
Medetomidine @ 0.04 mg/kg or 0.018 mg/lb ..... Atipamizole @ 0.2 mg/kg or 0.09 mg/lb

The dose for each antagonist is:

		Body Weight (lbs)/ml adm. IM											
Drug	**Conc. mg/ml**	**25**	**30**	**35**	**40**	**45**	**50**	**55**	**60**	**65**	**70**	**75**	**80**
Butorphanol (*Torbugesic*)	10	.45ml	.55ml	.65ml	.7ml	.8ml	.9ml	1.0ml	1.1ml	1.15ml	1.25ml	1.35ml	1.45ml

DRUG PROTOCOL FOR FEMALES & PUPS

	Ivermectin.	Corticosteroids (dexamethasone)	Telazol & But/Med	8way	Rabies
Pregnant Females	OK	**NO**	**NO**	**NO**	OK
Lactating Females	OK	OK	**NO***	**NO**	OK
Pups under normal age for vacc.	**NO****	na	**NO**	ok @ approp. age: 6 weeks for 8-way 16 weeks for Rabies	

***** best if it can be avoided, though we used Telazol once on female w/3 day old pups and came out ok; best if canid given time to metabolize drugs before returning to pups

****** wait until 5-6 weeks of age before administering Ivermectin

Justification:

Corticosteroids (dexamethasone) administered to pregnant females may cause an abortion

Any immobilizing drugs administered, particularly to pregnant females, could kill the pups so certainly avoid if possible; with lactating females, if you have to administer drugs, try to give the canid time to metabolize the drugs before returning to the pups

Page 2; 51: Maybe a short discussion on specifically what types of property damage is being referred to here? There are very few livestock operations on the AP, so depredation rates on livestock is relatively low. Wolves have been involved in very few depredation incidents over the years, and I'm not sure what other types of property damage sympatric canids would potentially cause? Most of the complaints we receive tend to be simple presence of canids on private property or a perceived reduction in observed game populations, which of course are not property.

Page 2; 54-55: Has there been any research done to analyze direct predation of canids on at risk ground nesting species as compared to potential benefits of canids through the control of other known nest predators?

Page 2; 57-59: In addition to collaborative research, the joint memorandum also instructs NCWRC to "review and evaluate statutory requirements for listing red wolves as state threatened in the five AP counties", to "evaluate, and if appropriate implement, adaptive approaches to regulate the take of coyotes that may result in incidental take of red wolves", and to "evaluate the status, management, and regulation of Controlled Fox Hunting Preserves". Just out of curiosity, what is the current status of these regulatory directives?

Page 3; 86-89: As part of the justification for this research the proposal states "Earlier research focused on many of the same objectives we suggest investigating here, but during a time of intense, active management. Specific management techniques are no longer being carried out and dynamics between sympatric canids are expected to have changed substantially."

Should specify what dynamics are expected to have changed. I would contend that management and the resulting dynamics on ARNWR, and Milltail particularly, have not changed significantly at all. This pack recently had similar GPS-collar based data gathered by DOT a few years ago, and I don't feel much if anything would be gained by replicating this research. We should continue to use our own VHF radio collars on the Milltail pack as the battery life lasts much longer and we can continue to monitor them as we always have, and not have to subject them to the frequent trapping for recapture and subsequent handling and processing outlined by this proposal. The joint memorandum from 2013 states that any research conducted should "promote the conservation and recovery of the red wolf and other canids on the AP." In the case of the Milltail pack especially, I think the potential risks far outweigh any potential benefits gained.

Page 4; 102-103: What information will be passed to whom specifically? I'm not sure it would be in the best interest of red wolf recovery if location information were to fall into the wrong hands.

Page 5; 132-136: This may be based on a false assumption as it is my understanding that the "federal lands only" alternative was not supposed to be our proposed alternative without first going through the NEPA process, which we are doing now. We don't yet know what the proposed alternative is going to be.

Page 6; 157: If "the most important requirement for SCR is the number of collared individuals" as stated, there is no need to initially focus trapping efforts in areas of known red wolf packs. Coyotes tend to utilize smaller home ranges than do wolves, and therefore would likely populate a particular area in higher numbers than wolves. In that sense, a greater number of collared animals may well be achieved outside of areas of known red wolf packs as long as trapping was conducted in productive habitat. Also, the premise of this proposed research is to target sympatric canids and not specifically target either species. It therefore seems contradictory and biased to initially target known red wolf packs through trapping efforts. I would suggest instead focusing on areas that known wolf packs have occupied in the past but now, due to mortality and lack of management over the last few years, the pack no longer

exists, leaving an area of unknown species composition (Mattamuskeet Ventures and Texas Plantation Gamelands are good examples). This would assist not only with the proposed research, but would provide an additional programmatic benefit of learning the species composition in current zones of ignorance. Targeting areas with known red wolf packs does not provide the additional benefit of learning species composition of an area (it is already known), and replicates data collection that has already been done. As stated above, I have concerns about targeting areas of known wolf packs, and feel the risks outweigh the potential benefits, especially since there are so few (only 3 known breeding pairs) left on the A.P. We don't need to further jeopardize them.

Page 6; 159-161: We typically wait until January to trap areas with potential red wolf puppies present in order to allow them to grow, minimizing risk of trap injury. Also, February is breeding season for wolves, and it is not a good idea to disrupt known red wolf pairs at this time, especially with the ever-present risk of injury that trapping inherently presents.

Page 6; 162-173: Releases should occur as close as possible to where the animal is trapped to avoid altering behavior and to avoid unnecessary risk to the animal attempting to get back home. This has been a recurring issue the last two or three years as the WRC has insisted that captured animals be released on ARNWR regardless of where they were captured. These releases need to happen at or near the capture site, even if that land is state owned or private property (with landowner permission), in addition to federal lands. Refuge compatibility could obviously be another issue. Also, the statement "it is most important to be able to trap and release on Alligator River NWR and the Dare County Bombing Range as those encompass the newly proposed RWRP recovery area" is based on an inaccurate premise as we have not selected a preferred alternative yet so we have no official proposed recovery area.

Page 7; 182: Are traps staked or are drags used? Both can work but appropriate equipment must be used to avoid stakes being pulled out of the ground, which often leads to the death of the captured animal. Make sure appropriate shock springs and swivels are used as well to minimize injury potential. An additional thought – make sure all trappers have secure kennels to place animals in while waiting for processing to occur. It is best to remove a captured animal from a trap as soon as possible to minimize potential injury, overheating, and escape, so have the trappers place the animals in a secure kennel right away. You'd be surprised at some of the flimsy wire cages some of them carry for this purpose. Others have used duct tape on the legs and muzzle – obviously not a good idea. Have a protocol in place for this.

Page 7; 187-190: Traps should also be covered or rendered inoperable during a hard freeze. A leg-hold trap cuts off blood circulation to the foot and can lead to frozen tissue during a hard freeze. This can lead to amputated toes and even feet.

Page 8; 215-219: We already have a protocol in place for chemical immobilization of red wolves developed by NCSU Vet school. We have used it for decades now on wolves and coyotes and there is no need to change it. Also, a syringe pole is not necessary. Simply restrain the head with a noose pole and inject with a regular syringe.

Page 9; 250-254: USFWS needs to be notified any time a red wolf is captured, injured or not, and should make the decision as to whether injuries are sufficient to euthanize the animal.

Page 9; 256-257: Red wolves absolutely should be vaccinated upon capture and treated for any diseases or illnesses present. I would recommend vaccinating coyotes before release as well. Remember the stipulation for collaborative research in the 2013 joint memorandum, that research identified should "promote the conservation and recovery of the red wolf and other canids on the AP." The wild red wolf population is far too small to be taking any unnecessary risks.

Page 10; 276-282: These animals do not automatically need to be euthanized, especially red wolves. The proposed research protocol already requires that any potential handler be vaccinated for rabies. Also, any previously captured wolf or coyote on the A.P. has already been vaccinated for rabies and other canid diseases. Animals can be quarantined for a period of time but euthanasia is not necessary.

Page 11; 298-310: Why are ear tags necessary? I would think a GPS collar that emits a VHF signal plus a PIT tag would be sufficient for identification. Also, we should use Trovan PIT tags to remain consistent with the ones already deployed on the A.P. Speaking of which, it would make more sense to use a radio-collar frequency range consistent with what is already deployed on the A.P. Not having the right set of gear when needed, or having to constantly switch between two separate sets of gear will prove to be problematic .

Page 11; 311-315: Skin biopsies are also not necessary. Genetic information can be collected from blood samples and sent to Lisette as proposed, and as we have always done. There is a protocol already in place for this.

Page 12; 332-335: Animals showing signs of mange should be held and treated for mange before release to avoid spreading it to surrounding canid population, particularly red wolves. Again, conservation of the species needs to be priority number one.

Page 12; 336-340: In the event of overheating, priority must be cooling/ensuring survival of the animal. After that assess any injuries, radio-collar, draw blood. Then weights, measurements, etc.

Page 13; 354-355: In regards to the VHF signal, we really need to continue using the 164-165 mHz frequency range already being used for canids on the A.P. While regular GPS locations may be sufficient for research purposes, there is often a need for RWRP personnel to be able to track canids in real time (depredations and other complaints, reports of injuries, den locations, telemetry flights, etc.) It is not practical to carry two separate sets of telemetry gear at all times (especially when thick vegetation or when walking long distances), or to gear aircraft with two sets of antennas, or to constantly have to switch between two sets of gear when time is a factor. There are many field-based scenarios where utilizing two sets of gear would be problematic at best. Previous researchers (including the ones cited in this proposal) utilizing VHF or GPS collars on canids for data collection within the red wolf recovery area have always used frequencies consistent with ours to help alleviate these problems.

Page 13; 358: I would set the VHF beacon to operate beyond 1600 hours daily. You occasionally run into situations (depredations or complaints for example) that require the need to track animals in real time beyond 1600 hours. Ours are set on 12 hour rotations – 0700 to 1900 (0800 to 2000 during daylight savings).

Page 14; 378: A flight every 30 days is not going to be enough to determine cause of mortality should the GPS function fail. We already fly between 50 and 100 times a year to monitor red wolves, I'm not sure an additional 12 is going to benefit anything.

Page 15; 411-412: We already do den work on red wolves. The dens should not be disturbed more than once so any data collected must be in conjunction with USFWS. With fewer than 25 red wolves currently known to exist in the wild, the survival of each and every pup is vital, so no unnecessary risks will be taken. Time spent at the den must be minimal to minimize the disturbance. Skin biopsies are not necessary. We collect a blood sample for genetics and that should suffice. I'm not sure if morphometric measurements are necessary but if done it must be completed quickly. PIT tags are implanted for future identification. We use Trovan and would prefer to keep this consistent with the canids already on the A.P.

Page 15; 413-432: Cameras at a red wolf den site are a bad idea. We have attempted the use of them a couple of times in the past. One time it caused a visible disturbance when the adults returned, and the other time it resulted in puppy deaths when the female would not re-enter the den. Again, each and every red wolf pup is vital. If attempts want to be made to experiment with cameras at den sites, use them at coyote dens but not wolf dens, at least until more is known about potential disturbance (2 to 5 meters is likely too close). Another issue with these cameras is that wolves, and likely coyotes as well, will typically move the pups to a new den site very soon after a disturbance. In the type of habitat found on the A.P., den sites are usually located in vegetation so thick cameras may be ineffective, and any human visit to the site is going to cause an unavoidable disturbance.

Page 16; 435: Red wolf carcasses go to the lab in Madison, WI as they always have. LE cases go to Asheland, OR. Coyotes can go to SCWDS.

Page 16; 436-442: We notify LE after every red wolf mortality. They decide if it will become an LE case and if they need to take possession of the animal. LE also probably won't allow genetic samples to be taken from animals they need to take possession of for evidence.

Aside from the specific concerns addressed above, I am also concerned by the overall scope of this proposal. I would prefer to see a research proposal more limited in scope with a clearer objective (for example, an analysis or quantification of predator/prey relationships on the A.P. would be beneficial), and to use equipment and protocols consistent with equipment and protocols already in place on the A.P. Sympatric canids should be targeted in current zones of ignorance (which is now the majority of the A.P.) instead of targeting known wolf packs.

If this proposal were carried out as written, it would effectively hand control and management of the red wolf program at the field level to the WRC. WRC plans to collar 25 "sympatric canids", and initially target known red wolf packs with their trapping efforts. There are only 23 known red wolves currently on the A.P. If they were to successfully radio-collar the majority of those wolves with collars emitting their own frequency range, it would severely limit our ability to monitor and manage this population. They also propose doing their own den work, using their own labs for necropsies, using separate protocols for data collection, etc. All this is concerning on two fronts. First, it is our (USFWS) legal mandate to manage and recover this federally listed species on the landscape. We do not turn over management to a state agency until the species is recovered to the point where federal protections are no longer needed. Second, the WRC has made it clear that their objective is to eradicate this species from the state of North Carolina. Turning monitoring and field management over to the WRC likely would not bode well for the recovery of this species.

While I think it is preferable in theory for the two agencies to collaboratively conserve and manage red wolves and other canids on the A.P., it is problematic when their respective objectives are polar opposites of one another. It is quite clear now, after exhaustive and repetitive reviews on the taxonomy and historical range of the red wolf, that the best available science indicates that this is indeed a valid listable species native to northeast NC. If the two agencies are to realistically work towards the conservation and management of canids on the A.P., the WRC needs to, at minimum, rescind their resolution requesting that red wolves be removed from the state of NC and declared extinct in the wild, and move towards listing the red wolf as a state listed threatened species. Then, in addition to collaborative research, we can explore joint regulatory efforts to reduce anthropogenic causes of red wolf mortality, take steps to minimize hybridization and control the coyote population as necessary, and collaboratively manage and recover red wolves on the A.P. Until then I am not comfortable handing over this level of monitoring and management of red wolves on the A.P. to WRC.

Canid Handling and Chemical Immobilization Workshop

customized for

U.S. Fish and Wildlife Service – Red Wolf Recovery Program

and

North Carolina Wildlife Resources Commission – Sympatric Canid Project

March 26-28, 2019

Instructor

Dr. Mark R. Johnson, DVM

Global Wildlife Resources

Day One

Date:	Tuesday, March 26
Location:	Coastal North Carolina National Wildlife Refuges Gateway Visitor Center, Manteo, NC – Conference Room
Time:	8:00 a.m. – 5:00 p.m.

Day Two

Date:	Wednesday, March 27
Location:	Coastal North Carolina National Wildlife Refuges Gateway Visitor Center, Manteo, NC – Conference Room
Time:	8:00 a.m. – 5:00 p.m.

Day Three

Date:	Thursday, March 28
Location:	Alligator River National Wildlife Refuge – Sandy Ridge Captive Red Wolf Facility
Time:	8:00 a.m. – 5:00 p.m.

Canid Handling and Chemical Immobilization Workshop
Customized for Red Wolf Recovery Program
March 26-28, 2019
Manteo, NC.
DRAFT OUTLINE

INTRODUCTION

A. INSTRUCTOR:

Mark R. Johnson DVM
Global Wildlife Resources
PO Box 1025, Freeland, WA 98249
E-mail: *mjohnson@wildliferesources.com*
Website: www.wildliferesources.com
Mobile: 406.570.3915

B. PARTICIPANTS

Introductions

C. WORKSHOP OBJECTIVES

- Develop confidence, skills, and knowledge for working with trapped and captive red wolves and coyotes using either physical restraint and/or chemical immobilization.
- Address the well-being of the animal as our highest priority which includes handling each canid with care, compassion, and respect. This is not just about getting our work done.
- Explore how to create a calm conscious manner to minimize the energy of conflict and reduce stress, struggles, and injuries associated with animal captures.
- Discuss the use of facilities, tools, strategies, and mannerisms for successful, safe, and humane canid capture in pen situations.
- Learn basic handling tools and techniques for physical restraint of canids including: scruff, lateral restraint, and hobbles without adding energy to any struggle.
- Become familiar with the Y pole: what it is, how it works, & how to properly use it.
- Acquire knowledge, confidence, and skills with the most current chemical immobilization drugs, drug delivery systems, and principles.
- Develop skill and understanding with animal care and monitoring vital signs of anesthetized wolves.
- Generate opportunity among workshop participants to discuss and practice canid handling and chemical immobilization with captive red wolves.

CAPTURE METHODS

A. HANDLING TRAPPED WOLVES

1. Y Pole – a humane tool for use with the syringe pole or a lead to physical restraint.
It is a safe extension of your hand. The quietest way to effectively handle canids.
Note: Use Y pole then syringe pole. Back away for the drugs to work.

a. Construction

Commercial Y poles or make your own.
Global Wildlife Resources, *GWR Products* for a lightweight, 2-piece aluminum Y pole. Recommended: buy one and have a local welder make copies.
Heart of the Earth Animal Equipment; *www.animal-traps.com* for a heavier one

b. Proper Technique for first contact – see GWR YouTube videos with dogs

Move in slowly with non-threatening manner and with good posture and confidence.
Only move in ways that build trust. Move slow and in small steps. Move in waves (stop & settle)
Utilize submissive "trance" when present.

2. Syringe Poles (avoid the term "jabsticks")

a. Tomahawk syringe pole with needle guard for 1cc or 3cc syringes.
Model PSP32. *www.livetrap.com*

b. Zoolu pole syringe – great for use with box traps
Heart of the Earth Animal Equipment, *www.animal-traps.com*

c. Campbell 1cc re-usable syringe pole
Small syringe pole for small volumes of BAM
Campbell Pet Company *https://www.campbellpet.com*

d. Safe T Flex Pole Syringe S100 (Neogen) re-usable syringe pole
Sold by livestock suppliers

B. HANDLING CAPTIVE WOLVES

1. Working in large pens

Note: It is important how we enter the pens. Earn comfort and trust to increase success.

- Facility design - large pen should have attached sub-enclosure and a shape to easily move animals. Use remote guillotine gates whenever possible.
- Holding pens ("sub-enclosures")
  - Attached to the pen where wolves can be funneled.
  - Remote guillotine gates – improves capture success and lowers energy
  - Creates confined location to effectively use Y pole or net.
  - May even have a security box for wolves to hide in – which captures them.

2. Security boxes

- Most canids like "den boxes"
- Canids can be urged to enter (with soft pressure) when boxes are in smaller sub-enclosures. Move them with Y poles.
- Should have door to close to keep them in and roof to lift to use Y pole and syringe pole.
- Ideally, wall would also drop to easily enter the box and process or remove the animal.

3. Walking a line - People can be assembled in a long line.

- Everyone must stay calm and relaxed. Minimize arm or body movement. No talking.
- Be small. No big tools in your hand. Bite sticks for safety. Or nets and Y poles.
- Keep *your* energy low and calm to keep the capture energy as low as you can.
- Follow one person's lead. Move a few steps at a time. Do not pressure the wolf. Give him time to see options.
- Move at the canid's pace. Give them time to think about their options.
- Move in waves. Soft pressure than stop and settle yourself. Look for canid to settle.
- If nets are used, position people with nets and shadow person with a Y pole at both ends of line along a wall.
- Move wolf toward Y poling corner or crate(s) or smaller enclosure.

4. Canvas Barrier - for guiding wolves to a Y poling corner or sub-enclosure

- The best material is a re-usable dark brown (?) cordura fabric 25 feet long by 5 feet high. Grommets are set along both ends and along the top edge.
- Plan, plan, plan. Long planning leads to more efficient & successful captures.
- Use caribiners to hook to fences, or make a chain of them to wrap around trees.
- At times weigh down the lower edge with the fold on the ground toward the wolf.
- Add calm people (with low energy) and Y poles.

5. Proper Y Pole Technique w captive wolves – see GWR video capturing Mexican wolf
Y pole will not work if canid wants to run. If/when it settles, slowly move a line of people to corner the animal. Calm and quiet to use and keep the submissive "trance"
If canid only runs in pen, then use barriers to move wolf into den box or nets for capture

B. NETS AND NETTING

1. Construction - Brands: Beckman, Ranger, and Frabill salmon nets

- 30" hoop diameter with 5-6 foot depth so net that can be twisted; 4-5 foot handle
- Hook-proof netting, thick cord to prevent cutting, mesh large enough to see and work through
- Basic principle is catch, twist, Y pole, and cover with towel.
- Important accessories: Y pole and towel

2. Technique and Strategy

- Good posture and relaxed attitude – stand up tall and straight
- Along a fence line: stand so your reach with the net is a few inches away from the fence
- Net should be held parallel to fence or a bit farther away; your body can hide it.
- Hide the net behind you and do not crouch. Good posture.

- Energetically invite the wolf to pass - *then quickly changer your mind*.
- Y pole person (with towel) should always shadow the net to act quickly.
- Place netters at each end of the line along a fence when walking a line

3. Accessories

a. Y Pole - a Y pole person should shadow the net person. When the wolf is caught quickly place the Y pole over the twist in the net to reduce the wolf's struggle.

b. Towel - after the Y pole place a towel over the wolf. This will reduce the wolf's struggle, reduce their stress, increase your safety to handle the net, and it looks far more professional and respectful.

c. Teach wolves to choose the Y pole
Learn good Y poling techniques and more wolves will accept it. Always add a towel.
Do not reach out with a Y pole to stop a wolf from running past
Over time, more wolves will tend to accept the Y pole over the net.

PHYSICAL RESTRAINT

A. Scruff - physical restraint of the head. (see video on YouTube channel GWRFeralDogs)
Three steps:
1. Ear in notch of thumb (this prevents squeezing the ears)
2. Fingers to corner of mouth (we will gather the cheeks)
3. Curl fingers. Thumbs stay parallel between ears. Do not scruff skin of neck to avoid choking animal

B. Lateral Restraint - animal on it's side (see video on YouTube channel GWRFeralDogs)
- Elbow at the base of the head. Hold lower front leg <u>above</u> the elbow.
- Elbow touches your knee. Do not put pressure on soft part of throat;

C. Headcover
- <u>All</u> animals benefit from a headcover at <u>all</u> times.
- Make sure it puts the animal in the dark. Can be as effective as a sedative.
- Wolf Quickmuzzle*: Four Flags Over Aspen, St. Clair MN, 800.222.9263*
- Towel when carrying wolf; Cover nets, traps, and crates as well.

D. Cloth Carrier
- MegaMover Portable Transport Unit - strong and light, maybe less durable.
- from Graham Professional *www.grahammedical.com*

E. Hobbles (see video on YouTube channel GWRFeralDogs)
- Not commonly used. Consider for safety when processing and for transport
- <u>*Always*</u> use a headcover first.
- Use short soft boat strap. NRS company – 3 foot straps, *www.nrsweb.com*
- Cross lower front leg and upper hind leg.
- Once around the top leg, once around the bottom leg, once around both legs
- Always wrap towards the body and above the carpal and tarsal joints.
- This is only intended for brief transport such as in a disaster rescue.

F. Crating A Wolf

1. Technique

Tip crate at 45 degree angle. Assign person to door.
Tail in first. Scruff is last person to let go.

2. Safety measures

Assign roles: Holding crate, controlling gate, tucking in legs, hips, scruff
Scruff is the last person to let go.

G. The Catch Pole

The catch pole may be one of the most commonly used tools for catching and controlling animals, yet they should be considered the last tool of choice.

1. Proper construction

- A rigid metal pole with a plastic coated adjustable cable loop.
- A swivel head and an instant release mechanism are most important.

2. Proper techniques

- See "Control Issues", Animal Sheltering Magazine. Jan/Feb 2013
- Those who have acquired the skill working with a Y pole recommend using the catch pole as if it is a Y pole.
- The crazier the animal gets the calmer we should be.

3. Things *not* to do

- No lifting. No pulling.
- Do not hang catch poles by their loops.

CHEMICAL IMMOBILIZATION

A. TERMINOLOGY

1. Anesthesia – lack of consciousness, an unresponsiveness. An anesthetic produces anesthesia. Examples: Ketamine and tiletamine; M-99 and carfentanil

2. Tranquilizer – induces a calming effect without affecting the central nervous system (CNS). Increasing from the recommended dose does not have increased action. Examples: zolazepam and acepromazine

3. Sedative – reduces an animal's response and *depresses CNS*. Stronger immobilization than tranquilizers, more side effects. Increasing from the recommended dose has increased action. Examples: xylazine and medetomidine

4. Antagonist - antidote; a drug which specifically counteracts another drug. Examples: yohimbine, tolazoline, and atipamizole

LAB 1: Needle and Syringes Lab

Learn safe and controlled use of needles and syringes
Safe recapping of needles; Handling syringe poles

IMMOBILIZING DRUGS

A. Dissociative anesthetics (Cyclohexamines) - ketamine and tiletamine

1. Ketamine - anesthetic; Schedule III; Used with a sedative

- Possibly the most versatile drug for chemical capture; wide safety margin
- Produces anesthesia w/ muscle tension
- Swallowing and ear-twitching reflexes generally remain intact
- Produces strong heart rate and breathing
- Can produce excessive salivation and seizures
- Recovering animals are <u>hypersensitive</u> to stimulus. Minimize stimulus during recovery.

2. Tiletamine – anesthetic; Schedule III ; Telazol® (500 mg in vial)

- Sold as TWO drugs: tiletamine (an anesthetic) and zolazepam (a tranquilizer)
- Sold as powder in 5 ml vial - add sterile water, vary concentration to meet your needs
- 2.5 times more potent than ketamine, but also with wide safety margin
- Can produce excessive salivation
- Muscle relaxation varies with species: tense in dogs, relaxed in wolves and bears.
- Limited shelf life when mixed with water LABEL DATE WHEN MIXED.

B. Sedatives (Alpha-2 agonists) - xylazine, medetomidine

1. Xylazine – sedative; Usually used with ketamine to produce a relaxed anesthesia

- Produces sedation, muscle relaxation, analgesia, slow heart, slow breathing
- Can promote bloat, vomiting, hypotension, loss of thermoregulation
- Used alone, animals will wake with sound or touch stimulus then return to "sleeping"
- Animals recover with a wobbly drunk-like state
- Can be antagonized with yohimbine, tolazoline, or Atipamezole

2. Medetomidine - sedative (Wildlife Pharmaceuticals [10 ml vial, 20mg/ml])

- 10-20 times more potent than xylazine, reduces volume of ketamine needed
- Same negative side effects as xylazine. Antagonize with atipamezole only.

C. Butorphanol - mild opioid; add butorphanol when using ketamine/xylazine combinations.

- Sold as TWO drugs: tiletamine (an anesthetic) and zolazepam (a tranquilizer)
- Ketamine/xylazine combinations can be inconsistent in their effects, tense, result in sudden wake-ups, and have tense and disoriented recoveries.
- Butorphanol will enhance xylazine effects and improve the quality of the immobilizations.
- Butorphanol is also a very strong analgesic.
- Ungulates: Add 0.05 - 0.1 mg/kg. Carnivores: 0.2 mg/kg.

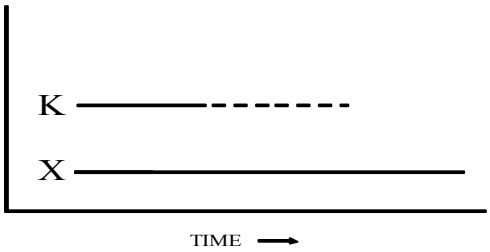
D. Alpha-adrenergic <u>Antagonists</u> - yohimbine, tolazoline, or atipamezole

1. <u>Yohimbine</u> - Yobine (20 ml vial, 2mg/ml); Antagonil (20 ml vial, 5mg/ml)
   Give 0.15mg/kg IV, IM, or SQ. For antagonizing xylazine. DOES NOT antagonize ketamine. Less reliable in bovids.

2. <u>Tolazoline</u> - (Tolazine, Wildlife Pharmaceuticals [100 ml vial, 100mg/ml])
   More consistent and effective than yohimbine in sheep and other ruminants.
   For antagonizing xylazine.

3. Atipamezole - (Wildlife Pharmaceuticals)
   Made for antagonizing medetomidine. Also antagonizes xylazine.
   Generally give equal volume of medetomidine, but follow label
   Generally give 1 mg for every 10 mg xylazine. Administer IM.
   Acts much more specifically on xylazine than yohimbine and tolazoline

E. BAM (See Handout K) - BAM is a Butorphanol, Azaperone, & Medetomidine mix from Wildlife Pharmaceuticals. Many wildlife agencies have adopted this drug combo though it is still currently classified as experimental. Effective in a wide variety of species. Quick knockdown. Produces a smoother and more rapid recovery than ketamine or Telazol combos. For more information visit: *http://www.zoopharm.net/drugs/pdf/BAM-V2.pdf*



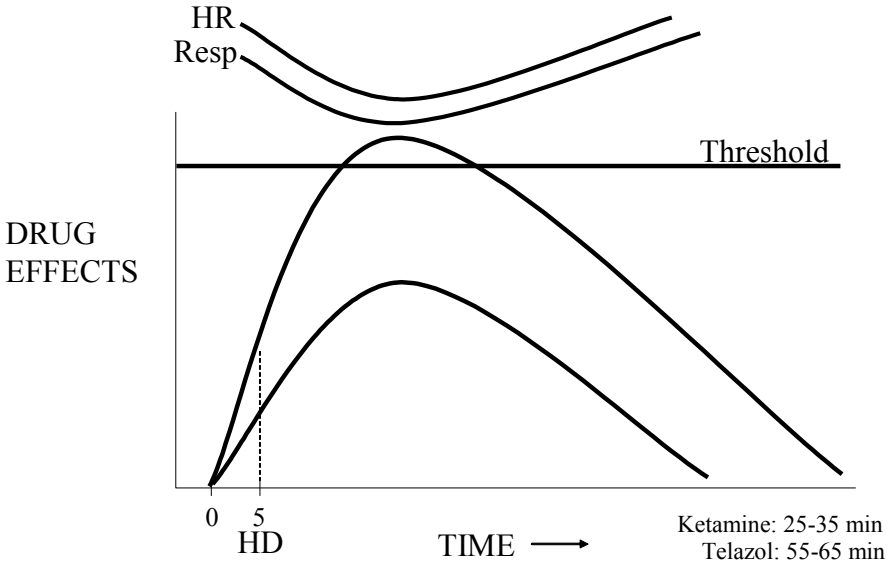
F. Accessory Drugs

1. Atropine sulfate - (small animal [0.5mg/ml] and large animal [2 mg/ml])
   Imitates fight or flight responses: i.e. stops salivation, increases heart rate
   Most commonly used to reduce excessive salivation or strengthen heart function
   Dilates pupils so protect eyes from sunlight
   Increases metabolism of the drug

2. Doxapram hydrochloride - (Dopram-V® in 20mg/ml concentrations)
   Stimulates breathing – short term so may require additional CPR
   Occasionally used to increase metabolism of ketamine or Telazol®

PRINCIPLES OF IMMOBILIZATION

B. KETAMINE/XYLAZINE EFFECTS

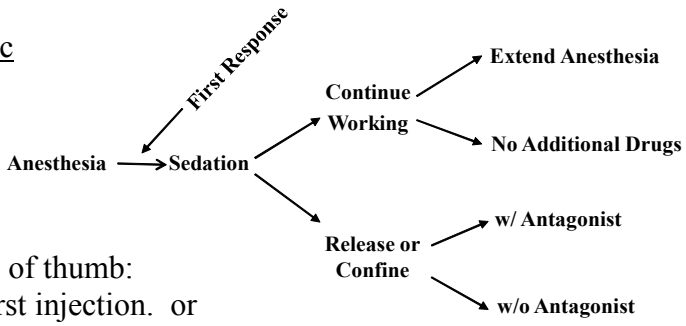


B. KETAMINE/XYLAZINE INTERACTIONS

Drug	*Effects on Animal*
1. Ketamine	→
	→
	→
2. Xylazine	→
	→
	→
3. K/X Combination	→
	→
	→

ADMINISTERING THE DRUG

A. GENERAL SCENARIO



B. OPTIONS WHEN ANESTHETIZED ANIMAL BEGINS TO RESPOND

1. Continue working

a. Extend anesthesia (redosing)
Give ½ original ketamine dose IM.
or give ¼ original ketamine dose IV for brief unresponsiveness

b. Work without more anesthetic
Check headcover.
Minimize stimulus.

2. Release (free-ranging) animal

a. Antagonize drug – two rules of thumb:
1) Give 45 minutes after first injection. or
2) Give 20 minutes after first response.

b. Allow animal to awake slowly without an antagonist
Reduces hypersensitivity when waking in a confined space.

LAB 2: Patient Monitoring Lab (with live animals)

Preparing for the final drugging lab on Day 3
Become confident with the stethoscope and monitoring vital signs with awake animal
Become comfortable working with the field form, animal, and team members
Practice conducting a physical exam and find blood vessels

ADDRESSING ANIMAL HEALTH

A. BASIC CARE

1. Ground Cloth

Another tool good for the animal, biologist, and profession.
Canvas - make with untreated canvas
(Vendor: Montana Canvas, *http://www.montanacanvas.com;* request wildlife handling cloth designed by Global Wildlife Resources; 3'x 5' or 5'x 5')
(Vendor: MegaMover Portable Transport Unit by Graham Professional *www.grahammedical.com*) Strong and light, may be less durable.

2. Body position

a. Sternal -
To ensure airway is open.
When animal is hot – exposes "armpits" (axillas) and groin to cool ground.
Strive to work ungulates in sternal position to minimize bloat. Position to encourage belching. Hold drugged ungulate with neck upright to prevent bloat and chin lower than larynx to move saliva away from larynx and prevent regurgitation.

b. Lateral (laying on side) - When animals are cold.
If ungulate is on side, keep right side down to observe left flank for bloat.

3. Headcover ± eye solution - ALWAYS USE A HEAD COVER (See Handout L)

All animals benefit from a head cover. Design a headcover to put them in the dark.
Good for animal. Safer for the biologist. Looks more caring and professional.
(Canids: Four Flags Over Aspen, *http://www.fourflags.com*
Ophthalmic solution may be better than ointment – Neither should ever have steroids

B. PATIENT MONITORING

1. Physical Exam (See Handout M)

This is the first procedure to do when the animal is in hand.
Create a customized exam and examine each animal. This includes first TPR.

2. TPR (Vital Signs)

a. **T**emperature – *Guide the body temperature, don't react to it.*
Ask two questions:
1. What temperature is the animal?
2. Which direction is the temperature going? – Record in chronological order.
A healthy temperature range for temperate climate mammals is 100-103 degrees F.

b. **P**ulse (Heart Rate) -
Use stethoscope to monitor heart rate. Find heart using hands on both sides of chest.
Search where elbow meets middle of rib cage (about 7th rib). Strongest on left side.
For back up use femoral pulse. Located in "femoral triangle" on inside of leg
Write femoral pulse in Comments on field form separate from Pulse (heart rate).

c. **R**espiration - Ask two questions:
1) What is the respiratory rate? (evaluate both rate and size of breath)
Watch chest or abdomen.
2) How does the airway sound? Listen to larynx with stethoscope for gurgling.
Adjust body position to minimize gurgling when possible.

d. Capillary Refill Time (CRT) and color of the gums.
Press on gums above canines (predators) or on dental pad (ungulates)
A healthy CRT is less than 2 seconds. Pink is healthy color.
Use CRT and color of gums to evaluate if heart rate and respiratory rates are within healthy range.

e. Pulse oximeter – seriously consider adding a pulse oximeter to your field equipment; monitors heart rate and oxygen in blood (SPO_2).

VETERINARY EMERGENCIES

A. Hypothermia –low body temperature, affects health and metabolism of drug

1. Prevention – regular monitoring and recording of body temperature, ground cloth, attention to weather conditions

2. Treatment – Move into sun (address where each person is standing), change body position, padding under the animal, sleeping bags, cover w/ reflecting blanket, chemical heat pads

B. Hyperthermia – high body temperature from internal or external sources; more common and serious for the animal. Reduces ability for blood to carry O_2 to the brain; rapid pulse and breathing, dark mucous membranes

1. Prevention – limit chase time, regular monitoring and recording of temperature, body position sternal to expose armpits and groin, attention to weather conditions.

2. Treatment – move into shade, wet ground and body, water and alcohol mix for severe conditions. Provide oxygen. stomach tubes w/ electrolytes IV fluids. Cold water enemas are *not* recommended – ineffective and removes ability to monitor temp.

C. Trap Injuries - be aware of the potential for pressure necrosis which is not visible.

1. Punctures – trim hair over puncture and flush with 10% betadine or nolvasan solution

2. Abrasions - trim hair around, clean debris from wound and flush repeatedly with 10% betadine or nolvasan solution

3. Cuts - trim adjacent hair to keep wound open, remove debris, flush repeatedly with 10% betadine or nolvasan solution, possibly pack w/ nolvasan ointment

4. Fractures and severed limbs **Never release an animal with a bandage, no exceptions!**

RECOVERY

Trapline - professional standard is to stay with animal until his head is up, it can swallow, and negotiate his airway.

Captive wolves - Allow to wake up separated from other wolves. Offer quiet and visual security.

LAB 4: Chemical Immobilization with <u>live animals</u> (hand injection):

1. Chemical immobilization and learning the animal's response to immobilizing drugs
2. Monitoring temperature, pulse, and respiration and other vital signs
3. Processing procedures (blood collection, radio-collaring, etc) appropriate for canids
4. Documenting chemical immobilization on a field form
5. Professional mannerisms maximizing animal care and field success

TOPICS FOR DISCUSSION

Debriefing to discuss chemical immobilization of red wolves

Open discussion and addressing loose ends.

Evaluations and Pass out Certificates of Training

Mark R. Johnson DVM.

Dr. Mark is the wildlife veterinarian and founder of Global Wildlife Resources (GWR) in Freeland, WA. GWR specializes in wildlife capture and handling and provides the most current and extensive training in wildlife chemical capture. His courses are invaluable to college students, state/federal/tribal wildlife professionals, zoo caretakers, game farms, veterinary technicians, veterinarians, and animal control officers.

Dr. Mark was Project Veterinarian for the U. S. Fish and Wildlife Service's 1995-96 gray wolf reintroduction program into Yellowstone National Park and central Idaho and was the wildlife veterinarian for Yellowstone National Park for four years - the first veterinarian working for NPS. He has taught canid capture and handling to the MN and Fargo Zoos as well as to many captive wolf programs. He is a primary instructor for USDA Wildlife Services and has taught exclusive courses for Michigan and Maine biologists. He is Affiliate Faculty of University of Montana.

In the past several years, his experience in handling wolves has led him to teach humane capture and handling of feral dogs around the world. This training is helping countries on every continent with rabies eradication programs & supporting humane methods for managing dog overpopulations. He assisted with three rescue trapping operations after Hurricane Katrina and his on-site courses included training in India and Palau.

With every course Dr. Johnson strives to support and empower each student and professional as well as improve the well-being of each animal handled for wildlife research and management. He is also learning from every course with new information, tools, and techniques and has acquired an exceptionally strong understanding of wildlife chemical immobilization in North America.

IN THE UNITED STATES DISTRICT COURT
FOR THE EASTERN DISTRICT OF NORTH CAROLINA
NORTHERN DIVISION
No. 2:15-CV-42-BO

RED WOLF COALITION, DEFENDERS OF WILDLIFE, and ANIMAL WELFARE INSTITUTE, Plaintiffs, v. UNITED STATES FISH AND WILDLIFE SERVICE; JIM KURTH, in his official capacity as Acting Director of the United States Fish and Wildlife Service; and MIKE OETKER, in his official capacity as Acting Regional Director of the United States Fish and Wildlife Service Southeast Region, Defendants.[1]	)	ORDER

This cause comes before the Court on cross-motions for summary judgment pursuant to Rule 56 of the Federal Rules of Civil Procedure. The appropriate responses and replies have been filed, and a hearing was held before the undersigned on October 17, 2018, at Raleigh, North Carolina. In this posture, the motions are ripe for ruling.

