limited to demographic information used in population viability analysis (age of sexual maturity, timing and frequency of births, survivorship, longevity, adult and juvenile dispersal and frequency of inter-island movements); carrying capacity (quantification of habitat quality, density by habitat type, and habitat availability); island-wide population surveys throughout the range; estimates of predation by brown treesnakes and hunters; identification of any other population-limiting factors (DoN 2010a, p. 135).

The proposed funding of two biologists to be stationed on Rota should help implement conservation actions on that island for the bat. These actions are expected to be very beneficial for the Mariana fruit bat.

The proposed conservation facilities at Finegayan will increase educational awareness of the species and provide a conservation benefit to the Mariana fruit bat and its habitat.

On Tinian, the DoN has proposed to alter the boundaries of the existing FAA Mitigation Area to include some of the largest tracts of limestone forest remaining on the island, and to develop and implement a plan to enhance the native forest within the Mitigation Area. These actions will improve the extent and quality of native forest on Tinian, which will benefit fruit bats if they establish permanent residence on the island in the future.

Summary

The proposed action is likely to adversely affect the Mariana fruit bat on Guam. Roughly 12% of the remaining recovery habitat on the island will be lost or degraded directly or indirectly as a result of the proposed action (see Table 10), and although this loss will not preclude the recovery or survival of the fruit bat, it will reduce the total number of bats the island can support. The abandonment of the Pati Point's Natural Area Mariana fruit bat colony on northern Guam is likely to occur as a result of noise and disturbance from increased aircraft overflights associated with training activities. These bats compose the entire population of the Mariana fruit bat on Guam. The bats abandoning the Pati Point colony are likely to move to areas where they will be exposed to illegal hunting activities. Increases in conservation law enforcement provided by DoN will minimize the likelihood these bats will be killed by hunters. By ensuring 12 years of funding for two biologists on Rota, the DoN will contribute to the conservation of an important Mariana fruit bat population.

2.5 CUMULATIVE EFFECTS

Cumulative effects include the effects of future State, tribal, local or private actions that are reasonably certain to occur in the action area considered in this Biological Opinion. Future Federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the Act.

The extent to which future development is addressed as a cumulative effect in the following analysis excludes any such future development that is expected to be interdependent with or interrelated to construction of federally-funded roads or is likely to be caused by other Federal actions that will be addressed in future section 7 consultations.

Overview of Cumulative Effects

Civilian development, human-caused wildfires and the transport of non-JGPO-related items through Ports may reduce the geographic extent and quality of habitat for the species addressed in this consultation.

Civilian Development Activities

Urbanization, agriculture, and other forms of development on are likely to result in the loss, fragmentation, or degradation of forest and wetland habitat within the action area. Development is likely to result in increased noise and predator densities in the vicinity of sites occupied by listed species. Changes in water quality and water level in freshwater wetlands may occur as a result of civilian development activities. Increases in population will result in increased human noise disturbance in urban areas as well as in outdoor recreation areas.

Guam

The DoN provided a list of known future projects lacking a Federal nexux on Guam in their Final EIS for the proposed JGPO action (DoN 2010b and Pepi 2010, pers. comm.) of known future projects lacking a Federal nexus on Guam. The DoN reviewed all known future non-Federal projects to determine if any of the projects will potentially be located within recovery habitat for the Mariana fruit bat, Guam Micronesian kingfisher, and the Mariana crow. Only one project is proposed within that recovery habitat: 4.5-acre (1.8-ha), 236-unit condominium complex. This project obtained approval from the Guam Land Use Commission in November 2007, and construction is planned for 2010 through 2012.

Human population increases unrelated to the proposed JGPO action that exceed the capacity of the currently planned civilian development described above are reasonably certain to occur. The DoN's Final EIS (DoN 2010b, vol. 2, p. 16-3) reported an annual rate of increase in Guam's population of 1.6% during the 2000 through 2008 period and that, in the absence of the proposed JGPO action, that rate would be 1.2% from 2010 through 2020, and would drop to 0.9% for the 2020 through 2030 period. Guam's 2008, population was 175,877 (U.S. Census Bureau 2008, as cited in DoN 2010b, vol. 2, p. 16-3).

Guam's land use planning maps (Government of Guam 2009, p. 2-14) indicate housing and industrial development will be targeted to minimize impacts to recovery habitat areas. Significant areas of recovery habitat are zoned for development as tourist/resort (Government of Guam 2009, p. 2-14). It is our understanding that development of many of the tourist/resort areas will entail creation of federally-funded roadways and infrastructure; therefore these projects will be addressed, pursuant to the Act, in separate section 7 consultations.

Project-related development of housing for construction workers, as well as development by civilians indirectly related to the proposed action during the construction period, is likely to result in an abundance of housing which may be left occupied after the construction period (Table 11). Housing for approximately 11,000 new non-project-related Guam residents will be developed during the project construction period. The availability of vacant project-related housing during the post-JGPO construction period is likely to reduce the level of other new civilian development. Our calculations indicate construction-worker housing is likely to constitute approximately 50% of total housing becoming available after the buildup period. Although the construction worker housing may not be of the size and development density sought by home-buyers during the post-construction period, availability of project-related housing is not likely to offset all future development pressure. During the construction period, non-project-related population increases on Guam may result in increased civilian development.

Table 11. Anticipated population growth and availability of housing on Guam during and following the JGPO construction period.

Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020
Non-Project-Related Population Increase (Based on Navy 2009, vol. 2 p. 16-3)											
Population Size	180,123	182,285	184,472	186,686	188,926	191,193	193,488	195,809	198,159	200,537	202,944
Cumulative Population Increase Unrelated to Project - During Construction Period	2,136	4,297	6,485	8,698	10,939						
Cumulative Population Increase Unrelated to Project - During Period when Vacant Project-Related Housing will be Available						2,267	4,561	6,883	9,233	11,611	14,017
Project-Related Population Increase (Navy 2009, vol. 1, p. ES – 7)											
Construction Worker Housing Capacity In Use by Project	4,400	10,785	18,017	21,798	23,095	14,972	4,832				
Project-Related Civilian Indirect/Induced Population	5,592	14,199	23,433	27,926	36,480	28,814	15,955	12,299	12,299	12,476	12,476
Total Project-Related Civilian Population	9,992	24,984	41,450	49,724	59,575	43,786	20,787	12,299	12,299	12,476	12,476
Cumulative Project-Related Housing Capacity Vacated						15,789	38,788	47,276	47,276	47,099	47,099

For a period after the peak period of construction, non-construction worker and construction worker housing vacancy rates will be high enough to absorb ongoing non-project related

increases in population for some time. Our calculations indicate future rates of civilian development are expected to be significantly reduced as a result of the increased housing supply resulting from the proposed JGPO action.

Tinian

Urbanization, agriculture, and other forms of development on are likely to result in the loss, fragmentation, or degradation of forest and wetland habitat on Tinian. Development is likely to result in increased noise and predator densities in the vicinity of sites occupied by listed species.

Wildfire Impacts to Recovery Habitat

Guam

Over a three-year period from 2000 through 2003, 2,020 arson fires were reported to have burned approximately 6,000 ac (2,428 ha) in Guam. Of the approximately 750 wildfires burning each year on Guam, approximately 80% are caused by arson (Wildland Fire Prevention and Education Team Final Report, 2003, as cited in Neill and Rea 2004, p. 6-7). The number of fires reported on non-DoN land increased from an average of 612 per year during the 1979 through 1989 period to an average of 786 per year during the 1991 through 2002 period; this change represents an increase of approximately 27% although improvements in fire reporting may account for some of this increase. However, the average annual total reported area burned by wildfires dropped by approximately 35% (2,000 ac) in the 1991 through 2002 period, compared with the 1979 through 1989 period. We anticipate the area burned by wildfires will continue to decline as a result of efforts by the U.S. Forest Service, Federal Emergency Management Agency, and the DoI Office of Insular Affairs. The U.S. Forest Service, for instance, anticipates providing funds to develop a robust fire suppression force led by a skilled fire management officer on Guam (Mahoney 2010, pers. comm.).

Although there is ongoing debate regarding the origin of savanna areas in Guam (Hunter-Andersen 2009 and Athens and Ward 2004), savanna areas are enlarging into previously forested areas as a result of human-caused wildfires. To estimate the rate of historical forest conversion to savanna, Greenlee (2010) delineated areas which appeared to be dominated by forest vegetation in 1975 aerial photographs and which are no longer forested in recent infrared imagery, and estimated that 1,119 ac (453 ha) of forest have been converted to savanna in southern Guam since 1975 (see Figure 15 in the General Effects section above). This estimate indicates the average rate of forest loss in southern Guam is approximately 37 ac/year (15 ha/year).

Transport of Non-JGPO-Related Items through Ports

Guam's human population will continue to grow even in the absence of the proposed action. Historically, Guam's population growth has shown annual rates of population growth that range from 1.2% to 2.4%. Currently, Guam is in a low growth phase. Annual population growth, without the proposed action, is projected to be 1.2% during the decade of 2010-2020 and 0.9% for the decade 2020-2030 (DoN 2010b, vol. 2 p. 16-3). This translates to a total of 25,000 new

Guam residents during the period 2010-2020. The proposed action is not expected to compensate for these increases in population and resultant risks to endangered species. While less than the growth attributable to the proposed action, this non-project growth is still important from a biosecurity perspective. Currently, the DoI Office of Insular Affairs funds brown treesnake interdiction, control, and research efforts that complement DoD funding for many of these same efforts. The DoI Office of Insular Affairs program includes the following measures in Guam, CNMI, and Hawaii:

Guam

1. 100% canine inspection of civilian sea cargo, civilian air cargo, and air passenger flights leaving Guam.
2. Establishment of snake-free quarantine areas for packing and storing cargo prior to transport.
3. Snake suppression in and around the snake-free cargo quarantine areas.
4. Snake control for natural resource protection.
5. Support for the brown treesnake rapid response efforts to ensure incidents outside Guam are adequately staffed and equipped.

CNMI: Interdiction support on three main islands (Saipan,Tinian, and Rota) includes:

1. Canine inspections of incoming cargo and aircraft (Saipan and Tinian established; funding has been provided for Rota).
2. Establishment of quarantine areas (Saipan and Tinian established; funding has been provided for facility at Port of Rota).
3. Rapid Response/Biosecurity Training (all islands).

Hawaii: Interdiction support in Hawaii includes:

1. Canine inspections of incoming cargo and aircraft.
2. Rapid Response/Biosecurity Training.

Interdiction efforts during 2009, appeared to be adequate for the volumes of aircraft and surface cargo shipped out of Guam. For example, canine inspections were completed for 99.8% of military aircraft, 96.6% of commercial aircraft, 94.6% of military household goods, and 98.6% of civilian household goods (Table 12). The DoI Office of Insular Affairs also funds brown treesnake suppression efforts for natural resource benefits, research on brown treesnake control, the implementation of brown treesnake barriers, and overall brown treesnake coordination efforts.

While the current brown treesnake inspection efforts are good (e.g., discussed above), there is still a risk of brown treesnake slipping through the system and establishing on other islands. Perry and Vice (2009) modeled brown treesnake risk of establishment associated with specific, existing shipping and transportation pathways and found an extremely high risk of brown treesnake establishment on Saipan, a very high risk for Rota, and a high risk for Tinian. Hawaii

Table 12. USDA-Wildlife Services canine inspection results for fiscal year 2009.

was also considered to be at a high risk of brown treesnake establishment. These risks are mitigated by effective interdiction. The loss of interdiction capacity or effectiveness would increase the likelihood of brown treesnake establishing in CNMI. There is no indication that DoI Office of Insular Affairs will reduce funding to brown treesnake interdiction in Guam or CNMI or that it will not provide program increases to keep up with the baseline growth of Guam's population and resultant risks associated with increased air transportation and sea shipping. Therefore, the risk of the transport of the brown treesnake from Guam to other locations in the Pacific will remain low.

The brown treesnake could also be introduced to the islands of the CNMI as a result of shipments originating from its native range in Australia, New Guinea, Indonesia, and the Solomon Islands. Rodda and Savidge (2007) state that "at the current time the risk of brown treesnake introductions to the Pacific from the snake's native range is considered to be relatively minor for two reasons: (1) the density of brown tree snakes is generally much lower in the snake's native range than it is in Guam, and (2) little cargo destined for tropical and subtropical areas originates in the snake's native range (e.g., Port Moresby, Honiara, Darwin, Halmahera).

Species-Specific Cumulative Effects

Guam Micronesian Kingfisher

As described in the Overview of Cumulative Effects section above, the effects of future development to Guam Micronesian kingfisher recovery habitat are expected to be insignificant. If the number and size of human-caused wildfires burning in southern Guam continues at historical rates, the amount of Guam Micronesian kingfisher recovery habitat remaining in southern Guam will be reduced below the threshold necessary for recovery within approximately nine years. However, the trend in annual area burned has been declining and we anticipate it will continue to decline as a result of ongoing and future Federal support of the development of local fire suppression resources. Therefore, we do not expect the recovery of the Guam Micronesian kingfisher will become habitat limited in southern Guam as a result of cumulative effects.

Guam Rail

Because the Guam rail utilizes edge habitat and shrubby areas, the effects of future development and human-caused wildfire (which increase the amount of edge habitat and shrubby areas) to the Guam rail on Guam are expected to be insignificant.

Mariana Common Moorhen

Increases in Guam and Tinian populations may result in reductions in the distribution and quality of wetlands used by this species. Changes in hydrology resulting from increased human use of ground water may reduce water levels in wetlands utilized by the Mariana common moorhen. Runoff from developed areas may result in decreases in the abundance of food for the Mariana common moorhen.

Mariana Fruit Bat

As described in the Overview of Cumulative Effects section above, the effects of future non-project-related development to Mariana fruit bat recovery habitat are expected to be insignificant; wildfire conversion of forest to grassland, however, is expected to continue. The effects of non-project-related development to Mariana fruit bat recovery habitat are expected to be insignificant. The trend in annual area burned has been declining and we anticipate it will continue to decline as a result of ongoing and future Federal support of the development of local fire suppression resources. Therefore, we do not expect the recovery of the Mariana fruit bat will become habitat-limited in southern Guam.

Mariana Crow

The two male Mariana crows on Guam will continue to be exposed to human persecution and predation by introduced predators. As described in the Overview of Cumulative Effects section above, the effects of future development to Mariana crow recovery habitat are expected to be insignificant. Although wildfires resulting from ongoing civilian actions in southern Guam are likely to continue to convert Mariana crow recovery habitat to savannah, the trend in annual area burned has been declining and we anticipate it will continue to decline as a result of ongoing and future Federal support of the development of local fire suppression resources. We do not expect the recovery of the Mariana crow will become habitat limited in southern Guam as a result of cumulative effects.

2.6 CONCLUSION

After reviewing the current status of the listed species identified in Table 1, the environmental baseline, the effects of the proposed action and the cumulative effects, it is the Service's biological opinion that the action, as proposed: is not likely to jeopardize the continued existence of the Guam Micronesian kingfisher, Guam rail, Mariana common moorhen, Mariana crow, and Mariana fruit bat. The Service reached these conclusions based on the following findings, the basis for which is presented in the preceding sections of this document.

Guam Micronesian Kingfisher

The Guam Micronesian kingfisher is currently extirpated from the wild; therefore, direct impacts to individuals will not occur as a result of the subject action. However, we have determined that the proposed project will adversely affect the Guam Micronesian kingfisher by removing areas of recovery habitat which, in the absence of the project, would have remained intact to provide for the feeding, breeding, and sheltering of this species once it is reintroduced. After implementation of the proposed project (including interrelated and interdependent effects) there is expected to be enough potential recovery habitat remaining on Guam to not preclude recovery of the Guam Micronesian kingfisher. However, only an estimated 815 ac (330 ha) in northern Guam and 343 ac (139 ha) will remain in southern Guam once project actions are considered.

Future cumulative effects of development to kingfisher recovery habitat are expected to be insignificant because housing developed during construction will be available for habitation by future Guam residents. If the number and size of wildfires burning in southern Guam continues at historical rates, the amount of Guam Micronesian kingfisher recovery habitat remaining in southern Guam will be reduced below the minimum threshold necessary for recovery within approximately nine years. Because the trend in annual area burned has been declining and we anticipate it will continue to decline as a result of ongoing and future Federal support of the development of local fire suppression resources, we do not expect the recovery of the Guam Micronesian kingfisher will become habitat-limited on Guam.

The DoN's proposed habitat management and protection measures will help protect and enhance some of the available Guam Micronesian kingfisher habitat on DoD and Government of Guam lands. The DoN's development and implementation of brown treesnake eradication and control measures and reintroduction planning will facilitate the successful reintroduction of the Guam Micronesian kingfisher to DoN lands on Guam. Additionally, the establishment of a wild kingfisher population outside of Guam will help safeguard the species and provide wild kingfishers for release on Guam.

On the basis of these findings, the Service concludes that the effects of the subject action, taken together with cumulative effects, are not likely to appreciably reduce the likelihood of both the survival and recovery of the Guam Micronesian kingfisher in the wild.

Guam Rail

Although the proposed action will result in a loss of habitat for Guam rails, there will still remain an adequate amount of habitat to provide for recovery of the species. The DoN's proposed habitat management and protection measures may help protect and enhance some of the

available Guam rail habitat on DoD and Government of Guam lands. The DoN's development and implementation of brown treesnake eradication and control measures and DoN's reintroduction planning will facilitate the reintroduction of the Guam rail to DoN lands on Guam. On the basis of these findings, the Service concludes that the effects of the proposed action, taken together with cumulative effects, are not likely to appreciably reduce the likelihood of both the survival and recovery of the Guam rail in the wild.

Mariana Common Moorhen

Most recent survey information indicates there are approximately 90 Mariana common moorhen on Guam, 154 of these birds on Saipan, 41 individuals on Tinian, and only two individuals on Rota (Takano and Haig 2004a, p. 247). The DoN's development and implementation of brown treesnake eradication and control measures, if successfully implemented in wetland areas, will result in future increases in Mariana common moorhen numbers on Guam. Because the quality of waterbird habitat in many of Guam's wetlands is poor, the DoN's implementation of wetland restoration in central Guam will benefit the Mariana common moorhen. Construction and live-fire training at Tinian ranges will expose the Bateha wetlands system to noise levels above 60 dB. The Bateha wetlands are richer in food sources than Tinain's Lake Hagoi. Although surveys indicate only four or fewer Mariana common moorhen are found at the Bateha wetlands, the noise associated with the proposed action will result in reduced Mariana common moorhen use of the high quality foraging area, constituting a significant disruption of their feeding. Mariana common moorhen is not known to breed in these seasonal wetlands.

Cumulative effects, including civilian development may result in reductions in the extent of wetland habitat in the CNMI. Coastal wetlands in the vicinity of Naval Base Guam could be affected by increased storm impacts and sea level rise resulting from climate change. Changes in precipitation resulting from climate change may affect the abundance and water levels in seasonal and permanent wetlands. Because wetland habitat degradation such as Fena Lake's eutrophication is thought to have resulted from a typhoon (Brooke 2007, pers. comm.), changes in typhoon frequency and severity resulting from climate change would affect the Mariana common moorhen.

Overall, the effects of the proposed action are not likely to appreciably reduce the likelihood of both the survival and recovery of the Mariana common moorhen in the wild because sufficient habitat and populations are likely to persist throughout its range at levels that retain the potential for recovery of this species.

Mariana Crow

The Mariana crow is known historically only from the islands of Rota and Guam (Baker 1951, p. 245). Currently, the only remaining Mariana crows known to occur in the wild are the approximately 60 breeding pairs and 24 non-breeding individuals on Rota and the two male individuals (previously introduced from the Rota population) on Guam. Both individuals are located on Andersen Air Force Base and are not within areas proposed for development (DoN 2010a, p. 237).

The proposed action will adversely affect the Mariana crow on Guam by removing areas of recovery habitat which, in the absence of the action, would have remained intact to provide for the feeding, breeding, and sheltering of this species. The acreage lost as a result of the project will total approximately 1,841 ac (745 ha) of recovery habitat that could have supported approximately 50 territorial Mariana crow pairs. This action will reduce the available habitat for recovery of the species to only 9,885 ac (4,000 ha) above the minimum required to allow for potential recovery. The future effects of non-project-related civilian development to crow recovery habitat are expected to be insignificant. We anticipate annual area burned by wildfires in southern Guam will continue to decline as a result of ongoing and future Federal support of local fire suppression resources such that the amount of recovery habitat remaining will be adequate to support the recovery of the Mariana crow.

The DoN's proposed habitat management and protection measures will help protect and enhance some of the available Mariana crow habitat on DoD and Government of Guam lands on Guam. The DoN's development and implementation of brown treesnake eradication and control measures, Mariana crow monitoring and research, and increased conservation law enforcement action, and ungulate control actions are likely to result in future increases in the survival and reproductive success of the Mariana crow on Guam. In order to benefit the Mariana crow throughout its range, the DoN will also ensure funding for two biologists to be based on the island of Rota. These biologists will facilitate conservation of a significant population of Mariana crows by implementing conservation actions to contribute to halting and reversing declines in the largest remaining wild population of the species. For these reasons, it is our opinion that the proposed action is not likely to appreciably reduce the likelihood of the survival and recovery of the Mariana crow in the wild.

Mariana Fruit Bat

Most recent survey information indicates there are fewer than 20 Mariana fruit bats on Guam, the bats are transient on Tinian, approximately 50 individuals occur on Saipan, Rota supports a population of between 1,200 and 1,400 individuals, and more than 5,000 Mariana fruit bats occur on nine other islands in the CNMI (Brooke, 2010, Boland 2009, pers. comm.; Brooke 2008, p. 1 and references cited therein; Brooke 2009, p. 1; CNMI Division of Fish and Wildlife 2000b, p. 4; CNMI Division of Fish and Wildlife 2000c, p. 35; Johnson 2001, p. 19; Navy 2009, p. 89; Wiles and Johnson 2004, p. 585).

The proposed action will adversely affect the Mariana fruit bat on Guam. Roughly 11% of the remaining recovery habitat on the island will be lost or degraded directly or indirectly as a result of the proposed action, and although this loss will not preclude the recovery of the fruit bat, it will reduce the total number of bats that the island can support. The abandonment of the Pati Point Natural Area's Mariana fruit bat colony on northern Guam is likely to occur as a result of noise and disturbance from increased aircraft overflights associated with training activities. The bats abandoning the Pati Point Natural Area's colony may move to areas where they will be exposed to illegal hunting impacts on Guam and Rota. The two conservation law enforcement staff funded by DoN will minimize the likelihood that Mariana fruit bats occurring on DoD lands will be impacted by hunting. DoN's proposed public education program will also better ensure future hunting impacts to this species on Guam are minimized. The DoD's funding of two

biologists on Rota for a period of 12 years may result in decreased hunting of the Mariana fruit bat on that island; thus potentially increasing the Rota bat population to the point where some Rota bats can recolonze Guam.

The DoN's proposed habitat management and protection measures may help protect and enhance some of the available Mariana fruit bat habitat on DoD and Government of Guam lands on Guam. The DoN's development and implementation of brown treesnake eradication and control measures, Mariana fruit bat monitoring and research, and increased conservation law enforcement actions are likely to result in future increases in the survival and reproductive success of the Mariana fruit bat. DoN's funding for two biologists on Rota will contribute significantly to halting and reversing the declines in that significant Mariana fruit bat population. On the basis of these findings, the Service concludes that the effects of the subject action, taken together with cumulative effects, are not likely to appreciably reduce the likelihood of both the survival and recovery of the Mariana fruit bat in the wild because sufficient habitat and populations are likely to persist throughout its range at levels that retain the potential for recovery of this species.

2.7 INCIDENTAL TAKE STATEMENT

Section 9 of the Act and Federal regulations pursuant to section 4(d) of the Act prohibit the take of endangered or threatened species, respectively, without special exemption. Take is defined as harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct. Harm is further defined by the Service to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavioral patterns, including, breeding, feeding, or sheltering. Harass is defined by the Service as intentional or negligent actions that create the likelihood of injury to listed species to such an extent as to significantly disrupt normal behavior patterns which include, but are not limited to, breeding, feeding or sheltering.

Incidental take is defined as take that is incidental to, and not the purpose of, carrying out an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking that is incidental to and not intended as part of the agency action is not considered a prohibited taking under the Act provided that such taking is in compliance with the terms and conditions of this Incidental Take Statement.

The measures described below are non-discretionary, and must be undertaken by DoN so that they become binding conditions to the applicant for the exemption in section 7(o)(2) to apply. The DoN has a continuing duty to regulate the activity covered by this incidental take statement. If DoN (1) fails to assume and implement the terms and conditions or (2) fails to require contractors to adhere to the terms and conditions of the incidental take statement through enforceable terms that are added to contract documents, the protective coverage of section 7(o)(2) may lapse. In order to monitor the impact of incidental take, DoN must report the progress of the action and its impact on the species to the Service as specified in this incidental take statement [50 CFR 402.14(i)(3)].

Amount or Extent of Take Anticipated

Based on our analysis presented in this Biological Opinion, the Service anticipates the following take may occur as a result of the proposed action:

1) Four Mariana common moorhens may be incidentally taken in the form of harassment on days when construction and live-fire exercises occur at the proposed Tinian firing ranges. Loud noise associated with the proposed action will result in reduced Mariana common moorhen use of the high quality foraging area, constituting a significant disruption of their feeding.

2) The Service anticipates that up to ten remaining Mariana fruit bats at the Pati Point natural area colony will be taken in the form of harassment due to loud aircraft noise resulting from the proposed action.

The Service will not refer the incidental take of any listed endangered or threatened migratory bird for prosecution under the Migratory Bird Treaty Act of 1918, as amended (16 U.S.C. §703-712), if such take is in compliance with the terms and conditions specified herein.

Effect of the Take

In the accompanying Biological Opinion, the Service determined that this level of anticipated take is not likely result in jeopardy to the Mariana common moorhen or the Mariana fruit bat.

2.8 REASONABLE AND PRUDENT MEASURES

Reasonable and prudent measures serve to minimize impacts on the individuals or habitats affected by the action. The Service believes the following reasonable and prudent measures are necessary and appropriate to minimize impacts of incidental take of the Mariana common moorhen and the Mariana fruit bat:

1) The DoN will implement the Conservation Measures set forth in the Project Description in this Biological Opinion.

2) The DoN will report on the progress of project implementation.

3) The DoN will minimize the level of incidental take of the Mariana fruit bat occurring as a result of aircraft operations on Guam.

4) The DoN will minimize the level of incidental take of the Mariana common moorhen occurring as a result of training activities on Tinian.

2.9 TERMS AND CONDITIONS

In order to be exempt from the prohibitions of section 9 of the Act, DoN must comply with the following terms and conditions, which implement the reasonable and prudent measures described above and specify reporting requirements. These terms and conditions are non-discretionary.

In order to implement the reasonable and prudent measure above, the following terms and conditions apply:

1) DoN shall implement the Conservation Measures in the Project Description of this Biological Opinion. We reiterate this requirement here for convenience and clarity. If there is any deviation from these conditions the Service shall be notified one (1) month prior to modifications of the Conservation Measures.

2) The DoN will:
   a) Submit annual reports detailing the implementation of the Conservation Measures, the other aforementioned Terms and Conditions, minimization measures and best management practices used to minimize impacts, and summaries of biological monitor reports. The first report will be due at the end of Fiscal Year 2011 (September). Reporting will be required until the Conservation Measures are fully implemented.

b) With assistance from the Service, develop and implement a methodology (e.g., spreadsheet, database) for tracking project actions as described in the Project Description including the timing and implementation of the conservation measures and the aforementioned Terms and Conditions. This project and mitigation tracking system should be completed within six (6) months from the date of this Opinion. The DoN will coordinate with the Service so that the tracking methodology is readily usable for both agencies in order to facilitate our joint monitoring (and DoN implementation) of the mitigation objectives outlined in this Opinion.

3) To determine the level of take DoN will:
   a) Monitor, a minimum of once a week, the number of Mariana fruit bats occupying all known roost sites on Andersen Air Force Base from one year prior to and one year after the proposed overflight increases are fully implemented. The monitoring methodology should, at a minimum, include direct counts of Mariana fruit bats utilizing a spotting scope at an appropriate distance to avoid disturbance impacts to the bats.
   b) Reports summarizing the methods and results of the above monitoring efforts shall be sent to the Service's Pacific Islands Fish and Wildlife Office (300 Ala Moana Blvd., Room 3-122, Box 50088, Honolulu, Hawaii 96850) every six (6) months until the monitoring is completed. Results for the bat monitoring will include a table of count results, bat behavior during training events, and weekly summary of the number of aircraft operations (by aircraft type) over occupied roost sites.

4) To determine the level of take DoN will:

   a) Develop and implement a program to monitor the effects of project noise on the numbers of Mariana common moorhen occupying the Bateha wetlands. The program will include surveying the Bateha wetlands within one week prior to and following a subset of periods of construction and training to determine the number of individuals and active nests present before and after training events. These surveys should only be conducted during the wet season as moorhens are not known to use the wetlands during the dry season.
   b) Write reports summarizing the methods and results of the above monitoring efforts shall be sent to the Service's Pacific Islands Fish and Wildlife Office (300 Ala Moana Blvd., Room 3-122, Box 50088, Honolulu, Hawaii 96850) every six (6) months when training is occurring on Tinian. Results for the moorhen monitoring will include a table of count results and summary of the activities occurring at the site associated with the survey (e.g., construction, live-fire training, etc.).

Reporting Requirements

The DoN shall inform the Field Supervisor of the Service's Pacific Islands Fish and Wildlife Office in Honolulu, Hawaii, in writing of take of any federally listed species within three (3) working days. The depository designated to receive specimens of any threatened or endangered species killed is the B.P. Bishop Museum, 1525 Bernice Street, Honolulu, Hawaii, 96817 (telephone: 808/547-3511). If the B.P. Bishop Museum does not wish accession to the

specimens, the permittee should contact the Service's Division Office of Law Enforcement in Honolulu, Hawaii (telephone: 808/861-8525; fax: 808/861-8515) for instructions on disposition. The Service's Pacific Islands Fish and Wildlife office (telephone: 808/792-9400) will also be informed within three (3) working days of any injured threatened or endangered species found and the actions taken.

2.10 CONSERVATION RECOMMENDATIONS

Section 7(a)(1) of the Federal (Act) directs Federal agencies to utilize their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species, to help implement recovery plans, or to develop information. The recommendations provided relate only to the proposed action and do not necessarily represent complete fulfillment of the Army's section 7(a)(1) responsibilities for the species. In order for the Service to be kept informed of actions minimizing or avoiding adverse effects or benefiting listed species or their habitats, the Service requests notification of the implementation of any conservation recommendations.

1) The DoD should replace the proposed project footprint with a project footprint such as the ones described in "Alternative 1" or "Alternative 8" in the Final EIS (DoN 2010b) to minimize project development within areas of Guam Micronesian kingfisher, Mariana crow, and Mariana fruit bat recovery habitat.

2) The DoD should restore limestone forest or ravine forest on 1,525 ac (617 ha) currently mapped by the U.S. Forest Service (2002) as "Scrub Forest, Leucaena Stand, Other Shrub/Grass, or Savanna Complex" to offset impacts to Guam Micronesian kingfisher, Mariana crow, and Mariana fruit bat recovery habitat within the project footprint. DoD should restore an additional 208 ac (84 ha) of limestone forest or ravine forest to offset anticipated impacts of civilian development to recovery habitat expected to occur as a result of the project.

3) In addition to ensuring project-related fires do not impact recovery habitat for listed species, the DoN should incorporate the following measures into fire management operations: (1) establish and maintain cooperative agreements with Government of Guam and local jurisdictions to ensure DoD fire suppression resources are able to assist with fire suppression efforts, as necessary, to protect remaining limestone forest and ravine forest from fire; (2) to facilitate fire management planning and implementation of daily fire suppression staffing, immediately establish remote automated weather stations on Guam and Tinian and maintain weather and fire danger data in the interagency weather information management system; (3) complete landscape-level forest restoration to convert grasslands in the Naval Munitions Site back to limestone forest or ravine forest; (4) restore any areas of forest burned on DoD lands, regardless of fire cause; (5) control public access at the Naval Munitions Site to minimize ignition of fires caused by the public.

4) In addition to incipient weed control the DoD should enhance limestone forest and ravine forest areas on DoD land currently mapped as recovery habitat for the Guam Micronesian kingfisher, Mariana crow, and Mariana fruit bat by implementing landscape-scale measures to control invasive plants.

5) The DoD should manage Fena Reservoir vegetation and water quality for recovery of the Mariana common moorhen.

6) The DoD should fund a study that examines the effects of noise on behavior and reproduction of the endangered Mariana crow. Of particular potential concern is disturbance to Mariana crows resulting from noise related to training on Guam; however, other sources of noise should also be investigated.

7) The DoD should provide assistance for implementation of a conservation incentive program for the Mariana crow on Rota, which is currently under development.

8) In addition to funding two conservation personnel to develop measures to benefit the Mariana crow and Mariana fruit bat, DoD funding for implementation of projects developed by these staff on Rota would provide even more substantial benefits to these species. We recommend that DoD develop the following specific projects to benefit the Mariana fruit bat:

    a. Socioeconomic research to shed light on the best methods for reducing illegal hunting of Mariana fruit bats (i.e., development of a conservation incentives program that can be implemented throughout the archipelago).

    b. Ecological and life history research to determine for example (i) the fruit bat's specific habitat requirements – habitat structure, composition, and habiat needs, (ii) refined estimates of rates of reproduction and survival, (iii) population-level impacts of illegal hunting and direct and indirect effecs of typhoons, and (iv) the best means to reestablish self-sustaining numbers of Mariana fruit bats on Guam.

    c. Other research and conservation actions as described and prioritized in the Draft Revised Recovery Plan for the Mariana Fruit Bat or Fanihi (USFWS 2009b).

9) DoD should fund or provide training and other support for local law enforcement and conservation officers to facilitate their conduction of patrols for and prosecutions of illegal hunting and other "take" of Mariana crows on Rota and Mariana fruit bats on Guam, Rota, and Saipan.

10) An anti-terrorism fence has been proposed to secure Andersen Air Force Base from intrusion of unauthorized people. Recent discussions between the DoN and the Service indicate that the DoN is proposing to build a fence that will effectively enclose the northern portion of Guam including Guam National Wildlife Refuge land. The fence would then not only serve as a protective fence for Andersen Air Force Base, it would also be an effective barrier for ungulates. We recommend this ungulate exclusionary fence be included in the DoN's Ungulate Management Plan.

11) The DoN should ensure National Wildlife Refuge staff are provided with unescorted access to Guam National Wildlife Overlay Refuge sites on DoD lands to increase implementation of recovery actions.

2.11 REINITIATION – CLOSING STATEMENT

If cargo originating from Guam is implicated in the transport of a brown treesnake to the CNMI, Hawaii, or continental U.S., the Service shall assess the ongoing risk of brown treesnake transport and will determine if additional brown treesnake interdiction measures or other actions are necessary to ensure the effects of the action are minimized.

This concludes formal consultation on this action. As required in 50 CFR §402.16, reinitiation of consultation is required where discretionary Federal agency involvement or control over the action has been retained (or is authorized by law) and if: (1) the amount or extent of incidental take is exceeded; (2) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion; (3) the agency action is subsequently modified in a manner that causes an effect to the listed species or critical habitat not considered in this opinion; or (4) a new species is listed or critical habitat designated that may be affected by the action. In instances where the amount or extent of incidental take is met, any operation causing such take must cease pending reinitiation.

If you have any questions concerning this Biological Opinion, please contact me at the letterhead address or by telephone at (808) 792-9400.

Sincerely,

Loyal Mehrhoff
Field Supervisor

APPENDIX A

SUMMARY OF BEST MANAGEMENT PRACTICES

GUAM AND TINIAN

(DoN 2010b, vol. 7, pp 2-4 – 2-23)

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
1	Erosion Control	A range of BMPs would control erosion during construction and operations to eliminate and/or minimize nonpoint source pollution in surface waters due to sediment. Erosion control BMPs include, but are not limited to, the following practices and procedures. **Construction:** • Erosion control through site approval process (whereby the Navy reviews each proposed project for its erosion potential, and involves the designated installation Natural Resource Specialist in the process). • Topsoil removed from the site would be placed in the immediate area and reused for re-compaction purposes (if appropriate, in accordance with geotechnical recommendations). • Soil exposed near water as part of the project would be protected from erosion with erosion control blankets (organic or synthetic fibers held together with net to cover disturbed areas) after exposure, and stabilized as soon as practicable (with vegetation matting, hydroseeding, etc.). • Flatten landfill slopes for increased soil stability. • Silt-containment (silt fences and other physical barriers that intercept runoff from drainage areas). • Re-vegetate as soon as possible after any ground disturbance or grading. • Minimize construction and grading during times of inclement weather. • Soil piles and exposed slopes covered during times of inclement weather. • Stockpiling of excavated materials behind impermeable berms and away from the influence of river waters and runoff. • Implement a re-vegetation program to ensure graded benches are fully vegetated as landfills mature. • Vegetation/mulch stabilization (applying coarse plant residue to cover soil surface. The vegetation/mulch should be free of invasive species viable reproductive parts, such as rhizomes, seeds, and plants). • Level spreader (non-erosive outlet for runoff to disperse flow uniformly across slope). • Rock outlet protection (rock protection placed at end of culverts). • Sediment basin (barrier that retains sediment from runoff).		X	X	X	X	X	X	X

Item	*BMP*	*Description*	*Activities*			*Resources*				
			Design	*Construction*	*Operation*	*Geological & Soil*	*Water*	*Terrestrial Biological*	*Marine Biological*	*Hazardous Materials*
		Operation: • Restrict vehicles in training areas (ensure that all training areas, including transit routes necessary to reach training areas, are clearly identified or marked. Restrict vehicular activities to designated/previously identified areas).								
2	Stormwater Management under the Clean Water Act (CWA): Stormwater Management Plan (SWMP)	In compliance with the federal CWA under Section 401, the proposed actions would require a SWMP. A SWMP is a document that describes the minimal procedures and practices used to reduce the surface flow and subsequent discharge of pollutants to storm drainage systems. Elements of a SWMP include structural and non-structural practices such as: • Check dams (small temporary stone dam across drainage). • Diversion dike/swale (berm or ditch that channels water to desired location). • Lined waterway (lined outlet for drainage). • Stormdrain inlet protection (permeable barrier around inlets reducing sediment let into storm drain). • Stormwater ponds and wetlands. • Infiltration practices (capture/temporarily store water before infiltrating into the soil). • Use of groundwater recharge wells and infiltration basins, where applicable. • Filtering practices (capture/temporarily store water and pass through filter beds of sand, organic matter, soil, or other media).	X	X	X	X	X	X	X	X

Item	*BMP*	*Description*	*Activities*			*Resources*				
			Design	*Construction*	*Operation*	*Geological & Soil*	*Water*	*Terrestrial Biological*	*Marine Biological*	*Hazardous Materials*
3	Stormwater Management under the CWA: Stormwater Pollution Prevention Plan (SWPPP)	Stormwater Management Pollution Prevention Plan (SWPPP). A SWPPP is a self-implementing plan for compliance with an installation's stormwater permit. • Facilities would be required to comply with the SWPPP during construction and then during day-to-day operations to ensure that stormwater remains free of contaminants. • The SWPPP requires development of pollution prevention measures to reduce and control pollutants in stormwater discharge. • Where applicable, provisions of any Construction General Permit(s) would be fully implemented on non-DoD properties. • Where applicable, consistency with CNMI and/or Guam Stormwater Management Manuals. • A site-specific SWPPP tailors the plan to the facility and associated activities most likely to have a negative impact on stormwater. Applicable SWPPPs would manage stormwater and erosion at each training location.		X	X	X	X	X	X	X
4	Water Quality Monitoring Plan (WQMP)	Development of Water Quality Monitoring Plan (WQMP). WQMPs evaluate the effectiveness of environmental permits and/or performance standards. Monitoring plans identify ambient or control conditions at a particular site and capture deviations from those conditions resulting from a project or operations of a facility. WQMPs may range in complexity from visual inspections for sedimentation and protection measure failure to laboratory or field analysis of chemical and biological effects on water quality or organisms (acute/chronic bioassay), dependent on a given water resource.		X	X	X	X	X	X	X

Item	*BMP*	*Description*	*Activities*			*Resources*				
			Design	*Construction*	*Operation*	*Geological & Soil*	*Water*	*Terrestrial Biological*	*Marine Biological*	*Hazardous Materials*
5	Leadership in Energy and Environmental Design (LEED) Certification	Current Navy/Marine Corps policy supports Leadership in Energy and Environmental Design (LEED). The policies support and facilitate Silver certification for bases. LEED is a voluntary point system tool that measures the degree of sustainability features incorporated into a development. Some LEED requirements include: • Reduction of electrical energy use in buildings by 10% to save power. • Construction materials: use of local sources. Navy guidance and qualification for LEED Silver points requires that 50% non-hazardous waste and demolition debris are recycled. • Increased water efficiency. • Renewable energy. The sustainability/LEED initiatives would help reduce potable water use and should have a positive effect on demand for wastewater treatment.	X	X	X	X	X	X	X	X
6	Low Impact Development (LID)	The Navy would implement Low Impact Development (LID) design technology to make use of innovative methods to capture stormwater. Recommendations of a Comprehensive Drainage and LID Implementation Study would also be implemented. Examples of LID design include: • Grassed channel (channel stabilized by vegetation to convey water down a slope). • Grassed vegetation maintained on berms. • Integrated pest management, including proper handling of construction waste (cans, tires, drums, etc.) to avoid stagnant water collection that could harbor mosquitoes and other vectors. • Native plant landscaping. • Avoidance of pesticides and fertilizers. • Bio-retention strips. • Watershed-based management. A watershed protection management approach could consider: • Participating in the development of a watershed management plan. • Implementing and adopting specific watershed protection strategies. • Designing land use planning techniques that reduce or shift impervious cover and enhance percolation. • Work towards achieving important water resource goals.	X	X	X	X	X	X	X	X

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
		On Tinian, LID would include the use of ecologically, leach field friendly chemicals for treatment of wastewater.								
7	Energy Policy Act of 2005 (EPACT)	Energy Policy Act (EPACT) compliance includes analysis and life-cycle cost analysis using a simulated model and the following energy conservation measures: • Buildings achieve an energy consumption level that is 30% below the level achieved by ASHRAE Standard 90.1. • Use low energy consuming products that are either Energy Star-qualified or Federal Energy Management Program-recommended. • Optimize building orientation to reduce cooling loads or energy loads to cool the buildings. • Optimize building insulation. • Seal building envelope for air tightness. • Incorporate "cool roof" building designs. • Use motion detectors to reduce lighting and to setback cooling in unoccupied buildings. • Natural lighting.	X	X	X	X	X	X		X

Item	*BMP*	*Description*	*Activities*			*Resources*				
			Design	*Construction*	*Operation*	*Geological & Soil*	*Water*	*Terrestrial Biological*	*Marine Biological*	*Hazardous Materials*
8	Water Conservation Plan	Water Conservation Plans include as the use of: • Low-flow faucets. • Ultra-low-consumption toilets/urinals with electric flush sensors. • Low-flow showerheads. • Lower flow commercial-type "Energy Star" washing machines in housing units. • Energy and water-saving dishwashers (Energy Star). • Water softeners only as needed. • wastewater recycling in industrial washing and rinsing of aircraft and vehicles. • Water-efficient cooling systems. • Minimal landscape irrigation and no irrigation at housing. • Rainwater collection and reuse. • Meters installed at all facilities and key locations within the water distribution system that can significantly improve the ability to quickly identify leaks and take corrective action. In addition, educate the military population regarding practices that would conserve water (including full-load clothes washing).	X	X	X		X			
9	Hazardous Materials Management Plans (HMMP)	HMMPs describe implementation procedures for the transportation, storage, use, and disposal of hazardous materials. HMMPs would also include waste minimization plans that provide protocols designed to encourage and promote the efficient use of hazardous materials, substitute products that are less toxic whenever feasible, minimization of their use, and promote recycling and reuse of hazardous materials. HMMPs would contain procedures such as: • Hazardous materials spill/release control (use of secondary containment and leak detection methods in operations involving liquid hazardous substances). • Construction materials and all construction-related materials should be free of leachable pollutants. • Train personnel (DoD personnel and contractors are trained in proper labeling, container, storage, staging, and transportation requirements for hazardous substances. Also, they are trained in accordance with spill prevention, control, and cleanup methods).		X	X	X	X		X	X

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
		• Perform all vehicle maintenance activities at existing DoD maintenance shops. • Ensure that all personnel and contractors store, handle, and dispose of all POL per all applicable local and federal laws, regulations, and requirements. • As necessary, expand Defense Reutilization Marketing Offices (DRMO) hazardous materials storage, transportation, and disposal capacity prior to any expected increases. Note that a Joint Military Master Plan provides specific details regarding several new facilities. These new facilities would be required to store, handle, and dispose of the estimated increases in hazardous substances that would occur from the potential DoD unit transfers to Guam. • Contaminated topsoil removed from the site should be properly disposed of in an approved landfill in accordance with applicable regulatory requirements • Ensure that sediments to be dredged and soils to be excavated are well characterized, properly handled, and disposed of to minimize dispersal of any contaminants that may be present. • Temporary equipment laydown or construction staging areas would be located in previously disturbed (e.g., paved) areas. • Minimize the use of contaminated sites for new construction. When new construction occurs on sites where contamination and/or munitions and explosives of concern have been identified, ensure that the risk of human/ecological risk and exposure is minimized via the use of site-specific health and safety plans, engineering and administrative controls, and PPE. These site-specific health and safety plans must specifically address how these controls would be implemented to ensure the protection of human health and the environment. In addition, as appropriate conduct Phase I and II Environmental Site Assessments prior to construction activities and ensure that designs consider and address contaminated sites as appropriate.								

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
10	Hazardous Waste Management Program (HWMP)	HWMPs include waste minimization plans that provide protocols designed to encourage and promote the efficient use of hazardous waste, substitute products that are less toxic whenever feasible, minimize their use, and promote recycling and reuse of hazardous waste. HWMPs include the following recommendations: • Update and implement the existing HWMP to include procedures for the transportation, storage, use, handling, and disposal of hazardous waste. Also, modify project-specific hazardous waste disposal protocol as appropriate. • Ensure personnel and contractor training regarding project- and facility-specific hazardous waste plans. • The use of spill/release control (use of secondary containment and leak detection methods in operations involving liquid hazardous substances). • Ensure all DoD personnel and contractors are trained in accordance with the Guam public law (PL) 29-26 regarding the importation, handling, use, and application of pesticides (e.g., during maintenance, pre and post construction, and general operations activities). • Ensure appropriate housekeeping protocol (improving overall hazardous waste housekeeping practices, keeping area swept, wiping up spills, etc.). • Perform all maintenance activities at existing DoD maintenance shops. • Ensure that DRMO has sufficient hazardous waste storage, transportation, and disposal capacity prior to any expected increases. Note that a Joint Military Master Plan provides specific details regarding several new facilities. These new facilities would be required to store, handle, and dispose of the estimated increases in hazardous substances that would occur from the potential DoD unit transfers to Guam. • Ensure all federal, local, and DoD laws and regulations are being observed via inspections/audits/surveillances and implement corrective actions as necessary. Also ensure that all personnel and contractors manage, store, handle, transport, and dispose of hazardous wastes in accordance with applicable local (Guam EPA or CNMI Department of Environmental Quality (DEQ), USEPA, RCRA, and HSWA requirements. • Ensure that contaminated topsoil removed from sites is properly disposed		X	X	X	X			X

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
		of in accordance with applicable regulatory requirements. • Ensure that sediments to be dredged and soils to be excavated are well characterized, properly handled, and disposed of to minimize dispersal of any contaminants that may be present. • Temporary equipment laydown or construction staging areas would be located in previously disturbed (e.g., paved) areas. • Minimize the use of contaminated sites for new construction. When new construction occurs on sites where contamination and/or MEC has been identified, ensure that the risk of human/ecological risk and exposure is minimized via the use of site-specific health and safety plans, engineering and administrative controls, and PPE in accordance with CFR 29 1910.120 (hazardous waste operations and emergency response operations). These site-specific health and safety plans must specifically address how these controls would be implemented to ensure the protection of human health and the environment. In addition, as appropriate conduct Phase I and II Environmental Site Assessments prior to construction activities and ensure that designs consider and address contaminated sites as appropriate.								

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
11	Spill Prevention, Control and Counter-measures Plans (SPCC) and Facility Response Plans (FRPs)	• Update and implement existing SPCC plan to assess and respond to hazardous substance spills and/or releases. • Update and implement existing FRPs for responding to releases, leaks, or spills of hazardous substances. • Ensure DoD personnel are trained as to proper labeling, container, storage, staging, and transportation requirements for hazardous substances. Also, ensure they are trained in accordance with spill prevention, control, and cleanup methods. • Ensure petroleum, oil and lubricants (POL)/fuel transfers kept away from water bodies and a response/contingency plan is in place in the event of any releases, leaks, or spills. • Ensure proper labeling of all hazardous substance containers to prevent inappropriate storage or use. • Contaminant migration control (e.g., reducing contaminant migration pathways by preventing releases to drains, pipelines, and sewers and the use of absorbent pads and materials to prevent and control spills and releases). • Ensure that contaminants (e.g., oils, greases, lubrication fluids for heavy equipment) are properly stored at work sites and temporary construction staging areas to avoid spills, releases, and leaks. • Ensure that emergency response plans are in place for responding to releases, leaks, or spills of hazardous substances. • Minimize the risk of uncontrolled leaks, spills, and releases through industry and Navy accepted methods for spill prevention, containment, control, and abatement. • Minimize the risk of human exposure to contaminated media through the use of a site-specific health and safety plan, engineering and administrative controls, and appropriate personal protective equipment (PPE) (e.g., indicating where eye-wash stations, fire extinguishers, etc., are located).		X	X	X	X	X	X	X

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
12	Integrated Pest Management Plan (IPMP)	• DoD would develop and implement a comprehensive IPMP. This IPMP would encompass all activities regarding the importation, handling, storage, use, and application of pesticides as well as address prevention of the introduction of potential invasive species to Guam. • DoD personnel and contractors would be trained in accordance with Guam public law (PL) 29-26 regarding the importation, handling, use, and application of pesticides (e.g., during maintenance, pre and post construction, and general operations activities).		X	X					X
13	Munitions and Explosives of Concern (MEC)	• Comply with all applicable MEC protocol, procedures, and guidance including, but not limited to the Naval Ordnance Safety and Security Activity (NOSSA) Instruction 8020.15B Explosives Safety Review, Oversight, and Verification of Munitions Responses prior to any construction/demolition or other site activities. • Reduce the potential exposure to unexploded ordnance (UXO) through surveys or other means to identify and remedy this hazard prior to building upon a site. Work would be conducted by qualified UXO specialists. • Implement routine firing range clearance operations (e.g., annually or as needed), perform sampling and analysis as deemed necessary, and implement all applicable DoD MEC operations guidance to minimize or eliminate potential MEC explosion hazards and other adverse impacts (including depositions with potential to leach into the subsurface). • Implement land use controls, signage, periodic inspections, and other means to ensure no unauthorized access to firing ranges, MEC, and/or hazardous substances. • Train construction crews on identifying and responding to MECs encountered in the field. UXO personnel would be available to monitor earthmoving activities.		X	X		X		X	X

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
14	Land Use Planning and Project Design	Land Use Planning and Project Design BMPs include: • Minimize impacts through design, and incorporating site plans that attempt maximum land use efficiency. Place future industrial use sites in the vicinity of similar DoD industrial uses. • Use the community development planning process to minimize impacts to land use. • Maintain a perimeter buffer within DoD property boundaries. • Reduce seismic, liquefaction and ground shaking by following Unified Facility Code 3-310-04 Seismic Design for Buildings (USACE 2007). • Construction planning would avoid locating new buildings over unstable karst features to prevent collapse and reduce unnecessary compaction. • Avoid locating new building construction in flood hazard areas, or if necessary, fortify or elevate them above base flood elevation where possible. • Minimize land acquisitions. • Install utilities in existing corridors to the extent possible. • Avoid the acquisition of public facilities, such as park land, to the extent practical (FHWA).	X	X		X	X	X		
15	Natural Resource Management (Terrestrial Focused)	Various measures are currently used to minimize impacts to the terrestrial environment from project-related activities such as: • No-Training Areas within a 328-ft (100-m) radius around Mariana swiftlet caves at Naval Munitions Site (NMS). • No-Training Areas around wetlands with known Mariana common moorhen nesting activity. • Implement Brown Tree Snake (BTS) Control and Interdiction or Management Plans (COMNAV Instruction 5090.10A, dated February 2005; Andersen AFB 36 WG Instruction 32-7004 dated March 2006). • Prevent the spread of invasive species by implementing a training SOP; troops would receive awareness training and would inspect all gear and clothing (e.g., boots, bags, weapons, pants) for soil accumulations, seeds, invertebrates, and possible inconspicuous stow away BTS. • Trap BTS at swiftlet caves. The Navy has been contracting with USDA Wildlife Services to trap BTS at the swiftlet caves and in housing areas.		X	X		X	X		X

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
16	Natural Resource Management (Marine Focused)	Minimize contamination of the marine environment from project-related activities through actions such as: • Contractors are required to have and to implement a contingency plan to control and contain toxic spills, including petroleum products. Appropriate materials to contain and clean potential spills would be maintained and readily available at the work site. • All construction project-related materials and equipment placed in the water would be free of pollutants. The project manager and heavy equipment operators would perform daily pre-work equipment inspections for cleanliness and leaks. All heavy equipment operations would be postponed or halted should a leak be detected, and would not proceed until the leak is repaired and equipment cleaned. This information is written into the construction contract conditions. • Fueling of construction project-related vehicles and equipment would take place at least 50 feet away from the water, preferably over an impervious surface. With respect to construction equipment (dredging barges) that cannot be fueled out of the water, spill prevention booms would be employed to contain any potential spills. Any fuel spilled would be cleaned up immediately. • A plan would be developed and implemented to prevent construction debris from entering or remaining in the marine environment during the project.		X	X		X		X	X

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
17	Public Outreach/ Education	Develop and implement a Public Outreach Program to: • Inform residents, businesses, and service providers about the project schedule and other relevant information. • Implement public awareness education seminars and workshops regarding the dangers of munitions and explosives of concern (MEC) the importance of staying off firing ranges, and what to do if MEC is suspected or observed. • Promote public meeting announcements by posting ads and placing public notices in multiple places and on the internet. • Provide public meeting written materials translated in Chamorro and Filipino, supply an interpreter at public meetings. Mail announcements of public meetings to areas that may be disproportionately impacted by proposed actions (i.e., residents of Dededo, Yigo, Barrigada, Mangilao, Piti, Santa Rita, Agat, and Talofofo). • Mail announcements of public meetings to more rural areas in the south (i.e., Agat and Talofofo). • Hold public meetings in areas accessible to public transportation and in the southern region in locations accessible to as many people in that region as possible noting that public transportation may not be available in all rural areas.		X		X		X	X	X
18	Army Corps of Engineers (USACE)	USACE permit conditions and BMPs from recent Apra Harbor projects (that minimize degradation of water quality and impacts to fish and wildlife resources) provide the following recommendations (the project–specific permit may have additional conditions and protective measures): • All project-related materials and equipment (dredges, barges, etc.) placed in the water should be clear of pollutants prior to use; i.e., no project-related materials (fill, revetment rock, etc.) should be stockpiled in the water (intertidal zones, reef flats, etc.). • All debris removed from the marine/aquatic environment should be disposed at an approved upland or ocean-dumping site. • No contamination (trash or debris disposal, alien species introductions, etc.) of adjacent marine/aquatic environments (reef flats, channels, open ocean areas, stream channels, etc.) should result from project-related		X	X	X	X	X	X	

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
		activities. • Fueling of project-related vehicles and equipment should take place away from the water. • A contingency plan to control petroleum products accidentally spilled during the project should be developed. • Absorbent pads and containment booms should be stored on-site to facilitate the clean-up of accidental petroleum releases. • Any under-layer fills used should be protected from erosion with stones (or concrete cover layer units) as soon after placement as practicable. • Dredged material dewatering areas should be constructed and operated in accordance with all permit requirements. (Where applicable, a dewatering plan would be submitted to the GEPA prior to placing dredged material in upland placement sites.) • Whenever possible, dredged material would be reused. Where applicable, prior to disposal of dredge materials, a sampling and analysis plan would be submitted to the GEPA. • Provide advanced public notice of dredging activities to minimize conflicts with commercial shipping, recreational boating and other recreational activities. • Additional ship traffic should be addressed through scheduling and communications between Port Operations and contractors. In addition, USACE 404 and 401 permits require compliance with conditions and measures to protect water quality such as: • The installation of silt curtains in nearshore, shallow water areas to control turbidity. • Dredging operations may be suspended during inclement weather to prevent accidental release of dredged material and to ensure the integrity of silt curtains or other containment barriers, if utilized. • Water quality monitoring. • Adjustments resulting from water quality monitoring such as slowing or stopping operations.								
19	Transportation Federal Highway	Roadway project construction BMPs include the following recommendations: • Individual roadway projects should be designed and constructed in		X		X	X	X		X

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
	Administration-(FHWA) specific	accordance with the Safe, Accountable, Flexible, and Efficient Transportation Equity Act: A Legacy for Users (SAFETEA-LU) objectives. • Final roadway designs should avoid contaminated sites where possible. • Temporary equipment laydown or construction staging areas should be located in previously disturbed (e.g., paved) areas. • Material from demolition of existing road pavements should be stored in previously disturbed areas whenever possible. • Final roadway designs should include coordination with the responsible party to ensure that roadway construction does not interfere with ongoing remediation activities. • A Phase II environmental site assessment should be conducted for roadway projects with Right-of Way (ROW) acquisitions of non-residential property. • Individual roadway projects should be designed and constructed in accordance with recommendations of the project- and site-specific geotechnical investigation, and applicable geotechnical code requirements. • In accordance with Section 10106 (*General Requirements: Erosion and Sediment Control Plans*) of the GSESCR, an Erosion and Sediment Control Plan for roadway construction/work should be prepared, submitted to the GEPA for review and approval, and implemented in construction plans and practices to the maximum extent practicable. • Prevent leaks or spills of contaminants by ensuring all temporary equipment laydown or construction staging areas are constructed with secondary containment for storage of any hazardous or petroleum products (FHWA). • Locate temporary equipment laydown or construction staging areas in previously disturbed (e.g., paved) areas (FHWA).								

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
20	Noise Abatement	BMPs to abate noise from roadway construction include the following: • Ensure that all equipment items have the manufacturers' recommended noise abatement measures, such as mufflers, engine enclosures, and engine vibration isolators, intact and operational. • Inspect all construction equipment at periodic intervals to ensure proper maintenance and presence of noise control devices (e.g., mufflers and shrouding). • Turn off idling equipment. • Implement a construction noise monitoring program to limit the impacts. • Plan noisier operations during times least sensitive to receptors. • Avoid scheduling construction during nighttime hours (10:00 p.m. to 7:00 a.m.) and on weekends. • Keep noise levels relatively uniform and avoid impulsive noises. • Maintain good public relations with the community to minimize objections to the unavoidable construction impacts. • Provide frequent activity updates of all construction activities.		X	X			X		
21	Utilities	For roadway projects, planning and continued coordination with utility providers during the preliminary engineering and final design, and construction stages of the project should minimize or eliminate interruption in utility service to customers. • Where feasible, utility relocations should be undertaken prior to roadway construction activities.		X						
22	Cultural Resources	• Archaeological monitoring of medium probability areas during construction in consultation with the State Historic Preservation Officer. • For post review discoveries, an assessment would be made for National Register of Historic Places eligibility in consultation with the State Historic Preservation Office. • For areas or properties that have not been inventoried for historic properties, the DoD would follow Standard Operating Procedures as outlined in the Integrated Cultural Resources Management Plan and Section 106 consultation.		X	X	X				
23	Range Training Area Management	Update the existing training area management plans to include the new ranges. There are many management practices addressed in the plan including the following:			X	X	X	X	X	X

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
	Plan	• Remove expended rounds from the ranges periodically and transporting them to an appropriate recycling contractor or smelter in accordance with appropriate regulations. • Develop and implement a Range Safety Program to conduct or coordinate training area safety, emergency response (medical and fire), Explosive Ordnance Disposal, Training Mishap Investigations, safety training, and range inspections. • Develop and implement a Fire Management Plan. • Implement all applicable DoD Range Management procedures and protocol. • Adhere to protective measures established in natural and cultural resource management plans. • Controls for training area airspace in accordance with Federal Aviation Administration regulations and agreements, with an objective of use by multiple agencies with minimal interference and maximum safety. • Manage of movement and access into and within the training area by monitoring and controlling use of surface roads, shorelines and adjacent water areas, and airspace above the Range Training Area. • Publication of advanced notice for periods of range use to airman, mariners, and the general public as required for safe training area operations. • Comply with water protection measures and Military Handbook 1027/3B to minimize the potential for groundwater leachate to affect the production wells, proposed range maintenance activities and training operations would be in compliance with • Implement Military Handbook 1027/3B contains procedures for reducing potential impacts from ranges. These include adding soil amendments to maintain the soil pH between 6 and 8, maintaining vegetation on berms and drainage ways and turf on the range, contaminant monitoring, and reclamation and recycling of spent ammunition. • Implement a monitoring program to identify any early indications of lead movement so that action could be taken to address any potential water quality impacts.								

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
24	Environmental Protection Plan (EPP)	An Environmental Protection Plan (EPP) is required for projects at the discretion of the GEPA Administrator. EPPs are specifically identified in 22 Guam Annotated Regulations, Division II, Chapter 10, Section 10103.C.5 (d). EPPs would include nonpoint source control management measures including erosion and sedimentation control, vegetation, wildlife resource protection measures, fugitive dust control, solid and hazardous waste management and disposal procedures, nutrient management plan, integrated pest management strategy/plan, confined animal facilities management plan, irrigation water management plan, personnel safety procedures, work site maintenance, and typhoon contingency plans, as necessary, depending on the work, project, activity and facility function.		X	X	X	X	X	X	X
25	Seismic Design for Buildings (SD4B)	During project design and construction, hazards associated with earthquakes and fault rupture would be minimized by adherence to UFC 3-310-04 Seismic Design for Buildings (USACE 2007).	X	X		X				
26	Armed Forces Ballast Water Management Program	Ships must strictly comply with fuel transfer and ballasting procedures to ensure ballast water does not become contaminated with oil or any other waste. Ships using self-compensating fuel tanks are required to ensure adequate margin is preserved to prevent inadvertent discharges of oil with the compensating water. Navy ships must prevent the introduction of non-native organisms into natural ecosystems. Ship Ballast Water and Anchor System Sediment Control provide measures to prevent introductions of aquatic species.			X				X	
27	Awareness Training	Increase awareness training regarding the consequences of drug and alcohol use.		X	X					
28	Domestic Animal Control (MCO 11000.22)	Limits the number and type of household pets allowed per military family and requires microchip identification of pets.		X	X			X		

Item	BMP	Description	Activities			Resources				
			Design	Construction	Operation	Geological & Soil	Water	Terrestrial Biological	Marine Biological	Hazardous Materials
29	US Army Corps of Engineers (USACE)	Compliance with USACE 404 and 401 permit conditions such as: • The installation of silt curtains in nearshore shallow water areas to control turbidity. • Dredging operations may be suspended during inclement weather to prevent accidental release of dredged material and to ensure the integrity of silt curtains or other containment barriers, if utilized. • Water quality monitoring. • Adjustments resulting from water quality monitoring such as slowing or stopping operations. Arlington, Virginia 22202

Subject: Biological Opinion for the Department of Navy's Relocation of the U.S. Marine Corps from Okinawa to Guam and Associated Activities on Guam

Dear Captain Campbell:

This document transmits the U.S. Fish and Wildlife Service's (Service) Biological Opinion (Opinion) addressing the effects of the subject action as proposed by the Department of the Navy (DON) to the threatened Mariana fruit bat (*Pteropus mariannus mariannus*), and the endangered Mariana crow (*Corvus kubaryi*), Guam Micronesian kingfisher (*Todiramphus cinnamominus cinnamominus*), Guam rail (*Gallirallus owstoni*), and *Serianthes nelsonii*. The Opinion also addresses adverse effects to critical habitat for the Mariana fruit bat, Mariana crow, and Guam Micronesian kingfisher. The Opinion was prepared in accordance with the requirements of section 7 of the Endangered Species Act (ESA) of 1973 as amended (16 U.S.C. 1531 *et seq.*). The DON is the designated lead Federal agency for this consultation. This Opinion completely supercedes and replaces the 2010 DON Biological Opinion (2010-F-0122).

In addition, pursuant to the requirements identified in the Cooperative Agreement between the U.S. Air Force, DON, and the Service for the establishment and management of the Guam National Wildlife Refuge, we have provided coordination regarding potential impacts to the Guam National Wildlife Refuge Overlay from the proposed project. This consultation reviews anticipated effects to the listed species and their terrestrial habitats, including listed species habitat, on Guam. In this consultation, habitat is defined as the habitat that is currently suitable to support the survival and recovery of listed species.

Your October 1, 2014 letter, requested our concurrence with your determination that the subject action is not likely to adversely affect the endangered Mariana swiftlet (*Aerodramus bartschi*),

threatened green sea turtle (*Chelonia mydas*), and endangered hawksbill sea turtle (*Eretmochelys imbricata*) pursuant to section 7 of the ESA. Our assessments of project effects to these species are addressed in Appendix A.

This Opinion is based on information provided in your October 1, 2014, letter and biological assessment; updates to the biological assessment; email correspondence and discussions between the Service and DON; and our files. A complete project file for this consultation is in the Pacific Islands Fish and Wildlife Office (PIFWO) in Honolulu.

R. APPENDIX C – FIGURES 216

A. CONSULTATION HISTORY

September 8, 2010. The Service issued the Biological Opinion (BO) for the Joint Guam Program Office (JGPO) Relocation of the U.S. Marine Corps (USMC) from Okinawa to Guam and Associated Activities on Guam and Tinian (2010-F-01222; hereafter, 2010 DON BO) to the DON.

March 13, 2012. The DON informed the Service that they were proposing changes to the project as described in the 2010 DON BO. The DON discussed that the proposed live-fire training range complex (LFTRC) may be located along Route 15 or within the Naval Munitions Site (NMS) on Guam. The DON explained that they were in the process of preparing a draft supplemental environmental impact statement (Draft SEIS) that would include potential locations for the LFTRC on Guam.

September 17, 2012. The DON submitted their annual report on the implementation of conservation measures for the 2010 DON BO. The DON explained to the Service the implications of the 2012 National Defense Authorization Act (2012 NDAA) on the 2010 DON BO. The DON stated there would be a reduced force and number of dependents moving to Guam; and that the 2012 NDAA did not affect the existing awards for military construction but affected all future military construction projects, including some of the conservation measures in the 2010 DON BO. The DON provided a draft letter requesting an amendment to the 2010 DON BO.

September 20, 2012. The DON provided the Service with a draft conservation measure tracking sheet which showed the project activities (as described in the 2010 DON BO) that were affected by the 2012 NDAA.

October 11, 2012. The DON modified its Draft SEIS to accommodate changes to the proposed force structure and number of dependents being relocated to Guam, and the proposed alternatives for the LFTRC changed from information provided in March 2012 to include the LFTRC at Northwest Field (NWF) located on Andersen Air Force Base (AAFB).

October 12, 2012. The Service and DON discussed the proposed changes to the project and whether the changes constituted an amendment or a reinitiation of the 2010 DON BO. The Service stated that the 2010 DON BO would need to be reintiated due to substantive changes in the scope of the action.

January 30, 2013. The DON, the Service's Pacific Regional Office (RO), and the Regional Solicitor's Office via a conference call discussed the subjects of extirpated species consultation and the need to reinitiate versus amend the 2010 DON BO for the DON's " interim actions" that would occur between 2013 and 2015.

April 3, 2013. The Service received DON's request to reinitiate the 2010 DON BO and received the *Biological Assessment for the Reinitiation of Consultation for the Proposed Military Relocation to Guam; Fiscal Years 2010–2015*. The DON determined that the only federally listed species affected by the DON activities between fiscal years 2010 and 2015 was

the Mariana fruit bat. The DON determined that the project "may affect, but is not likely to adversely affect" the Mariana fruit bat.

April 9, 2013. The DON and the Service met to discuss DON's request to reinitiate the 2010 DON BO. The DON delivered a presentation on the proposed adjustments to the project, which included the relocation of approximately 5,000 USMC personnel and 1,300 dependents and the LFTRC alternative located at NWF, AAFB on Guam. The DON requested the reinitiated consultation only address the project activities that would be conducted between 2010-2015. The discussion focused on how to best address the "interim actions" that would occur between 2013 and 2015; the inclusion of the extirpated species, the Guam Micronesian kingfisher, Guam rail, and the Mariana crow, in the consultation; the status and implementation of conservation measures; and brown treesnake interdiction measures.

May 3, 2013. The Service acknowledged the receipt of the DON's request to reinitiate the 2010 DON BO. The Service determined that there was insufficient information to initiate consultation. The Service questioned the need to determine if reinitiation of consultation or an amendment would be the best mechanism to address DON's changes in the proposed action. The Service requested a table with a list of project activities and their associated or linked conservation measures that would mitigate impacts to the listed species. The Service also requested that the brown treesnake control and interdiction measures in the 2010 DON BO remain in the consultation.

May 7, 2013. The Service provided a draft table that tracked the conservations measures that should have or have been implemented as required by the 2010 DON BO.

May 30, 2013. The DON responded to the Service's letter of May 3, 2013, and provided the requested table (hereinafter "crosswalk table"). The crosswalk table listed project activities and linked conservation measures that avoid, minimize, and compensate for the impacts associated with the interim actions. DON also provided a color coding of all the conservation measures included in the 2010 DON BO to delineate which conservation measures have been implemented and those measures which have not been triggered or will not be implemented based on the proposed adjustments to the action.

June 13, 2013. The DON requested a meeting to discuss the crosswalk table and for the Service to provide the rationale to support including the Guam Micronesian kingfisher, Mariana crow, and Guam rail in the consultation.

July 8, 2013. The Service and DON met to discuss the following: 1) The Service discussed staffing workload and recommended a programmatic approach to the Marianas related DoD consultations being submitted to the Service office in the next 18 months; 2) The Service requested that the Guam Micronesian kingfisher, Mariana crow and Guam rail be included in the consultation. The DON requested the legal rationale requiring section 7 consultation on extirpated species. The Service stated they had a draft white paper in development that would address DON's request; 3) Standardized language for brown treesnake interdiction and rapid response efforts; 4) The Service acknowledged that they requested a reinitiation of the 2010 DON BO, which resulted in DON's April submittal of a reinitiation request; however the Service

thought an amendment may be more appropriate considering the interim actions are within the scope of the consultation; and 5) Both parties agreed further clarification and discussion on the crosswalk table were needed.

August 19, 2013. The Service provided rationale to the DON regarding the requirement under the ESA to consult on project impacts to the Guam Micronesian kingfisher, Mariana crow, and Guam rail.

August 22-23, 2013. The Service submitted comments on the crosswalk table to DON. Email correspondence was exchanged between the Service and DON on the crosswalk table.

August 28, 2013. The DON provided their reasons why they disagreed with the Service's August 19, 2013, rationale.

September 10, 2013. The DON requested a species list for this consultation, the DON Relocation of the USMC from Okinawa to Guam and Associated Activities on Guam (proposed project). The DON also provided the Service with the preliminary drafts of chapters 1 and 2 of the Draft SEIS.

September 11, 2013. During a conference call between DON and the Service, the participants agreed that the extirpated species issue required elevation to the Service's RO and Regional Office of the Solicitor.

September 30, 2013. The Service provided the DON with a species list of federally listed species and information on critical habitat for the proposed project.

October 1, 2013. The Service notified the DON that the Service completed their review of the August 28, 2013, correspondence from the DON. The Service determined that both agencies were at an impasse regarding the issue on consulting on project affects to the Guam Micronesian kingfisher, Mariana crow, and Guam rail. The Service informed the DON that this issue would be elevated to the Service's RO.

December 3, 2013. The DON and the Service discussed the development of the biological assessment for the proposed project and the initial approach on the conservation measures.

December 2013. The DON's Assistant General Counsel for Energy, Installations, and Environment reconfirmed the Service's RO position in discussions with the Department of the Interior's Deputy Solicitor for Fish, Wildlife, and Parks. The date of "December 2013" and meeting description are referenced in a January 30, 2014, letter from the DON to the Service.

January 30, 2014. The DON requested to terminate their request for reinitiation of the 2010 JPGO BO for their interim actions as described in their April 3, 2013, biological assessment.

February 24, 2014. The Service replied that they would consider the January 30, 2014, request from the DON; however before a decision could be made, the Service requested assurances that

key conservation measures outlined in the Service's letter would be implemented per the requirements of the 2010 DON BO.

March 21, 2014. The DON acknowledged receipt of the Service's February 24, 2014, response and requested a meeting to discuss issues outlined per the January 20, 2014, and February 24, 2014, correspondences.

April 15, 2014. The Service and DON met and discussed the following: The DON will reinitiate the 2010 DON consultation by submitting one consolidated biological assessment for the entire relocation to include 2010-2015 interim actions identified in the DON's request to consult, dated April 3, 2013, and the changes to the project (the reduction in USMC relocating to Guam and the proposed LFTRC and NWF). The DON will assess impacts and proposed conservation measures for all project activities and actions associated with the project.

May 6, 2014. A teleconference occurred between DON and the Service as a follow up to the April 15, 2014, meeting. Items discussed included the Service's review of completed and ongoing mitigation to assess interim legal compliance and the Service's and DON's points of contacts for the consultation.

May 15, 2014. The Service and DON discussed the twenty-three species located on Guam and the U.S. Commonwealth of the Northern Mariana Islands (CNMI) that were under consideration for listing as either threatened or endangered under the ESA. The Service also mentioned they are considering designating critical habitat for these species (if listed) and revising critical habitat for currently listed species on Guam and the CNMI.

May 23, 2014. The Service and DON met to discuss the development of the biological assessment, including preliminary thoughts on mitigation for habitat loss.

June 26, 2014. The DON discussed including mitigation in the consultation for the demolition and related function of the ungulate management fence at NWF, AAFB. The ungulate management fence is a conservation measure and requirement of the Intelligence, Surveillance, Reconnaissance, and Strike Capability (ISR) Biological Opinion that was issued to the Air Force.

July 22, 2014. The Service and DON discussed the status of this consultation and related briefings to regional and headquarters Service and DON counterparts; the status of the predictive modeling for the U.S. Department of Agriculture, Wildlife Service's (USDA) brown treesnake interdiction costs; and future coordination between the Service and DON on the proposed project's biological assessment.

September 16, 2014. The DON provided a presentation of the general contents of the biological assessment that would be submitted to the Service on October 1, 2014. During the meeting, the DON explained the main differences between the project as described in the 2010 Final EIS and the Draft SEIS. Other topics that were discussed were the species that would be included in the consultation and potential project impacts to their habitat, project construction chronology, training activities at the NMS, conservation measures, and proposed project activities on critical

habitat on Guam.

September 24 and 26, and October 15, 2014. The Service and DON discussed and corresponded via email regarding available sea turtle literature and information.

October 1, 2014. The DON transmitted a letter, dated September 30, 2014, requesting formal consultation on the potential adverse effects of the proposed DON military relocation to Guam to the Guam Micronesian kingfisher, Mariana fruit bat, Mariana crow, and Guam rail. The DON also requested informal consultation on the Mariana gray swiftlet, green sea turtle, hawksbill sea turtle, and the *Serianthes nelsonii*. The DON's letter included an enclosed biological assessment for the proposed action: the *Biological Assessment for the Re-Initiation of Consultation regarding the Proposed Military Relocation to Guam*, dated October 1, 2014 (hereafter, referred to as the BA).

October 2, 2014. The DON requested a map of the proposed listed species locations on Guam from the Service.

October 22, 2014. In response to the DON's request, the Service provided a map of the proposed threatened and endangered species' locations on Guam.

October 31, 2014. The Service acknowledged the receipt of the September 30, 2014, DON letter and BA for the proposed DON military relocation to Guam. The Service determined that the information in the 2014 DON BA was insufficient to reinitiate consultation and requested additional information from the DON on the proposed action necessary to initiate and complete this consultation. The Service outlined the requested information in a letter.

November 11, 2014. The DON transmitted a letter, dated November 7, 2014, and enclosure in response to the Service's October 31, 2014, request for additional information needed to reinitiate the formal consultation.

December 4, 15, and 19, 2014. The Service and DON corresponded via emails to further clarify the project description, and met to discuss mitigation for the loss of habitat on Guam as a result of the proposed project. During the December 19 meeting, the Service provided the DON with the *Framework for Mitigating the Impacts of Listed Species Habitat Loss on Guam*, dated December 19, 2014 (hereafter, referred to as the Mitigation Framework), and delivered a presentation on the Mitigation Framework.

December 19, 2014. The Service provided the DON with the updated Geographic Information System (GIS) layers for the recovery habitat for the Guam Micronesian kingfisher and Mariana crow.

December 19, 2014. The Service acknowledged receipt of the November 7, 2014, DON letter and enclosure and the December 19, 2014, DON email and table with the additional information necessary to initiate consultation. In these correspondences, the DON stated that the information on the peak noise levels for the proposed LFTRC would be provided to the Service on January 8, 2015. The Service also recognized the ongoing dialogue between the agencies on the project

impacts to the *Serianthes nelsonii* at NWF; however the Service did not concur with DON's determination that the proposed action "may affect, but is not likely to adversely affect" the *S. nelsonii*. The Service recommended that the DON request formal consultation on the project effects to *S. nelsonii*. The Service agreed to initiate the consultation on January 8, 2015 in good faith that above issues would be resolved by this date.

January 8, 2015. The Service and DON, met at the Marine Corps Base Hawaii on Oahu. The DON and USMC presented information on noise levels associated with the machine gun range they proposed to build and operate at the LFTRC at NWF, AAFB on Guam. The Service agreed that the requested information on noise levels was received during this meeting. The DON agreed to change their determination from a "not likely to adversely affect" to "may affect, likely to adversely affect" for project impacts to *S. nelsonii*. The DON and Service also agreed to communicate more effectively regarding issues related to the project consultation.

January 16, 2015. The Service and DON met to discuss the status of the consultation and additional clarifications to the project description and conservation measures. The DON provided information on changes to the project description, including updated acreage of recovery habitat that would be impacted by the project and the timing of range construction activities based on the data provided by the Service on December 19, 2014. The Service and DON also discussed the impacts to the critical habitat on Guam. The Service stated that based on the review of the information on the noise levels, they did not concur with DON's determination that the proposed action would "not likely to adversely affect" critical habitat for the Guam Micronesian kingfisher, Mariana crow, and Mariana fruit bat.

January 28, 2015. The Service requested written information on the changes to the project description, as discussed on January 16, 2015, from the DON. On January 31, 2015, the DON provided information on the project description changes via email and further clarified this information in a meeting on February 6, 2015.

January 28 to February 11, 2015. Emails were exchanged among U.S. Geological Survey (USGS), Fort Collins; the Service; and the DON on the noise levels and potential impacts to the close population facility located at NWF, AAFB. On January 30, 2015, a meeting was held to discuss noise levels and provide information on the future access and coordination that would be needed to access the facility. As a follow up to the January 30, meeting, the DON provided a response via email to questions about access and operations to the closed population facility on February 3.

February 3, 2015. The Service and DON conducted a site visit to the proposed Finegayan mitigation site on Guam.

February 3, 2015. The Service, via an email, stated that DON's proposed clearing of critical habitat for the relocation of the Guam National Wildlife Refuge (GNWR) headquarters was not acceptable. The Service stated that they were willing to identify alternative(s) proposed relocation sites. In addition, the Service confirmed completing the final Biological Opinion to the DON by May 18, 2015.

February 6, 2015. The Service and DON discussed: the logistics of the inspections of the surface danger zone (SDZ) in beach areas within the GNWR prior to the operation of the LFTRC; an update (and increase) in the number of acres of habitat that would be lost per listed species; conservation measures for *S. nelsonii*; USMC training at the NMS; and the Mitigation Framework.

February 12, 2015. The DON provided a response to the Service's request for additional mitigation to compensate for the loss of recovery habitat, as presented in the December 19, 2014, meeting and the Mitigation Framework. The DON provided a process for habitat conservation in one comprehensive document (INRMP) that is a planning and execution tool for the Navy, Air Force, Marine Corps and Army and is approved by the Joint Region Marianas Commanding Officer. Identifying mitigation ratios in the INRMP provides an incentive early in the planning process to avoid impacting mitigation sites and the associated increased cost to the program. DON included chapters 5 and 6 of the Marine Corps Air Station (MCAS) Miramar Integrated Natural Resource Management Plan (INRMP) to use as an example of how the DON proposes to address project and mitigation planning for this consultation and future DON consultations on Guam.. The DON stated that the Joint Region Marianas (JRM) will incorporate conservation measures of the BO into the INRMP.
February 13, 2015. The Service received updated information on the total number of acres of habitat for the Guam Micronesian kingfisher, Mariana crow, Mariana fruit bat, Guam rail, and *S. nelsonii* that would be lost as a result of the proposed project from the DON.

February 13, 2015. The Service sent an email to the DON that included recommended conservation measures for *S. nelsonii*. On February 18 and 19 and on March 4, 6, and 10, the DON and Service discussed by phone and corresponded via email about the conservation measures for *S. nelsonii*.

February 18, 2015. The Service requested clarification on the brown treesnake interdiction and control measures. The Service and DON discussed and corresponded about these measures on February 20, March 18 and 19, 2015.

February 20, 2015. The Service provided a preliminary draft of the Consultation History and Project Description sections of the BO for DON's review.

February 24, 2015. The Service and DON reconfirmed the due date of May 18, 2015, for the final DON BO. It was discussed that the due date of the Draft BO for the Navy's review would be April 27, 2015. The Service and DON also discussed the importance of a conservation measure which included maintaining a minimum of 30 outplanted individuals of *S. nelsonii*, parented from the Guam (*S. nelsonii*) adult tree, to adulthood. The DON stated that the Joint Region Marianas (JRM) has the responsibility to manage the conservation measures in the BO through JRM's INRMP.

February 28, 2015. The DON sent updated maps depicting the peak noise levels as a result of the operation of the LFTRC to the Service.

March 1, 2015. The Service provided a draft description of the project activities (based on the

BA) that are carried over from the 2010 DON BO into the proposed project for the DON's review.

March 3, 2015. The DON provided initial comments on the February 20, 2015, preliminary draft of the Consultation History and Project Description sections of this BO.

March 2-4, 2015. The Service and DON exchanged emails regarding the duration of the proposed project. The DON described the duration of the proposed project as indefinite.

March 5, 2015. The Service and DON met to discuss the Guam Micronesian kingfisher recovery needs on Guam and the Service's analysis of the amount of available habitat for the kingfisher on Guam. The DON also went through the calculations on the peak noise levels at the LFTRC and the SDZ. The DON stated that the peak noise levels presented in a model during the January 8, 2015, meeting no longer presented a valid estimate on peak noise levels and would provide the Service with new information using the noise calculations presented during the January 8, 2015, meeting on the peak noise levels within the LFTRC and SDZ. The Service also stated that a noise monitoring study should be developed and implemented during the operations of the LFTRC to validate the noise calculations on the peak noise levels. The DON presented a mitigation concept that included protecting large amounts of habitat for the recovery of the Guam Micronesian kingfisher on DoD land, and it was discussed that the DON and the Service should work together to develop language to present as a conservation measure for the proposed project.

March 5, 2015. The Service provided a map of the recovery habitat that is needed to support the recovery of threatened and endangered species in northern Guam. The purpose of this map was to provide guidance and information to DON regarding recovery habitat (within DoD lands) that should be protected and set aside in conservation status, as mitigation, for the proposed project. On the same date, the DON submitted an ambient noise study for the LFTRC (DON 2015a).

March 7, 2015. The DON provided comments on the preliminary draft sections of the Consultation History and Project Description, including the 2010 DON carry-over activities, to the Service. The DON also provided additional information on the peak noise levels at the LFTRC. The Service requested DON provide the rationale of why the new information on peak noise levels should replace the previously submitted (on January 8, 2015) peak noise levels.

March 9, 2015. The Service and DON discussed the intent of the brown treesnake interdiction and control measures and *S. nelsonii* conservation measures, and other clarification to the draft project description including the introductory paragraph to the conservation measures. On the same date, the Service requested via email that DON provide the rationale of why the new information on peak noise levels should replace the previously submitted (on January 8, 2015) peak noise levels.

March 10, 2015. The DON submitted a request for initiation of a Conference Opinion on proposed federally listed species. The DON determined that the proposed project *would not likely adversely affect* proposed federally listed species. On March 24, 2015, the Service

informed the DON via a conference call that the Service did not concur with their determination on the project effects to proposed federally listed species within the action area.

March 12, 2015. The DON provided additional information on the description of the LFTRC and number of construction workers that would contribute to the population increase over the life of the project.

March 13, 2015. The DON provided a statement via email that the January 8, 2015, model on peak noise levels should be replaced with the new information submitted on March 5 and 7, 2015, to the Service. The DON explained that the most current information on the peak noise levels at the LFTRC is coupled with the attenuation as appropriate for the directional aspects of position relative to the muzzle of the weapon, effects of humidity, vegetation, and a berm and an excerpt of the ambient noise study for the LFTRC (DON 2015a).

March 17 and 18, 2015. The Service requested information on the additional barriers that reduced the noise levels and effects on the listed species, as proposed by the DON on March 5 and 7. On March 19, 2015, the DON informed the Service that the additional barriers were intended to be Conservation Recommendations and would not be included in the Project Description. This change modified the DON's previous noise assessment provided on March 5, 2015.

March 17, 2015. The Service delivered a presentation to DON on the assessment of habitat in northern Guam for the recovery and survival of the Guam Micronesian kingfisher.

March 23, 2015. The Service and DON discussed conservation measures that would mitigate adverse effects to listed species as result of the proposed project. During this meeting, the DON stated the issue of concern was the Service's request that the DON should permanently set aside land for the recovery of the extirpated (listed) species (kingfisher, crow, rail) as mitigation for the proposed project. Given the broad implication of such an endeavor, the DON did not want to include their support of conserving land for future recovery of extirpated (listed) species on Guam as part of the proposed project. Both the DON and Service discussed establishing inter-agency conservation teams to work on commitments for land conservation. The DON requested that the Service include DON-drafted Conservation Recommendations, which would be submitted on March 25, 2015 to the Service, in the Biological Opinion.

March 24, 2015. The DON and Service discussed ongoing recovery efforts and requirements for the Guam Micronesian kingfisher.

March 25, 2015. The DON submitted proposed Conservation Recommendations to the Service.

March 27, 2015. The DON submitted via email revised conservation measures on project lighting requirements for the Mariana fruit bat and nesting sea turtles to the Service.

March 30, 2015. The DON via email clarified that the beach access road located outside the SDZ and northwest of the previously proposed new Service facilities would not be a stand-alone action and should be considered part of the proposed project. The DON stated that the

development of the beach access road would result in the clearing of 1.72 acre (ac) of designated critical habitat for listed species on Guam. On April 1, 2015, the Service reiterated to the DON that the clearing of critical habitat on the fee simple land at the GNWR was unacceptable as stated in the Service's February 3, 2015, email to the DON. The Service offered to work with the DON to identify alternative(s) to the proposed relocation that does not affect land with wildlife habitat value.

March 31, 2015. The DON submitted additional comments on the February 20, 2015, preliminary draft of the Consultation History and Project Description sections. The DON stated that the comments were mainly editorial and suggested the Service address the comments when the DON received the complete Draft Biological Opinion for their review.

March 31, 2015. The Service and DON discussed that the DON-drafted Conservation Recommendations will not be a part of the biological analysis and the beach access road would not be part of the project description. The DON inquired if an action alert for jeopardy was being issued for the consultation. The Service replied that they were not able to answer this question because the analysis has not been completed. The Service stated that they would have a Draft BO completed for the Service's internal review on April 17, 2015. In addition, both parties acknowledged that alternatives for the ISR Strike Fence would need to be further discussed.

April 13, 2015. The Service sent an email to the DON requesting clarification on their position on the reintroduction of native and listed species on DoD land on Guam. In this email, the Service stated that per a meeting on March 9, 2015, the Service and DON discussed reintroduction language (the same reintroduction language that was in the 2010 DON BO). During this meeting, the DON agreed that the reintroduction language could be included in the introduction paragraph to the Conservation Measures section of this Biological Opinion. However, on March 25, 2015, the DON sent the Service a list of proposed Conservation Recommendations. The first Conservation Recommendation included the reintroduction paragraph. The Service advised the DON that when the Service writes Conservation Recommendations for an action agency, these recommendations include items that the action agency is not currently doing or not currently committed to doing. Therefore, by including the reintroduction paragraph into the Conservation Recommendations, as requested by DON, the Service interprets this as DON reversing a previous commitment to allow the reintroduction of listed species on DoD land on Guam. The Service requested the DON provide clarification on this issue.

April 14, 2015. The Service and DON discussed that conservation recommendations in a biological opinion are not binding, and it is at the discretion of the action agency on their implementation. The Service and DON also discussed the reintroduction of native species language per the April 13, 2015, Service email sent to the DON. The Service requested that the language remain in this BO. The DON suggested that the Service include the reintroduction language in the introduction letter and in the baseline of this BO, as it is an action the DON will support in the future when threats are reduced. DON asked the Service for an update on the status of this BO. The Service stated that the Draft Biological Opinion would be available for DON's review on April 27, 2015, and that the analysis is in review at the RO.

April 16 and 17, 2015. The Service and DON exchanged emails regarding the ungulate fence conservation measure for *S. nelsonii*.

April 24, 2015. Office of the Secretary of Defense and Deputy Assistant Secretary of the Navy (Environment) met with Department of the Interior, Deputy Assistant Secretary for Fish, Wildlife, and Parts, the Deputy Director and Assistant Director for the Service, and Regional Director for the Service's Pacific Region to discuss staffing fixes and streamlining consultations. The Service and DoD agrees to develop a Memorandum of Agreement (MOA) to preserve a minimum amount of kingfisher habitat on DoD land in northern Guam.

June 4, 2015. The Service received updated information from the DON regarding the total number of acres of habitat for *Serianthes nelsonii*, Mariana crow, Guam rail, Mariana fruit bat, and the Guam Micronesian kingfisher that would be removed as a result of the proposed project.

June 11, 2015. The Service and DON entered into an MOA to ensure that sufficient amount of suitable survival and recovery habitat for the Guam Micronesian kingfisher is conserved and managed within DoD lands in northern Guam (see Appendix B).

June 26, 2015. The Service provided the DON with the Draft Biological Opinion for their review.

July 6, 2015. The Service received comments on the Draft Biological Opinion from the DON.

July 13, 2015. The Service received additional comments to the Draft BO entitled "Priority Issues" and "Top 5 Issues".

July 29, 2015. The Service met with DON and provided responses to DON comments received on July 6 and July 13. The agencies discussed both the DON comments and Service responses to comments.

July 31, 2013. Biological Opinion signed and submitted to DON

B. DESCRIPTION OF THE PROPOSED ACTION

The DON proposes to relocate USMC personnel from Okinawa, Japan to Guam; construct and operate a main cantonment area, including family housing; and construct and operate a live-fire training range complex (LFTRC); and conduct training activities on Guam. Project activities will occur on land administered by the Department of Defense (DoD) and the Government of Guam (for road and bridge work). The proposed action also includes activities that were initially proposed in the 2010 DON BO, and that will now be covered in this Biological Opinion. To be consistent with the BA (DON 2014a) and the Draft SEIS (2014b), these actions will be called "carry over" actions. The project description is based on information in the BA (DON 2014a), the Draft SEIS (DON 2014b), addendum to the BA (DON 2015b), and the DON's review of the Draft Biological Opinion (see Consultation History).

The proposed action includes the following components:

- Relocation of approximately 5,000 USMC personnel and 1,300 dependents from Japan to Guam
- Construction of the main cantonment within 1,213 acres at Finegayan, AAFB
- Construction of housing within 510 acres at AAFB
- Utilities and site improvement activities within DON-administered lands
- Road and bridge development and/or improvement within DON-administered lands and Government of Guam lands
- Construction and operation of the LFTRC at NWF, AAFB
- Establishment of a SDZ within NWF and the GNWR
- Development and operation of a hand grenade range at Andersen South
- Air craft training activities within the NMS and adjacent areas
- Conservation measures for federally listed species

Relocation of U.S. Marines and Population Growth on Guam

In furtherance of an agreement with the Government of Japan, the DON plans to relocate 5,000 USMC personnel and 1,300 dependents from Okinawa to Guam. Based on the most recent population estimate for Guam, which is approximately 161,000 residents (CIA 2015), the relocation is estimated to temporarily increase Guam's population by approximately 10,000 (DON 2014b, p. ES-4) or 6.2 percent by 2021. This number will decrease to about 7,400 additional residents after construction is completed in 2028 (DON 2014b, p. ES-4) or a 4.6 percent overall increase.

Probable Sources of Labor Supply

An estimated maximum number of 1,227 workers from Guam would work on construction projects related to the proposed project. A maximum of 3,227 workers from off-island would work on construction projects related to the proposed project. It is anticipated that the majority of off-island construction workers would be H-2B workers from the Philippines and other Pacific Islands. During the later years of construction (2025-2026), it is anticipated that more workers from Guam than from off-island would work on construction projects related to the proposed project.

Construction

The DON proposes over 130 separate construction projects on Guam (DON 2014a, Appendix A) to occur within a time period of thirteen years. The construction projects include clearing, grubbing, earthwork (such as digging, trenching, drilling, boring and/or cut and fill), processing and stockpiling of green waste, erosion and sediment control, roadways, sidewalks, curbs and gutters, traffic signs, temporary construction fence, perimeter / security fence, ungulate fence, landscaping and other site improvements. The construction projects also require removal of vegetation, stripping limestone rock, and removal and stockpiling of reusable topsoil. Typical equipment used would include heavy haul trucks, excavators, cranes, concrete trucks, cranes, backhoes, graders, and pick-up trucks. Construction activity would be temporary and localized

within existing noise contours that range from 60 to 85 dB average day-night sound level (ADNL) (DON 2014a, p. 64; see Operation of LFTRC section below for definition of ADNL). The use of heavy equipment can reach noise levels of 96 dB (USFWS 2006a, p. 15). No blasting or use of dynamite will occur as part of the proposed project. The construction activities are summarized below and details are provided in the BA (DON 2014a, pp. 9-18).

Main Cantonment

The proposed main cantonment development includes base operations and support facilities constructed within 1,213 ac at Finegayan, AAFB (DON 2014a; p. 2, 14-17, DON 2015b). An approximately 27,900-ft (8,500-m) long security fence will be constructed around the main cantonment perimeter. The main cantonment and support facilities are divided into the categories listed below, followed by examples of buildings/facilities for each category.

- Command core - Marine expeditionary brigade headquarters and command buildings
- Unit operations – 3rd Marine expeditionary brigade command element, 4th Marines, ground combat element infantry battalion 1 and 2, artillery battery, combat logistics battalion, 9th engineer support battalion and explosive ordnance disposal
- Base operations – base administration, fire station, public works, vehicle fueling, base auto shop, kennel, corrosion prevention and control, security
- Bachelor enlisted quarters and bachelor officer quarters
- Community support – dining facility, fitness center, recreation areas, education center, auditorium/theater, branch exchange, bank/credit union, food court/amusement center, medical/dental clinic, post office
- Training – battle training center, individual combat skills course

Family Housing

The proposed family housing will be located at currently existing family housing (510 acres of developed land) on AAFB. Family housing includes residences for accompanied permanent USMC personnel and their dependents and support and recreational facilities. Unaccompanied USMC personnel would stay at the main cantonment during their shorter-term (approximately 6 months) assignment to Guam. The proposed housing density at AAFB is 5.5 units per acre. The family housing area would be accessed by the existing family housing gate (the Santa Rosa Gate) at the northern end of Route 15, or from the AAFB Main Gate off Route 9. The existing family housing would be demolished and 912 family housing units would be constructed as replacements for the existing AAFB housing in addition to the 535 family housing units required for USMC families. All of the 1,447 family housing units would be integrated into one large housing pool where all eligible personnel and families would live.

Expansion of existing community support facilities, such as the child development center, youth center, and temporary lodging facility may be required. Other potential new facility construction may include a new temporary lodging facility, a new community center, and a new family support center.

Potable Water
Water for the family housing area would be provided by the current system, which would be modified to reroute the system along the new road alignments for the proposed family housing. There will be a connection from the AAFB well field water storage tank to the AAFB water system to provide water to the proposed family housing area. The new potable water distribution pipes would be installed underground at least 3-ft (0.9-m) deep. The width of the trench to install the pipes would be about 1.5 to 4 ft (0.46 to 1.2 m).

Wastewater Collection
The family housing wastewater collection system would include a network of gravity mains, manholes, two new wastewater pump stations, force mains and refurbishment of existing wastewater pump stations. The family housing wastewater collection system would use the existing connection to the Guam Water Authority's (GWA) wastewater collection system. Existing wastewater pump stations would be demolished as part of the proposed project. Wastewater would be conveyed to the Northern District Wastewater Treatment Plant for treatment and disposal.

Power
The existing AAFB main substation would have adequate capacity to serve the family housing, including the redeveloped housing units, new common facilities, and expanded common facilities. The distribution system would be rebuilt, enhanced, and reconfigured to accommodate the housing layout.

Solid Waste
Family housing areas would continue to have their solid waste handled as currently done for the existing AAFB housing area (Layon landfill).

Utilities and Site Improvements

The proposed action includes the development of on-site utilities, access roads, and related off-site infrastructure to support the main cantonment, family housing and LFTRC.

Grading and Earthwork
The utility and site improvement work includes major earth moving (mass grading) and limited fine grading along the roadway corridors and drainage systems. The cut and fill quantities associated with this mass grading would require approximately 5,300,000 cubic meters of structural fill material. The cut and fill quantities also assume a 2-ft (0.6-m) deep typical road pavement section including compacted base and pavement surfacing. The cut and fill quantities are based on the assumption that native material excavated on site is suitable for reuse as fill material. If soil testing and/or geotechnical recommendations indicate otherwise changes in grading or importation of material may be required. Contractors are required to obtain aggregate/soil from contractors/vendors who have local permits. Imported sand and other quarried products from abroad are subject to inspection by the Guam Department of Agriculture and require an importation permit. All sand and aggregate material imported must be accompanied by official records indicating chemical composition, pest-free certification, treatment certificate, and certificate of origin.

Although the Draft SEIS estimated that the amount of cut exceeds the amount of fill required, the DON contract does not prohibit quarry material from off-island. For example, any grading or other earthwork required during facility construction at any of the alternative sites would be implemented to balance cut and fill on-site to the extent possible. If off-site fill material were needed, it would be obtained from a permitted source. In addition, if a contractor needs fill material the excess cut from other DoD projects would be available for no additional cost as opposed to paying for fill material from a quarry (DON 2015b).

Best Management Practice for utilities includes the Comprehensive Waste Management Plan, August 2010 (DON 2010a or any applicable update), and the Integrated Solid Waste Management Plan for DoD Bases, Guam, February 20, 2013 (DON 2013a). Additional contractor requirements are as follows: process green waste on-site for reuse (goal of 100 percent) during construction; meet 50 percent diversion rate goal for construction/demolition debris through reuse (including such actions as concrete crushing and reuse as base material and grinding and reuse of asphaltic concrete from roads); and meet a goal of 50 percent diversion rate from disposal for project non-construction/demolition solid waste (not directly generated from materials used for erecting structures).

Based on the FAR 52.236-7, PERMITS AND RESPONSIBILITIES (DON 1991), the contractor shall, without additional expense to the government, be responsible for obtaining any necessary licenses and permits, and for complying with any Federal, State, and municipal laws, codes, and regulations applicable to the performance of the work. The contractor shall also be responsible for all damages to persons or property that occurs as a result of the contractor's fault or negligence. The contractor shall also be responsible for all materials delivered and work performed until completion and acceptance of the entire work, except for any completed unit of work which may have been accepted under the contract.

Reuse and Recycling Facility
Green waste processing and construction and demolition debris generated during construction will be handled by contractors at designated laydown areas. Contractors will be required to process the generated green waste as part of their assigned contract requiring 100 percent diversion of the green waste into mulch (trees and stumps) and compost (leaves and grass), and 60 percent minimum diversion of construction and demolition debris waste. The DON subject matter experts will review the contractor's green waste processing and composting facility operations plan to ensure that it meets industry and regulatory standards. The contractor will be responsible for obtaining the solid waste facility permit issued by Guam Environmental Protection Agency (GEPA) prior to commencing activities.

The construction and demolition debris and green wastes that cannot be recycled or reused, as well as wastes that are prohibited at Layon Landfill would be disposed at the Naval Base Guam Landfill, subject to ongoing discussions between the U.S. Environmental Protection Agency (USEPA), GEPA, and DON, and permitted private hardfill facilities (DON 2015b).

Electrical Substation

A main substation equipped with two 15-megavolt ampere, 34.5 kV-13.8 kV transformers will be constructed in the main cantonment area, south of the main gate. Provisions will be made in the substation for primary line connections to the planned 34.5-kV underground line from the Harmon Substation and to the planned 34.5-kV line from AAFB.

Water Distribution
A new transmission main, to be installed by the well field project, will convey water from the well field storage tank at AAFB to the boundary of the main cantonment area near the commercial/tactical vehicle gate. The DON proposes to construct a water pipeline from Route 3A near the commercial/tactical vehicle gate to the new two million gallon ground level water storage tank on Finegayan. The existing mains between some of the existing water wells on Finegayan will be demolished and realigned to the proposed roadways. The existing distribution mains servicing the abandoned Building 200 also will be removed. In the short term, the existing Finegayan water wells will provide the USMC water distribution system with water. The long-term plan will provide the USMC water distribution system with water from both the existing Finegayan wells and the well fields system.

Sanitary Sewer
The existing DoD wastewater collection system within the main cantonment area at the Finegayan site consists of a trunk sewer serving Building 200 and connected to the GWA wastewater collection system through a GWA interceptor sewer along Route 3. Wastewater is conveyed to the Northern District Wastewater Treatment Plant. Capacity evaluations of the existing collection system indicate the GWA interceptor sewer has adequate capacity for the project. The grading for the main cantonment area generally slopes downhill from north to south. A connection to the existing GWA interceptor sewer main along Route 3 is included.

Live-fire training range complex

The proposed LFTRC development area at AAFB NWF will require construction of the individual ranges, range support building, range towers, range access roads, and a perimeter fence (all within federally-controlled land at NWF), extending an ungulate exclosure fence (see Conservation Measures section) and the establishment of a SDZ within the NWF and the GNWR. The LFTRC would require construction of new electrical, telecommunication, wastewater and water lines and/or facilities configured to operate with the existing utility infrastructure of AAFB NWF (DON 2014a, pp. 18-22).

The proposed LFTRC would include five ranges and repairs to Route 3A. The individual ranges are described in more detail below (DON 2014b, p. 2-7).

Known Distance (*KD*) *Rifle Range*: The proposed KD Rifle Range would have 50 firing points for 5.56-millimeter (mm) weapons. The range would be 534 ft (163 m or 178 yards) wide and 1500 ft (457 m or 500 yards) from the farthest firing line to the target line. The target line would be flush with the ground, and there would be level ground from the 200 yard (183 m) firing line to the target line. The range would include a 25-foot (8-m) tall impact berm behind the target line. The range footprint would encompass approximately 18.5 ac (7.5 hectare [ha]).

KD Pistol Range: The KD Pistol Range would provide 25 firing points for training with 9-mm and 0.45-caliber (cal) weapons. The range would be 123 ft (37.5 m or 41 yards) wide by 150 ft (46 m or 50 yards) long with level ground from the firing line to the target line. The range would include a 12-ft (4-m) tall impact berm behind the target line and 12-ft (4-m) lateral berms. The range footprint would encompass approximately 0.4 ac (0.2 ha).

Non-standard Small Arms Range: The Non-standard Small Arms Range would provide 25 firing points, and be used for training with 5.56-mm weapons. The range would be 204 ft (62.5 m or 68 yards) wide by 328 ft (100 m or 109.4 yards) long with level ground from the 91 m firing line to the target line. There would be a 16-ft (5 m) tall impact berm behind the target line, and 16-ft (5-m) lateral berms. The range footprint would encompass approximately 1.5 ac (0.6 ha).

Modified Record of Fire Range (*MRF*): The proposed MRF Range would have 16 firing points for use by 5.56-mm weapons. This live-fire range area would be 525 ft (160 m or 175 yards) wide by 657 ft (200 m or 219 yards) in length with a 25-ft (8-m) tall impact berm at the far end of the range. The range footprint would encompass approximately 7.9 ac (3.2 ha).

MPMG Range: The proposed Multi-purpose Machine Gun (MPMG) Range would have eight stationary firing lanes to support training with 5.56-mm, 7.62-mm, and 0.50-cal weapons, as well as 40-mm inert training rounds (i.e., non-explosive). The range would be 525 ft (160 m or 175 yards) wide at the firing line, expanding to 1,050 ft (320 m or 350 yards) wide at the far end of the range. The range would be 3,281 ft (1,000 m or 1093.6 yards) long and would include a 25 ft (8 m) tall impact berm at the far end of the range. The range footprint would encompass approximately 59 ac (24 ha).

Except for the MPMG Range, the range footprints would be entirely cleared of vegetation and the range would be designed with berms to contain expended rounds of ammunition within the range footprint. The MPMG range would include more uneven terrain and with some vegetation. The purpose of the MPMG range is to simulate a more natural environment. Vegetation on the range would be designed using the Guam Landscaping Guidelines (DON 2011) and use appropriate or non-invasive species in order to reduce potential impacts associated with non-native vegetation.

The proposed LFTRC also would include three range observation towers, a target storage and maintenance shed, a ready issue ammunition magazine, covered bleachers, portable toilets, perimeter fencing, safety signage, parking, and lighting. Lighting will be designed to meet minimum safety, sustainable, antiterrorism, and force protection requirements. "Night-adapted lights" will be installed in the briefing and bleacher areas at NWF. Night-adapted lighting uses bulbs in red or other spectrums that allow a person's eyes to remain adapted to low light or night conditions while still providing enough light for work and safety. Illumination of the coastline or beach will be kept to an absolute minimum including the shielding of lights and directing lighting away from the forest or other wildlife habitat (see Conservation Measures section below).

The location and siting of firebreaks will be addressed in the fire management plan (see Conservation Measures section). The fire management plan, which is a component of the Range

Management Plan, will address issues as it relates to the potential for a fire to start on the range and how to control any fires.

Construction of LFTRC

Development of the LFTRC is anticipated to occur in two phases that would construct the smaller ranges and repair/improve Route 3A under one phase and construct the MPMG range under the second phase. Approximately 256 acres would be cleared as a result of the construction of the LFTRC (DON 2014a, p. 19). Proposed construction timelines are subject to availability of funding but are proposed as: 1) The dates for the KD ranges are March 2016 for the construction award, August 2019 for the completed construction, and start of range operations in February 2020, and 2) The dates for the MPMG ranges are January 2021 for the construction award, January 2024 for the completed construction, and range operation starting in December 2024.

Grading requirements for construction of the ranges and associated infrastructure would include 2,047,295 yd^3 (1,565,270 m^3) of cut and 1,932,392 yd^3 (1,477,420 m^3) of fill, resulting in a net of 114,903 yd^3 (87,850 m^3) of cut (DON 2015b). However, any grading and other earthwork required during facility construction at any of the ranges would be implemented to balance cut and fill on-site to the extent possible. If off-site fill material were needed, it would be obtained from a permitted source.

Operation of LFTRC

Range utilization would depend on the number of personnel required to complete annual individual training events, the duration of each event, and the training capacity of each range. However, the proposed live-fire operations at the LFTRC would occur between 7:00 a.m. and 7:00 p.m. for up to 39 weeks per year, and night operations (estimated to occur 2 nights per week over 39 weeks per year) would occur between 7:00 p.m. and 10:00 p.m. or 6:00 a.m. and 7:00 a.m. The estimated annual ammunition usage of the LFTRC by USMC and non-USMC personnel is 6,719,190 rounds (DON 2014b, p. 2-9) (Table 1).

Table 1. The estimated annual ammunition usage of the LFTRC (DON 2014b, p. 2-9).

Range	*Weapon*	*Ammunition Type*	*Estimated Ammunition Usage*		
			Day [1]	*Night* [1]	*Total*
Marine Corps					
KD Rifle Range	M16/M4	5.56-mm	1,533,300	322,800	1,856,100
	M249 SAW	5.56-mm	59,200	39,664	98,864
KD Pistol Range	M9	9-mm	324,956	19,328	344,464
Non-standard Small Arms Range	M16/M4	5.56-mm	569,356	403,500	972,856
	M249 SAW	5.56-mm	152,736	34,900	187,636
MRF Range	M16/M4	5.56-mm	304,920	62,820	367,740
	M249 SAW	5.56-mm	59,200	17,760	76,960
MPMG Range	M249 SAW	5.56-mm	377,104	0	377,104
	M40/M110	7.62-mm	13,824	4,104	17,928
	M240	7.62-mm	576,716	141,336	718,052
	M107	0.50-cal	3,520	0	3,520
	M2	0.50-cal	190,756	6,180	196,936
	MK19	40-mm inert	84,480	8,448	92,928
	M-203/ M-32 Grenade Launcher	40-mm inert	24,940	2,580	27,520
Marine Corps Total Estimated Use =			4,275,008	1,063,420	5,338,608
Joint Use (non-Marine Corps) Total Estimated Joint Use =			1,104,466	276,116	1,380,582
GRAND TOTAL (MARINE CORPS AND JOINT USE) =			**5,379,474**	**1,339,536**	**6,719,190**

Legend: SAW = Squad Automatic Weapon.

Notes: [1] "Day" operations would occur between 7:00 a.m. and 7:00 p.m. "Night" operations (estimated to occur two nights per week) would potentially occur between 7:00 p.m. and 10:00 p.m. or 6:00 a.m. and 6:59 a.m. Night firing training requirements need to be met during hours of darkness, dusk until dawn, and this timeframe differs from "acoustic" night (10 p.m. to 7 a.m.) used in noise modeling. Of the 1,063,000 rounds expected during darkness, only 326,000 rounds or 7% of the total number of rounds would occur during "acoustic" night, and no training is planned to occur between the hours of 10:00 p.m. and 6:00 a.m.

The noise levels at LFTRC are estimated at weighted day-night average sound levels (ADNL) within the immediate and adjacent areas and would range from 55 ADNL to greater than 85 ADNL, depending on the zone (area) (DON 2014a, p. 68). The ADNL is a metric that cannot be measured directly. Rather, it is calculated as the average sound level in decibels with a 10 dB penalty added to the night-time levels (10 p.m. to 7 a.m.). This penalty accounts for the fact that noises at night sound louder because there are usually fewer noises occurring at night so generally night-time noises are more noticeable. The day-night sound level (DNL) noise metric may be further defined, as appropriate, with a specific, designated time period (e.g., annual average day DNL, average busy month DNL). Noise levels due to .50 caliber or less small arms weapons use the average-weighted scale and are expressed as dB average-weighted DNL (ADNL).

The noise disturbance from the training will be impulse noise with very intense sounds of short duration (e.g., the discharge of a weapon). Firing noise from single shots merged in bursts, machine gun burst, and concurrent firing of multiple weapons would result in short periods of intense firing followed by periods of silence. Live-fire operations may occur for hours at a time, for 5 days a week, or not occur for multiple weeks in a row. The DON provided the Service with peak noise levels for the MPMG range using a formula to calculate peak noise levels at a specified distance from the source. Because the peak noise calculation did not account for sound

attenuation from the directional nature of the noise generated by the muzzle blast, terrain, ambient noise, vegetation, temperature, humidity, and other factors, the Service developed a model to estimate peak noise from the LFTRC (USFWS 2015a).

Surface Danger Zone

The DON proposes to establish a SDZ within the NWF and the GNWR (Figure 1). The SDZ would delineate areas that fired ammunition fragments or ricochet may land, forming the outermost limit of the LFTRC. The DoD standard for risk acceptance on ranges is a 99.9999% level of containment, which means the probability of munitions (for inert ordnance) or a hazardous fragment (for live ordnance) escaping the SDZ is one in a million. The SDZ projects north and outward over the GNWR-administered fee simple land and submerged lands. The DON would demarcate the SDZ beyond the shoreline through navigation map updates to alert maritime traffic of the potential hazard. For the land based perimeter of the SDZ, perimeter access roads (KD and MPMG), perimeter fencing and/or signage would indicate its boundaries for personnel and public safety. Approximately 3,701 acres (1,498 ha) acres of lands and submerged lands are required to support the SDZ. This includes approximately 142 acres (57 ha) of the Ritidian Point Unit (fee simple land) of the GNWR and 3,059 acres (1,238 ha) of the submerged lands of the Philippine Sea. No critical habitat within the GNWR would be cleared as a result of the proposed project.

Prior to operation of the LFTRC, the SDZ would be surveyed visually from observation towers to ensure the area is cleared of people. Since the GNWR has existing hours of operation (0800-1600) and the gate to the GNWR is locked outside of the hours of operation, the potential for incursion into the SDZ will be limited by the GNWR gate. However, when operation of the LFTRC is planned, the USMC would deploy USMC personnel to put up SDZ signage on trails and the beach at either end. If there are indications that people are in the area, a patrol would be deployed to ensure safety.

Although most of the SDZ area can be seen with binoculars from the observation towers at Ritidian Point at NWF, ground patrols within the GNWR are to ensure that the area under the surface danger zone is cleared of people prior to the operations of the LFTRC. Patrols would be conducted on the nesting beach prior to the operations of the LFTRC, which will operate daily up to 39 weeks per year. The purpose of the access is to ensure the water portion of the SDZ is clear of people. The Range Safety Specialist (RSS) would conduct a ground survey of three locations (Figure 1); however may only access one or two of these locations to clear the water portion of the SDZ. The RSS will access the location by using an all-terrain vehicle (ATV) (2 or 4 passenger Gator-type vehicle). The RSS will get out of the ATV and move to an area where the water portion of the SDZ can be seen (not on the beach). The RSS will use a pair of binoculars to clear the water portion of the SDZ. The RSS will walk back to the ATV and drive out the same trail taken to get to the access locations. Once the SDZ has been cleared, the RSS would notify Range Control and depart the area. The ground survey would last approximately 20 minutes.

As part of the RSS training package, personnel would be directed to not interact with sea turtles and report all sightings to the Service and coordinate with the GNWR on nesting surveys at the Refuge (see Conservation Measures).

Hand Grenade Range

In addition to the small arms training ranges collocated within the LFTRC, the proposed project also includes a development area for a separate HG Range at Andersen South. The proposed HG Range would include an approximately 0.9 ac-area developed as a hand grenade training complex for the M67 fragmentation grenade and will be connected to existing utility infrastructure where available. The following features would be developed within the hazard zone: a holding shelter for four persons, four throwing positions with grenade sumps, a range observation tower with ballistic glass, and a grenade "dudded" impact area. A grenade house would be collocated with the grenade throwing pits. There also will be a concrete munitions storage (i.e., magazine) surrounded on three sides by earthen berms for the temporary storage of hand grenades during training events.

In addition to the live-fire area, there would be a 1.0-ac non-live-fire training area developed adjacent to the range and outside of the SDZ. The training area would consist of a demonstration area with bleachers, an open practice throwing field with various targets and throwing positions, portable toilets, and a parking area. Inert practice grenades would be used at this training area to provide familiarization training prior to proceeding onto the live-fire area of the range.

Information and Communications

The proposed Information Technology/Communications (IT/Comm) development area would require inter-base connections between the proposed USMC main cantonment area, and other existing bases, the proposed LFTRC, and DON's 2010 Record of Decision-covered training facilities at Andersen South (DON 2010b). These hardwired connections would consist of conduits buried approximately 3-ft (0.9-m) deep. Off-site conduits would be encased in concrete and would have lockable manholes for security. Because redundant off-island communication paths are needed, an additional connection to the Tata Communications Cable Termination Facility (in Piti) from AAFB may be required. Off-site conduits would follow existing roads and rights-of-way between the facilities.

AAFB Well Field and Associated Water System

Increased water supply for the main cantonment area would come from the proposed AAFB well field, refurbished wells, and DON's existing water system. Based on conservative estimates, it is anticipated that to locate one well of sufficient yield to support production approximately three test wells would be required. During testing, only those wells with good water quality and capacity will be identified as production well sites. Test wells deemed unsuitable will be filled and capped and left in place, restored or converted to monitoring wells for management of the Northern Guam Lens Aquifer.

The development area would accommodate the construction of the approximately 22 test wells, 11 production wells, and associated equipment. The actual footprint of the final production wells and the access roads to each is not known at this time, but it would occur within the well field limits as shown (Figure 2).

During the design phase, the design contractor will conduct site investigations and drill test wells, determine locations of the wells, and design the entire water production system (wells, feeders, and storage tank). During the construction phase, the construction contractor will convert the test wells into production wells based on the locations identified in the design document and construct the water production system per the design specifications. Prior to start of work, efforts will be made by the design contractor to minimize disturbance to the limestone forest by inspecting the area with a DON biologist and identifying "already disturbed areas". In addition, the following actions would be implemented.

- Where disturbed areas cannot be identified, for each well location, a 14-ft (4.3-m) path will be created for the drill rig, trucks/vehicles and other equipment to get to the test well locations.

- An approximately a 100 ft x 100 ft (or 0.23 ac) work area will be required to set up the equipment at each test well location.

- For each test well, an 8 in. to 12 in. borehole will be drilled to a depth of approximately 500 ft to 600 ft below ground surface. A submersible pump will be placed at the bottom of the well, and a pump test and water sampling conducted. Based on the results of the pump test and water sampling, the well will either be abandoned or identified as a potential production well. For test wells identified as a potential production well, GIS survey coordinates will be taken and a stake placed at the test well site.

- A production well consists of well casing (approximately 10 to 12 in. diameter), screen, gravel pack, submersible well pump, pump motor housing, and surface/borehole seal. At each well station the following will be provided: well housing, discharge piping, and flow meter. Each well head will have electrical lines, water transmission pipes, and feeders to each well. The estimated disturbance area during construction is 100 ft x 100 ft (.23 ac).

- Locations of the water transmission and feeder lines will normally follow already disturbed areas made during test well drilling (path made by the drill rig/vehicles/equipment). A 20 ft to 30 ft wide strip will be required for construction of the pipelines, and manholes, valves, bends, anchor blocks, etc. as well as backfill material. The main transmission lines ranging from 8 in. to 16 in. will connect the well field storage tank facility to feeder lines. The individual well feeder lines, approximately 6 in. will connect the wells to the main transmission lines.

- In the well field storage tank facility area, there will be a booster pump, water treatment, storage tank, electrical room and central emergency backup generator and fuel storage tank. In addition to the 14-ft (4.3-m) path for cranes/vehicles/equipment, an

approximately 550 ft x 650 ft area (8.2 ac) will be disturbed during construction of the water storage tank and associated facilities.

- Unless cuttings or excavation materials are deemed contaminated or unacceptable as fill material, cuttings will be placed back into a borehole or trench. Unacceptable fill material or excess cuttings/excavation material will be removed from the site.

- When 68 ac (75 percent of the disturbance area) is reached, the construction contractor will stop work and re-evaluate to determine if 90 ac will be exceeded.

The new potable water production wells would feed a new well field collection tank, pump and water treatment facility (chlorination and fluoridation), all proposed within AAFB. The main cantonment area would be provided with a new ground level water storage tank supplied by the new well field storage tank.

Project Activities Carried Over from the DON Action addressed in the Service's 2010 BO

Andersen Air Force Base Operations

Currently, as of March 2015, the air combat element beddown facilities, air embarkation facilities, and associated buildings, a new north gate and access road with associated facilities are being constructed at AAFB.

There are two airfields on AAFB, the AAFB airfield with its north ramp and the south ramp runways. The facilities constructed at AAFB north and south ramps will be used by 12 permanently stationed MV-22 helicopters and will accommodate the loading of additional transient aircraft listed in Table 2. These aircraft will be used to conduct training and operational flights (sorties) including the following components: field carrier landing practice, familiarization-instrument, Marine air ground task force, tactical air operations center, and routine operations will occur in association with the air mobility campus and the air combat element. A training event consists of one aircraft performing a take-off, a training evolution, and a landing. These training operations will occur on airfields in current use by similar aircraft (Table 3) such as those addressed in the MITT Biological Opinion (USFWS 2015b, 66 pp.).

Table 2. Proposed aircraft loading (DON 2010b, vol 2, p. 2-91).

Element	*Number*	*Type*
Permanent stationed: Rotary wing	12	PCS (12) MV-22 (Assault Transport)
Fixed wing	12	F/A-18
Transients: Rotary wing	12	MV-22 Transport (Osprey)
	3	UH-1 Multipurpose Utility (Huey)
	6	AH-1 Attack (Super Cobra)
	4	CH53E
Fixed wing	2	KC-130
	24	F/A-18
	4-6	F-4 (visiting Allied Forces)

Table 3. Anticipated total flight operations at Andersen Air Force Base resulting from previous projects with the addition of the proposed action (Czech and Kester 2008).

Aircraft Type	**Anticipated Total Aircraft Operations per Year Andersen Air Force Base**			
	Previously Addressed	**DON Project**	**Total**	**% Increase**
Helicopter	19,029	19,489	38,518	102%
Jet/Propeller	25,697	6,424	32,121	25%

The new air combat element facilities will be used for aircraft operations, maintenance of MV-22 tilt rotor aircraft, and training and support functions. The air combat element facilities also will be used for USMC air control group training. The USMC air control group training involves coordination of air command, control, and defense units and the tactical air operations center. Training entails the operation of air traffic control radar and radio frequency emitters and facilities consisting of shelters, a portable tower, and electrical power sources. Tactical air operations center training involves the establishment and dismantling of these facilities within a 96-hour period. Training includes use of various emitters and sensors which need to be de-conflicted with other electronic equipment operating in the area. To minimize the constraints it puts on airspace availability, radar equipment, which generates strong electromagnetic radiation fields, will be operated for no more than one hour at a time. The air combat element beddown facilities will operate 24 hours per day and 7 days per week. Staffing levels will be contingent on surge and operational requirements of the air combat element facilities. Traffic will include government-owned vehicles, personal-owned vehicles, and shuttle buses from the proposed main cantonment area.

Approximately 1,000 annual field carrier landing practice and 79 annual familiarization-instrument flight events are proposed for Andersen Main Base. Field carrier landing practice operations entail one or more aircraft flying at a low altitude in almost circular patterns and involves landing on a simulated aircraft carrier during the day and, using night-vision goggles, at

night. Familiarization-instrument training, including autorotation and simulated engine-out approaches will occur on the improved airfields with the support of aircraft rescue and firefighting facilities.

Rotary-wing aircraft operations will occur at the AAFB airfields and in various proposed training areas on Guam. Fixed-wing aircraft operations will occur only in the immediate airfield environment of AAFB. Aircraft will then leave this area to conduct activities within established training areas of the MITT or other locations as described under MITT (USFWS 2015b, 66 pp.). Air traffic at the air combat element beddown and the north ramp will include helicopter, vertical lift aircraft, fixed-wing, and unmanned aircraft arrivals and departures.

In addition, a new air embarkation site is currently being built, as of March 2015, to serve as the passenger terminal for AAFB and temporary cargo storage. Air embarkation and disembarkation refers to the loading and unloading of passengers or cargo to and from aircraft. The passenger facilities are comparable to those of a small airport: luggage handling, waiting area, and ticket and documentation area. Cargo is staged for loading to aircraft or disbursement to warehouses or individual commands. Currently the Air Force has air embarkation facilities at the south ramp of the airfield. Once the new facility is built, the existing facility will be closed. The site will operate 24 hours per day and 7 days per week.

The project will result in noise levels in excess of 60 dB over the Guam landscape. Northern Guam will be periodically exposed to noise levels in excess of 93 dB PK15. Peak sound levels are the calculated peak noise level, without frequency weighting, expected to be exceeded by 15 percent of all events that might occur.

Andersen South

The proposed project will result in the construction of a military operations in urban terrain training area, a portion of which will be a modular unit and another will be reconstructed from the existing unit; a logistics and administration area; a convoy course; an advanced motor vehicles operators course; an aviation training landing zone; an aviation and maneuver area landing zone; Pioneer Road; other range roads; a perimeter fence; main, secondary, and range road gates; and the realignment of Route 15 at Andersen South.

Andersen South Operations

Convoy operations, maneuver training for military operations in urban terrain, and general maneuver and air-ground operations will vary, but may occur up to 5 days per week, 45 weeks per year, day and night. The maximum estimate is approximately 250 to 300 USMC personnel will participate in maneuver training at Andersen South each week, for a total annual throughput of 11,250 to 13,500 personnel. Convoy operations will typically consist of 7 to 10 vehicles (e.g., high mobility multipurpose wheeled vehicles) traveling in tandem along an established course. Military operations in urban terrain includes transporting units to Andersen South by helicopter or vehicle, maneuvering toward the military operations in urban terrain complex on foot or in vehicle, and engaging in integrated training at the military operations in urban terrain complex. Military operations in urban terrain at the reconstructed training area (also referred to as the

urban embassy component) will consist of 24 or more, multi-story concrete structures to simulate at least four city blocks.

The modular military operations in urban terrain (also referred to as the rural military operations in urban terrain) will consist of movable components that can be stacked and grouped into a number of configurations to present tactical situations to be overcome by training units. This modular military operations in urban terrain will consist of shipping containers that will be assembled on site to simulate a more rural village or set of suburban buildings located outside the core urban area. Forklifts or cranes will be used to reconfigure the modules of the military operations in urban terrain to add variety and diversity to training. The proposed military operations in urban terrain complex will include live-fire ranges, including a bleacher and shooting house that will be used for forced-entry training, and a hand grenade range and house. These will be suitable for units or organizations of up to 800 USMC personnel at a time, and will be used daily by 40 to 750 personnel. The military operations in urban terrain will operate day and night; night operations will comprise an estimated 15 percent of all operations. The military operations in urban terrain will be used by organizations based on Guam, transients, and visiting regional allied forces. Units using the military operations in urban terrain may bivouac in the vicinity, or arrive and depart daily.

Typically, dry runs and individual skills training will occur prior to the military operations in urban terrain exercise, which will involve fire teams (smallest unit of infantry, typically four or fewer individuals), and squad drills (a group of 8 to 12 individuals). Types of weapons that will be authorized for use at the military operations in urban terrain will include M16, M4, M249, and M240. Blanks, simulators, smoke grenades, diversionary devices (improvised explosive devices and booby traps that release smoke when activated), special effects small arms marking system (similar to paintball), and multiple integrated laser engagement system (small laser receivers scattered over the uniform of an individual soldier, which detect when the soldier has been shined by another soldier's firearm laser) are used instead of ammunition and explosives that would be used in a real combat situation.

Tactical motor vehicle operator training is a continuous requirement for USMC units. The proposed advanced motor vehicle operations course will consist of a route along which a series of obstacles will be placed for driver trainees to negotiate. This will include obstacles simulating terrain features such as narrow bridges, serpentine courses, brake modulation blocks, river crossing, side slope, pot holes, curb and ditch crossing, humps (similar to moguls on a ski slope), and narrow urban driving. The obstacles are connected with unpaved roads. The capacity of the advanced motor vehicle operations course facility will range from 25 to 60 personnel and will be used for individual, section, squad, or platoon training. An estimated 20 drivers per week will train at the advanced motor vehicle operations course, primarily with high mobility multipurpose wheeled vehicles. At two drivers per vehicle, an estimated 10 high mobility multipurpose wheeled vehicles will use the course during training events.

Convoy training consists of simulated threats and tactical scenarios to train in various defensive techniques. This area of Andersen South is currently used by the Air Force for expeditionary airfield and military operations in urban terrain training which has similarities to the proposed maneuver area training. The convoy training course is 2.5 mi (4 km) and will use existing and

new roadways (see Andersen South construction above) within areas identified for the maneuver training space. All existing roads will be open to motor vehicle use associated with maneuver area training; this will primarily be wheeled vehicles, but occasionally a tracked vehicle may be used in maneuver area training at Andersen South. The area will continue to support Air Force training, while also accommodating Marine Corps training requirements. Access to the site will be by vehicle or air lift. Air lifts will typically involve two to four CH-53 helicopters dropping off and picking up personnel twice a week.

Andersen South will support landing zones for aviation training and include helicopter support team training for ground units. Personnel train in rappelling from the helicopter and procedures that will be used in inserting and extracting troops via helicopter at combat locations. The air operation events associated with this air-ground training will typically consist of a pass for orientation, followed by a downwind approach, hovering at 30 ft (9 m) above ground level for approximately one minute at a designated landing zone and a departure. Since the maneuver area aviation training operations will be a component of training to meet the aviation training requirements, they are also described below under aviation training. Helicopter-insertion extraction activities include fast rope, rappelling, helocasting, and parachute operations. Helicopter insertion-extraction training operations will involve one pass for landing zone orientation, followed by an approach of the landing zone, hovering at approximately 30 ft (9 m) above ground level for approximately one minute, and then departing the landing zone. During each training event, approximately three helicopter insertion-extraction operations will be conducted at one or more closely located landing zones. Approximately 114 helicopter insertion- extraction events will occur at Andersen South per year. Confined area landing, external loads, and maneuver lift (see descriptions above) training will also occur on Andersen South at a frequency of 125, 63, and 720 events per year, respectively.

Shooting house operations, which are proposed to be located in Andersen South, are conducted in an enclosed structure and provide training in close-quarter skills, like room clearing and hallway navigation. No explosives are used; however, live-fire training operations with the 5.56 mm rifle will be authorized at the facility.

Naval Base Guam

Naval Base Guam (NBG) is located along the southern side of Apra Harbor on the western coast of Guam. The civilian Port of Guam flanks the northern side of the Harbor. The 2010 JPGO carry-over activities constructed and implemented within the NBG are described below. As of March 2015, the working dog kennel and the Apra Harbor wharf and utility upgrades and associated dredging and dredge disposal management activities are under construction.

Naval Base Guam Construction Projects

In-water ship berthing and embarkation areas, staging areas, an amphibious craft laydown area, a military working dog kennel relocation, a medical and dental clinic, washdown facilities, brown treesnake barriers, and quarantine areas will be developed at the NBG. In addition, a U.S. Coast Guard berthing and crew support building will be relocated to an area that is not currently forested. The military working dog kennel will be relocated from its existing site to a new site

on NBG. The proposed project location is in an existing laydown area for base maintenance with existing access roads and utility tie-ins. Associated with the aircraft carrier berthing at NBG are the shore-side facilities (recreation, gathering, laundry, waiting for transportation, and food and beverage sales), staging areas, new buildings, and parking. The Apra Branch Medical and Dental Clinic will be built on a previously disturbed area that is currently vacant. The Morale, Welfare, and Recreation area will be developed to provide food and beverage booths, seating for 500 people, 40 phone bank seats, 100 stalls for visitor and rental car parking, portable restrooms, laundry facilities, temporary lighting, and trash dumpsters.

All facilities will have security lights mounted on buildings or steel poles. Lighting along the wharves will consist of 1,000-watt high pressure sodium floodlights mounted on new or existing poles. Lighting will be shielded and aimed such that the majority of the illumination will be directed towards the wharf deck, extending over water approximately 100 ft (30.5 m). All actions related to development and improvement of waterfront facilities will occur in currently paved or landscaped areas. All utility distribution lines and ductwork will be located underground, generally within existing utility corridors.

The DON will develop permanent and temporary washdown, quarantine, and inspection areas at arrival areas on Guam at Apra Harbor (ship and amphibious vehicle loading and unloading) and AAFB (DON 2010c, p. 70) as follows.

1. A washdown, quarantine, and inspection facility will be built at Apra Harbor within 600 ft (183 m) of Victor Wharf to reduce the risk of exposure to invasive species after leaving the clean, biosecure area. During construction, invasive species and debris will be removed from the site. Prior to operation, the biosecure area will be inspected and will only begin operations when the area is invasive species-free. These facilities will provide vehicle cargo quarantine, inspection, and storage areas. These areas will be constructed with a brown treesnake barrier and active trapping for brown treesnakes will occur. These facilities will provide a pre-wash down area, vacuum equipment, wash racks (raised platforms with ramps at either end that facilitate cleaning and inspection of undercarriages), an inspection building, and fenced area that will meet the requirements for the use of inspection dogs and a cargo loading and inspection area. Specifically, these facilities will be built in a designated paved area with a wash down area and sufficient space for segregating "clean" from "dirty" equipment, cargo, and vehicles. The areas will be surrounded by brown treesnake barriers following specifications received from the Service: The barriers will be 4.5 ft (1.4 m) tall; made from pre-cast concrete with an outward projecting lip to deter snakes; the barriers will have only two gates providing one-way flow of traffic through the site; each gate made from sliding chain-link with fabric barriers or comparable materials to prevent snake ingress and egress.

2. When in Apra Harbor, the vehicles and equipment unloaded or loaded onto a ship will be inspected and receive a wash down on arrival and departure to prevent introduction of any pest or invasive species that may present a potential threat to agriculture, public health, or the natural resources of Guam or other Pacific Islands. All wash downs will be conducted and supervised by trained personnel in accordance with Armed Forces Technical Guide 31 (2008). Personnel from USDA may participate in inspections and

brown treesnake inspections will be conducted with involvement of USDA Animal and Plant Health Inspection Service (APHIS) personnel. Vehicles will be inspected (internally and externally) prior to passing into the biosecure area. The water used to wash vehicles will be captured and circulated through filters to prevent pests from spreading. All waste on board ships will continue to be steam sterilized prior to disposal in regulated landfills in accordance with base operating procedures.

3. Supplies for the Coast Guard Cutters are delivered to the wharves from existing DON supply warehouses where all supplies and material have undergone required USDA inspections upon arrival and before being transferred out of the warehouse and onto a U.S. Coast Guard ship. The U.S. Coast Guard ships will not be offloading supplies onto Guam from other locations (DON 2010c, p. 79).

4. Truck traffic at the wharf will be required to re-supply ships (DON 2010c, p. 85). Trucks may be from DON Supply or direct from commercial vendors. Equipment to move cargo will be brought to the wharf as needed. When an aircraft carrier is not berthed, the Port Operations building will be used for storage. All equipment and cargo will go through inspection procedures prior to being brought into "clean" areas or being loaded on to ships, regardless of vendor.

5. A washdown, quarantine, and inspection facility will also be built at the amphibious vehicle laydown area in Apra Harbor to reduce the risk of exposure to invasive species after leaving the clean, biosecure area. This facility will be adjacent to the shore so that amphibious craft can drive into the washdown, quarantine, and inspection facility. This facility will be built to the specifications described above for Victor Wharf with modifications to accommodate amphibious vehicles, specifically: the laydown area will have dedicated ramps for landing craft air cushion and amphibious assault vehicles in the quarantine area.

6. Typically, the Amphibious Task Force will arrive fully supplied to meet all training requirements or will be replenished as needed prior to training in the CNMI. If cargo is loaded or unloaded, inspection is required as described above for Victor Wharf. Cargo will be loaded and unloaded in the laydown area which will be of sufficient size to segregate "clean" from "dirty" cargos. If there is a training mission on Guam, the trucks will drive off the ships' stern ramps (and be inspected as described above). Other cargo may be offloaded by mobile crane. After inspection, cargo may be temporarily stored in a "clean" material handling equipment at the waterfront.

7. There are several projects in Apra Harbor. For all facilities, the DON will attempt to include USDA APHIS at the earliest possible time to plan for brown treesnake inspections. Planning for cargo storage will include considerations of the length of time for storage, risk of brown treesnake or other invasive species, and origin and destination of cargo. These considerations need to be vetted through the Biological Monitor (who will coordinate with other partners. Permanent barriers and moveable brown treesnake barriers will be used as the situation dictates.

8. The DON will develop permanent and temporary quarantine and inspection areas at a new Air Embarkation and Disembarkation area at Andersen Main Base to load and unload passengers and cargo from aircraft (DON 2010c, p. 62-63). USDA APHIS will be included in the design of this facility as early as possible to assist with planning. This facility will be surrounded by a brown treesnake barrier built to the specifications described above and will have inspection and quarantine areas to separate "clean" from "dirty" areas such that all aircraft, baggage, equipment, and cargo are 100 percent inspected upon arrival and 100 percent inspected upon departure. The aircraft carrier berthing will bring up to 59 aircraft to Guam that may beddown at AAFB. All transient aircraft will follow all existing invasive species inspection protocols, including brown treesnake protocols (DON 2010c, p. 83).

Naval Base Guam Operations

All amphibious training operations and conservation measures are assessed under the MITT Biological Opinion (USFWS 2015b, 66 pp.). Though new facilities will be constructed due to the proposed project, no additional amphibious training will occur in undisturbed areas, either new or increased frequency or tempo is proposed under the proposed project. Therefore, amphibious training will not be analyzed within this Biological Opinion.

New aviation training, called external load, will occur at Orote Airfield on NBG. The training requires access to pre-positioned cargo for practice, and ground access is needed for ground support team personnel. External loads cannot be carried across public roads or populated areas. External load training operations will involve one pass for landing zone orientation, followed by an approach of the landing zone, hovering approximately 30 ft (9 m) above ground level for approximately one minute while the ground support team attaches a load (e.g., concrete block, items in a cargo net, or a vehicle), departure of the landing zone vicinity with the load in tow, flying with the load in an arc, then returning to the landing zone with the load, and hovering for approximately 30 seconds while the ground support team retrieves the equipment, and then departing the landing zone vicinity. During each event, these operations will typically involve five repeated attachments and detachments of external loads at the same landing zone where the ground support team is positioned. Ground support teams will include up to 40 personnel at one time and will support landing zone operations. Approximately 10 to 12 wheeled vehicles (e.g., high mobility multipurpose wheeled vehicles) will be used by these teams. External load training will involve pick up and return from the same location on Guam.