BACKGROUND

Factual[2] and procedural background

The wild red wolf, or *Canis rufus*, is again close to extinction, with as few as forty wolves identified in the wild in April 2018. [DE 88 at 5]. In 1967, the red wolf was designated as an

[1] Jim Kurth and Mike Oetker have been substituted for defendants Daniel M. Ashe and Cynthia Dohner pursuant to Fed. R. Civ. P. 25(d).

[2] The factual background is comprised primarily of public record and undisputed facts as proffered by plaintiffs and reflected in defendants' combined response to plaintiffs' statement of uncontested facts and affirmative statement of uncontested facts. [DE 87]. Plaintiffs' appendices are at [DE 82, 83].

endangered species under the Endangered Species Preservation Act of 1966,[3] and, in 1980, the species was declared extinct in the wild. In 1986, the United States Fish and Wildlife Service (USFWS) instituted a special rule under Section 10 of the Endangered Species Act of 1973 to establish the reintroduction of red wolves in North Carolina, specifically on the Alligator River National Wildlife Refuge in Dare County. *See* 51 Fed. Reg. 41,790 (Nov. 19, 1986); 50 C.F.R. § 17.84.[4] The red wolf was designated as a non-essential experimental population under the Endangered Species Act–experimental status[5] would allow USFWS more discretion in devising an active management program and the non-essential designation was applied because the species was considered to be fully protected in six separate captive locations. *Id.* Four captive-bred pairs of red wolves were released to the Alligator River reintroduction site in 1987. The Red Wolf Recovery Area currently encompasses approximately 1.7 million acres in Dare, Hyde, Tyrrell, Washington, and Beaufort Counties, and includes four national wildlife refuges, a U.S. Air Force bombing range, state-owned, and private lands. *See* 60 Fed. Reg. 18,940.

The red wolf 10(j) rule prohibits the take[6] of a red wolf except in those limited circumstances. 50 C.F.R. § 17.84(c)(2). Intentional or willful takes of red wolves are not permitted in the Red Wolf Recovery Area unless it is in defense of a person's own life or the lives of others; the animal is in the act of killing livestock or pets; or the take has been authorized by USFWS project personnel after efforts by USFWS to capture the animal have been abandoned, provided

---

[3] Pub. L. 89-669, October 15, 1966, 80 Stat. 926, a predecessor to the Endangered Species Act of 1973.

[4] Referred to herein as the 10(j) rule or red wolf rule.

[5] An experimental designation further means that red wolves are treated as threatened, rather than endangered, species for purposes of Sections 4(d) and 9 of the ESA. *See Gibbs v. Babbitt*, 214 F.3d 483, 487 (4th Cir. 2000).

[6] "Take" is defined by the ESA to mean "harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct." 16 U.S.C. § 1532(19).

that the USFWS project leader has approved of the take in writing. *Id.* § (c)(4)(i); (iii); (v). All takes are additionally subject to reporting requirements. *Id.*

From the red wolf recovery program's inception, it was understood that the interaction between red wolves and humans in the Red Wolf Recovery Area would be an issue which would require effective management in order for reintroduction of the species to be successful. *See* Pl. App. 333-357 (USFWS Red Wolf Recovery/Species Survival Plan). To that end, USFWS issued an internal document in January 1999 entitled "Guidelines for Applying the Current Red Wolf Rule (April 13, 1995) to Requests to Remove red wolves from private land." Pl. App. 723. The 1999 Guidelines distinguished between problem wolves and non-problem wolves. Problem wolves are wolves which have engaged in actions that directly caused the loss of personal property and wolves which are exhibiting inappropriate behavior, such as a tolerance of humans, which may suggest the wolf would become a more serious problem. Under the 1999 Guidelines, reports of problem wolves would be addressed by field personnel within forty-eight hours, and problem wolves would be captured and removed if feasible, or authorization to landowners to effect a lethal or non-lethal take would be given. *Id.* Requests to retrieve non-problem wolves from private land, however, would be addressed within manpower limits, and whether traps would be set to capture the non-problem wolf would be subject to certain criteria. *Id.*

The 1999 Guidelines for implementing the red wolf 10(j) rule were drafted in response to continuous requests from two or three private landowners to remove red wolves from their property, in combination with the increase in red wolf population and the logistical and economic difficulties with continuing to try to honor all requests for red wolf removal. Pl. App. 731. USFWS noted that removal of non-problem wolves "may be detrimental to the conservation of the species by preventing natural expansion and recovery of the species, and by contributing to the

establishment of coyotes." *Id.*; *see also* Pl. App. 723. In essence, beginning in the late 1990s, USFWS focused efforts on addressing landowner complaints about problem wolves, and shifted away from making efforts to remove every wolf identified on private property. The 1999 Guidelines referenced addressing landowner concerns regarding the presence of non-problem wolves primarily in terms of capture and removal and other non-lethal take methods.

Coyotes were not present in the Red Wolf Recovery Area when the red wolf reintroduction program was initiated. As the presence of coyotes in the area increased in the late 1990s, USFWS implemented an adaptive management work plan to prevent coyote-red wolf interbreeding, which included the sterilization of coyotes in the wild and use of sterile coyotes as placeholders; placeholder coyotes would hold territories as against other coyotes territories until the placeholder territories were taken over by red wolves either naturally or by management action. *See* Pl. App. 500. In 2005, the Red Wolf Recovery Adaptive Work Plan included the dual goals of reducing interbreeding between red wolves and coyotes and building and maintaining the wild red wolf population in the Northeastern North Carolina recovery area. Pl. App. 808-814. Pup fostering, or placing captive-born red wolf pups in the den of wild wolf parents, was determined to be a "significant and useful population management tool in red wolf recovery". Pl. App. 470. In the 2007 Red Wolf 5-year Status Review, Pl. App. 491-548, the reintroduction of red wolves to the Red Wolf Recovery Area was determined to be a "remarkable success," with nearly 130 red wolves in the wild. *Id.* at 523.

"Recall[ing] that wolves were rather easily exterminated from the U.S. during the predator control efforts of the early 20th century, while at the same time the range of the coyote increased," Pl. App. 820, the 2010-2012 Red Wolf Adaptive Management Plan recognized that eliminating the breeding potential of eastern coyotes within the red wolf area would support increasing the red

wolf population. Pl App. 820-827. These same goals of reducing coyote interbreeding and increasing the wild red wolf population were repeated in the 2013-2015 Red Wolf Adaptive Management Plan. Pl. App. 846-859. Other than coyote interbreeding, the 2007 Status Report cited human interaction and gunshot mortality as the primary areas of concern for the viability of the wild red wolf population. Pl. App. 523-24.

On February 6, 2014, USFWS issued the first lethal take authorization to a private landowner under 50 C.F.R. § 17.84(c)(4)(v). Pl. App. 938-940. The authorization was in a letter from Leopoldo Miranda, Assistant Regional Director, Ecological Services. Pl. App. 938-940. USFWS renewed the February 2014 take authorization twice – once on September 23, 2014, and again on April 27, 2015.

In September 2014, USFWS noted that, over a period of several weeks, 228 letters requesting that red wolves be removed from private land had been received, Pl. App. 949, and by October 30, 2014, USFWS had received 405 individual requests to remove red wolves from private land. Pl. App. 951. On follow-up from USFWS personnel, however, it was determined that numerous individuals who had signed letters had thought they were signing a coyote hunting petition, while others stated that that they did not have red wolves on their property, or that they did not object to having red wolves on their property; other requests for removal contained no contact information or were duplicate requests from the same address. Pl. App. 949-951.

Citing population decline and growing stakeholder concerns, USFWS hired the Wildlife Management Institute "to conduct an independent evaluation of the Red Wolf Recovery Program that focused on supporting science, program management, and human dimensions." [DE 88 at 11] Miranda-Castro Decl. ¶ 4. On January 29, 2015, the North Carolina Wildlife Resources Commission passed resolutions requesting that defendants declare the red wolf extinct in the wild

in North Carolina and terminate the Red Wolf Reintroduction Program for free-ranging red wolves. Pl. App. 972-74.

Beginning in the winter of 2015, USFWS stopped conducting coyote sterilizations. Pl. App. 23, Harrison Dep. at 96. Releases of red wolves into Eastern North Carolina were also discontinued in 2015, as was pup fostering. Benjamin Dep. at 227-28; *see also* [DE 88 at 271] (June 30, 2015 Press Release: Service Halts Red Wolf Reintroductions Pending Examination of Recovery Program).

A second take authorization was granted by Pete Benjamin, Field Supervisor, to two additional landowners on May 20, 2015, Pl. App. 1006-7, which resulted in the lethal take of a red wolf on June 17, 2015. Pl. App. 1009. The red wolf that was killed was a non-problem, six-year old denning mother. Pl. App. 1013. In June 2015, USFWS issued an internal memorandum providing revised procedures for responding to landowner requests for removal of red wolves. Pl. App. 1020-22. The 2015 procedures provide that lethal take authorizations for specific wolves will be provided to landowners where removed wolves return to the subject property or where reasonable efforts to capture known wolves are unsuccessful. Unlike the 1999 Guidelines, the 2015 procedures do not distinguish between problem and non-problem wolves. *Id.* On June 30, 2015, USFWS publically announced that it would be conducting a "thorough and deliberate evaluation of the red wolf recovery program" and confirmed its commitment to "get[ting] the science right, [and] rebuild[ing] trust with our neighbors . . . state partners and many stakeholders . . .." [DE 88 at 272].

In October 2015, USFWS estimated there were 50-75 red wolves in the wild, and the last publically released population estimate shows an estimated 46-60 red wolves in the wild. Pl. App. 1114. Plaintiffs instituted this action in November 2015, and the Court issued a preliminary

injunction preventing the take of non-problem wolves on September 28, 2016. As of November 2017, as few as two or three breeding pairs of red wolves remain in the wild population. Pl. App. 258-59, Benjamin Dep. II at 145-46.

In May 2017, USFWS published an advance notice of its intent to develop a proposed rule, prepare a NEPA document, and convene two public scoping meetings. Miranda-Castro Decl. ¶ 7. USFWS completed a five-year status review of the red wolf on April 23, 2018, and intends to finalize its NEPA document and to either finalize or withdraw its proposed rule by November 30, 2018. *Id.* ¶¶ 9, 12, 13. During the rule-making process, USFWS states that it is continuing to actively manage the red wolf population by monitoring radio-collared red wolves; using remote sensing cameras and scent stations to assess movement, pack dynamics, and the general health of the wolves; and by using captive red wolves for educational purposes. *Id.* ¶ 14.

Plaintiffs' claims

Plaintiffs' amended complaint alleges that defendants have violated the Endangered Species Act (ESA), 16 U.S.C. § 1531 *et seq.*, as follows: that defendants have violated Section 9 by authorizing private take of red wolves without satisfying the requirements of 50 C.F.R. § 17.84(c)(4)(v); that defendants have violated Section 4 by administering the red wolf rule in a manner that is failing to provide for the conservation of red wolves; that defendants have violated Section 4 by failing to conduct the mandatory five-year status review of the red wolf species; and that defendants have violated Section 7 by failing to administer the red wolf recovery program in furtherance of the conservation purposes of the ESA and by failing to ensure that administration of the red wolf recovery program pursuant to 50 C.F.R. § 17.84(c) is not likely to jeopardize the red wolf's continued existence. [DE 20] Amd. Cmpl. ¶¶ 114-145. Plaintiffs further allege that defendants have violated the National Environmental Policy Act (NEPA), 42 U.S.C. §§ 4321-47,

by modifying their administration of the red wolf rule without completing an environmental assessment or environmental impact study. Amd. Cmpl. ¶¶ 146-151. At bottom, plaintiffs challenge defendants' actions in authorizing the lethal or non-lethal take of red wolves on private land without first satisfying the requirements of the governing regulations and in shifting their efforts and administering the red wolf rules and regulations in a manner resulting in a failure to provide for the conservation of the wild red wolf population.

DISCUSSION

In their motion for summary judgment, plaintiffs asks this Court to find that defendants are violating and will continue to violate the ESA and its implementing regulations as well as NEPA. Plaintiffs further request that the Court, pursuant to its equitable authority: maintain the injunction against the capturing and killing of non-problem wolves as issued by the Court as a preliminary injunction; order the USFWS to, within thirty days of the date of entry of this order, reinstate the coyote sterilization program and red wolf releases or explain why such action is not necessary for the conservation of the red wolf; and require that any subsequent modification to the historic implementation of the red wolf rule or the longstanding red wolf adaptive management program go through the required analysis under the ESA, NEPA, and the Administrative Procedures Act before they take effect.

In response, defendants argue that, due to recent changes to management of the red wolf population, plaintiffs' claims are moot and the Court lacks subject matter jurisdiction to consider them. Defendants further argue that, if plaintiffs' claims are not found to be moot, the USFWS' actions regarding the red wolves comply with the ESA and NEPA; defendants also contend that plaintiffs' request for mandatory injunctive relief must be denied because it lacks any basis in law or equity.

I. Standard of review

Generally, a motion for summary judgment may not be granted unless there are no genuine issues of material fact for trial and the movant is entitled to judgment as a matter of law. Fed. R. Civ. P. 56(a). Under the Administrative Procedures Act (APA), 5 U.S.C. § 702, which the Court has previously determined applies to plaintiffs' claims, "[s]ummary judgment . . . serves as the mechanism for deciding, as a matter of law, whether the agency action is supported by the administrative record and otherwise consistent with the APA standard of review." *Sierra Club v. Mainella*, 459 F. Supp. 2d 76, 90 (D.D.C. 2006). Thus, when reviewing agency action under APA, a court does not consider whether there are disputed issues of material fact, but rather must "determine whether or not as a matter of law the evidence in the administrative record permitted the agency to make the decision it did." *Occidental Eng'g Co. v. I.N.S.*, 753 F.2d 766, 769 (9th Cir. 1985).

Under the APA, agency action shall be set aside by a reviewing court if its "arbitrary, capricious, an abuse of discretion, or otherwise not in accordance with law." 5 U.S.C. § 706(2)(A). "Courts must conduct a 'searching and careful' inquiry into the agency decision, although this review is ultimately a 'narrow' one." *J.H. Miles & Co., Inc. v. Brown*, 910 F. Supp. 1138, 1146 (E.D. Va. 1995) (quoting *Citizens to Preserve Overton Park, Inc. v. Volpe,* 401 U.S. 402, 416 (1971)). Review of agency action under the APA is highly deferential, *Ohio Valley Envtl. Coal. v. Aracoma Coal Co.*, 556 F.3d 177, 192 (4th Cir. 2009), but a court must be mindful not to rubber-stamp agency decisions, as doing so would abdicate the judiciary's responsibility under the Act. *Nat. Res. Def. Council, Inc. v. Daley*, 209 F.3d 747, 755 (D.C. Cir. 2000) (citation omitted). Agency action must be deemed arbitrary and capricious where the agency has "relied on factors which Congress has not intended it to consider, entirely failed to consider an important aspect of

the problem, offered an explanation for its decision that runs counter to the evidence before the agency, or is so implausible that it could not be ascribed to a difference in view or the product of agency expertise." *Motor Vehicle Mfrs. Ass'n of U.S., Inc. v. State Farm Mut. Auto. Ins. Co.*, 463 U.S. 29, 43 (1983).

II. Mootness

As it concerns a threshold inquiry, the Court considers first defendants' argument that the Court now lacks subject matter jurisdiction over this case because plaintiffs' claims are constitutionally or prudentially moot.

Article III of the United States Constitution limits federal court jurisdiction to actual "cases" and "controversies" and requires that a dispute remains "live"; litigants must maintain a "personal stake" in the outcome throughout the course of litigation. *U.S. Parole Comm' n v. Geraghty*, 445 U.S. 388, 395– 96 (1980). "The requisite personal interest that must exist at the commencement of the litigation (standing) must continue throughout its existence (mootness)." *Id.* at 397 (quotation omitted). "Simply stated, a case is moot when the issues presented are no longer 'live' or the parties lack a legally cognizable interest in the outcome." *Powell v. McCormack*, 395 U.S. 486, 496 (1969). A federal court lacks subject matter jurisdiction to decide a case which is moot due to Article III's case or controversy requirement. *Com. of Va. ex rel. Coleman v. Califano*, 631 F.2d 324, 326 (4th Cir. 1980).

The doctrine of prudential mootness permits a court to, in its discretion, decline to enter injunctive and declaratory relief where the court can no longer provide an effective remedy and it would be imprudent to decide the case. *S-1 v. Spangler*, 832 F.2d 294, 297 (4th Cir. 1987); *Feldman v. Pro Football, Inc.*, 579 F. Supp. 2d 697, 706 (D. Md. 2008). In deciding whether issues have become prudentially moot, courts consider three factors: whether the specific relief

sought no longer has sufficient utility to justify a decision on the merits; the difficulty and sensitivity of the core issues in the case; and finally whether the challenged acts are capable of repetition yet likely to evade review. *Spangler*, 832 F.2d at 297-298; *see also Smyth v. Carter*, 88 F. Supp. 2d 567, 571 (W.D. Va. 2000). If a case or claim is determined to be prudentially moot, a court may avoid deciding the constitutional question of Article III mootness. *United States v. Under Seal*, 757 F.2d 600, 602 (1985); *Smyth*, 88 F. Supp. 2d at 570.

Defendants argue first that plaintiffs' third claim for relief, which seeks the undertaking of a five-year review of the red wolves as required by Section 4 of the ESA, 16 U.S.C. § 1533(c)(2), is constitutionally moot. The last five-year Section 4 species review had occurred in 2007, and, at the time of the filing of plaintiffs' complaint in 2015, no five-year review had been conducted since that time. Defendants assert that a new species status assessment of the red wolf was completed on April 19, 2018, and a five-year status review was completed on April 23, 2018. As the Court could not order defendants to conduct the Section 4 five-year review because it was conducted in April 2018, the Court, in its discretion, finds that its inability to order an effective remedy has rendered this claim prudentially moot. The Court need not, therefore, consider the constitutional question and plaintiff's third claim for relief is dismissed.

As to plaintiffs' remaining claims, the doctrine of prudential mootness is not applicable. Defendants argue[7] that because they have undertaken new rulemaking, and anticipate that a new red wolf 10(j) rule will be final by November 30, 2018, plaintiffs' claims which are based on the current 10(j) rule are moot. However, the claims before the Court are not particularly sensitive or difficult, and the specific relief sought by plaintiffs continues to have utility – while defendants have initiated the proposed rulemaking process, and *contend* that they will have a final rule in

[7] Defendants argue only that plaintiffs' remaining claims are prudentially moot.

place by November 30, 2018, there is no impediment to this Court enjoining defendants or providing declaratory relief pending publication of a final rule. *See Defs. of Wildlife v. Jackson*, 791 F. Supp. 2d 96, 111 (D.D.C. 2011) (request to prevent agency action until ESA Section 7 consultation has been completed not moot where consultation has been initiated during pendency of case). Because the "conclusion of the [rulemaking] process . . . lies somewhere in the [] future" plaintiffs' remaining claims are not prudentially moot and the Court will consider them on the merits. *W. Virginia Highlands Conservancy v. Norton*, 161 F. Supp. 2d 676, 680 (S.D.W. Va. 2001).

III. Analysis

Plaintiffs' ESA Section 9 claim relates to the grant of two lethal take authorizations under 50 C.F.R. § 17.84(c)(4)(v). It is well-established that "an agency action may be set aside as arbitrary and capricious if the agency fails to comply with its own regulations." *Nat'l Envtl. Dev. Ass'ns Clean Air Project v. Envtl. Prot. Agency*, 752 F.3d 999, 1009 (D.C. Cir. 2014) (internal quotation and citation omitted); *see also Steenholdt v. Fed. Aviation Admin.*, 314 F.3d 633, 639 (D.C. Cir. 2003) (federal agencies must follow own rules). The take authorizations issued in 2014 and 2015 failed to comply with the red wolf 10(j) rule, and therefore violated Section 9 of the ESA. *See Gibbs v. Babbitt*, 214 F.3d 483, 488 (4th Cir. 2000) (Section 9 take prohibition extended to experimental red wolf populations subject to exceptions). The take authorizations were issued under 50 C.F.R. § 17.84(c)(4)(v), which provides that:

> Any private landowner may take *red wolves* found on his or her property in the areas defined in paragraphs (c)(9)(i) and (ii) of this section *after* efforts by project personnel to capture such animals have been abandoned, *Provided* that the Service project leader or biologist has approved such actions in writing and all such taking shall be reported within 24 hours . . ..

50 C.F.R. § 17.84(c)(4)(v) (some emphasis added).

Contrary to defendants' arguments, the take authorizations failed to comply with the plain language of the red wolf 10(j) rule, which requires that red wolf take authorizations for a private landowner be approved "after efforts by project personnel to capture such animals have been abandoned." The February 2014 take authorization refers to unconfirmed canids[8] on the subject property, the extent of whose use of the property was also unconfirmed. The May 2015 take authorization cites no direct evidence of wolves on the subject property. However, in both authorizations, after noting that the properties are adjacent to a National Wildlife Refuge on which red wolves are known to occur, USFWS states that, in light of staffing commitments and lack of access to trap on the subject property, USFWS was foreclosed from pursuing animals that may be on the subject land "and *in that sense* must abandon efforts to capture and relocate the animal ourselves." *See* Pl. App. 939 (emphasis added).

The 2014 and 2015 take authorizations were issued because landowners had refused to give USFWS access to continue trapping or engaging in other efforts. Abandonment of USFWS efforts based on a landowner's refusal to grant USFWS access to their property cannot serve as a proper basis for issuing a lethal take authorization under § 17.84(c)(4)(v), as doing so would impermissibly tip the scales in favor of public demand and away from USFWS' congressionally mandated goal to recover and rehabilitate the red wolf in the wild. In addition to requiring USFWS to *actually* abandon attempts to capture red wolves on private land prior to issuing a take authorization, the red wolf 10(j) rule contemplates that USFWS would have abandoned efforts to capture *specific* red wolves prior to issuing a take authorization. The 2015 take authorization, for example, plainly states that USFWS has not even confirmed the presence of a red wolf on the

[8] Canid is defined as "any of a family (Canidae) of carnivorous animals that includes the wolves, jackals, foxes, coyote, and the domestic dog." https://www.merriam-webster.com/dictionary/canid (last visited October 30, 2018).

subject property. USFWS' expansive reading of the circumstances which would support issuing a take – including lethal take – authorization to a private landowner under the red wolf 10(j) rule impermissibly broadens the scope of wolves subject to take authorizations, and therefore conflicts with the ESA's "purpose to protect endangered and threatened" species. *Hill v. Coggins*, 867 F.3d 499, 510 (4th Cir. 2017) (quoting *Babbitt v. Sweet Home Chapter of Cmtys. for a Great Oregon*, 515 U.S. 687, 700 (1995)).

While the Court must afford deference to USFWS' construction of its 10(j) rule, where, as here, its interpretation operates against the USFWS' goal to recover the red wolf in the wild, the agency's "disregard for the statutory and regulatory context deserves no deference." *Nat'l Wildlife Fed'n v. Nat'l Marine Fisheries Serv.*, 524 F.3d 917, 931 (9th Cir. 2008). The take authorizations are further at odds with at least one USFWS scientist with the Red Wolf Recovery Program, who noted on several occasions that "our understanding [is] that foreclosure to access does not equate to abandonment of effort". Pl. App. 968 (Nov. 20, 2014 email from Beyer to Benjamin); Pl. App. 991 (Mar. 19, 2015 email from Beyer to Benjamin) ("My understanding is we would have to issue a permit after attempts to remove wolves have been abandoned. In this case we are not even recognizing or aware of any wolves present, have not made any capture efforts, and have denied similar requests.").

The 2014 and 2015 take authorizations represent a departure from long-standing USFWS guidelines to issue take authorizations only for problem wolves and were issued in conflict with the applicable red wolf 10(j) rule. The authorizations thus violated the ESA.

Plaintiffs remaining claims concern defendants' compliance with the ESA's conservation and consultation mandates and well as NEPA's requirement that agencies take a hard look at proposed actions which may have significant effects on endangered or threatened species. Section

4(d) of the ESA requires that the red wolf 10(j) rules must provide for the conservation of the listed species. 16 U.S.C § 1533(d); *see also Defs. of Wildlife v. Tuggle*, 607 F. Supp. 2d at 1116 (10(j) rules are "by definition the promulgation of the protective regulations for the species pursuant to the authority of ESA section 4(d)."). Section 7(a)(1) of the ESA, 16 U.S.C. § 1536(a)(1), "*requires* the Secretary [of the Interior] and the heads of all other Federal departments and agencies to use their authorities in order to carry out programs for the protection of endangered species." *Tennessee Valley Auth. v. Hill*, 437 U.S. 153, 182-83 (1978) (citation omitted) (emphasis added in *Tennessee Valley*). Section 7(a)(1)'s requirements apply to the USFWS. *Nat'l Wildlife Fed'n v. Norton*, 386 F. Supp. 2d 553, 567 (D. Vt. 2005).

Section 7(a)(2) of the ESA requires that each federal agency consult with the Secretary of the Interior ensure that agency action is not likely to jeopardize the continued existence of any endangered or threatened species. 16 U.S.C. § 1536(a)(2); *see also Fla. Key Deer v. Paulison*, 522 F.3d 1133, 1138 (11th Cir. 2008) (Section 7(a)(2) imposes two obligations on federal agencies, the first being "procedural and requir[ing] that agencies consult with the FWS to determine the effects of their actions on endangered or threatened species and their critical habitat" and the second being "substantive and requir[ing] that agencies insure that their actions not jeopardize endangered or threatened species or their critical habitat."). NEPA seeks to prevent damage to the environment by focusing government attention on the environmental effects of proposed agency action. *Marsh v. Oregon Nat. Res. Council*, 490 U.S. 360, 371 (1989). Any agency action having adverse effects on an endangered or threatened species may properly be considered significant action triggering NEPA hard-look requirements. *See Ctr. For Biological Diversity v. Nat'l Highway Traffic Safety Admin.*, 538 F.3d 1172, 1220 (9th Cir. 2008).

The Red Wolf Program having been declared a success in 2007, defendants, beginning in approximately 2014 and without consultation or formal review, determined to disregard management guidelines which had been in place since 1999 which distinguished between problem and non-problem wolves in regard to landowner take requests, to cease introductions of wolves into the wild, to cease pup-fostering, and to cease actively attempting to manage the threat from coyotes on the viability of the wild red wolf population. While a shift in any one or some of these activities may fall within the agency's discretion, when taken together, these actions go beyond the agency's discretion and operate to violate USFWS' mandate to recover this species in the wild. As defendants point out, due to a number of factors, including gunshot mortality and the increased presence of coyotes, the wild red wolf population began to gradually decline starting in 2006, but more than 100 red wolves remained in the wild in 2012-2013. *See* [DE 88 at 322]. Notably, however, the wild red wolf population saw a drastic decrease from 2013 to 2015, with only approximately fifty wolves in the wild in 2015. *See* Pl. App. 739. The population decrease coincides with defendants' making internal revisions to its guidelines and management policies, in response at least in part to mounting public pressure against red wolf recovery efforts, and defendants have failed to proffer any other evidence which could be deemed responsible for such change.

Allowing the wild red wolf population to continue to decline, while having access to methodologies which were previously successful in increasing or maintaining the wild population of the species, is an interpretation and application of the red wolf 10(j) rule that "is so implausible that it could not be ascribed to a difference in view or the product of agency expertise." *Motor Vehicle Mfrs.*, 463 U.S. at 43. It is undisputed that the reintroduction of the red wolf into the Red Wolf Recovery Area is not without its challenges, but absent a change in Congress' mandate or a

decision to delist or reclassify the red wolf under the ESA, the recent USFWS decisions to discontinue successful population management tools while increasing the likelihood that landowner lethal takes will be approved for wolves which historically would not have been subject to take, amount to a failure comply with its affirmative duty to "carry out conservation measures until conservation [is] no longer necessary." *Ctr. for Biological Diversity v. Vilsack*, 276 F. Supp. 3d 1015, 1031 (D. Nev. 2017); *see also Defs. of Wildlife v. Tuggle*, 607 F. Supp. 2d at, 1116-17 (Under ESA Section 4(d), USFWS has discretion to issue the regulations it deems necessary and advisable, but the regulation "shall" provide for the conservation of such species.").

Defendants' argument that their current red wolf management efforts are sufficient and within their discretion fails.

> while agencies might have discretion in selecting a particular program to conserve . . . they must in fact carry out a program to conserve, and not an "insignificant" measure that does not, or is not reasonably likely to, conserve endangered or threatened species. To hold otherwise would turn the modest command of section 7(a)(1) into no command at all by allowing agencies to satisfy their obligations with what amounts to total inaction.

Fla. Key Deer, 522 F.3d at 1147. Moreover, as was aptly stated by USFWS in 1999, "[w]ildlife are not the property of landowners but belong to the public and are managed by Federal and State governments for the public good. Such concepts and laws do not provide for taking or removal of wildlife from private lands in the absence of a problem." Pl. App. 730.

Defendants themselves have stated that actions such as those it has already undertaken would require compliance under ESA Section 7 and NEPA, Pl. App. 977, and there is no doubt that defendants' decisions to cease wolf introductions while simultaneously increasing the likelihood of authorized lethal takes by landowners "may adversely affect an endangered or threatened species". *Ctr. for Biological Diversity*, 538 F.3d at 1220 (quoting 40 C.F.R. § 1508.27(b)(9) and noting that action would trigger NEPA compliance if this factor is present).

In sum, plaintiffs' have satisfied their burden to demonstrate the above-described actions of defendants were arbitrary and capricious and otherwise violated Sections 9, 4, and 7 of the ESA as well as NEPA.

IV. Appropriate Relief

As the Court has found that summary judgment in favor of plaintiffs is appropriate as to all but plaintiffs' third claim for relief, the Court orders the following injunctive and declaratory relief.

A. Injunctive relief

On September 29, 2016, the Court entered a preliminary injunction enjoining defendants from taking red wolves, either directly or by landowner authorization, pursuant to 50 C.F.R. §§ 17.84 (c)(4)(v) and (c)(10) without first demonstrating that such red wolves are a threat to human safety or the safety of livestock or pets. The preliminary injunction remains in place and no appellate review has been conducted. Plaintiffs having demonstrated that judgment in their favor is appropriate all but one of their ESA and their NEPA claims, the Court finds that the preliminary injunction should be made permanent. Accordingly, defendants are hereby ENJOINED from taking red wolves, either directly or by landowner authorization, pursuant to 50 C.F.R. §§ 17.84 (c)(4)(v) and (c)(10) without first demonstrating that such red wolves are a threat to human safety or the safety of livestock or pets.

B. Declaratory relief

Plaintiffs have further demonstrated that they are entitled to declaratory relief as follows:

1. Defendants have violated the red wolf rule, 50 C.F.R. § 17.84(c)(2), and Section 9 of the ESA, 16 U.S.C. § 1538(a)(1)(G), by authorizing private landowners to take red wolves on their property without satisfying the express terms of 50 C.F.R. § 17.84(c)(4)(v);

2. Defendants have violated Section 4 of the ESA, 16 U.S.C. § 1533(d), by failing to provide for the conservation of the red wolf and failing to administer the red wolf

program in furtherance of the purposes of the ESA through its new interpretation and application of 50 C.F.R. § 17.84(c);

3. Defendants have violated Section 7(a)(1) of the ESA, 16 U.S.C. § 1536(a)(1), by failing to administer the red wolf recovery program in furtherance of the purposes of the ESA;

4. Defendants have violated Section 7(a)(2) of the ESA, 16 U.S.C. § 1536(a)(2), by failing to ensure that implementation of 50 C.F.R. § 17.84(c), in light of new information and modifications to the application of the red wolf rule, is not likely to jeopardize the continued existence of the red wolf;

5. Defendants have violated NEPA, 42 U.S.C. § 4332(2)(c), by failing to comply with NEPA requirements to determine the impacts of interpreting the take exemptions of the red wolf rule.

CONCLUSION

Accordingly, for the foregoing reasons, plaintiffs' motion for summary judgment [DE 79] is GRANTED IN PART and DENIED IN PART. Plaintiffs' third claim for relief is DISMISSED as MOOT, and plaintiffs' are entitled to summary judgment in their favor on their remaining claims. Defendants' motion for summary judgment [DE 85] is GRANTED IN PART as to plaintiffs' third claim for relief and DENIED IN PART as to plaintiffs' remaining claims. Declaratory and injunctive relief is ORDERED as provided above.

SO ORDERED, this 4TH day of November, 2018.

Terrence W. Boyle

TERRENCE W. BOYLE
CHIEF UNITED STATES DISTRICT JUDGE

From the Field: Implementing recovery of the red wolf—integrating research scientists and managers

Michael K. Stoskopf, Karen Beck, Bud B. Fazio, Todd K. Fuller, Eric M. Gese, Brian T. Kelly, Frederick F. Knowlton, Dennis L. Murray, William Waddell, and Lisette Waits

Abstract The United States Fish and Wildlife Service (USFWS) developed guidelines for the composition and role of endangered species recovery implementation teams, but few teams have been established and their success has not been evaluated. Using the recovery program of the red wolf (*Canis rufus*) as a model, we describe the genesis, function, and success of the Red Wolf Recovery Implementation Team (RWRIT) in helping guide the establishment of a viable red wolf population in eastern North Carolina. In operation since 1999, the RWRIT meets bi-annually to review USFWS progress and provide recommendations aimed at maximizing success of species recovery. The team is comprised of 8 research scientists from disciplines including population genetics, canid ecology, population ecology, veterinary medicine, and captive management. Representation from each of these disciplines is deemed necessary for proper evaluation of recovery progress and assessment of future needs. Meeting attendance by the USFWS field management team ensures both proper reporting of past progress and future implementation of management recommendations. Over time, RWRIT members have assumed specific assignments for data analyses, further contributing to the recovery effort. Through the combined efforts of the USFWS field team and the RWRIT, the threat of introgression of coyote (*Canis latrans*) genes into the red wolf population has been substantially curtailed within the recovery area, and red wolf numbers and range have increased. The RWRIT serves as an example of a recovery implementation team that is successfully incorporating the principles of adaptive management and whose template could be adapted to other endangered species.

Key words adaptive management, *Canis rufus*, endangered species, implementation, recovery, red wolf

Recovery of any endangered species is influenced by a range of political, economic, social, as well as biological issues (Tear et al. 1993, Scott et al. 1995, Lundquist et al. 2002). Reconciling disparate concerns and perspectives into a cohesive program requires planning and decision-making processes that consider conflicting interests of various stakeholders. However, for a recovery program to succeed, it is equally critical that professionals tasked with the responsibility for managing endangered species be able to move forward with timely decisions based on practical management needs and scientific knowledge (Westrum 1994). The United States Fish and Wildlife Service (USFWS) red wolf (*Canis rufus*) recovery program is an example of a program faced with complex issues, where man-

agement successes have been strengthened and accelerated by integrating active adaptive management with careful and timely scientific inquiry. This paper describes how this integration is being achieved via a designated "recovery implementation team."

The red wolf is an endangered species that once roamed an extensive range including the southeastern United States, and possibly the entire woodlands of eastern North America (Wilson et al. 2000, Nowak 2002, Grewal et al. 2004). Although listed as endangered in 1967 (USFWS, 1967), population decline and apparent hybridization with coyotes (*Canis latrans*) were recognized in the early 1960s (McCarley 1962, McCarley and Carley 1979). The remaining red wolves were removed from the wild in the mid- to late 1970s with the goals of establishing a captive breeding program and eventually restoring captive-bred animals to portions of their historical range (U.S. Fish and Wildlife Service [USFWS] 1989). In 1987 the first red wolves were released in easternmost North Carolina (Figure 1) with the plan to establish a viable population (Parker 1987). The reintroduction efforts faced a myriad of social, political, and biological issues as the Red Wolf Recovery Plan (USFWS 1989) was implemented (Henry and Lucash 2000, Phillips et al. 2003).

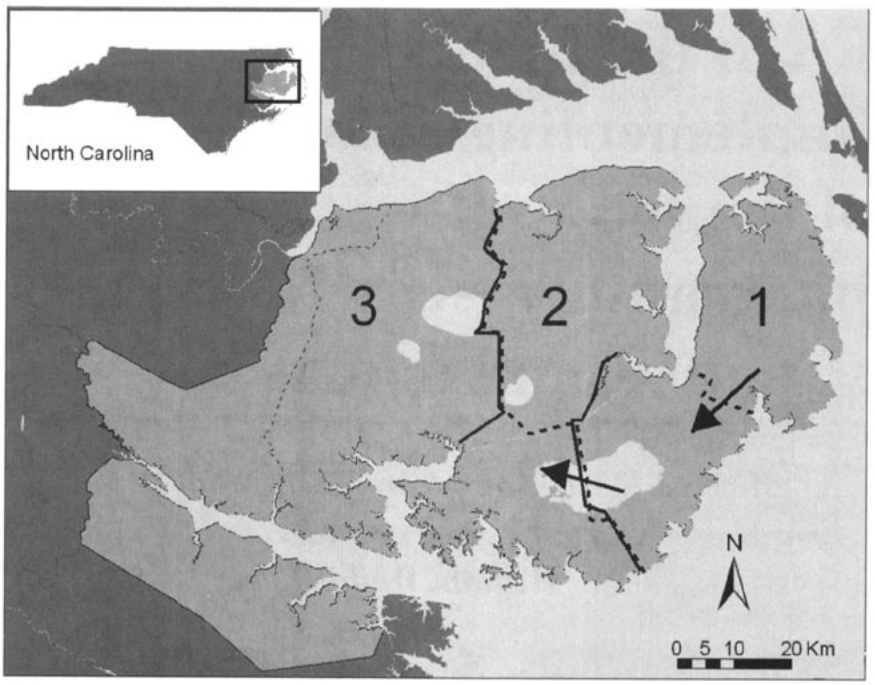

Figure 1. Changes in management zone boundaries within the Red Wolf Recovery Area of eastern North Carolina, as made in accordance with Red Wolf Adaptive Management Plans. The boundaries of the original management Zones 1, 2, and 3 (dashed lines) were first established in April 2000. In March 2002, as red wolf recovery proceeded, boundaries in the southern parts of the zones were moved west (solid lines); part of Zone 2 became Zone 1, while part of Zone 3 became Zone 2 (arrows). In August 2003 some management aspects of canids (i.e., sterilization vs. euthanasia) captured in the eastern half of Zone 3 (thin dotted line) began to follow guidelines applied to Zone 2.