Naval Munitions Site Operations

Company-level patrolling, jungle training, land navigation, and air-ground operations will occur on 5 to 7 consecutive days, 12 weeks per year, day and night, for a total annual throughput at the Naval Munitions Site of 1,440 Marines. Sixteen events are authorized under the MITT Biological Opinion (USFWS 2015b, 66 pp.), the number of days and weeks described above represent an increase of training events per year due to the proposed project (revised total of 28 events per year). This site is rural and rugged and is designated as the Southern Land Navigation Area, supporting foot land navigation training primarily for special forces personnel (USFWS

2015b, 66 pp.). Access to the NMS for training will occur via helicopter transport operations at proposed landing zones. Approximately eight CH-53 (heavy-lift transport helicopters) lifts will be required for a company-level training event. Personnel, hand-carried supplies, and equipment will typically be airlifted to the site on a Monday and lifted out on Friday of the same week. No other roads will be established and no vehicles will be used within the training site. The access road will have an associated parking area that will be periodically mowed to allow for parking and to reduce fuel loading and potential for fires. Foot trails will be established within the southern portion of the NMS due to repeated use during maneuver training.

Terrain flight, ground threat reaction, defensive maneuvering, confined area landing, and external load training will occur at the NMS. Terrain flights require a route with varying terrain for night flight with night-vision goggles, at 50 to 200 ft (15 to 61 m) above ground level. Training for terrain flights will occur only within the southern portion of the NMS, south of the southern extent of Fena Reservoir. Aircraft will leave AAFB and transit to southern Guam using standard military flight procedures (i.e., greater than 1,000 ft [305 m] above ground level). Aircraft may fly over land or over water on their way to the NMS. A typical training event may involve an aircraft leaving AAFB, moving to the east over the ocean, traveling along the coast at an altitude greater than 1,000 ft (305 m) until approximately the Talofofo River, and then flying up the river to the NMS still at an altitude equal to or greater than 1,000 ft (305 m). Flights may go up the Ugum River at altitudes of 1,000 ft (305 m) or greater above ground level until they reach 9,843 ft (3,000 m) from the mouth of the river at Highway 4 and then flights may conduct low-level terrain flights. Once the aircraft crosses into the NMS below Fena Reservoir (training restriction line), pilots will then be authorized to conduct low-level (50 to 200 ft (15 to 61 m) above ground level) terrain flights within the southern NMS. Low-level flights will not occur over the munitions bunkers, the main NMS, the area to the east of the munitions bunkers, over Fena Reservoir, or over the Almagosa Springs.

Ground threat reaction training requires a tactical flight maneuver area or route (similar to terrain flight routes) where ground-based electromagnetic radiation threat simulators may be placed. Defensive maneuvers are also conducted along a route over land or water. Differing helicopter types (AH-1, CH-53E, UH-1) and the MV-22 tilt rotor aircraft, will be used to conduct terrain flights, ground threat reaction, and defensive maneuvers training; however, terrain flights training operations are low altitude tactics and the ground threat reaction and defensive maneuvers training is conducted more in a tactical navigation area than along a route. Ground threat reaction is also low-altitude training like terrain flights, while defensive maneuver training is higher in altitude (equal to or greater than 1,000 ft [305 m] above ground level). Approximately 100 terrain flights, 94 ground threat reaction, 94 defensive maneuvers, and 1,104 maneuver lift flights per year will occur in the NMS.

Confined area landing training operations will also occur at the NMS. Confined area landing training consists of one pass of the landing zone for orientation, a downwind approach, followed by the landing, and takeoff. To meet qualification requirements, confined area landing training events typically will have five associated operations. Typically, a number of different, closely located landing zones, will be used during the training event. There will be approximately 125 confined area landing training operations per year at the NMS. Approximately 63 external load

training operations per year will also occur at the NMS and are described under "Naval Base Guam Operations".

Roadways

The proposed road projects on Guam will enable and improve roadway connectivity, capacity, and pavement strength for military construction and deployment in support of the proposed project. Some of these road projects will be funded by DoD pursuant to the Defense Access Roads program. The projects that are not funded by DoD will be the responsibility of the Government of Guam Department of Public Works or the Federal Highways Administration. Logistical routes for construction-related transport will connect the Port of Guam with NBG, AAFB, the proposed main cantonment, the NMS, and existing concrete batch plants, rock quarries, and precast concrete panel fabrication sites associated with the military buildup on Guam.

In addition to improvements to the construction routes, increased traffic associated with the presence of the military personnel and their dependents will require roadway modifications. As a result of the recent transportation and traffic studies on the island of Guam, 50 individual road projects have been proposed but would occur within urban areas. The more extensive roadwork projects will either occur within previously developed areas of Guam such as residential and commercial areas, or they will not entail impacts to woody vegetation or other natural resources potentially utilized by listed species (for instance, pavement strengthening will not require any additional disturbance to areas outside of the existing roadbed) (Table 4). However, the Agana Bridge 1 Replacement Project occurs along Route 1 and has the potential to impact wetland habitat.

Table 4. DON Actions Associated with the Military Relocation to Guam that are Carried Over from the 2010 DON BO (modified from Table 1-1, DON 2014a, p. 3)

Location	Action
AAFB	Location for the Marine Corps Air Combat Element and construction of associated facilities at AAFB North Ramp
AAFB	Construction of air embarkation facilities at AAFB South Ramp
AAFB	Construction of the North Gate and access road at AAFB, including a new Entry Control Point facility
Andersen South	Development of a training range complex to include maneuver training and landing zones
Apra Harbor	Waterfront functions at Apra Harbor to support embarkation, including wharf and utility upgrades, and associated berth dredging and dredge disposal management
Apra Harbor	Relocation of Military Working Dog Kennel
Apra Harbor	Relocation of U.S. Coast Guard
Apra Harbor	New Medical Clinic
Apra Harbor	Apra Harbor Embark Operations
Naval Munitions Site	Training activities, including aviation training and nonfiring operations training
Naval Munitions Site	Access to the NAVMAG area using the existing hiking trail as the access road (No Construction Required)

Naval Munitions Site	Use of Parsons Road area for the location of additional ammunition storage at NAVMAG
Roadway Project (by FHWA and Guam Department of Public Works[GDPW])	Route 1 and Route 8 intersection and improvement (Hagåtña) ("Guam Road Network" [GRN]1) – (Part of Hagåtña Bridge Replacement Project Scope)
Roadway Project(s)	Route 1 and Route 3 intersection and roadway improvements (Dededo) (GRN2)
Roadway Project	Replacement of Hagåtña (Agaña) Bridge #1 with reinforced concrete (GRN3)
Roadway Project	Route 11 roadway improvements from the port to Route 1, including pavement strengthening (GRN4)
Roadway Project	Widening of the Route 1 and Route 11 intersection, adding a second left turn lane and pavement strengthening (GRN5)

Term of the Proposed Action

The proposed project includes carry-over activities per the 2010 DON BO and new proposed activities as described above. The proposed construction activities would continue and occur over a 13-year period from 2015 to 2028. In addition, construction of the LFTRC is expected to be completed in January 2024. After the construction is completed, there will be about 6 months of equipment outfitting and testing before the range will be operational. There is no planned end date for the operation of the proposed action; therefore the duration of the project is indefinite.

CONSERVATION MEASURES TO AVOID OR MINIMIZE PROJECT IMPACTS

The project's conservation measures are designed to avoid or minimize project effects to listed species and their habitats or to contribute to the recovery of a listed species. The conservation measures are intended to represent a comprehensive summary of those measures that were proposed in the BA (DON 2014a), addendum to the BA (DON 2015b), and through discussions and email correspondence between the DON and the Service. Conservation measures are considered part of the proposed action and are vital to determining the scope of the proposed action. Implementation of conservation measures is required under the terms of the proposed action. The Service's effects analyses and determinations assume proposed project conservation measures will be implemented in full. Any changes to, modifications of, or failure to implement these conservation measures may result in a need to reinitiate this consultation. Modifications to aspects of the conservation measures described, that provide protection equal to or greater than the protection afforded by the measure, as it is proposed in this Project Description, may be substituted for those provided in this Biological Opinion with the Service's written concurrence. The conservation measures will be implemented prior to or concurrent with construction unless otherwise stated. After completing the conservation measures, the long-term management of the natural resources will be incorporated into the JRM INRMP (DON 2014a, p. 35). Based on discussions and meetings between the DON and Service, the Service understands that the implementation of the conservation measures would be the responsibility of the DON; however conservation measures over the long-term would be managed by the JRM. The JRM's mission is to provide executive level installation management support to all DoD components and tenants

through assigned regional installations on Guam and the Northern Mariana Islands in support of training in the Marianas.

General Conservation Measures to Contribute to the Recovery of Listed Species

1. Forest Enhancement

   The DON will implement a forest enhancement project on approximately 1,000 acres in Finegayan (Figure 3). The forest enhancement project will include:
   - Installation of ungulate exclusion fences around approximately 1,000 acres
   - Active removal of ungulates (i.e. trapping, snaring, shooting) with the goal of eradication within the fenced areas
   - Invasive plant removal
   - Propagation, planting, and establishment of dominant and rare species characteristic of native limestone forest habitats (e.g., *A. mariannensis*, *G. mariannae*, *F. prolixa*, *M. citrifolia*, *C. micronesica*, *W. elliptica*, *S. nelsonii*, *H. longipetiolata*, *T. rotensis*)

   When a DON-related project is initiated that results in clearing of recovery habitat, a commensurate amount of forest enhancement will begin. The exact amount of recovery habitat that will be cleared will depend on final design specifications. The DON's forest enhancement project will enhance at least the same number of acres of recovery habitat as that cleared by the proposed action. The DON expects that approximately 1,000 acres of forest will need to be enhanced as part of the Project Description (Table 6). The timeline of initiation of forest enhancement projects will be based on the construction timeline for the proposed action. The first construction funds that are released for a project that will clear recovery habitat will also trigger the initiation of the forest enhancement funding. The sequence of forest enhancement will be: (1) ungulate exclusion fence, (2) ungulate removal, (3) invasive plant control, and (4) native plant establishment.

2. Guam *Serianthes* Adult Tree

   a. DON will propagate, plant, and maintain a minimum of 30 individuals of *Serianthes nelsonii*, parented from the Guam *Serianthes* adult tree, within the forest enhancement areas. Outplanting methods and maintenance success criteria will be developed in coordination with the DON and the Service. Over the long term, the outplanted individuals will be managed by JRM through the JRM INRMP to ensure survivorship into adulthood.

   b. DON will ensure that seeds from the Guam adult Serianthes tree will be collected by entities specified on recovery permits, provide storage for these seeds, and provide funds for *Serianthes* seed viability testing. Seed storage and viability testing shall occur at a certified facility (*e.g.*, National Center for Genetic Resources Preservation or Lyon Arboretum). The DON will ensure the seeds are appropriately prepared or treated for shipping per the instructions of the certified facility.

c. The DON will protect the adult Guam *Serianthes* tree from ungulates through one of the following options.

i. DON will construct and maintain a fence, with a minimum buffer of 100 feet, around the forested area surrounding the Guam adult *Serianthes* tree to protect the tree and its seedlings from ungulates. The DON will remove all ungulates from the fenced area either prior to the completion of the fence construction or within six months of the fence construction.

OR

ii. DON will construct and maintain a fence around the LFTRC to encompass the area within the existing Ritidian ungulate fence (per the ISR Strike Biological Opinion and NWF Beddown project) and the Guam adult *Serianthes* tree. The DON will remove all ungulates from the fenced area either prior to the completion of the fence construction or within six months of the fence construction.

iii. This fence shall be completed within two years of award of the construction for the portion of the live fire training range complex that removes the Ritidian ungulate fence.

d. DON would allow access to the *Serianthes* adult tree at NWF for seed collection and seedling rescue provided (1) the need to collect seed and/or rescue seedling has been coordinated in advance with the Service, AAFB, and JRM, and (2) adequate timing and coordination is permitted for DON to process the access request. Access requests would be coordinated through Range Control, which is the entity responsible for scheduling all training events on military ranges.

3. Sea Turtle Public Outreach and Coordination

The DON, in cooperation with the Guam Department of Aquatic and Wildlife Resources (DAWR), has undertaken an educational program to inform military and civilian personnel about sea turtle nesting and the potential impacts to the species from nest disturbance, direct harassment of sea turtles, beach disturbance, and other threats. The DON has developed and distributed sea turtle conservation posters, tri-fold brochures and activity booklets for elementary school children. These educational materials have been distributed to local dive shops on Guam, and will continue to be used and refined throughout the construction period of the proposed relocation. As part of the RSS training package, personnel would be directed to not interact with sea turtles and report all sightings to the Service and coordinate with the GNWR on nesting surveys at the Refuge.

Brown Treesnake Control and Suppression

The DON has initiated support for large-scale, long-term efforts to refine methods for brown treesnake (BTS) control that will reduce the snake population on a landscape level more cost-effectively and increase the efficacy of capturing snakes in low-density situations. In early FY12, the DON coordinated with the Service, USDA, and U.S. Geological Survey (USGS) on priority BTS projects. The development of a bait formulation for BTS suppression was determined to be the highest priority project need. The USDA National Wildlife Research Center (NWRC) was funded for a multi-year project by the DON at the start of fiscal year 2013 to implement the bait formulation project.

The DON will implement selected projects identified as priorities in the BTS Technical Working Group Strategic Plan that are compatible with the military mission on Guam for up to 10 years from the start of main cantonment construction, subject to Congressional funding guidelines and restrictions. DON and the Service acknowledge financial support is subject to the availability of funds, and no provision herein shall be interpreted to require obligation of payment of funds in violation of the Anti-Deficiency Act, 31 U.S.C Section 1341.

The DON's intent with these projects is to identify and use successful technology to severely suppress or eradicate brown treesnakes. DON will install a BTS barrier to exclude brown treesnakes from approximately 160 acres (65 ha) after the current experimental suppression activities within the Habitat Management Unit (HMU) has been determined to be successful. If the DON is successful at eradicating brown treesnakes within the 160 acres, the DON will install a second brown treesnake barrier to exclude brown treesnakes from approximately 300 acres (121 ha).

In response to decreased BTS densities, the rodent and feral cat population is expected to increase. In order to address this anticipated increase the DON will implement rodent and feral cat control. Rodent control would benefit recovery habitat as rodents consume seeds of native plants. Feral cat control would benefit the recovery of endangered birds as cats predate on native birds.

Conservation Measures to Minimize the Effects of Construction

1. Contractor Education Program. The DON contractor education program ensures that construction contractor personnel are informed of the biological resources in the project area, including invasive species, special-status species, avoidance measures, and reporting requirements. The measure is intended to prevent inadvertent effects to terrestrial biological resources due to lack of awareness of resource presence, sensitivities, and protective measures. The measure will be implemented during pre-construction and construction.

2. Contractor Plans and Specifications: All construction will occur within the limits of construction shown in the plans and specifications. This measure is intended to prevent additional habitat loss. The measure will be implemented during pre-construction and construction.

3. Pre-Construction Surveys for the Mariana Fruit Bat. For projects within or in the vicinity of suitable fruit bat habitat, surveys following the Service-approved JRM protocol (USFWS 2009a) will be conducted one week prior to the onset of work. If a fruit bat is present within 492 ft (150 m) of the project site, the work will be postponed until the bat has left the area. The measure is intended to prevent avoid and minimize potential effects to fruit bats, and will be implemented during pre-construction and construction.

4. Guam Landscaping Guidelines. Appropriate or non-invasive species will be planted in all new landscapes. This measure is intended to reduce potential effects associated with non-native vegetation, promote habitat for native species, reduce water consumption, and reduce the need for fertilizers. The measure will be implemented during construction.

5. LFTRC Range Berm Controls. LFTRC range berms will contain native or non-invasive herbaceous vegetation, and other engineering controls. This measure will help to manage stormwater runoff and control erosion, and the berm will minimize the number of bullets that may fall outside the range footprint. The measure will be implemented during construction.

6. Lighting Installation. Lighting will be designed to meet minimum safety, sustainability, antiterrorism, and force protection requirements. Hooded-lights will be used to the maximum extent practicable at all new roads and facilities within known sea turtle land habitat and fruit bat roost areas. Either hooded or "night-adapted" lights will be installed at the LFTRC. Illumination of forest, coastline, or beach will be consistent with range safety and security requirements and kept to an absolute minimum including the shielding of lights and directing lighting away from the forest or other wildlife habitat. This measure will be implemented during pre-construction, construction, and during operations.

7. Monitoring. The DON will be responsible for oversight of avoidance, minimization, and conservation measures implementation by the contractors for projects associated with the proposed action. The DON shall ensure that construction remains within the limits of construction and that sensitive resources are avoided, unless otherwise specified in this Project Description. This measure will be implemented during pre-construction, construction, and operations.

Conservation Measures to Minimize the Effects of Invasive Species

Regional Biosecurity Plan. To address invasive species pathways and encourage a more holistic approach to managing invasive species, the DON funded the development of a Regional Biosecurity Plan (RBP) for Micronesia and Hawaii (formerly referred to as the Micronesia Biosecurity Plan). Individual activities for various species will continue, but the DON and others agree it is more efficient to manage pathways and prescribe corrective measures for a suite of species which will be monitored at discrete control points over time. The RBP will provide stakeholders in Micronesia and Hawaii with a platform for coordination and integration of inter-agency invasive species management efforts such as control, interdiction, eradication, and

research. The final RBP was completed in March 2015 (DON 2015c). Several of the recommendations are incorporated into the Project Description as BMPs:

1. Onsite vegetation waste management procedures. Green waste will be handled by the contractors at designated laydown areas within the limits of construction. Contractors will be required to divert all the green waste. The larger-sized green waste consisting of trees and stumps will be processed into mulch and the smaller sized green waste will be processed into compost. A proposed green waste processing facility at NBG Landfill may also be used to process green waste generated during construction. The DoD will seek permit authorization from the GEPA for the proposed green waste processing facility. (Refer above to Construction – Utilities and Site Improvements for additional detail.)

2. DON's Final Guam Landscaping Guidelines. The DON has developed a manual providing landscaping design guidelines specific to appropriate plant selection and establishment for all the DON construction activities on Guam (DON 2011). This manual implements required DON policies including, but not limited to:
    a. use of native regional plants for landscaping;
    b. design, use, and promoting construction practices that minimize adverse effects on natural habitat;
    c. pollution prevention by reducing fertilizer and pesticide use, integrated pest management practices, recycling green waste (composting), and minimizing runoff;
    d. implementing efficient water practices; and
    e. preventing the introduction of invasive species.

    The above measure is intended to reduce potential effects associated with non-native vegetation, promote habitat for native species, reduce water consumption, and reduce the need for fertilizers.

3. Biosecurity outreach and education - The DON has initiated and will continue to implement a targeted, comprehensive outreach and education program for DoD and civilian populations for biosecurity focused on prevention. As a starting point, the DON contracted for the development of biosecurity outreach and education materials. The contractor has designed and produced an activity booklet, a two-sided, tri-fold, educational brochure with an associated poster that differentiates native from introduced species, defines invasive species, describes the known impacts of invasive species on native species and ecosystems, and what can be done to prevent and control invasive species. This effort also included the development of radio public service announcements (PSA) in three languages, and a television PSAs both of which aired for one month in September of 2013 during peak broadcasting times.

    The DON's biosecurity outreach and education program has already begun concurrent with the actions that were initiated under the 2010 EIS ROD (DON 2010b). The DON will develop additional informational videos, expand the radio PSAs broadcasts, and other print media as well as active public outreach concurrent with the arrival of the first major influx of USMC personnel in 2020 and continue for an additional 5 years.

4. HACCP planning. Hazard Analysis Critical Control Point (HACCP) planning is a pathway management tool that provides a comprehensive method to identify risks and focus procedures to prevent spread of species through pathways. Construction work could unintentionally spread non-target (potentially invasive) species. These non-targets could hitchhike on construction equipment or be included in shipments of materials and supplies from locations outside of Guam. The pathways used by invasive species to move into new locations are not always obvious. Many problematic species, diseases, and parasites have been transferred to new locations as undetected (and unplanned) hitchhikers. HACCP planning is a management tool that provides a structured method to identify risks and focus procedures. Understanding pathways and developing plans to reduce non-target species and prevent biological contamination is necessary to avoid unintended spread of species.

   In August of 2011, the DON sponsored several HACCP training courses for DON employees and construction contractors. A HACCP Planning Overview for Managers was held on August 8, 2011, and 2 two-day HACCP Planning courses were held August 9 through 12, 2011. Over 60 people attended the three courses. Additional trainings are held at the various project sites when there is worker turnover.

   a. All construction contracts will contain a requirement to develop a HACCP Plan which will identify risks and potential pathways for non-native species and will outline procedures for controlling and removing risks identified. Construction contractors are required to provide documentation that supports prevention, worker awareness training, and control of non-native invasive and pest species in the project area and efforts to prevent the movement of non-native invasive species to areas outside the project area, whether in a purposeful or inadvertent manner. The contractor is responsible for ensuring that employees receive applicable environmental and occupational health and safety training and keep up to date on regulatory requirements for specific training for the type of work to be conducted onsite.

   b. Construction contracts also will contain a requirement for inspections and proper re-use or disposal of vegetation to avoid contributing to the further spread of the coconut rhinoceros beetle. The construction contractors are to identify and implement control measures to prevent the inadvertent movement of non-native, invasive species to Guam and to and from the project site to other locations. The contractor is required to establish appropriate facilities that comply with all environmental laws and regulations, provide training for proper vehicle hygiene, and promptly take corrective and preventative actions for noncompliance. This includes vehicle washdown and inspection for soil and other materials and appropriate control measures are implemented to prevent the inadvertent movement of non-native invasive species from the project site to other locations.

   c. All HACCP planning and implementation related to the proposed action will be the responsibility of the awarded project contractor(s) to ensure that proper

control measures are used throughout the construction activities to prevent the inadvertent movement of invasive species from one location to the project site, and/or from the project site to other locations. It will be the responsibility of DON to review and concur with the development phase of the HACCP planning process to ensure proper compliance by these contractors.

d. HACCP plans will be approved and inspected by the DON.

5. Monitoring to evaluate effectiveness of HACCP

The DON shall provide training, review, and technical guidance on HACCP plan development, implementation, and revision during the construction phase of the buildup on Guam. The HACCP planning covers Guam-related rapid response actions. The DON contracted a baseline ecosystem monitoring study for projects on AAFB in 2011. Transects were focused on areas where newly introduced species were most likely to occur. The intent of the project was to establish a baseline of both native and non native plants present prior to the beginning of planned construction activities. The baseline will serve as a reference for subsequent monitoring efforts conducted concurrently with construction in order to aid in evaluating the success of implemented HAACCP plans. The baseline will also provide a basis of comparison relative abundance of invasive species during construction as well as whether any species detected during long-term monitoring are newly introduced or were present prior to the beginning of construction. The AAFB project was completed in December 2012.

To document the effectiveness of the HACCP implementation at construction sites, the DON has developed and implemented a long-term monitoring program for terrestrial vegetation. For any clearing of vegetation that is adjacent to or contiguous with recovery habitat, the perimeter and 98.4 ft (30 m) into the habitat will be surveyed to identify vegetation community species composition. This survey will be repeated six months and at one year after vegetation removal to ensure effectiveness of HACCP implementation (clean equipment, supplies, and materials) during construction activities. If new nonnative, invasive species are detected, the DON will notify the Service and the DON will develop and implement an eradication plan or control effort to prevent infestation.

The DON will develop an early detection and rapid response component for when an incipient invasive species is discovered in the proposed action area.

6. Brown treesnake interdiction

a. JRM has established a comprehensive brown treesnake interdiction program to ensure that military activities, including the transport of civilian and military personnel and equipment to and from Guam, do not contribute to the spread of brown treesnake to other islands or regions. Brown treesnake interdiction requirements are specified in DoD instructions (i.e., 36 Wing Instruction 32-7004, Brown Tree Snake Control Plan and COMNAVMAR Instruction 5090.10A,

Brown Tree Snake Control and Interdiction Plan). The proposed action will continue to comply with these established procedures.

b. The DON will fund any increase of current federally funded brown treesnake interdiction measures (in Guam, CNMI, and Hawaii) where the increase is related to direct, indirect and induced growth caused by the USMC relocation to Guam. The fiscal year (FY) 2010 level of funding for the Federal interagency BTS interdiction effort on Guam, CNMI, and Hawaii and 2010 transportation levels associated with outbound cargo from Guam for the U.S. or U.S. territories will be used as the baseline. Any increase in funding will continue and become part of the DON's Brown Treesnake interdiction funding under authority of the Brown Tree Snake Control and Eradication Act (7 USC § 8501 note) (USFWS 2010a). The Service agrees that it is not DON's responsibility to fund increased interdiction measures *that are identified* more than one year after the end of the fiscal year both USMC relocation construction has ended and the permanent non-transient USMC military units have relocated to Guam. For the purposes of this Project Description, interdiction is defined as: "to hinder, prohibit, or prevent the brown treesnake from becoming established in new locations by conducting inspection and suppression processes."

   Since the original BO on DON was issued in 2010, the DON has worked with USDA and the Service to determine brown treesnake interdiction cost increases. To date, there has been no measurable increase in interdiction costs according to USDA.

c. Coordination with the USGS regarding the Brown Treesnake Research Closed Population Facility at NWF (located adjacent to the LFTRC and SDZ) – The DON will ensure through briefings or information packages that the personnel using the LFTRC know the importance of the facility and maintaining the integrity of the fence. An SOP will be developed as part of the Range Management Plan for the LFTRC to ensure the above and that USGS will be immediately notified in the event that the fence is accidentally damaged so the fence can be quickly repaired.

Conservation Measures to Minimize the Effects of Fire

The LFTRC and the Hand Grenade Range would be managed in accordance with Marine Corps Order (MCO) 3550.10, Policies and Procedures for Range Training Area Management, which addresses safe, efficient, effective, and environmentally sustainable use of the range area and includes fire management.

Fire management is a key component of range management. The DON goal is to reduce the effects of fires by limiting their frequency, size, and severity while still allowing the USMC to maintain a high level of combat readiness. In order to avoid or minimize impacts to listed

species or recovery habitat, the range management plan will include the following elements of fire management:

1. A Fire Danger Rating System tailored to the specific military uses at the LFTRC and the local weather and fuel conditions will be established. Weather readings will be taken every hour by remote automated weather stations (RAWS) on the installation. This information is immediately available to Range Control, who will use the output from the remote automated weather stations to determine the level of fire danger. This, in turn, determines any restrictions placed on military training for that hour. Restrictions are relayed to troops in the field via radio transmission. By restricting highly fire prone activities during periods of high fire danger, the likelihood of a fire start is reduced. Additionally, fires that are ignited are more likely to occur during periods of low or moderate fire danger, making them easier to control and extinguish.

2. Fuels management. All available fuel management techniques will be considered for fire break, fuel break, or fuel management area. Standard on-the-ground application is limited to mechanical cutting, herbicide application, and prescribed fire. If herbicide is to be applied, care will be taken to ensure there is no overspray into adjacent forested areas.

3. Locations and standards of fire breaks and fuel breaks. Fire breaks are similar to four-wheel-drive roads and are cleared of all vegetation to mineral soil. Fuel breaks are swaths of cut, burned, grazed or otherwise modified vegetation so that a fire's behavior is reduced. The fuel break widths are determined by fuels, topography, and prevailing winds. Fuel management corridors will be established and maintained providing areas through which fire will not carry. These corridors will provide several distinct areas where fire may be contained in order to prevent a catastrophic fire event. Each corridor will be approximately 100 to 300 m wide, although terrain, safety concerns, or protected resources may constrain the width in some areas. Fire breaks and fuel breaks shall be established immediately adjacent to the forest edge, along the outer perimeter of each range, so that there is no herbaceous vegetation along the edge of the forest.

   Fuel specifications within the corridor require that canopy cover not exceed 20 percent. Cover of fuel within the fuel management corridors will be measured at a scale of 10 meters. Within the fuel management corridors, no 10- by 10-meter area will have greater than 20 percent cover of fuel. Cover ‘starts/stops’ at the edge of a plant clump's canopy. The clump includes the dead herbaceous fuel on the ground. The frequency of a fuel break's upkeep is dependent on the speed of regrowth and/or colonization. If the vegetation within the range footprint is less than three feet tall, then no active management would be needed to maintain fuels at the < 3-ft height in the 40-60-m inner edge of the fuel break area.

4. Standard Operating Procedures (SOP). SOPs outline responsibilities for fire prevention, Fire Danger Rating System usage, staffing levels, equipment caches, fuel modifications, proper fire suppression actions, and post-fire reports. The SOPs also include fire prevention briefings to be given to range users prior to commencement of training,

notification lists in case of fire, operational decision charts for fires, and maps of resources, fuels, fire breaks, and Fuel Management Areas.

5. Range Control approval and guidance. Prior to firing all pyrotechnics (including tracers), Range Control approval and guidance must be obtained. Fire Department and Range Control personnel will have the authority to stop live-fire training for non-compliance with any training regulation and/or SOPs.

6. Fire Suppression. Water trucks (pickup truck with a tank in the back) will be on-site as a first responder vehicle. Water trucks may be supported by a fire truck or helicopter, as warranted.

7. The Service will be provided a 30-day review period, from the date of receipt of the draft draft Range Management Plan (including the fire management plan), to provide comments and recommendations for the DON's consideration. The Rire Management Plan will be finalized for the LFTRC prior to operation of the first range at the LFTRC.

Conservation Measures to Minimize the Effects of Training

1. Aviation Training in NMS (see Naval Munitions Site Operations above in the Project Description). All aviation training will be conducted so that flights will approach the southern portion of the NMS over the Talofofo River watershed and Fena Reservoir at heights of 1,000 ft (305 m) or greater above ground level. Flights may go up the Ugum River at altitudes of 1,000 ft (305 m) or greater above ground level until they reach 9,843 ft (3,000 m) from the mouth of the river at Highway 4 and then flights may conduct low level terrain flights. Low-level training flights will be restricted to the southernmost portion of the NMS where Mariana swiftlets are not commonly present. This measure is intended to avoid and minimize effects to swiftlets, and will be implemented during operations.

2. Ground Training in NMS (see Naval Munitions Site Operations above in the Project Description). The DON will maintain 328-ft (100-m) no training buffers around the known Mariana swiftlet nesting caves (*e.g.*, Mahlac Cave, Fachi Cave, Maemong Cave) in NMS. This measure is intended to avoid and minimize effects to Mariana swiftlets, and will be implemented during operations.

C. OTHER ACTIONS CONSIDERED FOR THE ANALYSIS

Although not part of the project description, a Memorandum of Agreement (MOA) between the DON and the Service regarding conservation of the Guam Micronesian kingfisher recovery habitat in northern Guam was signed by both parties on June 11, 2015. The purpose of the MOA is to ensure that a sufficient amount of suitable survival and recovery habitat (thereinafter "habitat") is conserved and managed in accordance with Federal agency obligations under section 7(a) of the ESA in northern Guam to support the reintroduction of the Guam Micronesian kingfisher (kingfisher). Another purpose of the MOA is to ensure that the DON meet the

purpose and need for the proposed action to relocation the USMC to Guam (DON and Service 2015c, p. 1; also see Appendix B).

The Service has determined that approximately 8,178 total acres are required on lands currently under the custody and control of DoD in northern Guam to provide sufficient habitat for the reintroduction and eventual recovery of the kingfisher. To facilitate kingfisher recovery goals, the DON agrees to designate approximately 5,234 acres under the custody and control of the DoD in northern Guam as identified in the MOA (DON and Service 2015c). These 5,234 acres have been identified by the Service as habitat for the kingfisher needed to offset impacts of the Guam Military Relocation (the proposed action). The DON and Service recognize that the designation of the 5,234 acres may also provide a conservation benefit to other federally-listed species with similar habitat requirements (*e.g.*, Mariana crow, Mariana fruit bat) (DON and Service 2015c, p. 3).

For the 5,234 acres of land identified, the Service required enhanced management activity to ensure this habitat supports the reintroduction of the kingfisher. Accordingly, starting in fiscal year 2016, the DON commits to provide an additional $2 million per year of funding for management activities above execution year INRMP funding levels (adjusted for inflation) for the next ten years, subject to Congressional authorization and appropriation. Upon expiration of this ten-year period, parties will reassess progress of recovery efforts and future funding may be available from DON (see section V4 of MOA, DON and Service 2015c).

D. ANALYTICAL FRAMEWORK FOR THE JEOPARDY/ADVERSE MODIFICATION ANALYSES

Jeopardy Determination

In accordance with policy and regulation, the jeopardy analysis of this Biological Opinion relies on four components: (1) *Status of the Species*, which evaluates the range-wide condition of the Guam Micronesian kingfisher (kingfisher), Mariana crow (crow), Guam rail (rail), Mariana fruit bat (bat), and *Serianthes nelsonii*, the factors responsible for that condition, and the survival and recovery needs of each species; (2) the *Environmental Baseline*, which evaluate the current condition of the kingfisher, crow, rail, bat, and *S. nelsonii* in the action area, the factors responsible for that condition, and the relationship of the action area to the survival and recovery of each affected species; (3) the *Effects of the Action*, which determines the direct and indirect impacts of the proposed Federal action and the effects of any interrelated or interdependent activities on the kingfisher, crow, rail, bat, and *S. nelsonii*; and (4) *Cumulative Effects*; which evaluates the effects of future, non-Federal activities in the action area on the kingfisher, crow, rail, bat, and *S. nelsonii*.

In accordance with the policy and regulation, the jeopardy determination is made by evaluating the effects of the proposed Federal action in the context of the kingfisher, crow, rail, bat, and *S. nelsonii* current status, taking into account any cumulative effects, to determine if implementation of the proposed action is likely to cause an appreciable reduction in the likelihood of both the survival and recovery of the kingfisher, crow, rail, bat, and *S. nelsonii* in the wild.

The jeopardy analysis in this Biological Opinion places an emphasis on consideration of the range-wide survival and recovery needs of the kingfisher, crow, rail, bat, and *S. nelsonii* and the role of the action area in the survival and recovery of the kingfisher, crow, rail, bat, and *S. nelsonii* as the context for evaluating the significance of the effects of the proposed Federal action, taken together with cumulative effects, for purposes of making the jeopardy determination.

Adverse Modification Determination

This Biological Opinion does not rely on the regulatory definition of "destruction of adverse modification" of critical habitat at 50 CFR 402.02. Instead, we have relied upon the statutory provisions of the ESA to complete the following analysis with respect to critical habitat.

In accordance with policy and regulation, the adverse modification analysis in this Biological Opinion relies on four components: (1) the *Status of Critical Habitat*, which evaluates the range-wide condition of designated critical habitat for the kingfisher, crow, and bat in terms of primary constituent elements (PCEs), the factors responsible for that condition, and the intended recovery function of the critical habitat at the range-wide scale; (2) the *Environmental Baseline*, which evaluates the condition of the critical habitat in the action area, the factors responsible for that condition, and the recovery role of affected critical habitat units in the action area; (3) the Effects of the Action, which determines the direct and indirect impacts of the proposed Federal action and the effects of any interrelated or interdependent activities on the PCEs and how that will influence the recovery role of affected critical habitat units; and (4) *Cumulative Effects*, which evaluates the effects of future, non-Federal activities in the action area on the PCEs and how that will influence the recovery role of affected critical habitat units.

For the purpose of the adverse modification determination, the effects of the proposed Federal action on kingfisher, crow, and bat critical habitats are evaluated in the context of the range-wide condition of the critical habitat at the range-wide scale, taking into account any cumulative effects, to determine if critical habitat at the range-wide scale would remain functional (or would retain the current ability for PCEs to be functionally established in areas of currently unsuitable but capable habitat) to serve its intended recovery role for the kingfisher, crow, and the bat.

The analysis in this Biological Opinion places an emphasis on using the intended range-wide recovery function of kingfisher, crow, and bat critical habitats and the role of the action area relative to those intended functions as the context for evaluating the significance of the effects of the proposed Federal action, taken together with cumulative effects, for purposes of making the adverse modification determination.

E. ACTION AREA

The term "action area" is defined in the implementing regulations for section 7 at 50 CFR 402.02 as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action."

The action area for this consultation is the island of Guam (Figure 4). The specific areas likely to be affected, directly or indirectly, by the proposed action are discussed in detail in the BA. In

addition to what is detailed in the BA, the following effects from the action may be Guam-wide: 1) effects from introduction of invasive species by the proposed action could spread throughout the whole island of Guam and 2) the population increase resulting from the proposed action will cause additional human disturbance throughout the island, including at recreation sites, hunting areas, traffic along roads, etc.

F. STATUS AND ENVIRONMENTAL BASELINE OF THE SPECIES

STATUS OF THE SPECIES

Status of the Guam Micronesian Kingfisher

Legal Status

The Guam Micronesian kingfisher (*Todiramphus cinnamominus cinnamominus*; "sihek" in Chamorro; hereafter, referred to as the kingfisher) was listed under the ESA as endangered in 1984 (USFWS 1984, 9 pp.). A revised recovery plan for the kingfisher was completed in 2008 (USFWS 2008a, 117 pp.). On October 28, 2004, the Service designated critical habitat for the kingfisher on approximately 376 ac (152 ha) in the fee simple portion of the GNWR (USFWS 2004, 117 pp.).

Species Description and Current Known Range

The kingfisher is endemic to the island of Guam in the Mariana Islands. Other subspecies, *Todiramphus* [=*Halcyon*] *c. pelewensis* and *T. c. reichenbachii*, exist on Palau (Republic of Palau) and Pohnpei (Federated States of Micronesia), respectively. The Guam subspecies is a small, sexually dimorphic forest kingfisher (Baker 1951, pp. 227–228). The adult male has a cinnamon-brown head, neck, upper back, and underparts. A black line extends around the back of the neck and the eye ring is black. The adult female resembles the male except that the upper breast is paler, as are the chin and throat, with the rest of the underparts and underwing coverts white (Jenkins 1983, p. 21). Immature birds have the crown washed in greenish-blue, and a whitish chin and throat. Underparts are buffy-white in the immature male, but may be paler in the female (Jenkins 1983, p. 21).

The kingfisher is extirpated in the wild on Guam but persists in captivity at the Guam DAWR facility and 24 U.S. mainland zoos and institutions. In response to the decline of Guam's native birds in the 1980s, the Association of Zoos and Aquariums (AZA) initiated the Guam Bird Rescue Project. Between 1984 and 1986, 29 kingfishers were translocated from Guam to zoos in the U.S. mainland to start a captive breeding program. The breeding program has been managed under the auspices of the AZA's *Micronesian Kingfisher Species Survival Plan* (Bahner et al. 1998, 54 pp.).

Life History

In the wild, kingfishers nest in cavities and feed primarily in mature, second growth limestone forest, and, to a lesser degree, in scrub limestone forest (Jenkins 1983, pp. 22–23). Kingfishers

are also known to use coastal strand vegetation containing coconut palm as well as riparian habitat. However, Jenkins (1983, p. 22) reported the kingfisher was probably most common along the edges of mature limestone forest. Few data exist about specific nest sites of the kingfisher in the wild, but in one study in northern Guam (Marshall 1989), 16 nest sites were correlated with closed canopy cover and dense understory vegetation. The report by Marshall (1989) indicated that kingfisher nest cavities were excavated from the soft, decaying wood of standing dead trees averaging 43cm (17 in) in diameter (Marshall 1989, p. 475). Kingfisher nests have been reported in a number of tree species including *Ficus* spp. (banyan), *Cocos nucifera* (coconut), *Artocarpus* spp. (breadfruit), *Pisonia grandis* (umumu), and *Tristiropsis obtusangula* (faniok) (Baker 1951, p. 228; Jenkins 1983, p. 24; Marshall 1989, p. 475).

Kingfisher breeding activity in the wild is thought to be concentrated from December to July (Baker 1951, p. 228; Jenkins 1983, p. 24). Pairs may excavate their own nests in soft trees, arboreal termitaria (the nests of termites [*Nasutitermes* spp.]), arboreal fern root masses, or they may utilize available natural cavities such as broken tree limbs (Jenkins 1983, p. 24; Marshall 1989, p. 474). Jenkins (1983, p. 23) observed that some excavated cavities were never used as nesting sites, which suggests that the process of excavating nest sites may be important in pair-bond formation and maintenance.

Both male and female kingfishers incubate eggs, and brood and feed nestlings (Jenkins 1983, p. 24). Clutch sizes from wild populations (n=3) were either one or two eggs (Baker 1951, p. 228; Jenkins 1983, p. 24) and clutch sizes of one to three eggs have been reported in the captive population (Bahner et al. 1998, p. 21). Incubation, nestling, and fledgling periods for populations of kingfishers in the wild are unknown. However, incubation and nestling periods of captive birds averaged 22 and 33 days, respectively (Bahner et al. 1998, p. 21).

Although there is still more to learn about the breeding behavior of Guam Micronesian kingfishers, it is known that the nest excavation and courtship stages are crucial to successful reproduction. Kingfishers excavate multiple cavities in trees before selecting a suitable nest site. Courtship includes cavity excavation, male feeding the female, and vocal duetting (simultaneous calling between members of a pair). These activities are common and are thought to function in both pair-bond maintenance and territorial maintenance (USFWS 2008a, p. 24; Bahner et al. 1998, p. 18). The breeding season for this species on Guam is reported to range from December to June, however, within the managed population (in captivity) we have seen reproduction in all months of the year with January through July being the prime breeding period. During the breeding season, it is important to minimize disturbance within the territorial range of breeding pairs. Based on experience with the managed population, Guam kingfishers are especially sensitive to stress which would likely be increased by noise and disturbance, and compounded during the breeding season (B. Bahner, Philadelphia Zoo, pers. comm. 2015). Additionally, anything that disrupts the availability of prey items in their territory would be detrimental would negatively affect kingfishers. There is no known recommended buffer around active kingfisher nests; however in captivity nesting kingfishers have sometimes been monitored by cameras to avoid disturbing breeding birds (Bahner et al. 1998).

In the wild, the kingfisher is known to feed on invertebrates and small vertebrates, including insects, segmented worms, hermit crabs, skinks, geckoes, and possibly other small vertebrates

(Marshall 1949, p. 210; Baker 1951, pp. 228–229; Jenkins 1983, p. 23). The species typically forages by perching motionless on exposed branches or telephone lines and swooping down to capture prey off the ground with their bill (Jenkins 1983, p. 24). They also will capture prey off nearby foliage and have been observed gleaning insects from bark (Maben 1982, p. 78).

Records of kingfisher distribution and intraspecific territorial behavior suggest this species maintains exclusive year-round territories in the wild (Jenkins 1983). Research and observations of the related Pohnpei kingfisher show this species has a "helper" social system where birds from previous nests may stay in the parental territory for several years. Pohnpei kingfishers defend their approximately 8.1 hectare (20 ac) territories from conspecifics (Kesler and Haig 2007a, pp. 386-387). Kesler and Haig (2007b, pp. 769–770) determined that kingfisher home ranges on Pohnpei consist of mixed forest and open areas and at least part of this area includes mature forest. It should be noted that Guam Micronesian kingfisher territories may differ from Pohnpei Micronesian kingfisher territories due to differences in forest structure (Mueller-Dombois and Fosberg 1998, pp. 269–275, 288–291). However, information on the related Pohnpei kingfisher as a surrogate species to the Guam Micronesian kingfisher represents the best available scientific information on kingfisher territory size and home ranges in the Pacific islands to date.

The life expectancy of the kingfisher in the wild is unknown. However, demographic data from captive kingfishers suggest that life history traits such as lifespan and reproductive span differ between the sexes. In captivity, males have a longer lifespan (23 years) than do females (15 years). Both males and females can reproduce at 1 year of age. In captivity, males have been observed to breed as old as 19 years, while females have not been observed to breed beyond the age of 12 (AZA 2014, p. 4).

Current Status

The kingfisher is currently extirpated from the wild. It was considered "fairly common" and occurred throughout forested areas on Guam in 1945 (Baker 1951, p. 229). Populations in southern and central Guam disappeared by the 1960s (Jenkins 1983, p. 25) and 3,023 individuals were recorded in 1981 in northern Guam (Engbring and Ramsey 1984, p. 34). The northern Guam population subsequently declined rapidly, and by 1985, fewer than 30 individuals were recorded on Guam (Marshall 1989, p. 474) and the taxon was considered extirpated from the wild by 1988 (Wiles et al. 2003, p. 1,354). Predation by the brown treesnake is considered the main cause of the decline of the kingfisher population on Guam (Savidge 1987, USFWS 2008a, p. iv). Between 1984 and 1986, 29 kingfishers were captured and sent to zoological institutions in the U.S. mainland (Hutchins et al. 1996, p. 4). Currently, the captive population consists of 155 adult kingfishers (86 males and 69 females) in captive rearing facilities (GMKF Recovery Team 2015, p.3). In 2015, the Service provided funding to the Boorkfield Zoo in Illinois to install 30 new cages, which would increase the population by more than 25 percent.

The goal of the captive kingfisher propagation program is to grow the population while trying to maintain genetic diversity above 90 percent heterozygosity. The current captive population was founded by 16 of the 29 individuals brought into captivity. The current gene diversity is 87.74 percent; with the potential to reach 92.45 percent (AZA 2014, p. 4).

Threats (see also the General Environmental Baseline section of this Opinion)

The Service intends to reintroduce the kingfisher into the wild on Guam. For that effort to be successful, the following threats need to be addressed. The following discussion is adapted from Service (2014, p. 2):

- Loss or Degradation of Habitat
    - Incremental habitat loss due to fire, especially in southern Guam (Department of Agriculture 2010), and urban and agricultural development is increasingly threatening the long-term conservation of the kingfisher because of the continued loss of habitat on Guam.
    - Ongoing and proposed plans by DoD to expand training and operations on Guam are threatening much of the remaining kingfisher habitat.
    - The persistence of large, feral ungulate populations is likely to further degrade remaining forest habitats, thus lowering their value for kingfisher recovery.

- Predation
    - Predation risk from brown treesnakes currently prevents effective reintroduction of the kingfisher to Guam.

- Stochastic Events
    - Typhoons will continue to degrade forest and the affected forest areas may require several years to regenerate.
    - Although birds in the Mariana Islands have evolved with typhoons, typhoons in concert with low population numbers, habitat loss, and behavioral and genetic consequences of captive breeding could negatively affect the recovery of the Guam Micronesian kingfisher.
    - Climate models indicate that hurricanes in the northwestern Pacific are expected to increase in intensity, frequency, and duration by 2200 and continue to increase further into the future (Emanuel et al. 2008, p. 360). These storm increases will likely have a significant effect on habitat and survival of listed species on Guam.

Survival and Recovery Needs

For purposes of this Opinion, the "survival condition" of the kingfisher in the wild represents the level of reproduction, numbers, and distribution necessary to support a persistent population on Guam that is fully protected by the ESA. For purposes of this Opinion, the "recovery condition" of the kingfisher is the survival condition where the threats to the species have been addressed such that the protections of the ESA are no longer necessary to ensure perpetuation of the survival condition of the kingfisher in the wild.

The recovery plan (USFWS 2008a) for the kingfisher calls for a total viable population of 2,000 adult kingfishers on Guam within two subpopulations of 1,000 adults each. One subpopulation would be located in northern Guam, and one subpopulation would be located in southern Guam to reduce the risk of a second extirpation event due to random, stochastic events. For the purpose of population viability modeling to identify viable subpopulations that would meet a minimum population growth rate to achieve recovery, we assumed that the 1,000 adults are 500 breeding pairs (see Environmental Baseline section for kingfisher). The area requirements for a breeding pair (approximately 20.0 acres; Kesler and Haig, 2007a) is less than the combined area for an individual non-breeding adult male (average of 17.5 acres; Kesler and Haig 2007a) and an individual non-breeding adult female (average of 14.1 acres; Kesler and Haig 2007a). Thus the total area for recovery will be minimized by assuming all 1,000 adults are in breeding pairs. Additional area may be needed if a significant number of adult kingfishers forgo breeding in any year.

Each subpopulation must have brown treesnakes and other predators controlled to a level where establishment of a sustainable kingfisher population is feasible and habitat to support this population level must be protected and managed. In the interim, the kingfisher also may need to be established in the wild on other islands outside their native range to reduce the detrimental consequences of long-term captivity and to spread the risk from stochastic events. Although any population(s) established on other islands outside of the kingfisher's historical range would be considered temporary and would not contribute toward the recovery goal of two subpopulations of 1,000 adults each on Guam, the ability to translocate wild birds versus captive birds to Guam would increase success of their recovery and survival on Guam. However, ultimately the recovery of the kingfisher is dependent on having adequate protected habitat free of threats on Guam to provide for the two subpopulations.

New management actions that have occurred in the last five years include:

- Construction of the 136-ac (55-ha) Habitat Management Unit (HMU) brown treesnake and ungulate exclosure fence at Anderson Air Force base. Ungulate removal within the HMU is near completion by DoD per a section 7 consultation requirement (USFWS 2006b).
- In 2014, the USDA-APHIS Wildlife Services, in coordination with the National Wildlife Research Center, the DoD-Environmental Security Technology Certification Program, and the Department of Interior-Office of Insular Affairs, conducted a test of aerial application of a brown treesnake toxicant (acetaminophen) over forested areas in AAFB (Dorr et al. 2014, unpublished data). The results of this study within the approximately 136-acre (55-hectare) HMU on AAFB may result in the reduction of snake numbers to a low enough level to allow kingfishers to survive and reproduce within this snake-proofed area on Guam. The knowledge gained from this study will help with potential future improvements to the method and efficiency of the delivery of the acetaminophen to snakes on Guam.
- Construction of a 312-ac (112-ha) ungulate exclosure fence at Northwest Field on AAFB by DoD per Biological Opinion requirements (USFWS 2006b and USFWS 2006c).

- Construction of a multi-species exclosure fence within the fee simple portion of the GNWR at Ritidian Point, Guam.
- Construction of 4,400 ft of coated chain link fence along Route 2A on the perimeter of NBG by DoD per Biological Opinion requirements (USFWS 2010a). The fence provides an ungulate exclosure for the 3,114 ac (1,260 ha) of the main base of NBG. The fencing project is intended to effectively close off Orote peninsula from any new ungulate incursions and only entry control gates will be left unfenced. Ungulate removal within NBG is ongoing.

Recommendations for Future Actions (adapted from USFWS 2008a; USFWS 2014a, p. 3):

- Maintain or increase genetic diversity in the captive kingfisher population by implementing management strategies to exploit the potential gene diversity in the captive populations at the DAWR and AZA facilities.

- Predator Monitoring and Control
  - Continue efforts to develop and refine brown treesnake control techniques and support small-scale and large-scale control and/or eradication efforts on Guam.

- Reintroduction / Translocation
  - Develop a reintroduction plan for the kingfisher on Guam and set aside and protect recovery areas to facilitate its de-listing as soon as possible following the reintroduction of the kingfisher on Guam.

- Protection and restoration of kingfisher recovery habitat, including permanent protection as conservation areas and fencing to exclude brown treesnakes and ungulates.

Status of the Mariana Crow

Legal Status

The Mariana crow ("aga" in Chamorro) was listed as endangered throughout its range in 1984 and critical habitat was designated on Guam and Rota (USFWS 1984, pp. 33881-33885; 2004, pp. 62944-62990). No significant new information regarding the biological status has come to light since listing to warrant a change in the federal listing status of the Mariana crow. On October 28, 2004, the Service designated critical habitat for the Mariana crow on approximately 376 ac (152 ha) in the fee simple portion of the GNWR (USFWS 2004, 117 pp.).

Species Description and Known Range

The Mariana crow is the only member of the genus *Corvus* occurring in Micronesia (Jenkins 1983, p. 25). This species is known historically only from the islands of Rota and Guam, but is now extirpated from Guam. Preliminary genetic studies indicate that the Rota population is most likely a genetic subset of the Guam population (Tarr and Fleischer 1999, p. 946).

Life History and Population Dynamics

Mariana crows are omnivorous, and their diet includes a wide variety of plants and animals, including insect larvae, centipedes, grasshoppers, mole crickets, praying mantis, earwigs, hermit crabs, skinks, geckos, and bird eggs (Jenkins 1983, p. 26, 31; Tomback 1986, p. 399; Ha and Ha 2010a, pp. 8-10; Faegre *in press*). Faegre (*in press*) observed 619 food captures from approximately 36 wild crows and found that 14 percent of food captures were of plant-based foods, and 86 percent were from animal prey; 65 percent of animal prey were of insects or their larvae.

Mariana crows use forested habitats including limestone, strand, ravine, agricultural forests, and secondary forests (Jenkins 1983, p. 25, 32). However, evidence suggests they are most abundant in native limestone forests (Morton et al. 1999, p. 13, 41; Ha et al. 2011a, p. 25; Ha et al. 2011b, p. 240) and nests are found exclusively in native trees (Morton et al. 1999, p. 13, 33; Ha et al. 2011a, 2012, and 2013, pp. 32, 25, and 24-31, respectively). Nesting occurs in closed canopy forests in trees that are on average 17 cm in diameter at breast height, 8.7 m high, and 290 m from roads (Morton et al. 1999, p. 32).

Breeding likely occurs all year on Rota, while peak nesting activity generally occurs between August and February (Morton et al. 1999, p. 12; Ha et al. 2013, p. 31). A minimum of 65 days is necessary to build the nest, incubate the eggs, and rear the brood through fledging (Morton et al.1996, p. 21). Both parents generally participate in all aspects of breeding, although the female incubates most of the time (Morton et al. 1996, p. 21). The incubation period is 21 to 23 days, and the nestling period is 36 to 39 days (Morton et al. 1996, p. 21). After fledging, Mariana crows will typically remain in family groups until the following breeding season, a period that averaged 241 days (SE = 33, median 197 days) for 15 banded family groups (Morton et al. 1996, p. 21). However, the period of parental attendance after fledging varies widely, from 99 to 537 days (USFWS 2005a, p. 19). Mariana crows will often reinitiate the nest cycle within two weeks after abandoning an empty nest, and within four weeks after losing a clutch or brood (USFWS 2005a, p. 18).

Mariana crows generally produce only a single brood per year; however, nest failure and other factors lead to multiple nest attempts each breeding season. From 1996 to 1999, 32 crow pairs on Rota constructed a mean of 2.2 nests per year (SE = 0.14, n = 78), with one pair building as many as seven nests in one season; however, not all nests resulted in egg deposition (Morton et al. 1999, p. 14, 36). Zarones et al. (2014, pp. 6-7) examined 204 active nests on Rota from the 1996 to 2009 breeding seasons and documented, on average, a clutch size of 2.57 (SD = 0.8, n = 82), 1.39 nestlings per nest that hatched (SD = 0.5, n = 106), 1.25 fledglings per nest that fledged (SD = 0.4, n = 68), and an overall nest success rate of 25.7 percent. The proportion of monitored pairs that produced at least one fledgling per breeding season ranged from 0.21 to 0.73, with an overall rate of 0.49 over the entire study period. During the 2013 breeding season, 16 of the 46 pairs (35 percent) successfully fledged young (Kroner 2014, p. 3). The estimated pair breeding success rate for 2013 was down from 60 percent in 2008 (Zarones et al. 2014, p. 7) and 57 percent in 2012 (Ha et al. 2013, pp. 59-60).

Little is known regarding lifespan, age of sexual maturity, and length of reproductive life in Mariana crows. The oldest known wild crow was at least 18 years old when last observed on Rota in 2014 (A. Kroner and S. Faegre, University of Washington, pers. comm. 2014). This same adult male was at least 17 years old when he was last seen feeding a fledgling in 2013. Another male was 14 years old when he last produced a chick in 2009, and a 15-year-old female was observed with a fledgling in 2014 (S. Faegre, University of Washington, pers. comm. 2014). Although it was originally thought that Mariana crows begin breeding around 3.5 years old (Morton et al. 1999, p. 2), a radio-tagged male Mariana crow built his first nest at 16 months of age and was observed feeding a fledging at 21 months of age. Two other banded crows, a female and a male, successfully fledged young in 2011 and 2013, just after they turned two years old (A. Kroner and S. Faegre, University of Washington, pers. comm. 2014). A banded female was observed at a recently failed nest when she was approximately 1.5 years old (A. Kroner and S. Faegre, University of Washington, pers. comm. 2014).

Survival to one year of age for male and female Mariana crows banded on Rota between 1990 and 2010 was 49.9 and 75.2 percent, respectively (Ha et al. 2010b, p. 25). Annual survivorship for adult males and females was 83.5 and 82.7 percent, respectively (Ha et al. 2010b, pp. 25-26). Recent analyses suggest that first-year survival has increased to 0.65 and adult survival has remained steady at about 0.80 since 2010 (R. Ha, University of Washington, pers. comm. 2014).

Mariana crows are known to be highly susceptible to disturbance from human activities (Morton 1996, p. 60, 62, 72; Ha, R. 2015, pers. com.; Ha et al. 2011, p. 5). Based on observations of disturbance of crow nests on Guam, Morton (1996, p. 72) recommended a 300-meter radius for a buffer zone around active crow nests; Morton's recommendations were based on observations of crows reacting to facility/grounds maintenance, brown treesnake trapping, research activities, loud music, and human voices. One Mariana crow nest on Guam was abandoned due to disturbance from maintenance activity and from radio noise coming from a sound system 150 meters away (Morton 1996, p. 62). Ha et al. (2011, p. 236) found that nest sites were always greater than 300 meters from any buildings, and that actual nest sites were almost twice as far from roads and buildings as random sites.

Distribution, Status, and Threats

Guam

Although the Mariana crow was once present throughout Guam (Baker 1951, p. 246), the population has been declining since at least the 1960's (Engbring and Ramsey 1984, p. 30; Engbring et al. 1986, p. 92) and is now extirpated. The last known crow of Guam origin was observed in 2001, and the last known wild Mariana crow that was captive-reared from Rota and released on Guam was observed in 2012 (J. Quitugua, DAWR, pers. comm. 2014). Predation by brown treesnakes is the overriding factor in the extirpation of Mariana crows from Guam (USFWS 2005a).

Suitable habitat for Mariana crows is still present on Guam. As described below in the Environmental Baseline for the Mariana Crow, we estimate that 24,919 acres (10,084 ha) of Mariana crow habitat is left on Guam. More information on crow habitat is provided in the Environmental Baseline for the Mariana Crow section below.

Rota

In 1976, Mariana crows were considered relatively common and widely distributed on Rota (Pratt et al. 1979, p. 234). Reanalysis of the first island-wide survey for the species on Rota in 1982 using current density estimate methods resulted in a population estimate of 1,491 birds (815-3115 birds, 95 percent confidence interval) (Engbring et al. 1986, pp. 92-95; F. Amidon, USFWS, pers. comm. 2014). The most recent island-wide pair survey on Rota was conducted during the 2013 breeding season and documented 46 breeding pairs; an approximate 94 percent decrease in the population since 1982 (Kroner 2014, p. 3). The primary threats to the Mariana crow on Rota are suspected to be predation by cats, human persecution, and habitat destruction (USFWS 2014b, p. 3), but evidence is limited and substantially more research is needed.

Mariana crow telemetry studies were conducted from 2009-2013 and will begin again in the 2014-2015 nesting season. Before telemetry studies began on Rota there was no evidence available to suggest feral cats (*Felis silvestris*) were predating crows. The lack of evidence was likely due to high scavenging and decomposition rates, and the extreme unlikelihood of finding a fresh carcass in time to retrieve any useful information regarding cause of death. Since telemetry efforts began, nine recently-deceased, radio-tagged Mariana crows have been found with evidence suggesting cat predation, and one untagged adult was taken in for care and later died after receiving what a veterinarian confirmed as an infected cat bite (Ha et al. 2013, pp. 5-6).

Recovery Criteria for the Mariana Crow

The following criteria are taken from the Draft Revised Recovery Plan for the Mariana Crow (USFWS 2005a).

1. The Mariana crow may be considered for downlisting from endangered to threatened status when all of the following criteria are met:
    a. Mariana crow occur in two populations, one on Rota consisting of a minimum of 75 territorial pairs, and 1 in northern Guam consisting of a minimum of 75 territorial pairs;
    b. Both populations are stable or increasing based on quantitative surveys or demographic monitoring that demonstrates an average intrinsic growth rate (λ) not less than 1.0 over a period of at least 10 consecutive years;
    c. Sufficient Mariana crow habitat, based on quantitative estimates of territory and home range size, is protected and managed to achieve criteria 1 and 2 above;
    d. Brown treesnakes and other introduced predators found to be a threat to Mariana crow are controlled at a sufficient level to achieve criteria 1 and 2 above;
    e. Brown treesnake interdiction efforts are in place to prevent the establishment of brown treesnakes on Rota; and
    f. Efforts to resolve Mariana crow and landowner conflicts have been implemented.

2. The Mariana crow may be removed from the Federal list of threatened and endangered species when all of the following criteria are met:
    a. Mariana crow occur in three populations, one on Rota consisting of a minimum of 75 territorial pairs, one on northern Guam consisting of a minimum of 75

territorial pairs, and one in southern Guam consisting of a minimum of 75 territorial pairs;

b. All three populations are stable or increasing based on quantitative surveys or demographic monitoring that demonstrates an average intrinsic growth rate (λ) not less than 1.0 over a period of at least 10 consecutive years;
c. Sufficient Mariana crow habitat, based on quantitative estimates of territory and home range size, is protected and managed to achieve criteria 1 and 2 above;
d. Brown treesnakes and other introduced predators are controlled at a sufficient level to achieve criteria 1 and 2 above;
e. Brown treesnake interdiction efforts are in place to prevent the establishment of brown treesnakes on Rota;
f. Efforts to resolve Mariana crow and landowner conflicts have been implemented; and
g. A monitoring plan has been developed and is ready for implementation, to cover a minimum of five years post-delisting, to ensure the ongoing recovery of the species and the continuing effectiveness of management actions.

Since the draft revised recovery plan was published in 2005, additional work on population viability of the Mariana crow has occurred. This recent assessment of population viability indicated that 75 territorial breeding pairs may not be viable over the long-term due to potential inbreeding depression (O'Grady et al. 2006) and projected increases in tropical storm intensity, duration, and frequency (Emanuel et al. 2008) and that 100 territorial breeding pairs may be a more appropriate recovery target (Amidon 2012, unpubl. data).Therefore, the Service now considers 100 territorial breeding pairs as our recovery target for each of the three regions identified above.

Survival and Recovery Needs on Rota

Management and recovery actions that have occurred in the last five years (USFWS 2014b, pp. 3-4) include:

- Banding: The University of Washington's Rota Avian Behavioral Ecology Program (RABEP) has banded 80 Mariana crows since 2005 (Ha et al. 2013 pp. 5-6; Kroner 2014, p. 3). Re-sight data has been used to develop age-specific survivorship models.
- Nest monitoring: RABEP have conducted nest monitoring for the Mariana crow on Rota since 2005. Efforts provide data that is used for analyses of nesting success and demographics.
- Mariana crow mortality monitoring: From 2009 to 2013, transmitters were attached by RABEP to 32 Mariana crows that were tracked and monitored for the life of the battery (n=14), until death of the bird (n=12), loss of the signal (n=1), or until the harness was removed (n=5) (Ha et al. 2013, pp. 5-6).
- Habitat and natural process management and restoration: The Mariana Crow Conservation Area (MCCA) was established on Rota through an MOA between the Commonwealth of the Northern Mariana Islands (CNMI) and PIFWO (USFWS 2011, pp. 1-4).
- Human interaction monitoring and management: The Mariana Crow Incentive Plan (2012-2014) compensated participants on Rota with a monetary award in exchange for

protecting occupied crow habitat and allowing access for population monitoring and feral cat control on their land (USFWS 2012a, pp. 1-8). The goal of the plan was to change human perceptions of the Mariana crow and protect valuable habitat.

- Predator monitoring and control: The University of Washington Rota Island Feral Cat Removal Project began cat removal efforts on Rota in February 2012 (Ha et al. 2013, p. 49). As of June 2014, the project removed 589 cats from areas in and around crow territories (Leo 2014, p. 3). The Institute for Wildlife Studies took over cat control efforts on Rota in October 2014.
- Captive care: Captive care of sick or injured crows is conducted on an as-needed basis by RABEP captive care specialists.
- Release of rehabilitated crows: Crows are released into the wild after they have been rehabilitated and reared to at least 2 years of age. Two crows were successfully released after being taken in as fledglings and reared to adulthood in captivity (Hannon 2014, pp. 1-3).
- Strategic planning / threats management planning: The Service in cooperation with the Mariana Crow Recovery Team conducted an exercise in structured decision making (SDM) to determine which actions should be taken now and over the next several years to maximize the probability of preventing extinction and set the foundation for at least one stable to increasing population in the wild (see below). The two primary objectives driving the SDM were to prevent the extinction of the Mariana crow and to ensure a viable stable or increasing population in the wild.

Recovery actions still needed to prevent the extinction of the Mariana crow on Rota:

- Implement priority actions identified in the Mariana crow SDM exercise:
  - Predator control on Rota
  - Phased approach to captive propagation, beginning with rear and release program
- Identify and manage sources of adult and juvenile mortality
- Improve public perception of the crow to reduce potential human persecution
- Protect important habitat on Rota and Guam
- Research and reduce the threat of the brown treesnake on Rota and Guam

<u>Survival and Recovery Needs on Guam</u>

Management and recovery actions that have occurred in the last five years include:

- Construction of a 312-ac (112-ha) ungulate exclosure fence at Northwest Field on AAFB by DoD per Biological Opinion requirements (USFWS 2006b). However, the DON has proposed to build the proposed LFTRC within this mitigation site, which is also located on Overlay Refuge.
- Construction of the 136-ac (55-ha) Habitat Management Unit (HMU) brown treesnake and ungulate exclosure fence at AAFB. Ungulate removal within the HMU is near completion by DoD per a section 7 consultation requirement (USFWS 2006c).
- Construction of a multi-species exclosure fence within the fee simple portion of the GNWR at Ritidian Point.
- Construction of 4,400 ft of coated chain link fence along Route 2A on the perimeter of NBG by DoD per Biological Opinion requirements (USFWS 2010a). The fence provides

an ungulate exclosure for the 3,114 ac (1,260 ha) of the main base of NBG. The fencing project is intended to effectively close off Orote peninsula from any new ungulate incursions and only entry control gates will be left unfenced. Ungulate removal within NBG is ongoing.

- In 2014, the USDA-APHIS Wildlife Services, in coordination with the National Wildlife Research Center, the DoD-Environmental Security Technology Certification Program, and the Department of Interior-Office of Insular Affairs, conducted a test of aerial application of a brown treesnake toxicant (acetaminophen) over forested areas in AAFB (Dorr et al. 2014, unpublished data). The results of this study within the approximately 136-acre (55-hectare) HMU on AAFB may result in the reduction of snake numbers to a low enough level to allow kingfishers to survive and reproduce within this snake-proofed area on Guam. The knowledge gained from this study will help with potential future improvements to the method and efficiency of the delivery of the acetaminophen to snakes on Guam.

Recovery actions still needed to allow the reintroduction of the Mariana crow to Guam

- Development and implementation of large-scale, long-term methods for brown treesnake control that will reduce the brown treesnake population on a landscape level.
- Protection and restoration of Mariana crow habitat in northern and southern Guam including in-perpetuity protection as conservation areas and fencing to exclude brown treesnakes and ungulates.
- Continued management of the fenced exclosures at Northwest Field, the HMU, and NBG as described above.

Status of the Guam Rail

Legal Status

The Guam rail (*Gallirallus owstoni*; ko'ko' in Chamorro; hereafter, rail) was listed as endangered on Guam in 1984 (USFWS 1984, pp. 2485-2488). An experimental, nonessential population of rails occurs on Rota. The rails on Rota are treated as threatened species, rather than as endangered species, for the purposes of sections 4(d) and 9 of the ESA (USFWS 1989, pp. 43966-43970). Critical habitat for the rail has not been designated on Guam.

Species Description and Current Known Range

The Guam rail is endemic to the island of Guam in the Mariana Islands. The species is derived from the closely related barred rail (*Gallirallus torquatus*) of the Philippines and Indonesia (Ripley 1977). No closely related species occur in Micronesia. The rail is medium-sized and capable of short burst of flight (1 to 2 m), but is seldom observed in flight (Jenkins 1979, p. 404). Rails are about 28 cm (11 in) in total length (Taylor 1998, p. 258). Guam rails have elongated and laterally compressed, particularly in the neck and breast regions, bodies allowing the birds to move rapidly through dense vegetation.

The rail is extirpated in the wild on Guam but persists in captivity at the Guam DAWR facility and twelve U.S. mainland zoos (AZA 2014, p. 1). Efforts to establish a nonessential experimental population on the island of Rota has been underway since 1989. The establishment

of a wild population on Rota will ensure that a source wild population is available for future repatriation of rails to Guam when brown treesnakes have been controlled or eradicated on Guam (USFWS 1989, p. 43967). On Cocos Island (a small islet approximately 1.6 km (1 mi) off the southern coast of Guam), breeding pairs of rails have become established in a predator-controlled habitat through efforts associated with a Safe Harbor Agreement and activities permitted under section 10(a)(1)(A) of the ESA (USFWS 2008b; USFWS 2008c, p. 1-2). This agreement, signed in 2008, has allowed for the establishment of Guam rails on private land owned and managed by Cocos Island Resort and public land owned by the Government of Guam and managed by the Guam Department of Parks and Recreation. The rails are monitored to learn more about survivorship, breeding behavior, habitat preference and nesting success.

Life History

The Guam rail formally occurred in most habitat types on Guam, including forest, savanna, secondary grassland, agricultural areas, mown grass bordering scrub communities, mixed woodland and scrub, and fern thickets (Jenkins 1979, p. 405-406; Taylor 1998, p. 259). Guam rails were predominantly observed using scrubby secondary growth area and the edges of mixed forest areas (Jenkins 1979, Engbring and Ramsey 1984). Jenkins (1979) reports that they were seldom observed in the interior of mature limestone forests or savanna areas and did not occur in wetlands. As Guam was probably mostly limestone forest before the arrival of humans (Forsberg 1960), the rail may have become more common after much of the mature forest had been converted to scrubby second-grown or mixed forest (Engbring and Ramsey 1984).

The diet of the Guam rail is comprised of snails, slugs, lizards, insects, and vegetable matter such as seeds and palm leaves; the rail feeds on food items from the surface of the ground, especially snails and slugs after rain showers (Jenkins 1979, pp. 405-406). They chase low-flying insects and feed on seeds and flowers from low grasses and shrubs, stretching up to reach items 40 cm above the ground. They often forage along edge habitat but seldom venture far from cover (Jenkins 1979, p. 404; Taylor 1998, p. 259). During the dry season the rails were reported to damage crops such as tomatoes, cucumbers and melons, but such damage probably resulted from their obtaining moisture rather than food. Rails also ingest coral chips and pieces of small shell for grit (Jenkins 1979, p. 405-406). They are able to forage at night, but are most active during the dawn and dusk (Jenkins 1979, p. 404-406; Taylor 1998, p. 259).

Guam rails are monogamous and breed throughout the year (Jenkins 1979, p. 406; USFWS 1990a, p. 9), with a possible peak breeding period during the rainy season (May-October) (Perez 1969 as cited in the USFWS 1990a, p. 9). They can lay two to four eggs per clutch and both parents share in the construction of the nest. Nests are located on dry ground in dense grass, are a shallow cup of interwoven loose and rooted grass, and are built by both sexes (Jenkins 1979, p. 406; Taylor 1998, p. 260). Incubation of eggs is 21 days (Beck 1985, unpubl. data cited in USFWS 1990a, p. 9) with both sexes sharing the nesting duties. The eggs hatch asynchronously, and the young are precocial, leaving their nests within 24 hours of hatching to forage with the aid of their parents (Jenkins 1979, p. 406).

In captivity, Guam rails can live up to 17 years, while females can reach 16 years old. Median life expectancy for captive males is 9.5 years; captive female median life expectancy is slightly lower at 5.7 years (AZA 2014, p. 5). The median life expectancy of Guam rails in the wild is unknown. Both males and females can begin reproducing at approximately 5 months old. Males have bred until the age of 11, and females as old as 9 years old have successfully reproduced. Breeding in captivity is complex, as males can be extremely aggressive and have at times injured or killed females. In captivity, clutch sizes range from one to six eggs, averaging 2.1 eggs, with an incubation period of 19 days.

Population Dynamics and Status

Guam rails were once distributed throughout Guam (USFWS 1990a, p.7). They first disappeared from southern Guam in the early 1970's (Jenkins 1979). In 1981, the population was reduced to approximately 2,300 individuals and only existed in northern Guam (Engbring and Ramsey 1984, p. 28). In 1983, estimates of the population size indicated that fewer than 100 individuals remained on Guam and 22 individuals were moved to captive propagation facilities (Haig and Ballou 1995, p. 446). The rail was extirpated on Guam by 1987 (Wiles et. al. 1995, p. 38).

There have been two releases of rails on Guam since this species has been listed as endangered. In 1998, 16 rails were released in "Area 50" at AAFB in northern Guam (Beauprez and Brock 1999). A temporary brown treesnake barrier was constructed around Area 50 and snake populations in the barrier were reduced through snake control. Breeding was documented, although the small population was extirpated by predators, mainly feral cats. In 2003, a second release of 44 rails occurred in a brown treesnake-reduced area of the Munitions Storage Area on AAFB (P. Wenninger, DAWR, pers. comm. 2008). Efforts to reduce cat predation on the rails were limited due to difficulty in obtaining approval to control cats in the area. By 2008, rails no longer were present in the Munitions Storage Area (P. Wenninger, DAWR, pers. comm. 2008; USFWS 2009b, p. 5).

On Rota, over 800 captive-bred Guam rails have been released between 1989 and 2008 in an effort to establish an experimental wild population (Witteman and Beck 1990, Beck 1991, Brock and Beck 1995, Beauprez and Brock 1996-1999a, P. Wenninger, DAWR, pers. comm. 2008). The introduction to the island of Rota, which is outside the historical range of the species, was justified because primary habitat on Guam had been altered through the establishment of the introduced, predatory brown treesnake (USFWS 1989, p. 43966). Improvements in managing the captive flock have increased the number of rails available for each release and the larger release cohorts have increased the likelihood of population establishment. Population estimates in 2002 indicated 100 rails were present on the northeast end of Rota near two release sites, Duge and Saguagaga. Based on surveys conducted in July 2013, there are approximately 125 rails on Rota (S. Medina, DAWR, pers. comm. 2013). However, released birds still suffer mortality primarily due to feral cat predation, which slows population establishment. Current release strategies include intensive cat trapping and a review and update of monitoring protocol for rails on Rota.

On Cocos Island, sixteen captive bred rails were released in November 2010. Prior to the release, rats (*Rattus* spp.) were eradicated on Cocos Island. Guam rails are successfully breeding

(16 nests and 12 chicks have been observed) on Cocos Island. Sightings of unbanded adults have been documented, which suggests that chicks are surviving into adulthood (S. Medina, DAWR, pers. comm. 2013).

As of December 30, 2014, the Guam rail captive population is distributed among 14 institutions, with the Guam DAWR facility holding 116 birds and the 13 Association of Zoos and Aquariums (AZA) facilities housing 46 birds. At that time, current gene diversity was 88 percent in the DAWR facility and 83 percent at the AZA facilities (AZA 2014, p. 4). When gene diversity falls below 90 percent in a founding population, it is expected that reproduction will be compromised by, among other factors, lower hatch rates, small clutch sizes, and greater neonatal mortality (Ross et al. 2006). However, there still remains the potential to increase the gene diversity in DAWR and AZA facilities over the long term (AZA 2014, p. 6). The DAWR and AZA work cooperatively and closely coordinate on the transfer of birds to facilities, as needed, in order to manage the genetic diversity within the captive Guam rail population (AZA 2014, p. 4). These facilities also support the releases of individuals into the wild on Rota.

Threats (adapted from USFWS 2014c, p. 2-5):

- Loss or degradation of habitat –
    - Agricultural and urban development is a factor in habitat loss and degradation on Guam.
    - Nonnative snake predation. The brown treesnake continues to limit efforts to reestablish rails on Guam.
    - Cat predation. Feral cats continue to limit efforts to reestablish rails on Guam and impact the rail experimental population on Rota.
    - Rodent predation. Because rats have been eradicated and are absent from Cocos Island, there is continued efforts to prevent the reintroduction of rats to this island. Rats can negatively impact rails by consuming eggs and preying on chicks.
    - Stochastic events – Although birds in the Mariana Islands have evolved with typhoons, typhoons in concert with low population numbers, habitat loss, and behavioral and genetic consequences of captive breeding could negatively affect the recovery of the Guam rail.

Survival and Recovery Needs

Before the Guam rail is considered for downlisting from endangered to threatened, the repatriation of 1,000 birds to northern Guam and 1,000 birds to southern Guam (total = 2,000 individuals; USFWS 1990a, p. 33) would need to occur and brown treesnakes would need to be controlled on Guam (USFWS 1990a, p. 33-34). No criteria were defined for delisting. Traill et al. (2009) proposed a minimum population target of 5,000 individuals as an appropriate target for species conservation.

New management actions that have occurred in the last five years include:

- Brown treesnake eradication and control using acetaminophen, as a toxicant to the snake, is being conducted within the approximately 136-acre (55-hectare) Habitat Management

Unit on AAFB. In 2014, the USDA-APHIS Wildlife Services, in coordination with the National Wildlife Research Center, the DoD-Environmental Security Technology Certification Program, and the Department of Interior-Office of Insular Affairs, conducted a test of aerial application of a brown treesnake toxicant (acetaminophen) over forested areas in AAFB (Dorr et al. 2014, unpublished data). The results of this study indicate that development of a scalable automatic bait application system could be used in the near future for large landscape scale brown treesnake control and suppression (Dorr et al. 2014, unpublished data). The project may result in the reduction of snake numbers to a low enough level to allow for rails to survive and reproduce within this snake-proofed area on Guam.

- Management unit planning – On Guam, a management plan, funded by DoD, is currently being developed for the HMU on AAFB. The plan will consider the reintroduction of Guam rails to this site.
- Predator control – Cat control is conducted on Rota and will continue with increased efforts from additional funding by the Service in fiscal year 2015.

Recommendations for Future Actions (adapted from USFWS 2014c, p. 3):

- Maintain or increase genetic diversity in captive rail population – Implement management strategies to exploit the potential gene diversity in the captive populations at the DAWR and AZA facilities.
- Predator monitoring and control
    - Continue efforts to develop and refine brown treesnake control techniques and support small-scale and large-scale control and/or eradication efforts on Guam.
    - Continue and increase efforts to control and eradicate brown treesnakes on Guam and prevent introduction of brown treesnakes on other Mariana Islands.
    - Implement large-scale cat control and/or eradication.
- Reintroduction / translocation
    - Consider alternative sites for establishing other experimental populations.
    - Develop reintroduction plan for Guam rails on Guam and set aside and protect recovery areas for these rails on Guam.
- Revise recovery objectives and criteria – Revise recovery plan.
- Population monitoring and viability analysis – Continue population and demographic monitoring on Rota and Cocos Island.
- Protection and restoration of Guam rail recovery habitat including in-perpetuity protection as conservation areas and fencing to exclude brown treesnakes and ungulates.

Status of the Mariana Fruit Bat

Legal Status

The Mariana fruit bat (*Pteropus mariannus mariannus*; "fanihi" in Chamorro; hereafter, fruit bat) was listed as endangered on Guam in 1984, but was downlisted to threatened in 2005 when it was determined that all fruit bats on Guam and throughout the Commonwealth of the Northern Mariana Islands (CNMI) comprise a single subspecies (USFWS 2005b, p. 1191). In 2004 critical habitat for the fruit bat was designated at the Guam National Wildlife Refuge Ritidian Unit (USFWS 2004, p. 62944).

Species Description

The Mariana fruit bat is a medium-sized fruit bat in the family *Pteropodidae* that weighs 0.66 to 1.15 pounds. Males are slightly larger than females. The underside (abdomen) is black to brown with gray hair interspersed that creates a grizzled appearance. The shoulders (mantle) and sides of the neck are bright golden brown, but may be paler in some individuals. The head varies from brown to dark brown. The well-formed, rounded ears and large eyes give the face a canine appearance.

Current Known Range

The Mariana fruit bat is a subspecies endemic to the Mariana archipelago (Guam and the CNMI), where it was historically present on every island except Uracas (Wiles et al. 1989, p. 69). The fruit bat is currently thought to be extirpated from Tinian (USFWS 2009c, pp. 269-272; USFWS 2014d, pp. 2-3).

Life History

The diet of the fruit bat is comprised of fruits, nectar, pollen, and some leaves (Wiles and Fujita 1992, pp. 26-31; Wiles and Johnson 2004, p. 591), and it uses several forest types for foraging, roosting, and breeding, including native primary and secondary limestone forest, volcanic (or ravine) forest, old coconut plantations, and groves of *Casuarina equisetifolia* (Glass and Taisacan 1988, pp. 6–13; Worthington et al. 2001, pp. 137–138; Wiles and Johnson 2004, pp. 589–591). Most fruit bats roost during the day in maternity colonies at sites to which they show a high level of fidelity (unless disturbed). A small proportion of fruit bats, usually males, roost alone or in small groups called bachelor colonies. Fruit bats will abandon roost sites if disturbed and have been reported to move to new locations as far as 10 kilometers (km) (or 6 miles) away (USFWS 1990b, p. 9). Any fruit bat colony can be disturbed by humans close enough to be smelled; which can be up to 200 m (656 ft) away (J. Boland, pers. obs. 2009). In addition, fruit bats have flushed from maternal roosts in response to aircraft overflights on Guam with noise levels above 90 dB (SWCA 2012, p. 23, 37). When colonies are disturbed, fruit bats may be negatively affected in a variety of ways, including but not limited to, destruction of social structures, direct injury, disruption of energetic and hormonal balance, forced relocation to lower quality habitat, abandonment of non-volant young, and disruption of breeding activities (Wingfield et al. 1998, pp. 191-204; Heideman 2000, pp. 469-499; Klose et al. 2006, p. 341; CNMI 2010, p. 7).

Within colonies, fruit bats typically group themselves into harems (one male and 2-15 females) or bachelor groups (predominantly males; Wiles 1987a, pp. 93-94; J. Boland, unpubl. data). Unlike most Pteropus species, mating and the presence of nursing young have been observed in Mariana fruit bats throughout the year on Guam and Rota (Wiles 1987a, pp. 93-94; CNMI 2010, p. 12; CNMI 2011, p. 12; J. Boland, unpubl. data). Data is limited for age of sexual maturity,

reproductive rates, length of gestation, and lifespan of Mariana fruit bats. Female bats of the family Pteropodidae generally have a gestation period of 4.6- 6.3 months and one offspring per year (Pierson and Rainey 1992, pp. 1-17). Many Pteropus species typically do not give birth before 18 months of age (Pierson and Rainey 1992, pp. 1-17; McIlwee and Martin 2002, p. 76). Based on these reproductive traits, several authors have suggested that Pteropus bats have a low maximum population growth rate and thus a slow rate of recovery when a population is diminished (Pierson and Rainey 1992, p. 1-17; McIlwee and Martin 2002, p. 76).

Population Dynamics and Status

The total population of the Mariana fruit bat is estimated to be approximately 6,000 animals (USGS 2010, p. 36; CNMI 2011, p. 6). Surveys suggest populations are stable or declining throughout most of their range (Table 5). A notable exception to the declining trend is the island of Rota, where the population has increased since 2008 (CNMI 2008, p. 11; CNMI 2011, p. 6). The population increase on Rota is due to a recent decrease in illegal hunting at roost sites of fruit bat maternity colonies, and the decrease in illegal hunting can be attributed to an increase in enforcement of wildlife regulations that began in 2009 (CNMI 2010, pp. 7-9).

The fruit bat population on Rota is estimated at approximately 2600 (CNMI 2011; p. 6). Although comprehensive surveys have not been conducted on Saipan, there have been no confirmed observations of maternity colonies in recent years, and the island-wide population is expected to be less than 50 individuals (T. Willsey, CNMI DLNR, pers. comm. 2014). The population of fruit bats on Guam is estimated to be less than 30 bats (SWCA 2013, pp. 19-22; DON 2013b, pp. 11-15). The most recent and last colony to exist on Guam was at Pati Point, but recent surveys indicate that this colony no longer exists (Figure 5) (SWCA 2013, pp. 13). On July 3, 2014, a survey was conducted on Andersen Air Force Base which resulted in 10 observations of bats; analyses are still in progress to determine duplicate observations and detection probability given the amount of area surveyed on the Base (DON 2014c).

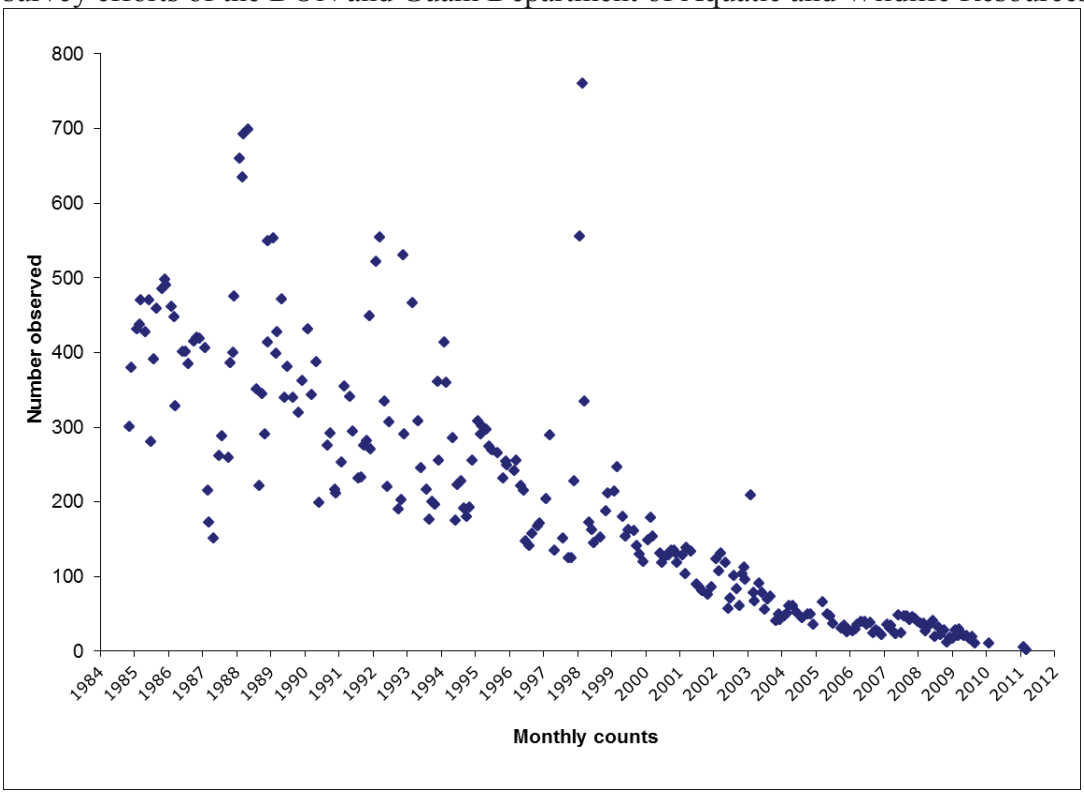

Table 5. Summary of population estimates for the Mariana fruit bat throughout the Mariana archipelago from 1983-2010 (USFWS 2014d, p. 2).

Island	**Area square mile (square kilometer)**	**Estimated minimum number of bats 1983-1984[1]**	**Estimated number of bats 2000[2]**	**Estimated number of bats 2008[3]**	**Maximum number of bats counted 2010[4]**
Maug	0.8 (2.0)	< 25	not surveyed	not surveyed	11
Asuncion	2.9 (7.4)	400	not surveyed	not surveyed	573
Agrihan	18.3 (47.4)	1,000	1,000	not surveyed	858
Pagan	18.4 (47.7)	2,500	1,500	not surveyed	1,017
Alamagan	4.3 (11.0)	0[5]	200	not surveyed	86
Guguan	1.5 (4.0)	400	350	not surveyed	226
Sarigan	1.9 (5.0)	125	200	not surveyed	157

Anatahan	12.5 (32.3)	3,000	1,000	not surveyed	150
Saipan	47.5 (122.9)	< 50	not surveyed	not surveyed	not surveyed
Tinian	39.3 (101.8)	< 25	not surveyed	0	not surveyed

[8] Direct counts for all maternity colonies in May 2010 plus departure/arrival counts at extra-colonial sites in April 2010

Figure 5. Direct counts of fruit bats at the historical fruit bat maternity colony at Pati Point on Andersen Air Force Base from 1984-2011 (A. Brooke, pers. comm. 2014, data compiled from survey efforts of the DON and Guam Department of Aquatic and Wildlife Resources).

Threats (adapted from USFWS 2014d, pp. 4-5):

- Loss or degradation of habitat:
  - Human development is a factor in habitat loss on all inhabited southern islands and on northern islands with military activity.

  - Feral ungulates and Philippine sambar deer (*Rusa marianna*) degrade habitat on many of the Mariana Islands. The successful eradication of feral ungulates from Sarigan and Anatahan suggests that similar projects may succeed on other islands. However, once grazing and browsing pressure is removed, the potential invasion of native forest by alien plants may be a more difficult and long-term recovery issue.
- Human disturbance:
  - Illegal hunting is a threat to Mariana fruit bats throughout its range. Although law enforcement activity has increased since 2009 (CNMI 2008, 2009a-b, 2010), illegal hunting of fruit bats on Rota continues and will likely resume to historical levels unless consistent, effective law enforcement efforts in tandem with education and outreach programs continue. Fruit bats appear to be extirpated from Tinian and are declining on Saipan and Guam, and illegal hunting is thought to have greatly contributed to the decimation/decline of those populations (Wiles and Payne 1986; Wiles and Glass 1990; Sheeline 1991; Stinson et al. 1992; Wiles 1992; Esselstyn et al. 2006). As with Rota, recovery of the fruit bat on human-inhabited islands will not likely be possible without strong education programs combined with effective control of illegal hunting.
- Nonnative snake predation – The brown treesnake is thought to prey on non-volant young left at the roost during the night, thus preventing the recruitment of young bats into the breeding population. Effective control of brown treesnakes must be achieved before fruit bat population on Guam can recover. The interdiction, control, and ultimate eradication of brown treesnakes in the archipelago are the focus of major, ongoing projects, and the fruit bat is likely to benefit from these efforts in the long term. This prognosis would change drastically if the brown treesnake were to become established widely throughout the archipelago.
- Stochastic events – Typhoons and volcanic eruptions result in mortality, reduced population viability, and habitat loss. Natural disasters can be especially damaging to the viability of smaller fruit bat populations (e.g., on Guam, Saipan, Aguiguan, and Maug). The significant loss of habitat on Anatahan after the volcanic eruption in 2003 resulted in the loss of a substantial fruit bat population that has not yet recovered.

Survival and Recovery Needs

Before the Mariana fruit bat is considered for delisting, the Service proposes that stable or increasing populations should exist on three of the five southern islands (Saipan, Tinian, Aguiguan, Rota, and Guam), and six of the northern islands where Mariana fruit bats have persisted historically (Anatahan, Sarigan, Guguan, Alamagan, Pagan, Agrihan, Asuncion, and Maug; USFWS 2009d, pp. 37-39). Of the six northern islands that require stable or increasing fruit bat numbers, two of these must include Pagan, Anatahan, or Agrihan. Since publication of the draft revised recovery plan in 2009, new information on the Mariana fruit bat has resulted in changes to how we look at recovery for the species. We now consider recovery in terms of stable or increasing subpopulations of sufficient size distributed across Guam and the Mariana Islands. To meet recovery objectives, stable or increasing fruit bat subpopulations should at a minimum be distributed on the islands that currently have extant populations (USFWS *in*

review). The final version of the Mariana fruit bat recovery plan is currently in review, and recovery criteria stated here may change upon completion of the final plan

Of the six northern islands, the only evidence for a possibly increasing population is on Asuncion (USGS 2010, p. 33). Of the five southern islands, only Rota has achieved an increasing population. Although a conservation area containing some important habitat for fruit bats was recently established on Rota (USFWS 2011, pp. 1), there is not currently enough protected fruit bat habitat on Rota, Guam, Tinian, or Saipan to support substantial population recovery on any of those islands. Even if sufficient habitat is set aside in conservation to support recovery of populations, controlling illegal hunting may continue to be a challenge that limits recovery of the species.

New management actions (adapted from USFWS 2014d, pp. 4-5):

- Monitoring and analysis of population viability – Technical assistance was obtained in 2008 to analyze fruit bat survey data from Rota and refine survey methods and the existing monitoring program (CNMI 2008, 2009a-b, 2010).
- Law enforcement and compliance – On the island of Rota, the Service and the CNMI Division of Fish and Wildlife (DFW) have increased law enforcement actions since 2009. With support from Service law enforcement and federal discretionary funds, CNMI Conservation Officers have participated in nine fruit bat-related arrests on Rota, all resulting in convictions. Enforcement actions have contributed to a decrease in illegal hunting, and approximate doubling of the fruit bat population on Rota.
- Development of monitoring protocol – Experts were consulted to review and refine survey methods for fruit bats to develop standardized, quantitative monitoring that permits data comparison at multiple timescales. Standard operating procedures were developed for CNMI DFW (CNMI 2009a) and a monitoring protocol was developed for Service for fruit bat surveys in the Northern Mariana Islands (Mildenstein and Boland 2010).
- Surveys / inventories – Surveys were conducted on Anatahan, Sarigan, Guguan, Alamagan, Pagan, Agrihan, Asuncion, and Maug in 2010 (USGS 2010). A base-wide survey was conducted on AAFB in 2014 (DON 2014c)
- Habitat and natural process management and restoration – The Mariana Crow Conservation Area was established on Rota through an MOA between the CNMI and the Service (USFWS 2011). This area encompasses 444 hectares (1097 acres) and contains some high-quality foraging and roosting habitat for fruit bats.
- Outreach and education – Discussions were initiated with CNMI DFW and CNMI Public School System (PSS) to develop outreach and education materials and opportunities to curb illegal hunting. Several education and outreach programs were funded by the Service, Bat Conservation International, Disney, and Lubee Bat Conservancy, and these programs were implemented on Rota through a local non-profit. An education curriculum was developed with the CNMI PSS, but has not yet been implemented.

Recommendations for Future Actions (adapted from USFWS 2014d, pp. 5-6):

- Outreach and education – Decrease illegal hunting by developing and supporting outreach and education programs that emphasize the value of and need to protect fruit bats and other native plant and wildlife species in the Marianas.

- Law enforcement and compliance – Decrease illegal hunting by continuing to provide technical and financial assistance to CNMI DFW enforcement officers to facilitate apprehension and prosecution of poachers.
- Ungulate monitoring and control
    - Decrease habitat loss by eradicating feral ungulates on islands where they exist, and preventing their introduction on other islands where fruit bat recovery is desired.
    - Decrease habitat loss by controlling deer in areas of high-quality fruit bat habitat.
- Habitat and natural process management and restoration
    - Improve habitat through support of native forest restoration, especially on Guam, Saipan, and Tinian.
    - Set aside enough high-quality habitat including in-perpetuity protection of conservation areas to support the recovery of fruit bat populations on three of the five southern islands.
- Human interaction monitoring and management
    - Limit military training in areas occupied by fruit bats to activities that will not disturb fruit bats or their habitat.
    - Limit urban development in areas occupied by or potentially used for roosting and foraging by fruit bats.
- Population monitoring and viability analysis – Continue monitoring fruit bat numbers on Anatahan to understand the fluctuation of numbers in response to volcanic activity.
- Population monitoring and viability analysis – Hire and ensure consistent employment of a full-time, resident DFW or Service biologist who is charged with monitoring the fruit bat population on Rota according to established protocols (CNMI 2009a, Appendix 1).
- Predator / herbivore monitoring and control
    - Development and implementation of large-scale, long-term methods for brown treesnake control that will reduce the brown treesnake population on a landscape level on Guam.
    - Continue and increase efforts to prevent introduction of brown treesnake populations on other Mariana Islands.

Status of *Serianthes nelsonii*

Legal Status

Serianthes nelsonii, "hayun lågu" or "tronkon guafi" in Chamorro was listed as endangered in 1987 (USFWS 1994, p. 1). No critical habitat has been designated for this species.

Species Description and Current Known Range

Serianthes nelsonii is a large tree in the pea family (Fabaceae, subfamily Mimosoideae). Adult trees can reach heights over 30 m (98 ft) and diameters over 1.5 m (4 ft) (USFWS 1994, p. 11). Its bark is smooth and light brown in color. Fine rusty hairs cover the flowers, seed pods, and newer vegetation growth. Leaves are doubly pinnate with many pairs of leaflets. Flowers are brush-like with pink and white coloration, and fruits are hard, dry, brown pods (Stone 1970, p. 304). Seedlings closely resemble those of a small introduced tree, *Leucaena leucocephala*

(tangantangan), but can be discerned by the fine pubescence on new leaf buds (USFWS 1994, p. 6).

Serianthes nelsonii is endemic to the islands of Guam and Rota (USFWS 1987, p. 4907). Recorded specimens on Guam were mostly from northern limestone forests, but a few trees were recorded in southern clay soils (USFWS 1994, p. 8). Currently, the last remaining wild adult tree on Guam is located at NWF, AAFB in northern Guam. A new fence was constructed to exclude ungulates in 2012 by AAFB, the *Serianthes* tree and seedlings are monitored monthly by DoD. DoD has conducted research on limiting factors for seedlings, fallen seeds collected and stored for future use. In 2014, 31 *S. nelsonii* seedlings supplied to the Service by JRM were planted at the GNWR in northern Guam (Demeulenaere et al. 2015, p. 4). The 31 seedlings are maintained with 2 previously outplanted saplings on the GNWR. On AAFB, one outplanted sapling is located in the Tarague Basin.

The history of *S. nelsonii*'s abundance and distribution on Rota is poorly known (USFWS 1994, p. 7), but surveys in 1994 estimated 121 adult trees with very little regeneration (Wiles et al. 1996, p. 232). Current estimates for Rota are 40 to 50 wild adult trees with little to no regeneration (J. Manglona, CNMI DLNR, pers. comm. 2015).

Life History and Ecology

Serianthes nelsonii is recorded mainly from limestone soils, with a few historical occurrences in clay soils in Guam (USFWS 1994, p. 8). Most of the adult trees in Rota occur on or near steep limestone cliffsides, and the last wild adult tree in Guam is located in rugged limestone karst habitat at NWF. What little is known about pollination, seed dispersal, phenology, flowering, and fruiting for this species comes mainly from incidental reports (USFWS 1994, p. 11). Fruiting occurs throughout the year, as seed pods have been observed during all months of the year (USFWS 1994, pp. 11-13). Similarly, flowering has been recorded during all months of the year, with one report (Schreiner and Nafus 1991, as cited in USFWS 1994, p. 11) reporting the highest proportion of branches with flowers in May and June. This report also indicated leaf production throughout the year with declines during the dry season from January to June. Age of reproduction in the wild is also unknown, but flowers and pods have been observed on cultivated trees as young as 10 years old (USFWS 1994, p. 13).

Serianthes nelsonii, being a large, canopy tree species, provides habitat for a number of smaller species. This species supports a diverse community of arthropods including predator species such as spiders and mantids that may control other potentially problematic insect populations (Wiles et al. 1996, p. 233). *S. nelsonii* also hosts a variety of epiphytes including ferns, orchids, and other plants such as *Ficus* sp., and *Freycinetia reineckei* (Wiles et al. 1996, p. 233-234).

Population Dynamics and Status

The total wild population of *Serianthes nelsonii* is estimated to be 50 adult trees, with almost all of the population occurring in Rota, and a single wild adult tree in Guam. In addition, there are outplanted occurrences on each island, all younger than 20 years of age. Seedling propagation and outplanting on Rota have been ongoing with limited success over the past 20 years, mainly

in the Isang area in southern Rota, and between the main villages of Songsong and Sinapalo. Approximately 10 outplanted individuals in Rota have survived to a reproductive age (J. Manglona, CNMI DLNR, pers. comm. 2015). Twenty seedlings were outplanted in 1999 in the Tarague Basin, on AAFB in Guam (M. Marutani, University of Guam, pers. comm. 2015). To date, only one of these saplings has survived (AAFB 2015), but has not produced any seed pods (A. Gawel, USFWS, pers. obs. 2014). In 2009, approximately 30 seedlings were planted at the GNWR; all but 5 have survived (J. Cruce, USFWS, pers. comm. 2015). In 2014, 31 seedlings were donated to GNWR by JRM and outplanted and are being maintained by the Guam Plant Extinction Prevention Program (Demeulenaere 2015, p. 4) and GNWR staff.

Recent *Serianthes nelsonii* recovery efforts on Guam and Rota have been dependent on funding, the amount of available propagated seedlings in nurseries, and the seedling to adult survival rates in the wild. In early 2015, the total number of nursery seedlings and saplings in Guam and Rota was estimated at 300 individuals, with approximately 200 in Guam nurseries. However, this estimation may change rapidly if outplanting seedling survival is low. Recent studies from AAFB indicated that although many seeds fall from the Guam adult tree and many of the seeds germinate, there is very limited survival under the mother tree (AAFB 2015). Both islands' populations have constant regeneration of wild seedlings that are several days to several months old. However, these seedlings experience incredibly high turn-over, and in recent decades, none have been known to survive to adulthood in the wild (J. Manglona, CNMI DLNR, pers. comm. 2015; AAFB 2015, pp. 4-5). Although wild seedling survival is bleak, progress has been made on increasing the likelihood of survival of outplanted individuals with new methods of insect control and exclusion, given insect herbivory and damage are the major cause of outplanted seedling early mortality (E. Demeulenare, GPEPP, pers. comm. 2015).

Threats (adapted from USFWS 2012b, pp. 10-14):

- Loss and degradation of habitat – Development from construction and military training has decreased the total recovery habitat for this species. *Serianthes nelsonii* habitat continues to be degraded by ungulates (Wiles et al. 1996, p. 234; DON 2013c), i.e. feral pigs and Philippine deer (*Rusa mariannae*), and by encroachment of invasive plants. In addition, declines in pollinators, seed dispersers, and insectivores have contributed to habitat loss (Wiles et al. 1996 p. 230).
- Introduced predators and herbivores – Introduced deer and pigs feed on *Serianthes nelsonii* (Wiles et al. 1996, p.234; Morton et al. 2000, p. 230). A number of invertebrate predators and herbivores also have been reported on this species: mealybugs (*Dysmococcus brevipes*, *D. neobrevipes*, *Ferrisia virgate*, and *Planococcus* sp.), caterpillars of *Eurema blanda*, termites (USFWS 2012b), and katydids (A. Moore, University of Guam, pers. comm. 2014). In addition, insect predation occurs on seed pods in Rota, but the insect is unknown (USFWS 2012b).
- Stochastic events – Typhoons have resulted in damage and mortality to this species as well as damage to habitat (USFWS 2012b).

Survival and Recovery Needs

For *Serianthes nelsonii* to be considered for delisting, the Service proposes that at least four populations be established on each island – Guam and Rota – each with a 10-year average of 500

or more reproductive plants (USFWS 1994, p. 26). The populations should have age structures comprised of a large proportion of adult trees as well as seedlings and immature trees (USFWS 1994, p. 26). In addition, the Service recommends that the populations on Rota be separated by at least 1 km (0.621 mi), and that at least one of the populations in Guam should be in the southern part of the island (USFWS 1994, p. 26).

To achieve recovery needs, the Service outlines the following recovery actions (adapted from USFWS 1994, pp. 27-37):

- Additional surveys are needed on both islands since the last surveys for this tree were in 1994. To prevent ungulate degradation and herbivory, subpopulations should be fenced wherever possible. Methodology to control insect pests should be developed and implemented. Existing individuals need to be monitored for survivorship, new threats, and any possible evidence of regeneration. Public education and community involvement should also be encouraged and developed.
- Conduct research important to the management of *Serianthes nelsonii*. The ecology, life history, and habitat requirements of *S. nelsonii* are poorly understood and should be studied. Although a number of insect pests have been identified, many remain unidentified, and their ecology, specific effects, abundance, and especially control methods need to be investigated. The Service also recommends genetic studies, especially on the variation between Guam and Rota populations, as well as any effects from small population size and inbreeding.
- Augment current populations and reintroduce to historical range. Plans for augmentation and reintroduction should be developed for both Guam and Rota. Areas for outplanting should be identified and secured, and plants should be propagated and transplanted to the identified areas.
- Prevent clearing of forest next to *S. nelsonii*. Maintenance of an intact forest canopy next to *S. nelsonii* will reduce the potential of edge effects and for high winds during typhoons to break tree limbs and trunks.
- Implement standardized control procedures for insect pests after research on insect control determines appropriate methodology.

New management actions that have occurred in the last five years include:
Since *Serianthes nelsonii* was listed in 1987, outplanting of individuals have been attempted with limited success. However, several recovery projects aimed at understanding and improving outplanting efforts and management of individuals have begun since 2012:

- The last remaining adult tree in Guam is fenced to prevent access by ungulates. The Air Force has funded research to look at ecology, seedling survival, propagation methods, and health and life history of the adult tree (AAFB 2015).
- The Service has funded a project with the CNMI Division of Forestry in Rota to outplant and maintain *Serianthes nelsonii* in fenced plots on private property.
- The Service has funded a multi-year project for *Serianthes nelsonii* recovery on the GNWR to be managed by a full-time biologist. This person will work with the Guam Plant Extinction Prevention Program to maintain the *S. nelsonii* seedlings that were outplanted at the GNWR in 2014. The Service is collaborating with Guam Department

of Agriculture, DoD, the University of Guam, and the Guam Plant Extinction Prevention Program.

Recommendations for Future Actions (adapted from USFWS 2012b, pp. 17-18)

- Captive propagation for genetic storage and reintroduction:
    - Continue to collect seeds from all existing populations and propagate at multiple locations to increase success.
    - Perform genetic studies to determine if Guam and Rota populations are distinct.
- Captive propagation protocol development – Protect seed pods with a fine mesh covering to prevent predation by arthropods before seeds mature.
- Reintroduction / translocation implementation:
    - Propagate and maintain all outplanted individuals on the GNWR to a size where insect herbivory is less likely to cause mortality. This will likely be when plants produce multiple branches and the main stem achieves a girth sufficient enough to withstand damage from *Eurema blanda* butterflies laying eggs in the plant's tissue.
- Ungulate control – Continue to protect all populations against disturbances from feral ungulates.
- Invertebrate control research – Research and identify the effects of invertebrate predation on seeds and seedlings of *S. nelsonii.* If determined to be a limiting factor, develop and implement control measures to protect the species.
- Population biology research – Research the use of mechanical pollination to enhance outbreeding of the species.
- Surveys / inventories – Resurvey the historical range of the species to determine if previously unknown or newly reestablished populations exist.
- Threats research:
    - Research what factors are limiting the natural recruitment of individuals in Guam.
    - Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species.
- Ecosystem-altering invasive plant species control – Control invasive introduced plant species within fenced exclosures.
- Site / area / habitat protection – Develop and implement effective measures to reduce the impacts of agricultural and urban development and hurricanes (typhoons).
- Fire protection – Develop and implement a fire management plan for all populations.
- Alliance and partnership development – Continue to work with GNWR, Guam Rare Plant Restoration Group, and other land managers to continue implementation of ecosystem-level restoration and management to benefit this species.

F. ENVIRONMENTAL BASELINE OF THE SPECIES

General Environmental Baseline

Below we provide a general overview of the status of, and threats to, limestone forest habitat within the action area, followed by species-specific environmental baseline sections. We focus

on habitat in this overview section as the three bird species are extirpated, there is one remaining adult *Serianthes nelsonii* tree, and only a very small population of Mariana fruit bats left on Guam. Therefore, protecting the remaining habitat on Guam is critical for the future recovery for all the listed species addressed in this Biological Opinion.

Limestone karst forests on Guam

Limestone karsts are sedimentary rock outcroppings consisting primarily of calcium carbonate and are recognized as important ecosystems, with high species diversity (Mueller-Dombois and Fosberg 1998, p. 217; Clements et al. 2006, pp. 733-734). The high species diversity on karsts arises from the numerous ecological niches created by complex terrains and variable climatic conditions (Clements et al. 2006, p. 734). On Guam, karst is found on an uplifted karst plateau in the northern half of the island and on uplifted weathered volcanic terrain in the southern half (Fosberg 1960, p. 54; Stone 1970, p. 12; Mueller-Dombois and Fosberg 1998, p. 241). The limestone soils of north and south Guam were historically forested (Stone 1970, p. 14; Mueller-Dombois and Fosberg 1998, p. 270; Guam Department of Agriculture 2010, p. 7), and limestone forest on Guam is composed primarily of mature growth of native trees and plants with a moderately dense canopy 10-30 m high (DAWR 2006, p. 19). We define primary limestone forest as forest with vegetation that was never cleared and is dominated by native species (Fosberg 1960, p. 56; DAWR 2006, p. 218).

Primary limestone forests are critical for Guam's native flora and fauna (Stone 1970, p. 22; USFWS 2005a, p. iv; DAWR 2006, p. 28; DON 2014b, p. 3-40). They retain key functional components of native forests such as large native trees and high canopy cover (Fosberg 1960, p. 56; Mueller-Dombois and Fosberg 1998, p. 217 and 270; DON 2014b, p. 3-40), and are necessary for the recovery of listed species on Guam (Jenkins 1983, p. 22; Michael 1987; Morton et al. 1999, p. 22). Intact primary limestone forests harbor greater tree species diversity than degraded habitat (Stone 1970, p. 22) and provides habitat for a broad diversity of wildlife; these forests are also highly productive and often store more carbon than degraded forests (Caves et al. 2013, p. 7). The primary limestone forest on AAFB is considered some of the best native limestone forest left on Guam to serve as habitat for listed species (Morton 1996, p. 69).

Threats to Guam's limestone forests

Over the past several centuries, Guam has lost much of the native forest to agriculture, a growing human population, economic development, and military activities (Mueller-Dombois and Fosberg 1998, p. 270; USFWS 2009d, p. 27). The distribution of primary limestone forest on Guam has been steadily declining (Fosberg 1960, p. 54; DAWR 2006, p. 28). Although little is known about the nature of Guam's vegetation before World War II, progressive alteration of the island's vegetation clearly began with human colonization (Fosberg 1960, p. 54). On limestone soils, native forest was cleared and replaced by coconut plantations, open fields and gardens, pasture, and secondary forest (Mueller-Dombois and Fosberg 1998, p. 242). During World War II, large areas were cleared and some habitat was destroyed during heavy fighting (Fosberg 1960, p. 54).

Currently, the remaining limestone forests on Guam face numerous threats including habitat fragmentation and loss, lack of management, introduced ungulates, invasive species, typhoons, forest conversion, and loss of pollinators (USFWS 2005a, p. 27; DAWR 2006, p. 28; USFWS 2008a, p. 17-18). These combined threats will degrade the habitat quality of remaining limestone forests and limit the acres of high quality primary limestone forest habitat available to recover listed species on Guam. Currently, forested areas cover approximately 48 percent of Guam (DAWR 2006, p. 31), with only 13 percent of Guam covered with limestone forests (Brown 2005 as cited in DAWR 2006, p. 28).

Habitat Fragmentation, Degradation, and Loss

Habitat fragmentation is a change in habitat configuration caused by clearing, development, invasive species, typhoons, and ungulates that causes remaining habitat to occur in patches among areas of non-habitat (Noss et al. 2006, p. 213). Habitat fragmentation creates edges that have different properties than the habitat itself. For example, edges often have different microclimate patterns that are drier, less shaded, and warmer than forest interiors; they are often areas with increased predation and serve as entry points into native habitats for invasive vegetation, pests, and pathogens (Noss et al. 2006, p. 228). Edges can affect avian density up to 60 m into the forest, and affect the forest canopy up to 150 m (Murcia 1995, p. 59). Habitat fragmentation and edges can result in localized extinctions, shifts in community composition, increases in invasive species, increased predation, and in suitable habitat becoming unsuitable due to pollution, invasive species, physical size, or barriers blocking access to habitats (Groom and Vynne 2006, p. 174; Noss et al. 2006, 38 pp). Habitat fragmentation has been implicated in reduced species richness, avian abundance, productivity, and food supply (Blake and Karr 1987, VanderWerf 1993, Burke and Nol 1998, Trine 1998, Porneluzi and Faaborg 1999). Overall, edges have deleterious effects to wildlife populations and ecological processes (Murcia 1995, p. 58; Laurance 2000, p. 134) and may affect forests at larger landscape scales (Laurance 2000, p. 134).

Habitat degradation and loss on Guam has been caused by various human activities including agriculture, mining, forestry, fires, infrastructure development, military training, urbanization, industry, pollution (including light, noise, and toxic chemicals), and changes in community and ecosystem structure due to invasive species (Groom and Vynne 2006, p. 164; USFWS 2008a, p. 17). Habitat loss and degradation from human activities is a threat to recovery of listed species on Guam (USFWS 2008a, p. 17; USFWS 2012c, p. 3).

Introduced Ungulates

Non-native ungulate species that occur in Guam include pigs (*Sus scrofa*), Philippine deer (*Cervus mariannus*), and Asiatic water buffalo (*Bubalis bubalis*). Ungulates have caused severe damage to Guam's forests by browsing on plants, causing erosion, inhibiting plant growth and regeneration, and facilitating the establishment of invasive plants, which can impede forest regeneration by displacing or smothering native species (USFWS 2009d, p. 27). For example, deer and pigs foraging on fallen fruits and seedlings of the native breadfruit (*Artocarpus mariannensis*), an important fruit bat food, in combination with impacts from typhoons, have resulted in a decline in the number of native breadfruit trees on Guam (Wiles 2005; p. 509).

Introduced pigs are extremely destructive and have both direct and indirect effects on native plant communities. While rooting in the soil in search of invertebrates and plant material, pigs directly affect native plants by disturbing and destroying vegetative cover and trampling plants and seedlings. They may also reduce or eliminate plant regeneration by damaging or eating seeds and seedlings. Pigs are a major vector for the establishment and spread of competing invasive non-native plant species, by dispersing plant seeds on their hooves and coats as well as through the spread of their feces (Diong 1982, pp. 169-170), and by fertilizing the disturbed soil with their feces (Matson 1990, p. 245; Siemann et al. 2009, p. 547). Pigs feed preferentially on the fruits of many non-native plants, spreading the seeds of these invasive species through their feces as they travel in search of food. In addition, rooting pigs contribute to erosion by clearing vegetation and creating large areas of disturbed soil, especially on slopes (Smith 1985, pp. 190, 192, 196, 200, 204, 230–231; Stone 1985, pp. 254–255, 262–264; Medeiros et al. 1986, pp. 27–28; Scott et al. 1986, pp. 360–361; Tomich 1986, pp. 120–126; Cuddihy and Stone 1990, pp. 64–65; Aplet et al. 1991, p. 56; Gagne and Cuddihy 1999, p. 52).

On Guam, feral pigs were introduced in the 1600s, established a feral population by 1772, and distributed island wide by the early 1900s (Conry 1988, p. 26). As documented in other locations, wallowing, rooting, and trampling are common in most forested areas and can be locally severe (Conry 1988, p. 27). A large complex of wallows and feeding sites in Tarague Basin on AAFB measured over 5.7 ac (2.3 ha), and was stripped of all ground cover with no tree regeneration (Conry 1988, p. 27). On AAFB, densities of Philippine deer and feral pigs were estimated at 1.8 deer per hectare (0.8 deer per acre) and 0.4 pigs per hectare (0.2 pigs per acre), which are some of the highest densities recorded in the world (Knutson and Vogt 2003, unpubl. manuscript).

Philippine deer were introduced to Guam in the 1770s (Safford 1905, p. 76), and are distributed throughout the island (Conry 1988, p. 27). Heavy browsing pressure has been documented, even at relatively low densities, and browse lines are common (Conry 1988, p. 27). Deer populations in the 1990s appeared to be expanding (Wiles et al. 1999, p. 193), and may be the largest in Micronesia (p. 200). Philippine deer have caused significant changes in forest structure and species composition in native ecosystems on Guam, and are not considered compatible with conservation of native ecosystems and recovery of endangered species (Wiles et al. 1999, p. 193).

The Asiatic water buffalo was introduced to Guam in the 1600s from the Philippines (Conry 1988, p. 27). High densities, and the gregarious habits of Asiatic water buffalo, have resulted in habitat damage such as mud wallows, broad trails, vegetation trampling, and tracks, and some areas were so heavily trampled that ground cover has been denuded and soil erosion scars and slumping are evident (Conry 1988, pp. 27-28). Asiatic water buffalo occur primarily on the Ordnance Annex and surrounding non-Navy lands in southern Guam, with a population estimated at 50-60 animals (USFWS 2008a, p. 18).

Conversion of Forest to Savanna in Southern Guam

Savanna areas in southern Guam are enlarging into previously forested areas as a result of human-caused wildfires and grazing (Stone 1970, p. 14; Mueller-Dombois and Fosberg 1998, p. 242). To estimate the rate of historical forest conversion to savanna, Greenlee (2010) delineated

areas that were dominated by forest vegetation in 1975 aerial photographs and compared them to recent infrared imagery. Based on this analysis, approximately 1,119 ac (453 ha) of forest was converted to savanna in southern Guam since 1975; this estimate indicates the average rate of forest loss in southern Guam is approximately 37 ac/year (15 ha/year) (Greenlee 2010).

Habitat Destruction and Modification by Typhoons
Guam has been affected by typhoons in 37 of the last 50 years (USFWS 2005a, p. 32). Super-typhoons (with wind gusts of over 240 km (150 mi) per hour) occur approximately once every five years (the last one, Pongsona, occurred in 2002). Typhoons destroy native vegetation by opening the canopy and modifying the availability of light, and create disturbed areas conducive to invasion by non-native pest species (Asner and Goldstein 1997, p. 148; Harrington et al. 1997, pp. 539-540). Typhoons also can cause defoliation (loss of leaves), uprooting of trees, and breakage of stems, branches, and trunks of trees depending on the severity and duration of the storm and its point of impact (Brokaw and Walker 1991, p.442). Super-typhoons fragment and decrease the suitability of existing habitat, and exacerbate the effects of introduced plants and ungulates (USFWS 2005a, p. 34). Following a typhoon, forest canopies may be disrupted, facilitating the establishment and spread of introduced plants. Climate models indicate that hurricanes in the northwestern Pacific are expected to increase in intensity, frequency, and duration by 2200 and continue to increase further into the future (Emanuel et al. 2008, p. 360). Therefore, we expect habitat destruction and modification by typhoons to increase in the future.

Loss of Pollinators, Seed Dispersers, and Frugivores
The loss of forest birds on Guam by brown treesnakes has caused a disruption in the ecosystem services provided by birds as pollinators, seed dispersers, and frugivores (Mortenson et al. 2008, p. 2146; Caves et al. 2013, p. 7). Seeds are dispersed significantly farther from parent trees on islands with birds compared to Guam, and seed ingestion by birds doubles to quadruples the chance of germination for plant species (Rogers 2011, p. 2). The combination of loss of seed dispersal and reduced germination can produce major changes in the spatial pattern, abundance, and diversity of Guam's forests as a result of bird loss (Rogers 2011, p. 2). In addition, seed set and seedling recruitment were significantly higher on Saipan than Guam for bird pollinated trees (Mortensen et al. 2008, p. 2146). These studies concluded that the loss of ecosystem services provided by birds will cause a loss in species diversity, distribution, and abundance; slow regeneration of degraded forests; and reduce plant species recruitment (Mortensen et al. 2008, p. 2146 and 2153; Rogers 2011, p. 2; Caves et al. 2013, p. 5).

Human Disturbance
The listed birds and bat on Guam are also threatened by disturbance from human activities including, but not limited to, noise from military training (aircraft, munitions, firing ranges, vehicles, etc.), noise from recreational pursuits (hiking, and hunting), human voices, and construction noises. These disturbances not only negatively affect species, but reach into forested interiors and degrade the quality of habitat for listed species. The listed birds and bat addressed in this consultation are all sensitive to human disturbance, and as development continues on Guam, disturbance-free forested habitats are increasingly rare on Guam.

Land Management on DoD Lands

The majority of remaining limestone forests on Guam are found on DoD lands at AAFB and the Naval Base Guam's NMS. As noted above, the primary limestone forest on AAFB is considered some of the best native limestone forest left on Guam to serve as habitat for listed species (Morton 1996, p. 69). The Service and the DoD (USAF, U.S. Navy, and JRM) have worked together over the past 20 years to manage DoD lands for threatened and endangered species. In 1993, a Cooperative Agreement (Agreement) was established between the USAF, U.S. Navy, and the Service for purposes of establishing and managing the GNWR Overlay on DoD lands. The GNWR includes approximately 152 ha of fee simple Service-owned land and 9,106 ha of Overlay Refuge on land owned by DoD. The Agreement, which is still in effect, affirms the parties commitment for a "coordinated program centered on the protection of endangered and threatened species and other native flora and fauna, maintenance of native ecosystems, and the conservation of native biological diversity in cooperation with the Guam Department of Agriculture-Division of Aquatic and Wildlife Resources, consistent with the national defense mission of the Navy." Notably, all signatory parties to the Agreement agreed that Navy lands included within the GNWR shall be managed and administered, consistent with the national defense mission of the Navy, for the following goal: to consult under section 7 of the Endangered Species Act (ESA) on proposed Federal actions that are funded, authorized, or carried out by the Federal government within the Refuge, inclusive of Overlay Refuge lands, "that may impact habitat of endangered or threatened species even if those species are extirpated from the affected area, but are not extinct."

Management of listed species habitat on DoD lands has occurred with some success. The approximately 73-ha (180-ac) Haputo Ecological Reserve Area (ERA) on AAFB and the 12-ha (30-ac) Orote Point ERA on NBG are but two examples. Both were established in 1984, prior to the Agreement, as mitigation for the Kilo Wharf project. The 54-ha (133-ac) Habitat Management Unit (HMU) on AAFB was developed as mitigation under the 2006, informal consultation on the Beddown of Training and Support Initiative at the Northwest Field (USFWS 2006c, p. 2), and currently serves as an experimental site for brown treesnake research and control.

However, in contrast, the DoD has recently proposed to build a LFTRC within an existing 312-acre mitigation site on Overlay Refuge at Ritidian Point on AAFB (DON 2014a, p. 22). This mitigation site is a requirement under the 2006 ISR Strike Biological Opinion (USFWS 2006b). After years of working with partners in selecting and preparing the site, constructing and maintaining the ungulate fence, and spending over $1.1 million (AAFB 2015, p. 15), the proposed construction of LFTRC may result in the loss and degradation of listed species habitat, which was to be protected for listed species, and may result in the removal (as part of this proposed action) of parts or all of the ungulate fence.

Another example showing a lack of success to protect and carry-through conservation and management actions on Overlay Refuge is "Area 50", which was established near NWF on AAFB in 1991 to exclude ungulates and control brown treesnakes in an exclosure. The DOI and USAF were working collaboratively towards building a pre-stressed concrete barrier for brown treesnake control at the site, when the USAF restricted access to the site and ended the conservation project.

In addition, cooperation between the DoD and the Service for land management actions on Overlay Refuge lands has not progressed as originally intended after signing of the Agreement. As DoD and Service staff changed, access became more and more challenging until it reached a point where Service biologists could no longer access Overlay Refuge lands. In recent years, access has improved on Overlay Refuge lands.

The DoD agencies have also not historically managed ungulates to full success on DoD lands to benefit listed species or their habitats. For many years, the DoD relied on a Volunteer Conservation Officer (VCO) program to "manage" ungulates on DoD property. These hunting efforts were not effective to manage or control the large ungulate populations on DoD lands. The lack of ungulate eradication can have significant adverse effects to native plants. Recently, the DON has installed an ungulate fence and is removing ungulates from NBG.

Finally, the Sikes Act requires the DoD to develop and implement INRMPs for military installations across the United States. INRMPs are prepared in cooperation with the Service and State/Territorial fish and wildlife agencies to ensure proper consideration of fish, wildlife, and habitat needs. The Service, Guam DAWR, and JRM have been working together to finalize a new INRMP; however, the draft INRMP has still not been approved by the Service or DAWR.

The DON also has installed approximately 4,400 ft of coated chain link fence along Route 2A on the perimeter of NBG. The fence provides an ungulate exclosure for the 3,114 ac (1,260 ha) of the main base of NBG. The fencing project is intended to effectively close off Orote peninsula from any new ungulate incursions and only entry control gates will be left unfenced. These gates are manned twenty-four hours a day/seven days a week. The fencing project was initiated in 2013 and is complete.

In addition, per negotiations in the JGPO 2010 Biological Opinion (USFWS 2010a, p. 51) the DON has committed to support the re-introduction of native endangered or threatened species on DoD lands on Guam consistent with species recovery plans. When the DON and Service mutually agree the constraints to reintroduction of native threatened or endangered species on DoD lands on Guam have been minimized to a point that a feasible and successful re-introduction of the affected species is more probable than not, the DON will work with the Service to develop a re-introduction plan and supporting programmatic biological opinion that ensures such re-introduction efforts are consistent with the species recovery plans and the military mission on Guam.

DoD has had limited success in fulfilling requirements under Biological Opinions. The lack of management on DoD lands significantly increases the uncertainty that adequate habitat will be protected and managed for the conservation of listed species on Guam.

Previous or On-going DoN Projects Addressing the Conservation and Management of the Mariana Swiftlet

- 2000-2015: USDA BTS trapping around NMS caves.
- 2010-2015:

  - Quarterly surveys of NMS caves (Mahlac, Maemong, and Fachi) to estimate population size and monitor trends.
  - Surveys for potential additional swiftlet caves on NMS.
- 2012-2015:
  - Evaluation and development of new techniques to estimate swiftlet population size.
  - BTS control (trapping, bait tubes, and hand removal) at swiftlet caves.
  - BTS surveys to assess activity and use at swiftlet caves.
  - Operational assessment of current BTS control methods around swiftlet caves and field examination of what affects interception rates.
  - Assessment of whether BTS predation on captive birds (surrogate species) increases in the vicinity of rodent-baited traps.
  - Collection, necropsy, and data analysis of BTS to evaluate diet composition and predation of swiftlets.
  - Assessment of target and non-target take at BTS bait tube stations.
- 2014: Swiftlet roosting/nesting abundance study.
- 2014: Assessment of BTS activity and control methods at caves.
- 2014: Remote monitoring system to estimate and monitor swiftlet population size, spatial distribution of roosting birds, monitor nests and rodents.

Previous or On-going DoN Projects Addressing the Conservation and Management of ESA-listed, ESA Proposed, and GovGuam-listed Plant Species

Serianthes nelsonii:

- Reconstructed the ungulate fencing around the area of the Ritidian tree.
- Monitoring of seedling emergence and growth throughout the study showed 488 seedlings emerged beneath the Ritidian tree, only 4 seedlings exhibited a lifespan greater than 200 days (DoN 2014). These results were unexpected because past reports indicated deer browsing was the major cause of in situ seedling death. The ungulate exclusion fence was intact throughout the study and deer or pigs could not have been responsible for the seedling mortality.
- Nursery propagation trials using seed from the Ritidian tree determined:
  - optimum light levels for growth. In situ and nursery insect pests that caused seedling mortality were the butterfly Eurema blanda and Acacia whitefly (Trialeurodes acacia).
  - the influence of shade on seed germination and initial seedling growth was quantified for optimal growth in nursery and in situ plants.
  - Effects of experimental treatments of nitrogen, phosporous, potassium, and mycorrhizae.

<u>Brown treesnake predation</u>

The primary threat to native forests birds on Guam for over 60 years has been the non-native brown treesnake. Since the accidental introduction of the brown treesnake to Guam around 1950, Guam's avifauna has been decimated, with most of the native birds disappearing from Guam's forests (Savidge 1987, p. 660). The brown treesnake was found to be the main cause of

the decline of the native forest birds on Guam as it opportunistically preys upon eggs, nestlings, and adult birds (Savidge 1986, 1987, p. 660; Conry 1988). Extirpations of all but two resident forest avian species in southern Guam occurred within 27 to 32 years after the accidental introduction of the brown treesnake. In northern Guam, the average time for the bird populations to decline by 90 percent was 8.9 years (Wiles et al. 2003). Brown treesnakes have been reported to prey on Mariana fruit bats (USFWS 2009d, p. 8). Data collected from 1982 to 2006 at the Pati Point fruit bat colony suggest the brown treesnake preys on non-volant fruit bat pups, thereby inhibiting fruit bat recruitment on Guam (USFWS 2010b, p. vii). Brown treesnake densities are high on Guam and in the 1990s were estimated at 20 individuals per ac (50 per ha) in favorable habitats (Rodda and Savidge 2007, p. 315). The persistence of high densities of brown treesnakes has limited recovery efforts to reestablish the Mariana crow, Guam Micronesian kingfisher, and Guam rail populations in the wild on Guam.

In 2014, the USDA-APHIS Wildlife Services, in coordination with the National Wildlife Research Center, the DoD-Environmental Security Technology Certification Program, and the Department of Interior-Office of Insular Affairs, conducted a test of aerial application of a brown treesnake toxicant (acetaminophen) over forested areas in AAFB (Dorr et al. 2014, unpublished data). The results of this study indicated that development of a scalable automatic bait application system could be used in the near future for large landscape scale brown treesnake control and suppression (Dorr et al. 2014, unpublished data). This significant development makes reintroduction of the extirpated avian species a real possibility on Guam (USFWS 2015c). As control efforts continue, we expect that the Guam Micronesian kingfisher, Mariana crow, and Guam rail will be re-introduced onto Guam in the foreseeable future (L. Mehrhoff, USFWS, pers. comm. 2013). With the potential for brown treesnake to be controlled, it is imperative that a sufficient area of forested habitat be conserved in Guam to allow for recovery of these species (USFWS 2015c).

Control of brown treesnakes on DoD lands

The DoD has a long history of working cooperatively with natural resource agencies and stakeholders to prevent the dispersal of brown treesnakes to other Pacific islands and refine techniques to control snakes on Guam. As mentioned above, the DoD and the DOI have recently supported the successful development and application of an aerially dispersed toxicant to control brown treesnake numbers over a landscape on Guam. The DoD also provides funding and support to USDA Wildlife Services to maintain active snake traps around air and sea ports, and housing on DoD lands. As a requirement of a Biological Opinion, the DoD also maintains active snake traps in areas adjacent to the Mariana swiftlet caves at the NMS. The goal is to decrease brown treesnake numbers in swiftlet habitat and reduce the predation of swiftlets by snakes. Because swiftlet habitat within forested areas overlaps with habitat for the Guam Micronesian kingfisher, Mariana crow, Mariana fruit bat, and the Guam rail, snake trapping also benefits these species.

In fiscal year 2014, the DoD funded three projects that will explore methods to detect brown treesnakes and/or evaluate movement of snakes within a landscape. These projects potentially will provide information used to refine rapid response actions and brown treesnake eradication efforts. The DoD continues to work cooperatively with the Brown Treesnake Working Group to identify and implement future brown treesnake projects.

Climate Change

Climate models indicate that hurricanes in the northwestern Pacific are expected to increase in intensity, frequency, and duration by 2200 and continue to increase further into the future (Emanuel et al. 2008, p. 360). These storm increases will likely have a significant effect on habitat and survival of listed species on Guam. We do not expect that additional climate change features including increases in temperature, precipitation, and sea level (Australian Bureau of Meteorology and CSIRO 2011, Ch. 6, p. 178) will significantly affect listed species on Guam.

Environmental Baseline for the Guam Micronesian Kingfisher

Guam Micronesian kingfishers are extirpated from the action area; however, habitat suitable for the survival and recovery of the species (hereafter, kingfisher habitat) is present. For purposes of this Biological Opinion, the "survival condition" of the kingfisher in the wild represents the level of reproduction, numbers, and distribution necessary to support a persistent population on Guam that is fully protected by the ESA. For purposes of this Opinion, the "recovery condition" of the kingfisher is the survival condition where the threats to the species have been addressed such that the protections of the ESA are no longer necessary to ensure perpetuation of the survival condition of the kingfisher in the wild on Guam. Under those circumstances, the kingfisher would qualify for de-listing under the ESA.

As further described below, the role of the action area for the survival and recovery of the Guam Micronesian kingfisher is to provide protected habitat sufficient for two recovery populations (one in north Guam and one in south Guam) of sufficient size to each support 500 territorial breeding pairs in habitat where threats are managed and controlled. Because DON lands within the action area include approximately 75 percent of the kingfisher's habitat in northern Guam, and 43 percent in southern Guam, protection of habitat sufficient to help support two subpopulations (one in northern Guam and one in southern Guam) on DON lands in the action area is essential to the survival and recovery of the kingfisher.

Rationale for Delineation of Guam Micronesian Kingfisher Habitat

Survival and recovery of the Guam Micronesian kingfisher has required maintaining a population in captivity while threats from the brown treesnake are addressed on Guam. Retaining lands containing kingfisher habitat on Guam is essential for recovery and survival of the species. The success of such efforts is dependent on protecting a sufficient amount of habitat within the kingfisher's historical range to support two subpopulations of kingfishers upon reintroduction to northern and southern Guam.

Recently, we updated and conducted an detailed habitat assessment for the Guam Micronesian kingfisher on Guam (USFWS 2015c). Our goals were 1) to identify lands suitable for reintroduction of the species; 2) to determine how much habitat was needed to support survival and recovery of the species, based on the kingfisher recovery plan criteria (USFWS 2008a, p. vi); and 3) to develop a method to offset loss of remaining habitat so that a minimum amount of

habitat needed to support the species is permanently protected. The methods used to calculate kingfisher habitat are provided below.

Methods for Habitat Calculations for the Guam Micronesian Kingfisher

Recovery Targets
The recovery plan for the Guam Micronesian kingfisher (USFWS 2008a) requires the following criteria to be met for delisting. First, there must be two subpopulations of at least 1,000 adult kingfishers (one in northern and one in southern Guam). In addition, both populations must be either stable or increasing based on quantitative surveys or demographic monitoring that demonstrates an average intrinsic population growth rate of greater than 1.0 over a period of at least 10 consecutive years. Third, sufficient habitat, based on quantitative estimates of territory and home range sizes, must be protected and managed to support the population size and trajectory criteria identified above. Finally, brown treesnakes and other introduced predators need to be controlled over 10 consecutive years at a level sufficient to achieve the first and second criteria, above.

Habitat needed to support the Guam Micronesian kingfisher survival and recovery
The following analysis was completed to determine the amount of kingfisher habitat on Guam that must be protected and managed to support both the survival and recovery of this species. This analysis relies on known and estimated life history requirements of the kingfisher and closely related species, and the findings in the final revised recovery plan for the kingfisher (USFWS 2008a).

Delineation of Survival and Recovery Habitat
As noted in the Status of the Guam Micronesian Kingfisher section above, kingfishers utilize a mosaic of forested and open habitats for foraging and breeding. However, as forested habitats, especially mature forest, are likely limiting, the analysis focused on identifying forested habitats as recovery habitat for the kingfisher. This approach was taken for two reasons. First, kingfishers need forested habitat for breeding, so forested habitat is essential to the species. Second, typhoon impacts to forested habitat are not well understood. Therefore, by focusing on forested habitats we provide a more conservative estimate of kingfisher habitat needed for its survival and recovery in the wild on Guam.

All areas identified as limestone, ravine, coconut, and palma brava (*Heterospathe elata*) forests in the 2006 Forest Service landcover map of Guam (Liu and Fischer 2006) were considered to be potential kingfisher habitat. The amount of available habitat was updated by removing all forested areas cleared since the landcover map was completed. This process used 2011 satellite imagery of Guam (USFWS, unpublished data) and other reported clearing (USFWS, unpublished data).

The remaining forested areas were subdivided into potential and non-potential recovery habitat based on forest patch area and isolation. Forest areas that were sufficiently large to hold a kingfisher territory were identified using a "territory building" algorithm (USFWS unpublished algorithm) developed using the Raster package (Hijmans 2014) in the statistical program R. This algorithm accounted for the size of the territory and percentage of forested habitat per territory,

thereby omitting areas that were insufficient in size or placement of forested habitat to meet the criteria of a kingfisher territory. We classified forest patches as too isolated for recovery habitat if they were of insufficient size to hold three or more territories and if they were greater than 0.87 mile (1.4 km) (the maximum dispersal distance reported by Kesler and Haig 2007c for the Pohnpei Micronesian kingfisher) from the nearest neighboring forested area supporting three or more territories. The results of these analyses indicate that there is approximately 14,997 acres of kingfisher habitat in northern Guam and 13,314 acres of kingfisher habitat in southern Guam.

Estimated Population Size and Area Needed for Recovery

1. Each breeding kingfisher pair requires 20 acres of habitat (Kesler and Haig 2007a, Pohnpei subspecies of the Micronesian kingfisher). Therefore, under ideal conditions 10,000 acres of habitat will be needed to support a stable kingfisher population with 500 breeding pairs in northern Guam, where the breeding pairs are using 100 percent of the habitat throughout the year, the habitat is in ideal condition to support kingfishers, and there is never any loss of habitat due to manmade or natural disturbances such as fires or storms. These ideal conditions are unrealistic and not sustainable. Consequently additional area is needed for a more realistic estimate of kingfisher recovery habitat, as follows.

2. Density estimates for Guam Micronesian kingfisher in undeveloped areas of northern Guam give an average density of 4 acres per bird (adults and juveniles; calculated with data from northern Guam for the Guam subspecies of the Micronesian kingfisher in Engbring and Ramsey 1984). Thus, the 10,000 acres will actually support 2,500 adult and juvenile kingfishers. This density estimate includes areas that are periodically not used as territories, but are an integral part of the kingfisher habitat, allowing for natural disturbances such as storm, tree falls, landslides, etc.

3. A stable age distribution with 1,000 adult kingfishers gives a population comprised of 38.24 percent adults (calculated with data on the Tuamotu subspecies of the Micronesian kingfisher in Kesler et al. 2012). Thus, 38.24 percent of 2,500 birds are 956 adults, equaling 478 breeding pairs in 10,000 acres; each pair requiring approximately 21 acres (10,000 acres ÷ 478 pairs). An additional 22 breeding pairs (44 adults) are needed to reach the recovery threshold of 500 breeding pairs (1,000 adults). An additional 462 acres of habitat is needed for these 22 breeding kingfishers. Thus the total habitat needed to support 1,000 adults (500 breeding pairs) is 10,462 acres.