Although the reintroduction area was initially considered uninhabited by coyotes, by the mid-1990s it was apparent coyotes had infiltrated the area and hybridization with red wolves was recurring (Phillips et al. 2003). Due primarily to the renewed hybrid threat and termination of the reintroduction of red wolves into Great Smoky Mountains National Park (Henry 1998), the USFWS decided it needed to re-evaluate its red wolf recovery effort in light of what had been learned over the previous decade. A key step in this review process involved a Population and Habitat Viability Assessment (PHVA) organized by the USFWS in 1999 and facilitated by the Conservation Breeding Specialists Group of the World Conservation Union, Species Survival Commission (IUCN SSC) (Kelly et al. 1999). The diverse assemblage of attendees, representing a variety of expertise and interests, agreed that introgression of coyote genes into the red wolf population was the principal threat to recovery success (Kelly et al. 1999). The group also recognized this issue required urgent attention before hybridization became so pervasive as to virtually ensure the genetic swamping of the only extant free-ranging population of red wolves. However, 2 views of how to address the hybrid threat emerged from the PHVA; one believed research was integral to addressing the problem, and the other expressed concern that research efforts would distract from the primary goal of maintaining the only free-ranging population of red wolves in the world. A consensus agreement was reached on this debate and resulted in an overarch-

ing workshop statement, including:

> "...our primary recovery focus must be protecting and promoting the growth of a self-sustaining, non-hybridizing population of red wolves in the wild and sustaining an active captive component. Actions to be taken will use an adaptive management approach that will not compromise the ability to achieve this goal." (USFWS 1999:52)

This level of agreement among the diverse participants of the PHVA set the stage for designing an adaptive management plan (*cf.* Lancia et al. 1996) that would reduce the threat of wolf-coyote hybridization. This plan (Kelly 2000) diverged from conventional endangered species management because it involved an incremental process tailored to modify field protocols according to past success in eliminating the threat of hybridization. Specifically, it required the release area to be segregated into several defined management zones, each managed to provide an integrated optimization of risk reduction within the resource limitations available to the project (Figure 1). As nonwolf canids were removed from given zones and replaced with red wolves, management options could be adapted by modifying zone boundaries or adjusting specific management protocols.

Adoption of this plan, requiring frequent re-evaluation of data and attendant management adjustments, spawned close interactions between USFWS field biologists and scientists with backgrounds relevant to the work being undertaken. A Red Wolf Recovery Implementation Team (RWRIT) was formed to advise USFWS as they implemented the adaptive management plan; this team was created pursuant to Section 4(f)(2) of the amended Endangered Species Act (ESA), which authorizes the Secretary of the Interior to procure the services of appropriate public and private agencies, institutions, and other qualified persons to help implement endangered species recovery plans. Other USFWS-designated species-specific implementation teams, as opposed to planning teams, have been formed (e.g., black-footed ferret [*Mustela nigripes*], northern right whale [*Eubalaena glacialis*], Okaloosa darter [*Etheostoma okaloosae*], and southern sea otter [*Enhydra lutris*]; USFWS files), but they are rare and no formal description of one's workings or success has yet been documented.

Recovery implementation team composition

Selection of the RWRIT scientists and their leadership was important to the success of implementing and evaluating the adaptive management plan. The PHVA helped the USFWS identify individuals with the combined expertise and personality considered important in a functional RWRIT. The PHVA also provided insight to the breadth of expertise needed over the long term. This expertise included such diverse fields as systematics, genetics, population modeling, health management, and canid biology, behavior, ecology, and management. Social scientists were not required in this case because those issues were, and continue to be, successfully dealt with by the USFWS field management team in conjunction with non-governmental organizations (Henry and Lucash 2000). Direct experience with the red wolf was not a requisite criterion for RWRIT membership. In fact, due to the long and controversial scientific history of the red wolf, some team members were sought for their naiveté of red wolves to minimize preconceived notions regarding the problems the adaptive management plan addressed. Thus, a mixture of experienced and young research scientists with strong records of scientific productivity and interpersonal skills was selected. Each member of the RWRIT had to be willing to use a data-driven approach to decision-making while remaining open to challenges of interpretation. Each member also had to be willing to accept group decisions as well as devote considerable personal time toward solving issues associated with the red wolf program.

The RWRIT needed to be large enough to provide the scientific diversity needed to assess the broad range of critical issues, but small enough to support close working relationships among members and result in productive meetings (Clark and Westrum 1989). A basic philosophy was that if the RWRIT needed expertise from individuals or disciplines outside the RWRIT to address specific issues, guest scientists would be invited to participate in the appropriate meetings. Initially, a goal of 8 members and 4 alternates was considered. Interactions of the group and reliability of participation in early meetings were used to identify the core members of the RWRIT. Since then, the size and composition of the RWRIT (8 members, no alternates) has worked well, sustaining effective decision-making with absences at meetings being rare. The leader of

the RWRIT needed to moderate meetings efficiently while allowing for creative interactions among RWRIT members. To ensure this, a senior scientist at a local university was selected due to his demonstrated scientific and leadership skills.

Experienced and stable field team

The USFWS field team involved in the day-to-day operation and management of the red wolf recovery program was key to the success of the RWRIT. The field team attended all RWRIT meetings as nonvoting members and provided the necessary data and expertise for the meetings to progress effectively. This distinction between the teams initially caused some anxiety, but this subsided once roles had been fully elucidated. The field team is remarkably stable and has worked cohesively on the red wolf project for many years (Phillips et al. 2003). Scientists of the RWRIT recognize the field team as the most experienced red wolf biologists and essential for successful functioning of the RWRIT itself. In turn, the field team's willingness to listen to and implement recommendations made by the RWRIT has been a critical factor in the success of the program. Open communications between the 2 teams keeps RWRIT scientists aware of the implementation of recommendations and fosters respect for the dedication of the field team.

Getting started

The first meeting of the RWRIT was important in establishing the tenor of group interactions and future functioning. Subsequent meetings would focus on examining data related to specific questions within an established agenda, but the first meeting focused on developing operating procedures for decisions as well as the types of data and data formats the team preferred for review and evaluation. This was a step that helped acquaint members of the team and recognize proper working protocols. It also ensured that all members of the team had a common understanding of the Red Wolf Adaptive Management Plan (RWAMP).

The charge of the RWRIT was established a priori by the Team Leader of the Red Wolf Recovery Program (i.e., "Red Wolf Program Leader"). This task was defined specifically as reviewing progress on the RWAMP and recommending changes to the plan based on data provided by the USFWS. As the team gained experience, this charge evolved to include recommendations for data relevant to answering specific questions important to the field team in the day-to-day management of the wild red wolf population. The 2 charges were closely related, frequently blended, seldom distinct, fundamental to the Adaptive Management Paradigm (Walters 1986), and are the responsibilities that drive efforts of RWRIT members. From the beginning, per the ESA, RWRIT recommendations were strictly advisory, with decisions for implementation being at the discretion of the USFWS.

Ground rules established in the first meeting have rarely been adjusted. Some established the mechanics of operations. For example, it was decided a minimum of 6 RWRIT members would be required as a quorum for a functional meeting. Failure to achieve quorum would trigger an evaluation by the RWRIT Leader and the Red Wolf Program Leader to assess whether the RWRIT remained an appropriate mechanism. To date this has not been necessary due to continued strong and enthusiastic attendance.

Other rules provided guidance for RWRIT interactions. To reduce stifling potentially meritorious but perhaps unconventional ideas, the team adopted a basic rule indicating that speakers must present alternative solutions when challenging or negating a proposed idea or approach. Ideas would be withdrawn from consideration only after careful efforts to refine them failed to produce workable solutions. To the fullest extent possible, data would be used to support all positions.

Other procedural mechanisms established in the first meeting have had a beneficial effect on RWRIT operations. For example, tentative dates, times, and location of future meetings are established jointly early in the agenda of each meeting. In addition, the agenda of the next meeting is established near the completion of the current session, which probably produces a more dynamic agenda than a call just before the meeting. Opportunities to add agenda items at any time remain, but the draft of the agenda appears in the final minutes; serving as a reminder for participants as they prepare for the coming meeting.

An important activity reserved for the end of each meeting is an exercise in prioritizing "action items", which are further classified as either "tasks" (expected to be accomplished within the time frame of the meeting or between meetings); "projects" (longer duration activities); or "manuscripts" (the drafting of information for publication).

Individual RWRIT members are recognized as responsible for addressing each item. With many issues to consider and an active agenda, many more action items are identified than can typically be accomplished with the resources available. The action items established throughout the meeting and recognized as "projects" are assembled in a descriptive list and as a final exercise, each member of the RWRIT assigns a priority level to each item and the mean rating is computed. This rating is offered to the Red Wolf Program Leader as a recommendation for activities to pursue or fund. At the first meeting, a pattern was established where RWRIT members worked to identify key management questions and to focus scientific inquiry in areas of need with constant reference to the adaptive management plan. Assets are identified and resource limitations discussed so recommendations have a reasonable likelihood of implementation. Short proposals outlining the objective of projects and the team member(s) involved in the work are distributed to the RWRIT via the team's webpage. The webpage also includes team member contact information, minutes of meetings (see below), data sets, reports, press releases, publications, project descriptions, manuscripts in progress, and upcoming meeting agendas and related materials such as reports and summaries.

Since 2000 the RWRIT has met bi-annually, which is sufficient to respond in a timely manner to questions from the field and to strengthen collegial bonds among members. This schedule also allows sufficient time for the field team to implement recommendations and to document their progress and for RWRIT members to work independently on action items. Other factors affecting meeting schedules include a need to make recommendations ahead of budget deadlines and to accommodate schedules of the individual RWRIT members and the field team. The current pattern of meetings includes 1 meeting in March prior to the denning season and a second in October prior to intensive trapping efforts.

Staying flexible

Any group with dynamic tasks needs a mechanism for adjusting the nature of the group as it matures and as tasks change (Clark and Reading 1994). The concept of alternate members soon was abandoned because of the strong attendance by RWRIT members and because it reduced inefficiencies associated with updating new attendees. The ability to invite experts in areas not represented on the RWRIT provides a mechanism to maintain flexibility and adaptability. Periodic review of expertise needed for specific tasks and projects of the RWRIT keeps the issue of change before the team. In addition, there exists ample opportunity to discuss candidly both the pros and cons of the teams' efforts, either formally at the end of each meeting or informally during meals or after hours. The RWRIT Leader needs to recognize dissenting views and address contentious issues promptly and effectively. The fact that for most meetings the entire RWRIT was communally housed in rented accommodations further ensured the establishment of favorable personal relationships benefiting RWRIT interactions and discussion.

Complete minutes of RWRIT deliberations provide documentation of the team's discussions and recommendations. An iterative process of editing minutes is used by the RWRIT, ensuring important information developed at each meeting is recorded accurately and in language deemed appropriate by the participants. Notes are converted into a draft each evening and individualized, and printed copies are distributed to attendees the following morning for editing. All drafts are synthesized into the penultimate draft for further comment, which is followed by a final draft distributed electronically shortly after completion of the meeting. The RWRIT members have a week to return any corrections, after which the final minutes are completed and distributed electronically. The deliberations of the RWRIT are considered privileged communication, and all meeting participants are asked to limit discussions of information received at the meetings to individuals within their respective research groups. This policy allows RWRIT members access to sensitive and preliminary data and provides more freedom of discussion without concerns about inappropriate disclosure. Distribution of the minutes beyond the RWRIT is at the discretion of the Red Wolf Program Leader.

How well does it work?

The test of any system is how well it functions to meet the goals and objectives of the program it serves. In the 4 years since the first formal meeting of the RWRIT, key challenges to implementing the plan developed at the PHVA have been identified and strategies have been devised to provide practi-

cal solutions and evaluate success of recovery efforts. Perhaps more importantly, all RWRIT members and the entire red wolf field team have become close colleagues who look forward to each meeting. We enjoy the frank and open exchange of ideas, the ability to quickly address both practical and theoretical problems and make changes in management practices, and the successes in the field that result from the collaboration. The details of these changes and successes are the basis of several scientific papers, some already published or in press and others currently in preparation, but a brief summary is warranted.

Prior to 1998 all canids captured in the red wolf recovery area were assumed to be wolves unless they were so small as to be considered coyotes, if they were black, or if they looked part dog. If there was some indication that a single female wolf was consorting with a coyote or dog, pups she produced were removed (A. Beyer, USFWS, personal communication). Thus, the basic challenge of rapidly and confidently identifying animals as red wolves versus hybrids or coyotes, especially young animals, was identified early as a key concern of the PHVA and the field team. The RWRIT served as catalyst for developing an enhanced and improved genomic testing protocol by expanding the ability to assess alleles at 19 loci (Miller et al. 2003). A priority placed on obtaining genomic assessments of the entire group of founders in the captive breeding program, as well for coyotes in the vicinity of the wolf release zones, greatly improved the confidence in the genomic data now available. Genetic analyses were integrated with pedigree and morphometric data to develop decision trees for all captured animals (Table 1). Extension of the DNA analysis capabilities to fecal samples increased the potential for assessing presence of red wolves, as well as undesired non-red wolves, in the field samples without the need of capturing and handling animals (Adams et al. 2003). Additional research efforts were directed at using this technology for assessing red wolf population size (J. R. Adams and L. P. Waits, University of Idaho, unpublished data).

To evaluate progress of the adaptive management plan, RWRIT scientists wanted detailed and current descriptions of animal locations, their genotypes, and canid inventory efforts in relation to geographic areas. A coordinated Geographic Information System (GIS) database system is now used at all RWRIT meetings to examine recovery progress. This is steadily approaching the goal of a real-time data view as data entry and validation challenges are addressed and data summaries are refined. These tools help identify areas where data are insufficient to define the status of canids and help develop strategies to eliminate so-called "areas of ignorance" by concentrating efforts in areas needing more attention. In addition, they have lead to improved ground telemetry efforts and more efficient use of resources and personnel.

Modeling effects of coyote genomic intrusion, using more refined data sets and newer models than available at the PHVA, provided RWRIT scien-

Table 1. Decision path for genetic results of red wolves (RW) captured in the experimental population area in northeastern North Carolina, applied in fall of 2003 (explanation of genetic result classifications given in Miller et al. 2003). Decision parameters listed in the following priority: Genetic testing; Pedigree; Morphology; Mate.

	Capture location[a]	
Decision parameter	Zone 1	Zone 2
1. Genetic test: 100% RW (pedigree 100% RW)	Release	Release
1. Genetic test: 100% RW but cannot exclude 75% RW hypothesis	Consider pedigree (go to 2)	
2. Pedigree is 100% to 87.5% RW	Release	Release
2. Pedigree is 87% to 75% RW or unknown	Consider morphology (go to 3)	
3. Morphologically "hybrid-like"	Euthanize	Sterilize
3. Morphologically "RW-like"	Consider mate (go to 4)	
4. Mate is ≥75% RW	Release	Release
4. Mate is <75% RW or uncertain	Euthanize	Sterilize 1 mate
1. Genetic Test: 75% RW or 75% RW but cannot exclude 50% RW hypothesis	Consider pedigree (go to 5)	
5. Pedigree is <75% RW	Euthanize	Sterilize
5. Pedigree is ≥75% RW or unknown	Consider morphology (go to 3)	

[a] See Figure 1.

tists new insights into impacts of genomic intrusion (e.g., Miller et al. 2003). This allowed for key insights to establishing acceptable risks defined in the decision trees. This also assisted in the making of informed recommendations for modifying approaches to the various management zones for red wolf recovery. Recently, the RWRIT initiated an effort to conduct detailed analyses of home range, spatial interactions, habitat use, and demographic attributes of all radiomonitored red wolves since 1986, with the objective of developing a population viability model to help guide future management and recovery actions. Den management techniques via implementation of early genomic sampling and use of cross-fostering of wild-caught and captive bred pups into wild litters have been developed (cf. Kitchen and Knowlton, *in press).* Methodology also has been enhanced to conduct surgical procedures to support the use of hormonally intact but sterile hybrids and coyotes to serve as sterile buffers (i.e., temporary territory placeholders that discourage establishment of new, intact nonwolves) in peripheral management zones (Figure 1).

The net result of such activities has led to an increase in the area occupied by red wolves, total number of red wolves, and number of red wolf social units, as well as a major decrease in the total area where the status of canids, in general, is unknown (B. B. Fazio, USFWS, unpublished data). Such changes in these metrics were identified in the RWAMP as key indicators of the successful management of wolf-coyote hybridization. Importantly, coyotes or hybrids have essentially been eliminated from fully half of the red wolf recovery area. To date, genetic intrusion into the red wolf population has been largely controlled, albeit through aggressive intervention.

The effective functioning of the RWRIT has ensured that issues identified at the PHVA as described in the RWAMP have been, or are being, successfully addressed by USFWS. And as should be expected, the original red wolf adaptive management plan is now revised to include 5 years of evolving adaptive management (Fazio et al. 2004). The approach taken by the RWRIT represents a good example of successful application of the Adaptive Resource Management paradigm and is likewise consistent with, and respectful of, concerns raised by the participants at the PHVA that the primary goal of conserving the only free-ranging population of red wolves not be overshadowed by the desire to conduct research. Indeed, the USFWS recently highlighted the efforts of the Red Wolf Recovery Program in a videotape on how the use of sound science is key to meeting its mission.

We believe the recent tangible success in red wolf recovery is a direct result of conducting the PHVA, crafting a RWAMP, establishing the RWRIT, and the cooperation and close interaction between the RWRIT and the USFWS field team directly tasked with red wolf recovery. Endangered species recovery should involve a strong linkage between scientific investigation under the rubric of adaptive management and the appropriate blend of social, political, and economic issues (Clark et al. 1994). In light of the mixed past success in recovering endangered species in the United States (Crouse et al. 2002, Gerber and Hatch 2002), we believe, based on the success of the RWRIT, that recovery implementation teams can serve as an effective vehicle for helping guide recovery programs and actions.

Acknowledgments. The authors thank the USFWS and the Morris Animal Foundation for financial support of activities reported in this manuscript and the red wolf field team for its excellent efforts and cooperation with the RWRIT.

ABSTRACT

Understanding the mechanisms that govern interspecific hybridization is vital to mitigating its impacts on endangered species. Research suggests that behavioral mechanisms such as mate choice and social disruption can regulate the rate at which hybridizing species interbreed. We investigated hybridization events between endangered red wolves (*Canis rufus*) and coyotes (*Canis latrans*) in eastern North Carolina to evaluate potential factors that may promote hybridization between these species. Specifically, we examined spatial location, breeding experience, breeder origin (captive vs wild), breeder ancestry (pure vs hybrid), and past history of the animal. There were over four times (126 vs 30) as many red wolf litters as hybrid litters over a 13 year time period. Over half of the hybridization events followed the disruption of a stable breeding pair of red wolves due to mortality of one or both breeders. Of these 69% were due to anthropogenic causes, primarily gunshot mortality prior to the red wolf breeding season. Both male and female red wolves interbred with coyotes, although a majority (90%) of the events we observed involved females. Wolves that produced hybrid litters tended to be young, first-time breeders with slightly higher levels of coyote ancestry. Only 16% of the hybrid litters were produced in the inner core of the red wolf recovery area. Our results suggest that disruption of stable breeding pairs of red wolves facilitates hybridization, jeopardizing future recovery of the red wolf. They also indicate the importance of behavioral forces, especially social stability, in regulating hybridization.

1. Introduction

Human activity has the potential to disrupt dynamics between hybridizing species, which can cause hybridization and introgression to emerge as conservation threats (Rhymer and Simberloff, 1996; Allendorf et al., 2001). As with any conservation problem, developing solutions requires recognizing the mechanisms that influence the process. For hybridization, that requires understanding the mechanisms that cause previously reproductively isolated species to interbreed. Species introductions (Rhymer and Simberloff, 1996; Stigall, 2010), habitat destruction and ecological homogenization (Seehausen et al., 2008; Crispo et al., 2011), and the spread of domesticated species (Likre et al., 2010; Champagnon et al., 2012) have been implicated as processes that may facilitate these shifts.

Still, these forces primarily influence whether hybridizing species come into contact, not necessarily whether individuals will interbreed. There is increasing recognition that behavioral processes such as mate choice (Pfennig, 2007; Reyer, 2008; Svedin et al., 2008; Gilman and Behm, 2011; Robbins et al., 2014), interspecific competition (Wolf et al., 2001; Krosby and Rohwer, 2010; Sacks et al., 2011), and Allee effects (Lode et al., 2005) can influence the rate of hybridization. The potential for behavioral forces to moderate hybridization and introgression may be a critical factor that would influence conservation schemes.

Understanding the mechanisms that govern interspecific mating is vital to recovery of species threatened by hybridization, especially the critically endangered red wolf (*Canis rufus*) in eastern North Carolina. Historically red wolves were distributed across eastern North America, but overharvest, habitat destruction, and hybridization with coyotes (*Canis latrans*) led to extinction in the wild by 1980 (Paradiso and Nowak, 1972; Nowak, 2002; USFWS, 1990). Beginning in 1987, captive red wolves were reintroduced into eastern North Carolina and today a population of about 80–100 individuals occupies the 600 000 hectare Albemarle Peninsula (Phillips and Parker, 1988; Phillips et al., 2003; Bartel and Rabon, 2013).

At the same time, coyotes expanded their range into North Carolina (Hill et al., 1987) and in 1993 the first hybridization event between a reintroduced red wolf and a coyote was detected (Phillips et al., 2003). A subsequent population viability analysis

suggested that hybridization was the greatest threat to red wolf recovery (Kelly et al., 1999). This led to the development of an aggressive adaptive management plan by the US Fish and Wildlife Service (USFWS) and the Red Wolf Recovery Implementation Team (RWRIT, Stoskopf et al., 2005) to limit hybridization and introgression. The genetic composition of the population is managed by an active monitoring program combined with genetic testing to remove hybrid individuals from the landscape (Stoskopf et al., 2005; USFWS, 2007; Bartel and Rabon, 2013).

Such aggressive practices have been implemented based on the hypothesis that a small red wolf population would be genetically swamped by coyotes without human intervention (Kelly et al., 1999). This is predicated on the assumption that when sympatric, red wolves and coyotes will breed indiscriminately. However, this assumption has not been tested empirically. Fredrickson and Hedrick (2006) modeled red wolf viability and found that positive assortative mating and aggressive interactions between the species were the most important factors in maintaining population viability. They developed hypothetical values for those parameters because empirical estimates did not exist. USFWS field biologists have observed red wolves displacing and occasionally killing coyotes and hybrids (USFWS, 2007). Otherwise, there is little understanding of how mate choice and social structure influence interactions between these species. Given the importance of social dynamics on the ecology of mammalian carnivores, there is potential for behavioral processes such as mate choice, social structure, and competition to limit hybridization (Rutledge et al., 2010; Sacks et al., 2011; Shurtliff, 2011). Conversely, disrupting these social systems may in turn influence reproductive patterns (Brainerd et al., 2008; Borg et al., in press) and hybridization rates (Rutledge et al., 2010).

We examined breeding records and individual histories of red wolves involved in hybridization events from 2001 to 2013 to elucidate factors that facilitate interbreeding between these species. Specifically, we asked the following questions: (1) Do age, prior breeding experience, and origin of the wolf influence the likelihood of hybridization, (2) are individuals with mixed red wolf/coyote ancestry more likely to hybridize, (3) are hybridization events evenly distributed across the recovery area, and (4) are hybrid litters produced under particular scenarios or breeder histories? If breeding between these species is indiscriminate, we would expect young dispersing red wolves to be the most likely individuals to encounter and breed with a coyote. Breeding opportunities within wolf packs are often restricted to a dominant breeding pair, which forces individuals in search of mates to disperse outside the pack (Mech and Boitani, 2003; Sparkman et al., 2012). In this system dispersing would increase the likelihood of an individual encountering a coyote considering that wolf packs are known to exclude coyotes within their range (USFWS, 2007). This is similar to observations of eastern wolf (*Canis lycaon*) packs in southern Canada (Benson and Patterson, 2013). We predicted that hybridization would increase from east to west, since the western portion of the study area has the fewest wolves, least stringent management, and closest proximity to the mainland coyote population. Also, we hypothesized that individuals with mixed red wolf/coyote ancestry would be involved in more hybridization events. By examining the characteristics and history of red wolves responsible for hybridization events with coyotes, we can better understand the mechanisms that govern hybridization, aiding recovery of this species.

2. Materials and methods

2.1. Genetic monitoring

Every spring USFWS biologists track female red wolves to locate active dens that contain pups. Blood samples are collected from pups and genetic testing is conducted to assess their ancestry and place them within the red wolf pedigree (Adams, 2006; Bohling et al., 2013). Since the implementation of the adaptive management plan in 2000 monitoring of red wolf dens and genetic testing of captured canids, including pups, became standard, which improved detectability of hybridization events (Stoskopf et al., 2005; USFWS, 2007). As a result, we only considered hybridization events that have occurred since 2000 for this study. USFWS biologists possessed permits for capturing and handling red wolves that have been jointly issued by the USFWS, Association of Zoos and Aquariums Reintroduction Scientific Advisory Group, and IUCN Species Survival Commission Reintroduction Specialist Group.

Parentage for red wolf and hybrid litters was determined following the methods of Adams (2006) and Bohling et al. (2013). To summarize, each pup was genotyped at 17 microsatellite loci and assigned to red wolf parents using genetic and field data, allowing for $\leqslant 1$ mismatch for a parent pair. Based on this pedigree we were able to estimate an individual's ancestry by averaging the amount of red wolf ancestry possessed by the parents as traced through the pedigree. In the case of hybrid litters, typically only the red wolf parent was identified, although in several situations the non-red wolf parent was later captured and determined to be a parent using genetic analysis. Several hybrid litters were detected when hybrid offspring were captured as juveniles and later assigned to a red wolf parent. Three hybrid litters fit this scenario; thus, the exact size of those litters could not be determined.

2.2. Location

The adaptive management plan divided the peninsula into three zones with different management goals (Stoskopf et al., 2005) (Fig. 1). Zone 1, the easternmost portion of the peninsula, serves as the core red wolf population and coyotes and hybrids captured in this area are euthanized. In Zone 2, directly west of Zone 1, hybrid individuals are euthanized but coyotes are sterilized under the hypothesis that sterile individuals would serve as territorial placeholders that discourage undetected coyotes from dispersing into the peninsula (Bartel and Rabon, 2013). Zone 3 is the furthest west section and falls at the junction of the peninsula and the mainland. Management practices in Zone 3 vary, but many sections of this area are managed similarly to Zone 2. This entire region has been designated as the Red Wolf Experimental Population Area (RWEPA).

We classified each hybrid and red wolf litter to a Zone based upon where it was detected (Zone 1, 2, or 3) and used a χ^2-squared test of independence to evaluate the distribution of each type of litter across all three zones. As noted, some hybrids were discovered as adults. In these situations, once the red wolf parent was identified via genetic testing we assigned the location of these litters according to the home range of that red wolf during the prior breeding season.

2.3. Breeder experience

To examine the impact of breeder experience on hybridization we compared both the age and prior breeding experience of red wolves that produced hybrid and red wolf litters. For breeding experience we classified each litter according to whether it was produced by a first-time breeder or an experienced breeder. This was only performed for females since the sample size of male red wolves was low (see Section 3.1). We defined first-time breeder as any individual producing its first known litter of pups, regardless of whether it was a hybrid or red wolf litter. An individual was considered an experienced breeder once it had produced a second litter. We compared the proportion of total red wolf and hybrid litters that were born to experienced breeders using a χ^2

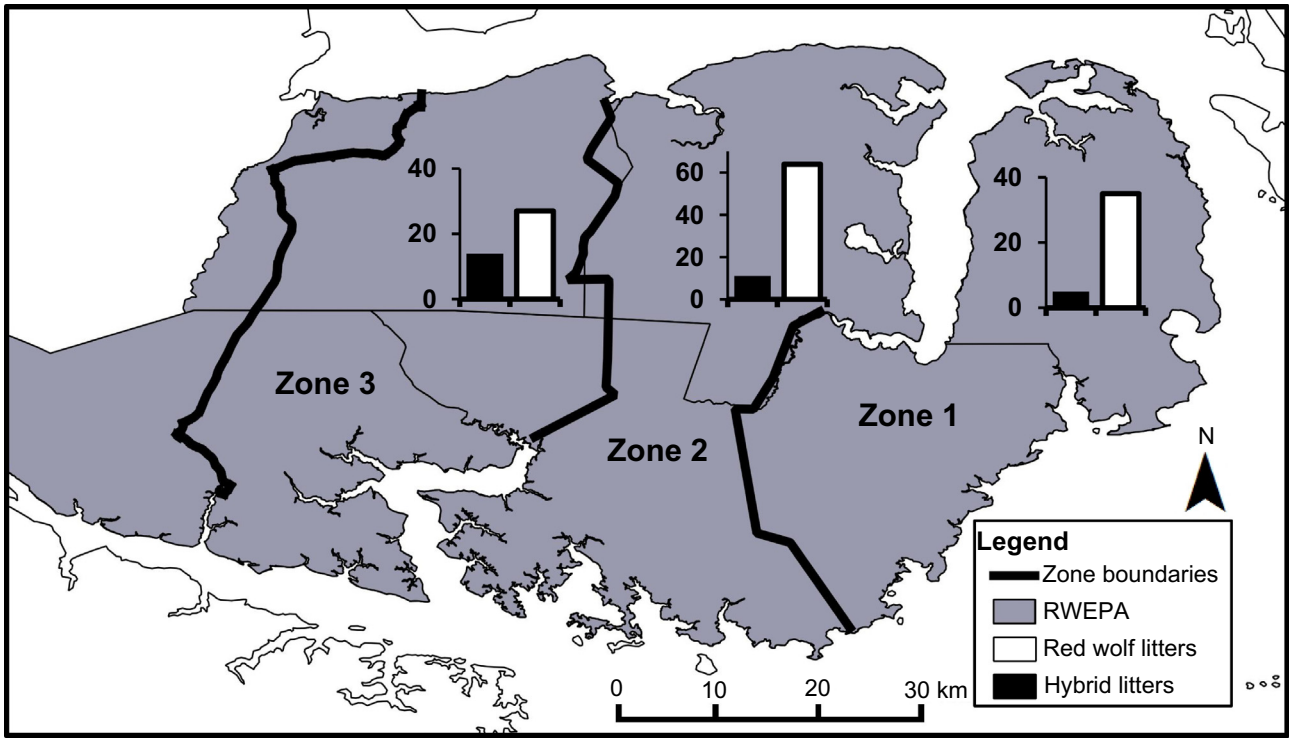

Fig. 1. Map of the Red Wolf Experimental Population Area (RWEPA) and the spatial distribution of hybrid and red wolf litters from 2001 to 2013. The thick black lines indicate the boundaries of the management zones 1, 2, and 3. The number of hybrid and red wolf litters per zone indicated by the graphs within each zone boundary. White columns represent red wolf litters, black hybrid litters.

test of independence. The effect of breeder age was measured by comparing the overall age of individuals responsible for hybridization events to the age of individuals producing red wolf litters. For three females the year of birth was unknown (Table 1).

2.4. Breeder origin

Over the past two decades the USFWS has released captive individuals and individuals raised in island-propagation programs to augment the wolf population. The island-propagation program consists of releasing captive red wolves to isolated, unoccupied barrier islands in the southeastern US so they can acclimate to the wild (Phillips et al., 2003). We hypothesized that the unfamiliarity of captive and island-raised individuals with the RWEPA would inhibit their ability to locate red wolf mates, increasing the likelihood that they would encounter and breed with a coyote. Using the pedigree we were able to determine the origin of each red wolf (wild, captive, and island-born) and whether it produced any litters. We also noted wolves produced through cross-fostering, which involves integrating recently born captive pups into wild litters to provide an input of genetic diversity (Bartel and Rabon, 2013).

2.5. Breeder ancestry

The hybridization event that occurred in 1993 between a female red wolf and male coyote resulted in introgression of coyote genetic material into the red wolf population. Two F1 hybrid males from this event bred with female red wolves and their offspring backcrossed with the red wolf population. The USFWS and RWRIT decided that any individual possessing >87.5% red wolf ancestry based on pedigree assignment would remain in the population (Stoskopf et al., 2005). A large segment of population now consists of these backcrossed individuals that have a slight amount of known coyote ancestry (87.5–98% red wolf) (Adams, 2006; Bohling et al., 2013). Our goal was to determine whether these admixed individuals had a higher propensity to hybridize than 'pure' wolves. We calculated the average ancestry of individuals involved in hybridization events using the pedigree and compared that to the ancestry of individuals producing red wolf litters using a two-tailed *t*-test. We applied an arcsin transformation to ancestry values prior to analysis.

Even though red wolves and coyotes hybridize, there are noticeable differences in morphology, behavior, and ecology between the species (Phillips and Henry, 1992; Nowak, 2002; Phillips et al., 2003; Hinton and Chamberlain, 2014). Hybrids are intermediate between the two species; thus, we predicted that a red wolf would be more likely to select a hybrid as a mate than a coyote. However, since aggressive management practices remove hybrids from the landscape, we hypothesized that the production of hybrid litters would be primarily driven by interbreeding with coyotes. Since the non-red wolf parent was identified for several hybrid litters, we evaluated the ancestry of these animals using two methods to determine if they were coyotes or individuals of mixed ancestry. First, ancestry of non-red wolf individuals was assessed using the Bayesian clustering program STRUCTURE 2.3 (Pritchard et al., 2000; Falush et al., 2003). We used four known genetic groups as training sets: coyotes ($N = 94$) from North Carolina, Virginia, and Texas; gray wolves ($N = 38$) (*Canis lupus*) from Idaho and Alaska; domestic dogs ($N = 28$); and founders of the captive red wolf population ($N = 17$). Our previous work (Bohling and Waits, 2011; Bohling et al., 2013) showed that these four groups form distinct clusters when applied to STRUCTURE in a free-clustering framework. In the STRUCTURE analysis, individuals from our four known genetic groups were assigned a POPFLAG designation of 1 and the 'Use Population Information' option was used as the ancestry model with the default parameter settings and the correlated allele frequency model. Unknown individuals were given the

[a] Identification number of the individual wolf involved in the hybridization event.
[b] F – female; M – male.
[c] Based on the red wolf pedigree.
[d] Birth location of individual.
[e] Wild-born individual from the reintroduced population in North Carolina.
[f] For these individuals the age of birth could not determined.
[g] These litters were detected after USFWS biologists captured the hybrids as juveniles and genetic testing assigned parents.
[h] Refers to the management zone that the litter was discovered.
[i] The individual that bred with the red wolf was unable to be determined for all litters.
[j] History of the location and/or red wolf prior to the production of the hybrid litters.
[k] No significant history was recorded for these individuals.
[l] The individual the red wolf had paired with had been erroneously identified as a red wolf.

POPFLAG = 0 designation, which means their genotypes were not used to estimate allele frequencies. The number of populations was set to four with a burn-in period of 100 000 reps followed by 1 000 000 MCMC repetitions.

For each genetic cluster STRUCTURE produces a probability value that an individual's genotype originated from that group. We considered an individual 'admixed' using two different criteria following Bohling and Waits (2011). If an individual had a probability of assignment $\geqslant 0.1$ for two or more species, we considered that evidence of admixture under our 'Relaxed' criterion. STRUCTURE estimates credibility intervals around each probability value. If the 90% credibility intervals for the values of two or more genetic groups did not overlap zero, we considered this strong evidence of admixture under our 'Conservative' criterion. Our reasoning was to provide two perspectives for interpreting individual ancestry (Bohling and Waits, 2011; Latch et al., 2011). A concern with comparing these results with the red wolf pedigree is that the pedigree is based on theoretical expectations of inheritance while the STRUCTURE results are based on model-estimates using genetic data. To examine if there was any bias in using ancestry estimates based on the pedigree, we compared ancestry estimates produced by both methods for all red wolves involved in hybrid and wolf reproductive events using a paired *t*-test.

Miller et al. (2003) developed a maximum-likelihood assignment test specifically for this red wolf–coyote system. This Canid Assignment Test (CAT) uses genotypes of founders of the captive red wolf population and coyotes from Texas, Virginia, and North Carolina to simulate genotypes of red wolves, coyotes, F1 and F2 hybrids, and F1 × backcrosses with each parental species. Maximum-likelihood tests are then used to estimate the probability of an individual's genotype originating from those six classes. This test is used by the USFWS in conjunction with the pedigree assignment in management decisions and we included those results for another perspective on ancestry.

2.6. Breeder history

We assessed breeder history for each red wolf involved in known hybridization events. The information we collected focused on qualitative descriptions of specific events experienced by the wolves and/or the pack they were associated with. These events were documented by USFWS biologists as they monitored individual wolves over the course of the main period of dispersal and breeding (October–March). Examples of significant events included but were not limited to dispersal, displacement, formation of a new pack, disruption of breeding pairs, and mortality of an associated breeder. In the case of mortalities, a necropsy was conducted to determine whether the cause of mortality was natural or anthropogenic.

3. Results

3.1. Location

From 2001 to 2013, 30 hybrid litters and 126 red wolf litters were documented by USFWS biologists and confirmed via genetic testing (Fig. 2). The mean number of hybrid litters per year was 2.2 ($\pm 1.4\sigma$) whereas the mean number of red wolf litters was 9.7 ($\pm 1.7\sigma$). The average number of pups were higher in hybrid litters (5.5) than red wolf litters (4.2) ($p = 0.001$). In a majority of the cases (27 of 30) a female was confirmed as the red wolf parent of a hybrid litter. A total of 23 female red wolves were involved in hybridization events; most only produced one hybrid litter. Two females were responsible for two hybrid litters each and another was responsible for three. The three male red wolves that produced hybrid litters were responsible for one each.

A majority of the hybrid litters were found in Zones 3 ($n = 14$) and 2 ($n = 11$), with the lowest number in Zone 1 ($n = 5$) (Fig. 1). Conversely, red wolf litters were more evenly distributed (Zone 1 = 35, Zone 2 = 64, Zone 3 = 27). The distribution of red wolf and hybrid litters across the zones was significantly different ($\chi^2 = 8.05$, $p = 0.02$). All red wolves that produced hybrid litters were originally born in the wild except for one female wolf that was born in the island propagation program. Most of the females responsible for red wolf litters were also wild-born ($n = 43$), but four cross-fostered and three island-born females also produced litters. Among males that produced red wolf litters, 47 were wild-born, six island-born, one captive-born, and one cross-fostered.

3.2. Breeder experience

Since a majority of the hybrid litters were produced by females, we only examined breeding age and experience for female red wolves. Among hybrid litters, 16 of 27 involved a female breeding for the first time. This was a significantly higher ($\chi^2 = 8.8$, $p = 0.003$) than the proportion of red wolves litters that involved a first-time breeding female (35 out of 120). Across all litters, the average age of female red wolves responsible for hybrid litters (4.2 years ± 1.6σ) was less than the average age of those responsible for red wolf litters (5.2 years ± 2σ; $p = 0.007$).

3.3. Breeder ancestry

There was no significance difference between the values of ancestry produced by the pedigree and STRUCTURE for individual red wolves ($p = 0.89$). Thus, we report results from the pedigree. Due to the low number of males involved in hybrid litters, we restricted comparisons to female wolves to ensure adequate sample sizes. The average red wolf ancestry of females involved in hybrid events was 0.939 while those involved in red wolf litters had an average of 0.963. Following data transformation, these values were not significantly different ($t = 2.02$, $p = 0.128$). For males, the average amount of red wolf ancestry was 0.947 for those that produced red wolf litters and 0.854 for those producing hybrid litters, but we did not test statistical significance due to low sample size.

The suspected non-red wolf parent was identified by USFWS biologists using field observations for 16 hybrid litters. Two litters involved the same non-red wolf parent: a male that had been mistakenly identified as a red wolf based on morphological examination in the field. Genotypes were obtained for 10 of these non-red wolf parents. Based on the STRUCTURE results, only three individuals appeared to be pure coyotes using the 0.9 q-value threshold (Fig. 3). Two additional individuals also appeared to be coyotes, for they had q-values of 0.81 and 0.77, respectively, for the coyote cluster and no other q-value >0.1. For these five individuals the credibility interval surrounding the q-value for only the coyote cluster did not overlap zero. Four of these individuals we classified as coyotes by the CAT; one, 30272, was classified as a coyote × F1 backcross (Table 2).