4. The 10,462 acres supports the minimum number of breeding kingfishers needed to reach recovery, and does not provide for natural population fluctuations below the recovery threshold. For instance, climate change is predicted to increase the frequency, intensity and duration of storms in the area of the Mariana Islands by several percent over the next 100 years (Emanuel et al. 2008, p. 360); this will likely increase the fluctuation of the northern Guam kingfisher population. To prevent the kingfisher population from fluctuating below the recovery threshold, additional habitat is required for protection against current and future severe storms. Severe storms (strong - category 3 and above - typhoons and super-typhoons) currently affect Guam once a year on average (FWS

analysis of the Joint Typhoon Warning Center best track data 1975-2014). Climate modeling indicates that these storms will increase in the future. A single severe storm can affect habitat, survival, and reproduction. A 10 percent increase in breeding pairs (50 pairs) requiring an additional 1,050 acres of habitat will serve as added protection against population fluctuations due to climate change and other unforeseen natural and manmade events.

5. The area needed to support a viable northern Guam kingfisher subpopulation that maintains itself above the minimum recovery threshold is estimated to be 11,512 acres. This minimum area assumes that the habitat is restored and managed as follows: restoration of kingfisher habitat requires establishing land cover to 56 percent forested that support trees greater than 17 inches in diameter, and 44 percent open or low cover areas for foraging; management of kingfisher habitat requires the continual control of invasive plants, ungulates, non-native predators such as the brown treesnake, rats, and cats, as well as protection from fire. These restoration and management activities have never been fully demonstrated on Guam and so their success remains an assumption. Predator, weed and ungulate control activities can be very difficult in open wilderness terrain where access and monitoring are difficult. Because of this uncertainty in restoration and management of kingfisher habitat, additional habitat beyond the 11,512 acres may be required to achieve the recovery of kingfisher in northern Guam. This minimum recovery area (11,512 acres) also assumes that at least 1,000 adults are breeding, thus 500 breeding pairs. The area requirements for a breeding pair (approximately 20.0 acres; Kesler and Haig, 2007a) is less than the combined area for an individual non-breeding adult male (average of 17.5 acres; Kesler and Haig 2007a) and an individual non-breeding adult female (average of 14.1 acres; Kesler and Haig 2007a). Thus the total area for recovery will be minimized by assuming all 1,000 adults are in breeding pairs. Additional area may be needed if a significant number of adult kingfishers forgo breeding in any year.

Estimated Amount of Habitat Needed to Support Kingfisher Survival and Recovery
Based on the above analysis, the final area needed to support a viable Guam Micronesian kingfisher population that maintains itself above the minimum recovery threshold is estimated to be 11,512 ac for each kingfisher subpopulation in northern and southern Guam. Collectively, a total of 23,024 ac of habitat would be needed to support the survival and recovery of the kingfisher on Guam (Figure 6).

Summary of Remaining Habitat to Support the Survival and Recovery of Kingfishers on Guam

We estimate that there are currently 14,997 ac and 13,314 ac of kingfisher habitat in northern and southern Guam, respectively. However, kingfishers excavate nest cavities in trees over 17 inches in diameter that are located in closed canopy forests with dense understory vegetation, and this habitat type is limited on Guam due to extensive forest clearing and ungulate effects to forest regeneration. Additionally, natural disturbance events, such as severe typhoons, will continue to affect the availability of the large forest trees necessary to support kingfisher nesting, and these typhoons are expected to increase in intensity, frequency, and duration (Emanuel et al. 2008, p. 360). Therefore, while it currently appears there is adequate potential habitat to support

kingfisher survival and recovery, the actual suitable habitat is likely less; thus any loss of potential habitat must be carefully considered in regards to whether it appreciably reduces the likelihood of kingfisher survival and recovery in the wild.

For kingfisher habitat to support the survival and recovery of kingfisher, much of it will likely have to be restored, and all of it will have to be managed. Restoration of kingfisher habitat requires establishing land cover to approximately 56 percent forested that support trees greater than 17 inches in diameter, and approximately 44 percent open or low cover areas for foraging. Management of kingfisher habitat requires the continual control of invasive plants, ungulates, non-native predators such as brown treesnakes, rats, and cats, as well as protection from fire. Predator, weed and ungulate control activities can be very difficult in open wildness terrain where access and monitoring are difficult. Because of the uncertainty in restoration and management of kingfisher habitat, the Service developed a mitigation ratio to ensure kingfisher habitat to support the recovery of kingfisher on Guam would be protected and conserved (USFWS 2015c).

Mitigation Framework

In consideration of the on-going and increased habitat loss and degradation on Guam (as detailed in the General Environmental Baseline section) the Service has endeavored to finalize the draft Mitigation Framework (USFWS 2014e), including the mitigation ratio for habitat loss, to address future habitat conservation needs for the Guam Micronesian kingfisher (USFWS 2015c). As land management actions are proposed that will affect habitat needed for the recovery and survival of the kingfisher, it will be necessary to offset these effects by assuring that durable habitat will be protected and available for species reintroduction. This can be accomplished by ensuring that any habitat that is lost is offset with permanent habitat conservation at rates that ensure an adequate amount of habitat is needed to support the survival and recovery of the kingfisher on Guam.

The mitigation ratio took into account kingfisher habitat that were already protected in northern and southern Guam. For northern Guam, approximately 571 acres of kingfisher habitat is protected. There is no kingfisher habitat protected in southern Guam. Kingfisher habitat should be protected to the maximum extent possible until restoration and management practices for kingfisher habitat are proven to work.

The Mitigation Framework provides guidance to ensuring that adequate amounts of the habitat will be available for species reintroduction in the future. We have recommended to the DON that they should assure that any habitat that is lost as a result of proposed projects is offset with permanent habitat conservation at a rate that ensures the minimum amount of habitat needed to support kingfisher conservation will ultimately be available to support the recovery and survival of the species in the wild on Guam. Although not part of the project description, please refer to the MOA (DON and USFWS 2015), for information on kingfisher habitat that will be protected to ensure the survival and recovery of the kingfisher on Guam.

Environmental Baseline for the Mariana crow

Mariana crows are extirpated from the action area; however, habitat potentially suitable for the survival and recovery of the species (hereafter, crow habitat) is present. For the purposes of this biological opinion, the "survival condition" of the Mariana crow in the wild on Guam represents the level of reproduction, numbers, and distribution of each species that is necessary to support a persistent population on Guam. Achievement of the survival condition is facilitated by recovery planning and the protections afforded to listed species under the ESA. For purposes of this biological opinion, the "recovery condition" of these species is the survival condition where the threats to the species have been addressed such that the protections of the ESA are no longer necessary to ensure perpetuation of the survival condition of the listed species in the wild on Guam and Rota. Under those circumstances, the species would qualify for de-listing under the ESA.

As further described below, the role of the action area for the survival and recovery of the Mariana crow is to provide protected habitat sufficient for two recovery populations (one in north Guam and one in south Guam) of sufficient size to each support 100 territorial breeding pairs in habitat where threats are managed and controlled. Because DON lands within the action area include approximately 75 percent of the Mariana crow's habitat in northern Guam, and 43 percent in southern Guam, protection of habitat sufficient to help support two subpopulations (one in northern Guam and one in southern Guam) on DON lands in the action area is essential to the survival and recovery of the Mariana crow.

Rationale for delineation of crow habitat

Survival and recovery of the Mariana crow has required maintaining a population off-island or in captivity while threats from the brown treesnake are addressed on Guam. Retaining unoccupied habitat on Guam is essential for recovery of the species. The success of such efforts is dependent on protecting a sufficient amount of habitat within the Mariana crow's historical range to support a crow population upon reintroduction.

We conducted an updated detailed habitat assessment for the Mariana crow on Guam (USFWS 2015c). Our goals were 1) to identify lands suitable for reintroduction of the two species; 2) to determine how much habitat was needed to support survival and recovery of the species; and 3) to develop a method to offset loss of remaining habitat so that a minimum amount of habitat needed to support the species is permanently protected. The methods used to calculate crow habitat are provided below.

Methods for Habitat Calculations for the Mariana Crow

Recovery Targets
The delisting criteria from the draft revised recovery plan for the Mariana crow calls for a minimum of 225 territorial breeding pairs (75 on Rota, 75 in northern Guam, and 75 in southern Guam) (USFWS 2005a, p. v). Since the draft revised recovery plan was published in 2005, additional work on population viability of the Mariana crow has occurred. This recent assessment of population viability indicated that 75 territorial breeding pairs may not be viable over the long-term due to potential inbreeding depression (O'Grady et al. 2006) and projected increases in tropical storm intensity, duration, and frequency (Emanuel et al. 2008), and that 100

territorial breeding pairs may be a more appropriate recovery target (Amidon 2012, unpubl. data). Therefore, we used 100 territorial breeding pairs as our recovery target for this assessment for each of the three regions identified above.

A sustainable population of territorial pairs requires a floater population of juvenile and pre-breeding Mariana crows to replace any pair members that die. We utilized demographic information from the Rota population (Morton et al. 1999, Ha et al. 2010b, Zarones et al. 2013) to estimate a stable age distribution using the popbio package (Stubben and Milligan 2007) in the statistical program R (R Core Team 2014). We then used this distribution to determine the number of non-breeders needed to support the breeding population. Based on this analysis, an additional 96 adult Mariana crows (males and females), 54 juveniles and 42 pre-breeders, would be needed to support a breeding population of 100 territorial pairs at each of the three areas described above. We assumed that each of these birds would require space for foraging and roosting.

Finally, the long-term stability of the Mariana crow population is dependent on the availability of suitable breeding habitat and successful reproduction. Typhoons are a regular occurrence on Guam and Rota and are expected to affect the availability of suitable nesting sites and overall nesting success. Unfortunately, estimates of typhoon damage to nesting trees and demographic estimates of typhoon impacts on Mariana crow breeding success are limited. This assessment should be reconsidered when these data become available. In the interim, we will use more conservative estimates of habitat requirements and delineation of habitat areas (see below) to help account for some of these effects.

Density Estimates
Morton et al. (1999, p. 2) reported that Mariana crow territories ranged from 29.65 to 91.43 ac on Rota, with a mean territory size of 54.36 ac. Therefore, we utilized 54.36 ac as our estimate of forested habitat needed to support a breeding pair. Home range estimates for non-breeders were not available, and we do not currently have information on Mariana crow territory overlap. Therefore, we assumed that each bird would need approximately half a territory, 27.18 ac (11 ha).

Delineation of Crow Habitat
As noted above, Mariana crows are more likely to occur in native dominated forest. For this assessment, we assumed that all areas identified as limestone and ravine forests on the 2006 Forest Service landcover maps of Guam and Rota (Liu and Fisher 2006a,b) are potential Mariana crow habitat. We then updated the amount of available habitat on Guam by removing all forested areas cleared since the landcover map was completed using 2011 satellite imagery of Guam (Metevier 2014, unpubl. data). We then subdivided the remaining forested areas into potential and non-potential habitat based on forest patch area and isolation. We identified forest areas that were sufficiently large to support a Mariana crow territory using a "territory building" algorithm that we developed using the Raster package (Hijmans 2014) in the statistical program R. This algorithm accounted for the size of the territory and suitability of habitat, thereby omitting areas that were insufficient in size to meet the criteria of a Mariana crow territory. We then classified forest patches as too isolated for crow habitat if they were of insufficient size to hold three or more territories and if they were greater than 3.5 kilometers (the maximum

dispersal distance reported by Ha (2012, *in litt*.) for the Mariana crow on Rota) from the nearest neighboring patch of forest capable of supporting three or more territorial pairs. Remaining habitat for the Mariana crow is shown in Figure 7.

Estimated Crow Habitat Needed

Utilizing the recovery targets for the species and density information, approximately 5,436 acres of forest is needed to support 100 territorial breeding pairs. In addition, 2,609 acres of forested habitat would be needed to support the non-breeding crow population. Therefore, a total of 8,046 acres of forest habitat would be needed at each of the three regions (Rota, northern Guam, and southern Guam) to support the survival and recovery of the Mariana crow. However, the 8,046 acres supports the minimum number of breeding Mariana crows needed for survival and recovery of crows in the wild, and does not provide for natural population fluctuations below the recovery threshold. For instance, climate change is predicted to increase the frequency, intensity, and duration of storms in the area of the Mariana Islands by several percent over the next 100 years (Emanuel et al. 2008, p. 360), and this will likely increase the fluctuation of the northern Guam Mariana crow population and increase the acres of suitable habitat needed for the survival and recovery of the crow.

To prevent the crow population from fluctuating below the recovery threshold, additional habitat is required for protection against current and future severe storms. Severe storms (strong [category 3 and above] typhoons and super-typhoons) currently affect Guam every five to 10 years (FWS analysis of the Joint Typhoon Warning Center best track data 1975-2014). Climate modeling indicates that these storms will increase in the future (Emmanuel et al. 2008, p. 360). A single severe storm can significantly affect survival and reproduction in that breeding season. A 10 percent increase in breeding pairs (10 pairs) requiring an additional 544 acres of habitat will serve as added protection against population fluctuations due to climate change and other unforeseen natural and manmade events.

Based on the above analysis, the final area needed to support a viable Mariana crow population that maintains itself above the minimum recovery threshold is estimated to be 8,590 ac for each Mariana crow subpopulation in northern and southern Guam.

Remaining Crow Habitat on Guam

There is currently 13,962 acres of potential Mariana crow habitat left in northern Guam. However, very little of this remaining habitat is set aside for conservation (a total of 502 acres), and even less of that habitat is managed to control threats. There is currently 10,957 acres of Mariana crow habitat left in southern Guam. No crow habitat in southern Guam is set aside for conservation or managed to control threats.

In addition to lands being set aside for conservation, crow habitat needs to be managed for threats including brown treesnakes and other predators, invasive species, and ungulates. Most of the lands set aside for conservation are not currently managed to reduce threats. Therefore, it is urgent that habitat protection and management of Guam's forests begin immediately to prepare for the reintroduction, and potential recovery, of extirpated avian species. If crow habitat is degraded enough to no longer provide the ecological functions necessary to support Mariana

crows (for example, loss of native trees necessary for crow breeding and foraging), then this habitat will need to be removed from baseline calculations.

Furthermore, the habitat model does not account for differences in habitat quality. As described above, primary limestone forest is the highest quality habitat for the Mariana crow. Secondary limestone forest is of lower quality, but due to data mapping challenges, is counted equally in the habitat model. Given the current threats from military and civilian development, typhoons, invasive species, ungulates, and forest conversion, and the small amount protected habitat, it is imperative that conservation efforts begin to protect and enhance the quality of Mariana crow habitat on Guam.

Mitigation Framework
In light of on-going and increased habitat loss and degradation on Guam (as detailed in the General Environmental Baseline section) the Service has developed a draft Mitigation Framework to address future habitat conservation needs for the Mariana crow (USFWS 2015c). As land management actions are proposed that will affect recovery habitat needed for the conservation of the Mariana crow, it will be necessary to offset these effects by assuring that durable habitat will be protected and available for species reintroduction. This can be accomplished by ensuring that any habitat that is lost is offset with permanent habitat conservation at rates that ensure the minimum amount of habitat needed to support the survival and recovery of the Mariana crow on Guam.

The Mitigation Framework provides certainty that adequate minimum amounts of the remaining habitat will be available for species reintroduction in the future. We have recommended to the DON that they assure any habitat that is lost as a result of proposed projects is offset with permanent habitat conservation at a rate that ensures the minimum amount of habitat needed to support crow conservation will ultimately be available to support recovery of the species. Although not part of the project description, please refer to the MOA (DON and USFWS 2015), for information on kingfisher habitat that will be protected to ensure the survival and recovery of the kingfisher on Guam. The habitat that will be protected pursuant to the MOA may also provide conservation benefit to the Mariana crow (DON and USFWS 2015, p.3).

Environmental Baseline for the Guam Rail

Guam rails are extirpated from the action area; however, habitat suitable for recovery of the species ("recovery habitat") is present. For the purposes of this Section 7(a)(2) analysis on a species extirpated from the action area, we define "survival" of the species in terms of the amount of habitat needed to support a target recovered Guam rail population and "recovery" of the species as a point when this population is present on recovery habitat on Guam.

Rationale for delineation of recovery habitat

Survival and recovery of the Guam rail has required maintaining a population off-island or in captivity while threats from the brown treesnake are addressed on Guam. Retaining unoccupied habitat on Guam is essential for the recovery and survival of the species. The success of such

efforts is dependent on protecting a sufficient amount of habitat within the rail's historical range to support a viable rail population upon reintroduction on Guam.

Methods for Recovery Habitat Calculation for the Guam rail

Recovery Targets
Before the Guam rail is considered for downlisting from endangered to threatened, the repatriation of 1,000 birds to northern Guam and 1,000 birds to southern Guam (total = 2,000 individuals; USFWS 1990a, p. 33) would need to occur and brown treesnakes would need to be controlled on Guam (USFWS 1990a, p. 33-34). As mentioned above, no criteria were defined for delisting. However, Traill et al. (2009) proposed a minimum population target of 5,000 individuals as an appropriate target for species conservation.

Density Estimates
Engbring and Ramsey (1984) estimated Guam rail densities 0.07 to 0.33 birds per ha on Guam in 1981. The weka (*Gallirallus australis*), another rail species of conservation concern, had densities ranging from 0.3 to 0.8 birds per ha (Beauchamp 1987) while the Cocos buff-banded rails (*Gallirallus philippensis andrewsi*) typically had densities from four to nine birds per ha (Reid and Hill 2005). The Guam rail and weka densities both reflect species undergoing population declines. Therefore, their density estimates may not reflect the potential densities that could be obtained from a recovered population. However, because the maximum Guam rail density does overlap with the weka estimates it does serve as a good conservative estimate of potential densities until further data are collected. Therefore, to meet the population goal of 5,000 individuals on Guam we would need 41,184 ac (16,667 ha) (5,000 birds/0.3 birds per ha) of appropriate habitat on Guam. In addition, to meet the downlisting criteria of 1,000 birds in both northern and southern Guam then 8,236 ac (3,333 ha) (1,000 birds/0.3 birds per ha) of appropriate habitat would be needed in both northern and southern Guam.

Delineation of Recovery Habitat
Guam rails were predominately observed using scrubby secondary growth areas and the edges of mixed forest areas (Jenkins 1979, Engbring and Ramsey 1984). Jenkins (1979) reports that they were seldom observed in the interior of mature limestone forests or savanna areas and did not occur in wetlands. The Forest Service vegetation map of Guam includes the following vegetation types: 1) Limestone Forest, 2) Ravine Forest, 3) Palma Brava Grove, 4) Scrub Forest, 5) Leucaena Stand, 6) Casuarina Thicket, 7) Acacia Plantation, 8) Coconut Plantation, 9) Savanna Complex, 10) Strand Vegetation, 11) Other Shrubs and Grasses, 12) Agricultural Field, 13) Urban Builtup, 14) Urban Cultivated, 15) Barren Land, and 16) Wetlands (Liu and Fischer 2006a). Of these vegetation types, only Scrub Forest, Other Shrubs and Grasses, and Urban Cultivated were considered primary Guam rail habitats because they include shrubby edge habitats. The remaining forested areas were excluded because rails were less common in interior forested areas. Rails are thought to use the edges of these vegetation types, however, these areas are likely bordered by secondary scrub, shrub, and urban cultivated vegetation types which are included. Savanna complex also was not included though they may use the edge of this habitat types. Wetlands and barren lands were not included because the available data does not list these vegetation types being used by rails. Guam rails may use agricultural fields however there was no data available indicating they use these areas. Finally, Urban Builtup was excluded because

rails were not reported in urban areas and these areas likely do not contain appropriate habitat for the species.

In addition to vegetation type, patch size and proximity or distance between patches also were considered in the delineation of recovery habitat for the Guam rail. No information is available on the average size of a Guam rail territory. A related species, Lord Howe woodhens (*Gallirallus sylvestris*) have an average territory size of one to four ha (NSW National Parks and Wildlife Service 2002) while the weka (*Gallirallus australis*) have an average territory size of two or five ha depending on location (Beuchamp 1987). If we are conservative and assume the maximum territory of a Guam rail is similar to the weka then any patch less than 10 ha (the average territory size of two weka pairs [5 ha x 2]) and over one kilometer away from the nearest patch is likely too small and isolated to be viable habitat for rail recovery. In addition, all patches less than one ha (the minimum territory size of a Lord Howe woodhen) and 125 meters (the approximate radius of a five ha territory) from the nearest patch above one ha is considered too isolated and small to be viable habitat for rail recovery. Finally, any patch less than 10 ha and completely isolated by the nearest patch by lands classified as Urban Builtup (excluding roads) by the Forest Service is considered too isolated to be viable rail habitat due to the potential for urban developed areas to impede movement of rails. The remaining recovery habitat for the Guam rail is shown in Figure 8.

Estimated Recovery Habitat Needed
Based on the density information and the population goal of 5,000 individuals on Guam to achieve conservation of the Guam rail, we would need 41,184 ac (16,667 ha) (5,000 birds/0.3 birds per ha) of appropriate habitat on Guam. In addition, to meet the downlisting criteria of 1,000 birds in both northern and southern Guam then 8,236 ac (3,333 ha) (1,000 birds/0.3 birds per ha) of appropriate habitat would be needed in both northern and southern Guam.

Remaining Recovery Habitat on Guam

Based on the above, there are approximately 24,698 ac (9,995 ha) and 24,886 ac (10,063 ha) of recovery habitat in northern and southern Guam, respectively, for the Guam rail. However, very little of this habitat is protected for the conservation of the Guam rail. Although a quantitative habitat assessment of the protected areas for use by Guam rails has not been conducted, approximately 500 acres have been protected for the Mariana crow and Guam Micronesian kingfisher in northern Guam (USFWS 2015c, p. 3). Rails would be expected to use much of the edges of forest patches, secondary forest and scrub within the approximately 500 acres of protected habitat. No recovery habitat in southern Guam is set aside for conservation.

In 2012, the GNWR proposed approximately 125 acres of habitat on the GNWR's fee simple land to be managed for Guam rails. This area would eventually support the reintroduction of Guam rails within the GNWR. However, this proposal was put on hold in 2014 because of the DON's proposed establishment of the LFTRC surface danger zone within the fee simple land. The GNWR is in the process of evaluating the feasibility of this proposal and whether to move forward with it, in consideration of the proposed action and the future access constraints to the GNWR (J. Schwagerl, USFWS, pers. comm. 2015).

Lands set aside for conservation on Guam and recovery habitat needs to be managed for threats including brown treesnakes and other predators, invasive species, and ungulates. Most of the lands set aside for conservation are not currently managed to reduce threats. In addition, the loss, degradation, and fragmentation of recovery habitat due to urban development continues to threaten the Guam rail.

Environmental Baseline for the Mariana fruit bat

Mariana fruit bat population on Guam

Other than a few isolated periods of increase, Mariana fruit bats have been declining on Guam since the early 1900's (Wiles 1987b, p. 1; USFWS 2009d, pp. 6–7 and references cited therein). Although the decline of the fruit bat was likely initiated by the introduction of firearms and increased hunting efficiency in the early 1900's, predation by the brown treesnake contributed to continued decline (Wiles et al. 1987, p.148; Lemke 1992, p. 137; Wiles et al. 1995, p. 32; Janeke 2006, p. 3; Brooke 2008, p. 2; USFWS 2009d, p. 19, 30). By 1995, nearly all of Guam's remaining fruit bats were located on AAFB (Wiles et al. 1995, p. 39). In 2006, the only known maternity colony on Guam was located on AAFB at Pati Point and had less than 100 individuals (Janeke 2006, p. 4). By 2010 the Pati Point colony no longer existed, and no other colonies are known to currently exist on Guam (SWCA 2012, p. 20, DON 2014c, p. 2).

As described below, individual bats have been detected at multiple locations on Guam in the past seven years (Figure 9):

Northern Guam (GNWR, AAFB, Finegayan, and Haputo)

- In July 2014, a large-scale survey throughout AAFB resulted in an estimate of 8-21 bats (DON 2014c, p. 2).
- Surveys on AAFB in 2012 recorded 50 detections of bats at 84 stations, some of which could be the same individuals. Bats were primarily recorded along the cliffline extending from above the Combat Arms Training and Maintenance (CATM) Range east to Pati Point, in the MSA, and in the vicinity of the HMU (SWCA 2012, p. 58).
- In 2011, three bats were observed flying west along the beach in front of the headquarters at GNWR (Schwagerl, pers. comm., 2015).
- Extensive surveys throughout AAFB from December 2010 to December, 2011, resulted in a conservative estimate of approximately 25 fruit bats (DON 2014c, p. 48)
- From 2010-2013, a single bat was observed flying across Route 3A on six occasions; four observations of a bat flying into the HMU from Finegayan, and two observations of a bat flying out of the HMU into Finegayan in the late afternoon (J. Schwagerl, USFWS, pers. comm. 2015). Fruit bats from AAFB may use forested areas of Finegayan for foraging and roosting.
- During 10 observation days in 2008, one fruit bat was observed in the Haputo ERA and one in the northeastern portion of Finegayan (Brooke 2008, p. 1). The Haputo ERA contains some of the best remaining fruit bat habitat on the DON-managed lands (Brooke 2008, p. 2; DON 2010c; DON 2013b).

Naval Magazine, Naval Base Guam, and Southern Guam

- In August, 2014, two observations of a Mariana fruit bat in flight occurred at Fena Reservoir within the NMS (L. Takano, USFWS, pers. comm. 2014).
- In May and June of 2012 seven detections of a single fruit bat were recorded during surveys on six separate occasions at four locations on the NMS; it could not be determined whether observations were of a single individual or multiple individuals (DON 2014a, p. 48).
- In 2012, fruit bat surveys were conducted within the NMS and a private lands site located in southern Guam (DON 2013b). Seven observations were recorded of a solitary fruit bat in flight at NMS, but it could not be determined if these observations represent one, or multiple bats (DON 2013b, p. 11). These observations supplement fruit bat sightings previously documented in the vicinity of the NMS where foraging and roosting habitat is present (Brooke 2008, pp 1-2). No observations were recorded at the private lands site where suitable fruit bat roosting and foraging habitat is limited. However, known food plants of Mariana fruit bats are present in the vicinity and fruit bats may use the area for roosting, foraging, and commuting (DON 2013b, p. 12).
- One bat was sighted on NBG lands in 2008 during 90 hours of fruit bat surveys at 14 survey locations on or near NBG lands. (DON 2014a, p. 48).

Threats to the Mariana fruit bat on Guam

In addition to the threats described in the General Environmental Baseline section, the following threats also affect Mariana fruit bat populations on Guam.

Hunting
Humans have been using Mariana fruit bats as a food source since human arrival in the Mariana Islands, and consumption of bats represents a significant Chamorro cultural tradition (Lemke 1992, p. 135; Sheeline 1991, p. 14). Demand for fruit bats for human consumption is clearly demonstrated by the large commercial trade in bats that existed in the Marianas in the late 1960's until it became illegal through the Convention on International Trade of Endangered Species of Wild Fauna and Flora (CITES; Wiles and Payne 1986, p. 143; Stinson et al. 1992, p. 63-66; Wiles et al. 1997, p. 204; CITES 2015). It is estimated that approximately 221,000 fruit bats were imported to Guam between 1975 and 1989 (Wiles 1992, p. 54). Illegal hunting appears to be the key reason for the fruit bat's dramatic decline on Guam (Wiles 1987b, p. 154; Wiles and Brooke 2009; USFWS 2009d, p. vii).

Currently, although bats are protected by law on Guam, they are probably still hunted opportunistically on private property when they transit the island, and by deer hunters on AAFB (GNWR, unpublished data, 2005). For example, in 2007, construction of approach lighting at the north field on AAFB began, and included clearing of native limestone forest near Pati Point. During the construction period, reports were made of construction workers illegally hunting fruit bats at the Pati Point colony. The number of fruit bats at the colony declined from 55 bats (summer 2007) to 21 bats (December 4, 2008 survey) (PEER 2009). A recreational public hunting program has been in effect on AAFB since 1964, is still in effect (D. Lujan 2015, pers. comm.), and is managed by a small group of hunters known as the Volunteer Conservation Officers (VCOs). The public is authorized to hunt on weekends in designated areas, and VCOs may hunt after regular working hours during the week. All hunting effort is documented by the

VCOs. Currently, archery-only hunting is allowed in four areas (D. Lujan 2015, pers. comm.); shotgun and muzzle loading hunting is no longer allowed. Elimination of shotgun and muzzle-loading hunting is likely to reduce the chance of fruit bat hunting on AAFB; however, it is possible that fruit bats are still hunted opportunistically on AAFB. SWCA (2012, p. 58) reported that roosting fruit bats were approached by observers as close as 16 ft (5 m), and suggested that hunters could, without difficulty, shoot and kill a roosting bat.

Opportunistic hunting of fruit bats is suspected to occur during hunting of ungulates (Wiles 1987b, p. 154; Janeke 2006, p. 67; USFWS 2009d, p. 24; SWCA 2012, p. 60). In 2007, the Chief Conservation Officer (CCO) of the AAFB Hunting Program reported that poaching of deer was occurring in areas where hunting was not authorized. This same CCO issued Letters of Suspension to four VCOs, and a Removal from Program letter to one VCO for violations against Guam hunting regulations, Base Instructions and program depredation policies (PEER 2009).

Noise

Currently air traffic is the primary source of noise disturbance for fruit bats on Guam (SWCA 2008, p. 2-3; SWCA 2012, p. 23, 37). The first known study examining the effects of aircraft overflights on Mariana fruit bats on AAFB was conducted when a colony of approximately 400 bats still roosted at Pati Point (Morton 1996). During this study, roosting fruit bats responded to some low-altitude aircraft overflights with distress and flushing, which increased time spent in alert, aggression, and maintenance behaviors. Four-engine carriers and bombers generally elicited a greater response from roosting bats than fighter aircraft. Morton (1996, p. iii) suggested that higher levels of air-traffic volume would result in increased energy expenditure and perhaps roost abandonment by some or all of the bats.

In 2006, the effects on fruit bats from noise resulting from increased jet aircraft and helicopter use at AAFB were analyzed in the ISR Strike Biological Opinion (USFWS 2006b). In that consultation, noise effects were expected to adversely affect the Mariana fruit bat to the extent that the nearby Pati Point colony would be abandoned, and fruit bats relocating from Pati Point to other, less-protected areas on the island likely would be shot opportunistically by hunters (USFWS 2006b, p. 49). In the ISR Strike Biological Opinion, we concluded that fruit bats on Guam would be taken as a result of the proposed action, but that this take would not jeopardize the continued overall existence of the Mariana fruit bat (USFWS 2006b, pp. 49–52).

In 2007-2008, another study was conducted to document potential effects of aircraft noise on fruit bats at AAFB (SWCA 2008). During this period, the number of fruit bats at the Pati Point colony had decreased to an average of 40 bats. Aircraft noise affected the Mariana fruit bats by increasing maintenance behaviors following overflights compared to no overflights. However, the proportion of bats displaying maintenance behavior following an overflight was variable. Overflights did not appear to affect active thermoregulation. Six percent of overflights resulted in flushing events, and all flushing events were at noise levels exceeding 106 dBC, the highest reading being 122.6 dBC (SWCA 2008, pp. 2-3).

In 2010, another study was conducted to assess the effects of aircraft noise on Mariana fruit bats at AAFB (SWCA 2012). By 2010, the colony at Pati Point no longer existed. Although up to eight individual fruit bats were observed roosting there at any one time, most departed the site by

the end of each sampling period, indicating the site was no longer used as a colonial roost (SWCA 2012, p. 2). Increases in active thermoregulation (32 percent), maintenance (14 percent), locomotion (74 percent), and alertness (62 percent) were recorded during aircraft overflights. All flush events were at recorded peak noise levels above 90 dBA/101 dBC; the highest reading at 124.9 dBA/125.5 dBC (two F-15 aircraft). The observed flush events were associated with fighter, bomber, transport, and helicopter aircraft overflights (SWCA 2012, p. 23, 37).

In 2015, the MITT Biological Opinion was signed (USFWS 2015b) and the Service found that implementation of the MITT program, including aircraft overflights and other training, was compatible with a fruit bat roost site at Pati Point, but noise caused by nighttime training activities would adversely affect the foraging behavior of fruit bats at AAFB and NMS.

Some evidence suggests that fruit bats may also be affected by artillery noise at the existing CATM range at Tarague. When the fruit bat colony was still roosting at Pati Point, a DAWR Wildlife Biologist observed fruit bats avoiding the firing range area as they left the roost to fly to their foraging grounds. Some flew away from land over the ocean, and returned to land by the Tarague beach area. Others flew up to the cliff line heading towards MSA I (ISR Strike area). These observations occurred while the firing range was active around on two different days. During the time period between the two observations, the number of bats in the colony dropped from approximately 40 to less than 20 individuals. When the firing range was inactive, bats were observed to fly along the cliff line near the range (J. Quitugua, DAWR, pers. comm. 2015).

Typhoons

Mariana fruit bats evolved in the presence of typhoons, the principal natural disturbance in the archipelago, but today these storms are a threat to the species because they can exacerbate the effects of the anthropogenic threats listed above (USFWS 2009d, p. 34). Evidence from Rota suggests that typhoons may not be a substantial source of direct mortality for fruit bats (Stinson et al. 1992, p. 65; Esselstyn et al. 2006, p. 536). However, the synergistic effect of illegal hunting and severe storms on Mariana fruit bats is documented on Rota (e.g., Stinson et al. 1992; Esselstyn et al. 2006). Severe storms can alter fruit bat foraging and roosting behavior by decimating food resources, removing protective foliage cover, temporarily modifying forest structure, and changing vegetation composition, especially by facilitating encroachment of non-native species. Loss of food resources can drive bats to forage on the ground, during daylight hours, and closer to areas of human activity; thereby increasing their vulnerability to illegal hunting (Stinson et al. 1992, p. 65; Esselstyn et al. 2006, p. 532).

Recovery Criteria

A draft revised recovery plan for the Mariana fruit bat (USFWS 2009d) addressed actions needed for the survival and recovery needs of the Mariana fruit bat. Since publication of the draft revised recovery plan, new information on the Mariana fruit bat has resulted in changes to how we look at recovery for the species. We now consider recovery in terms of stable or increasing subpopulations of sufficient size distributed across Guam and the Mariana Islands. To meet recovery objectives, stable or increasing fruit bat subpopulations should at a minimum be distributed on the islands that currently have extant populations (USFWS *in review*). Actions

that reduce or eliminate the potential for self-sustaining populations of resident fruit bats on Guam may hamper or preclude recovery of the species. The reduction or elimination of this potential may take many forms: degradation or loss of habitat and resources required by the fruit bat for foraging, roosting, and reproduction; increased exposure of fruit bats to illegal hunting and other sources of human disturbance; and introduction of non-native predators that prey upon fruit bats. In order for the Mariana fruit bat's population to recover on Guam, sufficient amounts of functional habitat will need to be protected and restored on Guam (USFWS 2009d).

Guam contains a large proportion of the remaining native limestone forest in the southern inhabited Mariana Islands, and most of that habitat is located within DOD lands. Habitat loss and degradation, illegal hunting, predation by non-native predators, and human disturbance currently impact fruit bats within the action area. If threat levels increase within fruit bat habitat in the action area, it may further inhibit the potential for the species to recover.

Mariana fruit bat survival and recovery habitat

Although Mariana fruit bats have been observed in a variety of habitat types, they are more likely to occur in native primary or secondary limestone forest (see Status of the Species above). Mariana fruit bat populations that have been subject to intense hunting pressure (e.g., populations on Saipan, Tinian, Rota, and Guam) are sensitive to human presence, and in recent history, maternity roosts are not known to occur in close proximity to areas inhabited by humans (Wiles 1987b, p. 151; J. Boland, unpublished data 2008-2014). However, fruit bats may forage on or near human-inhabited lands, in spite of hunting pressure (Wiles 2006, pers. comm. as cited in USFWS 2006b; Boland 2008-2015, pers. obs.). Therefore, for this assessment, we assumed that all areas identified as limestone and ravine forests on the 2006 Forest Service landcover maps (Liu and Fisher 2006a) are potential habitat for the fruit bat on Guam. We then updated the amount of available habitat on Guam by removing all forested areas cleared since the landcover map was completed using 2011 satellite imagery of Guam (Metevier 2014, unpubl. data). Although primary limestone forest is higher quality habitat that secondary limestone forest, habitat quality was not accounted for in these calculations due to mapping challenges, and habitat quality as it relates to hunting and predation threats was also not accounted for. As such, our estimate of available survival and recovery habitat (hereafter, referred to as habitat) on Guam is likely inflated.

Using the methods above, the total area of potential fruit bat habitat on Guam was estimated to be 27,096 acres (Figure 9). In order for native limestone forest to serve as habitat for the fruit bat, it will need to be managed for threats to the species, including brown treesnakes, illegal hunting, invasive plant species, and ungulates. Only 576 acres of this habitat is set aside for conservation. Most of the lands set aside for conservation are not currently managed to reduce threats. Therefore, it is urgent that habitat protection and management of Guam's forests begin immediately to allow for recovery of the Mariana fruit bat. If habitat is degraded enough to no longer provide the ecological services necessary to support the fruit bat, then this habitat will need to be removed from baseline calculations.

Mariana fruit bat densities

Estimates of bat density have been calculated for each of the Mariana Islands (DON 2013d, p. 46). The highest bat density is found on the most protected island, Asuncion Island, and is 1.81 bats per forest hectare. Rota has the highest bat population density in the southern part of the archipelago with 0.36 bats/hectare. Using calculations established by DON 2013d (p. 26, 45), and our estimate of 27,096 acres of existing fruit bat habitat, the estimated carrying capacity for fruit bats on Guam is 14,970 bats.

Environmental Baseline for *Serianthes nelsonii*

Rationale for delineation of recovery habitat

Recovery of the *Serianthes nelsonii* requires the permanent protection of sites that contain individuals of this species (USFWS 1994, p. 27). The target for delisting *S. nelsonii* (as described above) requires augmenting existing populations and reestablishing this plant in its former range (USFWS 1994, pp. 33-36). The conservation of recovery habitat is essential, not only to reaching this target, but to ensuring the continued survival and recovery of this species.

Methods for Recovery Habitat Calculation for *Serianthes nelsonii*

On Guam and Rota, *Serianthes nelsonii* trees were reported at elevations ranging from 120 to 420 meters (USFWS 1994, p. 7) and were found primarily in native dominated forests on limestone or volcanic substrates (Raulerson and Rinehart 1991, p. 42; USFWS 1994, pp 6-7; Wiles et al. 1996, p. 229). We therefore assumed that all remaining limestone and ravine forest, as classified by the U.S. Forest Service (Liu and Fisher 2006a), between 120 and 420 meters elevation were potential habitat for the species. Therefore, approximately 11,668 acres of habitat for *S. nelsonii* remains on Guam (Figure 10).

Status of the Species in the Action Area

The action area encompasses the entire adult population of *Serianthes nelsonii* on Guam, and is comprised of one adult tree of unknown age. The last remaining adult tree continues to produce seeds, but the structure and health of the tree itself is precarious due to a variety of factors (DON 2014a, p. 58; AAFB 2015, p. 4). The tree has begun to lean in recent years (AAFB 2015, p. 4), and there has been historical storm damage, including snapping and loss of branches (J. McConnell, UOG, pers. comm. 2014). It is at further risk of toppling due to termite damage, which is visible along the trunk, and a large amount of saprophytic or epiphytic ferns which have concentrated growth within a shallow cavity on the trunk (AAFB 2015, p. 4). In addition, the canopy of the tree has experienced recent extensive defoliation, probably due to insect herbivory from *E. blanda* butterflies (AAFB 2015, p. 4).

The area surrounding the fenced tree is comprised of rugged primary limestone karst forest. Although the area around the tree is currently fenced to prevent ungulate access, researchers are trying to understand why seedling mortality around this adult is close to 100 percent mortality (DON 2014, p. 11). Ungulate incidence and browsing is evident outside the small exclosure around the tree, as are nearby areas of past disturbance from military activities (e.g., clearings, ordnance). However, the heavily forested area around the adult tree is diverse

with native plant species characteristic native limestone forests in the Marinas including, but not limited to, *Ochrosia mariannensis*, *O. oppositifolia*, *Eugenia reinwardtiana*, *Syzygium thompsonii*, *Macaranga thompsonii*, *Guamia mariannae*, and *Pisonia grandis*. Despite the presence of some pest species and habitat disturbance, the cliffline area surrounding the adult *S. nelsonii*, especially the forested karst outcrops, is relatively undisturbed, high quality, diverse habitat suitable for multiple protected species, including *S. nelsonii*.

A large portion of the LFTRC footprint is in habitat currently being managed to eradicate ungulates. This area was designated as mitigation for a previous DoD action (USFWS 2006b), and falls within the Overlay Refuge. In addition, the DoD has several current projects and projects in the near future that may affect *S. nelsonii* habitat (refer to General Environmental Effects section).

As mentioned above, several recovery actions have been initiated recently for this species. However, the adult within the footprint of this action remains the sole reproducing tree on the island of Guam. The Guam adult tree is particularly important for maintaining the genetic diversity within this species (USFWS 1994, p. 21). In addition, the individuals outplanted at the GNWR within the proposed SDZ, are offspring of the Guam adult tree. They constitute much of the entire Guam genetic lineage of *S. nelsonii*, and all are within the proposed project's footprint. Their survival is crucial to maintaining genetic diversity of this species. The 31 outplanted individuals on GNWR, four months after outplanting, have 100 percent survival and all have experienced physical growth. However, daily monitoring, netting to exclude large insects, regular watering, small insect removal by hand, and other protective treatments were applied (E. Demeulenare, pers. comm. 2015).

F. STATUS AND ENVIRONMENTAL BASELINE OF CRITICAL HABITAT

Status and Environmental Baseline of Guam Micronesian Kingfisher Critical Habitat

Approximately 376 ac (152 ha) were designated as critical habitat for the Guam Micronesian kingfisher on Guam (USFWS 2004, 46 pp). Critical habitat for the kingfisher was identified using guidelines from the Guam forest bird recovery plan (USFWS 1990a). Because the kingfisher does not exist in the wild and all suitable habitat presently is unoccupied, inclusion of unoccupied areas is essential to the conservation of this species. Recovery to the point where the protection afforded by listing is no longer necessary will require restoration of the kingfisher through release of captive birds and subsequent natural dispersal into areas of Guam that formerly were inhabited.

Primary Constituent Elements

The primary constituent elements required for the Guam Micronesian kingfisher for the biological needs of foraging, sheltering, roosting, nesting, and rearing of young are found in areas that support limestone, secondary, ravine, swamp, agricultural, and coastal forests

containing native and introduced plant species. These forest types include the primary constituent elements of:

1. Closed canopy and well-developed understory vegetation; large (minimum of approximately 17 in (43 cm) dbh), standing dead trees (especially *Tristiropsis obtusangula*, *Pisonia grandis*, *Artocarpus* spp., *Ficus* spp., and *Cocos nucifera*); mud nests of *Nasutitermes* spp. termites; and root masses of epiphytic ferns for breeding;
2. Sufficiently diverse structure to provide exposed perches and ground surfaces, leaf litter, and other substrates that support a wide range of vertebrate and invertebrate prey species for foraging kingfishers; and
3. Sufficient overall breeding and foraging area to support kingfisher territories of approximately 25 ac (10 ha) each.

Guam Critical Habitat Unit

The Guam critical habitat unit consists of approximately 376 ac (152 ha) of land in the fee simple portion of the GNWR. The vegetation in this designated unit consists of coastal, limestone, and secondary forests composed of native and introduced species that contain the full range of primary constituent elements required for the long-term conservation of the Guam Micronesian kingfisher in northern Guam. This unit includes forested areas along the northwestern coasts of the island that were occupied by kingfishers in the 1970s and early 1980s (USFWS 2004, p. 62951). This unit also encompasses essential conservation areas identified in the forest bird recovery plan for northern Guam (USFWS 1990a, p. 49), and areas identified for recovery in the revised recovery plan for the kingfisher (USFWS 2008a).

Current threats to Guam Micronesian kingfisher critical habitat in the action area include habitat loss, degradation, and fragmentation due to development, military training, and fire, human disturbance, introduced ungulates, invasive plants, and non-native predators. Actions that exacerbate these threats or result in new threats, individually or in combination, may result in appreciably decreasing habitat value or quality of habitat necessary for the recovery and survival of kingfishers on Guam.

Recent conservation actions in the Guam critical habitat unit include construction of a multi-species exclosure fence at the GNWR at Ritidian Point, brown treesnake trapping and ungulate removal within the exclosure fence; and outplanting of native trees.

Status of Mariana Crow Critical Habitat

In 2004, the Service designated approximately 376 ac (152 ha) on Guam, and 6,033 ac (2,552 ha) on Rota, as critical habitat for the Mariana crow (USFWS 2004, 46 pp). Critical habitat for the Mariana crow on Guam was identified using the recommendations provided by the Mariana crow recovery team for the draft revised recovery plan (USFWS 2004). The Service also used the recommendation of the recovery team to identify one unit for the Mariana crow on Rota (USFWS 2004). For the conservation of the Mariana crow, recovery recommendations and the draft revised recovery plan (USFWS 2005a) call for established populations in northern Guam, in southern Guam, and on Rota.

The Service included unoccupied habitat in the designated critical habitat for the Mariana crow on Guam because the occupied habitat (as of 2004) alone was not sufficient to provide for the conservation of the species. Mariana crows are territorial; each pair defends an area of a size determined by forest type and structure (Morton et al. 1999). The maximum density or carrying capacity of crow pairs in a particular area depends on both habitat quality (for foraging and breeding) and the spatial arrangement of territories. Because of the territorial nature of the Mariana crow, its small total population size, limited range, vulnerability to environmental threats, and recovery goals drafted for the species, inclusion of unoccupied areas on Guam is essential to the conservation of the species. Recovery to the point where listing is no longer necessary will require restoration of Mariana crows on Guam through natural dispersal, translocation, and/or release of captive birds in areas that were formerly inhabited but that are not currently occupied. For this population to persist over the long term, it must expand onto adjacent lands that now are unoccupied.

The critical habitat unit for the Mariana crow on Rota reflects the goal of establishing and maintaining a population of at least 75 territorial breeding pairs on Rota and the estimation of the areas necessary to meet this goal (USFWS 2004). However, a recent assessment of population viability indicated that 75 territorial breeding pairs may not be viable over the long-term and that 100 territorial breeding pairs may be a more appropriate recovery target (Amidon 2012, unpubl. data). Therefore, we currently 100 territorial breeding pairs as our recovery target for the Rota population; however the critical habitat unit has not yet been revised to reflect this.

Primary Constituent Elements

The primary constituent elements required by the Mariana crow for the biological needs of foraging, sheltering, roosting, nesting, and rearing of young are found in areas that support limestone, secondary, ravine, swamp, agricultural, and coastal forests composed of native and introduced plant species. Guam and Rota experience a high frequency of severe storms, and these regularly and significantly alter forest structure. Therefore, sufficient habitat area is necessary to absorb the variable impacts of these natural disturbances and still maintain the integrity of the primary constituent elements to support crow populations. These forest types provide the primary constituent elements of:

1. Emergent and subcanopy trees with dense cover for breeding such as *Neisosperma oppositifolia*, *Macaranga thompsonii*, *Intsia bijuga*, *Premna obtusifolia*, *Eugenia reinwardtiana*, *Ficus* spp., *Elaeocarpus joga*, and *Tristiropsis obtusangula*;
2. Sufficient area of predominantly native limestone forest to allow nesting at least 950 ft (290 m) from the nearest road and 203 ft (62 m) from the nearest forest edge and to support Mariana crow breeding territories (approximately 30 to 91 ac (12 to 37 ha)) and foraging areas for nonbreeding juvenile crows; and
3. Standing dead trees and plant species for foraging, such as *Aglaia mariannensis*, *Artocarpus* spp., *Cocos nucifera*, *Neisosperma oppositifolia*, *Hibiscus tiliaceus*, *Intsia bijuga*, *Leucaena*, *Ochrosia mariannensis*, *Pandanus tectorius*, *Neisosperma oppositifolia*, *Ficus* spp., and *Elaeocarpus joga*.

Threats

Threats to Mariana crow critical habitat on Rota and Guam include development, habitat clearing, human disturbance, habitat fragmentation and degradation, introduced ungulates, invasive plants, and non-native predators.

Environmental Baseline for Mariana Crow Critical Habitat

The Guam critical habitat unit consists of approximately 376 ac (152 ha) of land in the fee simple portion of the GNWR. This unit includes limestone, secondary, and coastal forests composed of native and nonnative plants and contains the full range of primary constituent elements needed for long term conservation of the Mariana crow on Guam. This area includes lands in the 1994 historical distribution of Mariana crows in northern Guam (Wiles et al. 1995) and areas that contained crows in northern Guam in 1981 (Engbring and Ramsey 1984). This unit was also identified by the Mariana crow recovery team as important recovery habitat in the draft revised Mariana crow recovery plan (USFWS 2005a).

Current threats to Mariana crow critical habitat in the action area include habitat loss, degradation, and fragmentation due to development, military training, and fire, human disturbance, introduced ungulates, invasive plants, and non-native predators. Actions that exacerbate these threats or result in new threats, individually or in combination, may result in appreciably decreasing habitat value or quality of habitat necessary for the recovery and survival of Mariana crows on Guam.

Recent conservation actions in the Guam critical habitat unit include construction of a multi-species exclosure fence at the GNWR at Ritidian Point, brown treesnake trapping and ungulate removal within the exclosure fence; and outplanting of native plants.

Status and Environmental Baseline of Mariana Fruit Bat Critical Habitat

Approximately 376 ac (152 ha) were designated as critical habitat for the Mariana fruit bat on Guam (USFWS 2004, 46 pp). Critical habitat was identified using the guidelines provided by the Mariana fruit bat recovery plan (1990). Although the current population of Mariana fruit bats on Guam is small, and most bats roost in a limited area, the foraging behavior and diverse diet of the fruit bats cause them to use most of the island for foraging, as documented by Wiles et al. (1995). Thus, all of the designated critical habitat for this species is used for foraging and/or roosting and is considered occupied.

Primary Constituent Elements

The primary constituent elements required by the Mariana fruit bat for the biological needs of foraging, sheltering, roosting, and rearing of young are found in areas supporting limestone, secondary, ravine, swamp, agricultural, and coastal forests composed of native and introduced plant species. These forest types provide the primary constituent elements of:

1. Plant species used for foraging, such as *Artocarpus* spp., *Carica papaya*, *Cycas circinalis*, *Ficus* spp., *Pandanus tectorius*, *Cocos nucifera*, and *Terminalia catappa*; and

2. Remote locations, often within 328 ft (100 m) of clifflines that are 260 to 590 ft (80 to 180 m) tall, with limited exposure to human disturbance and that contain mature *Ficus* spp., *Mammea odorata*, *Casuarina equisetifolia*, *Macaranga thompsonii*, *Guettarda speciosa*, *Neisosperma oppositifolia*, and other tree species that are used for roosting and reproductive activity.

Guam Critical Habitat Unit

The Guam critical habitat unit consists of approximately 376 ac (152 ha) of land in the fee simple portion of the GNWR. The vegetation in this unit consists of coastal, limestone, and secondary forests composed of native and introduced plant species and contains the full range of primary constituent elements needed for the conservation of the Mariana fruit bat. This area is important because it contains areas used for foraging by the last known Mariana fruit bat colony (currently abandoned) on Guam. This area also contains roosting and foraging sites historically and currently used by bats (USFWS 2004, p. 62951; J. Schwagerl, Service, pers. comm. 2015). This unit also encompasses essential conservation areas identified in the Mariana fruit bat recovery plan (USFWS 1990b); the draft revised recovery plan (USFWS 2009d) does not contain specific areas for recovery.

Current threats to Mariana fruit bat critical habitat in the action area include habitat loss, degradation, and fragmentation due to development, military training, and fire, human disturbance, introduced ungulates, invasive plants, and non-native predators. Actions that exacerbate these threats or result in new threats, individually or in combination, may result in appreciably decreasing habitat value or quality of habitat necessary for the recovery and survival of fruit bats on Guam.

Recent conservation actions in the Guam critical habitat unit include construction of a multi-species exclosure fence at the GNWR at Ritidian Point, brown treesnake trapping and ungulate removal within the exclosure fence; and outplanting of native plants including *Serianthes nelsonii*.

G. EFFECTS OF THE ACTION

Exposure Analysis Approach

The Service has developed an analysis framework for section 7 consultations that incorporates the general structure, primary concepts, and nomenclature of the U.S. Environmental Protection Agency's ecological risk assessment framework (USFWS 2005c). Factors causing adverse effects are called "stressors" and beneficial effects are called benefits. In this approach, the Service determines the resources that will be exposed to the proposed action's stressors and benefits by evaluating the location, timing, duration, frequency, and intensity of potential exposure to each stressor and benefit, and identifying the physical, chemical, and biotic features that will be directly and indirectly exposed. Then the causal relationships between sources of stressors and benefits and the response of listed resources are analyzed. The exposure analysis

also estimates future changes in the abundance or distribution of listed species expected to result from exposure to stressors and benefits.

The proposed action's stressors and benefits may include the following actions:

- Construction and operation of the main cantonment at Finegayan
- Construction and operation of family housing on AAFB
- Construction and operation of the LFTRC
- Utilities and site improvements
- Construction of well field and associated AAFB distribution system
- Roadway projects
- Training at NMS
- Construction of facilities at Apra Harbor
- Construction of new facilities at AAFB
- Hand grenade range at Andersen South
- Aviation training at NMS and AAFB
- Forest enhancement project at Finegayan
- Brown treesnake exclosure projects
- Invasive species planning

For purposes of this analysis, the term of effects associated with the permanent destruction of listed species habitat caused by the above construction projects and associated with the operation of the above facilities is considered to be indefinite.

NOTE: As mentioned above, although not part of the project description, an MOA between the DON and the Service regarding conservation of the Guam Micronesian kingfisher recovery habitat in northern Guam was signed on June 11, 2015. The purpose of the MOA is to ensure that a sufficient amount of suitable survival and recovery habitat is conserved and managed in accordance with Federal agency obligations under section 7(a) of the ESA in northern Guam to support the reintroduction of the Guam Micronesian kingfisher and to ensure that the DON meet the purpose and need for the proposed action (DON and Service 2015c, p. 1). Because of the signatory level of the MOA, it provides a high level of assurance that commitments in the MOA will be carried forward to benefit the kingfisher and its habitat on Guam. However, in the absence of implementation of the MOA, our analysis in this Biological Opinion may need to be revisited.

General Effects of the Action

The following section discusses the likely effects of the proposed action on listed species and habitats. The analysis is followed by an assessment of how those effects will specifically affect the Mariana fruit bat, Mariana crow, Guam Micronesian kingfisher, Guam rail, and *Serianthes nelsonii*, and their habitats.

Habitat Loss, Degradation, and Fragmentation (All Species)

The proposed action will result in habitat loss, degradation, and fragmentation (including edge effects) from clearing, indirect and induced development, fire, and noise. Definitions and descriptions of habitat fragmentation and edge effects are described above in the Environmental Baseline section. The habitat loss, degradation, and fragmentation will decrease the amount of suitable habitat for recovery of listed species on Guam. Habitat suitable for the survival and recovery of the Guam Micronesian kingfisher, Guam rail, Mariana crow, Mariana fruit bat, and *Serianthes nelsonii* has been delineated on Guam (Amidon *in litt*., 2012). The amount of habitat for each species that will be cleared by the proposed action is shown in Table 6.

Table 6. Anticipated loss of listed species habitat on Guam resulting from project-related development.

The most severe effects on listed species habitat from habitat fragmentation and edge effects will be on AAFB near Ritidian point from construction of the LFTRC. This area currently contains a

large expanse (over 350 acres) of high-quality primary limestone forest that serves as occupied habitat for the Mariana fruit bat and *Serianthes nelsonii*, and unoccupied habitat for the Mariana crow, Guam rail, and Guam Micronesian kingfisher (see figures 11 and 12). This primary limestone forest is also adjacent and contiguous with the Guam National Wildlife Refuge, providing an even larger forested area serving as habitat for listed species. In total approximately 90 acres of primary limestone forest and 91 acres of secondary limestone forest would be cleared for construction of the LFTRC (DON 2014b, p. 5-339).

In addition to the approximately 194 acres of listed species habitat that will be cleared for the LFTRC (Table 6), approximately 10,000 m (6 mi) of new edge will be created (Figure 12). As discussed in the Environmental Baseline, edge effects have deleterious effects to wildlife populations and ecological processes (Murcia 1995, p. 58; Laurance 2000, p. 134). Edge effects can affect avian density up to 60 meters into the forest, and affect the forest canopy up to 150 m (Murcia 1995, p. 59), and may affect forests at larger landscape scales (Laurance 2000, p. 134). In combination with the effects of increased noise from operation of the LFTRC and additional overflights from AAFB (see below), we expect that the habitat quality of some of the remaining primary limestone forest near Ritidian point will be degraded and no longer provide the same ecosystem services it currently does. This will have an adverse effect on the potential for the remaining habitat to serve as habitat for listed species. As discussed in Environmental Baseline, there is little remaining primary limestone forest on Guam. The result of construction of the LFTRC is habitat degradation and permanent loss of some of the best remaining primary limestone forest on Guam.

In total, approximately 1,020 ac of habitat will be cleared and permanently lost as a result of the proposed action in both north and south Guam. The loss of limestone forest and listed species habitats furthers the long-term trajectory of loss of native forested habitat on Guam, and threatens the future potential for recovery of listed species on Guam. Given the small amount of habitat left on Guam off-setting measures to protect remaining limestone forest and listed species habitats is needed. The effects of habitat degradation and loss are further discussed in the species-specific sections below

Habitat Conservation and Management
Under the proposed action, the DON will implement a forest enhancement project on approximately 1,000 ac in Finegayan to offset loss of listed species habitats. This project could lead to enhanced and better-quality habitat for listed species at the forest enhancement project site. However, there is some level of uncertainty that the forest enhancement site would be protected in the long term because the DON has a history of proposing military development within established mitigation sites. For example, as part of this proposed action, the DON will clear primary limestone forest that was intended to be conserved for listed species and demolish the surrounding ungulate fence built by the USAF as mitigation in the ISR Strike BO (USFWS 2006b) and NWF Beddown (USFWS 2006c).

In addition, as part of DON 2010 (USFWS 2010a, p. 64), the DON also planned to develop a portion of the Federal Aviation Administration (FAA) Mitigation Area on Tinian developed for the Tinian monarch (*Monarcha takatsukasae*). This mitigation area (936 acres) was designated in a Biological Opinion (1-2-98-F-06) for the Federal Aviation Administration dated

January 4, 1999. The DON also entered into agreement with the CNMI to designate this mitigation area as a conservation area for the protection of the endangered and threatened species, particularly the Tinian monarch. This agreement and assurance of protection of the conservation area is further discussed in the final rule to delist the Tinian monarch (USFWS 2004, pp. 56360-56371). However, the DON's upcoming CNMI Joint Military Training (CJMT) EIS also contains alternatives which would develop a portion of the FAA mitigation site (DON 2015d). Further, as described above in the Environmental Baseline, the DON did not follow through on agreements to conduct brown treesnake research and control at Area 50 on AAFB after years or work at the site.

The DON's history of planning for development in previously established mitigation sites required by Biological Opinions, or at long-term research sites, leads us to question the certainty as to whether this forest enhancement site will still be present when listed species addressed in this Biological Opinion are reintroduced to Guam. However, recent discussions with DON and the recently signed MOA by Deputy Assistant Secretary reaffirms DON's commitment for listed species recovery on Guam. We expect the conservation measures in the proposed action to be implemented fully and the MOA to have a long-term beneficial effect to listed species.

Under the MOA, the DON will protect and manage approximately 5,234 acres of Guam Micronesian kingfisher habitat on DON lands in northern Guam for conservation and restoration of kingfisher habitat (DON and USFWS 2015). While the MOA that was signed to protect these lands focuses on kingfisher habitat, the protection and management of these lands may also benefit the Mariana crow, Guam rail, Mariana fruit bat, and *Serianthes nelsonii*.

Under the MOA, the DON will work cooperatively with the Service to identify, develop and implement specific management activities and projects on the 5,234 acres to support the following: 1) brown treesnake control and suppression to facilitate the larger goal of suppressing snake population levels that will ultimately support kingfisher survival and recovery; 2) support for brown treesnake control and eradication methods development, focusing on tools and techniques needed for landscape level survival and recovery of the kingfisher; 3) ungulate fencing and eradication; 4) control of small mammalian predators; 5) invasive plant control and eradication; 6) native plant restoration; and, 7) localized control of introduced invertebrates that may negatively impact kingfisher nesting/fledging. The DON has funded and initiated a number of projects to support the seven focal activities identified above. The DON will continue these activities with items (2) and (3) prioritized for continued funding (DON and USFWS 2015, p. 3) The level of funding for these activities may vary depending on the activities to be implemented in a given year, but will not exceed $2 million annually for the first ten years (starting in fiscal year 2016) (DON and USFWS 2015, pp. 4-5). Upon the expiration of the ten-year period, the DON and Service would reassess the progress of recovery efforts pursuant to the MOA.
.

DoD Civilian Employee and Indirect/Induced Development (All Species)
The proposed action will result in a population increase on Guam. Between the years 2021 and 2023 the population with the proposed action is projected to be 5.6 percent higher than it otherwise would have been without the proposed action (DON 2014b, page 4-419). During the construction period, additional off-island workers will move to Guam to fill non-Federal non-

construction jobs such as teacher and food service worker. The DON refers to this population increase as "indirect" or "induced" growth. There would be a maximum estimated population increase of 1,082 persons from indirect/induced growth; the number of indirect/induced population growth ranges from 89 people in 2015 to 1,082 people in 2021, and decreases to a steady-state of 453 people by 2028 (DON 2014b, page 4-126).

We derived the area that will be developed by the new civilian population within each U.S. Census Subdivision on Guam by calculating the current development footprint per person within each Census subdivision and applying that to the Census subdivision's anticipated increase in population. We assumed the induced population size would remain at 453 people (DON 2014b, p. 4-126) past 2028. Based on the U.S. Forest Service 2002 land cover map (U.S. Forest Service 2002) and 2008 U.S. Census Bureau data (U.S. Census Bureau 2008), we calculated that each person has a development footprint of 0.09 ac. We applied this anticipated new development evenly across areas zoned for development based on current Government of Guam land use plans (Government of Guam 2009, p. 2-14 and 2007, p.1) on slopes less than 30 percent and calculated anticipated effects of development resulting from the indirect/induced population. Based on this, we calculated that no more than three acres of habitat in north Guam for the kingfisher, crow, *Serianthes* tree, and fruit bat and no more than 17 acres for the rail will be lost as a result of induced population growth. In addition, the induced population growth will increase human disturbance throughout the island of Guam to wildlife and their habitats.

Wildfire (All Species)
The proposed action may result in wildfires burning listed species habitat. Fires could start from live-fire training (including use of tracers), bivouacking with campfires, arson, barbeques, debris burning, cigarette smoking, aircraft mishaps, and vehicular malfunctions. Between 1991 and 2002, an average of 28 fires per year burned on DON lands on Guam (DON 2013e, p. 4-8), with 429 ac (174 ha) burned per year. Most of the area burned was savanna grasslands (DON 2013e, p. 4-8). This is approximately double the average annual number of fires on DON lands from 1979 to 1989, though the burned acreage on DON lands was similar (425 ac per year (172 ha per year)). Arson and debris burning account for approximately 70 percent of fires, and 87 percent of area burned, on DON lands from 1979 to 2002. Smoking (8 percent), unknown (3 percent), and miscellaneous causes (including children, campfires, and equipment) account for approximately 4 percent of fires on DON lands on Guam (Nelson 2009, Ch. 3 p. 4).
Fires can lead to a variety of direct, indirect, and interrelated affects to wildlife and their habitats. Fire can burn habitat resulting in habitat loss, fragmentation, and degradation, and loss of foraging and breeding habitat. Fires could expose Mariana fruit bats to smoke, resulting in respiratory distress.

To minimize the effects to listed species resulting from fire burning listed species habitats, the DON proposes to develop and implement a fire management plan, a component of the Range Management Plan,at the LFTRC. The fire management plan will be prepared to minimize fire threat associated with the firing ranges on surrounding habitat and listed species, specifically the adult *Serianthes nelsonii* tree. The fire management plan will be developed and implemented to ensure that any fire sparked during training will not spread beyond the firing range and into forested habitat. Because the LFTRC is surrounded by recovery habitats, the development and

implementation of this fire management plan will be critical to ensure that the *S. nelsonii* tree, and listed species habitat, is not lost due to training activities.

In addition, the DON proposes to develop and implement a comprehensive Wildland Fire Management Plan for JRM lands (DON 2013e, p. 4-8). The goal of the plan is to protect high-value natural resource areas and operational facilities from catastrophic wildfire while conserving resources and military operational flexibility (DON 2013e, p. 5-66). The fire management plan will minimize the effects of fire from arson, debris burning, cigarette smoking and other activities from JRM operations on Guam. Additionally, the stationing of additional large helicopters on Guam, as part of the proposed action, may facilitate increased DON contributions to the suppression of fires threatening forest habitat on Guam.

Because a comprehensive Wildland Fire Management Plan for JRM lands and a fire management plan for the LFTRC will be developed, as described above in the Conservation Measures section, we anticipate that no additional habitat will be lost due to wildfires igniting as a result of the proposed action. Although the DON's comprehensive fire management plan may also minimize fire impacts on DoD lands on Guam by instituting fire prevention, detection, and suppression programs as well as implementing landscape-level fuel modifications in the Naval Munitions Site, the beneficial effects of this DON action are difficult to assess because these projects have not been adopted by DON at this time.

Ungulates (All Species)
As described in the Environmental Baseline, non-native ungulates have caused severe damage to Guam's native limestone forests. Construction of the main cantonment at Finegayan and the LFTRC at Ritidian Point will clear a large area of limestone forest currently used by ungulates and would displace and concentrate ungulates into adjacent areas, resulting in even higher densities and potentially greater habitat damage. These adjacent areas are often habitats for listed species. Therefore, increased ungulate density in adjacent habitats will degrade the habitat quality of these areas and reduce their suitability to serve as habitat for listed species. The JRM INRMP (DON 2013e, Appendix L) includes an Ungulate Management Plan for AAFB. The plan's objectives are to reach and maintain a sustained reduction of deer and pigs in 23 unfenced areas of the AAFB, and to completely remove ungulates from fenced management areas (DON 2013e, p. ES-1); however, this action has not yet been fully implemented and ungulates are still prevalent across AAFB.

National Wildlife Refuge Overlay

In 1993, a Cooperative Agreement (Agreement) was established between the Air Force, DON, and the Service for purposes of establishing and managing the GNWR Overlay on DOD lands. The Refuge includes approximately 152 hectares of fee simple Service land and 9,106 hectares of Overlay Refuge on land owned by DOD. The Agreement, which is still in effect, affirms the parties commitment to "provide habitats essential to the survival and recovery of endangered species" on Guam and to "develop and implement a long-term, comprehensive program to conserve and recover endangered and threatened species… not limited to brown treesnake control and eradication, wildlife habitat and ecosystem protection, endangered and threatened species recovery and reintroduction…". Notably, all signatory parties to the Agreement agreed

to consult under section 7 of the Endangered Species Act (ESA) on proposed Federal actions that are funded, authorized, or carried out by the Federal government within the Refuge, inclusive of Overlay Refuge lands, "that may impact habitat of endangered or threatened species even if those species are extirpated from the affected area, but are not extinct."

To date, only a limited amount of critical habitat has been designated on Guam - for the kingfisher, crow, and the Mariana fruit bat – all on lands owned and administered by the Guam National Wildlife Refuge (GNWR). Department of Defense lands on Guam include a substantial percentage of the total habitat available for recovery of the kingfisher, rail, and the crow. Seventy-two to seventy-five percent of the critical habitat proposed in 2002 was within the Overlay Refuge land (67 FR 63738 63772); however, only the 152 hectares of fee simple GNWR land were ultimately designated for the kingfisher, crow, and bat in 2004 (69 FR 629447 629446). In recognition of the commitments made by the DON and the Air Force under the Agreement, the Service exempted DOD lands from the designation of critical habitat on Guam in 2004.

Approximately 1,400 ac (567 ha) of the proposed action's project footprint within Guam National Wildlife Refuge Overlay boundaries are in the areas that were proposed as critical habitat for the Guam Micronesian kingfisher, Mariana crow, and Mariana fruit bat (67 FR 63738-63764). These areas were excluded from critical habitat designation pursuant to the Sikes Act (16 USC 670a-670o, 74 Stat. 1052, Public Law 86-797), as amended. These 1,400 ac will be cleared as part of the proposed action, and over 300 ac will lose their conservation function due to noise (see analysis below).