Two individuals had q-values indicative of F1 coyote–red wolf hybrids (Fig. 3). Using the red wolf pedigree, we were able to identify the red wolf and coyote parent for both of these individuals, confirming that they were F1 hybrids. Individual 30205 was the only individual for which the credibility intervals for the coyote and red wolf cluster did not overlap zero. Both individuals were classified as F1 hybrids by the CAT (Table 2). Two other individuals appeared to be F1 × red wolf backcrosses (75%), which were confirmed using the pedigree, and one (30145) produced credibility intervals for two clusters that did not overlap zero. The CAT also classified these individuals as F1 × red wolf backcrosses. One individual appeared to be a F1 coyote–dog hybrid × coyote backcross (~75% coyote, ~25% dog) using the 'Relaxed' criterion. To the CAT, which does not incorporate dog ancestry, this individual was a coyote.

3.4. Breeder history

Seven of the 30 hybrid litters had no notable previous history associated with the red wolf responsible for the litter (Table 1). Only two instances resulting in hybrid litters involved red wolves that were considered 'dispersers'. One was a female red wolf that had been displaced by a neighboring female wolf and settled with a non-red wolf mate. The other was a female that exhibited wide movement patterns during the breeding season and never paired

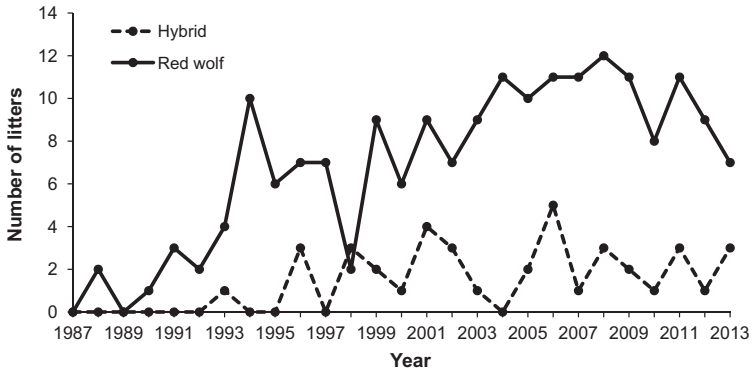

Fig. 2. Number of red wolf and hybrid litters produced each year since the reintroduction of red wolves into North Carolina. Beginning in 2000 the FWS implemented an adaptive management program to genetically monitor the population and reduce hybridization. As a result, for this study we focused solely on litters produced after 2001.

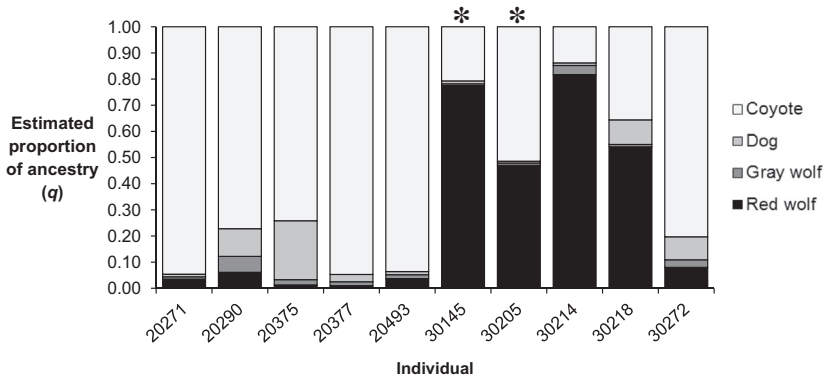

Fig. 3. STRUCTURE ancestry coefficients for the non-red wolf individuals responsible for hybridization events. Each bar represents an individual ancestry composition and each color reflects the ancestry value assigned to each species. This analysis was conducted with a dataset containing 17 polymorphic microsatellite loci. For individuals with a * above their bar plot, the STRUCTURE 90% credibility intervals did not overlap zero for two genetic groups. Individuals 30205 and 30218 were determined to be F1 coyote–red wolf hybrid using the pedigree. Individuals 30145 and 30214 were determined to be F1 × red wolf backcrosses using the pedigree.

Table 2
Results from the Canid Assignment Test (CAT) for non-red wolf individuals responsible for hybridization events. This test uses maximum-likelihood statistics to evaluate the probability of an individual belonging to six separate ancestry classes. The six classes are the two parental species (red wolf, coyote), F1 and F2 hybrid, and F1 backcrosses with each parental species. Values indicated the probability (p) that an individual's genotype can be excluded from that ancestry class. The most likely class is indicated by the term 'LMI'. Coyotes Specific Alleles (CSA) refers to number of alleles possessed by an individual that are found only in coyotes and not the founders of the red wolf population.

Individual	Most likely classification	Maximum-likelihood probability of assignment						CSA

[a] Red wolf × F1 hybrid backcross.
[b] Coyote × F1 hybrid backcross.

with a male red wolf. Three hybridization events were the result of a red wolf pairing with an individual that was previously believed to be a red wolf until genetic testing revealed otherwise. The previous history of these females was unknown. All three of these cases occurred in 2002 and 2003, soon after the implementation of the new management plan and strict genetic testing. Two of these cases involved the same female red wolf and male non-red wolf.

Half of the hybrid litters (16 of 30) followed the disruption of a stable breeding pair of red wolves prior to or during the breeding season. Most of these litters ($n = 9$) followed the death of one or both members of a breeding pair of red wolves by gunshot. Another two followed the death of a red wolf breeder by either poison or a trap injury. Two hybrid litters followed the "disappearance" of a breeder, meaning the FWS has lost radio contact with a breeding member of a red wolf pack. Five hybrid litters followed the disruption of a breeding pair by natural causes. One involved a female wolf whose male partner died naturally after a foreign object punctured a lung, causing a systemic lung infection. Another occurred when a female wolf mated with a non-red wolf after both the breeders in her pack died of mange. The third case involved a female whose mate was killed by another wolf. In two other situations a female red wolf had been paired with a sterilized coyote that was subsequently displaced or killed by a red wolf from another pack; these female red wolves then mated with non-red wolves.

To summarize, excluding the seven cases with no known history, 78% (18/23) of the hybrid events followed disruption of social groups. Of these, 61% (11/18) followed anthropogenic mortality, which could be an underestimate if the two individuals that "disappeared" had a similar fate. In situations of breeder disruption either the remaining breeder ($n = 7$) or a previously unmated member of the pack ($n = 9$) interbred with a non-red wolf.

4. Discussion

Exploring individual records of hybridization events in this red wolf–coyote system provides insights into mechanisms that may regulate interactions between these two species. There are several observations we can draw from the wolves involved in these events. First, a large number (90%) of hybridization events involved female red wolves. Based on genetic data, researchers have hypothesized that introgression between wolves and coyotes predominantly occurred when male wolves bred with female coyotes (Lehman et al., 1991; Mozón et al., 2014); our findings refute that hypothesis and support the genetic results of Hailer and Leonard (2008). It also matches the predictions of Wirtz (1999) that hybridization is driven by females from the rarer species selecting heterospecific mates from the more common species.

Ultimately, it appears that hybridization events tend to follow the disruption of stable breeding pairs of wolves, frequently due to anthropogenic actions such as gunshot mortality. In this system canids begin establishing pair bonds during a period that corresponds with the onset of hunting seasons for large mammals. The elimination of red wolf breeders during the breeding season forces reproductively active red wolves to quickly locate another

mate. A higher percentage of hybrid than red wolf litters were produced by first-time female breeders, which is likely due to the low natural turnover in red wolf breeders from year to year (Sparkman et al., 2011). We hypothesize that as stable red wolf pairs dissolve a social 'release' occurs for young wolves providing them with the opportunity to breed, which echoes findings from other wolf populations (Brainerd et al., 2008). The inexperience of these animals coupled with the timing of pair dissolution during the breeding season may facilitate selection of a heterospecific mate.

Such findings correspond with those from other mammalian carnivore social systems that have demonstrated sensitivity to disruption due to human activity (Tuyttens and Macdonald, 2000; Loveridge et al., 2007; Packer et al., 2009; Wallach et al., 2009; Rutledge et al., 2010; Davidson et al., 2011; Borg et al., in press). By pooling data from multiple wolf populations across Europe and North America, Brainerd et al. (2008) found breeder loss facilitated pack dissolution and abandonment of territory. Disrupting stable social systems in canids has cascading effects on intraspecific and, as shown by this red wolf system and wolves in southeastern Canada (Rutledge et al., 2010, 2011), interspecific interactions. Management of wolves must take into account the consequences of breeding pair dissolution for these events can facilitate genetic introgression into small populations.

The disparity between the number of red wolf and hybrid litters suggests that red wolf pairings are more common than those between red wolves and coyotes, which is encouraging considering coyotes outnumber wolves in portions of the RWEPA (USFWS, 2007; Bohling, 2011; Bartel and Rabon, 2013). Such patterns are heavily influenced by human management, which impacts our interpretation of these results. Regardless, the low number of hybridization events that could be attributed to naturally dispersing individuals suggests that even when sympatric these species do not breed randomly and red wolves seek conspecific mates. This is despite the fact that the red wolf population is increasingly inbred (Brzeski et al., 2014) and genetic diversity has declined over time (Bohling et al., 2013). Inbreeding avoidance can facilitate selection of a heterospecific mate (Palmer and Edmunds, 2000; Gee, 2003). In pack-forming canids inbreeding avoidance is linked with dispersal from natal packs (Sillero-Zubiri et al., 1996; vonHoldt et al., 2008; Sparkman et al., 2012), which could facilitate hybridization if dispersing increases the probability of interacting with heterospecifics. Despite the abundance of coyotes and limited gene pool, hybridization does not appear to be fueled by dispersing red wolves, which indicates some form of assortative mating may be operating in this system.

Many of the non-red wolf parents involved in these hybridization events had mixed ancestry. With the removal of hybrids from the landscape, we expected most hybridization events to involve coyotes; these results, however, suggest that red wolves may be selecting for admixed mates over pure coyotes if available. Both traditional trapping (USFWS, 2007; Bartel and Rabon, 2013) and non-invasive genetic sampling (Adams et al., 2007; Bohling, 2011; Bohling and Waits, 2011) reveal that coyotes vastly outnumber hybrids in this landscape, yet admixed individuals were responsible for 40% of the hybridization events when the non-wolf parent was identified. In hybrid systems in which there is a morphological, behavioral, ecological, or size disparity between the parental groups suggest, hybrids can serve as a bridge between the two parental groups and facilitate introgression (Dowling and Secor, 1997; Goodman et al., 1999; Seehausen et al., 2008; Duvernell and Schaefer, 2014). If red wolves are preferentially selecting admixed mates in this landscape, then efforts to remove hybrids must remain a management priority.

Characterizing the wolves involved in hybridization events is difficult due to the circumstances that surround these events. Any observed patterns could simply be a result of a random artificial selection due to the stochastic nature of anthropogenic mortality. For example, wolves involved in hybridization events tended to have slightly higher levels of coyote ancestry. However, this was not a strong pattern and could be a random artifact. Low sample size of hybridization events relative to red wolf litters, although good for red wolf conservation, limits our ability to draw inferences. Ascertainment bias may also influence the results since the breeding habits of red wolves that are not monitored are difficult to determine. This may explain the overwhelming bias toward female red wolves producing hybrid litters: USFWS biologists monitor female wolves as they begin to localize around a den site so they can locate the pups but do not do the same for males. Questions regarding the impact of genetic ancestry, breeding experience, and sex on hybridization could be best answered with mate choice experiments.

The realization that hybridization tends to follow the disruption of stable breeding pairs is important for management of the red wolf population. There has been a dramatic increase in the amount of gunshot and overall human-caused mortality over the past decade (Bartel and Rabon, 2013). For the adaptive management plan to be successful, more effort must be placed in reducing the number of red wolves killed by gunshot to facilitate efforts to restrict hybridization. A recent agreement between the North Carolina Wildlife Resources Commission and several environmental groups to limit coyote hunting in the RWEPA is a positive step toward achieving this goal (SELC, 2014).

Interpreting the spatial distribution of hybridization events and their significance for red wolf conservation is more complex. Trapping surveys indicate that wolves and coyotes are not evenly distributed across the RWEPA (USFWS, 2007; Bartel and Rabon, 2013). Non-invasive genetic surveys suggest that over 80% of the canids in Zone 1 are red wolves, whereas coyotes composed 70% of the population in Zone 3 (Bohling, 2011). Zone 2 is close to a 50–50 split between the two species. Thus, the abundance of hybridization events in Zone 3 could be simply a result of an abundance of coyotes and the inability of wolves to locate conspecifics, which matched our initial expectations and the classic 'desperation hypothesis' (Hubbs, 1955).

The distribution of hybrid events may also be linked to human social factors and land use practices. Zone 1 is predominantly composed of protected areas under public ownership and the first reintroductions occurred in this area, meaning the USFWS has longstanding relationships with many of the landowners. Expansion of the red wolf population westward has mainly occurred on private lands. Many of these landowners did not anticipate wolf colonization of their property, which has created friction between local communities and the USFWS as was highlighted in an independent review of the red wolf program (WMI, 2014). This conflict, combined with lack of protected refuges for wolves, lack of awareness among the hunting community, and proximity to the mainland coyote population, likely facilitates breeding pair disruption and the spatial pattern of hybridization events.

The management approach taken by the USFWS places value on protecting the genetic 'purity' of the population by limiting hybridization. Such efforts hinge on the commitment to protect a species that today is populated by descendants from just a few founders. The taxonomy and ancestry of these founders has been the source of controversy and some genetic studies suggest the red wolf is a relatively recent product of hybridization between coyotes and gray wolves (Lehman et al., 1991; Roy et al., 1996; vonHoldt et al., 2011). An alternative perspective is that red wolves align closely with eastern wolves in southeastern Canada, which represent a North American-derived wolf sharing a close evolutionary relationship with coyotes (Wilson et al., 2000; Hedrick et al., 2002; Kyle et al., 2006; Rutledge et al., 2012). The debate concerning these alternative hypotheses is ongoing (vonHoldt et al., 2011;

Rutledge et al., 2012). This uncertainty has fueled debate regarding the efficacy of investing resources in the protection of a population potentially derived from hybridization (Gittleman and Pimm, 1991; O'Brien and Mayr, 1991; Jenks and Wayne, 1992; vonHoldt et al., 2011). Further complicating matters is the perception that red wolves have a high propensity to hybridize, leading some to suggest management should be lessened allowing the population to assimilate with the surrounding coyote population (Kyle et al., 2006).

Our results provide a new perspective in this debate by revealing the extent to which human factors, both positive and negative, govern hybridization dynamics in this system. The opposing forces of management designed to maintain the red wolf gene pool and human disruption eroding reproductive boundaries impact our perception of potential red wolf recovery. The current introduced population has remained morphologically (Hinton and Chamberlain, 2014) and genetically (Adams et al., 2007; Bohling et al., 2013) distinct from the resident coyote population. We must recognize that human management as a principle factor in maintaining this pattern. At this point, though, management may operate as a zero-sum game, with facilitation of red wolf reproduction counteracting the impacts of pack disruption. In this case, the infrequency and stochasticity of hybridization events and low number of hybrids across this landscape (Adams et al., 2007; Bohling, 2011; Bohling and Waits, 2011) suggest behavioral processes play a role in maintaining the distinctiveness of the red wolf population.

Research has demonstrated the importance of behavioral forces in regulating interspecific hybridization and species boundaries (Wolf et al., 2001; Pfennig, 2007; Reyer, 2008; Svedin et al., 2008; Krosby and Rohwer, 2010; Sacks et al., 2011; Robbins et al., 2014). Even in the face of introgression, boundaries between parental groups can be maintained through behavioral mechanisms. Our findings mirror those of eastern wolves around Algonquin Park in which hunting disrupted pack dynamics and facilitated coyote introgression (Rutledge et al., 2010, 2011). Following restrictions on hunting in areas surrounding the park, the social dynamics of the population were restored and introgression became less frequent. Reducing manipulation, especially pack disruption, would reveal whether red wolves are capable of maintaining their genetic profile as eastern wolves have. Decisions regarding the future of red wolf management must account for the fact that human activity can facilitate hybridization and in turn impacts our interpretation of the relationship of this species to other canids.

Acknowledgements

Funding for this project was provided by the US Fish and Wildlife Service Red Wolf Recovery Team. We thank J. Adams and members of the USFWS Red Wolf Recovery Team for providing much needed information regarding the history of these animals. A. Beyer compiled the data regarding the history of wolves involved in hybrid events. The Waits Lab and three anonymous peer reviewers provided constructive comments that greatly improved the manuscript. We declare no competing interests in the publication of this manuscript.

ABSTRACT

One of the most endangered species is the red wolf, *Canis rufus*. Reintroduction of the red wolf began in 1987, but in 1993 hybridization between coyotes (*Canis latrans*) and wolves was documented. To reduce genetic introgression, coyotes and coyote–wolf hybrids were captured, sterilized, and released as "placeholders". Placeholders held territories until either displaced or killed by a wolf, or management personnel removed them before releasing a wolf. We evaluated the placeholder concept by examining the number of animals sterilized and released, likelihood of displacement by a wolf, factors influencing displacements, territory fidelity of placeholders, and survival rates and causes of mortality of placeholders and wolves. Of the 182 placeholders, 125 were coyotes and 57 were hybrids. From 1999 to 2013, 51 placeholders were displaced or killed by wolves, and 16 were removed by management personnel. Thus, 37% of the placeholders were displaced leading to occupancy by a wolf. Most displacements occurred in winter (43%) and were always by the same sex. Males were more likely to be displaced than females. Home range characteristics influencing the probability of displacement included home-range size (i.e., more placeholders displaced from larger home ranges) and road density (i.e., more placeholders displaced from home ranges with lower road density). Annual survival of placeholders was higher than wolves in 12 of 14 years, with cause-specific mortality similar among wolves and placeholders. Placeholders provided territories for wolves to colonize, yet reduced the production of hybrid litters, thereby limiting genetic introgression to <4% coyote ancestry in the wolf population.

Published by Elsevier Ltd.

1. Introduction

There is increasing concern about the status and distribution of many carnivore populations throughout the world (Schaller, 1996; Gittleman et al., 2001; Woodroffe, 2001; Ripple et al., 2014). With increasing human populations, many populations of carnivores are exposed to changes in land-use practices, increased habitat loss and fragmentation, increased human persecution, declines in natural prey species, increased disease transmission from domestic and wildlife species, illegal poaching, and increased competition with other carnivores (Gese, 2001; Sillero-Zubiri et al., 2004; Loveridge et al., 2010). As a result of these varied and diverse influences, many populations of large, medium, and small-bodied carnivores have undergone a general decline with some species now occupying a fragment of their former range (IUCN, 1990; Cole and Wilson, 1996; Woodroffe, 2001).

One threat facing a few carnivore species is hybridization resulting in genetic introgression with sympatric species (Wayne et al., 2004). While hybridization is an important evolutionary process (Allendorf et al., 2001), it poses a threat to the persistence and conservation of several wild canid species. Hybridization with domestic dogs poses a threat to the Ethiopian wolf (*Canis simensis*; Gottelli et al., 1994) and the European gray wolf (*Canis lupus*). Hybridization among several related canids in Ontario, Canada, could threaten the genetic integrity of a population of eastern wolves (*Canis lycaon*) in Algonquin Provincial Park (Patterson and Murray, 2008). In the United States, hybridization between red wolves (*Canis rufus*) and coyotes (*Canis latrans*) was identified as one of the greatest threats to conservation efforts and recovery of red wolves in eastern North Carolina (Kelly et al., 1999; Stoskopf et al., 2005). Reducing genetic introgression of coyote genes into the red wolf population presents a unique challenge for the U.S. Fish and Wildlife Service (USFWS), the agency charged with reintroducing and managing the current red wolf population (U.S. Fish and Wildlife Service, 1989, 2007).

In 1987, four pairs of red wolves were released at the Alligator River National Wildlife Refuge (ARNWR) in eastern North Carolina (Phillips and Parker, 1988). By 1993, the wolves had successfully bred and re-establishment of a free-ranging experimental population was considered to be a success (Phillips et al., 2003). The experimental population area primarily encompassed the Albemarle Peninsula, which did not have coyotes present during the initial reintroduction. However, by the early 1990s the presence of coyotes was documented and shortly thereafter hybridization between red wolves and coyotes occurred

0006-3207/Published by Elsevier Ltd.

(Adams et al., 2003; Phillips et al., 2003). In 1999, a population and habitat viability assessment recognized several threats to the free-ranging red wolf population (Kelly et al., 1999), with hybridization with coyotes being the greatest threat to recovery of the species. Subsequently, the USFWS adopted a Red Wolf Adaptive Management Plan (RWAMP) with one of the objectives to reduce hybridization between coyotes and red wolves (Kelly, 2000).

As part of the RWAMP (Kelly, 2000), sterilization of coyotes and hybrid animals was proposed to reduce genetic introgression into the red wolf population. While sterilization has been tested as a management tool to reduce predation on domestic livestock and wild neonatal ungulates (Bromley and Gese, 2001a; Seidler et al., 2014) and proposed as a method for population control (Mech et al., 1996; Haight and Mech, 1997), using sterilization to reduce genetic introgression was a novel application. In essence, sterilized coyotes and hybrids would be allowed to remain on the landscape, maintaining social bonds and territories (Bromley and Gese, 2001b; Seidler and Gese, 2012), and serve as "placeholders" that would maintain territories, thereby reducing residency of home ranges in the recovery area by reproductive coyotes or hybrids, and thus reducing the threat of hybridization with a red wolf (i.e., producing hybrid offspring if pairing with a red wolf occurred; Stoskopf, 2012) and facilitating expansion of the red wolf population. The sterile placeholders could be displaced from their territories by a red wolf, or the USFWS could remove these sterile animals and release red wolves at that site when either a captive or wild-born red wolf was available for release. Sterilization was not used to control or manage the coyote population in the recovery area, but to create non-reproductive territories with sterile animals that were incapable of successfully reproducing with intact red wolves.

In late 1999, a plan to sterilize coyotes and hybrids to serve as placeholders in the Red Wolf Recovery Experimental Population Area (RWREPA) in eastern North Carolina was initiated. In this paper, we introduce and evaluate the placeholder concept as a management tool, covering its use in the red wolf recovery area from 1999 to 2013. As part of this evaluation, we examined (1) the number of animals (coyotes and hybrids) that were sterilized and released as placeholders, (2) the likelihood of a placeholder being displaced by a red wolf and the biotic and abiotic factors influencing these displacements, (3) the degree of territory fidelity of placeholders (i.e., the likelihood of dispersing after being sterilized), (4) survival rates and causes of mortality of both placeholders and red wolves, and (5) the number of hybrid litters born per year in the recovery area. Ultimately, the management goal is the reduction and eventual elimination of genetic introgression from coyotes into the red wolf population, thus allowing for continued persistence of a free-ranging population of red wolves in the wild.

2. Materials and methods

2.1. Study area

The Red Wolf Recovery Experimental Population Area (RWREPA) study area was located in northeastern North Carolina on the Albemarle Peninsula and encompassed approximately 4900 km^2 (Fig. 1). The peninsula is part of the South Atlantic Coastal Plain and is a combination of tidal (estuarine) and non-tidal (palustrine) wetlands, and mixed upland forests. The western region is dominated by mixed pine-hardwood forests of loblolly pine (*Pinus taeda*), white oak (*Quercus alba*), hickory (*Carya tomentosa*), beech (*Fagus grandifolia*), tulip tree (*Liriodendron tulipifera*), sweetgum (*Liquidambar styraciflua*), and red maple (*Acer rubrum*) (Hartshorn, 1972). Pocosins are palustrine wetlands endemic to the Atlantic coast and are found throughout the study area. The acidic and nutrient poor soils of pocosins facilitate dominance by pond pine (*P. serotina*) although loblolly and longleaf pine (*P. lalustris*) are common. The vegetation of the central region exhibits a gradual west-to-east change from upland species to palustrine wetlands dominated by tupelo (*Nyssa sylvatica*), Atlantic white cedar (*Chamaecyparis thyoides*), loblolly pine, and bald cypress (*Taxodium distichum*) (Lynch and Peacock, 1982; Moorhead and Brinson, 1995). Estuarine wetlands have their highest incidence in the eastern region of the study area (mainly Dare and Hyde counties), primarily along the coastline and are dominated by black rush (*Juncus roemerianus*) with areas of wetland grasses (*Spartina alterniflora*, *S. patens*, *Cladium jamaicense*), marsh elder (*Iva frutescens*), and false willow (*Baccharis angustifolia*) (Moorhead, 1992).

Within the RWREPA the principal landowners were private timber and agricultural corporations with federal and state governments having the next highest proportions of land ownership. There were numerous wildlife refuges contained within the study area with the two largest being the ARNWR and Pocosin Lakes National Wildlife Refuge

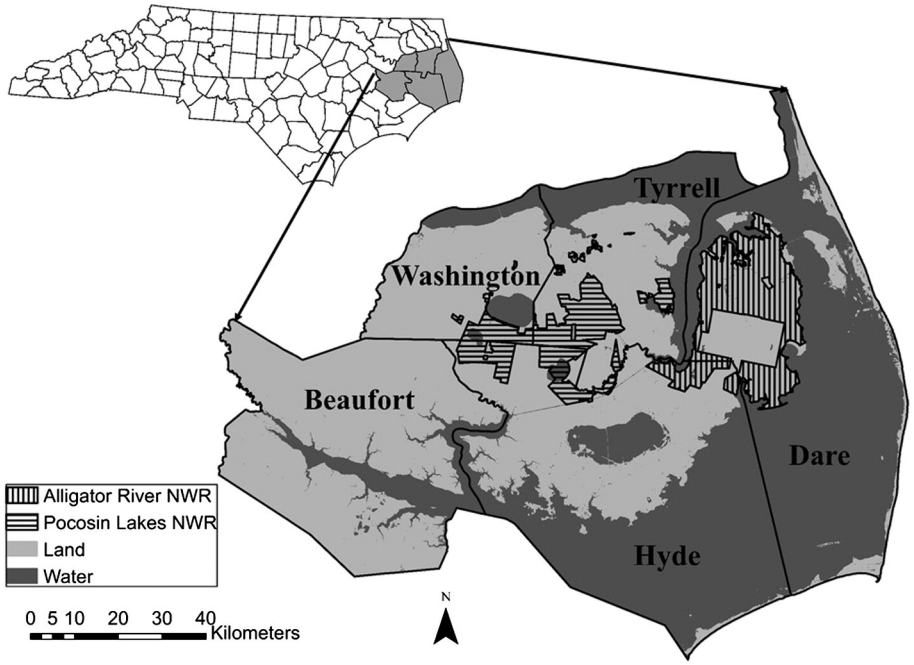

Fig. 1. The five county Red Wolf Recovery Experimental Population Area in northeastern North Carolina including the location of the two largest National Wildlife Refuges.

(PLNWR; Fig. 1). The ARNWR was located in the extreme northeastern section of the study area and was designated as the initial red wolf reintroduction site in 1987 due to a lack of coyotes and human presence, but with abundant prey (Phillips and Parker, 1988). Contained within the ARNWR was a 19,020-ha U.S. Air Force bombing range. The average annual rainfall for ARNWR was 145 cm without seasonal fluctuations, although 4.8 cm of snow falls annually during the winter (U.S. Department of the Interior, 2008). The 44,560-ha PLNWR was located in the central portion of the study area (Fig. 1). The total human population for the study area in 2010 was 105,124 people (U.S. Census Bureau, 2010).

2.2. Capture, sterilization, and monitoring of study animals

All capture, handling, aerial telemetry, and monitoring of red wolves, coyotes, and hybrids was conducted by USFWS personnel. Genetic analysis of blood samples collected from captured animals was used for species identification (Miller et al., 2003; Adams, 2006; Bohling et al., 2013). Beginning with the reintroduction in 1987, all red wolves released from captivity were equipped with a very high frequency (VHF) radio-collar (Telonics, Mesa, Arizona, USA; Phillips and Parker, 1988). Adults (>9 months old) born in the wild were trapped with a padded, foot-hold trap, immobilized, and fitted with a VHF radio-collar, body measurements and weight recorded, and a blood sample drawn. Pups born in the wild were implanted with an integrated transponder (PIT) tag (Trovan®; Beck et al., 2009). Radio-collared adult red wolves were located 2–3 times/week from an airplane or ground based vehicle. Starting in 2007, many red wolves were fitted with a GPS radio-collar (Lotek Wireless, Newmarket, Ontario, Canada) which obtained a location every 5 h (Dellinger et al., 2013).

Starting in 1999 and continuing through to 2013, adult (>9 months old) coyotes and hybrids within the RWREPA were sterilized to examine the feasibility of the placeholder concept. Captured coyotes and hybrids were either sterilized or removed (euthanatized) from the recovery area (Kelly, 2000; Gese et al., 2015), and thus there were no intact coyotes and hybrids monitored during this study. Upon capture in a padded, foot-hold trap, coyotes and hybrids were transported to a surgical facility, sterilized, then fitted with a VHF radio-collar (Telonics, Mesa, Arizona, USA), body measurements and weight recorded, and blood drawn. Females were sterilized by tubal ligation or spay, while males were vasectomized or neutered (Bromley and Gese, 2001b; Seidler and Gese, 2012). Animals spayed or neutered were classed as "hormones not intact", while animals undergoing tubal ligation or vasectomy were classed as "hormones intact" (Asa, 2005). All surgical procedures were conducted by a licensed veterinarian after the animals were anesthetized. Animals were monitored overnight for post-operative complications and released at their capture site the following day. Research techniques and animal care procedures were conducted under permits and standard operating protocols approved by the U.S. Fish and Wildlife Service.

Sterilized coyotes and hybrids wearing VHF radio-collars were located on a regular basis (2–3 times/week) during the same aerial telemetry flights as the red wolves. Locations of the placeholders provided spatial information including home range location and boundaries (USFWS, unpublished data) for the 182 placeholders (Fig. 2). Data were also recorded for the date of displacement, the species which displaced or killed the coyote or hybrid, and if available, the specific individual that displaced the placeholder. Because aerial telemetry was conducted during the day, we were concerned if the home ranges determined from daytime locations may underestimate space use (Gese et al., 1990). However, the average home range size of the 182 VHF radio-collared resident placeholders in the study area was 23.5 ± 12.0 (range 5.5–64.5 km^2), similar to the mean home range of 27.2 km^2 for coyotes later equipped with GPS-collars (Hinton, 2014).

2.3. Biotic and abiotic factors influencing displacement

For each placeholder's home range, we determined the percent composition of 10 land cover types within their home range using ArcGIS 10.2.2 (ESRI, Redlands, California, USA). Land cover types were obtained from LANDFIRE 1.3.0 (LANDFIRE 1.3.0., 2012) and included agriculture, sparse, developed, herbaceous, marsh, riparian, shrubland, swamp, forest, and water. Land ownership was compiled from state GIS databases and included federal, state, private, and non-governmental organizations (NGO). A digital representation of primary and secondary roads was obtained from the North Carolina Department of Transportation (https://connect.ncdot.gov/resources/gis/; accessed July 2014). The length of primary and secondary roads in each home range was

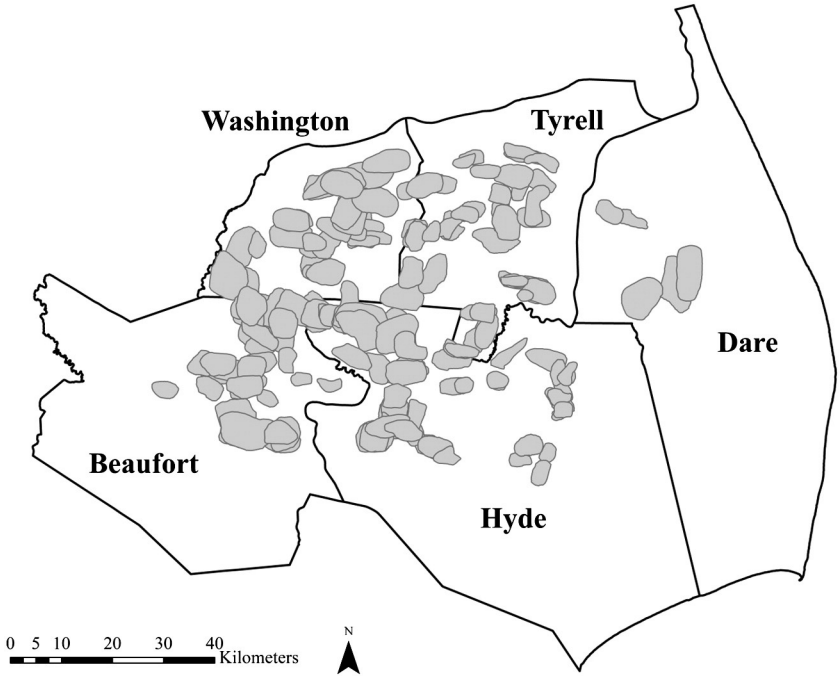

Fig. 2. Home ranges of placeholders (i.e., sterilized coyotes and hybrids) in the Red Wolf Recovery Experimental Population Area, North Carolina, 1999–2013.

converted to road density (km/km^2). We used generalized linear models (GLM) with a binomial distribution and logit link function to examine the influence of abiotic (home range characteristics) and biotic (placeholder characteristics) factors on the probability of being displaced ($y = 1$) or not displaced ($y = 0$) by a red wolf. Home range characteristics were assessed for each placeholder's home range, including home range size (km^2), road density (km/km^2), percent occurrence of each land cover type, dominant land cover type, percent occurrence of each land owner type, and dominant land owner type. Placeholder characteristics included sex of the placeholder, body length, and sterilization procedure (hormones intact or not intact). We developed separate GLMs to examine the effects of the home range and placeholder characteristics. Correlated variables ($r > 0.25$) were not allowed to enter the same model as additive or interactive effects.

We ranked all home range and placeholder characteristic GLMs and the null model using the Bayesian Information Criteria (BIC; Schwarz, 1978). Variables from the highest ranked model of home range characteristics were combined with variables from the highest ranked model of placeholder characteristics to generate a set of models containing both combinations of predictor variables, and we again used BIC (Schwarz, 1978) to compare models (Scheiner, 2004). All model development and analysis was conducted in the R statistical software (R Core Team, 2014).

2.4. Cause-specific mortality and survival rates

Radio-collared adult red wolves, coyotes, and hybrids were monitored 2–3 times/week allowing for the early detection of a mortality signal and facilitating recovery of the carcass to determine the cause of death. If applicable, a field necropsy was conducted, or if the cause of death was not apparent, the carcass was examined by a veterinary pathologist. We classified mortalities into one of three classes: anthropogenic, natural, or unknown. Anthropogenic mortality included any human-caused death not due to removal of coyotes or hybrids by agency personnel to make that home range available to a red wolf. Thus, anthropogenic mortality included causes of death from gunshot, vehicle collision, foul play, trapping, and poisoning. Foul play included suspected gunshot or suspected illegal take. Natural mortalities included health-related incidences such as disease or parasite load, and interspecific and intraspecific aggression resulting in death of the animal. A total of 182 placeholders and 410 red wolves were monitored from 1 January 1999 to 31 December 2013. We calculated annual survival rates for red wolves, sterile coyotes, and sterile hybrids using the program MICROMORT (Heisey and Fuller, 1985), but limited our survival analysis to the time period of 2000 to 2013 as there was only one sterile coyote and four sterile hybrids available for monitoring in 1999.

2.5. Composition of litters

During spring, personnel from the USFWS monitored radio-collared red wolves and located breeding females at active dens to determine the composition of the litter (Bohling and Waits, 2015; Gese et al., 2015). Pups born in the wild were implanted with an integrated transponder (PIT) tag (Trovan®; Beck et al., 2009) for future identification during subsequent capture operations in the fall when pups were large enough to be radio-collared. If the genetic origin of the litter was questionable, blood samples were obtained and examined using 18 nuclear DNA microsatellite loci to determine their ancestry and red wolf pedigree (Miller et al., 2003; Adams, 2006; Bohling et al., 2013).

3. Results

3.1. Displacement events

From 1999 to 2013, the USFWS captured, sterilized, and released 218 animals to serve as placeholders within the RWREPA. Of these, 15 were classed as transients (cf Gese et al., 1988), 13 were killed <3 months after release, and 8 disappeared (i.e., lost contact with the radio-collar) <3 months after release, thereby leaving 182 individuals for analysis. These 182 placeholders included 66 female and 59 male coyotes, and 26 female and 31 male hybrids. Of the 182 placeholders monitored, 51 were displaced by wolves (37 were spatially displaced by wolves from their territories and 14 were killed by a red wolf). In addition, 16 placeholders were removed by USFWS personnel and a red wolf released into the territory. Thus, 67 (37%) of the 182 placeholders were naturally displaced or artificially removed, leading to occupancy of the territory by a red wolf. During the same time period, 146 (35%) displacements out of 410 red wolves monitored were also documented. No coyote or hybrid displaced a red wolf; red wolves were displaced only by another red wolf. All displacements (100%) of placeholders were by a red wolf of the same sex. Similarly, for red wolves 98% of red wolf displacements were by a red wolf of the same sex.

Of the 51 naturally occurring displacements of placeholders, the frequency of displacements varied seasonally ($\chi^2 = 9.37$, df = 3, $P = 0.025$) with the most displacements occurring in winter (43%; 1 December–28 February), followed by spring (25%; 1 March–31 May), fall (18%; 1 September–30 November), and summer (14%; 1 June–31 August). Similarly, the 146 displacements of red wolves by red wolves varied seasonally ($\chi^2 = 31.64$, df = 3, $P < 0.001$) with most displacements occurring in winter (41%), followed by spring (26%), fall (25%), and summer (8%).

Although there were similar numbers of female (n = 92) and male (n = 90) placeholders, sterilized males were more likely to be displaced than sterilized females (males: 34.4% displaced, females: 21.7% displaced; $\chi^2 = 3.64$, df = 1, $P = 0.056$), regardless if the male was a sterile coyote (32.2%) or a sterile hybrid (38.7%; Fig. 3). Female placeholders that underwent tubal ligation and were hormonally intact were no more likely to be displaced than females that underwent a spay and were not hormonally intact (tubal ligation: 19.4% displaced; spay: 30.0% displaced; $\chi^2 = 1.025$, df = 1, $P = 0.31$; Fig. 4). Similarly, males that underwent vasectomy and were hormonally intact were also no more likely to be displaced than males that underwent a neuter surgery and were not hormonally intact (vasectomy: 32.9% displaced, neuter: 42.3% displaced; $\chi^2 = 0.519$, df = 1, $P = 0.47$; Fig. 4). The weight at capture of displaced female placeholders (13.21 ± 2.57 kg, standard deviation [SD]) was no different than female placeholders that were not displaced (13.50 ± 2.58 kg; $t = 0.450$, df = 30.499, $P = 0.65$). Similarly, the weight at capture of male placeholders that were displaced (15.84 ± 3.48 kg) was not different than the male placeholders that were not displaced (14.94 ± 2.58 kg; $t = -1.265$, df = 47.725, $P = 0.2119$).

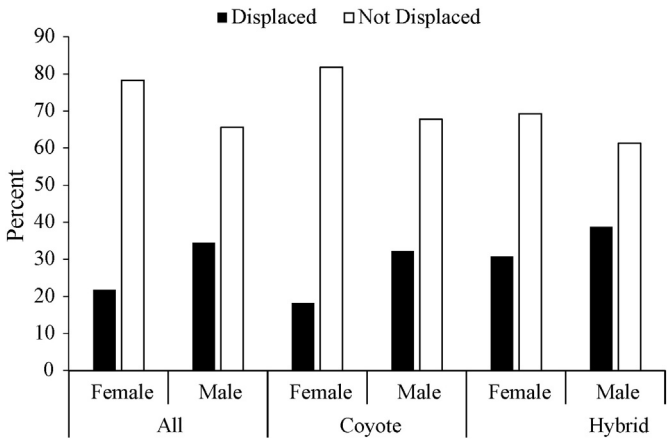

Fig. 3. The percent of male and female coyotes and hybrids serving as placeholders that were displaced and not displaced by red wolves in the Red Wolf Recovery Experimental Population Area, North Carolina, 1999–2013.

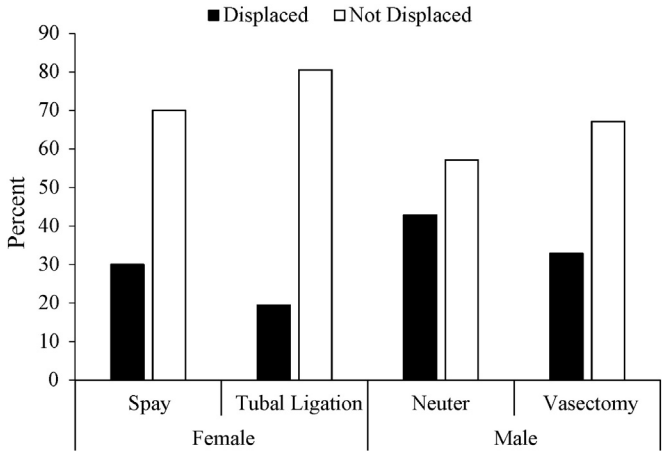

Fig. 4. The percent of 182 placeholders, sterilized by four methods, which were displaced and not displaced by red wolves in the Red Wolf Recovery Experimental Population Area, North Carolina, 1999–2013.

3.2. Biotic and abiotic factors influencing displacement

We examined the abiotic (home range characteristics) and biotic (placeholder characteristics) factors influencing the likelihood of a placeholder being displaced. Of the 63 models of home range characteristics examined plus the null model, the highest ranked was the null model followed by models containing home-range size or road density (Table 1). We found that the percent of placeholders displaced by a red wolf increased as home-range size increased (Fig. 5A). At home ranges <20 km^2, 17 of 85 (20%) placeholders were displaced by red wolves, while in contrast, 10 of 26 (38%) of the placeholders with home ranges >35 km^2 in size were displaced. In contrast, we found that the percent of placeholders displaced by a red wolf decreased with increasing road density, with displacements being highest at low road densities (Fig. 5B). All other models of home range characteristics had ΔBIC values >10 and model weights <0.01, thus home-range size and road density were carried forward to the combined models (Burnham and Anderson, 2002). Interestingly, neither the composition of land ownership or the dominant land ownership, nor the composition of land cover type or dominant land cover type influenced whether a placeholder was displaced by a red wolf.

Of the seven models of placeholder characteristics and the null model, the highest ranked was the null model followed by the univariate model of placeholder sex (Table 2). As described previously, we found male placeholders were more likely to be displaced than female placeholders (males: 34.4%, females: 21.7%). All other models of placeholder characteristics had ΔBIC values >4 and model weights <0.08, thus placeholder sex was the single variable carried over to generate the combined models. Of the eight combined models examined and the null model, the highest ranked model was the null model followed by the univariate model containing placeholder sex, then the univariate models containing home-range size and road density (Table 3).

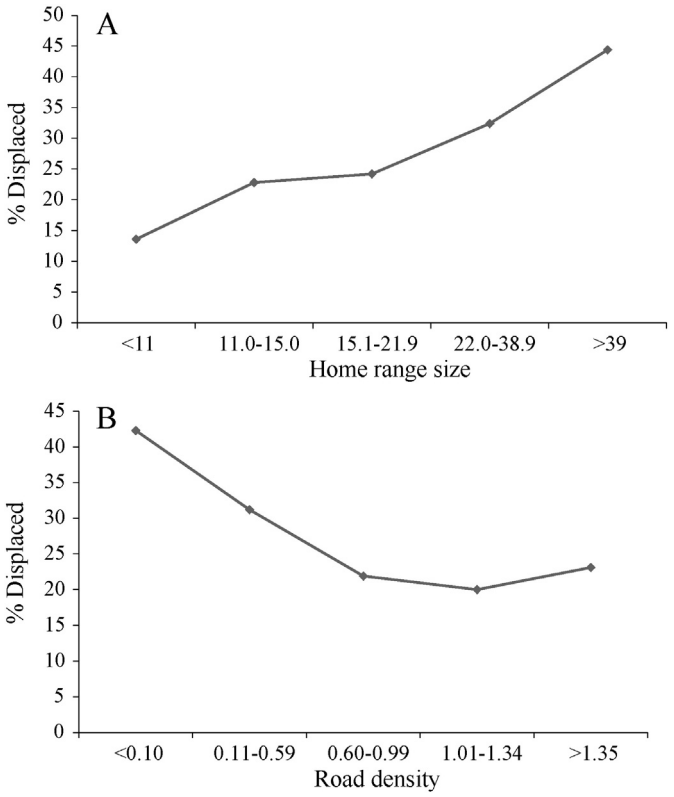

Fig. 5. The percent of placeholders displaced by a red wolf across (A) five classes of home-range size (km^2) of the placeholder, and (B) five classes of road density (km/km2) within a placeholder's home range, Red Wolf Recovery Experimental Population Area, North Carolina, 1999–2013.

3.3. Territory fidelity

Dispersal of juvenile animals from their natal home range is a common occurrence among most canid species. However, we emphasize that because only adult coyotes and hybrids >9 months of age were sterilized and used as placeholders, we only examined territory fidelity for adult canids in the study area (i.e., we did not include juvenile dispersal from their natal home ranges). Territory fidelity of adult canids was high during the study. During the 14 years of monitoring (2000–2013), of the 125 adult coyotes serving as placeholders, only 2 (1.6%) adult sterile coyotes dispersed from their resident territory. Of the 57 adult hybrid animals serving as placeholders, 4 (7.0%) adult hybrids dispersed from their territory. Similarly, of the 410 adult red wolves monitored during the same time period, 11 (2.7%) adult red wolves dispersed from their resident territory. In contrast to and for

Table 1

Home-range size (km^2) * Road density (km/km^2) + Sex	10.4	5	0.00

comparative purposes, we found that 103 (25.1%) of the juvenile red wolves dispersed at some time from their natal home range.

3.4. Survival rates and cause-specific mortality

We estimated annual survival rates for the 182 adult placeholders that were monitored for 137,784 radio-days (sterile coyotes: 84,093 radio-days; sterile hybrids: 53,691 radio-days) during 1999 to 2013. For comparison, we examined survival rates of 410 adult red wolves monitored for 388,587 radio-days during the same time period. In general, the sterilized adult placeholders (coyotes and hybrids combined) had higher survival rates than adult red wolves (Fig. 6). Mean annual survival was highest for sterilized hybrids (0.876 ± 0.11, standard deviation, SD), lowest for red wolves (0.80 ± 0.04) and intermediate for coyotes (0.843 ± 0.12). Red wolves exhibited higher annual survival than the placeholders in only two (14%) of the 14 years of the study, while placeholders had the highest survival in 12 (86%) of the 14 years monitored. Interestingly, sterilized coyotes had the highest survival in 6 (43%) of the 14 years and hybrids also had the highest survival in 6 (43%) of the 14 years.

Some sources of mortality among adult red wolves and adult placeholders were similar, while some specific causes were more species related (Table 4). Anthropogenic causes of mortality was similarly high for both adult red wolves and adult placeholders (red wolves vs. placeholders: $\chi^2 = 0.47$, 1 df, $P = 0.49$), and the number of deaths due to natural and unknown causes was similar

Table 4
Anthropogenic, natural, and unknown causes of mortality for adult red wolves and sterile placeholders (coyotes, hybrids) in the Red Wolf Recovery Experimental Population Area, northeastern North Carolina, 1999–2013.

	Red Wolves % (n)	Sterile Coyotes % (n)	Sterile Hybrids % (n)
Anthropogenic			
Gunshot	37.1 (91)	23.8 (10)	33.3 (8)
Vehicle	17.6 (43)	19.0 (8)	8.3 (2)
Foul Play	4.1 (10)	14.3 (6)	8.3 (2)
Trapping	2.4 (6)	4.8 (2)	4.2 (1)
Poisoning	2.4 (6)	0 (0)	0 (0)
Total	63.7 (156)	61.9 (26)	54.2 (13)
Natural			
Health-related	11.8 (29)	0 (0)	4.3 (1)
Interspecific	0 (0)	19.0 (8)	20.8 (5)
Intraspecific	5.7 (14)	0 (0)	0 (0)
Total	17.6 (43)	19.0 (8)	25.0 (6)
Unknown	18.8 (46)	19.0 (8)	20.8 (5)
Total deaths	245	42	24

(Table 4). A similar high percentage of red wolves and placeholders were killed by gunshot and foul play (red wolves vs. placeholders: $\chi^2 = 0.07$, 1 df, $P = 0.788$). Six red wolves were killed by poisoning and no placeholders were killed by poisoning (red wolves vs. placeholders: $\chi^2 = 1.65$, 1 df, $P = 0.199$). No red wolves were killed by placeholders (sterile coyotes or sterile hybrids), but 19% of the sterile coyote mortalities and 21% of the sterile hybrids mortalities were caused by interspecific aggression from red wolves (red wolves vs. placeholders: $\chi^2 = 50.36$, 1 df, $P = 0.0001$). Red wolves were rarely killed (~6% of mortality) by conspecifics (i.e., intraspecific aggression) and no placeholders were recorded as killed by conspecifics (red wolves vs. placeholders: $\chi^2 = 3.95$, 1 df, $P = 0.0469$).

3.5. Composition of litters

In general there was little variation in the number of hybrid litters from 2000 to 2013 with a mean of 2 hybrid litters/year (±1, standard deviation) with a maximum of 5 litters in 2006 and no hybrid litters in 2004 (Fig. 7). During the same time period, the number of red wolf litters has varied with a mean of 9 litters (±2) and ranged from 6 to 12 litters each year.

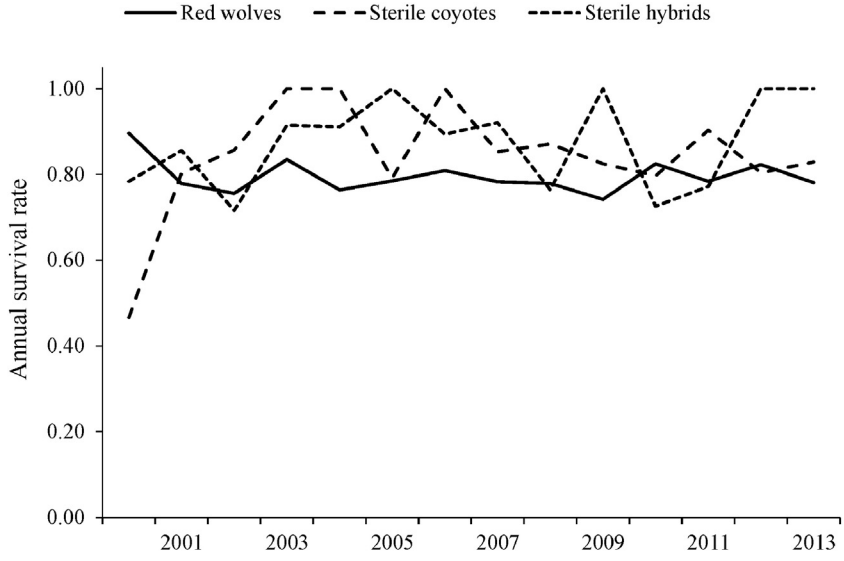

Fig. 6. Annual survival rates of adult red wolves (n = 410), sterilized adult coyotes (n = 125), and sterilized adult hybrids (n = 57), in the Red Wolf Recovery Experimental Population Area, North Carolina, 2000–2013.

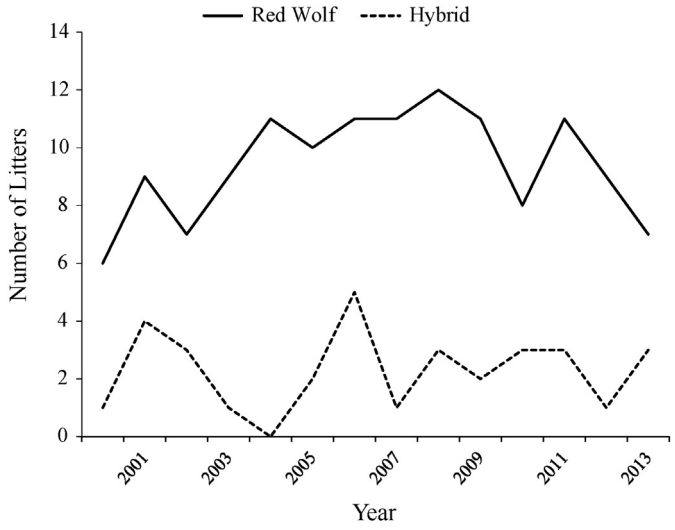

Fig. 7. The number of red wolf and hybrid litters in the Red Wolf Recovery Experimental Population Area, North Carolina, 2000–2013.

4. Discussion

Many factors threaten the persistence of canid populations throughout the world (Gittleman et al., 2001; Woodroffe, 2001; Ripple et al., 2014). Hybridization with coyotes followed by genetic introgression was identified as one of the greatest threats to recovery of red wolves in North Carolina (Kelly et al., 1999). Sterilization of coyotes and hybrid individuals was proposed to serve as placeholders to reduce hybridization and genetic introgression of the red wolf population (Kelly, 2000). This is the first documented case of using sterilization and the placeholder concept to mediate hybridization and genetic introgression between similar taxonomic canids. The primary objective of the placeholder concept was to limit opportunities for intact red wolves to produce viable offspring during mating events with coyotes or hybrid animals, as well as keeping space available for red wolves without the threat of producing hybrid offspring if pairing with a red wolf occurred (Stoskopf, 2012). These sterile placeholders could then be displaced from these territories by a red wolf, or these sterile animals could be removed and red wolves released into the now empty territory. Sterilization was not used to control or manage the coyote population in the recovery area, but to create non-reproductive territories with sterile animals that were incapable of successful reproduction (i.e., hybridization).

Natural displacements and strategic management removals of placeholders resulted in 37% of those sterile placeholders being replaced by red wolves in that territory. Displacements were unidirectional with red wolves displacing and replacing placeholders, but no placeholder displaced red wolves during the 14 years of monitoring. Interestingly, animals not having hormonal systems intact (i.e., animals spayed or neutered) were not displaced at a higher frequency than sterile animals with intact hormones (i.e., animals tubal ligated or vasectomized). Intact hormonal systems are generally believed to be necessary for pair bonding and territorial maintenance (Asa, 1995). The higher frequency of displacements in winter is not surprising given that the breeding season would compel animals to seek mating opportunities. The finding that male red wolves displaced male placeholders, and female red wolves displaced female placeholders reinforces the mating opportunity hypothesis.

We found that home range size and road density influenced the percentage of placeholders displaced by red wolves. At home ranges <20 km^2, 20% of the placeholders were displaced by red wolves, while 38% of the placeholders with home ranges >35 km^2 were displaced. Red wolves have larger home ranges (Chadwick et al., 2010) than coyotes, and may thus prefer to acquire larger areas in which to establish residency. Similarly, home ranges of placeholders that contained low road densities were preferred by red wolves, leading to higher displacement rates. Dellinger et al. (2013) reported red wolves avoided areas with high human density, and suggested red wolves will use human-associated landscapes, but modify their habitat selection patterns with increased human presence. Thus large home ranges with low road density appear to be preferred by red wolves and placeholders occupying said home ranges have a higher likelihood of being displaced. Interestingly, of the 26 placeholders with home ranges >35 km^2, the 10 placeholders displaced had a median home range size of 47 km^2 and a median road density of 0.48 km/km^2, while the 16 placeholders not displaced had a median home range size of 41 km^2 and a median road density of 0.63 km/km^2. Past studies on gray wolves have suggested wolves tended to survive where human density was low and road density was <0.58 km/km^2 (Thiel, 1985; Mech et al., 1988). Red wolves and coyotes used similar habitats and space (Hinton, 2014), thus the lack of habitat variables influencing displacements was likely due to similar habitat selection and requirements.

Annual survival rates of placeholders were higher than red wolves in 12 of the 14 years of monitoring. Coyotes and hybrids each had the highest survival rates in 6 of the 14 years. Even first generation hybrids had survival values more similar to coyotes than red wolves, indicating that hybridization conferred some level of increased survival abilities more reminiscent of coyotes. Perhaps the smaller body size, dietary breadth (Hinton, 2014), and behavioral plasticity of hybrids, which are more similar to coyotes than red wolves, also allowed for increased survival rates. Coyotes are adaptable to human-modified environments (Bekoff and Gese, 2003; Gehrt, 2004; Gese et al., 2012), and hybridization appeared to confer similar "coyote-like" survival traits to hybrid individuals.

While causes of mortality were similar among red wolves, coyotes, and hybrid animals, red wolves did experience a higher frequency of gunshot and health-related mortality. The high red wolf mortality due to gunshot is cause for concern as many of these mortalities occurred in the breeding season during the past 2–3 years (Hinton et al., in review) and not only limited potential litter production of red wolf pairs in the last 2 years (Fig. 7), but also opened opportunities for hybridization between red wolves and coyotes by reducing mating opportunities with red wolves (Bohling and Waits, 2015; Gese et al., 2015). While sterilization of placeholders does limit successful reproduction between red wolves and coyotes, it is impractical to capture and sterilize all coyotes in the recovery area.

While only 37% of the placeholders were naturally or artificially displaced leading to red wolf occupancy of the territory, the remaining 63% did protect space in which no hybrid litters could be produced. Ultimately, limiting genetic introgression into the red wolf population is the overall goal of the use of the placeholder concept. In 2014, the genetic composition of the wild red wolf population was estimated to include $<4\%$ coyote ancestry from recent introgression since reintroduction (Gese et al., 2015). Use of placeholders, combined with removal of coyotes and hybrids, release of captive adult red wolves, and cross-fostering of captive pups into wild red wolf litters, appeared to be effectively limiting genetic introgression into the red wolf population (Gese et al., 2015). Continued intensive management will likely be necessary in the future to limit hybridization and genetic introgression. Using the placeholder concept to limit hybridization in other canid species has potential. Hybridization with domestic dogs poses a threat to the Ethiopian wolf (Gottelli et al., 1994) and the European gray wolf, but sterilization to generate placeholders may not be an effective strategy in these situations because domestic dogs are the introgressing species and sterilizing all free-ranging domestic dogs would be impossible. Using the placeholder concept to reduce or limit hybridization among several related canids in Ontario and reduce the threat of genetic introgression into a population of eastern wolves in Algonquin Provincial Park (Patterson and Murray, 2008) may be more practical.

5. Conclusions

Sterilization has been used in the recent past to reduce predation rates by coyotes on domestic and native ungulates (Bromley and Gese, 2001a; Seidler et al., 2014), but using sterilization to limit genetic introgression into the red wolf population is the first use of sterile animals within the context of the "placeholder" concept. We emphasize that sterilization was not used to limit the distribution or size of the coyote population, but to reduce the incidence of hybridization between coyotes and red wolves and genetic introgression into the red wolf population. Results from this experiment demonstrate the utility of the placeholder concept to limit genetic introgression of coyotes into the recovering red wolf population in northeastern North Carolina. Territories were held by sterilized placeholders and then being successfully displaced by red wolves resulting in red wolf occupancy. Equally important was production of hybrid litters was limited to a few each year in the recovery area, and the genetic composition of the red wolf population in 2014 contained <4% coyote introgression. The utility and application of the placeholder concept may be practical for limiting genetic introgression in similar situations where an introgressing species threatens the genetic integrity of a sympatric carnivore.

STATE: North Carolina

GRANT TITLE: W79-Wildlife Management

PROJECT TITLE: Pilot Study – Using Fine Scale GPS Technology to Research Sympatric Canid Population Dynamics (Job 2.0?)

A. Problem and Need

The coyote (*Canis latrans*) is now abundant throughout the 100 counties in North Carolina (NC), and is managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plain region of NC (Hinton et al. 2012, Murray et al. 2014). In recent years as coyotes have increased their population, some have begun to make use of the Outer Banks region.

The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of captive-bred red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). This population increased until 2008 and peaked at around 130 individuals (Group Solutions, Inc. 2016), short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013). The AP has an estimated carrying capacity of 140-150 wolves (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). The exact number of red wolves is not known, but USFWS staff report a population estimate of 45-60 individuals with eight mortalities to date in 2016 (https://www.fws.gov/redwolf/index.html August 2016). Hybridization with coyotes and inbreeding depression are suspected factors that have affected red wolf population growth and viability since the inception of the Red Wolf Recovery Program (RWRP), while vehicular and gunshot mortality are known factors (Hinton et al. 2013). Because of hybridization between red wolves and coyotes, the AP supports a continuum of sympatric canids, hereafter referred to as "sympatric canids."

As part of a recent program review, the USFWS halted many aspects of the RWRP in 2015 and discontinued the coyote sterilization program, potentially affecting the spatial

Draft - Confidential

distribution and population dynamics of sympatric canids. Telemetry data from coyotes on the AP suggests that about 70% of coyotes are residents (i.e., those that defend set territories) while the other 30% are transients, with most being dispersing juveniles (Hinton et al. 2015). Transient coyotes do not defend set territories. Coyotes can travel long distances and become transient even as adults, especially when they lose their mate. Recently described as using "compensatory immigration," coyotes opportunistically fill spatial resource gaps by periodic transiency; when spots come open, individuals that do not yet have permanent territories and have been roaming in the area, are able to inhabit the new openings (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with other canids and humans, especially when they are utilizing of anthropogenic resources.

Though a rural area, human land uses occupy a significant portion of space on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011). Concerns about fear of attacks on humans and domestic pets, the effects of sympatric canids on white-tailed deer and other game populations, and homeowner property damage comprise many of the conflict calls regarding sympatric canids on the AP (Responsive Management, forthcoming data). Wildlife managers in this region frequently receive requests for information on canid management (C. Turner, personal communication, 2016).

The changes in state and federal canid management rules have resulted in confusion regarding residents' rights and options for management of property damage by sympatric canids. As a result, some citizens are unsure of the legal and most effective methods for canid conflict management. Adding to management complexity is the need to manage canids for conservation purposes, such as reducing predation on at-risk ground nesting species or reducing hybridization of sympatric canids.

In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of sympatric canids on the AP. A USFWS and NCWRC joint memorandum documented detailed action items for the joint management of sympatric canids on the AP, including specific research objectives which this proposal seeks to address (Attachment 2). As sympatric canids on the AP increase in number, monitoring their

Draft - Confidential

movements, particularly in relation to individuals of differing ancestry, could provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about sympatric canid populations and conflict management. Collection of finer temporal scale location data would help to manage interactions of sympatric canids with humans, as well as to support development of dynamic stochastic population models.

B. Objectives (after December 1, 2016-November 30, 2018)

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners.

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

At the end of this two-year pilot study, we will deliver an observational summary detailing the use of the GPS and sensor technology for spatial and population dynamics research on sympatric canids on the AP.

C. Expected Results and Benefits

As part of a pilot study, we will monitor the status of collared individuals by using a finer scale assessment of space and habitat use than previous studies. Earlier research focused on many of the same objectives we suggest investigating here, but during a time of intense, active

Draft - Confidential

management. Specific management techniques are no longer being carried out and dynamics between sympatric canids are expected to have changed substantially. The uncertainty regarding current dynamics presents a need for additional research in order to inform actions for the management of sympatric canids. Information gained from research may impact management rules and landowner's abilities to manage canids in some areas. Additionally, GPS technology has improved since earlier research was conducted allowing for more temporally detailed data collection and more nuanced analyses. Understanding how sympatric canids collectively use resources in areas of human-dominated landscapes will allow wildlife managers to tailor management options to local conditions. On the AP, row crop agriculture and hunting represent the primary and secondary land uses, respectively. Row crop agriculture is a significant nutrient resource on the landscape and, as opportunists, canids take advantage of such resources when they are available. Non-consumptive wildlife-driven tourism persists in all seasons and wildlife watching is a main draw for tourists in this area. For many tourists, the opportunity to see or hear large carnivores is the sole attraction for traveling to the AP. Information from this study will be provided to local constituents to establish a knowledge base regarding how sympatric canids use resources on private lands. Management and guidance could serve to prevent or minimize conflict while maximizing positive wildlife interaction opportunities for constituents. Development of a common understanding between wildlife managers and landowners based upon factual information is paramount for collaboratively achieving successful management of sympatric canids. The data collected in this pilot study is the foundation upon which this understanding and future management actions will be built.

The current level of hybridization between sympatric canids on the AP will be characterized using DNA gathered during this study. Body size exists as a continuum between coyotes and red wolves and has been documented as the most important factor for successful interspecific breeding pairs of these canids (Hinton 2014). Though both species have been found to use resources in similar manners, red wolves generally have more expansive home ranges and therefore may not use local resources as intensively as coyotes, depending on body size. Obtaining individual identification of study animals will allow managers, armed with spatial information, to infer how and why individuals in the canid species continuum exploit

Draft - Confidential

anthropogenic resources considering their life history traits.

In conjunction with prior research, data collected will contribute to knowledge on sympatric canid population dynamics on the AP. Estimating population size will allow managers to monitor population trends of sympatric canids and to examine the long and short-term impacts of different management strategies on their populations. While it is unknown whether sample size will allow for population estimation, obtaining population estimates for coyotes would provide wildlife managers with baseline data, when paired with annual mortality estimates, for monitoring changes in population abundance over time. Information on changes in abundance, reproductive dynamics, and habitat use could impact management strategies to influence long-term conservation outcomes. Results of this pilot study will allow managers to determine if future work will be necessary, what amount of effort will be required to achieve each objective, and whether or not population estimates will be an attainable goal.

D. Approach

The official Red Wolf Recovery Area (RWRA) covers approximately 6,900 square kilometers within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014). However, the USFWS has proposed the RWRA be constricted to the ARNWR and the Dare County Bombing Range in Dare county by the end of 2017. Due to these proposed RWRA changes, this study proposes to capture and radio-collar 25 sympatric canids within Dare, Hyde, and Tyrrell counties (hereafter referred to as “study area”); those counties being within and directly adjacent to the proposed new RWRA. The thematic subheadings below provide detailed descriptions of the approaches required for achieving the pilot study objectives.

Sampling Efforts

Trained NCWRC personnel will conduct live trapping of sympatric canids, with assistance from the USFWS RWRP biologists, and trained, experienced local trappers. NCWRC and USFWS wildlife personnel will select local trappers based on their past performance in trapping sympatric canids, but may also select trappers from the NCWRC coyote trappers list. NCWRC staff will train contracted trappers on specific trapping procedures before every trapping

Draft - Confidential

season. The project lead will supervise and coordinate all trapping activities including locations for installation and the operation of trap lines and handling of captured animals. Simultaneous personal trapping activities by contracted trappers will not be permitted while performing contracted trapping services, as specified in the draft service contract (Attachment 4).

Trapping efforts will follow a spatial capture-recapture (SCR) framework with a systematic targeted sampling design, focusing on areas that contain resources previously found to be used by sympatric canids (e.g. edge, agricultural fields, secondary roads, etc.) (Harris et al. 2013, Ivan et al. 2013), while attempting to sample a diversity of habitat types. This effort will allow us to increase the probability of detection of sympatric canids on the landscape (Tom 2012). While it is important to sample a wide range of habitats, the most important requirement for SCR is the number of collared individuals; this requirement provides flexibility in the other requirements for field sampling as needed (K. Pacifici, personal communication, 2016). We will initially focus trapping in areas of known red wolf packs, as advised by RWRP.

Trapping will take place during the breeding season when the likelihood of capturing females in the later stages of gestation or whelping females will be low. Capture efforts will be conducted from soon after 1 December 2017 – February 2018 and December 2018 – February 2019. Captured sympatric canids will be surrendered to NCWRC or the USFWS at capture sites. Trapping should occur on both public and private lands to obtain sampling coverage of the study area. Ideally, all federal and state lands would be accessible for trap and release (hereafter referred to as "capture") of sympatric canids, but it is most important to be able to trap and release on Alligator River NWR and the Dare County Bombing Range as those encompass the newly proposed RWRP recovery area and comprise the majority of land area for Dare county. Unlike Dare county, there are ample private lands that surround Pocosin Lakes NWR and Lake Mattamuskeet NWR in both Tyrrell and Hyde counties that may be utilized to effectively sample individuals who may use those federal lands, should they be excluded from capture activities. Capture on federal lands may require USFWS take permits and proposed activities may be subject to a compatibility assessment (P. Benjamin, personal communication, 2016). Scientific collection activities that take place on private lands will require agreements outlining conditions mutually decided by NCWRC and landowners (Attachment 3).

Draft - Confidential

To increase probability of detection of sympatric canids, the accessible study area will be partitioned by a grid, the cell size of which will based on the average annual home range size of resident coyotes previously reported for the AP, approximately 23 km^2 (Hinton et al. 2015). As a system of sampling, trap lines will be referred here as "traps," and the number of trap sets (i.e. the actual trapping device) and number of each trap set size may vary between traps as necessary. Sampling will be standardized within each grid cell by use of equal number of traps per cell, on average 3 per cell, each at an approximate length of 10 km (Andelt and Gipson 1979, Way et al. 2004).

Target canids will be captured by using Softcatch #3 Coyote 4x4 (Oneida Victor Inc. Ltd., P.O. Box 32398, Euclid, Ohio 44132, Hinton 2014, Schemnitz 1994), the EZ Grip #7 (Livestock Protection Company, P.O. Box 725, Alpine, Texas 79831, Frame and Meier 2007), or equivalent. Various lures and baits will be used to increase trapping efficiency (Frederick et al. 1989, Shipley 2012). Traps will be laid on the Monday of each week and will be opened at the time of deployment. Traps will be checked once daily at dawn, to reduce potential stress to trapped individuals and will not be operated on days where the temperature is expected to reach or exceed 80° F (R. Nordsven, personal communication, 2016) or during times of predicted inclement weather (e.g. snow, hail, high wind, etc., Sikes et al. 2011). To standardize effort and remain logistically realistic, traps should be open for three trap nights in a row before being removed. Trap sets that have been closed due to non-target bycatch or other circumstances may be reopened and all traps should be re-baited and lured as appropriate.

Trap set locations will be marked by NCWRC or USFWS personnel using handheld GPS units (Garmin GPSMAP 64S, 1200 E. 151st St., Olathe, KS 66062-3426) and given a sequential identification number. Traps will also be given an identification number and trap set points will be documented in ArcMap 10.4. Trappers will keep detailed records on trap set operation, non-target species trapped, and other relevant details. Non-target species will be released from traps after an in-field assessment of injuries, if any, and animals with life threatening injuries will be euthanized by the trap operator. Targeted recapture of collared canids will occur annually during the same months, to replace GPS collar batteries and drop-off collar release units in field. Trapping effort will be quantified (trap nights), the effective sample area will be

Draft - Confidential

estimated, the encounter (detection) probability will be estimated using a Gaussian detection model (Amundson et al. 2014), and an estimate of density for coyotes will be calculated using a modified Huggins closed-capture estimator in program MARK, if sample size allows (Harris et al. 2013, Ivan et al. 2013).

Animal Handling

Handling of canids will follow American Society of Mammalogists (ASM) guidelines (Sikes et al. 2011) and will be performed at the capture site. Chemical immobilization agents may be used depending on the number of field staff during processing (i.e., three or more staff required during non-chemical immobilizations, Craft 2007, M. Morse, personal communication, 2016).

Chemical Immobilization

Unless adequate numbers of personnel are available to safely employ mechanical restraint techniques, target animals will be anesthetized with the chemical immobilization agent BAM (Wildlife Pharmaceuticals, Inc., Windsor, CO 80550). BAM, a combination of Butorphanol tartrate, Azaperone tartrate and Medetomidine HCl., will be delivered by intramuscular injection by syringe pole to the hip. Dosage for canids is based on field trails performed by Wildlife Pharmaceuticals (Wildlife Pharmaceuticals, Inc. 2016) and the recommended dose for coyotes is 0.2CC and red wolves is 0.3CC, with adjunct doses of 0.1-0.2CC delivered if initial dosages do not cause induction (S. Kirschner, personal communication, 2017). Induction times for coyotes and wolves ranged from 5 to 10 minutes after initial and/or adjunct dosages (Wildlife Pharmaceuticals, Inc. 2016). After field handling is concluded the anesthesia will be reversed using two reversal agents, Atipamezole and Naltrexone, at double the CC of Atipamezole to BAM that was delivered (including adjunct doses, if given) and 0.5CC of Naltrexone. Recovery time from the reversal agents ranged from 10 to 25 minutes during field trails (Wildlife Pharmaceuticals, Inc. 2016). Field personnel will observe animals for signs of adverse effects for up to 30 minutes after reversal agents are delivered.

Mechanical Immobilization

Unlike other carnivore families, the submissive behavioral response of canids to

Draft - Confidential

perceived dominance reduces the need to use immobilization agents. Appropriate mechanical restraint techniques can reduce handling time of animals, allowing animals to reintegrate into social groups more quickly, subsequently reducing overall stress to the individual (Powell and Proulx 2003). Target canids will be mechanically restrained with a restraint pole, until two muzzles can be placed around the snout. While pinned with the restraint pole by one person, a second person will restrain the set of legs not in the trap against the ground and a third person will release the foot from the trap. This set of legs will then be restrained by the 3rd person as the restraint pole is removed. Once the restraint pole is removed the person restraining the front legs will also then restrain the head. The first person will then move forward with processing the captured animal.

Each animal will be placed on a towel or blanket to provide thermal protection from the ground, with eyes covered and lubricated with eye ointment; temperature will be monitored with a rectal thermometer. Overheating occurs at approximately 104-105°F for canids (AZA Canid TAG 2012) and the animal handling crew will monitor temperature at 5-minute intervals; if a temperature reading reaches 104°F, corrective actions will be taken and temperature will be monitored at 1-minute intervals. Should overheating occur, the individual will be removed from insulation to expedite the natural evaporative cooling process. During days that approach 80°F in temperature, measures will be taken to reduce heat stress, such as: wetting the animal with water, application of a cold pack to the groin area between the back legs, application of rubbing alcohol to foot pads, or immediate release (AZA Canid TAG 2012). If the injured individual is suspected to be a red wolf, based on morphometrics, USFWS staff will be contacted for a decision. In the event that trap caused injuries are determined to be life threatening through use of a trap injury score assessment (Frame and Meier 2007) the individual will be euthanized. In the event that NCWRC personnel cannot be present, trained USFWS personnel may collar and measure captured target animals and will provide data sheets to NCWRC staff. Target animals will not be vaccinated or otherwise treated for diseases, regardless of the presence of disease symptoms.

Non-target animals will be released on site. Captured domestic dogs will be immediately released from the trap set following an injury score assessment and only if no life-threatening

Draft - Confidential

injuries are present. If a domestic dog has sustained life threatening injuries and owner identification information is present on the dog, then the animal will be held in either a transportable kennel, or at a dog pen on a state game land that is equipped with such facilities, until the owner can retrieve the dog. The costs associated with injuries sustained to the dog will be the responsibility of the animals' owner. Law enforcement may be requested to help communicate with the animal's owner. If the animal does not have an identifiable owner and has incurred substantial life threatening injuries (i.e. compound fracture), the dog will be euthanized on site. Target animals showing signs of disease symptoms such as circling behavior, head tilt, muscle twitches, convulsions with jaw chewing movements and salivation ("chewing gum fits"), disorientation, incoordination, staggering caused by paralysis of the hind legs, seizures, and partial or complete paralysis will be euthanized and tested according to protocol set forth by the agency veterinarian, in order to determine if there may be a public health issue (M. Palamar, personal communication, 2016). USFWS will be contacted in cases of suspected red wolves. Staff involved in animal handling duties will have the pre-exposure rabies vaccination series completed prior to field work inception and will maintain rabies titer records through properly licensed medical services providers.

If staff is bitten and skin is broken by an animal while performing handling duties, they will be advised to immediately visit a local hospital or clinic for evaluation by healthcare professionals. The field coordinator will immediately notify supervisory staff and an injury report and workers' compensation claim will be opened for the incident. The animal will be euthanized and the head will be sent to the state lab for rabies testing; the body may be sent to the Southeastern Cooperative Wildlife Disease Study (SCWDS) laboratory for additional disease investigation.

Capture Processing and Marking

During canid handling, NCWRC personnel will record age class, sex, weight, total body length, head width, ear length, and tail length, visually assess ectoparasite load, look for and disinfect with betadine or iodine as needed any minor trap caused injuries, and affix GPS collars (Knick 1990, Sikes et al. 2011). All captured canids will be fitted with appropriately-sized GPS collars in the field based on morphometrics previously indicated as reliable thresholds for

Draft - Confidential

species categorization: hind foot length, weight, width of head, and tail length (Hinton 2014); analysis of DNA samples collected during trapping efforts will help to assign captured canids to position along the species continuum post release. Age of individuals will be estimated based on physical characteristics, including weight and tooth replacement (Knick 1990, Hinton 2014, Gier 1968), and captured canids will be aged into one of three classes: > 2 years old as adults, < 2 but > 1 year old as juveniles, and > 6 months but < 12 months old as pups (Hinton 2014). Reproductive status will be determined based on estimated age class and presence of gonadal descent during the breeding season for males and the presence of nipple swelling or previous suckling for females (Hutson and Racey 2004, Magee 2008, Mengel 1971).

Captured individuals will be ear marked using a button tag (model 410, Ketchum Mfg. Co. [or equivalent], PO Box 10, 11 Town Shed Road, Lake Luzerne, NY 12846) placed along the middle of the ear where they are most protected from loss, with a pin-type applicator (485sa Pow-R-ceps plier, Ketchum Mfg. Co. [or equivalent]) (Silvy 2012). The puncture site will be treated with an antiseptic to deter infections. Each sympatric canid will also be marked with an individually-numbered, glass-encapsulated, passive integrated transponder (PIT model HPT12, 12.5 mm, 134.2 kHz, Biomark, Inc., 703 South Americana Blvd., Suite 150, Boise, ID; Gannon et al. 2007), using a syringe-type implanter and replaceable needle (model MK10 [implanter], model N125 [needle], Biomark, Inc.). Successful PIT placement will be verified with a mini portable reader (model GPR Plus, Biomark, Inc.). The implantation site will be prepared by swabbing with 70% alcohol (Mrozek et al. 1995) and a sterilized new needle will be used for each injection. The standard implantation site for transponders is subcutaneously on the dorsal midline of the back, cranial to the shoulder blades (Ingwersen 2000).

A skin biopsy will be taken from all captured target canids by puncturing the pinna of the ear with a biopsy punch in the same location where the ear tag will be placed (Palamar 2014). The biopsied area will be disinfected with alcohol after sampling. The skin biopsy will be placed in a labeled (ID, date, and sample type) cryogenic tube filled with 95% ethanol as buffer and then stored in a freezer until sent out to a lab for genetic analysis (Palamar 2014, Tom 2012). A selection of hairs with the root bulla attached will be pulled from the belly and placed in paper envelopes (Janecka et al. 2007). Hair samples will serve as back up to tissue samples

Draft - Confidential

for genetic testing. All samples will be sent to the Laboratory for Ecological, Evolutionary and Conservation Genetics, at University of Idaho (875 Perimeter Drive, MS 1136, Moscow, ID 83844) for genotyping to determine species as well as individual identification, hybridization presence, and parentage analysis following previously developed protocols (Adams et al. 2007, Hinton 2014, Miller et al. 2003). The appropriate genetic analyses that examine the coyote-hybrid-wolf species continuum will be performed.