Surface Danger Zone over the Guam National Wildlife Refuge (All Species)

The proposed action will create a SDZ over approximately 68 percent of the GNWR at Ritidian Point during operation of the LFTRC. The SDZ will cover the GNWR access road, visitor center, offices, and other facilities and thereby limit access to the GNWR while firing occurs at the LFTRC. The limited access that GNWR staff will have to the refuge property during the 39 weeks per year the LFTRC is active will limit the amount of management that can occur at the GNWR. This could have an adverse effect on listed species by 1) preventing maintenance of the predator exclusion fence at the GNWR, 2) restricting brown treesnake efforts below what is necessary to remove brown treesnakes from the fenced exclosure, 3) limiting maintenance of native outplantings, 4) limiting invasive plant control, 5) limiting effective ungulate control, and 5) restricting the ability to manage the re-introduction of the Guam Rail. Per Section 2822 (Establishment of surface danger zone, Ritidian Unit, Guam National Wildlife Refuge) in the 2015 National Defense Authorization Act, the Service and the DON may enter into an agreement to establish and operate a SDZ over the GNWR. The agreement may include relocation and reconstruction of GNWR facilities, mitigation for impacts to wildlife species, and use of DoD personnel to complete GNWR conservation actions; however, this agreement is not in place yet. Therefore, we assume that the operation of the LFTRC will have an adverse effect on listed species by preventing the management, research, and monitoring that would have otherwise occurred at GNWR.

Noise (Guam Micronesian kingfisher, Mariana crow, Guam rail, Mariana fruit bat)

Overview of Noise Resulting From the Proposed Action
The proposed action will generate noise from the use of a variety of vehicles (construction equipment, trucks, fixed-wing aircraft, helicopters, , and other convoy vehicles) and weapons (small arms, demolitions, and other ammunition), and loud voices. Noise resulting from weapons training and construction on Guam will affect areas occupied by listed species and affect their habitat. Increased jet and helicopter aircraft traffic at Andersen Air Force Base will regularly expose the Mariana fruit bat to high levels of noise. Portions of the habitat for the Guam Micronesian kingfisher, Guam rail, Mariana crow, and Mariana fruit bat are in areas where elevated noise from jet and helicopter aircraft traffic, and weapons firing, will occur.

Below is a general overview of effects of noise on avian species; detailed species-specific accounts are provided in the effects analysis to each species.

Noise review
Studies on the effects of noise on wildlife report a wide range of reactions depending on the biology of the species, its previous exposure to the source noise, whether the species is breeding, the type of noise, and the lateral distance between noise source and the species. The variability in these reactions and their specific circumstances make it difficult to be certain how a particular species will react to noise from the proposed action.

A recent review of noise studies found that many, but not all, species abandon noisy areas (Francis 2015, p. 2). This review found that birds across all locations tended to avoid noisy areas, but that there were trait-specific differences including vocal frequency, nest placement, diet, and foraging location (Francis 2015, p. 1). Omnivorous species and species with animal-based diets were more sensitive to noise then birds with plant-based diets, potentially because noise interferes with prey detection (Francis 2015, p. 1). The review concluded that anthropogenic noise is an important ecological force that shapes the distribution of species by disrupting an organisms' ability to acoustically interact with its environment (Francis 2015, p. 11).

Avian responses to noise may range from flushing and body shifting to physiological responses such as an increase in heart rate or hormone balance (Brown 2000, p. 11; Barber et al. 2010, p. 181). Specific reactions will vary by species and by an individual's previous exposure to noise disturbance (Manci 1998, p. 15). Individuals with previous exposure to the noise may display less reaction to it then individuals without previous exposure (Andersen et al. 1989, Conomy et al. 1998a). This reduced reaction is believed to be a sign of habituation; however, the habituation may be individual or species specific. In general, a species can often habituate to human-generated noise when the noise is not followed by an adverse effect. Even when a species appears to be habituated to a noise, the noise may produce a metabolic or stress response (increased heart rate results in increased energy expenditure) though the response may or may not lead to changes in overall energy balance. Anthropogenic noise disturbance is known to alter animal behavioral patterns and lead to population declines (Barber et al. 2010, p. 181). Species that are commonly hunted often demonstrate behavioral (e.g., flushing, startle response) or physiological responses (e.g., increased heart rates, increased respiration rates) to gunshot sounds Larkin et al. (1996, pp. 21-52). Conomy et al. (1998a, p. 1,135-1,142) found that black ducks

(*Anas rubripes*) did not become habituated to noise. Larkin (1996, p. 1) in a review of noise effects on wildlife, reported that decreased responsiveness from wildlife after repeated noise is frequently observed and attributed to habituation. However, the degree of disturbance to which a species can habituate may be limited (National Park Service 1994, p. 5.17). Francis et al. (2011a, pp. 6-7) state that overall most species, even urban-adapted species, respond negatively to noise.

Habitat Degradation

There are multiple ways for anthropogenic noise to cause habitat degradation including noise pollution, masking of avian acoustic signals, changes in predation risk, and reduction in reproductive success. Noise pollution is defined as undesirable human noise, and has increased in most environments over the last century (Ortega 2012, p. 7). Noise pollution can affect birds in numerous ways including physical damage to ears; stress, fright and avoidance responses; changes in reproductive success and in vocal communication; and interference with ability to hear predators and other sounds (Ortega 2012, p. 8). Anthropogenic noise could be a factor driving bird species out of urban areas, even when other habitat requirements are still sufficient (Slabbekoorn and Ripmeester 2007, p. 73).

Most studies on habitat degradation from noise have focused on highways and gas drilling compressor pads, and these studies demonstrate that habitat near a noise source is less suitable than habitat farther away. Francis et al. 2011b (p. 1269 and 1278) found that compressor noise at gas wells caused a five percent lower occupancy of avian species near the pads. Bayne et al. (2008, p. 1190) found that passerine density was significantly influenced by chronic anthropogenic noise from gas compressors, and that noise levels from compressor stations affected birds up to 700 meters into the surrounding forest. The willow warbler (*Phylloscopus trochilus*) had a much lower density of territorial males within 0-200 meters from a highway compared to habitat farther away, yearling males were found 50 percent more often in the road zone, and the study indicated that the road zone probably serves as a sink for young males due to reduced habitat quality from noise (Foppen and Reijnen 1994, p. 99). These studies generally show that noise pollution can cause habitat degradation.

Masking

Anthropogenic noise that drowns out vocal communication between birds is called masking. Masking can have serious consequences because birds communicate vocally to attract mates and defend territories (Slabbekoorn and Ripmeester 2007, p. 1; Barber et al. 2010, p. 180; Ortega 2012, p. 10). Masking of communication necessary for territory defense and mate attraction may have a negative impact on reproductive success and exclude birds from otherwise suitable habitat (Halfwerk et al. 2011, p. 210). Halfwerk et al. (2011, pp. 217-218) suggest four mechanisms related to masking that could reduce avian reproductive success: (1) female birds interpret male songs masked by high noise as of lower quality and put less energy into the breeding cycle; (2) a noisy territory may be perceived of as being a lower quality and avoided, reducing the number of available territories for breeding; (3) increased noise levels cause physiological stress due to reduced foraging opportunities if prey are less easy to detect or because the bird has to spend more time scanning for predators; and, (4) noise could have a negative impact on parent-offspring communication.

Breeding
Anthropogenic noise can have negative effects on avian breeding (Slabbekoorn and Ripmeester 2007, p. 2; Halfwerk et al. 2011, p. 210; Ortega 2012, p. 10). Noise may affect egg production, incubation, brooding and nest abandonment (Ortega 2012, p. 10). Halfwerk et al. (2011, p. 210) found that females laid smaller clutches in noisier areas, and that noise recorded in April had a negative effect on the number of great tit fledglings independent of clutch size, compared to noise in March. High noise levels could lead females to breed later, allocate less energy to care of eggs and chicks, and cause communication difficulties between parents and offspring (Halfwerk et al. 2011, pp. 217-218).

Habib et al. (2007, p. 176) found that ovenbird pairing success was reduced, and more inexperienced birds were breeding for the first time, near noisy compressor sites compared to noiseless sites. This reduction in ovenbird pairing success near compressor sites was likely caused by noise interfering with a male's song, thereby inhibiting communication with females and reducing pair success (Habib et al. 2007, p. 176). Foppen and Reijnen (1994, p. 95) found that the zones nearest to a highway served as a sink for male willow warblers, and that the proportion of successful yearling males was 50 percent lower in the road zones compared to zones farther away from the highway. Delaney et al. (2002, p. 54) found that the nesting success of red-cockaded woodpeckers (*Picoides borealis*) near Fort Stewart, Georgia, was not significantly affected by experimental and passive military training noise. However, red-cockaded woodpeckers did flush from their nests repeatedly due to nearby (less than 100 meters) artillery and blank fire events, but returned to their nests quickly and without impact to nesting success (Delaney et al. 2002, p. 59).

In a study of the effects of helicopter noise from the Marine Corps Air Station Miramar (MCAS) on California gnatcatcher (*Polioptila californica californica*) reproduction, Hunsaker and Rice (2006, p. 101) found that noise levels at MCAS did not affect reproductive success. California gnatcatchers found and inhabited suitable nesting sites in spite of the noise environment, and the factors affecting nest success were habitat, topography, and rainfall. Awbrey and Hunsaker (1997, p. 3177) found that fixed-wing aircraft noise at Naval Air Station Miramar was correlated with fewer California gnatcatcher nest attempts and eggs laid, but that once a nest was established with eggs in it, military aircraft noise had no detectable influence on reproductive success. In Hawaii, Vanderwerf (2000, p. 9) studied the response of Oahu elepaio (*Chasiempis sandwichensis ibidis*) at eight nests to military noise (artillery blasts ranging from 89-116 dB). No elepaio flushed from a nest in response to artillery noise. A mild response was only observed twice by the same incubating male who raised his head and scanned the area after an artillery blast then resumed preening after 1-2 seconds (Vanderwerf 2000, p. 38).

There may be differences between the effects of chronic noise and intermittent loud noise in the responses of breeding birds. Birds that select nest sites with chronic noise may "accept" the noisy conditions and not abandon nests in response to the noise. However, birds that select nest sites during quiet times, and then become disturbed by noisy conditions later, may abandon nests (Ortega 2012, p. 10).

Hearing (for avian species, see Mariana fruit bat section below for bats)

Birds may also suffer physical damage to their ears from loud noise (Barber et al. 2010, p. 181). Damage can occur from single blasts (>140 dBA), multiple blasts (>125 dBA) or continuous exposure to noise at greater than 110 dBA (Ortega 2012, p. 9; Dooling and Popper 2007, p. 23). Birds are able to regenerate the sensory cells of the inner ear providing a way for them to recover from physical damage to the ear from loud noise, and so do not suffer permanent hearing loss like mammals (Dooling and Popper 2007, p. 5 and p. 25). However, in their review, Dooling and Popper (2007, p. 27) state that the effects of short, intermittent, and high intensity sounds on avian hearing are much less known than that from highway noise. Many birds appear to tolerate noise that can cause pain in humans, for example: seabirds at airports, wild turkeys (*Meleagris gallopavo*) near a rocket testing plant in Florida, and ospreys (*Pandion haliaetus*) at the Naval Surface Warfare Center, Dahlgren (Larkin et al. 1996, p. 31, and references within).

Noise from Construction (for avian species, see Mariana fruit bat section below for bats)
Noise from construction may affect habitats for listed birds. Construction as part of the proposed action will occur from 2015 to 2028; however, construction will be phased and will not occur at all places at once, or for the entire construction time period. Construction equipment will include standard heavy equipment including bulldozers, graders, haulers, large trucks. No blasting or use of dynamite will occur as part of the proposed project. The use of heavy equipment can reach noise levels of 96 dB (USFWS 2006a, p. 15). Based on ambient noise studies conducted above the cliff line at AAFB (DON 2014a, p.66), we expect that noise within the listed species habitats in Guam to range from 55 to over 65 dB. Therefore, noise from the construction of the proposed action may reach between 20-40 dB above ambient conditions.. Noise from construction of the proposed action would be temporary and intermittent. Construction noise reaching listed species habitats may rise above the disturbance threshold for listed species; however, this noise will be short-term in duration and will not lead to a permanent reduction in the capability of adjacent habitat to support the future survival and recovery of listed birds.

Noise from Aircraft (Guam Micronesian kingfisher, Mariana crow, Guam rail, Mariana fruit bat)
Studies on the impacts of aircraft overflights to wildlife have been primarily limited to work on ungulates (e.g., Krausman et al. 1998; Maier et al. 1998; Frid 2003; Landon et al. 2003; Krausman et al. 2004; Lawler et al. 2005), birds of prey (e.g., Andersen et al. 1989; Watson 1993; Trimper et al. 1998; Delaney et al. 1999; Palmer et al. 2003), and waterbirds (e.g. Ward et al. 1999; Conomy et al. 1998 a,b; Komenda-Zehnder et al. 2003). These studies report a wide range of reactions to overflights depending on the biology of the species, its previous exposure to overflights, whether the species is breeding, the type of aircraft, the altitude of the aircraft, and the lateral distance between aircraft and the species. The variability in these reactions and their specific circumstances make it difficult to be certain how a particular species will react to aircraft overflights.

Noise from aircraft is complex and wildlife response may depend on the type of aircraft and the species involved. In a literature review of waterfowl response to aircraft, avian response to aircraft was (cautiously) generalized as more intense with helicopters than fixed-wing aircraft, and stronger with slower fixed-wing aircraft than fast fixed-wing aircraft (Plumpton 2006, p. 3-1, 3-2). The proposed action will result in an increase in aircraft overflights over listed species

habitat. Therefore, we conclude that noise disturbance over listed species habitat in the flight paths will increase; however, the effects will be species-specific and are discussed further below.

Noise from LFTRC (Guam Micronesian kingfisher, Mariana crow, Guam rail, Mariana fruit bat)
Upon operation of the LFTRC, live-fire operations would occur between 7:00am and 7:00pm for up to 39 weeks per year, plus night operations (two nights per week over 39 weeks per year) would occur between 7:00pm and 10:00pm or 6:00am to 7:00am. The noise disturbance from the training will be impulse noise with very intense sounds of short duration (e.g., the discharge of a weapon). Firing noise from single shots merged in bursts, machine gun burst, and concurrent firing of multiple weapons would result in short periods of intense firing followed by periods of silence. Live-fire operations may occur for hours at a time, for 5 days a week, or not occur for multiple weeks in a row.

The DON conducted a noise study at AAFB at three sampling sites near the LFTRC and found that ambient noise was never below 50 dB, and on some days was above 65 dB almost 100 percent of the time (DON 2014a, p. 66). The DON provided averaged daily noise level (ADNL) in the Biological Assessment (DON 2014a, p. 68) and SEIS (DON 2014b, p. 5-356) for areas surrounding the LFTRC. In the areas closest to the training ranges the ADNL would increase approximately 20 to 25 dB over baseline conditions, with average daily sound levels rising above 85 dB.

However, peak noise is a more appropriate measure of noise for wildlife, and the U.S. Army Center for Health Promotion and Preventive Medicine (USACHPPM) recommends using peak decibel levels when discussing impulsive noise (USACHPPM 2005 in MCB Hawaii 2014, p. 33). The DON provided the Service with peak noise levels for the MPMG range using a formula to calculate peak noise levels at a specified distance from the source. Because the peak noise calculation did not account for sound attenuation from the directional nature of the noise generated by the muzzle blast, terrain, ambient noise, vegetation, temperature, humidity, and other factors, the Service developed a model to estimate peak noise from the LFTRC (USFWS 2015a).

The loudest noise would occur at the firing point, which in a worst-case scenario is at the MPMG firing line at 160 dB. Overall, we do not anticipate that the firing range will be able to be heard on most days outside the 65 dB line (though what is heard will vary based on a species' hearing range); and if it is heard we expect it to be a soft distant noise. It is known that at distances of several kilometers, received noise level can vary by as much as 50 dB above and below the mean due to changes in meteorological conditions (Delaney et al 2002, p. 57); however it is not possible for us to model those conditions at this time. A species-specific noise model is presented for each species below. This conclusion relies heavily on the noise modeling outcomes described above, and if noise from the LFTRC is different than expected, the conclusions described below must be revisited.

Effects from noise
We do not expect any listed birds to be close enough to the firing ranges' firing lines to be exposed to noise levels that cause physical damage to their ears, and therefore we do not expect hearing loss in birds to occur due to the proposed action. The DON will not begin, or continue,

firing at the LFTRC if a fruit bat is present in the area, and therefore we do not expect fruit bats to be exposed to noise levels that cause physical damage to their ears. However, we do expect that listed species habitat adjacent to the firing lines will be adversely affected by operation of the firing ranges. Species-specific details can be found in the sections below.

ISR Strike Ungulate Fence at Ritidian Point (Guam Micronesian kingfisher, Mariana crow, Mariana fruit bat)

As described above, the proposed action will demolish the ungulate fence built as mitigation required under the ISR Strike Biological Opinion (USFWS 2006b) to offset effects to the kingfisher, crow, and fruit bat. The DON proposed three alternatives for the fence. The first alternative, in Finegayan, was in much lower quality habitat than the primary limestone forest at Ritidian Point. The second two alternatives were located at Ritidian Point, adjacent to the LFTRC. As described below, most of this area will be too loud from operation of the LFTRC to support the kingfisher, crow, and fruit bat. Therefore, these locations cannot be considered adequate alternatives to the current ungulate fence at Ritidian Point.

Invasive Species (All species)

Implementation of the proposed project is likely to increase the risk of introducing or spreading non-native terrestrial and aquatic invasive species including plants, animals, and microbes. Pathways associated with anthropogenic activities have a relative risk of introducing and dispersing non-native invasive species. Hulme et al. (2008) described three broad mechanisms for non-native species introductions: importation as a commodity (e.g., purposeful importation as biocontrol, pet trade), arrival via transport vector, and natural dispersal. Of these mechanisms, Hulme et al. (2008) further described a framework for introductions that is supported by six principal pathways of which two could potentially occur via the implementation of DON: contaminant of a specific commodity and stowaway (independent of a commodity, like ballast water or airfreight). The pathways of contaminant and stowaway include, but are not limited to species transported via: construction equipment, personal protective equipment, delivery of supplies, materials, goods, foot traffic, vehicles or vessel traffic. Invasive species introduced as contaminants and stowaways could occur as a result of inadequate sanitation and inspection during and prior to movement. The repeated or routine movement of equipment and people increases the risk of introduction and establishment of a non-native invasive species.

It is important to understand that the "risk" of introduction and establishment of invasive species is highly variable across taxa and habitats. Identifying and analyzing risk for all the species that could be moved via DON-related activities is not practicable. Instead, a more efficient approach is to address pathways where numerous species from different taxa may be inadvertently introduced and implement prescriptive measures to control risks from the pathways. A pathway risk assessment will provide a structure for assessing where the greatest "risk" for a non-native species introduction occurs and locations where managing ingress or egress of these species is most efficient for control. Pathways must be controlled because repetition of an action has a direct effect on propagule pressure which as stated above increases the likelihood of a species to become established.

To address pathways and encourage a more holistic approach to managing invasive species, the DON funded the development of a Regional Biosecurity Plan (RBP) for Micronesia and Hawaii (formerly referred to as the Micronesia Biosecurity Plan). Individual activities for various species will continue, but the DON and others agree it is more efficient to manage pathways and prescribe corrective measures for a suite of species that will be monitored at discrete control points over time. The RBP will provide stakeholders in Micronesia and Hawaii with a platform for coordination and integration of inter-agency invasive species management efforts such as control, interdiction, eradication, and research. Several of the recommendations of the RBP are incorporated into the project action, and are detailed in the Conservation Measures to Minimize the Effects of Invasive Species section.

The DON is also committed to a comprehensive brown treesnake interdiction program, also detailed in the Conservation Measures section, to ensure that military activities, including the transport of civilian and military personnel and equipment to and from Guam, do not contribute to the spread of brown treensnakes (DON 2014a, p. 38). Brown treesnake interdiction requirements (e.g., trapping and inspections at ports, cargo facilities, and aircraft, inspections of household goods, biosecurity plans for training events) are specific in DoD instructions (i.e., 36 Wing Instruction 32-7004, *Brown Tree Snake Control Plan* and COMNAVMAR Instruction 5090.10A, *Brown Tree Snake Control and Interdiction Plan*) as well as the annual Work Financial Plan that is developed in cooperation with USDA Wildlife Services (DON 2014a, pp. 38-39).

In addition, the DON will fund any increase of current federally funded brown treesnake interdiction measures (in Guam, CNMI, and Hawaii) where the increase is related to direct, indirect and induced growth caused by the USMC relocation to Guam. The fiscal year (FY) 2010 level of funding for the Federal interagency brown treesnake interdiction effort on Guam, CNMI, and Hawaii and 2010 transportation levels associated with outbound cargo from Guam for the U.S. or U.S. territories will be used as the baseline. That funding will continue and become part of the DON's brown treesnake interdiction funding under authority of the Brown Tree Snake Control and Eradication Act (7 USC § 8501 note). The Service agrees that it is not DON's responsibility to fund increased interdiction measures *that are identified* more than one year after the end of the fiscal year both USMC relocation construction has ended and the permanent non-transient USMC military units have relocated to Guam. However, the Service understands the DON will continue to provide a baseline level of interdiction funding related to the direct, indirect, and induced-growth effects of its proposed action beyond one year.

Because of the DON's commitment to the RBP and brown treesnake interdiction and with full implementation of the biosecurity measures proposed as part of this action, we anticipate that the proposed action will prevent the introduction and spread of invasive species both within the action area, and beyond the borders of Guam.

Conservation Measures Associated with the Action (All Species)

In addition to measures to minimize the risk of invasive species described above, the proposed action also includes other measures, listed below and described in the Conservation Measures section, which will have a beneficial effect on listed species.

- Forest enhancement project in Finegayan
- Funding of selected projects identified as priorities in the Brown Treesnake Technical Working Group Strategic Plan
- Measures to minimize effects of construction including contractor education, following the Guam Landscaping Guidelines, contract specifications to avoid unintended clearing of habitat, and monitoring of implementation of conservation measures.

Effects of the Action – Guam Micronesian kingfisher

The Guam Micronesian kingfisher was once distributed throughout Guam, but significant population declines, resulting primarily from predation by the brown treesnake, resulted in their extirpation from Guam by 1988 (Wiles et al. 2003, USFWS 2008a). Currently, the kingfisher survives only in captivity. The Service is planning for the reintroduction of the kingfisher to Guam during the term of the proposed action. The success of the reintroduction is dependent on the protection and management of suitable habitat essential to kingfisher's survival and recovery in the wild on Guam. Kingfisher habitat is very limited on Guam and has been severely degraded by habitat fragmentation and loss, lack of management, introduced ungulates, invasive species, typhoons, and forest conversion due to the loss of birds that function as pollinators, seed dispersers, and frugivores in the forest.

In addition to the general effects of the action discussed above, a species-specific effects analysis for the Guam Micronesian kingfisher is provided below.

Noise

Aircraft
As detailed in the general effects of the action section, birds tend to avoid noisy areas but their response to noise may vary depending on the traits of the species or individual. There is no information on the effects of chronic and peak aircraft noise levels on Guam Micronesian kingfisher. The effect of aircraft noise on the kingfisher is likely similar to other Guam native species; frequent loud over-flights may alter behavior, impair reproduction, and change habitat use in habitat next to the airfields at AAFB (Wiles et al. 1995, p. 46), although the extent of these effects are unknown for the kingfisher.

Potential effects of aircraft overflights have been conducted on Mariana crows (Morton 1996) another Guam bird species and another cavity-nesting bird, the red-cocked woodpecker (*Picoides borealis*). Morton (1996, p. 62) found no evidence that aircraft overflights contributed directly to nest abandonment or nest failure during the study. However, Morton (1996, p. 61) did report three observations of Mariana crows reacting to aircraft. The most severe of these interactions was a pair leaving their nest several times in response to a helicopter flying less than or equal to 400 ft (120 m) above the ground. In general, the observations of Mariana crows flushing from nests were all due to aircraft below 1,000 ft (305 m) above the ground (Morton 1996, p. 61). Delaney et al. (2002, p. 42) determined that breeding red-cocked woodpeckers did not flush from their nests during incubation or early brooding phase when military helicopters were greater than 98.4 ft (30 m) from nests.

Operation of the LFTRC

As described in the Environmental Baseline, the Service has delineated habitat on Guam to provide a sufficient amount of habitat for the Guam Micronesian kingfisher so the species can be reintroduced to Guam once threats are controlled. The forest within the footprint of LFTRC and adjacent areas is habitat for the kingfisher (Figure 6) and includes some of the most pristine primary limestone habitat in northern Guam. In order to serve as suitable habitat for kingfishers, the area must be free of threats that would preclude kingfishers from using the habitat as a nesting territory (for example, brown treesnakes and human disturbance). The noise pollution from operation of the LFTRC would cause disturbance to breeding kingfishers during courtship and nesting stages. As stated in the Status of the Species, the nest excavation and courtship stages are crucial to successful reproduction for the kingfisher. During the breeding season, it is important to minimize disturbance within the territorial range of breeding pairs. Based on experience with the managed population, Guam kingfishers are especially sensitive to stress which would likely be increased by noise and disturbance, and compounded during the breeding season (B. Bahner, Philadelphia Zoo, pers. comm. 2015). The noise from the LFTRC would result in the habitat degradation within the footprint and immediately adjacent to the LFTRC, and therefore make the habitat unsuitable for breeding kingfishers.

Guidance on potential effects of noise on endangered wildlife was taken from USFWS (2006a), Pater et al. (2009), and Dooling and Popper (2007). The Service guidance for noise disturbance to spotted owls (*Strix occidentalis caurina*) and marbled murrelets (*Brachyramphus marmoratus*) state that noise disturbance will reach the level of take when 1) project-generated sound exceeds ambient nesting conditions by 20-25 decibels (dB) and 2) project-generated sound, when added to existing ambient conditions, exceeds 90 dB (USFWS 2006a, p. 1). Noise from operation of the LFTRC meets both these criteria for disturbance reaching the level of take. In addition, for the purposes of noise disturbance, extreme noise is defined as 101-110 dB, and any noise above that level is not covered by the guidance (USFWS 2006a, p. 5). For extreme sound levels of 101-110 dB (the highest analyzed in the guidance document) disturbance of spotted owls or marbled murrelets is expected up to 400 m (1320 ft) from the source noise (USFWS 2006a, p. 8). In addition, Delaney et al. (2000, 2001) and Pater et al. (1999) developed noise response thresholds for the red-cockaded woodpecker based on a number of military noise sources. Their results showed that woodpeckers did not flush during the nesting season when the sound exposure levels (SEL) for .50-caliber blank fire was less than 82 dB and for small-caliber live fire events were less than 79 dB (Delaney et al. 2002, p 18).

As stated above, the habitat adjacent to the LFTRC would likely become unsuitable for breeding Guam Micronesian kingfishers (in the future when kingfishers are reintroduced to Guam). Based on the Service guidance above, disturbance reaching take could occur at 20 dB above ambient conditions (ambient is 60 dB) or when noise exceeds 90 dB. Given the sensitivity of breeding kingfishers to noise and disturbance, the Service's guidance, Delaney et al. 2002 study (*e.g.* woodpeckers did not flush at nose levels less 79 dB), we have chosen the 80-dB threshold for noise disturbance of kingfisher as a conservative estimate that would preclude them from using suitable habitat for breeding. Based on the 80-dB threshold and the Service's noise modeling (Figure 13), approximately 319 acres of kingfisher habitat will be degraded by noise from the LFTRC and not suitable habitat for the kingfishers once the LFTRC becomes operational.

Habitat Loss, Degradation, and Fragmentation

There is currently 14,997 ac and 13,314 ac of kingfisher habitat in northern and southern Guam, respectively. The proposed action will directly and permanently remove approximately 1,015 ac in northern Guam and three ac will be lost to induced growth. Furthermore, as stated above, we estimate 319 ac will be exposed to noise at levels that will likely prevent Guam Micronesian kingfisher breeding activities, for a total habitat loss of 1,334 ac of kingfisher habitat in northern Guam. The 1,334 acres of habitat lost would have been able to support 63 breeding kingfisher pairs (1,334 ac ÷ 21 ac per breeding pair) or approximately 12 percent of the 500 pairs needed in northern Guam for recovery. In southern Guam, the proposed action will directly remove six acres of mostly low quality kingfisher habitat.

For northern Guam, the removal and degradation of habitat includes some of the best remaining primary forest on Guam, at Ritidian Point on AAFB. As discussed in the General Effects section, the most severe effects on recovery habitat from habitat fragmentation and edge effects will be on AAFB at Ritidian Point from construction of the LFTRC. This area currently contains a large expanse (over 350 acres) of high-quality primary limestone forest within the Overlay Refuge. This primary limestone forest is also adjacent and contiguous with critical habitat for the kingfisher within the fee simple land of the GNWR, together providing an even larger forested area serving as habitat for the kingfisher. This area will be further fragmented by the presence of over six miles of additional habitat edges on AAFB alone, and three acres will be lost to induced growth (as detailed in the General Effects section).

Other Human Disturbance

The proposed training at the NMS in southern Guam and the operation of the main cantonment facilities at Finegayan will increase human presence and noise in kingfisher habitat in these areas. The cantonment is near the Haputo ERA and other areas of kingfisher habitat (Figure 6). Increased human disturbance in these areas could deter kingfishers, when reintroduced back to Guam, from utilizing these areas for sheltering, foraging and breeding.

Conservation Measures for the Kingfisher
The DON has proposed to offset, in part, these adverse effects by implementing conservation measures. Risks will be minimized by best management practices regarding spread of non-native species and fire. The DON also has proposed to implement biosecurity conservation measures including landscape-level brown treesnake eradication and control, recommendations from the RBP, HACCP planning, and brown treesnake interdiction program, which will be beneficial to the kingfisher because it will help reduce the current brown treesnake population and potentially prevent other invasive species from becoming established on Guam.

As part of the proposed action, the DON also proposes to implement a forest enhancement project at Finegayan, in low-quality secondary forest, to benefit listed species, including the kingfisher. This forest is not currently usable by kingfishers and will likely require a decade or more of growth and management before it can support kingfishers. However, the DON has proposed the enhancement of the site to include installation of ungulate exclusion fences around

the 1,000 acres; active removal of ungulates (i.e. trapping, snaring, shooting) with the goal of eradication within the fenced areas; invasive plant removal; and the propagation, planting, and establishment of dominant and rare species characteristic of native limestone forest habitats. Therefore, although this site would not fully compensate for the loss of primary limestone forest, the enhancement of forest and protection of the site is expected to provide some benefit to the kingfisher.

Summary

As described in the Status of the Species and Environmental Baseline sections, habitat fragmentation and loss, lack of management, introduced ungulates, invasive species, typhoons, and forest conversion have continued to negatively affect forest habitat on Guam to an extent that the current amount of remaining forest habitat suitable for the kingfisher is severely degraded and nearly at the minimum needed for its survival and recovery in the wild. The loss of 1,334 ac of habitat that could support 63 breeding kingfisher represents a loss of approximately nine percent of remaining kingfisher habitat in northern Guam and the capacity to support approximately 12 percent of the 500 breeding pairs needed for recovery. Although the six ac of habitat in southern Guam would not support a breeding pair, the loss of six ac would reduce the overall amount of kingfisher habitat in southern Guam.

Among the adverse effects to the kingfisher as detailed above and in the General Effects section, the habitat loss and degradation of the limestone forest in northern Guam, including the loss of the habitat to support 63 breeding kingfishers in Guam, is the most significant, persistent, and adverse effect to the kingfisher as a result of the proposed action. In addition, the increased human disturbance within the action area could deter kingfishers, when reintroduced back to Guam, from utilizing these areas for sheltering, foraging and breeding. However, implementation of the conservation measures and DON's protection and management of approximately 5,234 acres of kingfisher habitat in northern Guam per the MOA will mitigate for the loss of kingfisher habitat, and will help ensure that kingfisher habitat will be available for the survival and recovery of the species on Guam.

Effects of the Action – Mariana Crow

In addition to the general effects of the action discussed above, a species-specific effects analysis for the Mariana crow is provided below.

Noise

Aircraft
From 1994 to 1995 a study was conducted at AAFB on the potential effects of aircraft overflights on Mariana crows (Morton 1996). No evidence was found that aircraft overflights contributed directly to nest abandonment or nest failure during the study (Morton 1996, p. 62). In fact, one nest was constructed within one km (0.6 mi) of the north runway during a large aircraft training exercise (Tandem Thrust). However, Morton (1996, p. 61) did report three observations of Mariana crows reacting to aircraft. One observation was of alarm calling and an increase in vigilant, alert, and standing behavior from an adult attending a nest after an unknown

aircraft (76-92 dBA, > 1,000 ft (305 m) above ground level) flew over the nest. Another observation was of a Mariana crow returning to a nest while an unidentified cargo aircraft flew overhead. The adult remained standing at the nest and alarm calling for the duration of the overflight (approximately two minutes). No sound levels or altitude was reported for the aircraft. The final observation was of a pair of Mariana crows responding to six F-16s and four KC-135s (≤ 86 dBA, no altitude reported) departing the base. The pair was observed alarm calling and flying for 12 minutes after the overflights. In addition to these observations, Morton (1996, pp. 60-61) also summarized previous observations of Mariana crow and aircraft interactions by other biologists on Guam. The most severe of these interactions was a pair leaving their nest several times in response to a helicopter flying less than or equal to 400 ft (120 m) above the ground. Other observations also included adults flushing from the nest and leaving eggs unattended. In general, the observations of Mariana crows flushing from nests were all due to aircraft below 1,000 ft (305 m) above the ground (Morton 1996, p. 61). Mariana crows reacting to aircraft by alarm calling and other minor behaviors occurred when aircraft were above this elevation.

The proposed action will increase the frequency and duration of aircraft noise on Guam and the increased noise may affect the potential for habitat to be suitable in the future for Mariana crows. Current and previous DoD consultations have implemented flight restrictions in the Northwest Field area of AAFB (USFWS 2010a, p. 63; USFWS 2015b, Appendix B, p. 10) to minimize noise disturbance to listed species and their habitats. Because the proposed action has no flight restrictions in this area, there will be an increase in the frequency and duration of aircraft noise above that currently in operation at AAFB, and this may affect the suitability of crow habitat in the area. As noted above, Mariana crows have been observed to flush from their nests in response to aircraft below 1,000 ft (305 m) (Morton 1996, p. 61). Therefore, we expect that habitat in the NWF area of AAFB may be unsuitable in the future if Mariana crows are reintroduced and flight restrictions not implemented. We do not anticipate that the increase use of aircraft will preclude the use of habitat by the Mariana crow elsewhere on Guam.

Operation of the LFTRC

Mariana crows are known to be highly susceptible to disturbance from human activities (Morton 1996, p. 60, 62, 72; Ha 2015, pers. com.; Ha et al. 2011, p. 5). Based on observations of disturbance of crow nests on Guam, Morton (1996, p. 72) recommended a 300-meter radius for a buffer zone around active crow nests; Morton's recommendations were based on observations of crows reacting to facility/grounds maintenance, brown treesnake trapping, research activities, loud music, and human voices. One Mariana crow nest on Guam was abandoned due to disturbance from maintenance activity and from radio noise coming from a sound system 150 meters away (Morton 1996, p. 62). Ha et al. (2011, p. 236) found that nest sites were always greater than 300 meters from any buildings, and that actual nest sites were almost twice as far from roads and buildings as random sites. Captive Hawaiian crows (Alala, *Corvus hawaiiensis*) exhibited signs of distress, including pathological auto-plucking, distress calling, and reduced food intake, in response to military activities at Pohakuloa Training Area in Hawaii (Morton 1996, p. 60).

As described in the Environmental Baseline, the Service has delineated habitat on Guam to provide a sufficient amount of habitat for the Mariana crow so the species can be reintroduced to Guam once threats are mitigated. The forests adjacent to the LFTRC are classified as Mariana

crow habitat (Amidon 2012, *in litt*.). In order to serve as suitable habitat for the Mariana crow, the area must be free of threats that would preclude the crow from using the habitat as a nesting territory (for example, brown treesnakes and human disturbance). The noise pollution from operation of the LFTRC could lead to habitat degradation adjacent the LFTRC, and make the habitat unsuitable for nesting Mariana crows. The habitat may still be suitable for foraging or dispersing juvenile crows.

Guidance on potential effects of noise on endangered wildlife was taken from Service (2006a), Pater et al. (2009), and Dooling and Popper (2007). The Service guidance for noise disturbance to spotted owls (*Strix occidentalis caurina*) and marbled murrelets (*Brachyramphus marmoratus*) says that noise disturbance will reach the level of take when 1) project-generated sound exceeds ambient nesting conditions by 20-25 decibels (dB) and 2) project-generated sound, when added to existing ambient conditions, exceeds 90 dB (USFWS 2006a, p. 1). We used the spotted owl and marbled murrelet guidance as a surrogate for the Mariana crow as it is the best available noise disturbance framework for listed species.

Noise from operation of the LFTRC meets both these criteria for disturbance reaching the level of take. In addition, for the purposes of noise disturbance, extreme noise is defined as 101-110 dB, and any noise above that level is not covered by the guidance (USFWS 2006a, p. 5). For extreme sound levels of 101-110 dB (the highest analyzed in the guidance document) disturbance of spotted owls or marbled murrelets is expected up to 400 m (1320 ft) from the source noise (USFWS 2006a, p. 8). In addition, Delaney et al. (2000, 2001) and Pater et al. (1999) developed noise response thresholds for the red-cockaded woodpecker based on a number of military noise sources. Their results showed that woodpeckers did not flush during the nesting season when the sound exposure levels (SEL) for.50-caliber blank fire was less than 82 dB (Delaney et al. 2002, p 21).

Unlike the spotted owl or marbled murrelet example above, no disturbance take of Mariana crows is currently expected as they are extirpated from Guam. However, the habitat adjacent to the LFTRC may be unsuitable for Mariana crows in the future when crows are reintroduced to Guam. Based on the Service guidance above, disturbance that meets the definition of take could occur at 20 dB above ambient conditions (ambient is 60 dB) or when noise exceeds 90 dB. Given the sensitivity of crows to noise both on Guam and Rota, we have chosen the 80 dB threshold for noise disturbance of crows that would preclude them from using suitable habitat for breeding. Based on the Service's noise modeling described above, approximately 319 acres of Mariana crow habitat will be degraded by noise from the LFTRC and not suitable habitat for Mariana crows once the LFTRC becomes operational (Figure 14).

As described above, a species can often habituate to human-generated noise when the noise is not followed by an adverse effect. However, even when a species appears to be habituated to a noise, the noise may produce a metabolic or stress response (increased heart rate results in increased energy expenditure) though the response may or may not lead to changes in overall energy balance. Based on our knowledge of Mariana crow behavior, we assume that reintroduced crows may habituate to noise levels below 80 dB, but not above it.

Habitat Loss, Degradation, and Fragmentation

There is currently 13,962 ac and 10,957 ac of potential Mariana crow habitat in northern Guam and southern Guam, respectively. The proposed action will directly and permanently remove approximately 1,010 ac of crow habitat and three ac will be lost to induced growth. Furthermore, as stated above, we estimate 319 ac will be exposed to noise at levels that will likely prevent Mariana crow breeding activities, for a total habitat loss of 1,332 ac of Mariana crow habitat. The 1,332 ac of habitat lost to the proposed action would have been able to support 24 territorial crow pairs or 24 percent of the 100 pairs needed in northern Guam for recovery. In southern Guam the proposed action will directly remove approximately five acres of low quality Mariana crow habitat.

In northern Guam, the removal and degradation of habitat includes some of the best remaining primary limestone forest on Guam, at Ritidian Point on AAFB. As discussed in the General Effects of the Action section, the most severe effects on crow habitat from habitat fragmentation and edge effects will be at Ritidian Point from construction of the LFTRC. This area currently contains a large expanse (over 350 ac) of high-quality primary limestone forest within the Overlay Refuge. This primary limestone forest is also adjacent and contiguous with critical habitat for the Mariana crow within the fee simple land of the GNWR, together providing an even larger forested area serving as habitat for the Mariana crow. This area will be further fragmented by the presence of over six miles of additional habitat edges on AAFB alone.

Habitat Conservation and Protection

The protection and management of approximately 5,234 acres of kingfisher habitat on DON lands in northern Guam per the MOA (DON and Service 2015c) will benefit the Mariana crow because habitat for crow habitat also would be protected and managed. Thus, adverse effects to the crow would be offset, in part, by implementing the actions in the MOA but also the conservation measures in this consultation. Risks will be minimized by best management practices regarding spread of non-native species and fire.

In addition, as part of the proposed action, the DON proposes to implement a forest enhancement project at Finegayan, in low-quality secondary forest, to benefit listed species, including the crow. This forest is not currently usable by crows and will likely require a decade or more of growth and management before it can support crows. However, the DON has proposed the restoration of the site to include installation of ungulate exclusion fences around the 1,000 acres; active removal of ungulates (i.e. trapping, snaring, shooting) with the goal of eradication within the fenced areas; invasive plant removal; and the propagation, planting, and establishment of dominant and rare species characteristic of native limestone forest habitats. Therefore, although this site would not fully compensate for the loss of primary limestone forest, the restoration of forest and protection of the site is expected to provide some benefit to the crow.

Other Human Disturbance

The proposed training at the NMS in southern Guam and the operation of the main cantonment facilities at Finegayan will increase human presence and noise in crow habitat. The cantonment is near the Haputo ERA and other areas of crow habitat (Figure 15). Increased human

disturbance in these areas could deter Mariana crows, when reintroduced back to Guam, from utilizing these areas for sheltering, foraging and breeding.

Summary

As described in the Status of the Species and Environmental Baseline sections, habitat fragmentation and loss, lack of management, introduced ungulates, invasive species, typhoons, and forest conversion have continued to negatively affect forest habitat on Guam to an extent that the current amount of remaining forest habitat suitable for the Mariana crow is severely degraded and close to the minimum needed for its survival and recovery in the wild. The loss of 1,332 ac of habitat represents a loss of approximately 10 percent of remaining crow habitat in northern Guam. The proposed action will adversely affect the Mariana crow by permanently clearing areas of crow habitat which, in the absence of the project, would have remained intact to provide for the future recovery of the species. In addition, project-related noise will further reduce the amount of crow habitat suitable for this species' breeding, feeding and sheltering. However, the DON's protection and management of 5,234 acres of crow habitat in northern Guam will off-set the loss of Mariana crow habitat from project construction, and will help ensure that crow habitat will be available for future survival and recovery of the species on Guam. The DON also has proposed to implement biosecurity conservation measures including landscape-level brown treesnake eradication and control, recommendations from the RBP, HACCP planning, and brown treesnake interdiction program, which will be beneficial to the crow because it will help reduce the current brown treesnake population and potentially prevent other invasive species from becoming established on Guam.

Effects of the Action – Guam Rail

The Guam rail was once distributed throughout Guam, but significant population declines, resulting primarily from habitat loss and predation by the brown treesnake and feral cats, resulted in their extirpation from Guam by 1987 (Wiles et al. 1995, p. 38). The Guam rail is now found only in captivity and in one experimental population on Rota consisting of between 60 to 80 birds (Wenninger 2008, pers. comm.). The Rota population is a designated non-essential experimental population under section 10 of the Act. As of June 2008, there were approximately 158 Guam rail in captivity on Guam and in mainland zoological institutions (USFWS 2008c, p. 5). Because the Guam rail is extirpated from the wild on Guam, no adverse effects to individual rails are expected to be caused by the proposed action. However, recovery of the species on Guam will depend on the re-establishment of a wild population on Guam and sufficient habitat to support a recovered population, as summarized in the Status and Baseline section. Project impacts to recovery habitat, effects of brown treesnake introduction to Rota, and beneficial effects of project conservation measures are detailed below.

Noise

Aircraft
As detailed in the General Effects section, birds tend to avoid noisy areas but their response to noise may vary depending on the traits of the species or individual. There is no information on the effects of chronic and peak aircraft noise levels on Guam rails. However, the effect of

aircraft noise on the Guam rail is likely similar to other Guam native species; frequent loud over-flights may alter behavior, impair reproduction, and change habitat use in habitat next to the airfields at AAFB (Wiles et al. 1995, p. 46). In 1981, surveys were conducted within habitats adjacent to runways at AAFB and NWF on Guam. Results from the surveys indicated that Guam rails were absent in these areas (Engbring and Ramsey 1984, p. 13-16). Although there could be factors other than aircraft noise that attributed to their absence in these areas, a review of noise studies indicates that many species abandon noisy areas (Francis 2015, p.2).

The proposed action will increase the frequency and duration of aircraft noise on Guam and the increased noise may affect the potential for habitat to be suitable in the future for Guam rails. Current and previous DoD consultations have implemented flight restrictions in the Northwest Field area of AAFB (USFWS 2010a, p. 63; USFWS 2015b, Appendix B, p. 10) to minimize noise disturbance to listed species and their habitats. Because the proposed action has no flight restrictions in this area, there will be an increase in the frequency and duration of aircraft noise above that currently in operation at AAFB, and this may affect the suitability of rail habitat in the area. Because of the lack of information on rail response to aircraft overflights, it is difficult to know if an increase in aircraft overflight noise will preclude the use of habitat by Guam rails in the NWF area in the event rails are reintroduced. We do not anticipate that the increase use of aircraft will preclude the use of habitat by the Guam rail elsewhere on Guam..

Operation of the LFTRC
As described above, Guam rails are secretive and wary, and respond to disturbance from human activity. At the Guam DAWR captive facility, Guam rails negatively respond to bushcutters, which produce a noise level of 87 db (http://www.makita.biz/mm4.html). In response to this noise disturbance, captive rails destroy their nests (S. Medina, DAWR, pers. comm. 2015). Captive Guam rails also destroy their eggs and chicks (less than 10 days old) in response to human disturbance within 11 to 15 m (36 to 49 feet) of their nest. However, this behavior may be attributed to a combination of the disturbance and the stress of breeding in captivity (S. Medina, DAWR, pers. comm. 2015). On Rota, wild Guam rails have been observed to flush from their nest in response to an approaching human, but would return to incubate the eggs in a short period of time. In other instances, incubating birds would remain on their nests when approached by a person (P. Wenninger, DON, pers. comm. 2015).

The LFTRC will be in operation during day and night hours for 39 weeks out of the year, with thousands of DoD personnel using the ranges throughout the year. The total annual ammunition usage at the LFTRC is 6,719,190 rounds. The noise disturbance from the live-fire training will result in impulse noise with very intense sounds of short duration (e.g., the discharge of a weapon). Given the intensity and frequency of human activity and noise levels at the LFTRC, we anticipate that Guam rails would avoid the LFTRC and surrounding area completely while the ranges are in operation. Although there is limited information on Guam rail's tolerance to noise, based on the best available information, we know that Guam rails negatively respond to noise levels of 87 db. Therefore, we have chosen 85 dB as a conservative threshold for noise disturbance that would preclude Guam rails from using recovery habitat for breeding, foraging, or sheltering. We can reasonably expect that all recovery habitat within a 85-db noise contour would be avoided by rails. Therefore, we predict that approximately 51 acres of Guam rail

recovery habitat surrounding the LFTRC will be unsuitable for Guam rails because of the noise (Figure 16).

Habitat Loss and Degradation Caused by the Proposed Action

There are approximately 24,698 ac and 24,886 ac of recovery habitat in northern and southern Guam, respectively, for the Guam rail. Approximately 1,055 ac of recovery habitat in northern Guam and 90 ac in southern Guam will be developed within the project vegetation clearing footprint as a direct result of the proposed action (Table 6, Figure 16). Therefore, there will be 23,643 ac of potential recovery habitat in northern Guam and 24,796 in southern Guam remaining after implementation of the proposed project.
In addition, approximately 17 ac of Guam rail recovery habitat on Guam are expected to be cleared through indirect or induced development impacts of the action throughout the island. After implementation of development directly and indirectly related to the proposed project, the project will result in the loss of 1,162 ac of rail habitat or two percent of the remaining rail habitat on Guam.

Although the degradation and loss of habitat, lack of management, introduced ungulates, invasive species, typhoons, and forest conversion continue to negatively affect habitat for rails on Guam (as described in the General Effects) and the proposed project will contribute to this declining habitat baseline, the amount of habitat loss is not expected to appreciably reduce the likelihood that the remaining habitat would support the recovery and survival of the Guam rail. Furthermore, this area will be fragmented by the presence of over six miles of additional habitat edges on AAFB alone, however, negative effects to rails from fragmentation would be minimal because this species is able to use edge habitat. Similarly, because the Guam rail utilizes shrubby vegetation and edges, fires caused by training in the vicinity of the Andersen South and Route 15 Range Complex and other training areas are not expected to result in loss of habitat for the Guam rail.

Conservation Measures to Benefit the Guam Rail

Recovery habitat remaining on DoD lands comprises a substantial percentage of the total habitat available for the recovery of the Guam rail. The DON's proposed conservation measures are intended to support reintroduction of native endangered or threatened species on DoD lands on Guam consistent with species recovery plans. In further support of such recovery efforts, the DON intends to actively participate in recovery committees for endangered or threatened species on Guam.

The DON has committed to provide sustained funding throughout the construction phase of the project for the development of methods to eradicate or significantly suppress brown treesnakes island-wide to facilitate the recovery of listed species on Guam. If successful, landscape-level implementation of brown treesnake suppression on DoD and other lands will facilitate reintroduction of the Guam rail. This in turn is expected to reduce the rate of nest predation and adult bird mortality.

In addition, as part of the proposed action, the DON proposes to implement a forest enhancement project at Finegayan, which will benefit the rail. The DON has proposed the restoration of the site to include installation of ungulate exclusion fences around the 1,000 acres; active removal of ungulates (i.e. trapping, snaring, shooting) with the goal of eradication within the fenced areas; invasive plant removal; and the propagation, planting, and establishment of dominant and rare species characteristic of native limestone forest habitats.

The protection and management of approximately 5,234 acres of kingfisher habitat on DON lands in northern Guam per the MOA (DON and Service 2015c) may benefit the rail because an undetermined amount of habitat for the rail also would be protected and managed within the 5,234 acres. Thus, adverse effects to the rail would be offset, in part, by implementing the actions in the MOA but also by implementing the conservation measures in this consultation.

Summary

As described in the Status of the Species and Environmental Baseline sections, the degradation and loss of habitat, lack of management, introduced ungulates, invasive species, typhoons, and forest conversion have continued to negatively affect habitat for the Guam rail. Noise from the operation of the LFTRC will diminish the value of the surrounding recovery habitat for Guam rails. This disturbance, combined with the loss of (1,162 ac + 51 ac) 1,213 ac recovery habitat on Guam, further degrades and decreases the amount of habitat that would be available to recover the Guam rail. The increased human disturbance in the NMS, Haputo ERA, and habitat within the Finegayan area would likely result in these areas becoming less suitable for Guam rails.

The DON's implementation of biosecurity conservation measures including landscape-level brown treesnake eradication/control, recommendations from the RBP, HACCP planning, and brown treesnake interdiction program, will be beneficial to the Guam rail because it will help reduce the current brown treesnake population and potentially prevent other invasive species from becoming established on Guam. In addition the DON will protect and managed approximately 5,234 ac in northern Guam and conduct a forest enhancement project on approximately 1,000 acres in Finegayan of habitat, which also will provide some benefit to the rail.

Effects of the Action – Mariana Fruit Bat

In addition to the general effects of the action discussed above, a species-specific effects analysis for the Mariana fruit bat is provided below.

The Service proposes that recovery of the Mariana fruit bat will require subpopulations on each island where they are currently extant, and those subpopulations must be of sufficient size to avoid genetic and demographic risks associated with small populations (USFWS *in review*). Less than 50 wild fruit bats are estimated to remain on Guam (USFWS 2009d, p. 8 and references therein; SWCA 2012, p. 32; USFWS *in review*, p. 7-8 and references therein). Resilience of the Guam fruit bat population is expected to be low given the critically small

starting population, the species' slow reproductive rate (USFWS 2009d, p. 17 and references therein), infrequent and unpredictable immigration from other islands (DON 2013d, p. 78), and abundant, widespread, and uncontrolled threats (USFWS 2009d, p. 19-33 and references therein). Based on our estimate of 27,096 acres of existing survival and recovery habitat for the Mariana fruit bat (Metevier 2014, unpubl. data), the estimated carrying capacity for fruit bats on Guam is 19,847 bats (DON 2013d, p. 26, 45).

Given the small population of Mariana fruit bats remaining on Guam, recovery will likely depend on immigration or translocation of fruit bats from Rota (Esselstyn et al. 2006, p. 531) and long-term conservation and maintenance of fruit bat habitat on Guam. The Mariana fruit bat has high energetic demands associated with flight and year-round breeding, and as such depends on a steady and ample supply of fruiting and flowering plants that are distributed patchily through space and time (Wiles and Fujita 1992, pp. 26-31; USFWS 2009d, p. vi,; Amitai et al. 2010, p. 2693; Downs et al. 2012, p. 344). To meet requirements for breeding, feeding, and sheltering, a self-sustaining population of Mariana fruit bats will rely on threat-managed, native limestone forest habitat containing diverse food resources that are available throughout the year.

Noise

Most of the bat species in the genus Pteropus do not echolocate, and less information is available about their hearing than for bats that echolocate. We have no specific information on hearing for the Mariana fruit bat. The available literature indicates that fruit bats are most sensitive to noise frequencies between 10 and 20 kHz, insensitive to frequencies below one kHz, and able to detect frequencies 40 kHz or greater (DON 2014a, p. 64 and references within). From approximately four kHz to just under 20 kHz the fruit bats have more sensitive hearing than humans (DON 2014a, p. 64). Overall, fruit bat audiograms are similar to humans (DON 2014a, p. 64), and it is possible that noise from the proposed action would be heard by fruit bats as it would be heard by humans.

There is limited understanding of what sound levels may adversely affect Mariana fruit bats, and most information is from observations of fruit bat reactions to aircraft overflights. The following reactions to aircraft noise have been reported:

- Fruit bats have been reported to flush at noise levels exceeding 106 dBC (SWCA 2008, pp. 2-3) and at peak noise levels above 90 dBA/101 dBC (SWCA 2012, p. 23, 37).
- Fruit bats at a maternity colony on Rota flushed when a helicopter was within 200 m and a military jet aircraft (type unknown) flew overhead within 300 m (J. Boland, pers. obs., 2009 and 2010).
- Successive launches of F-14 repeatedly flushed 50 bats from a roost site and F-14s (95, 106 dBA) also caused agitated vocalization and flushing (Grout 1993 in Morton 1996, p. 67).
- Increases in active thermoregulation (32 percent), maintenance (14 percent), locomotion (74 percent), and alertness (62 percent) of Mariana fruit bats were recorded after aircraft overflights (SWCA 2012, p. 23, 37).

Based on this information, we can assume that aircraft overflights resulting in noise over 90 dB may flush roosting Mariana fruit bats. However, flush rates may not adequately reflect a

species' sensitivity to human disturbance (Peters and Obis 2006, p. 1383). Effects to individual Mariana fruit bats are only documented in the SWCA (2012) study, which occurred after the Pati Point colony site was no longer used; however, this study did not report noise levels of overflights that may have disturbed (other than flushing) individual fruit bats. Therefore, we do not have direct data on how an individual fruit bat on Guam will react to noise disturbance from the proposed action. For the purposes of this consultation, we will assume that, at a minimum, noise over 90 dB may flush a roosting Mariana fruit bat. Noise levels above ambient levels and below 90 dB are likely to cause other stress reactions, including increases in active thermoregulation, maintenance, locomotion, and alertness.

Stress reactions caused by human disturbance can have an adverse effect on fruit bats by increasing energetic demands, disrupting hormonal balance, and forcing relocation to lower quality habitat (Klose et al. 2006, p. 347, and references therein; CNMI 2010, p. 7). All of these factors can lead to reduced time foraging, sheltering, or breeding and adversely affect survival. When a disturbance is experienced by a Mariana fruit bat colony, individuals may disperse on their own or in smaller groups (CNMI 2010, p.6). In some cases, the degree of colony dispersal (i.e., how many individuals leave the main colony) may be related to the degree and/or type of human disturbance. For example, if hunters are frequently targeting bats along commuter flyways near the colony roost site, some individuals may disperse away from the roost site temporarily, but eventually return. However, if hunters fire directly into a colony at their day roost, the entire colony abandons the site (CNMI 2010, p. 7). When fruit bats on Rota are forced to disperse from colonies as a result of human disturbance, infant mortality may increase because dependent, non-volant pups that are too big for the mother to carry are likely abandoned. Forced dispersal may negatively affect the reproductive potential of the population because access to mates is compromised (CNMI 2010, p. 7). Even without dispersal, high levels of stress from any disturbance can disrupt reproductive cycles and/or lead to miscarriage (Wingfield et al. 1998, p. 192-193, Heideman 2000, p. 169-199, Klose et al. 2006, p. 347).

Construction noise

Noise from construction of the proposed action may affect Mariana fruit bats in the vicinity of the construction. Construction of the proposed action will occur from 2015 to 2028; however, construction will be phased and will not occur at all places at once, or for the entire construction time period. Construction equipment will include standard heavy equipment including bulldozers, graders, haulers, large trucks. No blasting or use of dynamite will occur as part of the proposed action. The use of heavy equipment can reach noise levels of 96 dB (USFWS 2006a, p. 17). "Based on ambient noise studies conducted at AAFB (DON 2014a, p. 66), we expect that ambient noise in fruit bat habitats on Guam to range from 55 to above 65 dB. Ambient noise levels at clifflines is likely louder than ambient noise inside the forest (DON 2015a). We expect that noise from construction of the proposed action will rise, at times, above ambient conditions, and above the disturbance thresholds discussed above for the Mariana fruit bat.".

Mariana fruit bats in the vicinity of construction could be disturbed or harassed by noise and human presence. In order to avoid disturbance to Mariana fruit bats in the vicinity of construction, the DON will conduct surveys for Mariana fruit bat one week prior to onset of construction in areas within or in the vicinity of fruit bat habitat. If a fruit bat is present within

492 ft (150 m) of the project site, the work will be postponed until the bat has left the area (DON 2014a, p. 33). The DON clarified that this conservation measure does not mean that work will halt if a fruit bat enters the vicinity of a construction site while construction is on-going (C. Cobb, DON, 2015, pers. comm.). In general, Mariana fruit bats are likely to avoid construction sites due to human presence and noise disturbance, and seek other locations to roost and forage. If a fruit bat is present near a construction site and not seen (for example, roosting below a cliffline) then it may be harassed or harmed by the proposed action.

Noise from construction of the proposed action would be temporary and intermittent. Construction noise reaching fruit bat habitat may rise above the disturbance threshold for the Mariana fruit bat; however, this noise will be short-term in duration and will not lead to a permanent reduction in the capability of the habitat to serve as suitable habitat for the Mariana fruit bat.

Aircraft

As described above, and in the Environmental Baseline, most of the disturbance information for Mariana fruit bats is based on studies from aircraft overflights. The proposed action will result in an increase in military jet traffic and helicopter operations over occupied Mariana fruit bat habitat on AAFB. Based on the documented effects of noise on Mariana fruit bats and other wildlife (described above and in the "General Effects" section) and the best available information about the response of Mariana fruit bats to aircraft noise (USFWS 2006b, pp. 35-39 and references cited therein; Morton 1996; SWCA 2008; SWCA 2012; SWCA 2013), the adverse impacts of noise caused by the proposed action on the Mariana fruit bat on AAFB are expected to be substantial.

Noise effects were reviewed under the ISR Strike Biological Opinion (USFWS 2006b) and were determined to adversely affect the Mariana fruit bat to the extent that the remaining colony site would be abandoned. Ongoing and anticipated noise resulting from jet aircraft and helicopter use of the main runways at AAFB (actions analyzed in the ISR Strike Biological Opinion) was expected to result in the incidental take of the remaining bats at Pati Point, due to harassment from aircraft noise (USFWS 2006b, p. 49). In addition, harassed bats moving from Pati Point to less protected areas were expected to be lost to opportunistic hunting (USFWS 2006b, p. 37). The Pati Point colony has been abandoned, and only scattered bats remain on AAFB (DON 2014c, p. 2). These remaining bats are likely to be further harassed from the increase in aircraft overflights from the proposed action. Because noise from the ISR Strike Biological Opinion and this Biological Opinion will occur contemporaneously, it would not be possible to attribute the take to a single project.

Mariana fruit bats are suspected to migrate from Rota to Guam periodically following typhoons, and the migrants are suspected to return to Rota when the effects of the storm have subsided (Wiles and Glass 1990, p. 3; Esselstyn et al. 2006, p. 536). Migrants from Rota are thought to have occupied the Pati Point roost site on Guam in the past (Esselstyn et al. 2006, p. 535-536; Wiles and Glass 1990, p. 2-3). We suspect that if Rota migrants are greeted by unacceptable levels of noise disturbance from increased air traffic at AAFB, it may cause them to return to Rota prematurely. A premature return to Rota under post-typhoon conditions may expose bats to high levels of hunting and decreased food and habitat availability.

It is also possible that the increased noise near Pati Point, and on AAFB in general, will preclude the reestablishment of a fruit bat colony in northern Guam. If the fruit bat population on Guam were to increase, individuals and colonies are not likely to establish roost sites in areas with high levels of human foot, vehicular, or aircraft traffic, due to hunting-induced sensitivities to human-presence (i.e., humans are predators), and sensitivity to loud noise and vibration from aircraft (see data presented above and in Environmental Baseline).

Operation of the LFTRC
As described above, Mariana fruit bats are known to be highly susceptible to disturbance from human activities, including from firing ranges. Mariana fruit bats have been observed avoiding the CATM range while it is active, by flying out to sea or in the opposite direction (J. Quitugua, pers. comm. 2015). Operation of the LFTRC is expected to be louder than the CATM range, and therefore we anticipate that fruit bats will avoid the LFTRC while it is active.

Species that are commonly hunted often demonstrate behavioral (e.g., flushing, startle response) or physiological responses (e.g., increased heart rates, increased respiration rates) to gunshot sounds (Larkin et al. 1996). Knight et al. (1987; p. 175) found that American crows nesting in urban areas were less wary of people than American crows nesting in rural habitat and attributed the difference to the hunting of rural crows. Barron et al. (2012; p. 915) found that American crows avoided areas with live-fire exercises in a similar fashion and suggested that species hunted by humans will be more adversely affected by human activity, including military training (e.g., live-fire training) than species that are not hunted. As stated by Morton and Wiles (2002, p. 161), "Poaching is a particularly insidious activity because not only does it impact fruit bats through mortality, it reinforces behavioral avoidance of humans. Consequently, roosting or foraging fruit bats that might not otherwise be disturbed by some human activities … may become unduly sensitized to them because of illegal hunting." Based on observations Rota, fruit bat colonies on Rota have abandoned areas where they were hunted and have not returned to occupy those areas in recent history (CNMI 2010; J. Boland 2015, pers. comm.). In addition, anecdotal evidence from numerous individuals who have conducted fruit bat research on Guam and the CNMI for many years indicate that fruit bats do avoid areas that have been previously subjected to hunting and also areas that experience live-fire activities (G. Wiles, Washington Department of Fish and Wildlife, personal communication, 2014; T. Mildenstein, University of Montana, personal communication, 2014; D. Janeke, HDR, Inc., personal communication, 2014). Further, in one study on AAFB, 84 percent of fruit bat observations during station counts were in areas without hunting or limited access hunting (SWCA 2012, p. 6).

There have been only three fruit bat observations within the proposed site for the LFTRC on AAFB since 2005 (DON 2014b and references therein, p. 5-332). Recent surveys by SWCA did not detect any Mariana fruit bats in the vicinity of the LFTRC (SWCA 2012, p. 27). However, Mariana fruit bats have been observed at the GNWR below the cliffline of the LFTRC, and the cliffline below the LFTRC is likely used by bats commuting between roosting areas and foraging grounds. Most fruit bats will depart from roost sites to foraging areas from one hour before to one hour after sunset (J. Boland unpublished data, 2008-2011). Therefore the range will be operational when bats can be expected to be commuting to foraging areas. We expect that any Mariana fruit bats that are able to hear that LFTRC in operation will avoid the area and seek out

a less disturbed area. While bats are capable of flying outside the disturbance zone, bats seeking alternate commuting corridors and/or foraging areas may be forced into lower quality habitat or exposed to increased risks of poaching and harassment. In addition, bats in the vicinity of the LFTRC when firing begins will likely flush and flee the area. As mentioned above, if reproductive females are exposed to stressors that cause flushing and dispersal, it can disrupt reproductive cycles, cause miscarriage, and cause abandonment of non-volant young (Wingfield et al. 1998, p. 192-193, Heideman 2000, p. 169-199, Klose et al. 2006, p. 347). Under current conditions, we would not anticipate that fruit bats will be close enough to the firing line to suffer any hearing damage; however an increase in bat populations on Guam could result on the presence of more bats near the firing lines of the LFTRC.

In addition, the forested habitats surrounding the LFTRC are classified as habitat for the Mariana fruit bat. In order to serve as suitable habitat for the Mariana fruit bat, the area must be free of threats that would preclude bats from using the habitat for foraging, roosting, or breeding (for example, brown treesnakes and human disturbance). The noise pollution from operation of the LFTRC will likely lead to habitat degradation in habitat adjacent the LFTRC, and make the habitat unsuitable for Mariana fruit bats.

Given the sensitivity of Mariana fruit bats to noise and human disturbance both on Guam and Rota, and because of the reaction of Mariana fruit bats to hunting disturbance (i.e. gunshots), we anticipate that Mariana fruit bats will avoid the LFTRC and surrounding areas completely while it is in operation. For this reason, we have conservatively chosen a 65 dB threshold for noise disturbance of Mariana fruit bats that would preclude them from using habitat for breeding, foraging, or sheltering. The 65 dB threshold is based on the high-end of current ambient noise levels; we can reasonably expect that all habitat with noise louder than 65 dB would be avoided by fruit bats given the level and type of noise (i.e., gunshots). Therefore, we predict that approximately 309 acres of Mariana fruit bat habitat in the vicinity of the LFTRC will be unsuitable for Mariana fruit bats (Figure 17).

Other Human Disturbance

The proposed construction of the main cantonment at Finegayan will increase human presence and noise in the area. The cantonment is near the Haputo ERA, which contains high-quality fruit bat habitat, where fruit bats have been observed in the past. Increased use of the Haputo ERA by humans could deter fruit bats from utilizing these areas for foraging or roosting.

Training will also occur at the NMS in southern Guam, where fruit bats are routinely observed. Training will include company-level patrolling, jungle training, land navigation, and air-ground operations on five to seven consecutive days, 12 weeks per year, day and night, for a total annual throughput at the NMS of 1,440 Marines. Training at the NMS will also include terrain flight, ground threat reaction, defensive maneuvering, confined area landing, and external load training. These training activities will result in an increase in noise and other human disturbance at the NMS. Solitary bats flushed as a result of project noise may travel to another area where the likelihood of poaching or harassment is greater overall than it is on DoD lands. Flight restrictions will limit low-level flights over much of the NMS and this will minimize, but not completely avoid, adverse noise impacts to the bat in this area.

Habitat Conservation and Protection

The protection and management of 5,234 acres of kingfisher habitat on DON lands in northern Guam per the MOA will have a beneficial effect on the survival and recovery of the Mariana fruit bat in Guam because these two species use similar habitat.

As part of the proposed action, the DON also proposes to implement a forest enhancement project at Finegayan, in low-quality secondary forest, to benefit listed species, including the fruit bat. The DON has proposed the enhancement of the site to include installation of ungulate exclusion fences around the 1,000 acres; active removal of ungulates (i.e. trapping, snaring, shooting) with the goal of eradication within the fenced areas; invasive plant removal; and the propagation, planting, and establishment of dominant and rare species characteristic of native limestone forest habitats. Although this site would not fully compensate for the loss of primary limestone forest in northern Guam, the enhancement of forest and protection of the site is expected to provide some benefit to the fruit bat

Summary

The proposed action is likely to adversely affect the Mariana fruit bat on Guam. Noise from construction, aircraft, operation of the LFTRC, and other military training activities will harm and harass fruit bats in the vicinity of the actions. This disturbance, combined with existing threats to the fruit bats in the Action Area (as described in the Environmental Baseline), will make reestablishment of a Mariana fruit bat colony at Pati Point unlikely. Increased human disturbance at AAFB, Finegayan and Haputo and the NMS may alter fruit bat behavior, increase stress reactions, or preclude use of high-quality foraging areas. Based on the increased disturbance throughout AAFB, shere bats are most common, it is likely that individual bats may be harassed repeatedly by the proposed action. Because AAFB was the last refuge for Mariana fruit bats on Guam, the increased human disturbance in this area will substantially inhibit future efforts for recovery of the Mariana fruit bat.

Further, any bats migrating from Rota to Guam after a typhoon or hunting event, may encounter unsuitable habitat and return to Rota prematurely. A premature return to Rota under post-typhoon conditions may threaten their survival through exposure to high levels of hunting and decreased food and habitat availability. Since the timeframe of the action is indefinite, it is reasonable to assume that a migration event will occur during the timeframe of this action.

In addition, roughly four percent of the remaining Mariana fruit bat habitat on the island will be lost or degraded directly or indirectly as a result of the proposed action (see Table 6) and induced growth. The areas of fruit bat habitat that are permanently cleared are areas which, in the absence of the project, would have remained intact to provide for the future survival recovery of the species. Although this loss will not preclude the recovery or survival of the Mariana fruit bat, it will reduce the total number of bats the island can support. The proposed action will reduce the current estimate for the carrying capacity of fruit bats on Guam (see Environmental Baseline above) by approximately 983 bats.