Blood will be collected from all juvenile and adult target canids by venipuncture of the brachial or jugular veins using a 22-28-gauge needle (M. Palamar, NCWRC veterinarian, personal communication, 2016). As per NCWRC veterinarian recommendations, approximately 12 ml of blood will be collected for each animal for possible future testing for diseases of importance to sympatric canid species as well as the humans and domestic animals that they may come into contact with. A minimum of two 6 ml lavender top tube (for whole blood with EDTA) will be filled. Samples should be refrigerated at all times; a cooler with ice will suffice while in the field. Samples should be sent to the NCWRC within 48 hours or frozen for later shipping. Skin scrapes will be collected from animals presenting signs compatible with sarcoptic mange (lesions) for possible future diagnostic purposes. Lesions will be scraped until blood is drawn; the scrapings will be placed onto a slide and covered with a piece of clear tape for later visual confirmation.

Should overheating occur, processing will be performed in the following prioritization order and the first five items will need to be completed before releasing any individuals: 1) trap injury evaluation, 2) collaring, 3) DNA (skin biopsy) sample collection, 4) morphometrics, 5) aging, 6) PIT tagging, 7) weight, 8) ear tagging, 9) reproductive status, 10) ectoparasite evaluation, 11) blood collection, and 12) skin scrape collection.

Collaring

Vertex Plus GPS Collars will be attached to 25 sympatric canids captured on the study area, 10 of which will be equipped with proximity sensors (Vectronic Aerospace GmbH, Carl-Scheele-Str. 12, 12489 Berlin, Germany). Project staff will pilot test proximity sensor technology for utility in analysis of spatial and temporal community dynamics. Proximity sensors trigger increased GPS location acquisition during those time intervals when two collared individuals

Draft - Confidential

come within a set distance from each other (http://www.vectronic-aerospace.com/wildlife-monitoring/sensors/uhf-id-tags, accessed August 2016).

To avoid instances of collar induced strangulation, only adult (>2 years old) male and female individuals will receive collars (Hinton 2014). ASM guidelines recommends a collar weight of <5-10% of a canids bodyweight, we will observe these guidelines (Sikes et al. 2011). Sympatric canids not releasable at a capture site will not be collared and will not become study animals.

GPS radio-collars will have both VHF and GPS Iridium locational systems as well as store-on-board capabilities. Radio-collar units will be programmed to record GPS coordinates once every 1.75 hours producing approximately 13 locations per day while cycling through the 24-hour time cycle. These settings will allow for a GPS battery life of 300 to 552 days, averaging 431 days. The VHF beacon will be in operation from 0800 – 1600 hours daily. GPS locations will be sent via satellite once per day and each transmission with contain 12 locations. The use of an integrated drop off firing mechanism should allow the collars to drop off within a maximum of approximately 548 days after deployment. The drop off schedule once set cannot be changed. The drop off firing mechanism is wired to a battery unit independent of the collar battery, therefore should the collar battery become depleted, the drop off mechanism will not be affected (C. Akakpo, Vectronic Aerospace GmbH, personal communication, 2016). Unless a collared individual is recaptured before the collar battery dies, the drop off mechanism will fire at the scheduled time frame post collar deployment.

Observation of sympatric canid habitat use and movements will occur through GPS data obtained with combination GPS/VHF radio-collars. VHF relies on triangulation, the process of estimating the location of a transmitter by using two or more compass bearings obtained by using directional antennas at known locations remote from the transmitter's position (White and Garrott 1990), whereas GPS uses a satellite based system to obtain location coordinates. There have been many published studies where one or both of these methods were used, with mixed success for determining various aspects of carnivore ecology throughout the United States (Hinton et al. 2012, Schrecengost et al. 2009, Sparkman et al. 2012). While GPS technology has developed rapidly in recent history, the real time functional advantage of VHF

Draft - Confidential

cannot be disregarded. When GPS technology falters or malfunctions, VHF can serve as replacement for data collection in addition to its use in real time monitoring of study animals. Canids will be minimally monitored for mortality approximately every 30 days by using VHF aerial telemetry techniques (Whitehouse and Steven 1977) as there may be a delay in satellite transmission of GPS location data due to weather, season, and animal behavior. Transient canids and individuals from breeding pairs that have lost a mate, have been found to use much larger areas versus paired residents, potentially increasing the opportunity for losing track of these individuals when GPS technology reaches its functional capacity or experiences malfunction. VHF data may also provide locations of canids in cover too dense for GPS units to function. Use of VHF telemetry techniques for data collection may be expanded as necessary for project needs.

Spatial Data Analyses

Both minimum convex polygon (MCP) and adaptive kernel (AK) home ranges (95%) and core use areas (50% and 25%) (Seaman and Powell 1996, Seaman et al. 1999) will be calculated from GPS data by using BIOTAS (Ecological Software Solutions LLC, 2016) and Geospatial Modelling Environment (Spatial Ecology, LLC, 2016) for ArcGIS 10.2.2 (Environmental Systems Research Institute, 2016) (Benson et al. 2006, Riley 2006, Tucker et al. 2008, Hinton 2014) for comparison to older studies. These estimations can also be calculated using VHF data, provided data minimum requirements are met. Spatial distribution in relation to habitat will also be estimated by dynamic Brownian bridge movement models as described by Hinton (2014) with R statistical software (R Core Team 2016) using the moveud package with habitat covariates important to each species (Bryne et al. 2014, Collier 2013, Kranstauber and Smolla 2013, C. Proctor, personal communication, 2016). Additionally, recent research into how canids shift their ranges will also be investigated for populations on the AP (Morin and Kelly, in review). Spatial overlap and co-occurrence will be assessed using methods described by Shipley (2012). Habitat and cover types will be estimated from digitized maps created by the SEGAP (Hinton 2014) or ortho files, as available (Shipley 2012). Percent composition of habitat and cover types within home ranges and core areas as well as edge density will be quantified (Shipley 2012). Habitat selection and cover type use effects on spatial distribution will be estimated at both the population (2nd order) and individual (3rd order) spatial scales using resource selection functions

Draft - Confidential

(Johnson et al. 2006, Manly et al. 2002, Shipley 2012). Effects of seasonality and time of day activity will also be explored. The spatial and temporal patterns of space use by sympatric canids will be studied using data generated from the interaction GPS collar sensors, particularly distance between individuals and duration of proximity.

Den Monitoring

Project staff will attempt to locate den sites for sympatric canids to get pup counts, morphometric measurements, age estimates, and skin biopsies. Project staff will also attempt to monitor pup survival during the pup rearing season by using remote cameras placed around the den site (Harrison and Gilbert 1985, Parks 1979, Way et al. 2001). Pups will be weighed, measured, and PIT tagged during May and June of each year when they become active but are still den-obligated (Gier 1968). We will investigate the use of remote camera traps for monitoring den behavior with a two-camera array around the den (H. Garbe, personal communication, 2016, Kays and Slauson 2008). This method has been successfully used to monitor kit fox pup survival (Kluever et al. 2013). Because coyotes have been found to be sensitive to den site disturbance, there is a general lack of data in the literature regarding this approach for monitoring pup survival. Approaching an experimental methodology systematically will be important for determining which methods are effective and which are not. As a starting point for testing this methodology, remote cameras will be placed two to five meters from main den entrances and set to take photos using a passive infrared sensor trigger (a beam that when broken by movement through it, triggers the camera to take a series of photos) with a time restriction between photo intervals to limit the number of photos taken and maximize the space on the memory card for the time period between camera checks (Kluever et al. 2013). Cameras will be checked six days after deployment and will be redeployed (i.e. new batteries and memory card, if required); cameras will remain at each den site until radio-collar data indicates the den site has been moved (Kluever et al. 2013). Cameras will be not be redeployed to a new coyote den site during a season if that breeding pair has already moved the den once due to the disturbance of camera presence/deployment.

Draft - Confidential

Mortalities

If a collared animal dies during the project, the carcass will be sent to SCWDS for necropsy. Red wolves will be sent to the SCWDS laboratory for necropsy, unless it is determined to be a law enforcement case. In potential law enforcement cases, the NCWRC Division of Wildlife Management Chief and USFWS Ecological Services Raleigh Field Office Field Supervisor will be contacted and requested to contact the appropriate law enforcement personnel, immediately after determining the need for law enforcement involvement. The carcass and all relevant information will then be turned over to law enforcement; the GPS-collar will be removed and genetic samples will be taken from the individual prior to release to law enforcement.

E. Project Personnel

Andrea Shipley has worked for the North Carolina Wildlife Resources Commission as a Canid Biologist since February 2016. Prior to that, she worked as a Wildlife Biologist for a non-profit located in northeastern Nevada as well as in several different field biologist oriented positions. Andrea has a background in carnivore and spatial ecology, having earned her MS in Biological Sciences from Eastern Kentucky University and BS in Biological Sciences from Rutgers University; Andrea will act as project lead and coordinator.

Brandon Sherrill has worked for the North Carolina Wildlife Resources Commission as a Mammalogist since December 2013. Prior to that, he worked as an educator at the North Carolina Museum of Natural Sciences and as a regional wildlife biologist for the South Carolina Department of Natural Resources. Brandon earned a BS and MS in Fisheries, Wildlife, and Conservation Biology from North Carolina State University; Brandon will act as project supervisor.

Krishna Pacifici, Research Assistant Professor at NCSU, will be the quantitative analysis collaborator on the project. Krishna's background and experience in quantitative ecology makes him well suited to consult and assist with advanced statistical analyses of spatial data.

Lisette Waits, Department Head and Distinguished Professor at the University of Idaho, will be the DNA analysis collaborator for the project, responsible for all DNA related sample processing and subsequent analyses.

Draft - Confidential

F. Schedule and Estimated Costs

The project will run from soon after December 1, 2017 through June 30, 2020. The estimated timeline for major tasks is as follows:

Year 1: Initiate field work soon after December 1, 2017 with assistance from 1-2 field technicians; 1 technician will be required for trapping and den monitoring efforts. Data collection will begin immediately after collar deployment and data will be managed by Andrea Shipley throughout the life of the project. Data analysis will be initiated after den monitoring season concludes, with guidance and assistance from Krishna Pacifici at North Carolina State University (NCSU). Report, manuscript and presentation production will be initiated concurrently with data analysis.

Year 2: Continue field work and data collection with assistance from 1-2 field technicians. Continue data analysis with guidance and assistance from Krishna Pacifici at NCSU. Continue and finalize report and manuscript production, and presentation at professional working groups and/or meetings.

GPS technology allows researchers to collect locational data at fine spatial and temporal scales through the deployment of collar units on wildlife study subjects. In this project, we propose to study a sample of sympatric canid populations with GPS radio-collars, in order to investigate the population parameters outlined in previous sections as well as species interactions. The purchase and use of this technology is critical to meeting the research objectives set forth in this document as well as in the document included in Attachment 1.

While GPS technology has evolved over the past 20 years, the cost of technology has plateaued. Upfront cost per unit remains relatively high, however project savings occurs at the back end when compared to older telemetry technology such as very high frequency (VHF)

Draft - Confidential

which require intensive labor to collect data at similar spatial and temporal scales. Pilot testing the proximity sensor enabled GPS-collars will allow investigation of the utility of this relatively new tool for community dynamics analysis by providing an increased locational data acquisition when individuals come within a set distance, or closer, from each other. Additionally, these sensors record the identities of the interacting individuals and the duration of their interactions. Using a trigger to temporarily switch GPS fix schedules will enable us to collect very fine scale data while conserving battery life, achieving project objectives in an efficient manner. Exploring the efficaciousness of this technology has the potential to positively impact future research projects requiring use of GPS-collars for data collection.

Aerial tracking will provide regular study animal surveillance useful to investigate cases of mortality, collar malfunction, or satellite data transmission delays, which can vary seasonally. In some situations, ground tracking could prove less expensive than aerial tracking. However, ground telemetry techniques require more than one biologist working in tandem to acquire accurate location estimates. This often translates to increased labor to collect data, particularly in large study areas. Aerial tracking will provide a more efficient and cost-effective method for surveilling study subjects in this large study area, requiring only one biologist and a contracted pilot. NCWRC personnel will perform aerial tracking along with the NCWRC pilot at a minimum frequency of every 30 days.

Use of local trappers to assist with sampling efforts provides several benefits. Local trappers have established, long-term relationships with private land owners, thereby providing access to private lands that might be otherwise difficult to secure. This will enable project biologists to obtain a representative sample of sympatric canids in the study area, as well as to operate more trap lines concurrently. This is particularly important when using a SCR sample design, as it will have direct implications on the resulting analyses and inferences.

As part of collaboration efforts, the project will contract the services of Krishna Pacifici, Research Assistant Professor in the Applied Ecology department at NCSU. Krishna's expertise is in quantitative ecology; consultation and assistance services provided will allow project biologists to make appropriate statistically relevant inferences from collected data.

Draft - Confidential

DNA analysis will be contracted to Lisette Wait's lab at the University of Idaho. Lisette's team at The Laboratory for Ecological, Evolutionary and Conservation Genetics has previous experience in analyzing red wolf and coyote hybrid molecular samples and has the most comprehensive DNA methodology for this sympatric canid species continuum in the nation. This expertise will facilitate expedient species identification on collared study animals besides landscape level population dynamics analysis.

I. Glossary

Abundance: Species abundance is the number of individuals per species, and relative abundance refers to the evenness of distribution of individuals among species in a community.

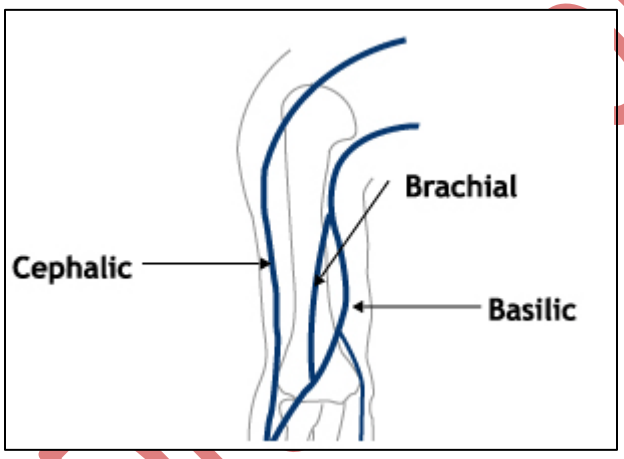
Adaptive kernel (AK): A probabilistic home range estimator based on the distribution and density of locations that has been collected over a period of time.

Adverse reactions: In pharmacology, any unexpected or dangerous reaction to a drug.

Aerial: Existing, happening, or operating in the air.

Annually: Once a year; every year.

Anthropogenic: Caused or influenced by humans.



Apex: Having no natural predators in its ecosystem.

Ataxia: The loss of full control of bodily movements.

Beacon: A radio beacon whose purpose is the investigation of the propagation of radio signals.

Biopsy: The removal for diagnostic study of a piece of tissue from a living body.

Brachial vein: One of a pair of veins accompanying the brachial artery and uniting with each other and with the basilic vein to form the axillary vein.

Breeding pair: A pair of animals which cooperate over time to produce offspring with some form of a bond between the individuals.

Carrying capacity: The maximum population size of the species that the environment can sustain indefinitely, given the food, habitat, water, and other necessities available in the environment.

Compensatory immigration: Individuals emigrating from areas with lower mortality to those with higher mortality; filling a deficiency of individuals in a population experiencing higher mortality. The increase in size or activity of one part of an organism or organ that makes up for the loss or dysfunction of another.

Composition: The combining of distinct parts or elements to form a whole.

Confidential

Co-occurrence: Refers to observation of the spatial overlap between two (or more) different individuals over a period of time.

Coordinates: Any of the scales or magnitudes that serve to define the position of a point.

Core use areas: An area within a home range exhibited by a dense concentration of location points; commonly estimated at 50% of the location data points.

Covariates: A variable that is possibly predictive of the outcome under study.

Cranial: Pertaining to the cranium or to the anterior (in animals) or superior (in humans) end of the body.

Cryogenic: Very low temperatures, e.g. -80°C.

Den-obligated: Restricted to a particular condition of life, in this case restricted to a den site.

Density: A measure of the number of organisms that make up a population in a defined area.

Deployment: To organize and send out (people or things) to be used for a particular purpose.

Depredation: The act of preying upon.

Depressed respiration: A decrease in the ability to exhale and inhale; respiration that has a rate below 12 breaths per minute or that fails to provide full ventilation and perfusion of the lungs.

Diagnostic: The process of determining by examination the nature and circumstances of a diseased condition.

Disorientation: Loss of one's sense of direction, position, or relationship with one's surroundings.

Distribution: The manner in which a biological taxon is spatially arranged.

DNA: (deoxyribonucleic acid) is a type of macromolecule known as a nucleic acid. It is shaped like a twisted double helix and is composed of long strands of alternating sugars and phosphate groups, along with nitrogenous bases (adenine, thymine, guanine and cytosine).

Dorsal: Situated on or toward the upper side of the body, equivalent to the back, or posterior, in humans; situated on or toward the posterior plane in humans or toward the upper plane in quadrupeds.

Duration: A continuous period of time.

Dynamic Brownian bridge movement models: Incorporates temporal and behavioral characteristics of movement paths into estimation of home range.

Ectoparasite: a parasite that lives on the outside of its host rather than within the hosts body; e.g. fleas and lice.

Effective trap area: Calculated by buffering each trap site by half the mean maximum distance traveled, each of these boundaries are dissolved, creating a measurable area.

Efficacious: Producing or capable of producing a desired effect.

Draft- Confidential

Efficient: Accomplishment of or ability to accomplish a job with a minimum expenditure of time and effort.

Euthanize: The act of putting to death painlessly or allowing to die, as by withholding extreme medical measures, a person or animal suffering from an incurable, especially a painful, disease or condition.

Expedient: Suitable for achieving a particular end in a given circumstance.

Evaporative cooling: reduction in temperature resulting from the evaporation of a liquid, which removes latent heat from the surface from which evaporation takes place.

Facilitate: Make an action or process easy or easier.

Genotyping: Investigate the genetic constitution of (an individual organism).

Gonadal descent: The act or process of descending from a higher to a lower location; testicular descent occurs during the breeding season annually.

GPS: Global Positioning System, is a radio navigation system that allows land, sea, and airborne users to determine their exact location, velocity, and time 24 hours a day, in all weather conditions, anywhere in the world.

Home range: an area over which an animal or group of animals regularly travels in search of food or mates, and that may overlap with those of neighboring animals or groups of the same species.

Hybridization: The result of mixing, through sexual reproduction, two animals or plants of different breeds, varieties, species or genera.

Immobilization agent: An active force or substance capable of producing an effect.

Implantation: To put or fix firmly.

Inbreeding depression: The reduced biological fitness in a given population as a result of inbreeding, or breeding of related individuals.

Inception: The establishment or starting point of an institution or activity.

Interspecific: Existing or occurring between different species.

Iridium: A satellite constellation providing voice and data coverage to satellite phones, pagers and integrated transceivers over the Earth's entire surface.

Jugular vein: Any of several large veins in the neck, carrying blood from the head and face.

Lacerations: A deep cut or tear in skin or flesh.

Locational: A position or site occupied or available for occupancy or marked by some distinguishing feature.

Malfunction: Fail to operate in the normal or usual manner

Methodology: A system of methods used in a particular area of study or activity.

Midline: A median line or plane of bilateral symmetry, especially that of the body.

Draft - Confidential

Minimum convex polygon (MCP): Completely enclose all data points by connecting the outer locations in such a way as to create a convex polygon.

Molecular samples: Genetic samples that may be used for investigation of genetic constitution of an individual.

Morphometrics: The process of measuring the external shape and dimensions of landforms, living organisms, or other objects.

Mortality: The state of being subject to death.

Non-target bycatch: Animals caught by accident that are not the target species being sought.

Parameters: A numerical or other measurable factor forming one of a set that defines a system or sets the conditions of its operation.

Parentage: The origin of something; the state or relation of a parent.

Passive integrated transponder: A microchip implant is an identifying integrated circuit placed under the skin of an animal.

Pinna: The external part of the ear in humans and other mammals; the auricle.

Plateaued: A period or state of little or no growth or decline.

Population dynamics: The branch of life sciences that studies the size and age composition of populations as dynamic systems, and the biological and environmental processes driving them (such as birth and death rates, and by immigration and emigration).

Population growth: The increase in the number of individuals in a population.

Population size: A group of organisms of the same species that live in the same area.

Population status:

Population trend: Changes over time and can include changes in ranging behavior and distribution, biogeography and life-history.

Population viability: The process that determines the probability that a population will go extinct within a given number of years.

Proximity: Nearness in space, time, or relationship.

Quantified: Express or measure the quantity of.

Quantitative: Relating to, measuring, or measured by the quantity of something rather than its quality.

Radio-telemetry: The use of radio waves for transmitting information from a distant instrument to a device that indicates or records the measurements.

Recumbency: The state of leaning, resting, or reclining.

Reintegrate: Restore (elements regarded as disparate) to unity.

Draft - Confidential

Remnant: A small remaining quantity of something.

Reproductive status: Relating to or effecting reproduction.

Spatial: Relating to, occupying, or having the character of space.

Spatial capture-recapture: A method commonly used in ecology to estimate an animal population's size. A portion of the population is captured, marked, and released. Marked animals are either recaptured or are tracked, each tracking location being considered a recapture.

Species Continuum: An aggregate of species capable of interbreeding, resulting in fertile hybrid offspring whose genetic composition may represent a varying array of phenotypes and genotypes from the parental species, at which the extreme ends of the spectrum are distinct.

Standardize: Cause (something) to conform to a standard.

Statistically relevant inferences: the process of deducing properties of an underlying distribution by analysis of data. Inferential statistical analysis infers properties about a population: this includes testing hypotheses and deriving estimates.

Stochastic population models: Ecological population modeling is concerned with the changes in population size and age distribution within a population as a consequence of interactions of organisms with the physical environment, with individuals of their own species, and with organisms of other species; stochasticity possesses some inherent randomness. In stochastic population models, the same set of parameter values and initial conditions will lead to an ensemble of different out puts.

Strangulation: The condition in which circulation of blood to a part of the body is cut off by constriction.

Stratifying: Form or arrange into strata, one of a number of portions or divisions likened to layers or levels.

Surveillance: Continuous observation of a place, person, group, or ongoing activity in order to gather information.

Survival: A living or continuing longer than, or beyond the existence of, another person, thing, or event.

Sympatric: Occurring within the same geographical area; overlapping in distribution.

Tachycardia: A heart rate that exceeds the normal resting rate. In general, a resting heart rate over 100 beats per minute is accepted as tachycardia in human adults.

Telemetry: See radio-telemetry.

Temporal: Of or relating to time.

Tooth replacement: The process of development of two successive sets of teeth, initially the deciduous set and consecutively the permanent set.

Transmitter: A set of equipment used to generate and transmit electromagnetic waves carrying messages or signals, especially those of radio or television.

Transponder: A device for receiving a radio signal and automatically transmitting a different signal.

Draft - Confidential

Vaccinate: Treat with a vaccine to produce immunity against a disease; inoculate.

Venipuncture: The puncture of a vein as part of a medical procedure, typically to withdraw a blood sample or for an intravenous injection.

VHF: Very high frequency is the ITU designation for the range of radio frequency electromagnetic waves (radio waves) from 30 MHz to 300 MHz, with corresponding wavelengths of ten to one meters.

II. State/Agency:

NORTH CAROLINA / NORTH CAROLINA WILDLIFE RESOURCES COMMISSION

III. Station Name:

FWS RALEIGH ECOLOGICAL SERVICES OFFICE

IV. Description of Proposed Action (attach additional pages as needed):

Conduct research project entitled "**Coyotes of the Albemarle: Spatial Ecology, Resource Selection, Demographics, and Interactions with a Sympatric Canid**"

The coyote (*Canis latrans*) is now abundant throughout the 100 counties in North Carolina (NC), where they are managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plains region of NC (Hinton et al. 2012, Murray et al. 2014).

Recently described as using "compensatory immigration," coyotes are able to opportunistically fill spatial resource gaps by periodic transiency (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with humans and other canids, especially while taking advantage of anthropogenic resources. Though a rural area, human land uses predominate on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011).

In 1968, individuals from a remnant population of red wolves were removed from Texas and Louisiana and a captive breeding program was initiated. The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). The red wolf population increased until 2008 and peaked at around 208 individuals (USFWS Red Wolf Recovery Program 2007), a few animals short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013), with an estimated carrying capacity of 140-150 for the AP (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). Red wolves presently inhabit an approximately 6900 square kilometer recovery area within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014).
Accurate up-to-date estimates of the population are unavailable, but USFWS staff report a population size of 45-60 individuals with three mortalities in 2016 (https://www.fws.gov/redwolf/index.html July 2016). Hybridization with coyotes, inbreeding depression, and gunshot mortality have all been suspected issues that have affected the population growth and viability since the inception of the Red Wolf Recovery Program (RWRP) (Hinton et al. 2013). In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of red wolves and other canids on the AP. A USFWS memorandum documented detailed action items for the joint management of canids on the AP, including specific research objectives which this proposal seeks to address (Attachment 1).

As coyotes on the AP increase in number, monitoring coyote movements, particularly in relation to red wolves, will provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about coyote population management. Collection of finer temporal scale location data will help to manage interactions of both canid species with humans, as well as to support development of dynamic stochastic population models.

Coyote and red wolves will be live trapped by cooperating NCWRC and USFWS staff, and private trappers using double coil size 3 foothold traps, during the breeding season (Nov-Feb for coyote, Jan-Feb for red wolves) in the tri-county area of Dare, Hyde and Tyrrell. Morphological measurements, incidents of injury, occurrence of ectoparasites, age classification, and reproductive status will be determined; blood and tissue samples will be taken for genetic analysis. All captured individuals that meet the age classification and weight requirements will be collared with GPS collar units. All captured and collared individuals will be released at the capture site. The objectives listed below will be achieved by obtaining measurements, samples and information from the captured, collared, and tracked individuals over the course of three years using GPS location data.

862

863

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners.

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

V. Pertinent Species and Habitat:

A. Include species/habitat: See section VI

B. Complete the following table:

SPECIES/CRITICAL HABITAT	STATUS[1]
Canis rufus	T

[1]STATUS: E = endangered, T = threatened, PE = proposed endangered, PT =proposed threatened, CH = critical habitat, PC = proposed critical habitat, C = candidate species

VI. Location:

A. Statewide

Albemarle Peninsula (see web address www.ncwildlife.org)

B. Section, township, and range (or latitude and longitude):

Dare, Hyde, Tyrrell counties

C. Distance (miles) and direction to nearest town:

As stated above

D. Species/habitat occurrence:

Canis rufus

VII. Determination of Effects:

A. Explanation of effects of the action on species and critical habitats in item V. B. (attach additional pages as needed):

SPECIES/CRITICAL HABITAT	IMPACTS TO SPECIES/CRITICAL HABITAT
Canis rufus	Trap induced injury is possible

B. Explanation of actions to be implemented to reduce adverse effects:

SPECIES/CRITICAL HABITAT	ACTIONS TO MITIGATE/MINIMIZE IMPACTS
Canis rufus	Use of appropriate trap types, daily trap checks, treatment of minor injuries, trapping season limitations and limitations on environmental conditions for trap operation

VIII. Effect Determination and Response Requested:

Species/ Critical Habitat	Determination[1]			Response[1] Requested
	NE	NA	AA	
Canis rufus		X		Concurrence

[1] Determination/Response Requested:

NE = No Effect. This determination is appropriate when the proposed action will not directly, indirectly, or cumulatively impact, either positively or negatively, any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested is optional but a "Concurrence" is recommended for a complete Administrative Record.

NA = Not Likely To Adversely Affect. The determination is appropriate when the proposed action is not likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat or there may be beneficial effects to these resources. Response Requested is a "Concurrence".

AA = Likely To Adversely Affect. This determination is appropriate when the proposed action is likely to adversely impact any listed, proposed, candidate species or designated/proposed critical habitat. Response Requested for listed species is "Formal Consultation". Response Requested for proposed or candidate species is "Conference".

Attachment 2: Joint Memorandum

MEMORANDUM

November 20, 2013

TO: All Interested Parties

FROM: "for" Cynthia K. Dohner, Director, Southeast Region, U.S. Fish and Wildlife Service
Gordon S. Myers, Executive Director, N.C. Wildlife Resources Commission

SUBJECT: Collaborative Conservation of Red Wolves and Other Canids on North Carolina's Albemarle Peninsula

---

Recovery of the federally-listed red wolf has been a priority for the U.S. Fish and Wildlife Service (FWS) for more than 20 years and is focused in North Carolina on the Albemarle Peninsula (AP; i.e., Hyde, Tyrrell, Washington, Beaufort, and Dare counties). Comprehensive stakeholder involvement and collaboration with other management agencies is critical to successful recovery of any at-risk species. The North Carolina Wildlife Resources Commission (WRC) is a key collaborator in this regard, as it has jurisdiction over all state-trust wildlife resources in N.C.

Since 2009, the FWS and WRC have worked to broaden our collaboration in the conservation and management of all canid species (including red wolves) on the AP. As these efforts have solidified, specific actions have been jointly identified by our two agencies that will improve conservation outcomes. These actions are categorized into five areas; collaboration, research, outreach, regulatory, and enforcement. Specific action items are outlined and prioritized within each of these categories in Attachment A.

This memo establishes the FWS's and WRC's commitment to initiate, or to continue, the efforts outlined in Attachment A. The common goal in this effort is to establish clear expectations and accountability for collaboration regarding the action items on Attachment A, thus resulting in enhanced and seamless canid conservation and management on the AP. This approach provides the best opportunity to achieve recovery goals for red wolves, while at the same time managing other canids to balance biological variables with social expectations. The dynamics of these canid species are complex and offer unique opportunities for innovation. Appropriate staff from each agency is hereby tasked with immediately developing a timeline to implement these actions. Through this commitment, we will continue to advance our collective conservation goals.

875

Attachment A

Action Items for Collaborative Conservation of Canids on North Carolina's Albemarle Peninsula (AP)
(*Note: Action Items are prioritized within category.*)

Collaboration

1. The N.C. Wildlife Resources Commission (WRC) and U.S. Fish and Wildlife Service (FWS) will formalize in writing the collaborative management of canids on the AP. This agreement should:
    a. include a clear mission statement, goals, objectives, and implementation strategies (ask and answer the "Why?");
    b. set a goal to define success regarding canid management on the AP;
    c. espouse a philosophy of canid management operating within the context of a three-legged stool (i.e., federal and state governments and stakeholders);
    d. as available, commit funding and staffing resources for field personnel to contribute to the conservation of the red wolf and management of coyotes;
    e. as available, commit funding to conduct research pertinent to canid management on the AP;
    f. establish polices and goals for developing a collaborative genetic archive for AP canids, a data sharing portal accessible by staff in both agencies, and reciprocal sharing of all historical data (including phenotypic and genotypic data and literature) of the red wolf;
    g. establish a foundation for developing and implementing an adaptive approach to canid management on private lands on the AP;
    h. initiate development of a collaborative canid research program;
    i. describe plans to conduct the next five year Red Wolf Program review;
    j. outline options for holding annual workshops with federal and state enforcement staff;
    k. outline plans to hold semi-annual coordination meetings regarding canid management on the AP; and
    l. develop milestones for future development of a management plan for all canids in the AP.

2. The FWS will initiate a review of the current Red Wolf Recovery Plan to determine if the state-of-our-knowledge or field conditions have changed such as to warrant its revision. Review and comments from the WRC will be considered in this evaluation.

3. The WRC, with support and participation of the FWS, will establish a "Canid Forum" (similar to that established for manatees in Florida) to facilitate communication and discussion regarding canid management and citizen science opportunities on the AP.

876

877

Attachment A

Research

1. The FWS and WRC will provide funding and logistical support for research identified by the Red Wolf Recovery Implementation Team, Red Wolf Program staff, other FWS staff, or the WRC that promote the conservation and recovery of the red wolf and other canids on the AP. Studies could include:
    a. tests of the "placeholder theory" on the AP, including behavior of sympatric canids,
    b. determining carrying capacity of canids on the AP,
    c. determining genetic profiles of canid species on the AP,
    d. evaluating predator-prey dynamics,
    e. studies of canid habitat use,
    f. epidemiology of diseases impacting canids on the AP,
    g. development of stochastic simulation models of sympatric canid population dynamics and habitat use, and
    h. canid dispersal dynamics

2. The FWS and WRC will conduct jointly-supported research to determine the attitudes and opinions of N.C. private landowners and other citizens concerning canids on the AP (i.e., human dimensions studies).

Outreach

1. The FWS and WRC will collaborate with other partners to design and implement broad-based outreach and marketing programs with clear goals, objectives, strategies, and measurable outcomes, including development of consistent agency messages and educating the public about canids on the AP.

Regulatory

1. The FWS and WRC will initiate a review and, if needed, subsequent rule-making to clarify concepts or rectify conflicts in current federal or state rules (including the current 10(J) rule).

2. The WRC will review and evaluate statutory requirements for listing red wolves as state threatened in the five AP counties.

3. As data demonstrating a relationship between coyote hunting and red wolf mortality become available, the FWS and WRC will evaluate, and if appropriate implement, adaptive approaches to regulate of take of coyotes that may result in incidental take of red wolves.

4. The WRC will evaluate the status, management, and regulation of Controlled Fox Hunting Preserves.

878

879

Attachment A

5. The WRC will develop BMPs (due care provisions) for coyote hunting, trapping, and live sale.

6. The WRC will compile, compare, and contrast canid hunting and trapping regulations and programs in other states, including, but not limited to, other states with other species of wolves.

Enforcement

1. The FWS and WRC will develop coordination strategies to improve enforcement of federal regulations protecting red wolves.

I, the cooperator or cooperator's representative, have been informed of the methods and the manner in which research devices will be used, and of the possible hazards associated with their use. I understand that NCWRC, (to include its officers, employees and agents) will: exercise reasonable precautions to safeguard all persons to prevent injury to target and non-target animals; guard against the mishandling of control devices and materials; and exercise due caution and proper judgment in all scientific collection operations. I understand that NCWRC may collect Global Positioning System (GPS) coordinates at the project site as part of component or activity tracking or as wildlife disease monitoring or research data. I, the undersigned cooperator, do hereby give my consent and concurrence to NCWRC, its employees, and its agents, to use, upon lands owned, leased, or otherwise controlled by me, and identified by this document, the following methods and devices (an attachment of additional devices and/or methods may be attached):

Statement of agreement: The landowner, cooperator, or representative, as listed above hereby give permission to NCWRC to perform trap and release of the species listed for scientific collection purposes. In consideration of these understandings, I, the cooperator or cooperator's representative, agree to: assume responsibility for injury to my property under my control, when said injury is not the result of negligence on the part of NCWRC (it's officers, employees, and agents); assist in maintaining such warning signs as NCWRC may place for the purpose of notifying persons entering onto such lands of the possible hazards associated with scientific measures in use thereon; and to give adequate warning of these possible hazards to persons I authorize to enter onto such lands. Further, I, the cooperator or cooperator's representative, agree not to concurrently use or allow to be used upon lands covered by this agreement, any canid depredation efforts during the scientific collection time period.

Research and Monitoring
Special Use Permit Application

Refuge Name:

Address:

Attn: (Refuge Official)

E-Mail:

Phone #:

For Official Use Only

Approved Permit #:

Station #:

Permit Term: from ____ to ____

Note: We do not require all information for each Research project. See instructions at the end of the notice and contact the refuge to determine applicability of a particular item. Attach additional sheets if the text spaces provided are inadequate.

1a) Identify the type of Permit you are applying for: **New** ◯ **Renewal** ◯ **Modification** ◯ **Other** ◯

1b) Have you applied, or do you intend to apply, to any other refuges for this same activity? ◯ **Yes** ◯ **No**

1c) If yes, which refuges?

Applicant Information

2) Principal investigator:

3) Is curriculum vitae or resume attached? **Yes** ◯ **No** ◯

4a) Affiliation/Sponsoring Organization:

4b) Relationship to affiliation/sponsoring organization (professor, staff, student, etc.):

5) Physical Address:

City/State/Zip:

6) Mailing Address: (if different than above)

City/State/Zip:

7) Phone #: 8) Fax #: 9) E-mail:

10) List **known** assistants/subcontractors/subpermittees: (Only required if the assistants/subcontractors/subpermittees will be operating on the refuge without the permittee being present.)

Name	Address	Phone #

Project Information

11) Title of project:

12) Is a full research proposal attached? Yes ◯ No ◯

Note: Depending on the research and monitoring project for which you are requesting a permit, we may ask you for the following project information (13 -25) if it is not included in your research proposal, or if you have not provided a full research proposal with this application. Please contact the specific refuge where the activity is being conducted to determine what information is required.

Attach additional sheets to the application if the text spaces provided are inadequate.

13) Describe project by specifically identifying timing, frequency, and how the project is expected to proceed:

14) Specifically identify location(s) and/or attach a map for the project: (GPS location(s) preferred)

15) Identify species or habitats being studied:

16) Purpose/hypothesis:

17) Expected benefits of research/monitoring:

18) Briefly describe project history and context of research/monitoring project:

19) Briefly describe project's relationship to other research/monitoring projects either known of or conducted by the applicant:

20) Identify the types of specimen collections to be taken **(see specimen collection clause in the instruction section #20)** or data to be collected during the proposed project:

21) List other cooperators and institutions involved in the project:

22) Generally identify the anticipated timeline for analysis, write-up and publication:

23) For research involving animals, attach an Assurance of Animal Care Form or an approval from an Institutional Animal Care and Use Committee? Is a form or approval attached? ◯ Yes ◯ No ◯ N/A

License/Insurance/Certifications/Permits

Note: Contact the specific refuge office where the research project is going to be conducted to determine if any type of license, insurance, certification(s), or permit(s) will be required. We may process this Special Use Permit while the applicant obtains them. Attach additional sheets to the application if the text spaces provided are inadequate.

24a) List and attach copies of any **licenses** you have for equipment operation (i.e., aviation or commercial boats), pesticide applications, transporters) or others if required:

License Type	Number	Expiration Date (if applicable)

24b) List and attach copies of any **insurance** you have (i.e general liability, flight/grounding, contaminants, medical evacuation, or others if required:

Insurance Type	Carrier	Expiration Date (if applicable)

24c) List and attach copies of any **certifications** you have, such as rat free, hull inspections, CPR/First Aid, or others if required:

Certificate Type	Expiration Date (if applicable)

24d) List and attach copies of any other Federal, State, or Tribal **permits** if required:

Permit Type	Permit Number	Expiration Date (if applicable)

Logistics and Transportation **Attach additional sheets if the text spaces provided are inadequate.**

25a) Does project require personnel to stay overnight on the refuge? **Yes** ◯ **No** ◯

25b) If yes, how many? ☐ And list known personnel involved in overnight stay below:

List Names	List Names	List Names	List Names

26) Specifically describe all major instrumentation/equipment/gear (i.e. use of drones) and materials used, if applicable or required:

27a) Provide details and schedule for the installation of instrumentation:

27b) Provide details and schedule for the removal of instrumentation:

27c) If instrumentation is permanent, describe need:

27d) If instrumentation requires a maintenance schedule, describe needs and schedule:

27e) Provide a data collection schedule:

28) Provide logistical arrangements for offsite transportation of samples:

29a) Provide detailed information on the logistics for onsite, intersite, and/or ship-to-shore transportation to or on the refuge, if required**:**

29b) Provide descriptions, license plate and/or identification numbers of vehicles used for onsite transportation, if required:

Vehicle Type	Plate/I.D./Registration #	Vehicle Type	Plate/I.D./Registration #

29c) Provide descriptions, license plate and/or identification numbers of vehicles used for intersite transportation, if required:

Vehicle Type	Plate/I.D./Registration #	Vehicle Type	Plate/I.D./Registration #

29d) Provide descriptions, license plate and/or identification numbers of vehicles used for ship-to-shore transportation, if required

Vehicle Type	Plate/I.D./Registration #	Vehicle Type	Plate/I.D./Registration #

30a) Is fuel cache needed? **Yes** ◯ **No** ◯ **N/A** ◯ 30b) Provide specific location(s) of fuel caches: (GPS coordinates preferred)

31) Attach Safety Plan if required. Is Safety Plan attached? **Yes** ◯ **No** ◯ **N/A** ◯

Work and Living Accommodations

32) Specifically describe onsite work and/or living accommodations, including spike camps:

33) Specifically describe on or offsite hazardous material storage or other on or offsite material storage space: (Including on and offsite fuel caches.)