However, the DON's protection and management of 5,234 acres of fruit bat habitat in northern Guam will off-set the loss of Mariana fruit bat habitat from project construction, and will help ensure that fruit bat habitat will be available for survival and recovery of the species on Guam. In addition, the DON's implementation of the forest enhancement project at Finegayan and the biosecurity conservation measures including landscape-level brown treesnake eradication/control, recommendations from the RBP, HACCP planning, and brown treesnake interdiction program, will be beneficial to the Mariana fruit bat because it will reduce the snake population on Guam and also help prevent spread of brown treesnakes to Rota and other Mariana islands.

Effects of the Action – *Serianthes nelsonii*

Records on the distribution and abundance of *Serianthes nelsonii* indicate that although never abundant, it was historically more abundant and more widely distributed than it is now. Surveys and samples from the early part of the 20th century had been taken from a number of trees both in northern and southern Guam, and subsequent records exist of trees both in the northern and southern parts of the island (USFWS 1994, p. 8). No individuals exist at the sites of Nelson's original collections, which today are the eastern portion of AAFB in northern Guam and Mt. Tenjo and Mt. Alutom in central/southern Guam. Since the 1970's, six mature trees have been recorded in the wild in Guam: three at Ritidian Point, one at Pati Point, and two others near the Tarzan River in the Government of Guam Cotal Conservation Area in south-central Guam (USFWS 1994, p. 8). All have since been cut down or have died with no surviving offspring except for the one remaining mature tree within the project's action area. Surveys in 1995 estimated 121 trees in 16 subpopulations on the island of Rota (Wiles et al. 1996, p. 232). However, current estimates indicate only about 40-50 of these trees have survived (J. Manglona CNMI DLNR, pers. comm. 2015). In addition, successful regeneration in the wild has not been documented since more widespread inventories began in approximately the 1970's (USFWS 1994, p. 8; J. Manglona, DLNR, pers. comm. 2015; AAFB 2015, pp. 4-5). Genetic studies are needed to determine population differences or similarities between the Guam and Rota trees. Current research and recovery efforts have kept *S. nelsonii* seeds from the two islands separate until future genetic work can determine how distinct the Guam tree is from the Rota trees.

Habitat Loss and Degradation Caused by the Proposed Action

This project will clear 945 acres of *S. nelsonii* recovery habitat and result in the loss of three acres from induced human population growth, out of approximately 11,668 acres available on Guam, leaving approximately 10,720 acres of recovery habitat. To construct the MPMG firing range, DON proposes to clear approximately 65 acres of limestone karst forest around the only adult *S. nelsonii* in Guam, leaving a minimum 100-ft buffer of forested area. An approximate 100 acres will be cleared for smaller ranges. The proposed action will clear limestone karst forest with historical locations of *S. nelsonii* near the adult tree.

Effects from Land Clearing and Training Activities

The proposed construction of the MPMG range will convert 65 acres of limestone karst habitat around the adult *S. nelsonii* tree to a cleared area with sparse vegetation, which may require

outside fill. To construct the LFTRC small ranges, DON will grade the limestone karst substrate, and move fill from an outside location for ground cover (DON 2014a, p. 18). Accidental additional clearing of habitat around the adult *S. nelsonii* and the introduction of potentially harmful species through personnel and equipment to *S. nelsonii* habitat will be minimized through best management practices outlined in Table 2-2 of the BA (DON 2014a). As part of the proposed action, ungulate eradication is also planned for this area (See Conservation Measures section). Ungulates can damage seedlings and surrounding habitat by uprooting, herbivory, or trampling; and they can damage adult trees by rubbing. If carried out in a timely fashion, eradication will prevent damage and mortality to the adult *S. nelsonii* and seedlings from ungulates.

The construction and maintenance of the LFTRC will convert the forest immediately surrounding the adult *S. nelsonii* tree from contiguous primary limestone karst forest habitat to fragmented edge habitat, which has implications for abiotic features such as microclimate and humidity, as well as biotic features such as species composition and frequency of interaction with animal species (Murcia 1995, pp. 59-60; Laurance 2000, p. 134). The specific changes and their extent into edge habitat are largely site specific (Murcia 1995). However, most empirical studies indicate that edge effects happen in up to 492 ft (150 m) of the created edge, and in a few cases, will extend further (Laurance et al. 1997, p. 1118; Laurance 2000, p. 135). This measurement is at least four times greater than the total width of the fragment of forest habitat containing the last *S. nelsonii* adult tree on Guam that will remain after the area is cleared for the LFTRC. Most studies indicate that the effects from created forest edges are largely negative, including increases in damaging wind penetration, decreased biomass, and increased susceptibility to fires and invasive species (Murcia 1995, pp. 59-60; Laurance et al. 1997, p. 1118; Nascimento and Laurance 2004, p. S136; Holway 2005, p. 565). Therefore, the proposed project will likely result in edge affects to the *S. nelsonii* tree, although the extent of the effects is unknown at this time.

Most of the area with modification and vegetation clearing for the MPMG range will be to the east of the adult *S. nelsonii*, increasing the tree's, and the remaining fragmented forest's, exposure to wind. The dominant wind direction in Guam is from the east or northeast (Guard et al. 1999, p. 2-6), and storms often approach from the east or southeast (Mendehlson et al. 2012, p. 206). Keeping the area east of the *S. nelsonii* buffer clear of vegetation will increase the tree's exposure to stronger winds such as those in tropical storms and typhoons, as well as persistent lower-speed winds, which can desiccate the tree and surrounding vegetation (Chen et al. 1995, p. 83; Gelhausen et al. 2000, p. 31; Laurance et al. 2002, p. 608). This effect will likely be exacerbated by decreased biomass characteristic of forest fragments and edges (Laurance 1997, p. 1118; Nascimento and Laurance 2004, p. S134). Because the structure of the tree has been weakened by previous storms, termite damage, epiphyte load, and defoliation due to insect damage (DON 2014a, p. 58; AAFB 2015, p. 4), increasing wind load to this tree could result in mortal structural damage. In addition, the adult *S. nelsonii* is taller than most surrounding canopy that would remain in the fragment. Larger trees and areas near unimpeded spaces, such as the firing range, are more susceptible to storm damage (Brokaw and Walker 1991), meaning the adult tree will be particularly susceptible to damage from future storms. To minimize adverse effects to the adult Guam *S. nelsonii*, the DON proposed bracing the tree. However, because of the tree's current structural condition, it is possible that this could do more damage

than help, and the Service has advised against this measure. Typhoon data for Guam collected since 1959 indicates that on average four typhoon events (sustained winds greater than or equal to 74 mi per hour (119 km per hour)) could occur each decade (DON JTWC pers. comm. 2010). Therefore, typhoons are likely to occur during the life of this project. Given that a cleared area would be maintained directly east of the *S. nelsonii* adult, there is an increased likelihood that high wind during a typhoon would break tree limbs or the trunk, causing mortal damage to the tree.

In addition to mechanical wind effects, conditions in the fragment containing the adult *S. nelsonii* will likely exhibit a decrease in humidity, increased evapotranspiration, and an increase in solar radiation to the understory (Laurance 2000, p. 134; Gelhausen, et al. 2000, p. 31). It is difficult to predict how this would affect adult and seedling survival and species composition within the *S. nelsonii* fragment in the action area. However, natural conditions in limestone karst forests are shaded, and Guam, as a whole, is normally very humid (greater than 70 percent humidity) (Guard et al. 1999, pp. 2-5). Seed crop, seedling germination, and growth increase during the rainy season (AAFB 2015, p. 9; Wiles et al. 1996, p. 233), implying moisture is important for seedling germination and growth. Preliminary results from light experiments on *S. nelsonii* seedlings showed higher growth in shade conditions greater than 50 percent (AAFB 2015, p. 4). This research also showed very high seedling turnover at the site of the mother tree (AAFB 2015, p. 4), but research is ongoing to pinpoint the causes. If methods for improving seedling survival are developed, conditions within the forest fragment may not be ideal for implementing them when the humidity, radiation, and wind conditions are less favorable as a result of the fragmentation. The health of the adult tree itself may also be compromised by drier conditions within the fragment.

Although measures to prevent invasion are proposed in best management practices, the increased invisibility of edges, especially those created through human modification, is well documented in other systems (Holway, 2005, pp. 561-565; Cadenasso and Pickett, 2001, p. 95; Didham et al. 2007, p. 490). Further, the edges and gaps that currently exist in the proposed action area are comprised of mostly invasive plants such as *Miscanthus* grasses, *Bidens alba*, and other weeds (A. Gawel, USFWS, pers. obs. 2011 – 2015). Plant invasions in the fragment will likely inhibit seedling growth, and invasive vines or epiphytes could increase structural damage or smother the *S. nelsonii* adult tree and seedlings. Invasive insects and other animals are also likely to increase in disturbed edge habitat (Holway, 2005, pp. 563; Laurance, et al. 2002, p. 608). Insect pests are one of the major threats to *S. nelsonii* (USFWS 1994, p. 15-19), and increased insect disturbance is expected on the adult and seedlings when edge habitat is created from this project.

In addition to increased vulnerability to invasive species, fragmented habitat may lead to a decrease in native species composition, including use by beneficial animals such as pollinators and seed dispersers. When habitat is fragmented, wide-ranging species, such as fruit bats, known to be important pollinators and seed dispersers (Banack 1998, pp. 1959-1960; Shilton et al. 1999, p. 222; Hodgkison et al. 2003, p. 498), are likely to decline (Woodroffe and Ginsberg 1998, p. 2127). The pollinators and seed dispersers of *S. nelsonii* are unknown, although records exist of Mariana fruit bats visiting *S. nelsonii* flowers in Rota (USFWS 1994, p. 13). Aside from fragmentation, the operation of the LFTRC may discourage fruit bats from using the area, even as a corridor between feeding and roosting sites (see analysis above). Even when the LFTRC is

not in operation, fragmented and disturbed habitat is less likely to be used by other native species such as Mariana crows (NRC 1997, p. 6) and possibly native seed-dispersers.

Fire management guidelines for the LFTRC and the hand grenade complex are described in the BA (DON 2014a, pp. 21-22). Implementation of these fire prevention measures will decrease the risk of wildlife fire and destruction near the adult *S. nelsonii*. Regardless, while savannah and other non-forest cover types of habitat are at greatest risk for fire in Guam (Guam Department of Agriculture 2010, p.22), forest edge areas experience considerable damage, even if fires do not penetrate far into forests (Guam Department of Agriculture 2010, p.33). Therefore, fire presents a risk to both the area with the adult tree and *S. nelsonii* habitat within and near this project area, especially the edges. Over 6.7 million rounds of ammunition are anticipated to be fired in the LFTRC annually, over 1.4 million of which are anticipated in the MPMG (DON 2014b, p. 2-9). With persistent gunfire, tracers, and rotating personnel smoking cigarettes, there will be constant risk of igniting a fire. Each incident that burns forest edges will create more opportunities for future fires to penetrate deeper into forest areas, and may decrease the buffer area within the fragment containing the adult *S. nelsonii* tree.

Effects to Research and Recovery

The proposed project will limit access to the adult *S. nelsonii* tree and seedlings for research, monitoring, and recovery. Currently, although the tree is located on a military installation, researchers with base approval have regular access to the adult tree. While DON proposes to allow access during the operation of this project, the additional process of coordinating access to an area that will have increased safety and security concerns, and that is proposed to be active for an estimated 39 weeks out of the year, will limit regular access. The LFTRC will likely have an unpredictable schedule that will adapt to the training needs of multiple DoD entities. This will have implications for regular monitoring of and potential response to threats to the adult tree and seedlings. It is also will likely limit the kinds of research that can be done on the tree and seedlings.

In addition, the proposed MPMG will require establishing a SDZ over the GNWR fee simple land, which will limit access to this area for research and recovery. The GNWR is currently an outplanting site for *S. nelsonii* because of its status as a conservation area, the availability of suitable habitat, and the Refuge's leadership in *S. nelsonii* recovery through a national grant that implements recovery actions for this species. Outplanting and maintenance of *S. nelsonii* seedlings has begun and is planned to continue in a number of suitable areas within the Refuge that fall within the SDZ (J. Cruce, USFWS, pers. comm. 2015). Limestone karst habitat suitable for *S. nelsonii* on the Refuge is mostly located within the SDZ. Areas of the Refuge fee simple that would fall outside of the SDZ are mostly comprised of strand, coconut plantation, or other habitats that would not be suitable for *S. nelsonii* outplanting. Operation of the MPMG may limit access to these outplanting sites. Seedling survival has been extremely limited in previous outplanting efforts, and the causes are still being investigated, but is likely due, in large part, to damage from insect herbivory and boring for egg-laying (J. McConnell, GPEPP, pers. comm. 2014; AAFB 2015, p.10). A large amount of time and labor are required to ensure seedling establishment, control for insect pests, and monitoring and response to any health changes (E. Demeulenaere, GPEPP, pers. comm. 2015). When the operation of the MPMG begins in 2021,

most of the seedlings outplanted on the Refuge will be between seven and five years old. As evidenced by the Tarague outplantings from 1999 (AAFB 2015, p. 6), the lack of regular maintenance, even when trees are over five years old, may result in mortality. Although DON proposes to coordinate access to the adult tree, the Refuge fee simple area will be closed during operation of LFTRC ranges, estimated at 39 weeks of the year (DON 2014b, p. 3-58). Unless regular access is coordinated for management actions, this will negatively affect the outplanted individuals on the Refuge, thereby adversely affecting the largest recovery action for this species in Guam thus far.

Summary

The proposed action will adversely affect the last remaining adult *S. nelsonii* tree in Guam and result in the loss of 948 acres of recovery habitat for this species. It also will negatively impact recovery efforts by limiting access to the adult tree, the wild seedlings around it, and outplanted *S. nelsonii* saplings at the Refuge. The fragmentation of habitat will cause ecological degradation that extends beyond the proposed vegetation clearing due to edge effects. As detailed above, the proposed action will likely damage the adult tree and seedlings by creating abiotic conditions less favorable to growth and survival, increasing fire risk, increasing invasability, increasing wind load, and decreasing the likelihood of pollination and seed dispersal. Of the impacts detailed above, increased wind load is likely the most significant, persistent, and unmitigated adverse effect. In the event of a severe wind storm, with the clearance of forest vegetation to the east of the adult tree that would otherwise act as a buffer to strong winds, structural damage or injury to the adult tree is highly likely, resulting in mortality. The adult tree and its descendants comprise the entire Guam genetic representation of *S. nelsonii*. Studies have not been done on its distinction, if any, from the Rota *S. nelsonii* trees, but the loss of this tree and its seedlings may significantly impact the genetic diversity of the species. These impacts will be offset, in part, by the conservation measures (see Conservation Measures section above).

The conservation measures, as well as continuing recent recovery efforts, will help to ensure the survival of the Guam population of *S. nelsonii*. The DON has proposed to outplant and maintain into adulthood 30 individuals parented from the Guam adult tree in a protected area. Therefore, adverse effects from the loss of genetic diversity, such as inbreeding depression, would be minimized. Because of new methods being employed and their success so far on outplanted seedling survival, these 30 individuals will have a high likelihood of survival if properly maintained, and if the area that they are outplanted to is truly protected from threats. DON has also proposed to fund seed storage and viability research, which will help preserve the genetic stock of the Guam population. Multiple ongoing interagency efforts, such as the maintenance of outplanted individuals at the GNWR, innovations in seedling and adult protection, and recent outplanting efforts in Rota will help ensure the continued survival of this species. The implementation of these conservation measures and best management practices, combined with the existence of adult trees in Rota, the existence of over 200 individuals in nurseries, and improved seedling survival strategies on both islands, make it unlikely that this project will preclude the recovery and survival of *S. nelsonii*. This determination is contingent on the full implementation of the conservation measures described above. If these conservation measures are not fully implemented, if new information suggests that the Guam population is distinct from

S. nelsonii in Rota, or if the baseline for this species experiences an unforeseen major decline, this determination will need to be reconsidered.

Effects of the Action – Guam Micronesian Kingfisher Critical Habitat

The Guam Micronesian kingfisher critical habitat on Guam was designated to support the recovery of the kingfisher by including unoccupied habitat that kingfishers can be translocated or released into when threats are managed (USFWS 2004). Critical habitat for the kingfisher was identified using guidelines from the Guam forest bird recovery plan (USFWS 1990a). Because the kingfisher does not exist in the wild and all suitable habitat presently is unoccupied, inclusion of unoccupied areas containing the primary constituent elements is essential to the conservation of this species. Survival and recovery of the kingfisher will require reintroduction of the kingfisher through release of captive birds and subsequent natural dispersal into areas of Guam that formerly were inhabited. Actions that affect the ability of the critical habitat unit to provide the conservation function for which it was designated may adversely affect critical habitat, regardless of whether the habitat features are actually physically altered.

The proposed project will not clear any designated critical habitat for the Guam Micronesian kingfisher.

The proposed LFTRC will be constructed immediately adjacent to, and above the cliff from, the Guam critical habitat unit at the Guam National Wildlife Refuge (Figures 11 and 12). The critical habitat unit is approximately 400 ft (122 m) below the nearest edge of the MPMG firing range. As discussed in the Effects of the Action – Guam Micronesian kingfisher, above, the noise from the firing range will rise substantially above ambient levels, and may preclude adjacent habitats from use by kingfishers in the future due to noise disturbance.

Noise from Construction of LFTRC

Construction of the MPMG range will take place over approximately three years beginning in 2021. Construction equipment will include standard heavy equipment including bulldozers, graders, haulers, large trucks. No blasting or use of dynamite will occur as part of the proposed project. The use of heavy equipment can reach noise levels of 96 dB (USFWS 2006a, p. 15). Noise levels within critical habitat, at the base of the cliff below the MPMG firing range, are anticipated to be 5-15 dB less than that above the cliff line (personal communication, M. Downing, Blue Ridge Research and Consulting, February 2014 in DON 2014b, p. 5-230). Therefore, we anticipate that noise from construction of the LFTRC would range between 81-91 dB within the critical habitat unit (without accounting for noise attenuation due to vegetation, humidity or other factors). Ambient noise within the critical habitat unit will depend on wind and surf conditions, and distance from the ocean. Based on ambient noise studies conducted above the cliff line at AAFB (DON 2014a, p. 66), we expect that ambient noise within the critical habitat unit is at least 60 to 65 dB. Therefore, noise from the construction of the MPMG firing range on AAFB may reach between 16 to 26 dB above ambient conditions in the critical habitat unit.

Noise from construction will not be heard within the entire critical habitat unit. While it is difficult to estimate what portions of the critical habitat unit will be affected, we assume that the noise above ambient levels would be heard in the portions of critical habitat immediately below the MPMG cliff line. In a conservative scenario, construction noise may be heard in a 100 ac (41 ha) portion of the 376 ac (152 ha) critical habitat unit (or 27 percent of the critical habitat unit).

Noise from construction of the MPMG would be temporary and intermittent. Noise reaching the critical habitat unit would likely only come from construction activities at the far north end of the MPMG range, which might occur for a few months to a year of the total construction time.

Construction noise within the critical habitat unit (81-91 dB) may rise above the disturbance threshold for the Guam Micronesian kingfishers of 80 dB (described in the Effects of the Action – Guam Micronesian kingfisher section). However, this noise will be short-term in duration and will not lead to a permanent reduction in the capability of the critical habitat unit to support recovery and survival of the kingfisher within the critical habitat unit.

Noise from Operation of LFTRC

The only noise from operation of the LFTRC that is likely to be heard within the Guam Micronesian kingfisher critical habitat unit is that from weapons firing at the MPMG range. Noise from the MPMG range will be long-term, intermittent, and high intensity noise occurring over multiple years for an indefinite period of time.

Based on the noise data shown in Figure 13, approximately two acres of Guam Micronesian kingfisher critical habitat, along a cliffline, will be exposed to noise levels above 80 dB. Therefore, we anticipate that noise from the MPMG range will only reach a small portion of the critical habitat unit. However, if environmental conditions are right (i.e. low surf and high winds blowing west) it is possible that firing at the range will be heard over a broader area; however we expect the sound would be very soft and barely above ambient levels. Therefore, operation of the MPMG range will not lead to a permanent reduction in the capability of the critical habitat unit to support recovery and survival of the kingfisher.

Effects of the Action – Mariana Crow Critical Habitat

Mariana crow critical habitat on Guam was designated to support the recovery of the Mariana crow by including unoccupied habitat that Mariana crows can be translocated or released into when threats are managed (USFWS 2004). Recovery of the Mariana crow requires restoration of a Mariana crow population on Guam (USFWS 2004; USFWS 2005a). Because the Mariana crow does not exist in the wild and all suitable habitat presently is unoccupied, inclusion of unoccupied areas containing the primary constituent elements is essential to the conservation of this species. Survival and recovery of the crow will require reintroduction of the crow through release of captive birds and subsequent natural dispersal into areas of Guam that formerly were inhabited. Actions that affect the ability of the critical habitat unit to provide the conservation function for which it was designated may adversely affect critical habitat, regardless of whether the habitat features are actually physically altered.

The proposed project will not clear any designated critical habitat for the Mariana crow.

The proposed LFTRC will be constructed immediately adjacent to, and above the cliff from, the Guam critical habitat unit at the Guam National Wildlife Refuge (Figures 11 and 12). The critical habitat unit is approximately 400 ft (122 m) below the nearest edge of the MPMG firing range. As discussed in the Effects of the Action – Mariana Crow, the noise from the firing range will rise substantially above ambient levels, and may preclude adjacent habitats from use by Mariana crows in the future due to noise disturbance.

Noise from Construction of LFRTC

Construction of the MPMG range will take place over approximately three years beginning in 2021. Construction equipment will include standard heavy equipment including bulldozers, graders, haulers, large trucks. No blasting or use of dynamite will occur as part of the proposed project. The use of heavy equipment can reach noise levels of 96 dB (USFWS 2006a, p. 15). Noise levels within critical habitat, at the base of the cliff below the MPMG firing range, are anticipated to be 5-15 dB less than that above the cliff line (personal communication, M. Downing, Blue Ridge Research and Consulting, February 2014 in DON 2014b, p. 5-230). Therefore, we anticipate that noise from construction of the LFTRC would range between 81-91 dB within the critical habitat unit (without accounting for noise attenuation due to vegetation, humidity or other factors). Ambient noise within the critical habitat unit will depend on wind and surf conditions, and distance from the ocean. Based on ambient noise studies conducted above the cliff line at AAFB (DON 2014a, p. 66), we expect that ambient noise within the critical habitat unit is at least 60 to 65 dB. Therefore, noise from the construction of the MPMG firing range on AAFB may reach between 16 to 26 dB above ambient conditions in the critical habitat unit.

Noise from construction will not be heard within the entire critical habitat unit. While it is difficult to estimate what portions of the critical habitat unit will be affected, we assume that the noise above ambient levels would be heard in the portions of critical habitat immediately below the MPMG cliff line. In a conservative scenario, construction noise may be heard in a 100 ac (41 ha) portion of the 376 ac (152 ha) critical habitat unit (or 27 percent of the critical habitat unit).

Noise from construction of the MPMG would be temporary and intermittent. Noise reaching the critical habitat unit would likely only come from construction activities at the far north end of the MPMG range, which might occur for a few months to a year of the total construction time.

Construction noise within the critical habitat unit (81-91 dB) may rise above the disturbance threshold for Mariana crows of 80 dB (described in the Effects of the Action – Mariana Crow section). However, this noise will be short-term in duration and will not lead to a permanent reduction in the capability of the critical habitat unit to support recovery of the Mariana crow.

Noise from Operation of LFTRC

The only noise from operation of the LFTRC that is likely to be heard within the Mariana crow critical habitat unit is that from weapons firing at the MPMG range. Noise from the MPMG

range will be long-term, intermittent, and high intensity noise occurring over multiple years on end.

Based on the noise data shown in Figure 14, approximately two acres of Mariana crow critical habitat, along a cliffline, will be exposed to noise levels above 80 dB. Therefore, we anticipate that noise from the MPMG range will only reach a small portion of the critical habitat unit. However, if environmental conditions are right (i.e. low surf and high winds blowing west) it is possible that firing at the range will be heard over a broader area; however we expect the sound would be very soft and barely above ambient levels. Therefore, operation of the MPMG range will not lead to a permanent reduction in the capability of the critical habitat unit to support recovery of the Mariana crow.

Effects of the Action – Mariana Fruit Bat Critical Habitat

The proposed action may affect Mariana fruit bat critical habitat and its primary constituent elements (USFWS 2004). Although the current population of Mariana fruit bats on Guam is small, the foraging behavior and diverse diet of the fruit bats cause them to use most of the island for foraging, as documented by Wiles et al. (1995). Thus, all of the designated critical habitat for this species is used for foraging and/or roosting and is considered occupied. Recent sightings of Mariana fruit bats at the GNWR within the critical habitat unit confirm this. Actions that affect the ability of the critical habitat unit to provide the conservation function for which it was designated (serving as habitat for roosting and foraging bats) may adversely affect critical habitat, regardless of whether the habitat features are actually physically altered.

The proposed project will not clear any designated critical habitat for the Mariana fruit bat. However, the proposed action will create disturbance that may affect the PCE (described above) requiring remote locations on clifflines with limited exposure to human disturbance. As described below, this primary constituent element will be adversely affected by the proposed action.

Construction

Construction of the MPMG range will take place over approximately three years beginning in 2021. Construction equipment will include standard heavy equipment including bulldozers, graders, haulers, large trucks. No blasting or use of dynamite will occur as part of the proposed project. The use of heavy equipment can reach noise levels of 96 dB (USFWS 2006a, p. 15). Noise levels within critical habitat, at the base of the cliff below the MPMG firing range, are anticipated to be 5 to 15 dB less than that above the cliff line (personal communication, M. Downing, Blue Ridge Research and Consulting, February 2014 in DON 2014b, p. 5-230). Therefore, we anticipate that noise from construction of the LFTRC would range between 81-91 dB within the critical habitat unit (without accounting for noise attenuation due to vegetation, humidity or other factors). Ambient noise within the critical habitat unit will depend on wind and surf conditions, and distance from the ocean. Based on ambient noise studies conducted above the cliff line at AAFB (DON 2014a, p. 66), we expect that ambient noise within the critical habitat unit is at least 60 to 65 dB. Therefore, noise from the construction of the MPMG

firing range on AAFB may reach between 16 to 26 dB above ambient conditions in the critical habitat unit.

Noise from construction will not be heard within the entire critical habitat unit. While it is difficult to estimate what portions of the critical habitat unit will be affected, we assume that the noise above ambient levels would be heard in the portions of critical habitat immediately below the MPMG cliff line. In a conservative scenario, construction noise may be heard in a 100 ac (41 ha) portion of the 376 ac (152 ha) critical habitat unit (or 27 percent of the critical habitat unit). Noise from construction of the MPMG would be temporary and intermittent. Noise reaching the critical habitat unit would likely only come from construction activities at the MPMG range, which might occur for a few years of the total construction time.

Construction noise within the critical habitat (81-91 dB) will rise above the disturbance threshold for Mariana fruit bats (described in the Effects of the Action – Mariana Fruit Bat section). This noise will be short-term in duration and will not lead to a permanent reduction in the capability of the critical habitat unit to support recovery of the Mariana fruit bat. However, during construction, the critical habitat unit will not serve as a remote location with limited exposure to human disturbance and this will limit the fruit bat's use of the clifflines for roosting or reproductive activity. Construction noise at this time, and for a period of time after while fruit bats still avoid the area, may have an adverse effect on the critical habitat unit serving as a remote location.

Operation of the LFTRC and aircraft overflights

Noise disturbance from the LFTRC and aircraft overflights could expose the critical habitat unit to increased human disturbance and preclude Mariana fruit bat roosting and reproductive activity. Based on the noise data shown in Figure 17, approximately two acres of fruit bat critical habitat, along a cliffline, will be exposed to noise levels above 65 dB. This includes approximately 150 linear meters (492 linear ft) of cliffline. There are approximately 2,500 m (6,652 feet) of cliffline within the critical habitat unit. Therefore, the amount of cliffline critical habitat precluded from use by the Mariana fruit bat is small.

In addition, based on the map of noise contours for aircraft at AAFB from the 2010 DON EIS (DON 2010b, Vol. 2, p. 6-25), we do not expect aircraft noise over the critical habitat unit to rise above ambient conditions.

H. CUMULATIVE EFFECTS

Cumulative effects include the effects of future State, tribal, local or private actions that are reasonably certain to occur in the action area considered in this Biological Opinion. Future Federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the ESA.

The extent to which future development is addressed as a cumulative effect in the following analysis excludes any such future development that is expected to be interdependent with or

interrelated to construction of federally-funded roads or is likely to be caused by other Federal actions that will be addressed in future section 7 consultations.

Overview of Cumulative Effects

Future state, local, or private actions that are reasonably certain to occur in the action area are listed below.

1) Development
    a. Civilian
        i. Commercial
        ii. Residential
        iii. Agriculture
    b. Territorial or local government
        i. Infrastructure projects
        ii. Other development
    c. Tourism
        i. Hotels and resorts
        ii. Roads and other infrastructure to support tourism
2) Wildfire
3) Invasive Species / Biosecurity
4) Natural Resource Management Projects

These actions may result in loss, fragmentation, or degradation of habitat for the listed species addressed in this Biological Opinion, or provide beneficial effects to listed species.

<u>Development</u>

The DON provided a list of known future projects lacking a Federal nexus on Guam in their Biological Assessment (DON 2014a, p. 85), and provided information on whether the future projects may affect terrestrial biological resources. No specific information was provided on whether the projects may potentially be located within habitats for the listed species addressed in this Biological Opinion. The DON presented fifteen reasonably foreseeable projects that may result in adverse cumulative effects to terrestrial biological resources on Guam. However, this list does not include projects deemed "present" and the Service assumes that some of these projects may be delayed into the future and thus contribute towards cumulative effects.

Guam's land use planning maps (Government of Guam 2009, p. 2-14) indicate housing and industrial development will be targeted to minimize effects to listed species habitat areas. However, development is likely to result in increased noise and predator densities in the vicinity of sites occupied by listed species. Population increases will result in increased human noise disturbance in urban areas as well as in outdoor recreation areas.

Civilian development

Because the information in the Biological Assessment did not provide data on how much listed species habitat may be lost from cumulative effects, we calculated an estimate based on population growth, density, and development zoning.

From 1950 to 2000, Guam's population grew at an average rate of 21 percent per decade (about 2.1 percent annually). However, population growth has slowed and is expected to stabilize over the next 20 years at around 1.5 percent per year (DON 2014b, p. 4-113). The population of Guam in 2010 was 159,358 (U.S. Census data in DON 2014b, p. 4-113). Using 2010 data, population density within developed areas on Guam (assuming all people live in the developed areas) was calculated to be 4.5 people per acre.

If we apply the projected annual growth of 1.5 percent to the next 20 years, the population of Guam, in the absence of the proposed project, would be 231,220 in 2035 (an increase of 71,862 people since 2010). Most future development will occur in north and central Guam (V. Torres, Government of Guam, pers. comm., 2010). Based on our analysis, if population density remains unchanged, the additional people will spread development into all the developable land in northern Guam zoned for non-tourist civilian development. Therefore, we estimate that 423 acres of remaining Guam Micronesian kingfisher habitat and 286 acres of remaining Mariana crow habitat would be developed in the absence of the proposed action by 2035.

Territorial or local government development
Many territorial or local government development projects may be funded by Federal monies, and therefore would not be included in this cumulative effects analysis. Based on the list of projects the DON provided that may affect terrestrial biological resources, such as a 60 MW power plant, a territorial prison, Guam airport expansion, and road projects, we expect that the majority of territorial and local government projects will be Federally funded and subject to a section 7 consultation.

Tourism development
Significant areas of listed species habitat are zoned for development as tourist/resort (Government of Guam 2009, p. 2-14). The Guam Tourism 2020 Plan calls for an increase in five-star luxury hotels and upgrades to existing private resorts (GVB 2014, p. 30). The Plan calls for growth of 1,500 hotel rooms by 2020, or six additional hotels (GVB 2014, p. 38). In 2012, Guam received 1,308,035 visitor arrivals and projects that by 2020 visitor arrivals could reach two million people, an increase of over 30 percent (GVB 2014, p. 34). The Plan also calls for tourism development to follow the World Tourism Organization's sustainable tourism principles that call for tourism to be developed in conjunction with maintaining essential ecological process and biological diversity (GVB 2014, p. 34).

It is our understanding that development of many of the tourist/resort areas will entail creation of federally-funded roadways and infrastructure; therefore these projects will be addressed in separate section 7 consultations. Other tourist/resort development may occur without Federal funding, but we are unable to project at this time how much listed species habitat will be lost due to these future developments.

Wildfire

The conversion of forest to savanna in southern Guam has been on-going for decades. Although there is ongoing debate regarding the formation of savannah areas in Guam (Hunter-Andersen 2009; Athens and Ward 2004), savannah areas have encroached into previously forested areas as a result of human-caused wildfires. Of the approximately 750 wildfires that burn on Guam each year, 80 percent are caused by arson (Guam Department of Agriculture 2010, p. 117). From 1979 to 2006 the number of acres burned by wildfire averaged 1.7 ha (4.2 ac) per year (Burdick et al. 2008, p. 471). We anticipate the area burned by wildfires will continue to decline as a result of efforts by the U.S. Forest Service, Federal Emergency Management Agency, and the DOI Office of Insular Affairs. The U.S. Forest Service, for instance, anticipates providing funds to develop a robust fire suppression force led by a skilled fire management officer on Guam (Mahoney 2010, pers. comm.).

To estimate the rate of historical forest conversion to savannah, Greenlee (2010) compared aerial photographs from 1975 and 2005 and estimated that 1,119 ac (453 ha) of forest has been converted to savannah in southern Guam since 1975. This estimate indicates the average rate of forest loss in southern Guam is approximately 37 ac/year (15 ha/year) (740 ha/20 years). However, the trend in annual area burned has been declining and we anticipate it will continue to decline as a result of ongoing and future Federal support of the development of local fire suppression resources. Therefore, we reduced the anticipated acreage burned over the next 20 years by 30 percent to 518 ha/20 years.

Invasive Species / Biosecurity

Guam is a central pass-through point for the transport of goods and people from Asia and North America, and represents the local consolidation hub for the rest of Micronesia (e.g. approximately 1.1 million people enter Guam per year and Guam is the primary shipment hub for cargo). As such, Guam is often the first island of introduction of non-native species entering Micronesia and represents the geographic first line of defense for invasive species prevention in many of the US-affiliated islands in the western Pacific as well as for preventing potential introduction pathways westward from Asia to Hawaii and North America. Over 1,000 species of introduced animals and plants are likely established on Guam, with dozens severely affecting the island's natural systems (Aubrey Moore pers. comm. in BTS TWG 2015). The most damaging alien invader to establish on Guam thus far is the brown treesnake, and the primary focus of biosecurity efforts on Guam has been preventing the spread of the brown treesnakes to other locations; however, other invasive species on Guam, such as the coconut rhinoceros beetle and little fire ant, also warrant attention. The Regional Biosecurity Plan (RBP), the Regional Invasive Species Council (RISC), and the Guam Invasive Species Advisory Committee (GISAC) have all been developed to reduce the risk of the introduction, establishment, and spread of invasive species to Guam. These comprehensive and collaborative efforts will reduce the risk of adverse cumulative effects from invasive species to the listed species covered in this Biological Opinion. The Department of Interior – Office of Insular Affairs (OIA) also funds brown treesnake suppression efforts for natural resource benefits, research on brown treesnake control, the implementation of brown treesnake barriers, and overall brown treesnake coordination efforts.

Natural Resource Management Projects

Most natural resource management projects that would benefit the listed species covered in this Biological Opinion will be federally funded. However, small scale projects may occur funded by the territorial or local governments. These projects may benefit listed species; however, their scale is likely to be insignificant compared to the loss of habitat from the proposed action or cumulative effects.

Species-Specific Cumulative Effects

Guam Micronesian kingfisher and Mariana crow
In northern Guam, habitat for the kingfisher and crow may be lost as a result of cumulative effects from civilian development. We estimate that 423 acres of remaining kingfisher habitat and 286 acres of remaining crow habitat would be developed in the absence of the proposed action by 2035. For the kingfisher this represents 3.6 percent of the potential remaining habitat in northern Guam. For the crow, this habitat loss represents 2.6 percent of the potential remaining habitat in northern Guam.

In southern Guam, habitat for the kingfisher and crow may be lost as a result of cumulative effects from wildfire. However, since the trend in annual area burned has been declining, and since we anticipate it will continue to decline as a result of ongoing and future Federal support of the development of local fire suppression resources, the amount of habitat lost to wildfire should decline.

Guam Rail
Habitat for the Guam rail may be lost from development or wildfire. Because the Guam rail utilizes edge habitat and shrubby areas, the effects of future development and human-caused wildfire (which increase the amount of edge habitat and shrubby areas) to the Guam rail on Guam are expected to be insignificant.

Mariana fruit bat and Serianthes nelsonii
In northern Guam, habitat for the Mariana fruit bat and *Serianthes nelsonii* may be lost as a result of cumulative effects from civilian development. Because the two species are not as habitat limited as the kingfisher and crow, we did not calculate the amount of remaining habitat for these species that would be lost as a result of cumulative effects; however we expect it to be in the range of what we estimated for the crow and kingfisher. We do not expect that the fruit bat or *Serianthes nelsonii* will become habitat limited as a result of cumulative effects.

In southern Guam, habitat for the fruit bat and *Serianthes nelsonii* may be lost as a result of cumulative effects from wildfire. However, since the trend in annual area burned has been declining, and since we anticipate it will continue to decline as a result of ongoing and future Federal support of the development of local fire suppression resources, the amount of listed species habitat lost to wildfire should decline.

I. CONCLUSION

After reviewing the current status of the listed species addressed in this Biological Opinion, the environmental baseline, the effects of the proposed action and the cumulative effects, it is the Service's biological opinion that the action, as proposed is not likely to jeopardize the continued existence of the Guam Micronesian kingfisher, Mariana crow, Guam rail, Mariana fruit bat and *Serianthes nelsonii*; and is not likely to adversely modify Guam Micronesian kingfisher critical habitat, Mariana crow critical habitat, and Mariana fruit bat critical habitat. The Service reached these conclusions based on the following findings, the basis for which is presented in the preceding sections of this document.

Guam Micronesian Kingfisher

The endangered Guam Micronesian kingfisher is endemic to Guam. The kingfisher is currently extirpated in the wild due to predation by the introduced brown treesnake, but a captive population is being maintained on the mainland for the purpose of reintroduction onto Guam. The reintroduction is dependent, in part, on protecting and managing 11,512 acres of kingfisher habitat to support a persistent population of 500 breeding pairs of the kingfisher in northern Guam where the proposed action is primarily located. A breeding population of 500 kingfisher pairs is also needed in southern Guam.

Currently, there are 14,997 acres of kingfisher habitat in northern Guam and 13,314 acres of kingfisher habitat in southern Guam that could potentially support 714 and 634 breeding pairs of the kingfisher, respectively. However, significant portions of this habitat are currently degraded and will require intensive management and restoration (e.g., ungulate and invasive plant control or eradication) before the habitat regains the capacity to effectively support kingfisher reproduction.

The proposed action will permanently destroy, fragment, or degrade approximately 1,334 acres of kingfisher habitat, including some of the best remaining primary forest in northern Guam. An additional 423 acres of kingfisher habitat in northern Guam is likely to be permanently destroyed by future, non-Federal actions reasonably certain to occur within the action area. The (1,334 ac + 423 ac) 1,760 ac of kingfisher habitat would have supported 83 pairs of breeding kingfishers or approximately 17 percent of the 500 breeding pairs needed for the recovery of this species in northern Guam. Therefore, the proposed action significantly reduces the potential for the remaining habitat in the north to support a subpopulation of kingfishers. Both subpopulations in northern and southern Guam are needed to ensure the survival and recovery of kingfishers.

Overall, the effect of the proposed action, when added to the environmental baseline for northern Guam, will significantly degrade and reduce the amount of kingfisher habitat in northern Guam. However, the protection and management of 5,234 ac of the kingfisher habitat in northern Guam pursuant to the MOA and implementation of conservation measures as detailed above will help ensure that sufficient amount of kingfisher habitat will be available for the survival and recovery of the kingfisher once the species is reintroduced to Guam. Therefore, the proposed action is not likely to appreciably reduce the likelihood of the survival and recovery of the Guam Micronesian kingfisher.

Mariana Crow

The Mariana crow is currently extirpated from the wild on Guam, and only is surviving outside the action area on the island of Rota. Therefore, direct impacts to individuals will not occur as a result of the proposed action. However, we have determined that the proposed project will adversely affect the Mariana crow by removing areas of Mariana crow habitat which, in the absence of the project, would have remained intact to provide for the feeding, breeding, and sheltering of this species once it is reintroduced to Guam. In southern Guam only six acres of Mariana crow habitat will be cleared by the proposed action, and thus the focus of our analysis in on northern Guam.

In northern Guam, potential crow habitat is limited relative to that needed to support a persistent crow population due to habitat loss and degradation, lack of management, and the presence of introduced ungulates, invasive species, and typhoons. Currently, there are potentially 13,962 acres of crow habitat in northern Guam that could potentially support 156 breeding crow pairs and 150 non-breeding crows. However, significant portions of this habitat are currently degraded and will require intensive management and restoration (e.g., ungulate, predator, and invasive plant control or eradication) before the habitat regains the capacity to effectively support crow reproduction.

The proposed action will permanently destroy, fragment or degrade approximately 1,332 ac of crow habitat, including some of the best remaining primary forest on Guam. An additional 286 acres of crow habitat is likely to be permanently destroyed by future, non-Federal actions reasonably certain to occur within the action area. About 8,590 acres of crow habitat is needed in northern Guam to support crow conservation in the wild. After the proposed action there will be approximately 12,344 ac or 87 percent of the remaining crow habitat in northern Guam. While 1,618 ac of habitat loss is substantial, considering the quality of habitat, there will be enough remaining crow habitat in northern Guam, after the proposed action and future non-Federal actions, to support the survival and recovery of the crow in northern Guam once the species is reintroduced.

The DON will protect and manage 5,234 ac of kingfisher habitat in northern Guam per the terms of the MOA. Within this 5,234-ac footprint, a large amount of habitat will be crow habitat. Therefore, the DON's protection and management of 5,234 acres of crow habitat in northern Guam will off-set the loss of Mariana crow habitat from project construction, and will help ensure that crow habitat will be available for the survival and recovery of the species on Guam. The DON also has proposed to implement a forest enhancement project and biosecurity conservation measures including landscape-level brown treesnake eradication and control, recommendations from the RBP, HACCP planning, and brown treesnake interdiction program, which will be beneficial to the crow because it will help reduce the current brown treesnake population and potentially prevent other invasive species from becoming established on Guam.

Overall, the effect of the proposed action, when added to the environmental baseline for northern Guam, will reduce the amount of Mariana crow habitat in northern Guam, but implementation of the conservation measures and the MOA would ensure an sufficient amount of crow habitat is

protected and managed to recover the crow in northern Guam. Therefore, the proposed action is not likely to appreciably reduce the likelihood of the survival and recovery of the Mariana crow.

Guam Rail

Although the proposed project will result in the loss and degradation of habitat for Guam rails, there will still remain an adequate amount of habitat to provide for recovery and survival of the species. Based on our analysis, there will be 23,643 ac of recovery habitat in northern Guam and 24,796 in southern Guam remaining after implementation of the proposed project. Approximately 48,439 ac of recovery habitat on Guam would be left to support the minimum Guam rail population size required to meet recovery goals.

The DON's implementation of biosecurity conservation measures including landscape-level brown treesnake eradication/control, recommendations from the RBP, HACCP planning, and brown treesnake interdiction program, will be beneficial to the Guam rail because it will help reduce the current brown treesnake population and potentially prevent other invasive species from becoming established on Guam.

The DON will protect and managed approximately 5,234 ac in northern Guam pursuant to the MOA and conduct a forest enhancement project on approximately 1,000 acres in Finegayan of habitat, which also will provide some benefit to the rail. In addition, the DON will implement brown treesnake control work to help prevent the spread to Rota (where an experimental population of rails are present) and reduce numbers of brown treesnakes on Guam.

Based on the above measures and our analysis, including the loss of habitat and increased human disturbance to habitat, and in consideration of cumulative effects (described above), the Service concludes that the effects of the proposed action, including the cumulative effects, are not likely to appreciably reduce the likelihood of both the survival and recovery of the Guam rail in the wild, because there will be enough remaining potential rail habitat on Guam, after the proposed action and future non-Federal actions, to support the survival and recovery of the rail once the species is reintroduced to Guam.

Mariana Fruit Bat

The proposed action will adversely affect the Mariana fruit bat on Guam. Roughly four percent of the remaining Mariana fruit bat habitat on the island will be lost or degraded directly or indirectly as a result of the proposed action, and although this loss will not preclude the recovery of the fruit bat, it will reduce the total number of bats that the island can support by approximately 983 bats. In addition, the proposed action will substantially increase disturbance levels at AAFB from construction projects, operation of the LFTRC, and an increase in aircraft overflights. This disturbance will result in take, in the form of harassment, of any Mariana fruit bats in the area, is likely to repeadtedly harass individual bats, and may preclude the future reestablishment of a maternal roost colony at AAFB.

The DON will protect and manage 5,234 ac of kingfisher habitat in northern Guam per the terms of the MOA. Because the habitat for kingfisher and fruit bats are similar, protection and

management of 5,234 ac pursuant to the MOA will have direct benefits to the fruit bat. In addition, the DON's proposed forest enhancement project may help enhance some of the available Mariana fruit bat habitat at Finegayan. The DON's brown treesnake interdiction and control work will help prevent the spread of brown treesnakes to other Mariana Islands that support the Mariana fruit bat, and the implementation of the brown treesnake exclosure projects will facilitate the future successful recolonization or reintroduction of the Mariana fruit bat to Guam. On the basis of these findings, the Service concludes that the effects of the subject action, taken together with cumulative effects, is not likely to appreciably reduce the likelihood of both the survival and recovery of the Mariana fruit bat in the wild because sufficient habitat and populations are likely to persist throughout its range at levels that retain the potential for recovery of this species.

Serianthes nelsonii

The proposed action will adversely affect the last remaining adult *Serianthes nelsonii* tree and its surrounding seedlings in Guam and result in the removal of 948 acres of habitat for this species. As detailed above in the Effects of the Action- *Serianthes nelsonii*, the proposed action will damage the adult tree and also negatively impact recovery efforts by limiting access to the adult tree at NWF, the wild seedlings around it, and outplanted *S. nelsonii* saplings at the GNWR. However, among the potential adverse effects to the tree, the increased wind load is likely the most significant, persistent, and unmitigated adverse effect. In the event of a severe wind storm, with the clearance of forest vegetation to the east of the adult tree that would otherwise act as a buffer to strong winds, structural damage or injury to the point of mortality of the adult tree is highly likely.

The DON has proposed to offset, in part, these adverse effects by implementing the conservation measures detailed above, including the Finegayan enhancement project. Although not included as a conservation measure, the MOA (DON and Service 2015c) also will provide a benefits to *Serianthes nelsonii* because a portion of the habitat within the 5,234-ac protected site would include habitat for *S nelsonii*. In addition, risks will be minimized by best management practices regarding spread of non-native species and fire. As stated above, seedling survival, both wild and outplanted, has been very low. However, research and renewed recovery efforts through recent projects are likely to improve survival in outplanted seedlings. The proposed outplanting of 30 individuals (seedlings from the Guam adult *Serianthes* tree to ensure the genetics of the Guam *Serianthes* population is maintained into the future) and maintaining these individuals to adulthood and the ability to continue to access (although potentially limited) the tree for research, seedling rescue, and seed collection will help to ensure the continued existence of this tree species in the wild on Guam.

Overall, the potential loss of the last remaining Guam adult *Serianthes* tree as a result of the proposed action is highly likely and cumulative effects are substantial. However, in consideration of the presence of adult *Serianthes* trees on Rota; the amount of remaining habitat on Guam to support outplanting efforts on Guam; the proposed enhancement and protected sites, and most importantly, the DON's proposal to maintain 30 individuals to adulthood on Guam, the Service concludes that the proposed action is not likely to appreciably reduce the likelihood of both the survival and recovery of the *Serianthes nelsonii* in the wild.

Guam Micronesian kingfisher critical habitat

The Guam critical habitat unit for the Guam Micronesian kingfisher consists of approximately 376 acres of land in the fee simple portion of the Guam National Wildlife Refuge. Upon operation of the LFTRC, noise from gunshots will reach a small portion (approximately two acres) of the critical habitat unit. Because only two acres of the critical habitat unit will be affected, this noise is unlikely to diminish the value of the critical habitat for the conservation of the species in the long-term. Therefore, we determine that the proposed action will not adversely modify the Guam critical habitat unit for the Guam Micronesian kingfisher.

This conclusion relies heavily on the noise modeling outcomes described above, and if noise from the LFTRC is heard over a greater area within the critical habitat unit, this conclusion must be revisited.

Mariana crow critical habitat

The Guam critical habitat unit for the Mariana crow consists of approximately 376 acres of land in the fee simple portion of the Guam National Wildlife Refuge. Upon operation of the LFTRC, noise from gunshots will reach a small portion (approximately two acres) of the critical habitat unit. Because only two acres of the critical habitat unit will be affected, this noise is unlikely to diminish the value of the critical habitat for the conservation of the species in the long-term. Therefore, we determine that the proposed action will not adversely modify the Guam critical habitat unit for the Mariana crow.

This conclusion relies heavily on the noise modeling outcomes described above, and if noise from the LFTRC is heard over a greater area within the critical habitat unit, this conclusion must be revisited.

Mariana fruit bat critical habitat

The Guam critical habitat unit for the Mariana fruit bat consists of approximately 376 acres of land in the fee simple portion of the Guam National Wildlife Refuge. The critical habitat unit is currently occupied, and is located at the base of the cliff below the LFTRC. Upon operation of the LFTRC, noise from gunshots will reach a small portion (approximately two acres) of the critical habitat unit. This noise may preclude the Mariana fruit bat from using this area for roosting as a remote place free of human disturbance. However, because only two acres will be affected, this noise is unlikely to diminish the value of the critical habitat for the conservation of the species in the long-term. Therefore, we determine that the proposed action will not adversely modify the Guam critical habitat unit for the Mariana fruit bat.

This conclusion relies heavily on the noise modeling outcomes described above, and if noise from the LFTRC is heard over a greater area within the critical habitat unit, this conclusion must be revisited.

J. INCIDENTAL TAKE STATEMENT

Section 9 of the Act and Federal regulations pursuant to section 4(d) of the Act prohibit the take of endangered or threatened species, respectively, without special exemption. Take is defined as harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct. Harm is further defined by the Service to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavioral patterns, including, breeding, feeding, or sheltering. Harass is defined by the Service as intentional or negligent actions that create the likelihood of injury to listed species to such an extent as to significantly disrupt normal behavior patterns which include, but are not limited to, breeding, feeding or sheltering.

Incidental take is defined as take that is incidental to, and not the purpose of, carrying out an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking that is incidental to and not intended as part of the agency action is not considered a prohibited taking under the Act provided that such taking is in compliance with the terms and conditions of this Incidental Take Statement.

The measures described below are non-discretionary, and must be undertaken by DON so that they become binding conditions to the applicant for the exemption in section 7(o)(2) to apply. The DON has a continuing duty to regulate the activity covered by this incidental take statement. If DON (1) fails to assume and implement the terms and conditions or (2) fails to require contractors to adhere to the terms and conditions of the incidental take statement through enforceable terms that are added to contract documents, the protective coverage of section 7(o)(2) may lapse. In order to monitor the impact of incidental take, DON must report the progress of the action and its impact on the species to the Service as specified in this incidental take statement [50 CFR 402.14(i)(3)].

Amount or Extent of Take Anticipated

Based on our analysis presented in this Biological Opinion, the Service anticipates the following take may occur as a result of the proposed action:

1) The Service anticipates that, over the duration of the proposed action, up to 30 Mariana fruit bats at AAFB and Finegayan could be repeatedly taken in the form of harassment leading to injury from loud aircraft noise, operation of the LFTRC, construction noise, and other human disturbance resulting from the proposed action. We do not anticipate mortality from the proposed action. This take level was determined based on the following factors:

   a. The current population of Mariana fruit bats on Guam is less than 30 individuals, primarily found on AAFB.

   b. Mariana fruit bats can traverse large areas and therefore are likely to come into close vicinity to the proposed action (aircraft noise, operation of the LFTRC, construction, other military training or human disturbance) multiple times during their

life-span.

c. Disturbance from the proposed action could have an adverse effect on fruit bats by increasing energetic demands, disrupting hormonal balances, forcing relocation to lower quality habitat or areas where poaching is more prevalent, disrupting reproductive cycles, and increasing stress levels. These behavioral and physiological responses represent harassment that is reasonably likely to significantly disrupt normal behavior patterns including breeding, feeding or sheltering.

d. Because of the frequency and duration of training events at AAFB and Finegayan we expect that each of the 30 bats may be harassed multiple times over the duration of the proposed action.

Incidental take of the kingfisher, rail, and crow as a result of the proposed action cannot be anticipated at this time. Once these species are reintroduced on Guam, the Service will revise this Incidental Take Statement, as appropriate, to address such take.

Effect of the Take

In the accompanying Biological Opinion, the Service determined that this level of anticipated take is not likely result in jeopardy to the Mariana fruit bat or result in the destruction or adverse modification of Guam Micronesian kingfisher critical habitat, Mariana crow critical habitat, or Mariana fruit bat critical habitat.

K. REASONABLE AND PRUDENT MEASURES

Reasonable and prudent measures serve to minimize impacts on individuals or habitats affected by the action. The Service believes the following reasonable and prudent measures are necessary and appropriate to minimize the impacts of incidental take on the Mariana fruit bat:

1) The DON shall implement the Conservation Measures set forth in the Project Description in this Biological Opinion.

2) The DON shall minimize the level of incidental take of the Mariana fruit bat occurring as a result of construction and operation of the Proposed Action.

3) The DON shall monitor the level of incidental take of Mariana fruit bat.

4) The DON shall compensate for removal of the ungulate fence required by the Incidental Take Statement in the Service's Biological Opinion addressing the ISR Strike Action.

5) The DON shall report on the progress of project implementation related to take of the Mariana fruit bat.

L. TERMS AND CONDITIONS

In order to be exempt from the prohibitions of section 9 of the Act, DON must comply with the following terms and conditions, which implement the reasonable and prudent measures described above and specify reporting requirements. These terms and conditions are non-discretionary.

In order to implement the reasonable and prudent measure above, the following terms and conditions apply:

1) DON shall implement the Conservation Measures in the Project Description of this Biological Opinion. We reiterate this requirement here for convenience and clarity.

2) To minimize the level of incidental take of Mariana fruit bat the DON shall:

    a. Halt construction if a fruit bat is present within 492 ft (150 m) of a construction site, at any point during the construction cycle, until the fruit bat leaves the area of its own accord. Information regarding the presence of fruit bats at a construction site shall be provided to the Service on an annual basis.

    b. Use hooded lighting within 482 ft (150 m) of all potential fruit bat roost habitat.

    c. Provide educational materials regarding Mariana fruit bat appearance, behavior, and biology to all personnel using the LFTRC so that they can correctly identify any fruit bats near or within the LFTRC during operation. If a fruit bat is sighted down range during operation of the LFTRC, all use of the range will cease until the fruit bat has left the area of its own accord.

    d. Search for Mariana fruit bat maternity colonies, on a semi-annual basis, in all areas of AAFB that could be affected by the proposed action including 1) all fruit bat habitat within the 65 dB noise contour from the LFTRC shown on Figure 17 and 2) all fruit bat habitat that will be subject to increased noise levels from aircraft overflights. Searches will begin one year prior to the operation of the LFTRC and one year prior to the proposed overflight increases. Surveys will proceed on a semi-annual bases for the first five years, then conducted annually for the length of the project. If a fruit bat maternity colony is found the Service should be notified within one week of the finding.

3) To determine the level of take the DON shall:

    a. Monitor all known roost sites, at a minimum once a quarter, from one year prior to and one year after the proposed overflight increases are fully implemented and during all years in which operation of the LFTRC is active. The monitoring methodology should, at a minimum, include direct counts of Mariana fruit bats utilizing a spotting scope at an appropriate distance to avoid disturbance impacts to the bats.

b. Conduct a noise study at the GNWR and at Ritidian Point upon operation of the MPMG range at the LFTRC. The noise study will occur during the first year of operation of the LFTRC. Multiple stations should record noise levels during operation of the MPMG at the GNWR and at Ritidian Point. The monitoring stations will be approved by the Service in coordination with the DON. Noise monitoring should occur during day and night activities over multiple days (minimum of ten days) at least once a quarter to address seasonal and climatic changes. Weather conditions during monitoring should be closely recorded including temperature, humidity, and wind direction. The results of the surveys will be provided to the Service (Ecological Services and Refuges) on a quarterly basis, with a final report due within three months of the conclusion of the study.

c. Submit reports summarizing the methods and results of the above monitoring efforts shall be sent to the Service's Pacific Islands Fish and Wildlife Office (300 Ala Moana Blvd., Room 3-122, Honolulu, Hawaii 96850) every year until the monitoring is completed.

4) The DON shall

a. Finalize an agreement with the Service, prior to any construction of the LFTRC, regarding the future location of the ISR Strike-related ungulate fence. The DON is responsible for reconstructing the fence, removing ungulates within the fenced exclosure, and re-planting any native outplantings that occurred within the current ISR Strike fence at Ritidian Point. The DON will be responsible for maintaining the fence and continuing any forest enhancement as required under the Incidental Take Statement in the Service's Biological Opinion on the ISR Strike action. Construction of the new ungulate fence and ungulate removal within the fenced area shall be completed by December 2022. If an agreement is not reached, and work on the new fenced exclosure has not begun by January 2017, then the DON shall be out of compliance with both the DON and ISR Strike-related Biological Opinions.

5) The DON shall:

a. Submit annual reports detailing the implementation of the above Reasonable and Prudent Measures and Terms and Conditions. The first report shall be due at the end of October 2016. Annual reports due by the end of October shall be submitted as long as the proposed action is still operating.

Term and Condition for Reporting and Salvage Requirements

Where practical, an attempt should be made to salvage specimens of listed species incidentally taken by the proposed action as modified by the above RPA. The DON shall inform the Field Supervisor of the Service's Pacific Islands Fish and Wildlife Office in Honolulu, Hawaii, in writing of any salvaged specimens of any federally listed species within three (3) working days. The depository designated to receive specimens of any threatened or endangered species killed is the B.P. Bishop Museum, 1525 Bernice Street, Honolulu, Hawaii, 96817 (telephone: 808/547-

3511). If the B.P. Bishop Museum does not wish accession to the specimens, the permittee should contact the Service's Division Office of Law Enforcement in Honolulu, Hawaii (telephone: 808/861-8525; fax: 808/861-8515) for instructions on disposition. The Service's Pacific Islands Fish and Wildlife office (telephone: 808/792-9400) shall also be informed within three (3) working days of any injured threatened or endangered species found and the actions taken.

M. CONSERVATION RECOMMENDATIONS

Section 7(a)(1) of the ESA directs Federal agencies to utilize their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species, to help implement recovery plans, or to develop information. The recommendations provided relate only to the proposed action and do not necessarily represent complete fulfillment of the DON's section 7(a)(1) responsibilities for the species. In order for the Service to be kept informed of actions minimizing or avoiding adverse effects or benefiting listed species or their habitats, the Service requests notification of the implementation of any conservation recommendations.

The Conservation Recommendations below only include actions that the DON is not currently implemented or has not already committed to implement. They are meant to be recommendations and suggestions for future actions.

1) To further support species recovery efforts, the DON will actively participate in recovery committees for endangered or threatened species on Guam. The DON will work with the Service to develop a re-introduction plan and supporting programmatic biological opinion that ensures such re-introduction efforts are consistent with the species recovery plans.

2) To assist with Endangered Species Act (ESA) section 7 consultations and to further support species recovery on Guam and in the Commonwealth of the Northern Mariana Islands (CNMI), the Deputy Assistant Secretary of the Navy (Environment) and the U.S. Fish and Wildlife Service (Service), Pacific Regional Director established a team (Team) to explore establishment of potential conservation area(s) on Guam and in the CNMI as part of a broader consultation solution. As part of that broader solution, the Team is considering the establishment of conservation area(s) and/or the implementation of conservation actions throughout Micronesia to enhance endangered and endemic species protection and recovery in the Mariana archipelago.

3) The DON should replace the proposed project footprint for the LFTRC with an alternative that does not clear the primary limestone forest at Ritidian Point, does not demolish the ungulate fence at Ritidian Point, and does not put a SDZ over the GNWR.

4) The DON should manage Overlay Refuge land on Guam for recovery of listed species including protecting conservation lands in-perpetuity, conducting ungulate control and/or eradication, fencing for ungulates and non-native predators (including brown treesnake),

conducting invasive species control, and outplanting native species. Native forests should be restored to conditions more closely representative of the forest types described by Fosberg (1960).

5) The DON should work with the Government of Guam to identify, protect, and manage listed species habitat throughout Guam.

6) In addition to ensuring project-related fires do not effect habitat for listed species, the DON should incorporate the following measures into fire management operations: (1) establish and maintain cooperative agreements with Government of Guam and local jurisdictions to ensure DON fire suppression resources are able to assist with fire suppression efforts, as necessary, to protect remaining limestone forest and ravine forest from fire; (2) to facilitate fire management planning and implementation of daily fire suppression staffing, immediately establish remote automated weather stations on Guam and maintain weather and fire danger data in the interagency weather information management system; (3) complete landscape-level forest restoration to convert grasslands in the Naval Munitions Site back to limestone forest or ravine forest; (4) restore any areas of forest burned on DON lands, regardless of fire cause; (5) control public access at the Naval Munitions Site to minimize ignition of fires caused by the public.

7) The DON should extend the security fence around Ritidian Point and the LFTRC to connect with clifflines that serve as barriers to ungulates. The DON should remove all ungulates within this perimeter fence to help restore the land for native species.

8) The DON should continue to work with the Service to develop a Marianas-wide strategy for listed species conservation and develop a Programmatic BO to address all future DoD actions on Guam.

9) Once the SDZ from the LFTRC is established, the DON should provide consistent, reliable, and easy access to the GNWR for researchers, managers, and GNWR staff.

10) The DON should work with the Service to develop a re-introduction plan for listed species once threats to the species have been managed or controlled on Guam such that species re-introduction is feasible.

11) The DON should place barriers at strategic places around the LFTRC to reduce sound transmission into listed species habitats.

Brown treesnake/Invasive species:

12) The DON should fully fund and implement actions identified in the RBP to avoid the spread of invasive species to and from Guam, and within Micronesia.

Guam Micronesian kingfisher:

13) The DON should provide funding for establishing a wild back-up Guam Micronesian kingfisher population outside of Guam (recovery action 3.9 in the recovery plan). Such a population could hedge against the risk of the captive population being loss to disease or catastrophe. Furthermore, a successful wild population should minimize the progressive loss of behavior or genetic traits suited to survival in the wild as opposed to a captive environment, and could thus ultimately improve the likelihood of successful reintroduction to Guam.

Mariana crow:

14) The DON should provide funding for recovery actions for the Mariana crow on Rota in order to enhance the population on Rota to provide for future reintroduction to Guam. Recovery actions needing funding include

    a. Predator monitoring and control on Rota;
    b. Captive propagation of the Mariana crow on Rota; and
    c. Identification and management of sources of adult and juvenile mortality.

Mariana fruit bat:

15) Recovery of the fruit bat population on Guam will likely depend on immigration or translocation of fruit bats from Rota. Consistent protection and monitoring of the fruit bat population on Rota is required to ensure its persistence.

    a. The DON should provide financial and technical assistance to support actions of off-island Law Enforcement personnel (Federal or CNMI DFW from Saipan) conducting surveillance, investigations, and poaching deterrence on Rota. Although the fruit bat population on Rota has increased in recent years due to an increase in enforcement of wildlife protection laws, illegal hunting continues to be the primary threat to this population. Fruit bats continue to be a high-demand cultural delicacy on Rota, and social and familial obligations prevent local authorities from effectively enforcing wildlife protection laws because people feel accountable to each other, but not necessarily to outside agencies, laws, or institutions.

    b. The DON should provide financial and technical assistance for conservation and research projects that include training and employment for local CNMI and Guam residents. Direct involvement of local community in conservation and research efforts has been shown world-wide to be one of the most effective ways to change local attitudes about poaching; not only does direct engagement promote appreciation of the species' intrinsic value, but it also provides an alternative economic value to the species or system, and with this a greater probability of sustained success.

c. The DON should provide financial and technical assistance for research on captive Mariana fruit bats. Long-term research examining life history parameters and reproductive cycles of captive Mariana fruit bats is needed to model population growth, predict population trends in light of a species' response to human and environmental stressors (e.g., hunting and natural disasters), and to insure effective management and conservation of critical habitat. We do not have this information for the Mariana fruit bat and have, to date, been extrapolating from other species of flying fox. Without species-specific knowledge of life history and reproduction, effective population analyses, an accurate determination of species recovery and subsequent delisting will not be possible. To avoid negatively affecting the wild fruit bat population while acquiring knowledge needed for their conservation, recovery, and management, efforts examining life history and ecology using rehabilitated wild bats and an existing captive population should be utilized. There are currently over 75 adult and juvenile fruit bats at the Rota Zoo and the owner of the zoo is willing to cooperate with local and federal agencies, or private organizations on research projects using his captive fruit bat colony. The Rota Zoo has the only known captive breeding colony of Mariana fruit bats. With appropriate financial and technical support, and collaboration with the Rota Zoo, there is great potential to acquire valuable, and much needed information on the life history and reproductive potential of the Mariana fruit bat.

d. The DON should provide technical and financial assistance for monitoring the fruit bat population on Rota. The CNMI DFW receives federal assistance to support employment of a wildlife biologist to monitor and conduct research on the Rota fruit bat population. However, this position has not been consistently filled and has been vacant for the last several years. When the position is vacant, the fruit bat population is not monitored and there is no record of population fluctuations, disturbance events, colony movements, etc. Although a resident biologist on Rota is the optimal way to ensure effective monitoring of the fruit bat population, regular and consistent efforts from off-island biologists could provide an acceptable alternative if the CNMI DFW's bat biologist position remains vacant or inconsistently occupied.

Serianthes nelsonii

16) The DON should fund a study to identify any genetic differences between the Guam *Serianthes* tree and the Rota *Serianthes* trees / population.

Proposed species:

17) The DON should conduct full surveys of the proposed action area to identify all proposed species locations and suitable habitat.

N. REINITIATION – CLOSING STATEMENT

This consultation may need to be reinitated if the following situations arise:

- If cargo originating from Guam is implicated in the transport of a brown treesnake to the CNMI, Hawaii, or continental U.S., the Service shall assess the ongoing risk of brown treesnake transport and will determine if additional brown treesnake interdiction measures or other actions are necessary to ensure the effects of the action are minimized.

- If a maternal fruit bat roost colony is located at AAFB.

- If peak noise levels at the LFTRC are higher than the peak noise levels described in the Project Description.

- If listed species are reintroduced to Guam, the Service may need to reinitiate consultation to assess the effects of the proposed action on the listed species in the Action Area.

- If the June 11, 2015 MOA is not implemented.

This concludes formal consultation on this action. As required in 50 CFR §402.16, reinitiation of consultation is required where discretionary Federal agency involvement or control over the action has been retained (or is authorized by law) and if: (1) the amount or extent of incidental take is exceeded; (2) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion; (3) the agency action is subsequently modified in a manner that causes an effect to the listed species or critical habitat not considered in this opinion; or (4) a new species is listed or critical habitat designated that may be affected by the action. In instances where the amount or extent of incidental take is met, any operation causing such take must cease pending reinitiation.

If you have questions regarding this Biological Opinion, please contact me at the letterhead address or by telephone at (808) 792-9400.

Sincerely,

Kristi Young
Acting Field Supervisor

Subject: Informal Consultation for the Joint Guam Program Office Relocation of the U.S. Marine Corps from Okinawa to Guam and Associated Activities on Guam

Dear Captain Campbell:

The U.S. Fish and Wildlife Service's (Service) received your letter on October 1, 2014, requesting our concurrence that the subject project may affect, but is not likely to adversely affect the federally endangered Mariana swiftlet (*Aerodramus bartschi*), the federally endangered hawksbill sea turtle (*Eretmochelys imbricata*) (hereafter referred to as the hawksbill turtle), and the federally threatened green sea turtle (*Chelonia mydas*) (hereafter referred to as the green turtle). Our analysis and finding in this consultation are based on your letter dated September 30, 2014, your Biological Assessment (BA) (DON 2014a), and other information available to us. This response is in accordance with section 7 of the Endangered Species Act of 1973 (ESA), as amended (16 U.S.C. 1531 *et seq.*). A complete administrative record is on file in our office.