Sign, date, and print this form and return it to the refuge for processing. By signing this application, I agree my operations will conform to the information I have provided in this application, and I understand that any deviations or changes to this information must receive prior written approval.

34) Signature of Applicant: _____Date of Application: _____

NOTICES

No Members of Congress or Resident Commissioner shall participate in any part of this contract or to any benefit that may arise from it, but this provision shall not pertain to this contract if made with a corporation for its general benefit.

The Permittee agrees to be bound by the equal opportunity "nondiscrimination in employment" clause of Executive Order 11246.

PRIVACY ACT STATEMENT

Authority: The information requested is authorized by the National Wildlife Refuge System Administration Act (16 U.S.C. 668dd-ee) and the Refuge Recreation Act (16 U.S.C. 460k-460k-4).

Purpose: To collect the applicant's information to process permits allowing for: research and monitoring activities by students, universities, or other non-FWS organizations.

Routine Uses: The information will be used by the refuge's administrative office for processing Research and Monitoring Special Use permits. More information about the routine uses maybe found in the Systems of Records Notice, FWS-5 National Wildlife Refuge Special Use Permits.

Disclosure: Providing the information is voluntary. However, submission of information is required to process and approve research and monitoring activity usage on the National Wildlife Refuge System.

PAPERWORK REDUCTION ACT STATEMENT

We are collecting this information subject to the Paperwork Reduction Act (44 U.S.C. 3501) to evaluate the qualifications, determine eligibility, and document permit applicants and to respond to requests made under the Freedom of Information Act and the Privacy Act of 1974. The information that you provide is required to obtain or retain a benefit; however, failure to provide all required information is sufficient cause for the U.S. Fish and Wildlife Service to deny a permit. False, fictitious, or fraudulent statements or representations made in the application may be grounds for revocation of the Special Use Permit and may be punishable by fine or imprisonment (18 U.S.C. 1001). According to the Paperwork Reduction Act of 1995, an agency may not conduct or sponsor and a person is not required to respond to a collection of information unless it displays a currently valid OMB control number. OMB has approved this information collection and assigned control number 1018-0102.

ESTIMATED BURDEN STATEMENT

The public reporting burden for this information collection varies based on the requested specific refuge use. We estimate the relevant public reporting burden for the Research and Monitoring Activity Special Use Permit Application form is to average 5 hours per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden, to the Service Information Collection Clearance Officer, Division of Policy, Performance, and Management Programs, Fish and Wildlife Service, Mail Stop BPHC, 5275 Leesburg Pike, Falls Church, VA 22041-3803. Please do not send your completed form to this address.

GENERAL CONDITIONS AND REQUIREMENTS

1) Responsibility of Permittee: We shall consider the permittee, by operating on the premises, to have accepted these premises with all facilities, fixtures, or improvements in their existing condition as of the date of this permit. At the end of the period specified or upon earlier termination, the permittee shall give up the premises in as good order and condition as when received except for reasonable wear, tear, or damage occurring without fault or negligence. The permittee will fully repay the Service for any and all damage directly or indirectly resulting from negligence or failure on his/her part, and/or the part of anyone of his/her associates, to use reasonable care.
2) Operating Rules and Laws: The permittee shall keep the premises in a neat and orderly condition at all times, and shall comply with all municipal, county, and State laws applicable to the operations under the permit as well as all Federal laws, rules, and regulations governing national wildlife refuges and the area described in this permit. The permittee shall comply with all instructions applicable to this permit issued by the refuge official in charge. The permittee shall take all reasonable precautions to prevent the escape of fires and to suppress fires and shall render all reasonable assistance in the suppression of refuge fires.

3) Use Limitations: The permittee's use of the described premises is limited to the purposes herein specified and does not, unless provided for in this permit, allow him/her to restrict other authorized entry onto his/her area; and allows the U.S. Fish and Wildlife Service to carry on whatever activities are necessary for: (1) protection and maintenance of the premises and adjacent lands administered by the U.S. Fish and Wildlife Service; and (2) the management of wildlife and fish using the premises and other U.S. Fish and Wildlife Service lands.

4) Transfer of Privileges: This permit is not transferable, and no privileges herein mentioned may be sublet or made available to any person or interest not mentioned in this permit. No interest hereunder may accrue through lien or be transferred to a third party without the approval of the Regional Director of the U.S. Fish and Wildlife Service and the permit shall not be used for speculative purposes.

5) Compliance: The U.S. Fish and Wildlife Service's failure to require strict compliance with any of this permit's terms, conditions, and requirements shall not constitute a waiver or be considered as a giving up of the U.S. Fish and Wildlife Service's right to thereafter enforce any of the permit's terms or conditions.

6) Conditions of Permit not Fulfilled: If the permittee fails to fulfill any of the conditions and requirements set forth herein, the U.S. Fish and Wildlife Service shall retain all money paid under this permit to be used to satisfy as much of the permittee's obligation as possible.

7) Payments: All payment shall be made on or before the due date to the local representative of the U.S. Fish and Wildlife Service by a postal money order or check made payable to the U.S. Fish and Wildlife Service.

8) Termination Policy: At the termination of this permit the permittee shall immediately give up possession to the U.S. Fish and Wildlife Service representative, reserving, however, the rights specified in paragraph 11 below. If he/she fails to do so, he/she will pay the U.S. Fish and Wildlife Service, as liquidated damages, an amount double the rate specified in this permit for the entire time possession is withheld. Upon yielding possession, we will still allow the permittee to reenter as needed to remove his/her property as stated in paragraph 11 below. The acceptance of any fee for the liquidated damages or any other act of administration relating to the continued tenancy is not to be considered as an affirmation of the permittee's action nor shall it operate as a waiver of the U.S. Fish and Wildlife Service's right to terminate or cancel the permit for the breach of any specified condition or requirement.

9) Revocation Policy: The Regional Director of the U.S. Fish and Wildlife Service may revoke this permit without notice for noncompliance with the terms hereof, or for violation of general and/or specific laws or regulations governing national wildlife refuges, or for nonuse. It is at all times subject to discretionary revocation by the Director of the Service. Upon such revocation the U.S. Fish and Wildlife Service, by and through any authorized representative, may take possession of said premises for its own and sole use, and/or may enter and possess the premises as the agent of the permittee and for his/her account.

10) Damages: The U.S. Fish and Wildlife Service shall not be responsible for: any loss or damage to property including but not limited to crops, animals, and machinery; injury to the permittee or his/her relatives or to the officers, agents, employees, or any other(s) who are instructed to be on the premises; the sufferance from wildlife or employees or representatives of the U.S. Fish and Wildlife Service carrying out their official responsibilities. The permittee agrees to hold the U.S. Fish and Wildlife Service harmless from any and all claims for damages or losses that may arise to be incident to the flooding of the premises resulting from any associated Government river and harbor, flood control, reclamation, or Tennessee Valley Authority activity.

11) Removal of Permittee's Property: Upon the expiration or termination of this permit, if all rental charges and/or damage claims due to the U.S. Fish and Wildlife Service have been paid, the permittee may, within a reasonable period as stated in the permit or as determined by the U.S. Fish and Wildlife Service official in charge, but not to exceed 60 days, remove all structures, machinery, and/or equipment, etc., from the premises for which he/she is responsible. Within this period the permittee also must remove any other of his/her property including his/her acknowledged share of products or crops grown, cut, harvested, stored, or stacked on the premises. Upon failure to remove any of the above items within the aforesaid period, they shall become the property of the U.S. Fish and Wildlife Service. .

INSTRUTIONS FOR COMPLETING APPLICATION

You may complete the application portion verbally, in person, or electronically and submit to the refuge for review. Note: Please read instructions carefully as not all information is required for each activity. Contact the specific refuge where the activity will take place if you have questions regarding the applicability of a particular item. We may add special conditions or permit stipulations to permit prior to approval.

1a-1c) Identify if permit application is for new, renewal, or modification of an existing permit, whether or not you have or will be applying to another refuge for the same activity, and for which refuge(s). Permit renewals may not need all information requested. Contact the specific refuge headquarters office where the activity is going to be conducted to determine applicability of this requirement.

2-3) Provide principal investigator or applicant full name. Attach principal investigator's Curriculum Vitae or Resume, if required. Permit renewals generally do not require a Curriculum Vitae or Resume if the project is a continuation of a previously issued permit being conducted by the same investigator. Contact the specific refuge office to determine applicability of this requirement.

4-9) Provide investigator's physical and/or mailing address, phone, fax, e-mail, affiliation and/or sponsoring organization, and relationship to affiliation or organization (title, professor, student, etc.).

10) Provide the names and addresses of assistants, subcontractors, or subpermittees. We may require names and addresses if the assistants, subcontractors or subpermittees will be operating on the refuge without the permittee being present. Volunteers, assistants, subcontractors, or subpermittees accompanied by the permittee need not be identified.

11) Provide title of research or monitoring project.

12a-12b) Attach a full research or monitoring proposal, if required. Permit renewals generally do not require a project proposal if the project is a continuation of a previously issued permit being conducted by the same investigator. Contact the specific refuge office to determine applicability of this requirement.

13) Provide detailed information on the activity, including timing, frequency, how the project is expected to proceed, etc. Permit renewals may not need activity description, if the activity is unchanged from previous permit. Most repetitive research projects do not require an activity description for each visit to the refuge. Contact the specific refuge office to determine applicability of this requirement.

14) Identify specific location (GPS coordinates preferred) if not a named facility, and/or attach a map of the location. Permit renewals may not require a location if the project is essentially unchanged from the previous permit. Contact the specific refuge office to determine applicability of this requirement.

15) Identify species or habitats being studied.

16-17) Specifically identify purpose or hypothesis of the research or monitoring project and describe expected benefits. Permit renewals may not need to identify purpose or hypothesis if the project is a continuation of a previously issued permit being conducted by the same investigator. Contact the specific refuge office to determine applicability of this requirement.

18) Briefly describe project history and context. Permit renewals should describe previous research activities as part of a previously issued permit being conducted by the same investigator. Contact the specific refuge office to determine applicability of this requirement.

19) Briefly describe project's relationship to other research/monitoring projects either known of or conducted by the applicant, if applicable. Include a brief statement of how the research or monitoring permit being applied for will add to or supplement other ongoing research or monitoring on the same, or related, species or habitats. Contact the specific refuge office to determine applicability of this requirement.

20) Identify specimen collections to be taken or types of data to be collected. You may use specimens collected under this permit, any components of any specimens (including natural organisms, enzymes, genetic materials or seeds), and research results derived from collected specimens for scientific or educational purposes only, and not for commercial purposes unless you have entered into a Cooperative Research and Development Agreement (CRADA) with us. We prohibit the sale of collected research specimens or transfers to third parties for commercial purposes. Breach of any of the terms of this permit will be grounds for revocation of this permit and denial of future permits. Furthermore, if you sell or otherwise transfer for commercial purposes collected specimens, any components thereof, or any products or research results developed from such specimens or their components without a CRADA, you will pay us a royalty rate of 20 percent of gross revenue from such sales. In addition to such royalty, we may seek other damages and injunctive relief against you. Permit renewals may not need to identify samples taken if the project is a continuation of a previously issued permit being conducted by the same investigator. Contact the specific refuge office to determine applicability of this requirement.

21) List other cooperators and institutions involved in the project, if applicable. Contact the specific refuge office to determine applicability of this requirement.

22) Generally, identify the anticipated time line for analysis, write-up, and publication of project results. Include whether the project is a single, or multiple year project. Identification of an actual publication where the results are printed is not necessary. However, applicants should include the anticipated dissemination of project results. Contact the specific refuge office to determine applicability of this requirement.

23) Check box acknowledging a completed Assurance of Animal Care Form or an Institutional Animal Care and Use Committee (or equivalent) that has granted approval has been completed, and has been submitted to refuge station, if required. Contact the specific refuge office to determine applicability of this requirement.

24a-24d) Specifically identify types and numbers of licenses, insurance, certifications, and other State, Federal, or Tribal permits if required. Contact the specific refuge headquarters office where the project is going to be conducted to determine applicability of these requirements, and to coordinate the simultaneous applications of any of these requirements while this Special Use Permit is being processed.

25a-25b) Provide the number of and/or name(s) of any personnel required to stay overnight on the refuge, if applicable.

26) Identify all equipment (including drones) and materials that will be used, if required. Permit renewals may not require a list of equipment if the project is essentially unchanged from a previously issued permit. Contact the specific refuge office to determine applicability of this requirement.

27a-27e) Identify types and schedule(s) of installation of any instrumentation, data collection, and maintenance schedule of instrumentation, if required. Permit renewals may not require a list of equipment if the project is essentially unchanged from a previously issued permit. However, schedules of installation of any instrumentation, data collection, and maintenance schedule of instrumentation may still be required. Contact the specific refuge headquarters office where the project is going to be conducted to determine applicability of this requirement.

28) Identify logistical arrangements for offsite transportation of samples taken, if applicable.

29a-29d) Describe and provide vehicle descriptions and license plate or identification numbers of all vehicles, including boats and airplanes, if required. Motor vehicle descriptions are only required for permittee vehicle, and/or if the vehicle will be operated on the refuge without the permittee being present. Motor vehicles that are accompanied by the permittee as part of a group (convoy) activity need not be identified if cleared in advance by refuge supervisor. Specifically describe ship-to-shore, intersite (between islands, camps, or other sites) and onsite transportation mechanisms, and license plate or identification numbers, if required.

30a-30b) Identify specific location(s) of fuel cache(s) (GPS coordinates preferred), if required.

31a-31b) Attach safety plan, if required. Contact the specific refuge office to determine applicability of this requirement.

32) Specifically describe onsite work and/or living accommodations, if required. Include descriptions and locations (GPS coordinates preferred) of spike camps or other remote work and/or living accommodations that are not part of the base of operations. Contact the specific refuge office to determine applicability of this requirement.

33) Specifically describe onsite and offsite hazardous material storage, or other onsite material storage space (including on and offsite fuel caches), if required. Contact the specific refuge office to determine if descriptions of hazardous material storage or other onsite material storage are required.

34) Sign, date, and print the application. Click on the Print button to print the application (if using the fillable version). The refuge official will review and, if approved, fill out the remaining information, sign, and return a copy to you for signature and acceptance.

THIS APPLICATION FORM IS NOT VALID AS A PERMIT
BUT MAY BE USED AS A REFERENCE DOCUMENT ATTACHED TO THE OFFICIAL PERMIT.
ONLY OFFICIAL REFUGE PERSONNEL MAY ASSIGN A VALID PERMIT NUMBER AND PERMIT TERM
TO THIS APPLICATION FORM AFTER THE PERMIT HAS BEEN APPROVED.

North Carolina Coastal Refuge Complex Refuge Research Proposal Guidelines

A research proposal including a justification and description of the work to be done on the refuge is required before approval of a special use permit. Below are the necessary requirements for a proposal to be considered. In addition, refuge staff reserves the right to ask more detailed questions before approving a project. Proposals should be submitted electronically as a Microsoft Word document or hard copy to the refuge manager.

Cover Page
The cover page must contain the following information:

- Title of proposal
- Current date
- Investigator(s)—name, title, organizational affiliation, address, telephone and fax numbers and e-mail address of all investigators or cooperators
- Proposed starting date
- Estimated completion date
- List of all partners and funding sources of the project
- Signatures of principal investigator(s) and other appropriate institutional officials

Abstract
The abstract should contain a short summary description of the proposed study, including reference to major points in the sections "Statement of Issue," "Objectives," and "Methods and Procedures."

Statement of Issue
Provide a clear precise summary of the problem to be addressed and the need for its solution. This section should include statements of the importance, justification, relevance, timeliness, ability to be generalized, and contribution of the study. Describe how any products will be used, including any anticipated commercial use. What is the estimated probability of success of accomplishing the objective(s) within the proposed timeframe?

Objectives/Hypotheses
A very specific indication of the proposed outcomes of the project should be stated as objectives or hypotheses to be tested. Project objectives should be measurable. Provide a brief summary of what information will be provided at the end of the study and how it will be used in relation to the problem. These statements should flow logically from the statement of issue and directly address the management problem.

Establish data quality objectives in terms of precision, accuracy, representativeness, completeness, and comparability as a means of describing how good the data need to be to meet the project's objectives.

Study Area
Provide a detailed description of the geographic area(s) to be studied and include a clear map delineating the proposed study area(s) and showing specific locations where work will occur.

Methods and Procedures
This section should describe as precisely as possible, how the objectives will be met or how the hypotheses will be tested. Include detailed descriptions and justifications of the field and laboratory methodology, protocols, and instrumentation. Explain how each variable to be measured directly addresses the research objective/hypothesis. Describe the experimental design, population, sample size, and sampling approach (including procedures for sub-sampling). Summarize the statistical and other data analysis procedures to be used. List the response variables and tentative independent variables or covariates. Describe the experimental unit(s) for statistical analysis. Also include a detailed project time schedule that includes start, fieldwork, analysis, reporting, and completion dates.

Quality Assurance/Quality Control
Adequate quality assurance/quality control procedures help ensure that data and results are:

- Credible and not an artifact of sampling or recording errors.
- Of known quality.
- Able to stand up to external scientific scrutiny.
- Accompanied by detailed method documentation.

Describe the procedures to be used to ensure that data meet defined standards of quality and program requirements, errors are controlled in the field, laboratory, and office, and data are properly handled, documented, and archived. Describe the various steps (e.g., personnel training, calibration of equipment, data verification and validation) that will be used to identify and eliminate errors introduced during data collection (including observer bias), handling, and computer entry. Identify the percentage of data that will be checked at each step.

Specimen Collections
Clearly describe the kind (species), numbers, sizes, and locations of animals, plants, rocks, minerals, or other natural objects to be sampled, captured, or collected. Identify the reasons for collecting, the intended use of all the specimens to be collected, and the proposed disposition of collected specimens. For those specimens to be retained permanently as voucher specimens, identify the parties responsible for cataloging, preservation, and storage, as well as the proposed repository.

Special Requirements, Permits, and Concerns
Provide information on the following topics where applicable. Attach copies of any supporting documentation that will facilitate processing of your application.

Refuge Assistance
Describe any refuge assistance needed to complete the proposed study, such as use of equipment or facilities or assistance from refuge staff. It is important that all equipment, facilities, services, and logistical assistance expected to be provided by the Service be specifically identified in this section so all parties are in clear agreement before the study begins.

Ground Disturbance
Describe the type, location, area, depth, number, and distribution of expected ground-

disturbing activities, such as soil pits, cores, or stakes. Describe plans for site restoration of significantly affected areas.

Proposals that entail ground disturbance may require an archaeological survey and special clearance prior to approval of the study. You can help reduce the extra time that may be required to process such a proposal by including identification of each ground disturbance area on a U.S. Geological Survey 7.5-minute topographic map.

Site Marking and/or Animal Marking
Identify the type, amount, color, size, and placement of any flagging, tags, or other markers needed for site or individual resource (e.g., trees) identification and location. Identify the length of time it is needed and who will be responsible for removing it. Identify the type, color, and placement of any tags placed on animals (see special use permit for stipulations on marking and handling of animals).

Access to Study Sites
Describe the proposed method and frequency of travel to and within the study site(s). Explain any need to enter restricted areas. Describe the duration, location, and number of participants, and approximate dates of site visits.

Use of Mechanized and Other Equipment
Describe any vehicles, boats, field equipment, markers, or supply caches by type, number, and location. You should explain the need to use these materials and how long they are to be left in the field.

Safety
Describe any known potentially hazardous activities, such as electro-fishing, scuba diving, whitewater boating, aircraft use, wilderness travel, and wildlife capture, handling, or immobilization.

Chemical Use
Identify chemicals and hazardous materials that you propose using within the refuge.

Indicate the purpose, method of application, and amount to be used. Describe plans for storage, transfer, and disposal of these materials and describe steps to remediate accidental releases into the environment. Attach copies of Material Safety Data Sheets.

Animal Welfare
If the study involves animals, describe your protocol for any capture, holding, marking, tagging, tissue sampling, or other handling of these animals (including the training and qualifications of personnel relevant to animal handling and care). If it is required that your institutional animal welfare committee review your proposal, you must include a copy of their recommendations. Describe alternatives considered, and outline procedures to be used to alleviate pain or distress. Include contingency plans to be implemented in the event of accidental injury to or death of the animal. Include State and Federal permits. Where appropriate, coordinate with and inform State natural resource agencies.

Additional information or sections that may be requested for the proposal:

Literature Summary

This section should include a thorough but concise literature review of current and past research that pertains to the proposed research, especially any pertinent research conducted at refuges within the North Carolina Coastal Refuge Complex. A discussion of relevant legislation, policies, and refuge planning and management history, goals, and objectives should also be included.

Literature Cited

List all reports and publications cited in the proposal.

Peer Review

Provide the names, titles, addresses, and telephone numbers of individuals with subject-area expertise who have reviewed the research proposal. If the reviewers are associated with the investigator's research institution, or if the proposal was not reviewed, please provide the names, titles, addresses, and telephone numbers of three to five potential subject-area reviewers who are not associated with the investigator's institution. These individuals will be asked to provide reviews of the proposal, progress reports, and the draft final report.

Budget

The budget must reflect both funding and assistance that will be requested from the Service and the cooperator's contributions on an identified periodic (usually annual) basis.

Personnel Costs

Identify salary charges for principal investigator(s), research assistant(s), technician(s), clerical support, and others. Indicate period of involvement (hours or months) and pay rate charged for services. Be sure to include adequate time for data analysis and report writing and editing.

Fringe Benefits

Itemize fringe benefit rates and costs.

Travel

Provide separate estimates for fieldwork and meetings. Indicate number of trips, destinations, estimated miles of travel, mileage rate, air fares, days on travel, and daily lodging and meals charges. Vehicle mileage rate cannot exceed standard government mileage rates if Federal funds are to be used. Charges for lodging and meals are not to exceed the maximum daily rates set for the locality by the Federal government (contact North Carolina Coastal Refuge Complex for appropriate rates).

Equipment

Itemize all equipment to be purchased or rented and provide a brief justification for each item costing more than $1,000. Be sure to include any computer-related costs. For proposals funded under a Service agreement or contract, the refuge reserves the right to transfer the title of purchased equipment with unit cost of $1,000 or more to the Federal government following completion of the study. These items should be included as deliverables.

Supplies and Materials
Purchases and rentals under $1,000 should be itemized as much as is reasonable.

Subcontract or Consultant Charges
All such work must be supported by a subcontractor's proposal also in accordance with these guidelines.

Indirect Charges
Identify the indirect cost (overhead) rate and charges and the budget items to which the rate is applicable.

Cooperator's Contributions
Show any contributing share of direct or indirect costs, facilities, and equipment by the cooperating research institution.

Outside Funding
List any outside funding sources and amounts.

Personnel and Qualifications
List the personnel who will work on the project and indicate their qualifications, experience, and pertinent publications. Identify the responsibilities of each individual and the amount of time each will devote. A full vita or resume for each principal investigator and any consultants should be included here.

Deliverables:
All deliverables must be submitted to refuge staff no later than six months after the end of the project. Any extensions must be added as an amendment to the special use permit. Copies of publications that may extend outside of this six month period are still required as they become available. Interim deliverable timelines will be agreed on at the time of the issuing of the permit.

Deliverables that are required are as follows:

Reports and Publications
- Progress report(s) (usually quarterly, semiannually, or annually; may be required)
- Draft final and final report(s) (always required)
- The refuge manager appreciates opportunities to review manuscripts in advance of their publication.

Data Files
Provide any spatial (Geographic Information Systems [GIS]) and non-spatial data files that is generated and submitted as part of the research. Non-spatial data must be entered onto DVDs or an external data drive in Microsoft Access or Microsoft Excel. Spatial data, which includes Global Positioning System (GPS)-generated files, must be in a format compatible with the refuge's GIS system. A condition of the permit will be that the Service has access to and may utilize in future mapping and management all GIS information generated.

Metadata
For all non-spatial and spatial data sets or information products, documentation of information (metadata) describing the extent of data coverage and scale, the history of

where, when, and why the data were collected, who collected the data, the methods used to collect, process, or modify/ transform the data, and a complete data dictionary must also be provided as final deliverables. Spatial metadata must conform to Service (FGDC) metadata standards.

Specimens and Associated Project Documentation
A report on collection activities, specimen disposition, and the data derived from collections must be submitted to the refuge following refuge guidelines.

Other:
Researchers must provide the refuge manager with all of the following:

- Copies of field notes/notebooks/datasheets.
- Copies of raw data (in digital format), including GIS data, as well as analyzed data.
- Copies of all photos (digital photos preferred), slides, videos, and films.
- Copies of any reports, theses, dissertations, publications or other material (such as news articles) resulting from studies conducted on refuge.
- Detailed protocols used in study.
- Aerial photographs.
- Maps/GIS data.
- Interpretive brochures and exhibits.
- Training sessions (where appropriate).
- Survey forms.
- Value-added software, software developed, and models.

Additional deliverables may be required of specific studies.

STATE: North Carolina

GRANT TITLE: W79-Wildlife Management

PROJECT TITLE: Pilot Study – Using Fine Scale GPS Technology to Research Sympatric Canid Population Dynamics (Job 2.0?)

A. Problem and Need

The coyote (*Canis latrans*) is now abundant throughout the 100 counties in North Carolina (NC), and is managed as nongame with no closed season or bag limit (NC Wildlife Resources Commission 2016). Previously restricted to the West and Midwest regions of the United States, by the early 1990s coyotes had expanded their range into the Albemarle Peninsula (AP), which is situated in the northeast coastal plain region of NC (Hinton et al. 2012, Murray et al. 2014). In recent years as coyotes have increased their population, some have begun to make use of the Outer Banks region.

The United States Fish and Wildlife Service (USFWS) released a non-essential, experimental population of captive-bred red wolves (*Canis rufus*) on the Alligator River National Wildlife Refuge (ARNWR) in 1987 (Hinton et al. 2013). This population increased until 2008 and peaked at around 130 individuals (Group Solutions, Inc. 2016), short of the recovery goal of 220 in the wild (USFWS Red Wolf Recovery Program 2013). The AP has an estimated carrying capacity of 140-150 wolves (Hinton et al. 2013, Kelly et al. 1999, USFWS Red Wolf Recovery Program 2007). The exact number of red wolves is not known, but USFWS staff report a population estimate of 45-60 individuals with eight mortalities to date in 2016 (https://www.fws.gov/redwolf/index.html August 2016). Hybridization with coyotes and inbreeding depression are suspected factors that have affected red wolf population growth and viability since the inception of the Red Wolf Recovery Program (RWRP), while vehicular and gunshot mortality are known factors (Hinton et al. 2013). Because of hybridization between red wolves and coyotes, the AP supports a continuum of sympatric canids, hereafter referred to as "sympatric canids."

As part of a recent program review, the USFWS halted many aspects of the RWRP in 2015 and discontinued the coyote sterilization program, potentially affecting the spatial

Commented [JM1]: The 220 animals in the wild is the minimum population number in the Recovery Plan divided into 2-3 mainland sites.

Commented [JM2]: Currently population estimate is 25-40 and there has been 6 known red wolf mortalities in 2017.

Draft - Confidential

distribution and population dynamics of sympatric canids. Telemetry data from coyotes on the AP suggests that about 70% of coyotes are residents (i.e., those that defend set territories) while the other 30% are transients, with most being dispersing juveniles (Hinton et al. 2015). Transient coyotes do not defend set territories. Coyotes can travel long distances and become transient even as adults, especially when they lose their mate. Recently described as using "compensatory immigration," coyotes opportunistically fill spatial resource gaps by periodic transiency; when spots come open, individuals that do not yet have permanent territories and have been roaming in the area, are able to inhabit the new openings (Hinton 2016). These periods of transiency can sometimes bring coyotes into conflict with other canids and humans, especially when they are utilizing of anthropogenic resources.

Though a rural area, human land uses occupy a significant portion of space on the AP. The AP is comprised of approximately 30% agricultural fields, 50% forest and coastal marshes, and 20% "other" land cover types on federal, state and private lands (Dellinger 2011). Concerns about fear of attacks on humans and domestic pets, the effects of sympatric canids on white-tailed deer and other game populations, and homeowner property damage comprise many of the conflict calls regarding sympatric canids on the AP (Responsive Management, forthcoming data). Wildlife managers in this region frequently receive requests for information on canid management (C. Turner, personal communication, 2016).

The changes in state and federal canid management rules have resulted in confusion regarding residents' rights and options for management of property damage by sympatric canids. As a result, some citizens are unsure of the legal and most effective methods for canid conflict management. Adding to management complexity is the need to manage canids for conservation purposes, such as reducing predation on at-risk ground nesting species or reducing hybridization of sympatric canids.

In 2013, NCWRC and USFWS established a committee to oversee the collaborative management and conservation of sympatric canids on the AP. A USFWS and NCWRC joint memorandum documented detailed action items for the joint management of sympatric canids on the AP, including specific research objectives which this proposal seeks to address (Attachment 2). As sympatric canids on the AP increase in number, monitoring their

Commented [JM3]: Would like to know a bit more about calls Chris is receiving like volume of calls, how many potential involve red wolves, etc.

Commented [JM4]: What types of property damage is being referred to here? Red wolves have been confirmed in livestock depredation 7 times in the 30 years of the program in NC. Is this a product of the unfortunate lumping of coyotes, domestic dogs, hybrids and red wolves as sympatric canids?

Commented [JM5]: Would be interesting to analyze the direct predation by canids on ground nesting birds as compared to the potential benefits from canids (red wolves) preying on other known nest predators? Or if there has been documented cases of red wolves preying on ground nesting species.

Commented [JM6]: Does not acknowledge the dramatic decrease in the red wolf population because of the lumping as sympatric canids.

Draft-Confidential

movements, particularly in relation to individuals of differing ancestry, could provide important data to NCWRC and USFWS staff for science-based local and landscape-level decisions about sympatric canid populations and conflict management. Collection of finer temporal scale location data would help to manage interactions of sympatric canids with humans, as well as to support development of dynamic stochastic population models.

B. Objectives (after December 1, 2016-November 30, 2018)

Objective 1: Use GPS collar and proximity sensor technology to test performance under various conditions and evaluate the frequency and accuracy of the scheduled fix rates.

Objective 2: Use fine scale GPS data collection for investigating annual and seasonal spatial dynamics of sympatric canids: home range and core area sizes, amount of overlap in home range and core areas, movement pathways and daily activity patterns, and cover type selection and preference.

Objective 3: Use fine scale GPS data collection for investigating the number and age structure of offspring for family groups of collared sympatric canids.

Objective 4: Use fine scale GPS data collection for investigating sources of mortality for sympatric canids.

Objective 5: Use fine scale GPS data collection for preventing and mitigating canid conflicts with landowners.

Objective 6: Determine genetic profiles of sympatric canids through DNA identification of all captured individuals, parentage, and presence of hybridization.

At the end of this two-year pilot study, we will deliver an observational summary detailing the use of the GPS and sensor technology for spatial and population dynamics research on sympatric canids on the AP.

C. Expected Results and Benefits

As part of a pilot study, we will monitor the status of collared individuals by using a finer scale assessment of space and habitat use than previous studies. Earlier research focused on many of the same objectives we suggest investigating here, but during a time of intense, active

Commented [JM7]: Concern that the objectives are largely focused on testing GPS collars, which is more appropriately done on a more common species such as coyotes and not on a species with low population numbers such as red wolves. As discussed in the meeting, many of these types of objectives have been done for red wolves, particularly on the Refuge.

Commented [JM8]: FWS already conducts over 75 telemetry flights/year followed up by ground reconnaissance to assess collared red wolf and coyote causes of mortality.

Commented [JM9]: Potential concerns about what data is to be shared with private landowners.

Commented [JM10]: The attached Section 7 document states it is a three year project.

Draft. Confidential

management. Specific management techniques are no longer being carried out and dynamics between sympatric canids are expected to have changed substantially. The uncertainty regarding current dynamics presents a need for additional research in order to inform actions for the management of sympatric canids. Information gained from research may impact management rules and landowner's abilities to manage canids in some areas. Additionally, GPS technology has improved since earlier research was conducted allowing for more temporally detailed data collection and more nuanced analyses. Understanding how sympatric canids collectively use resources in areas of human-dominated landscapes will allow wildlife managers to tailor management options to local conditions. On the AP, row crop agriculture and hunting represent the primary and secondary land uses, respectively. Row crop agriculture is a significant nutrient resource on the landscape and, as opportunists, canids take advantage of such resources when they are available. Non-consumptive wildlife-driven tourism persists in all seasons and wildlife watching is a main draw for tourists in this area. For many tourists, the opportunity to see or hear large carnivores is the sole attraction for traveling to the AP. Information from this study will be provided to local constituents to establish a knowledge base regarding how sympatric canids use resources on private lands. Management and guidance could serve to prevent or minimize conflict while maximizing positive wildlife interaction opportunities for constituents. Development of a common understanding between wildlife managers and landowners based upon factual information is paramount for collaboratively achieving successful management of sympatric canids. The data collected in this pilot study is the foundation upon which this understanding and future management actions will be built.

The current level of hybridization between sympatric canids on the AP will be characterized using DNA gathered during this study. Body size exists as a continuum between coyotes and red wolves and has been documented as the most important factor for successful interspecific breeding pairs of these canids (Hinton 2014). Though both species have been found to use resources in similar manners, red wolves generally have more expansive home ranges and therefore may not use local resources as intensively as coyotes, depending on body size. Obtaining individual identification of study animals will allow managers, armed with spatial information, to infer how and why individuals in the canid species continuum exploit

Commented [JM11]: It is accurate that some of the management techniques are not currently being used, but it should be noted that FWS may begin to using some of them in the future and perhaps during the life of this project.

Commented [JM12]: Little has changed regarding management on the Refuge itself and particularly with the Milltail pack.

Commented [JM13]: Clarification on exactly what is being referred to here.

Commented [JM14]: Red wolves only, no other "large" carnivores, if coyotes would even be considered large. Or is this meant to refer to black bears as well? Could use clarification.

Commented [JM15]: Potential concern depending on what type of information is shared.

Draft - Confidential

anthropogenic resources considering their life history traits.

In conjunction with prior research, data collected will contribute to knowledge on sympatric canid population dynamics on the AP. Estimating population size will allow managers to monitor population trends of sympatric canids and to examine the long and short-term impacts of different management strategies on their populations. While it is unknown whether sample size will allow for population estimation, obtaining population estimates for coyotes would provide wildlife managers with baseline data, when paired with annual mortality estimates, for monitoring changes in population abundance over time. Information on changes in abundance, reproductive dynamics, and habitat use could impact management strategies to influence long-term conservation outcomes. Results of this pilot study will allow managers to determine if future work will be necessary, what amount of effort will be required to achieve each objective, and whether or not population estimates will be an attainable goal.

Commented [JM16]: Would likely be better suited for a coyote population size estimate in an area with no other sympatric canids.

D. Approach

The official Red Wolf Recovery Area (RWRA) covers approximately 6,900 square kilometers within Beaufort, Dare, Hyde, Tyrrell, and Washington counties (Wildlife Management Institute 2014). However, the USFWS has proposed the RWRA be constricted to the ARNWR and the Dare County Bombing Range in Dare county by the end of 2017. Due to these proposed RWRA changes, this study proposes to capture and radio-collar 25 sympatric canids within Dare, Hyde, and Tyrrell counties (hereafter referred to as "study area"); those counties being within and directly adjacent to the proposed new RWRA. The thematic subheadings below provide detailed descriptions of the approaches required for achieving the pilot study objectives.

Commented [JM17]: It is more accurate to refer to it as the Non-essential Experimental Population (NEP) boundary.

Commented [JM18]: Need to discuss the protocol if a red wolf is captured that is already wearing a radio-collar. Initial thought that FWS would be notified to determine the age of the collar and a decision to be made on whether to replace release the animal with the existing collar, replace it with a new VHF collar based on the age of the collar or replace it with a GPS collar. This should be part of the decision tree that was discussed at the meeting.

Commented [JM19]: As discussed in the meeting, this is not currently accurate as we are in the middle of the NEPA process to analyze a range of alternatives of which this is only one of the alternatives. No decisions have been made in this regard.

Sampling Efforts

Trained NCWRC personnel will conduct live trapping of sympatric canids, with assistance from the USFWS RWRP biologists, and trained, experienced local trappers. NCWRC and USFWS wildlife personnel will select local trappers based on their past performance in trapping sympatric canids, but may also select trappers from the NCWRC coyote trappers list. NCWRC staff will train contracted trappers on specific trapping procedures before every trapping

Draft - Confidential

season. The project lead will supervise and coordinate all trapping activities including locations for installation and the operation of trap lines and handling of captured animals. Simultaneous personal trapping activities by contracted trappers will not be permitted while performing contracted trapping services, as specified in the draft service contract (Attachment 4).

Trapping efforts will follow a spatial capture-recapture (SCR) framework with a systematic targeted sampling design, focusing on areas that contain resources previously found to be used by sympatric canids (e.g. edge, agricultural fields, secondary roads, etc.) (Harris et al. 2013, Ivan et al. 2013), while attempting to sample a diversity of habitat types. This effort will allow us to increase the probability of detection of sympatric canids on the landscape (Tom 2012). While it is important to sample a wide range of habitats, the most important requirement for SCR is the number of collared individuals; this requirement provides flexibility in the other requirements for field sampling as needed (K. Pacifici, personal communication, 2016). We will initially focus trapping in areas of known red wolf packs, as advised by RWRP.

Trapping will take place during the breeding season when the likelihood of capturing females in the later stages of gestation or whelping females will be low. Capture efforts will be conducted from soon after 1 December 2017 – February 2018 and December 2018 – February 2019. Captured sympatric canids will be surrendered to NCWRC or the USFWS at capture sites. Trapping should occur on both public and private lands to obtain sampling coverage of the study area. Ideally, all federal and state lands would be accessible for trap and release (hereafter referred to as "capture") of sympatric canids, but it is most important to be able to trap and release on Alligator River NWR and the Dare County Bombing Range as those encompass the newly proposed RWRP recovery area and comprise the majority of land area for Dare county. Unlike Dare ~~county~~County, there are ample private lands that surround Pocosin Lakes NWR and Lake Mattamuskeet NWR in both Tyrrell and Hyde counties that may be utilized to effectively sample individuals who may use those federal lands, should they be excluded from capture activities. Capture on federal lands may require USFWS take permits and proposed activities may be subject to a compatibility assessment (P. Benjamin, personal communication, 2016). Scientific collection activities that take place on private lands will require agreements outlining conditions mutually decided by NCWRC and landowners

Commented [JM20]: Concern over multiple captures of red wolves due to the ever present possibility of trap injuries or other issues, particularly with folks that may not be used to conducting this type of trapping and since the wild population numbers are currently so low.

Commented [JM21]: As discussed in the meeting, the focus would more appropriately be focused in areas where we are unsure of red wolf presence and would also be areas with a greater chance of having coyotes.

Commented [JM22]: Due to the low population numbers and potential risks to red wolves, we do not trap during the breeding season (e.g. February) in areas with red wolves. All trapping of red wolves should occur in January and potentially late December.

Commented [JM23]: As discussed in the meeting, if any trapping is to be conducted on Federal lands it will need to be done by FWS personnel due to the difficulty of the process for allowing non-federal personnel to conduct activities on the refuge. Additionally, the objectives focus largely on landowner conflicts and resources, which are not an issue on the Refuge and there also likely isn't a large enough coyote population in established wolf areas to address the objectives.

Commented [JM24]: As discussed in the meeting, it would require a Compatibility Determination and some level of NEPA. So it was decided the pilot study would focus on non-Federal lands.

Draft - Confidential

(Attachment 3).

To increase probability of detection of sympatric canids, the accessible study area will be partitioned by a grid, the cell size of which will based on the average annual home range size of resident coyotes previously reported for the AP, approximately 23 km^2 (Hinton et al. 2015). As a system of sampling, trap lines will be referred here as "traps," and the number of trap sets (i.e. the actual trapping device) and number of each trap set size may vary between traps as necessary. Sampling will be standardized within each grid cell by use of equal number of traps per cell, on average 3 per cell, each at an approximate length of 10 km (Andelt and Gipson 1979, Way et al. 2004).

Target canids will be captured by using Softcatch #3 Coyote 4x4 (Oneida Victor Inc. Ltd., P.O. Box 32398, Euclid, Ohio 44132, Hinton 2014, Schemnitz 1994), the EZ Grip #7 (Livestock Protection Company, P.O. Box 725, Alpine, Texas 79831, Frame and Meier 2007), or equivalent. Various lures and baits will be used to increase trapping efficiency (Frederick et al. 1989, Shipley 2012). Traps will be laid on the Monday of each week and will be opened at the time of deployment. Traps will be checked once daily at dawn, to reduce potential stress to trapped individuals and will not be operated on days where the temperature is expected to reach or exceed 80° F (R. Nordsven, personal communication, 2016) or during times of predicted inclement weather (e.g. snow, hail, high wind, etc., Sikes et al. 2011). To standardize effort and remain logistically realistic, traps should be open for three trap nights in a row before being removed. Trap sets that have been closed due to non-target bycatch or other circumstances may be reopened and all traps should be re-baited and lured as appropriate.

Trap set locations will be marked by NCWRC or USFWS personnel using handheld GPS units (Garmin GPSMAP 64S, 1200 E. 151st St., Olathe, KS 66062-3426) and given a sequential identification number. Traps will also be given an identification number and trap set points will be documented in ArcMap 10.4. Trappers will keep detailed records on trap set operation, non-target species trapped, and other relevant details. Non-target species will be released from traps after an in-field assessment of injuries, if any, and animals with life threatening injuries will be euthanized by the trap operator. Targeted recapture of collared canids will occur annually during the same months, to replace GPS collar batteries and drop-off collar release

Commented [JM25]: Please work with Ryan regarding the use of trap stakes and drags as both can cause injury or death if not used properly.

Commented [JM26]: Traps should be covered or rendered inoperable during a hard freeze. A leghold trap can cut of blood circulation to the foot and can lead to frozen tissue during a hard freeze. Concerns private trappers not use to methods used to limit trap injuries as they are not typically trapping for release.

Commented [JM27]: Concerns over repeated trapping of red wolves.

Draft- Confidential

units in field. Trapping effort will be quantified (trap nights), the effective sample area will be estimated, the encounter (detection) probability will be estimated using a Gaussian detection model (Amundson et al. 2014), and an estimate of density for coyotes will be calculated using a modified Huggins closed-capture estimator in program MARK, if sample size allows (Harris et al. 2013, Ivan et al. 2013).

Animal Handling

Handling of canids will follow American Society of Mammalogists (ASM) guidelines (Sikes et al. 2011) and will be performed at the capture site. Chemical immobilization agents may be used depending on the number of field staff during processing (i.e., three or more staff required during non-chemical immobilizations, Craft 2007, M. Morse, personal communication, 2016).

Chemical Immobilization

Unless adequate numbers of personnel are available to safely employ mechanical restraint techniques, target animals will be anesthetized with the chemical immobilization agent BAM (Wildlife Pharmaceuticals, Inc., Windsor, CO 80550). BAM, a combination of Butorphanol tartrate, Azaperone tartrate and Medetomidine HCl., will be delivered by intramuscular injection by syringe pole to the hip. Dosage for canids is based on field trails performed by Wildlife Pharmaceuticals (Wildlife Pharmaceuticals, Inc. 2016) and the recommended dose for coyotes is 0.2CC and red wolves is 0.3CC, with adjunct doses of 0.1-0.2CC delivered if initial dosages do not cause induction (S. Kirschner, personal communication, 2017). Induction times for coyotes and wolves ranged from 5 to 10 minutes after initial and/or adjunct dosages (Wildlife Pharmaceuticals, Inc. 2016). After field handling is concluded the anesthesia will be reversed using two reversal agents, Atipamezole and Naltrexone, at double the CC of Atipamezole to BAM that was delivered (including adjunct doses, if given) and 0.5CC of Naltrexone. Recovery time from the reversal agents ranged from 10 to 25 minutes during field trails (Wildlife Pharmaceuticals, Inc. 2016). Field personnel will observe animals for signs of adverse effects for up to 30 minutes after reversal agents are delivered.

Commented [JM28]: FWS personnel would like to be involved on the handling and collaring of all red wolves, whenever possible.

Commented [JM29]: Two biologists and one note taker, if available. We typically do not chemically immobilize red wolves during processing.

Commented [JM30]: We have a better, cleaner and safer chemical immobilization protocol developed specifically for red wolves by the NCSU Vet School. Butorphanol @ 0.4mg/kg w/ Dexmedetomide @ 0.04mg/kg
Antagonist: Naloxone @ 0.02mg/kg w/ atipamizole @ 0.2mg/kg

Commented [JM31]: We have had better luck restraining the head with a catch pole and hand injecting the animal instead of using a syringe pole.

Draft - Confidential

Mechanical Immobilization

Unlike other carnivore families, the submissive behavioral response of canids to perceived dominance reduces the need to use immobilization agents. Appropriate mechanical restraint techniques can reduce handling time of animals, allowing animals to reintegrate into social groups more quickly, subsequently reducing overall stress to the individual (Powell and Proulx 2003). Target canids will be mechanically restrained with a restraint pole, until two muzzles can be placed around the snout. While pinned with the restraint pole by one person, a second person will restrain the set of legs not in the trap against the ground and a third person will release the foot from the trap. This set of legs will then be restrained by the 3rd person as the restraint pole is removed. Once the restraint pole is removed the person restraining the front legs will also then restrain the head. The first person will then move forward with processing the captured animal.

Each animal will be placed on a towel or blanket to provide thermal protection from the ground, with eyes covered and lubricated with eye ointment; temperature will be monitored with a rectal thermometer. Overheating occurs at approximately 104-105°F for canids (AZA Canid TAG 2012) and the animal handling crew will monitor temperature at 5-minute intervals; if a temperature reading reaches 104°F, corrective actions will be taken and temperature will be monitored at 1-minute intervals. Should overheating occur, the individual will be removed from insulation to expedite the natural evaporative cooling process. During days that approach 80°F in temperature, measures will be taken to reduce heat stress, such as: wetting the animal with water, application of a cold pack to the groin area between the back legs, application of rubbing alcohol to foot pads, or immediate release (AZA Canid TAG 2012). If the injured individual is suspected to be a red wolf, based on morphometrics, USFWS staff will be contacted for a decision. In the event that trap caused injuries are determined to be life threatening through use of a trap injury score assessment (Frame and Meier 2007) the individual will be euthanized. In the event that NCWRC personnel cannot be present, trained USFWS personnel may collar and measure captured target animals and will provide data sheets to NCWRC staff. Target animals will not be vaccinated or otherwise treated for diseases, regardless of the presence of disease symptoms.

Commented [JM32]: Morphometrics should not be the sole indicator of species.

Commented [JM33]: As stated previously, FWS personnel should be notified whenever a red wolf or an animal that could possibly be a red wolf is captured and would like to be involved in the handling and immobilization of all red wolves, whenever possible. No red wolves or animals suspected as possibly being red wolves should be euthanized without direct FWS involvement and an FWS decision to do so.

Commented [JM34]: Due to the high value of each individual red wolf with such a low population, all red wolves should be treated with vaccinations and for other diseases, visible and non-visible. Capture operations are risky for these animals and if we are going to undertake that risk we need to do whatever we can while they are in hand to give them the highest chance of survival and successful reproduction.

Draft - Confidential

Non-target animals will be released on site. Captured domestic dogs will be immediately released from the trap set following an injury score assessment and only if no life-threatening injuries are present. If a domestic dog has sustained life threatening injuries and owner identification information is present on the dog, then the animal will be held in either a transportable kennel, or at a dog pen on a state game land that is equipped with such facilities, until the owner can retrieve the dog. The costs associated with injuries sustained to the dog will be the responsibility of the animals' owner. Law enforcement may be requested to help communicate with the animal's owner. If the animal does not have an identifiable owner and has incurred substantial life threatening injuries (i.e. compound fracture), the dog will be euthanized on site. Target animals showing signs of disease symptoms such as circling behavior, head tilt, muscle twitches, convulsions with jaw chewing movements and salivation ("chewing gum fits"), disorientation, incoordination, staggering caused by paralysis of the hind legs, seizures, and partial or complete paralysis will be euthanized and tested according to protocol set forth by the agency veterinarian, in order to determine if there may be a public health issue (M. Palamar, personal communication, 2016). USFWS will be contacted in cases of suspected red wolves. Staff involved in animal handling duties will have the pre-exposure rabies vaccination series completed prior to field work inception and will maintain rabies titer records through properly licensed medical services providers.

If staff is bitten and skin is broken by an animal while performing handling duties, they will be advised to immediately visit a local hospital or clinic for evaluation by healthcare professionals. The field coordinator will immediately notify supervisory staff and an injury report and workers' compensation claim will be opened for the incident. The animal will be euthanized and the head will be sent to the state lab for rabies testing; the body may be sent to the Southeastern Cooperative Wildlife Disease Study (SCWDS) laboratory for additional disease investigation.

Capture Processing and Marking

During canid handling, NCWRC personnel will record age class, sex, weight, total body length, head width, ear length, and tail length, visually assess ectoparasite load, look for and disinfect with betadine or iodine as needed any minor trap caused injuries, and affix GPS collars

Commented [JM35]: Problematic on Refuges

Commented [JM36]: FWS retains the decision making on euthanasia for red wolves.

Commented [JM37]: It should not be automatic that staff being bitten during a capture should result in a red wolf being euthanized, particularly if that animal is displaying no signs of disease. We can't afford to lose any individuals in such a low population without sufficient cause. And no euthanasia of a red wolf should occur without FWS involvement in the decision making process. If needed, animals can be quarantined at Sandy Ridge.

Draft - Confidential

(Knick 1990, Sikes et al. 2011). All captured canids will be fitted with appropriately-sized GPS collars in the field based on morphometrics previously indicated as reliable thresholds for species categorization: hind foot length, weight, width of head, and tail length (Hinton 2014); analysis of DNA samples collected during trapping efforts will help to assign captured canids to position along the species continuum post release. Age of individuals will be estimated based on physical characteristics, including weight and tooth replacement (Knick 1990, Hinton 2014, Gier 1968), and captured canids will be aged into one of three classes: > 2 years old as adults, < 2 but > 1 year old as juveniles, and > 6 months but < 12 months old as pups (Hinton 2014). Reproductive status will be determined based on estimated age class and presence of gonadal descent during the breeding season for males and the presence of nipple swelling or previous suckling for females (Hutson and Racey 2004, Magee 2008, Mengel 1971).

Captured individuals will be ear marked using a button tag (model 410, Ketchum Mfg. Co. [or equivalent], PO Box 10, 11 Town Shed Road, Lake Luzerne, NY 12846) placed along the middle of the ear where they are most protected from loss, with a pin-type applicator (485sa Pow-R-ceps plier, Ketchum Mfg. Co. [or equivalent]) (Silvy 2012). The puncture site will be treated with an antiseptic to deter infections. Each sympatric canid will also be marked with an individually-numbered, glass-encapsulated, passive integrated transponder (PIT model HPT12, 12.5 mm, 134.2 kHz, Biomark, Inc., 703 South Americana Blvd., Suite 150, Boise, ID; Gannon et al. 2007), using a syringe-type implanter and replaceable needle (model MK10 [implanter], model N125 [needle], Biomark, Inc.). Successful PIT placement will be verified with a mini portable reader (model GPR Plus, Biomark, Inc.). The implantation site will be prepared by swabbing with 70% alcohol (Mrozek et al. 1995) and a sterilized new needle will be used for each injection. The standard implantation site for transponders is subcutaneously on the dorsal midline of the back, cranial to the shoulder blades (Ingwersen 2000).

A skin biopsy will be taken from all captured target canids by puncturing the pinna of the ear with a biopsy punch in the same location where the ear tag will be placed (Palamar 2014). The biopsied area will be disinfected with alcohol after sampling. The skin biopsy will be placed in a labeled (ID, date, and sample type) cryogenic tube filled with 95% ethanol as buffer and then stored in a freezer until sent out to a lab for genetic analysis (Palamar 2014, Tom

Commented [JM38]: What is the purpose of the ear tags? They've been used in the past, but were a source of infection and irritation, and were routinely pulled out. With the use of PIT tags, ear tags are needed less.

Commented [JM39]: To be consistent with existing red wolves and coyotes that have been captured it would be beneficial to use PIT tags by Trovan or to at least make sure whatever is used can be read by both agencies.

Commented [JM40]: There is an existing protocol with the same lab you are using for obtaining genetic information from blood samples only, as we have always done, which makes it unnecessary to take a skin biopsy.

Draft - Confidential

2012). A selection of hairs with the root bulla attached will be pulled from the belly and placed in paper envelopes (Janecka et al. 2007). Hair samples will serve as back up to tissue samples for genetic testing. All samples will be sent to the Laboratory for Ecological, Evolutionary and Conservation Genetics, at University of Idaho (875 Perimeter Drive, MS 1136, Moscow, ID 83844) for genotyping to determine species as well as individual identification, hybridization presence, and parentage analysis following previously developed protocols (Adams et al. 2007, Hinton 2014, Miller et al. 2003). The appropriate genetic analyses that examine the coyote-hybrid-wolf species continuum will be performed.

Blood will be collected from all juvenile and adult target canids by venipuncture of the brachial or jugular veins using a 22-28-gauge needle (M. Palamar, NCWRC veterinarian, personal communication, 2016). As per NCWRC veterinarian recommendations, approximately 12 ml of blood will be collected for each animal for possible future testing for diseases of importance to sympatric canid species as well as the humans and domestic animals that they may come into contact with. A minimum of two 6 ml lavender top tube (for whole blood with EDTA) will be filled. Samples should be refrigerated at all times; a cooler with ice will suffice while in the field. Samples should be sent to the NCWRC within 48 hours or frozen for later shipping. Skin scrapes will be collected from animals presenting signs compatible with sarcoptic mange (lesions) for possible future diagnostic purposes. Lesions will be scraped until blood is drawn; the scrapings will be placed onto a slide and covered with a piece of clear tape for later visual confirmation.

Should overheating occur, processing will be performed in the following prioritization order and the first five items will need to be completed before releasing any individuals: 1) trap injury evaluation, 2) collaring, 3) DNA (skin biopsy) sample collection, 4) morphometrics, 5) aging, 6) PIT tagging, 7) weight, 8) ear tagging, 9) reproductive status, 10) ectoparasite evaluation, 11) blood collection, and 12) skin scrape collection.

Collaring

Vertex Plus GPS Collars will be attached to 25 sympatric canids captured on the study area, 10 of which will be equipped with proximity sensors (Vectronic Aerospace GmbH, Carl-Scheele-Str. 12, 12489 Berlin, Germany). Project staff will pilot test proximity sensor technology

Commented [JM41]: FWS maintains blood samples for all captured red wolves.

Commented [JM42]: Animals showing signs of mange should be held and treated before release to heal that individual and avoid spreading it to the surrounding canid population, particularly red wolves. Conservation of red wolves needs to be the a priority.

Commented [JM43]: Several people commented with concerns on the prioritization. 1) cool/assess injuries/ensure survival of the animal, 2) radio collar animal, 3) draw blood, then the rest only if you are able to do it safely.

Draft - Confidential

for utility in analysis of spatial and temporal community dynamics. Proximity sensors trigger increased GPS location acquisition during those time intervals when two collared individuals come within a set distance from each other (http://www.vectronic-aerospace.com/wildlife-monitoring/sensors/uhf-id-tags, accessed August 2016).

To avoid instances of collar induced strangulation, only adult (>2 years old) male and female individuals will receive collars (Hinton 2014). ASM guidelines recommends a collar weight of <5-10% of a canids bodyweight, we will observe these guidelines (Sikes et al. 2011). Sympatric canids not releasable at a capture site will not be collared and will not become study animals.

GPS radio-collars will have both VHF and GPS Iridium locational systems as well as store-on-board capabilities. Radio-collar units will be programmed to record GPS coordinates once every 1.75 hours producing approximately 13 locations per day while cycling through the 24-hour time cycle. These settings will allow for a GPS battery life of 300 to 552 days, averaging 431 days. The VHF beacon will be in operation from 0800 – 1600 hours daily. GPS locations will be sent via satellite once per day and each transmission with contain 12 locations. The use of an integrated drop off firing mechanism should allow the collars to drop off within a maximum of approximately 548 days after deployment. The drop off schedule once set cannot be changed. The drop off firing mechanism is wired to a battery unit independent of the collar battery, therefore should the collar battery become depleted, the drop off mechanism will not be affected (C. Akakpo, Vectronic Aerospace GmbH, personal communication, 2016). Unless a collared individual is recaptured before the collar battery dies, the drop off mechanism will fire at the scheduled time frame post collar deployment.

Observation of sympatric canid habitat use and movements will occur through GPS data obtained with combination GPS/VHF radio-collars. VHF relies on triangulation, the process of estimating the location of a transmitter by using two or more compass bearings obtained by using directional antennas at known locations remote from the transmitter's position (White and Garrott 1990), whereas GPS uses a satellite based system to obtain location coordinates. There have been many published studies where one or both of these methods were used, with mixed success for determining various aspects of carnivore ecology throughout the United

Commented [JM44]: As discussed in the meeting, FWS would like to collar all red wolves captured. If effort and the potential risk of injury has already occurred such as is the case with any capture, then we would like to take advantage of having the red wolf in hand to place a VHF collar on it regardless of whether or not it meets the criteria for this project.

Commented [JM45]: Needs clarification. Why would trapping be occurring for this project in an area where a canid could not be released?

Commented [JM46]: For ESA listed species, the VHF frequency range is 164-165 mHz. Not only is this in keeping with policy, but it is consistent with the existing collars and allows for real time tracking of canids by FWS personnel for suspected depredations/complaints, reports of injuries, den locations, telemetry flights, etc. Previous researchers utilizing GPS collars on canids within the NEP boundary have used VHF frequencies within the 164-165 mHz range.

Commented [JM47]: Our recommendation based on our monitoring of red wolves is to set the VHF beacon to 12 hour rotations, with it set on from 0700 to 1900 (0800 to 2000 during daylight savings) because we have run into situations where we needed to do real time tracking past 1600.

Commented [JM48]: Concern over the short life span of the collars and need to recapture.

Draft - Confidential

States (Hinton et al. 2012, Schrecengost et al. 2009, Sparkman et al. 2012). While GPS technology has developed rapidly in recent history, the real time functional advantage of VHF cannot be disregarded. When GPS technology falters or malfunctions, VHF can serve as replacement for data collection in addition to its use in real time monitoring of study animals. Canids will be minimally monitored for mortality approximately every 30 days by using VHF aerial telemetry techniques (Whitehouse and Steven 1977) as there may be a delay in satellite transmission of GPS location data due to weather, season, and animal behavior. Transient canids and individuals from breeding pairs that have lost a mate, have been found to use much larger areas versus paired residents, potentially increasing the opportunity for losing track of these individuals when GPS technology reaches its functional capacity or experiences malfunction. VHF data may also provide locations of canids in cover too dense for GPS units to function. Use of VHF telemetry techniques for data collection may be expanded as necessary for project needs.

Commented [JM49]: FWS currently flies to monitor collard canids 1 to 2 times a week, partially to detect mortalities in a timely manner to more likely be able to determine the cause of death. For any collared canids, we would like to add those frequencies to our flights so they can be monitored much more frequently. Which is another reason the frequencies should be in the same range as the existing collars. Does the VHF beacon on the GPS collars have a mortality mode?

Spatial Data Analyses

Both minimum convex polygon (MCP) and adaptive kernel (AK) home ranges (95%) and core use areas (50% and 25%) (Seaman and Powell 1996, Seaman et al. 1999) will be calculated from GPS data by using BIOTAS (Ecological Software Solutions LLC, 2016) and Geospatial Modelling Environment (Spatial Ecology, LLC, 2016) for ArcGIS 10.2.2 (Environmental Systems Research Institute, 2016) (Benson et al. 2006, Riley 2006, Tucker et al. 2008, Hinton 2014) for comparison to older studies. These estimations can also be calculated using VHF data, provided data minimum requirements are met. Spatial distribution in relation to habitat will also be estimated by dynamic Brownian bridge movement models as described by Hinton (2014) with R statistical software (R Core Team 2016) using the moveud package with habitat covariates important to each species (Bryne et al. 2014, Collier 2013, Kranstauber and Smolla 2013, C. Proctor, personal communication, 2016). Additionally, recent research into how canids shift their ranges will also be investigated for populations on the AP (Morin and Kelly, in review). Spatial overlap and co-occurrence will be assessed using methods described by Shipley (2012). Habitat and cover types will be estimated from digitized maps created by the SEGAP (Hinton 2014) or ortho files, as available (Shipley 2012). Percent composition of habitat and cover types within home ranges and core areas as well as edge density will be quantified (Shipley 2012).

Draft - Confidential

Habitat selection and cover type use effects on spatial distribution will be estimated at both the population (2nd order) and individual (3rd order) spatial scales using resource selection functions (Johnson et al. 2006, Manly et al. 2002, Shipley 2012). Effects of seasonality and time of day activity will also be explored. The spatial and temporal patterns of space use by sympatric canids will be studied using data generated from the interaction GPS collar sensors, particularly distance between individuals and duration of proximity.

Den Monitoring

Project staff will attempt to locate den sites for sympatric canids to get pup counts, morphometric measurements, age estimates, and skin biopsies. Project staff will also attempt to monitor pup survival during the pup rearing season by using remote cameras placed around the den site (Harrison and Gilbert 1985, Parks 1979, Way et al. 2001). Pups will be weighed, measured, and PIT tagged during May and June of each year when they become active but are still den-obligated (Gier 1968). We will investigate the use of remote camera traps for monitoring den behavior with a two-camera array around the den (H. Garbe, personal communication, 2016, Kays and Slauson 2008). This method has been successfully used to monitor kit fox pup survival (Kluever et al. 2013). Because coyotes have been found to be sensitive to den site disturbance, there is a general lack of data in the literature regarding this approach for monitoring pup survival. Approaching an experimental methodology systematically will be important for determining which methods are effective and which are not. As a starting point for testing this methodology, remote cameras will be placed two to five meters from main den entrances and set to take photos using a passive infrared sensor trigger (a beam that when broken by movement through it, triggers the camera to take a series of photos) with a time restriction between photo intervals to limit the number of photos taken and maximize the space on the memory card for the time period between camera checks (Kluever et al. 2013). Cameras will be checked six days after deployment and will be redeployed (i.e. new batteries and memory card, if required); cameras will remain at each den site until radio-collar data indicates the den site has been moved (Kluever et al. 2013). Cameras will be not be redeployed to a new coyote den site during a season if that breeding pair has already moved the den once due to the disturbance of camera presence/deployment.

Commented [JM50]: FWS personnel currently conduct red wolf den work and in order to eliminate the need for more than one disturbance to the den site, FWS personnel should be present for all red wolf den work.

Commented [JM51]: Concerns over the need for skin biopsies on pups when needed information can be obtained from the blood draw.

Commented [JM52]: As discussed at the meeting, there are a lot of concerns regarding den disturbance and placing cameras at a red wolf den site as it greatly increases the likelihood of den/litter abandonment, which we cannot afford in such a low population.

Commented [JM53]: If the desire is to experiment with cameras at den sites, they should be deployed at coyote den sites.

Draft - Confidential

Mortalities

If a collared animal dies during the project, the carcass will be sent to SCWDS for necropsy. Red wolves will be sent to the SCWDS laboratory for necropsy, unless it is determined to be a law enforcement case. In potential law enforcement cases, the NCWRC Division of Wildlife Management Chief and USFWS Ecological Services Raleigh Field Office Field Supervisor will be contacted and requested to contact the appropriate law enforcement personnel, immediately after determining the need for law enforcement involvement. The carcass and all relevant information will then be turned over to law enforcement; the GPS-collar will be removed and genetic samples will be taken from the individual prior to release to law enforcement.

Commented [JM54]: As discussed in the meeting, upon death of an ESA listed animal the carcass and parts must be retained in FWS custody until there has been a necropsy performed by the FWS Labs in either Madison, WI or Ashland, OR, if it is a law enforcement case.

Commented [JM55]: The FWS office in Manteo should be contacted. We contact LE for every red wolf mortality and they determine if it is an LE case or not and if they should take possession of the carcass. LE will not allow genetic samples to be taken from the carcass until after the case is complete.

E. Project Personnel

Andrea Shipley has worked for the North Carolina Wildlife Resources Commission as a Canid Biologist since February 2016. Prior to that, she worked as a Wildlife Biologist for a non-profit located in northeastern Nevada as well as in several different field biologist oriented positions. Andrea has a background in carnivore and spatial ecology, having earned her MS in Biological Sciences from Eastern Kentucky University and BS in Biological Sciences from Rutgers University; Andrea will act as project lead and coordinator.

Brandon Sherrill has worked for the North Carolina Wildlife Resources Commission as a Mammalogist since December 2013. Prior to that, he worked as an educator at the North Carolina Museum of Natural Sciences and as a regional wildlife biologist for the South Carolina Department of Natural Resources. Brandon earned a BS and MS in Fisheries, Wildlife, and Conservation Biology from North Carolina State University; Brandon will act as project supervisor.

Krishna Pacifici, Research Assistant Professor at NCSU, will be the quantitative analysis collaborator on the project. Krishna's background and experience in quantitative ecology makes him well suited to consult and assist with advanced statistical analyses of spatial data.

Lisette Waits, Department Head and Distinguished Professor at the University of Idaho, will be the DNA analysis collaborator for the project, responsible for all DNA related sample processing and subsequent analyses.

Commented [JM56]: Since trapping is a big part of the project, it would be beneficial in the project personnel descriptions to give an indication of experience conducting capture operations.

Draft - Confidential

F. Schedule and Estimated Costs

The project will run from soon after December 1, 2017 through June 30, 2020. The estimated timeline for major tasks is as follows:

Year 1: Initiate field work soon after December 1, 2017 with assistance from 1-2 field technicians; 1 technician will be required for trapping and den monitoring efforts. Data collection will begin immediately after collar deployment and data will be managed by Andrea Shipley throughout the life of the project. Data analysis will be initiated after den monitoring season concludes, with guidance and assistance from Krishna Pacifici at North Carolina State University (NCSU). Report, manuscript and presentation production will be initiated concurrently with data analysis.

Year 2: Continue field work and data collection with assistance from 1-2 field technicians. Continue data analysis with guidance and assistance from Krishna Pacifici at NCSU. Continue and finalize report and manuscript production, and presentation at professional working groups and/or meetings.

GPS technology allows researchers to collect locational data at fine spatial and temporal scales through the deployment of collar units on wildlife study subjects. In this project, we propose to study a sample of sympatric canid populations with GPS radio-collars, in order to investigate the population parameters outlined in previous sections as well as species interactions. The purchase and use of this technology is critical to meeting the research objectives set forth in this document as well as in the document included in Attachment 1.

While GPS technology has evolved over the past 20 years, the cost of technology has plateaued. Upfront cost per unit remains relatively high, however project savings occurs at the back end when compared to older telemetry technology such as very high frequency (VHF)

Commented [JM57]: Need to make sure appropriate data is made available to FWS to maintain existing databases (e.g. studbook, mortality database, etc.).

Draft - Confidential

which require intensive labor to collect data at similar spatial and temporal scales. Pilot testing the proximity sensor enabled GPS-collars will allow investigation of the utility of this relatively new tool for community dynamics analysis by providing an increased locational data acquisition when individuals come within a set distance, or closer, from each other. Additionally, these sensors record the identities of the interacting individuals and the duration of their interactions. Using a trigger to temporarily switch GPS fix schedules will enable us to collect very fine scale data while conserving battery life, achieving project objectives in an efficient manner. Exploring the efficaciousness of this technology has the potential to positively impact future research projects requiring use of GPS-collars for data collection.

Aerial tracking will provide regular study animal surveillance useful to investigate cases of mortality, collar malfunction, or satellite data transmission delays, which can vary seasonally. In some situations, ground tracking could prove less expensive than aerial tracking. However, ground telemetry techniques require more than one biologist working in tandem to acquire accurate location estimates. This often translates to increased labor to collect data, particularly in large study areas. Aerial tracking will provide a more efficient and cost-effective method for surveilling study subjects in this large study area, requiring only one biologist and a contracted pilot. NCWRC personnel will perform aerial tracking along with the NCWRC pilot at a minimum frequency of every 30 days.

Use of local trappers to assist with sampling efforts provides several benefits. Local trappers have established, long-term relationships with private land owners, thereby providing access to private lands that might be otherwise difficult to secure. This will enable project biologists to obtain a representative sample of sympatric canids in the study area, as well as to operate more trap lines concurrently. This is particularly important when using a SCR sample design, as it will have direct implications on the resulting analyses and inferences.

As part of collaboration efforts, the project will contract the services of Krishna Pacifici, Research Assistant Professor in the Applied Ecology department at NCSU. Krishna's expertise is in quantitative ecology; consultation and assistance services provided will allow project biologists to make appropriate statistically relevant inferences from collected data.

Draft - Confidential

DNA analysis will be contracted to Lisette Wait's lab at the University of Idaho. Lisette's team at The Laboratory for Ecological, Evolutionary and Conservation Genetics has previous experience in analyzing red wolf and coyote hybrid molecular samples and has the most comprehensive DNA methodology for this sympatric canid species continuum in the nation. This expertise will facilitate expedient species identification on collared study animals besides landscape level population dynamics analysis.

G. Geographic Location

Three counties of the Albemarle Peninsula of North Carolina (Dare, Hyde, and Tyrrell counties).

Commented [JM58]: Should be expanded to include Beaufort and Washington Counties since they are part of the NEP, if the only reason for excluding them is the assumption that the decision was already made to pull all red wolves back to Federal land in Dare and Hyde County.

I. Glossary

Abundance: Species abundance is the number of individuals per species, and relative abundance refers to the evenness of distribution of individuals among species in a community.

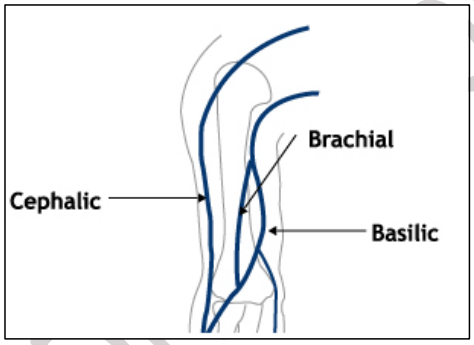
Adaptive kernel (AK): A probabilistic home range estimator based on the distribution and density of locations that has been collected over a period of time.

Adverse reactions: In pharmacology, any unexpected or dangerous reaction to a drug.

Aerial: Existing, happening, or operating in the air.

Annually: Once a year; every year.

Anthropogenic: Caused or influenced by humans.



Apex: Having no natural predators in its ecosystem.

Ataxia: The loss of full control of bodily movements.

Beacon: A radio beacon whose purpose is the investigation of the propagation of radio signals.

Biopsy: The removal for diagnostic study of a piece of tissue from a living body.

Brachial vein: One of a pair of veins accompanying the brachial artery and uniting with each other and with the basilic vein to form the axillary vein.

Breeding pair: A pair of animals which cooperate over time to produce offspring with some form of a bond between the individuals.

Carrying capacity: The maximum population size of the species that the environment can sustain indefinitely, given the food, habitat, water, and other necessities available in the environment.

Compensatory immigration: Individuals emigrating from areas with lower mortality to those with higher mortality; filling a deficiency of individuals in a population experiencing higher mortality. The increase in size or activity of one part of an organism or organ that makes up for the loss or dysfunction of another.

Composition: The combining of distinct parts or elements to form a whole.

Confidential

Co-occurrence: Refers to observation of the spatial overlap between two (or more) different individuals over a period of time.

Coordinates: Any of the scales or magnitudes that serve to define the position of a point.

Core use areas: An area within a home range exhibited by a dense concentration of location points; commonly estimated at 50% of the location data points.

Covariates: A variable that is possibly predictive of the outcome under study.

Cranial: Pertaining to the cranium or to the anterior (in animals) or superior (in humans) end of the body.

Cryogenic: Very low temperatures, e.g. -80ºC.

Den-obligated: Restricted to a particular condition of life, in this case restricted to a den site.

Density: A measure of the number of organisms that make up a population in a defined area.

Deployment: To organize and send out (people or things) to be used for a particular purpose.

Depredation: The act of preying upon.

Depressed respiration: A decrease in the ability to exhale and inhale; respiration that has a rate below 12 breaths per minute or that fails to provide full ventilation and perfusion of the lungs.

Diagnostic: The process of determining by examination the nature and circumstances of a diseased condition.

Disorientation: Loss of one's sense of direction, position, or relationship with one's surroundings.

Distribution: The manner in which a biological taxon is spatially arranged.

DNA: (deoxyribonucleic acid) is a type of macromolecule known as a nucleic acid. It is shaped like a twisted double helix and is composed of long strands of alternating sugars and phosphate groups, along with nitrogenous bases (adenine, thymine, guanine and cytosine).

Dorsal: Situated on or toward the upper side of the body, equivalent to the back, or posterior, in humans; situated on or toward the posterior plane in humans or toward the upper plane in quadrupeds.

Duration: A continuous period of time.

Dynamic Brownian bridge movement models: Incorporates temporal and behavioral characteristics of movement paths into estimation of home range.

Ectoparasite: a parasite that lives on the outside of its host rather than within the hosts body; e.g. fleas and lice.

Effective trap area: Calculated by buffering each trap site by half the mean maximum distance traveled, each of these boundaries are dissolved, creating a measurable area.

Efficacious: Producing or capable of producing a desired effect.

Draft - Confidential

Efficient: Accomplishment of or ability to accomplish a job with a minimum expenditure of time and effort.

Euthanize: The act of putting to death painlessly or allowing to die, as by withholding extreme medical measures, a person or animal suffering from an incurable, especially a painful, disease or condition.

Expedient: Suitable for achieving a particular end in a given circumstance.

Evaporative cooling: reduction in temperature resulting from the evaporation of a liquid, which removes latent heat from the surface from which evaporation takes place.

Facilitate: Make an action or process easy or easier.

Genotyping: Investigate the genetic constitution of (an individual organism).

Gonadal descent: The act or process of descending from a higher to a lower location; testicular descent occurs during the breeding season annually.

GPS: Global Positioning System, is a radio navigation system that allows land, sea, and airborne users to determine their exact location, velocity, and time 24 hours a day, in all weather conditions, anywhere in the world.

Home range: an area over which an animal or group of animals regularly travels in search of food or mates, and that may overlap with those of neighboring animals or groups of the same species.

Hybridization: The result of mixing, through sexual reproduction, two animals or plants of different breeds, varieties, species or genera.

Immobilization agent: An active force or substance capable of producing an effect.

Implantation: To put or fix firmly.

Inbreeding depression: The reduced biological fitness in a given population as a result of inbreeding, or breeding of related individuals.

Inception: The establishment or starting point of an institution or activity.

Interspecific: Existing or occurring between different species.

Iridium: A satellite constellation providing voice and data coverage to satellite phones, pagers and integrated transceivers over the Earth's entire surface.

Jugular vein: Any of several large veins in the neck, carrying blood from the head and face.

Lacerations: A deep cut or tear in skin or flesh.

Locational: A position or site occupied or available for occupancy or marked by some distinguishing feature.

Malfunction: Fail to operate in the normal or usual manner

Methodology: A system of methods used in a particular area of study or activity.

Midline: A median line or plane of bilateral symmetry, especially that of the body.

Draft - Confidential

Minimum convex polygon (MCP): Completely enclose all data points by connecting the outer locations in such a way as to create a convex polygon.

Molecular samples: Genetic samples that may be used for investigation of genetic constitution of an individual.

Morphometrics: The process of measuring the external shape and dimensions of landforms, living organisms, or other objects.

Mortality: The state of being subject to death.

Non-target bycatch: Animals caught by accident that are not the target species being sought.

Parameters: A numerical or other measurable factor forming one of a set that defines a system or sets the conditions of its operation.

Parentage: The origin of something; the state or relation of a parent.

Passive integrated transponder: A microchip implant is an identifying integrated circuit placed under the skin of an animal.

Pinna: The external part of the ear in humans and other mammals; the auricle.

Plateaued: A period or state of little or no growth or decline.

Population dynamics: The branch of life sciences that studies the size and age composition of populations as dynamic systems, and the biological and environmental processes driving them (such as birth and death rates, and by immigration and emigration).

Population growth: The increase in the number of individuals in a population.

Population size: A group of organisms of the same species that live in the same area.

Population status:

Population trend: Changes over time and can include changes in ranging behavior and distribution, biogeography and life-history.

Population viability: The process that determines the probability that a population will go extinct within a given number of years.

Proximity: Nearness in space, time, or relationship.

Quantified: Express or measure the quantity of.

Quantitative: Relating to, measuring, or measured by the quantity of something rather than its quality.

Radio-telemetry: The use of radio waves for transmitting information from a distant instrument to a device that indicates or records the measurements.

Recumbency: The state of leaning, resting, or reclining.

Reintegrate: Restore (elements regarded as disparate) to unity.

Draft - Confidential

Remnant: A small remaining quantity of something.

Reproductive status: Relating to or effecting reproduction.

Spatial: Relating to, occupying, or having the character of space.

Spatial capture-recapture: A method commonly used in ecology to estimate an animal population's size. A portion of the population is captured, marked, and released. Marked animals are either recaptured or are tracked, each tracking location being considered a recapture.

Species Continuum: An aggregate of species capable of interbreeding, resulting in fertile hybrid offspring whose genetic composition may represent a varying array of phenotypes and genotypes from the parental species, at which the extreme ends of the spectrum are distinct.

Standardize: Cause (something) to conform to a standard.

Statistically relevant inferences: the process of deducing properties of an underlying distribution by analysis of data. Inferential statistical analysis infers properties about a population: this includes testing hypotheses and deriving estimates.