Project Description

The Department of Navy (DON) proposes to relocate U.S. Marine Corps (USMC) personnel from Okinawa, Japan to Guam; construct and operate a main cantonment area, including family housing; and construct and operate a live-fire training range complex (LFTRC); and conduct training activities on Guam. Project activities will occur on land administered by the Department of Defense (DoD) and the Government of Guam (for road and bridge work). The proposed action includes the following components:

- Relocation of 5,000 USMC personnel and 1,300 dependents from Japan to Guam
- Construction of the main cantonment within 1,213 acres at Finegayan, Andersen Air Force Base (AAFB)
- Construction of housing within 510 acres at AAFB
- Utilities and site improvement activities within DON-administered lands
- Road and bridge development and/or improvement within DON-administered lands and Government of Guam lands
- Construction and operation the LFTRC at AAFB
- Establishment of a surface danger zone (SDZ) within Northwest Field (NWF), AAFB and the Guam National Wildlife Refuge (GNWR)
- Development and operation of a hand grenade range at Andersen South
- Air craft training activities within the Naval Base Guam's Naval Munitions Site (NMS) and adjacent areas

In addition, per an email correspondence from the DON (DON 2015b), the proposed project also includes surveying the water portion of the SDZ from three locations on the GNWR (Figure 1). The Range Safety Specialist (RSS) would access these locations using an ATV-type vehicle (*e.g*, 2 or 4 passenger Gator vehicle). The portion of the SDZ that cannot be observed by radar would be accessed by an existing dirt road and the RSS would park the vehicle along the road and walk into the locations depicted on Figure 1 to view the radar "blind spots". It is expected that the RSS would not need to walk the beach and would use a pair of binoculars to view the water portion of the SDZ from a static vantage point on the edge of the beach near the road. The RSS would drive out the same dirt road taken to access the locations. The above activity would take no more than 20 minutes.

A detailed project description is included in the BA (DON 2014a), the Draft SEIS (DON 2014b), addendum to the BA (DON 2015a), and the Biological Opinion for the subject project (USFWS 2015), and is hereby incorporated by reference into this informal consultation.

The conservation measures below are a subset of the conservation measures that are proposed in the BA (DON 2014a), addendum to the BA (DON 2015a), and via email correspondence between the DON and the Service. These conservation measures are intended to avoid and minimize effects to the Mariana swiftlet, green turtle, and hawksbill turtle. Any changes to, modifications of, or failure to implement these avoidance and minimization measures may result in a need to reinitiate this consultation.

Conservation Measures to Minimize the Effects of Construction

1. Contractor Education Program. The DON contractor education program ensures that construction contractor personnel are informed of the biological resources in the project area, including invasive species, special-status species, avoidance measures, and reporting requirements. This measure is intended to prevent inadvertent effects to terrestrial biological resources due to lack of awareness of resource presence, sensitivities, and protective measures. This measure will be implemented during pre-construction and construction.

2. Contractor Plans and Specifications. All construction will occur within the limits of construction shown in the plans and specifications. This measure is intended to prevent additional habitat loss. This measure will be implemented during pre-construction and construction.

3. Guam Landscaping Guidelines. Appropriate or non-invasive species will be planted in all new landscapes. This measure is intended to reduce potential effects associated with non-native vegetation, promote habitat for native species, reduce water consumption, and reduce the need for fertilizers. This measure will be implemented during construction.

4. LFTRC Range Berm Controls. LFTRC range berms will contain native or non-invasive herbaceous vegetation, and other engineering controls. This measure will help to manage stormwater runoff and control erosion, and the berm will minimize the number of bullets that may fall outside the range footprint. This measure will be implemented during construction.

5. Lighting Installation. Lighting will be designed to meet minimum safety, sustainability, antiterrorism, and force protection requirements. Hooded-lights will be used to the maximum extent practicable at all new roads and facilities within known sea turtle land habitat and fruit bat roost areas. Either hooded or "night-adapted" lights will be installed at the LFTRC. Illumination of forest, coastline, or beach will be consistent with range safety and security requirements and kept to an absolute minimum including the shielding of lights and directing lighting away from the forest or other wildlife habitat. This measure will be implemented during pre-construction, construction, and during operations.

6. Monitoring. The DON will be responsible for oversight of avoidance, minimization, and conservation measures implementation by the contractors for projects associated with the proposed action. The DON shall ensure that construction remains within the limits of construction and that sensitive resources are avoided, unless otherwise specified in the Project Description. This measure will be implemented during pre-construction, construction, and operations.

Conservation Measures to Minimize the Effects of Invasive Species

Regional Biosecurity Plan. To address invasive species pathways and encourage a more holistic approach to managing invasive species, the DON has funded the development of the Regional Biosecurity Plan (RBP) for Micronesia and Hawaii (formerly referred to as the Micronesia Biosecurity Plan). Individual activities for various species will continue, but the DON and others agree it is more efficient to manage pathways and prescribe corrective measures for a suite of species which will be monitored at discrete control points over time. The RBP will provide stakeholders in Micronesia and Hawaii with a platform for coordination and integration of inter-agency invasive species management efforts such as control, interdiction, eradication, and

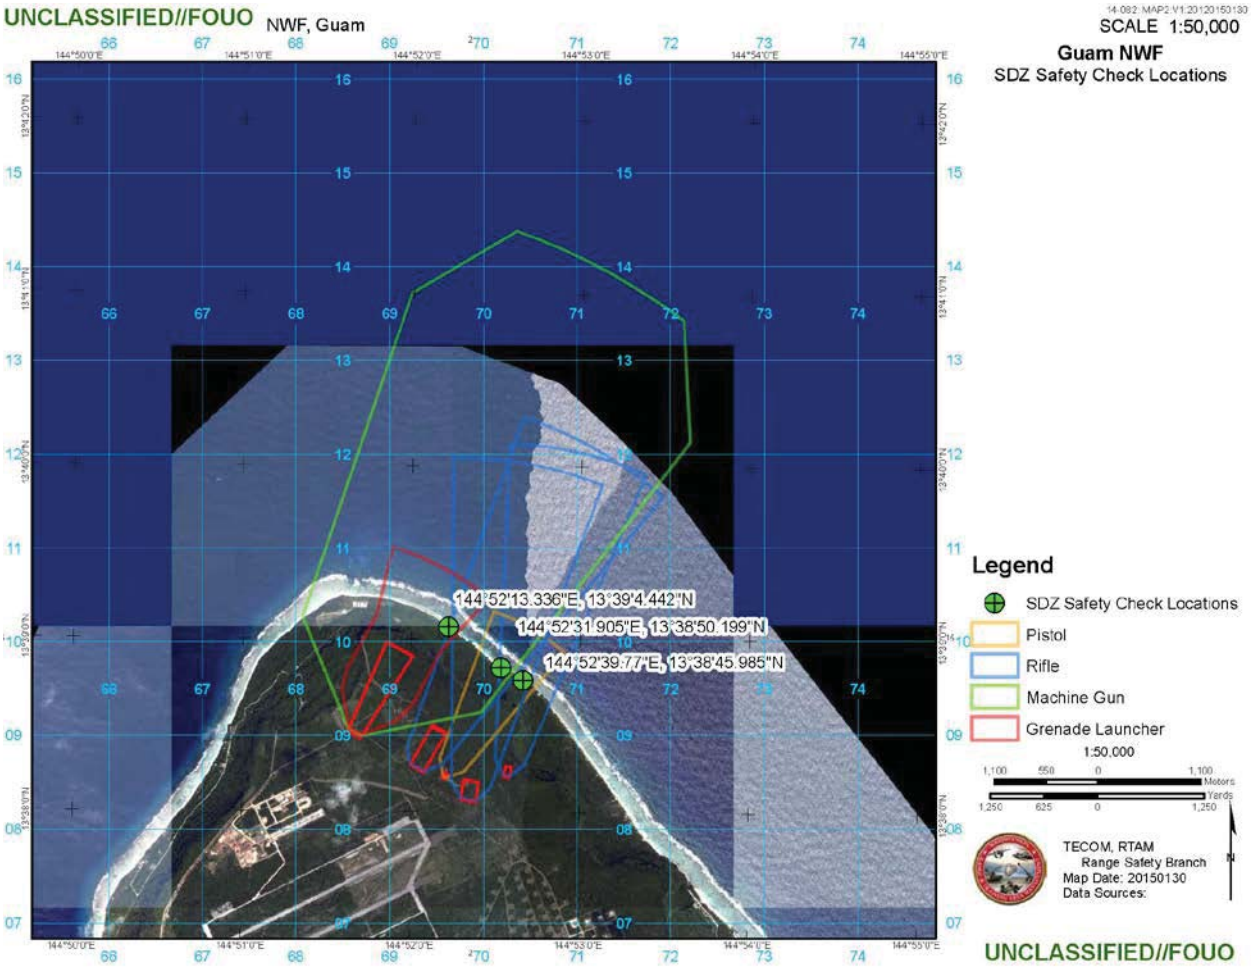

Figure 1. Safety check locations to view the radar "blind spots" of the SDZ, located on the Guam National Wildlife Refuge.

research. The final RBP was completed in 2015 (DON 2015b). Several of the recommendations are incorporated into the Project Description as BMPs:

1. Onsite vegetation waste management procedures. Green waste will be handled by the contractors at designated laydown areas within the limits of construction. Contractors will be required to divert all the green waste. The larger-sized green waste consisting of trees and stumps will be processed into mulch and the smaller sized green waste will be processed into compost. A proposed green waste processing facility at the NBG Landfill may also be used to process green waste generated during construction. The DoD will seek permit authorization from the Guam Environmental Protection Agency for the proposed green waste processing facility.

2. DON's Final Guam Landscaping Guidelines. The DON has developed a manual providing landscaping design guidelines specific to appropriate plant selection and

establishment for all the DON construction activities on Guam (DON 2011). This manual implements required DON policies including, but not limited to:

a. use of native regional plants for landscaping;
b. design, use, and promoting construction practices that minimize adverse effects on natural habitat;
c. pollution prevention by reducing fertilizer and pesticide use, integrated pest management practices, recycling green waste (composting), and minimizing runoff;
d. implementing efficient water practices; and
e. preventing the introduction of invasive species.

The above measure is intended to reduce potential effects associated with non-native vegetation, promote habitat for native species, reduce water consumption, and reduce the need for fertilizers.

3. Biosecurity outreach and education. The DON has initiated and will continue to implement a targeted, comprehensive outreach and education program for DoD and civilian populations for biosecurity focused on prevention. As a starting point, the DON contracted for the development of biosecurity outreach and education materials. The contractor has designed and produced an activity booklet, a two-sided, tri-fold, educational brochure with an associated poster that differentiates native from introduced species, defines invasive species, describes the known impacts of invasive species on native species and ecosystems, and what can be done to prevent and control invasive species. This effort also included the development of radio public service announcements (PSA) in three languages, and a television PSAs both of which aired for one month in September of 2013 during peak broadcasting times.

   The DON's biosecurity outreach and education program has already begun concurrent with the actions that were initiated under the 2010 Environmental Impact Statement's Record of Decision (DON 2010). The DON will develop additional informational videos, expand the radio PSAs broadcasts, and other print media as well as active public outreach concurrent with the arrival of the first major influx of USMC personnel in 2020 and continue for an additional 5 years.

4. Hazard Analysis Critical Control Point (HACCP) planning. HACCP planning is a pathway management tool that provides a comprehensive method to identify risks and focus procedures to prevent spread of species through pathways. Construction work could unintentionally spread non-target (potentially invasive) species. These non-targets could hitchhike on construction equipment or be included in shipments of materials and supplies from locations outside of Guam. The pathways used by invasive species to move into new locations are not always obvious. Many problematic species, diseases, and parasites have been transferred to new locations as undetected (and unplanned) hitchhikers. HACCP planning is a management tool that provides a structured method to identify risks and focus procedures. Understanding pathways and developing plans to reduce non-target species and prevent biological contamination is necessary to avoid unintended spread of species.

a. All construction contracts will contain a requirement to develop a HACCP Plan which will identify risks and potential pathways for non-native species and will outline procedures for controlling and removing risks identified. Construction contractors are required to provide documentation that supports prevention, worker awareness training, and control of non-native invasive and pest species in the project area and efforts to prevent the movement of non-native invasive species to areas outside the project area, whether in a purposeful or inadvertent manner. The contractor is responsible for ensuring that employees receive applicable environmental and occupational health and safety training and keep up to date on regulatory requirements for specific training for the type of work to be conducted onsite.

b. Construction contracts also will contain a requirement for inspections and proper re-use or disposal of vegetation to avoid contributing to the further spread of the coconut rhinoceros beetle (*Oryctes rhinoceros*). The construction contractors are to identify and implement control measures to prevent the inadvertent movement of non-native, invasive species to Guam and to and from the project site to other locations. The contractor is required to establish appropriate facilities that comply with all environmental laws and regulations, provide training for proper vehicle hygiene, and promptly take corrective and preventative actions for noncompliance. This includes vehicle washdown and inspection for soil and other materials and appropriate control measures are implemented to prevent the inadvertent movement of non-native invasive species from the project site to other locations.

c. All HACCP planning and implementation related to the proposed action will be the responsibility of the awarded project contractor(s) to ensure that proper control measures are used throughout the construction activities to prevent the inadvertent movement of invasive species from one location to the project site, and/or from the project site to other locations. It will be the responsibility of DON to review and concur with the development phase of the HACCP planning process to ensure proper compliance by these contractors.

d. HACCP plans will be approved and inspected by the DON.

5. Monitoring to evaluate effectiveness of HACCP

a. The DON shall provide training, review, and technical guidance on HACCP plan development, implementation, and revision during the construction phase of the buildup on Guam. The HACCP planning covers Guam-related rapid response actions. The DON contracted a baseline ecosystem monitoring study for projects on AAFB in 2011. Transects were focused on areas where newly introduced species were most likely to occur. The intent of the project was to establish a baseline of both native and non native plants present prior to the beginning of planned construction activities. This baseline will serve as a reference for

subsequent monitoring efforts conducted concurrently with construction in order to aid in evaluating the success of implemented HACCP plans. The baseline will also provide a basis of comparison for relative abundances of invasive species during construction, as well as whether any species detected during long-term monitoring are newly introduced or were present prior to the beginning of construction. The AAFB project was completed in December 2012.

b. The DON will develop an early detection and rapid response component for when an incipient invasive species is discovered in the proposed action area.

6. Brown treesnake interdiction

a. JRM has established a comprehensive brown treesnake (*Boiga irregularis*) interdiction program to ensure that military activities, including the transport of civilian and military personnel and equipment to and from Guam, do not contribute to the spread of brown treesnake to other islands or regions. Brown treesnake interdiction requirements are specified in DoD instructions (i.e., 36 Wing Instruction 32-7004, Brown Tree Snake Control Plan and COMNAVMAR Instruction 5090.10A, Brown Tree Snake Control and Interdiction Plan). The proposed project will continue to comply with these established procedures.

b. The DON will fund any increase of current federally-funded brown treesnake interdiction measures (in Guam, CNMI, and Hawaii) where the increase is related to direct, indirect and induced growth caused by the USMC relocation to Guam. The fiscal year 2010 level of funding for the Federal interagency brown treesnake interdiction effort on Guam, CNMI, and Hawaii and 2010 transportation levels associated with outbound cargo from Guam for the U.S. or U.S. territories will be used as the baseline. Any increase in funding will continue and become part of the DON's brown treesnake interdiction funding under authority of the Brown Tree Snake Control and Eradication Act (7 USC § 8501 note) (USFWS 2010a). The Department of Interior agrees that it is not DON’s responsibility to fund increased interdiction measures *that are identified* more than one year after the end of the fiscal year both USMC relocation construction has ended and the permanent non-transient USMC military units have relocated to Guam. For the purposes of this consultation, interdiction is defined as: “to hinder, prohibit, or prevent the brown treesnake from becoming established in new locations by conducting inspection and suppression processes.”

c. Rapid Response – Brown treesnake management, research, and coordination efforts have been refined and progressed to the point where U.S. Department of Agriculture-Animal and Plant Health Inspection Service, Wildlife Services inspection rates for cargo and flights departing Guam are almost 100 percent (BTS TWG 2015).

d. Coordination with the U.S Geological Survey (USGS) regarding the Brown Treesnake Research Closed Population Facility at NWF (located adjacent to the

LFTRC and SDZ) – The DON will ensure through briefings or information packages that the personnel using the LFTRC know the importance of the facility and maintaining the integrity of the fence. An SOP will be developed as part of the Range Management Plan for the LFTRC to ensure the above and that USGS will be immediately notified in the event that the fence is accidentally damaged so the fence can be quickly repaired.

Conservation Measures to Minimize the Effects of Training to Mariana Swiftlets

1. Aviation Training in NMS. All aviation training will be conducted so that flights will approach the southern portion of the NMS over the Talofofo River watershed and Fena Reservoir at heights of 1,000 ft (305 m) or greater above ground level. Flights may go up the Ugum River at altitudes of 1,000 ft (305 m) or greater above ground level until they reach 9,843 ft (3,000 m) from the mouth of the river at Highway 4 and then flights may conduct low level terrain flights. Low-level training flights will be restricted to the southernmost portion of the NMS where Mariana swiftlets are not commonly present. This measure is intended to avoid and minimize effects to swiftlets, and will be implemented during operations.

2. Ground Training in NMS. The DON will maintain 328-ft (100-m) no training buffers around the known Mariana swiftlet nesting caves (*e.g.*, Mahlac Cave, Fachi Cave, Maemong Cave) in NMS. This measure is intended to avoid and minimize effects to Mariana swiftlets, and will be implemented during operations.

Conservation Measures to Minimize the Effects of Increased Human Presence at Nesting Sea Turtle Beaches

1. Sea Turtle Public Outreach and Coordination. The DON, in cooperation with the Guam Department of Aquatic and Wildlife Resources (DAWR), has undertaken an educational program to inform military and civilian personnel about sea turtle nesting and the potential impacts to the species from nest disturbance, direct harassment of sea turtles, beach disturbance, and other threats. The DON has developed and distributed sea turtle conservation posters, tri-fold brochures and activity booklets for elementary school children. These educational materials have been distributed to local dive shops on Guam, and will continue to be used and refined throughout the construction period of the proposed USMC relocation. As part of the Range Safety Specialist (RSS) training package, personnel would be directed to not interact with sea turtles and report all sightings to the Service and coordinate with the GNWR on nesting surveys at the Refuge.

Action Area

The term "action area" is defined in the implementing regulations for section 7 at 50 CFR 402.02 as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action."

The action area for this consultation is the island of Guam (Figure 2). The specific areas likely to be affected, directly or indirectly, by the proposed action are discussed in detail in the BA. In addition to what is detailed in the BA, the following effects from the action may be Guam-wide: 1) effects from introduction of invasive species by the proposed action could spread throughout the whole island of Guam and 2) the population increase resulting from the proposed action will cause additional human disturbance throughout the island, including at recreation sites, hunting areas, traffic along roads, etc.

Status of the Species

Mariana swiftlet

Listing status - The Mariana swiftlet was federally listed as endangered on August 27, 1984 (USFWS 1984). A five-year status review was completed in 2010 (USFWS 2010b) and a recovery plan for the Mariana swiftlet was completed in 1991 (USFWS 1991). No critical habitat rules have been published for this species.

Species description - The Mariana swiftlet (*Aerodramus bartschi*) was formerly considered a subspecies of the widespread Vanikoro swiftlet (*A. vanikorensis*), but genetic studies support that it is a distinct species (Thomassen et al. 2005, p. 274). It is a small swift with dark, gray-brown plumage on the upper parts, a slightly paler rump, and paler underparts, and the plumage of both sexes is alike. Weights of 21 birds averaged 7.4 grams (range = 6.4 to 9.0 grams). Other measurements include: wing, average of 107.6 mm and 108 mm; tail, average of 52.3 mm; exposed culmen, average of 4.0 mm; tarsus, average of 10.4 mm, and wingspan, maximum of 233 mm (USFWS 1991, p. 1; https://ecos.fws.gov, *accessed* 9 April 2015). It is the only resident swift in the Mariana Islands, and could potentially be confused with migratory swallows, or the fork-tailed swift (*Apus pacificus*), a rare vagrant (USFWS 1991, p. 1).

Life history - Mariana swiftlets are aerial insectivores that nest in limestone caves and can echolocate (USFWS 1991, p. 2; Reichel et al. 2007, p. 686 and references therein; Valdez et al. 2011, p. 301). They forage over a wide variety of habitats, including cleared and forested areas, but favor ridge crests and open grassy savannas (USFWS 1991, p. 6). Large flocks have been reported to form in the evening, with birds feeding close to the ground until it is dark (Chantler and Driessens 1995, p. 130).

Mariana swiftlets produce a single egg which is incubated for approximately 23 days (range 17-30 days), and chicks fledge after approximately 47 days (range 40-55 days; Reichel et al. 2007, p. 686). Eggs are laid in cup-shaped nests made of moss and saliva attached to cave walls or ceilings. Assessment of guano on Saipan indicate Hymenoptera, especially flying ants (*Formicidae*), were the most common insect prey followed by Coleoptera (Kershner et al. n.d.).

Analysis of guano from swiftlets on Aguiguan showed that their diet consisted primarily of Hymenoptera, with a small percentage of Hemiptera (Valdez et al. 2011, p. 301).

Status and distribution - The Mariana swiftlet is endemic to Guam, Rota, Aguiguan, Tinian, and Saipan, but has declined on all islands and is extirpated from Rota and Tinian (Cruz et al. 2008, p. 233; Valdez et al. 2011, p. 301 and references therein; USFWS 1991, p. 7-14). Based on the most recent data available in our files, the current range-wide population estimate for Mariana swiftlets is approximately 1,493 swiftlets on Guam (DON 2014a, p. 8), over 6,100 swiftlets on Saipan (CNMI DFW 2011, p. 36), and approximately 400 swiftlets on Aguiguan (Cruz et al. 2008, p. 240) for a total of approximately 7,993 swiftlets. In addition, a small population was introduced and currently persists on Oahu, Hawaii (Wiles and Woodside 1999, p. 57, as noted in Valdez et al. 2011, p. 301).

Threats - The causes for the decline of Mariana swiftlets are mostly unknown, but human disturbance, predation, pesticides, and disease have been hypothesized as having a role (USFWS 1991, p. 18-22). Swiftlets have been documented to flush, or fail to enter their caves when humans are near or within their caves (Wiles and Woodside 1999, pp. 57, 61). Swiftlet sensitivity to human presence has resulted in injuries to chicks and adults, and could result in damage to eggs (Wiles and Woodside 1999, p. 61). Sources of human disturbance have included Japanese soldiers during World War II, guano mining, hunters, hikers, and vandalism.

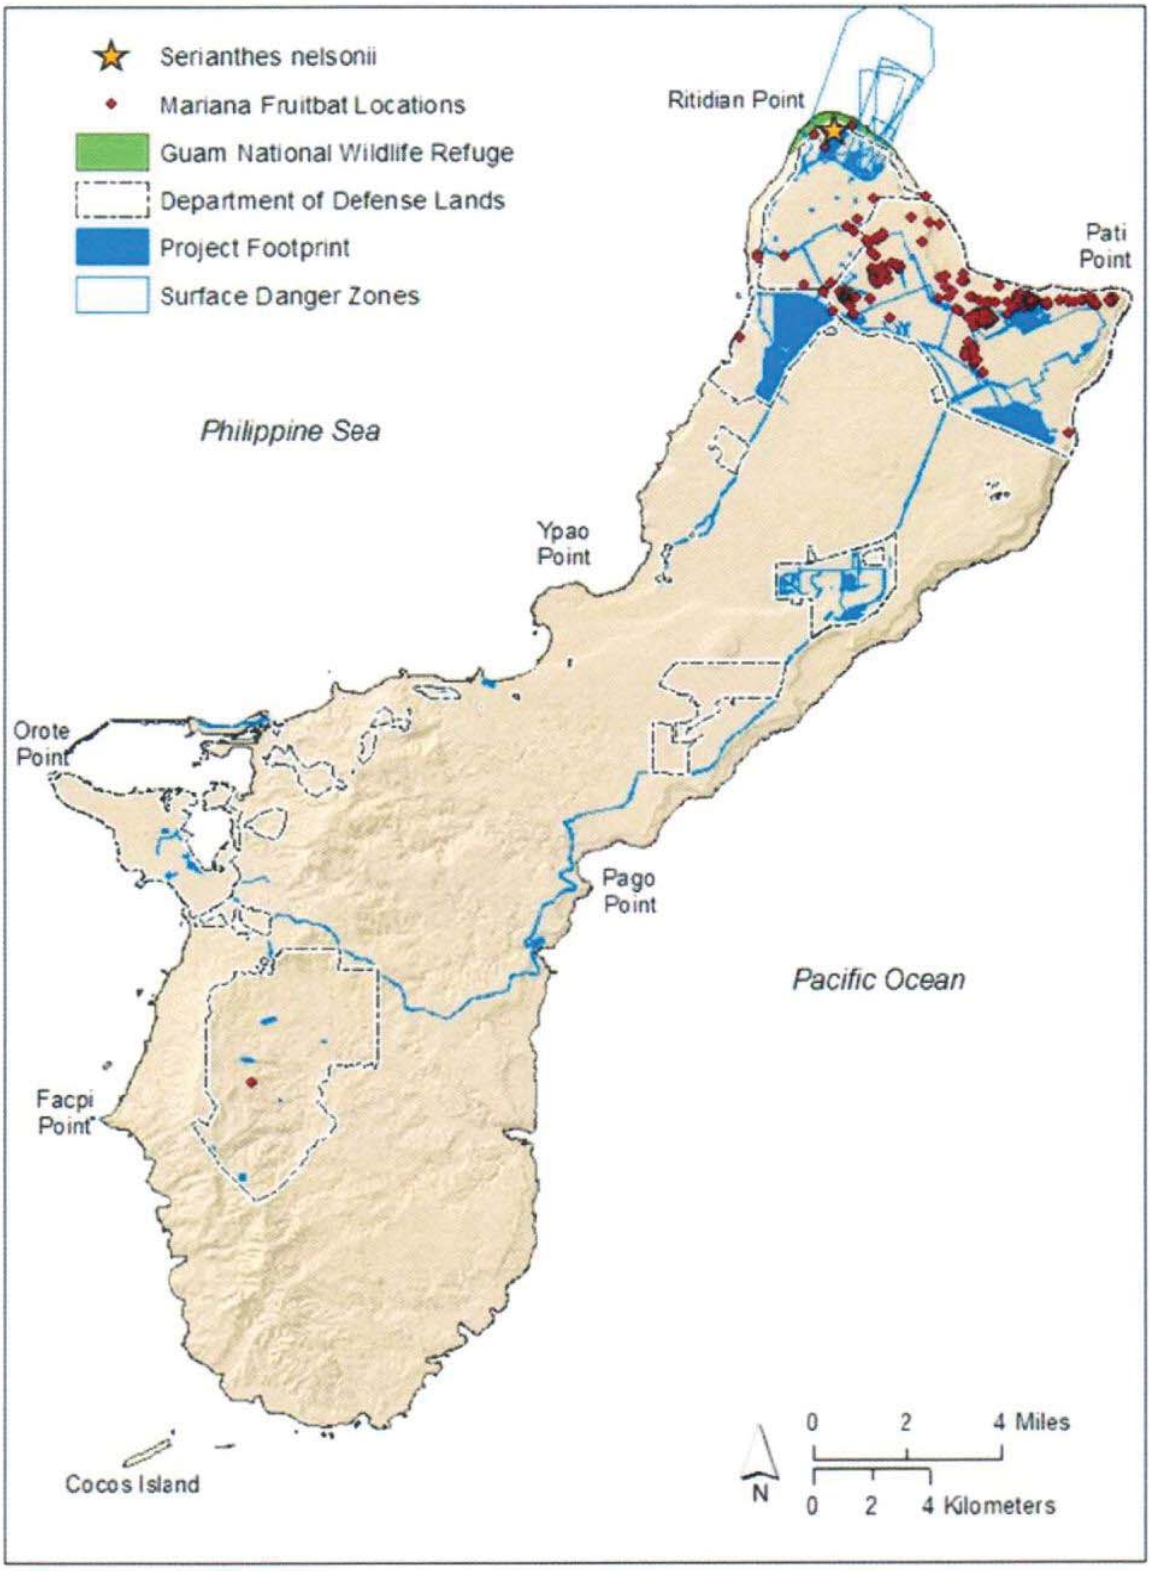

Figure 2. Action Area.

Brown treesnake predation on swiftlets is considered to be a regular event, and there are recent observations of brown treesnake predation on swiftlets in Mahlac cave on Guam (DON 2012). The use of pesticides such as DDT has been suspected of causing the decline of swiftlet populations on Guam (Diamond 1984, p. 452), but the concentrations of pesticide residues found in swiftlet guano have not supported this hypothesis (Grue 1985, p. 301). On Saipan, non-native cockroaches are known to destroy swiftlet nests by consuming the saliva that holds the nests to the walls or ceilings (Cruz et al. 2008, p. 242). Savidge et al. (1992, p. 206) investigated the role of disease in the decline of birds on Guam and determined that there is no evidence that it has played a significant role. The typhoons that frequently occur in the area may cause periodic declines in swiftlet populations, but are not expected to threaten the species as a whole since the species has survived numerous such events during its evolutionary history (USFWS 1991, p. 22).

Green sea turtle

Listing status - The green turtle is listed as endangered in Florida and on the Pacific coast of Mexico, and as threatened throughout the rest of its range (NMFS and USFWS 1978). The National Marines Fisheries Service (NMFS) and Service have recently proposed to relist the green turtle based on 11 different distinct population segments (DPS's). The new proposal, if finalized, will uplist their status, along with the rest of the Central West Pacific DPS, to endangered. This DPS includes the Mariana Islands, southern Japanese Islands, the Marshall Islands, the islands of Belau, and parts of Melanesia (NMFS and USFWS 2015, p. 15311). The entire DPS is estimated to have approximately 6,500 nesting females (NMFS and USFWS 2015, p. 15311). Persistent threats to this DPS include continued poaching and development of nesting beaches in addition to ongoing detrimental changes to marine habitats both from in-water and upland sources (NMFS and USFWS 2015, p. 15313). These threats continue to hinder their recovery when compared to other DPS's analyzed in the listing proposal, and therefore, is one of the three DPS's – of 11 proposed worldwide – that is proposed for uplisting to endangered. There is no critical habitat within coastal water or on nesting beaches in the Mariana Islands, although critical habitat for the green turtle occurs within coastal waters in portions of its range (NMFS 1998).

Species description - The green turtle grows to a maximum size of 4 ft (1.2 m) in carapace (upper shell) length and 440 lbs (200 kg) in body mass (https://ecos.fws.gov, *accessed* 5 June 2015). It has a heart-shaped shell, small head, and single-clawed flippers (NMFS and USFWS 1998a, p. 7). Hatchlings generally have a black carapace, white plastron, and white margins on the shell and limbs. The adult carapace is smooth, keelless, and light to dark brown with dark mottling; the plastron is whitish to light yellow. Adult heads are light brown with yellow markings. Identifying characteristics include four pairs of costal scutes, none of which borders the nuchal scute, and only one pair of prefrontal scales between the eyes (NMFS and USFWS 1998a, p. 8; https://ecos.fws.gov, *accessed* 5 June 2015).

Life history - Most green turtles spend the majority of their lives in coastal foraging grounds, and rely on marine algae and seagrass for their diet. Green turtles use nesting beaches that are characterized by intact dune structures, native vegetation, little to no artificial lighting, and beach temperatures between 26 and 35 degrees Celsius (NMFS and USFWS 2015, p. 15275, and references within). All species of sea turtles have high site fidelity to their hatching (natal)

beaches, returning close to their own hatching site to lay their nests, usually nesting multiple times over a nesting season.

The green turtle nesting season varies with locality. A female can lay multiple clutches within a nesting season at about 10 to 15-day intervals. Clutch size varies but can consist of about 100 eggs each. Hatchlings generally emerge at night and dig upward in a communal effort and take 2 to 3 days before reaching the surface. Newly emerged hatchlings are strongly photopositive and can be disoriented away from their path to the sea by artificial lighting (NMFS and USFWS 1998a, p. 18).

Status and distribution - Green turtles have a circumglobal distribution, occurring throughout tropical, subtropical, and to a lesser extent, temperate waters. Their movements within the marine habitat are not fully understood, but they are known to inhabit coastal waters of over 140 countries, and nest at 468 known sites worldwide (NMFS and USFWS 2015, p. 15275).

The NMFS and Service completed a five-year status review in 2007 (NMFS and USFWS 2007). An estimated 108,761 to 150,521 females nest each year among sampled nesting sites throughout its range. Among 23 sides for which data enables an assessment of the threatened population, 10 nesting populations are increasing, 9 are stable, and 4 are decreasing. Long-term continuous data sets (greater than 20 years) are available for 9 sites, all of which are either increasing or stable (NMFS and USFWS 2007, p. 14).

Threats - The causes for the decline of green turtle numbers are similar to the hawksbill turtles (refer to *Threats to Sea Turtles - Nesting Environment* below)

Hawksbill sea turtle

Listing status - The hawksbill turtle was federally listed as endangered throughout its range. Critical habitat was designated in nesting beach areas and marine areas in 1982 and 1998, respectively (USFWS 1992, NMFS 1998). Recovery plans for populations of the hawksbill turtle were completed in 1993 and 1998 (NMFS and USFWS 1993, 1998b).

Species description - The hawksbill turtle is one of seven species of sea turtles found throughout the world. One of the smaller sea turtles, it has overlapping scutes (plates) that are thicker than those of other sea turtles. This protects them from being battered against sharp coral and rocks during storm events. Adults range in size from 30 to 36 inches (0.8-1.0 m) carapace length, and weigh 100 to 200 lbs (45-90 kg). Its carapace (upper shell) is dark brown with faint yellow streaks and blotches and a yellow plastron (under shell). The name "hawksbill" refers to the turtle's prominent hooked beak (website https://ecos.fws.gov, *accessed* 15 June 2015).

Life history - Hawksbill turtle movement within the marine environment is not fully understood. Adult hawksbill turtles were once considered to be relatively non-migratory, but are now thought to use a mixed migration strategy. Studies have revealed that some turtles remain close to their rockery and others are highly mobile, traveling hundreds to thousands of kilometers between nesting and foraging areas (NMFS and USFWS 2013, p. 11 and references therein).

Hawksbill turtles typically feed in the vicinity of rock or reef habitat in shallow tropical waters with little turbidity (Witzell 1983). Throughout their range, hawksbill turtles feed on sponges but their primary diet differs depending on the region occupied. For example, in the northeastern Australia Great Barrier Reef, the primary food item was algae (72.2 percent) followed by sponges, soft corals, invertebrate species (total 23 percent), and inorganic material (5.4 percent) (Bell 2012).

Female hawksbill turtles exhibit strong fidelity of their choice of nesting sites and can lay multiple clutches at approximately two-week intervals within one nesting season (Witzell 1983). Female hawksbill turtles usually select a nest site within the cover of woody vegetation, although some will use grass or open sand if the preferred cover is not accessible (NMFS and USFWS 1998b, p. 17). There is much variation in clutch size from site to site (Witzell 1983). Maragos (1991) estimated 130 eggs per clutch for Palauan hawksbill turtles, and in eastern Caribean clutch size is closer to 150 eggs per clutch (Corliss et al. 1989).

Status and distribution - Hawksbill turtles are circumtropical in distribution, generally occurring from 30 degrees north to 30 degrees south latitude within the Atlantic, Pacific, and Indian Oceans and associated bodies of water (NMFS and USFWS 1998b). They prefer nearshore areas where they can forage on their preferred diet of marine sponges. Like green turtles, they rely on nesting beaches that have little to no artificial lighting. Hawksbill turtles usually select a nest site within the cover of woody vegetation, although they will nest occasionally in grass or open sand (NMFS and USFWS 1998b, p. 17).

The NMFS and Service completed a five-year status review in 2013 (NMFS and USFWS 2013). An estimated 22,004 to 29,035 hawksbill turtles nest each year among 88 sites within nesting beach in the Atlantic, Indian, and Pacific regions. Among the 63 sites for which historic trends could be assessed, all 63 (100 percent) showed a decline during the long-term period of greater than 20 to 100 years. Among the 41 sites for which recent trend data are available, NMFS and Service determined that 10 (24 percent) were increasing, 3 (7 percent) stable, and 28 (68 percent) were decreasing (NMFS and USFWS 2013, p. 24).

Threats to Sea Turtles – Nesting Environment

Green and hawksbill turtles, both historically common in tropical nearshore waters, have been significantly reduced over the past few centuries due to a variety of factors. The significant reduction in numbers of green turtles due to development of coastal areas for industry and tourism, meat and egg harvest in different parts of the world, and accidental catch in other fishery industries led to the listing of this species (NMFS and USFWS 1978, 32803-32807). While hawksbill turtles share many of the same threats, their numbers also declined because their shells were widely used for ornamental and practical uses (NMFS and Service 1998b, p. 4). Today, harvest continues to be a major threat in the Pacific islands, but development of historical nesting beaches also has drastically reduced populations of both sea turtles in the Pacific (NMFS and USFWS 2015, p. 15311). Threats to the green turtles on nesting grounds, as outlined in their recovery plan (NMFS and Service 1998a), are representative of those also faced by hawksbill turtles (NMFS and Service 1998b). Storm events, including typhoons, may destroy nests because of flooding or piling of eroded sand on the nest site. Beach erosion due to wave action

may decrease the availability of suitable nesting habitats and result in a decline in the nesting rate. A number of non-native and native predators dig into nests and prey upon incubating eggs, while some predators, including birds, may take hatchlings just prior to or during their emergence from nests.

Human crowding of nesting beaches can disturb nesting females and prevent laying of eggs. Flashlight use, beach fires, and artificial lighting on human structures may deter females from coming up onto a beach or may disorient hatchlings as they emerge from nests and try to find the sea (Witherington and Martin 1996, pp. 4-5). Emerging hatchlings may respond to the effects of artificial lighting by causing hatchlings to move in the wrong direction (*misorientation*) and/or interfere with their overall ability to orient (*disorientation*), which causes hatchlings to move in circles attempting to orient in the correct direction. Both behaviors can result in hatchling mortality through exhaustion, dehydration, predation, and other causes (Mann 1977, p. 54; Witherington and Martin 1996, pp. 4-5).

Human presence on nesting beaches also may lead to an increase in the presence of domestic pets (which can depredate nests) and litter (which may attract wild predators). Humans may inadvertently trample nests through recreational beach activities and increase sand compaction, which may damage nests or hatchlings. Bonfires also may damage strand vegetation and alter behavior by nesting females who are sensitive to smells such as smoke. Humans may introduce exotic vegetation in conjunction with beach development that can overrun nesting habitat or make the substrate unsuitable for digging nest cavities. Construction on or in the vicinity of sea turtle nesting beaches can result in sand compaction, beach erosion, and increase in direct and ambient light pollution. The rate of habitat loss because of erosion and escarpment may be increased when humans attempt to stabilize the shoreline, either through re-nourishment or through placement of hard structures, such as sea walls or pilings. Off-road vehicle traffic also contributes to habitat loss through erosion, especially during high tides or on narrow beaches where driving is often concentrated on the high beach and fore dune.

One of the most substantial threats to nesting sea turtles in the Pacific islands remains the illegal poaching of adults and eggs (NMFS and Service 1998a, NMFS and Service 2015, p. 15313). The direct harvest of adult nesting females can increase the rate of local extinction. Harvesting of eggs reduces the chance that recruitment will replace the reduced breeding population.

Environmental Baseline

Status of the species within the action area-Mariana swiftlet
A nest/roost cave on Ritidian Point was previously used by Mariana swiftlets, but this cave was abandoned by the late 1970s (USFWS 1991, p. 9). The reason for the abandonment is unknown, but is likely related to human disturbance or predation, since negative effects from pesticides and disease are not supported by available data (USFWS 1991, p. 18-22; Grue 1985, p. 301; Savidge 1986, p. 9). The Mariana swiftlet currently occurs in three known caves on Guam within the Naval Munitions Site (Mahlac, Maemong, and Fachi; DON 2012, p. 8) (Figure 3). Monthly counts at the three caves fluctuate, but approximately 90 percent of the swiftlet population on Guam is thought to nest/roost within the Mahlac cave (DON 2012, p. 8). In 2014, the average number of swiftlets was 1203 ± 120 at Mahlac, 226 ± 38 at Maemong, and 64 ± 61 at Fachi

(DON 2014, p. 1). The estimate of the Guam population was 1,150 birds in 2008 (Grimm 2008, p. 1), and by 2014 the estimate was 1493 ± 171 (DON 2014, p. 8).

In 2012 surveys for Mariana swiftlets were conducted in an area within the Naval Munitions Site (NMS) and a Private Lands Site (PLS) as part of the biological inventory for the Guam SEIS (DON 2013). The NMS study area is located in the northwestern portion of the NMS in the Santa Rita municipality of Guam. The PLS is located southeast of the NMS in the Talofofo municipality of Guam. No swiftlets were observed during surveys at the NMS, despite the survey stations being 1.3-2.8 mi (2.1- 4.5 km) from three known occupied swiftlet nesting caves (DON 2013, p. 17). Numerous detections of foraging swiftlets were documented during surveys within the PLS. Swiftlet observations within the PLS were 1.6- 3.1 mi (2.6- 5 km) from the three known occupied caves in the northeastern portion of the NMS (DON 2013, p. 12-15).

Status of the species within the action area-green sea turtle

Green turtles are regularly recorded in the waters around Guam (NMFS and USFWS 1998a, p. 12; Eldredge 2003, p. 653). No published estimates exist for the number of sea turtles that inhabit Guam. However, approximately 1,000 to 2,000 green turtles inhabit island reef areas in the southern island of the CNMI (Kolinski et al. 2004, pp. 98, 111). Aerial counts of all sea turtles are regularly performed twice monthly by DAWR by circumnavigating Guam's shoreline. The highest single-day count from the last two years of available data (2010-2011) was 92 turtles (DAWR, unpublished data), and DAWR staff estimate that the highest one-day counts are close to the total population of resident sea turtles (both green and hawksbill) in Guam's nearshore waters (B. Tibbatts, DAWR, pers. comm. 2015).

Although many historical nesting beaches in Guam are no longer suitable for sea turtle nesting due to onshore development and other persistent threats, green turtles continue to nest on multiple Guam beaches. A higher numbers of nests have been recorded in Guam between the months of February and July, but this correlates strongly to the number of surveys performed each month (Bonham 2014, p. 13). Therefore, green turtles can potentially nest during any month on Guam's beaches, and a peak nesting season is yet to be defined. Based on green turtle nesting data collected between 1975-2013 on Guam, about 92 total eggs were present in excavated nests that were analyzed (Bonham 2014, p. 16). Hatchling success was 87 percent and emergence success was 86 percent (Bonham 2014, p. 16). Since more frequent systematic monitoring began on the GNWR beaches in 2013, 17 green turtle nests were recorded during 2013, 4 in 2014, and 18 in 2015, as of May (GNWR 2014a, pp. 1-3; GNWR 2014b, p. 4; J. Cruce, USFWS, pers. comm. 2015). The approximately 5-km stretch of beaches at GNWR, most of which falls within the proposed SDZ, is one of the most active sea turtle nesting sites in Guam. Several crawls were recorded at Haputo Beach in 2008, and this beach has historical records of nesting (NBG 2012, p. 3).

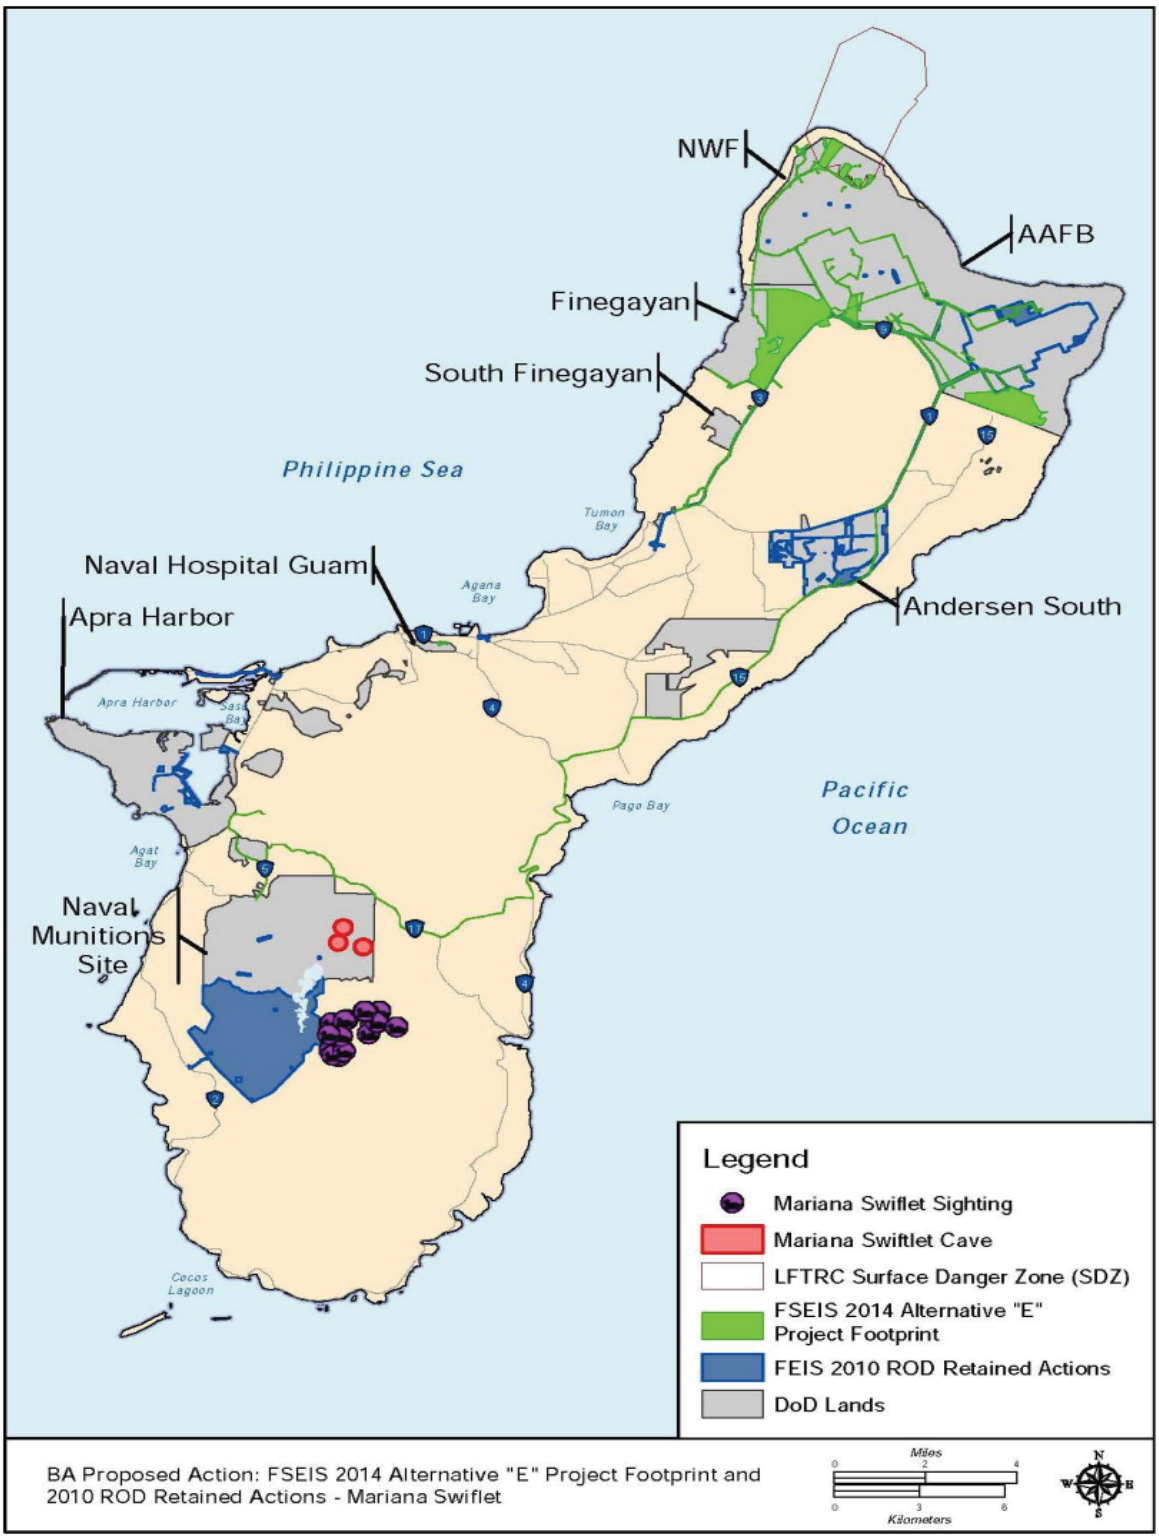

Figure 3. Mariana swiftlet locations and project footprint (DON 2014b).

Status of the species within the action area-hawksbill turtles

Hawksbill turtles are frequently sighted in the near-shore waters surrounding Guam (Grimm and Farley 2008, p. 1), although not as frequently as green turtles. Nesting data compiled by DAWR since 1975 included 15 recorded hawksbill nests in Guam. Between 1991 and 1994, hawksbill turtles nested in Sumay Marina, Guam, during varying months including October, December, February, and March (S. Wusstig, DAWR, pers. comm. 2009). The most recent documented hawksbill turtle nest was in 2009 (Bonham 2014, p. 15). Although not documented in recent years, it is possible that hawksbill sea turtles could nest at Ritidian or other historical nesting beaches on DoD property, Haputo, Double Reef, Tarague, Spanish Steps, or Dadi, if favorable nesting conditions are maintained there.

Effects of the Action

Mariana swiftlet

On Guam, all three of the caves currently occupied by Mariana swiftlets are located within the Naval Base Guam's NMS, and none of the project's ground activities will occur within or near the swiftlet caves located at the NMS. However, new aviation training flight paths are proposed over the Talofofo River watershed, the primary foraging area for swiftlets on Guam, and over the NMS area. Flights may also occur over the Ugum River watershed that supports swiftlet foraging near the mouth of the river. Foraging by most members of the swift family is likely limited to 328 ft (100 m) above the tree canopy because of the reduction in insect prey above that level (Chantler and Driessens 1995, p. 20). Tree canopy height plus 328 ft (100 m) is expected to be well below 1,000 ft (305 m) above ground level, thereby reducing risk of bird/wildlife aircraft strike hazard, but noise generated by the aircraft may still affect swiftlet foraging behavior, as has been documented in other species (refer to General Effects section of the Biological Opinion, USFWS 2015).

Mariana swiftlets on Guam are known to forage within 3.1 miles (5 km) of their nest/roost caves (DON 2013, p. 12), but it is not known if they will forage further away from nest/roost caves as this has not been examined for this species. The proposed LFTRC is over 20 miles (32 km) away from the known occupied swiftlet caves. However, there is a cave on Ritidian Point that was previously used by swiftlets and abandoned in the 1970's (USFWS 1991, p. 9). In addition, suitable foraging habitat is also present at Ritidian Point and seasonal insect blooms could attract swiftlets to Ritidian Point. Live fire within the LFTRC could preclude reoccupation of the Ritidian cave by swiftlets due to noise disturbance; however, we do not currently have enough information on swiftlet behavior to know if this would occur.

As stated above, conservation measures included in the project description that will avoid and minimize effects to Mariana swiftlets include:

1. The DoD will maintain 328-ft (100-m) no training buffers around the known Mariana swiftlet nesting caves (e.g., Mahlac Cave, Fachi Cave, Maemong Cave) in the Naval Munitions Site.
2. To avoid noise impacts and bird/wildlife aircraft strike hazard risks, all aviation training will be conducted such that flights approach the southern portion of the Naval Munitions

Site over the Talofofo River watershed and Fena Reservoir at heights of 1,000 ft (305 m) or greater above ground level. Flights may go up the Ugum River at altitudes of 1,000 ft (305 m) or greater above ground level until they reach 9,843 ft (3,000 m) from the mouth of the river at Highway 4 and then low-level terrain flights may begin. Otherwise, low-level training flights (DON 2010, p. 54) will be restricted to the southernmost portion of the Naval Munitions Site (DON 2010, p. 35) where swiftlets are not commonly present.

Adverse effects to Mariana swiftlets that nest and shelter in the caves are not expected. If construction noise, noise from aircraft overflights, or noise from the LFTRC disturbs foraging swiftlets, they would likely avoid the disturbance and forage elsewhere. There have been no reports of aircraft striking Mariana swiftlets on Guam. Conservation measures included in the project description, such as invasive species control and habitat restoration, may benefit the Mariana swiftlet. Overall, effects from the proposed action to the Mariana swiftlet are expected to be discountable.

Green and hawksbill sea turtles

The proposed action would result in the increase of recreational use at nesting beaches, increase in light pollution at nesting beaches, create noise disturbance from the operation of the LFTRC, and potentially hinder data collection by biologists on nesting beaches because of limited access to nesting beaches at the GNWR. To minimize impacts to sea turtles from recreational beach users, DON proposes to continue an education and outreach program about sea turtles and to use hooded lights to the maximum extent practicable. Educational outreach described in the proposed action is comprised of creating posters, brochures, and elementary school booklets that are distributed to local dive shops. Tarague Beach on AAFB and the Spanish Steps beach on NBG continue to have multiple sea turtle nests recorded annually, and nesting is possible at a number of other beaches on DOD property. These nesting beaches are open to personnel with access and are expected to experience an increase in recreational activities as a result of personnel moving to Guam through the proposed action. Educating beach users can minimize harmful activities associated with increased recreation like artificial lights or fires at night or bringing pets to nesting beaches. As mentioned above, darkness is important on nesting beaches as artificial lights can interfere with the ability of hatchlings to orient themselves. The use of hooded lights to the maximum extent practicable will help minimize artificial lighting and maintain conditions suitable for nesting on beaches. DON is also proposing to implement biosecurity measures and the development of a HACCP as best practice measures, which will minimize the likelihood of spreading invasive species that can harm nests and hatchlings such as biting ants and plants that are can root quickly and penetrate nests.

Although the SDZ will be monitored from observation towers, ground patrols would also be conducted on the nesting beach prior to the operations of the LFTRC, which will operate daily up to 39 weeks per year. As part of the RSS training package, personnel would be directed to not interact with sea turtles and report all sightings to the Service and coordinate with the GNWR on surveys at the Refuge (see Conservation Measures). The limited amount of time spent on beach edge closest to the road for the survey of the water portion of the SDZ, combined with implementing RSS training for sea turtles and coordination with the GNWR on presence of

nesting sea turtles at Refuge will minimize the likelihood of disturbance to nesting sea turtles and hatchlings by RSS personnel.

Currently, GNWR staff survey beaches at least weekly. Monitoring needs to be at least this frequent to facilitate nest excavations and to track important biological information on nesting sea turtles. Frequent monitoring is also important because evidence of crawls and nests weather away as time passes. Therefore, it is crucial that regular monitoring is coordinated between RSS and GNWR staff. As mentioned above, a "nesting season" is still largely speculative on Guam, and continued frequent monitoring can help researchers and managers determine these temporal patterns with more certainty. Further, this information will enable conservation and management by being able to accurately track the status of nesting females in the region, be able to detect declines, and respond with appropriate management actions. The operation of the LFTRC may limit regular access to beaches within the SDZ for up to 39 weeks a year. However, because GNWR will be coordinating scheduling of nesting surveys with the RSS, monitoring should be able to still occur with some regularity.

Nesting sea turtles may be exposed to noise disturbance from the operation of the LFTRC. The beach areas at GNWR may receive peak noise levels from the LFTRC of up to about 100 dB and average day-night level values between 65-74 dB (USFWS 2015). It is difficult to predict how this noise would affect nesting behavior. Sea turtles have ears that are well adapted to perceiving in-water noise, but they are poor receptors of aerial sounds (Hetherington 2008, p. 197). For aerial sounds, green turtles can only detect a limited frequency range (200-700 Hz), with best sensitivity at the low tone region of about 300-400 Hz (Ridgeway et al. 1969, p. 888). Large-caliber guns, like the ones proposed for use in the LFTRC tend to give off low-frequency sounds (16-100Hz) while small-caliber weapons can range between 150-2,500 Hz (Ylikoski et al. 1995, p. 3). Several studies have investigated behavioral responses of sea turtles when exposed to underwater noises such as airguns. In one study, green and loggerhead turtles (*Caretta caretta*) grew agitated when exposed to seismic airgun noise exceeding 166 dB at 1m (McCauley et al. 2000, p. 699), and sea turtles observed in the wild near airguns behaved in a startled way, usually by rapidly diving (DeRuiter and Doukara 2010, p. 1726). Based on the available literature, there are no data that indicates that proposed noise levels and frequency range of the weapons at LFTRC would have adverse effects on nesting sea turtles. Although turtles would be exposed to noise disturbance from the LFTRC, it is unlikely that sea turtles will be deterred from nesting on the beaches at the GNWR.

Because of the conservation measures detailed in the project description, including the use of hooded lights, an educational outreach program, and frequent monitoring, adverse effects to green and hawksbill sea turtles that nest on the beaches in the action area are not expected. Therefore, the effects from the proposed action to green and hawksbill turtles are expected to be discountable.

Conclusion

Based on the above information, including the proposed conservation measures, and our analysis, we concur with your determination that the proposed project may affect, but is not likely to adversely affect the Mariana swiftlet, green turtle, and hawksbill turtle. Unless the project description changes or new information reveals that the effects of the proposed action may affect listed species in a manner or to an extent not considered, or a new species or critical habitat is designated that may be affected by the proposed action, no further action pursuant to section 7 of the ESA is necessary.

Although conservation recommendations are not typically included in informal consultations, we ask that you consider the following measures to further prevent disturbance to nesting females, their nests, and emerging hatchlings on beaches.

Conservation Recommendations

- Avoid the use of artificial lighting at or near nesting turtle beaches. However, if lighting is used, use of hooded lights near or on nesting turtle beaches should be a requirement.
- Personnel should refrain from smoking while on nesting beaches to prevent deterring nesting females, as they can be sensitive to scent (J. Cruce, USFWS, pers. comm. 2015).
- If personnel encounter a nesting sea turtle or hatchlings, every possible measure will be taken to leave them alone. Personnel should keep at least a 5-meter distance from any individual turtle onshore, and any lights should be directed away and turned off.
- Personnel should keep beaches free from litter and debri, which can tangle nesting females and impede hatchlings.

We appreciate your efforts to protect listed species. If you have questions regarding this consultation or questions concerning the Mariana swiftlet, please contact Fish and Wildlife Biologist, Leilani Takano (phone: 671-989-6745). If you have questions regarding nesting sea turtles, please contact Ann Marie Gawel, Fish and Wildlife Biologist (phone: 671-989-6746).

Sincerely,

Kristi Young
Acting Field Supervisor

Q. APPENDIX B – MEMORANDUM OF AGREEMENT BETWEEN THE DEPARTMENT OF THE NAVY AND THE U.S. FISH AND WILDLIFE SERVICE REGARDING CONSERVATION OF GUAM MICRONESIAN KINGFISHER RECOVERY HABITAT IN NORTHERN GUAM

MEMORANDUM OF AGREEMENT

Between

THE DEPARTMENT OF THE NAVY
And
THE U.S. FISH AND WILDLIFE SERVICE

Regarding

CONSERVATION OF GUAM MICRONESIAN KINGFISHER RECOVERY HABITAT
In
NORTHERN GUAM

I. PARTIES

This Memorandum of Agreement (MOA) is entered into by and between the Department of the Navy (DON) and the U.S. Fish and Wildlife Service (USFWS), hereinafter referred to as "the Parties."

II. PURPOSE AND SCOPE

A. The purpose of this MOA is to ensure that:

1. A sufficient amount of suitable survival and recovery habitat (hereinafter "habitat") is conserved and managed in accordance with federal agency obligations under section 7(a) of the Endangered Species Act, 16 U.S.C. § 1536(a) in northern Guam to support the reintroduction and recovery of the Guam Micronesian kingfisher (hereinafter "kingfisher"); and

2. The DON can meet the purpose and need for the proposed action to relocate U.S. Marines to Guam (hereinafter "Guam Military Relocation") in accordance with its responsibilities under Title 10 of the U.S.C.

B. The provisions of this MOA will inform the Parties' respective present and future mitigation actions and decisions under section 7(a) of the Endangered Species Act (16 U.S.C. § 1531 et seq.), including those mitigation actions and decisions under subsection 7(a)(2) currently pending regarding the DON's proposed relocation of U.S. Marines to Guam as discussed in paragraph.IV.E below.

III. AUTHORITY

A. Section 7(a) of the Endangered Species Act (ESA), 16 U.S.C. § 1536(a)

B. Section 101 of the Sikes Act, 16 U.S.C. § 670a (as amended)

C. Title 10 U.S.C. § 5063

D. This MOA neither modifies existing agency authorities nor reduces, expands, or transfers any of the respective statutory or regulatory authorities and responsibilities of the Parties.

IV. BACKGROUND

A. Private and public development on Guam has reduced the amount of potentially available habitat for the kingfisher to a point where it has created uncertainty regarding whether there will be a sufficient amount habitat preserved for the future reintroduction and ultimate recovery of the kingfisher on Guam which supports the entire native range of the species.

B. The endangered kingfisher is currently extirpated on Guam. The USFWS has depicted "survival and recovery habitat" for the kingfisher on Guam in Figure 1 (hereinafter "kingfisher habitat"). The Parties agree that conservation of habitat of sufficient quality and quantity to support the reintroduction and ultimate recovery of the endangered kingfisher is needed on Guam.

C. The Parties have a responsibility under the ESA to conserve and protect endangered species.

D. The USFWS currently estimates that approximately 11,512 acres of habitat for the kingfisher is needed across all of northern Guam to support its survival and recovery in the wild. The USFWS has identified approximately 14,997 acres of potential kingfisher habitat in northern Guam, of which approximately 10,742 acres are located on lands currently under the custody and control of the Department of Defense (DoD) (Figure 1). The USFWS estimates that 8,178 acres of these 10,742 acres need to be conserved in northern Guam to provide reasonable certainty that sufficient habitat for the species will remain available for reintroduction and recovery of the kingfisher. The Parties further agree that lands in northern Guam not currently under the custody and control of DoD are also required to support the reintroduction and ultimate survival of the kingfisher in the wild.

E. The DON is proposing to relocate approximately 5,000 Marines as part of the Guam Military Relocation. This proposal is central to the U.S. Government's rebalancing of forces in the Pacific. The purpose and need for the proposed action is to ensure that the relocated Marines are organized, trained, and equipped as mandated in section 5063 of Title 10 of the U.S.C., to satisfy individual live-fire training requirements, and to establish an operational U.S. Marine Corps (USMC) presence in Guam in

accordance with April 2012 adjustments to the May 2006 United States-Japan Roadmap for Realignment Implementation.

F. The Guam Military Relocation would result in the clearing of approximately 1,015 acres of kingfisher habitat in northern Guam on lands currently under the custody and control of DoD. In addition, the USFWS estimates that an additional 319 acres will be indirectly impacted by the proposed action thereby resulting in a total impact to kingfisher habitat of approximately 1,334 acres in northern Guam.

V. GENERAL PROVISIONS

A. The USFWS has determined that approximately 8,178 total acres are required on lands currently under the custody and control of DoD in northern Guam to provide sufficient habitat for the reintroduction and eventual recovery of the kingfisher (Figure 2). To facilitate kingfisher conservation goals, the DON agrees to designate approximately 5,234 acres under the custody and control of the DoD in northern Guam as identified on Figure 3, to a status that will provide durable habitat protection needed to support native habitat restoration and land management for the survival and recovery of the kingfisher. These 5,234 acres have been identified by the USFWS as habitat for the kingfisher and needed to offset impacts of the Guam Military Relocation. The Parties recognize that the designation of the 5,234 acres under this paragraph may also provide a conservation benefit to other Federally-listed species with similar habitat requirements (e.g. Mariana crow, Mariana fruit bat).

B. Consistent with the Joint Region Marianas (JRM) Integrated Natural Resources Management Plan (INRMP) developed in accordance with section 101 of the Sikes Act, the DON agrees to actively restore native habitat and manage, in collaboration with the USFWS, the 5,234 acres identified in Figure 3 consistent with DoD's obligations under the 7(a) of the ESA and the Sikes Act to benefit the survival and recovery of the kingfisher. The DON will work cooperatively with the USFWS to identify, develop and implement specific management activities and projects on these 5,234 acres to support the following: 1) brown treesnake (BTS) control and suppression to facilitate the larger goal of suppressing snake population levels that will ultimately support kingfisher survival and recovery; 2) support for BTS control and eradication methods development, focusing on tools and techniques needed for landscape level survival and recovery of the kingfisher, 3) ungulate fencing and eradication; 4) control of small mammalian predators; 5) invasive plant control and eradication; 6) native plant restoration; and, 7) localized control of introduced invertebrates that may negatively impact kingfisher nesting/fledging. The DON has funded and initiated a number of projects to support the seven focal activities identified above. The DON agrees to continue these activities with items (2) and (3) prioritized for continued funding.

C. The JRM INRMP will be completed by DON within 365 days of signing of the MOA. This timeline is contingent upon the USFWS providing its specific concerns with the 2013 draft INRMP to the DON within 45 days of the signing of this MOA. Any delay by the USFWS in providing comments to the DON will result in a corresponding

extension of this 365-day time period. In accordance with the Sikes Act, the DON will coordinate with the USFWS on specific INRMP projects and goals. Such coordination will include, but is not limited to, the annual INRMP review.

D. Recognizing the importance of DoD's mission in northern Guam, within 120 days of the signing of the Record of Decision (ROD) for the Guam Military Relocation, the DON may, in collaboration with the USFWS, identify an alternative configuration for the 5,234 acres of habitat identified in Figure 3 as necessary to enable the DoD to meet its national defense requirements. While the DON anticipates that the 5,234 acres identified in Figure 3 will enable DoD to meet its requirements, DoD must conduct a thorough assessment to ensure current and future military requirements are appropriately considered. The revised map (acreage) must total at least 5,234 acres and be derived from areas identified in Figure 2 and provide contiguous landscape and connected forested habitat corridors. If an alternative configuration is not defined within 120 days of the signing of the ROD, the Parties agree to default to the acreage identified in Figure 3.

E. DON will provide durable habitat protection for the 5,234 acres identified in Figure 3 or as modified in subparagraph V.D. However, should an emerging national defense requirement dictate that some of the aforementioned 5,234 acres be cleared or otherwise made unsuitable for kingfisher survival and recovery, in coordination with the USFWS, the DON will identify and substitute habitat of equal or greater quality, as determined by the USFWS, to replace the impacted habitat. If habitat of equal or greater quality cannot be identified, then additional acreage suitable for kingfisher survival and recovery will be placed in durable protection to offset the loss of higher quality habitat. The amount of habitat will be determined based on the kingfisher mitigation framework developed using the best available information at that time. The Parties recognize that any substituted habitat must provide contiguous landscape and connected forest habitat corridors. The DON commits to rigorously exploring other alternatives to support an emerging national defense requirement and will only use lands within the 5,234 acres to meet the requirement if absolutely necessary.

F. For the land identified on Figure 3 (or as amended via the process described in subparagraph V.D of this MOA), the USFWS requires enhanced management activity to ensure this habitat supports reintroduction of the kingfisher. Accordingly, starting in Fiscal Year (FY) 2016, the DON commits to provide an additional $2 million per year of funding above execution year INRMP funding levels (as adjusted for inflation) for the next ten years, subject to Congressional authorization and appropriation. This additional funding will be used to support projects that fall within one of the seven focal activities identified under subparagraph V.B of this MOA, according to priorities established jointly by DON and the USFWS. Upon expiration of this ten-year period (FY 2026), the Parties mutually agree to reassess progress of recovery efforts. If, following this assessment, the USFWS determines that it remains possible to recover the kingfisher on Guam, the DON commits to extend the additional $2 million per year in funding for another five years. Subsequently, the Parties will reassess the progress of recovery efforts every five years. So long as the USFWS determines that it remains

possible to recover the kingfisher on Guam, and until the kingfisher is delisted, every five years the DON and USFWS will identify activities and a schedule of implementation that the USFWS determines are sufficient to conserve and enhance the habitat needed to support the survival and recovery of the kingfisher on these 5,234 acres. The DON will implement these activities, dedicating $2 million annually in accordance with the JRM INRMP. The Parties recognize that the level of funding may vary depending on the activities to be implemented in a given year, but will not exceed $2 million annually. The Parties may also subsequently modify, as necessary, the focal activities identified in subparagraph V.B of this MOA to be implemented on the 5,234 acres.

G. If the provisions of subparagraphs V.A to F of this MOA are not implemented as described herein, barring mutual agreement by the Parties, the Guam Military Relocation section 7 ESA consultation will require re-initiation. In addition, nothing in this MOA is intended to affect the responsibility of the USFWS and DON to re-initiate consultations pursuant to 50 CFR § 402.16, or the re-initiation regulation then applicable.

H. If new scientific information indicates the amount or extent of habitat needed for the survival and recovery of the kingfisher is different than identified herein, as determined by the USFWS, the Parties will revise this MOA in accordance with paragraph VI of this MOA.

I. The DON will maintain management authority on kingfisher habitat on Guam under the custody and control of DoD unless DoD transfers management authority to another military service, in which case the responsibilities under this MOA that apply to DON shall transfer to the military service that assumes land management authority.

J. In accordance with established security procedures to grant access to military facilities, USFWS staff shall be provided reasonable access to kingfisher habitat identified on lands under the custody and control of the DoD. DON commits to working with the USFWS to help streamline the security approval process.

VI. MODIFICATIONS, INTERPRETATIONS, ENFORCEABILITY AND TERMINATION

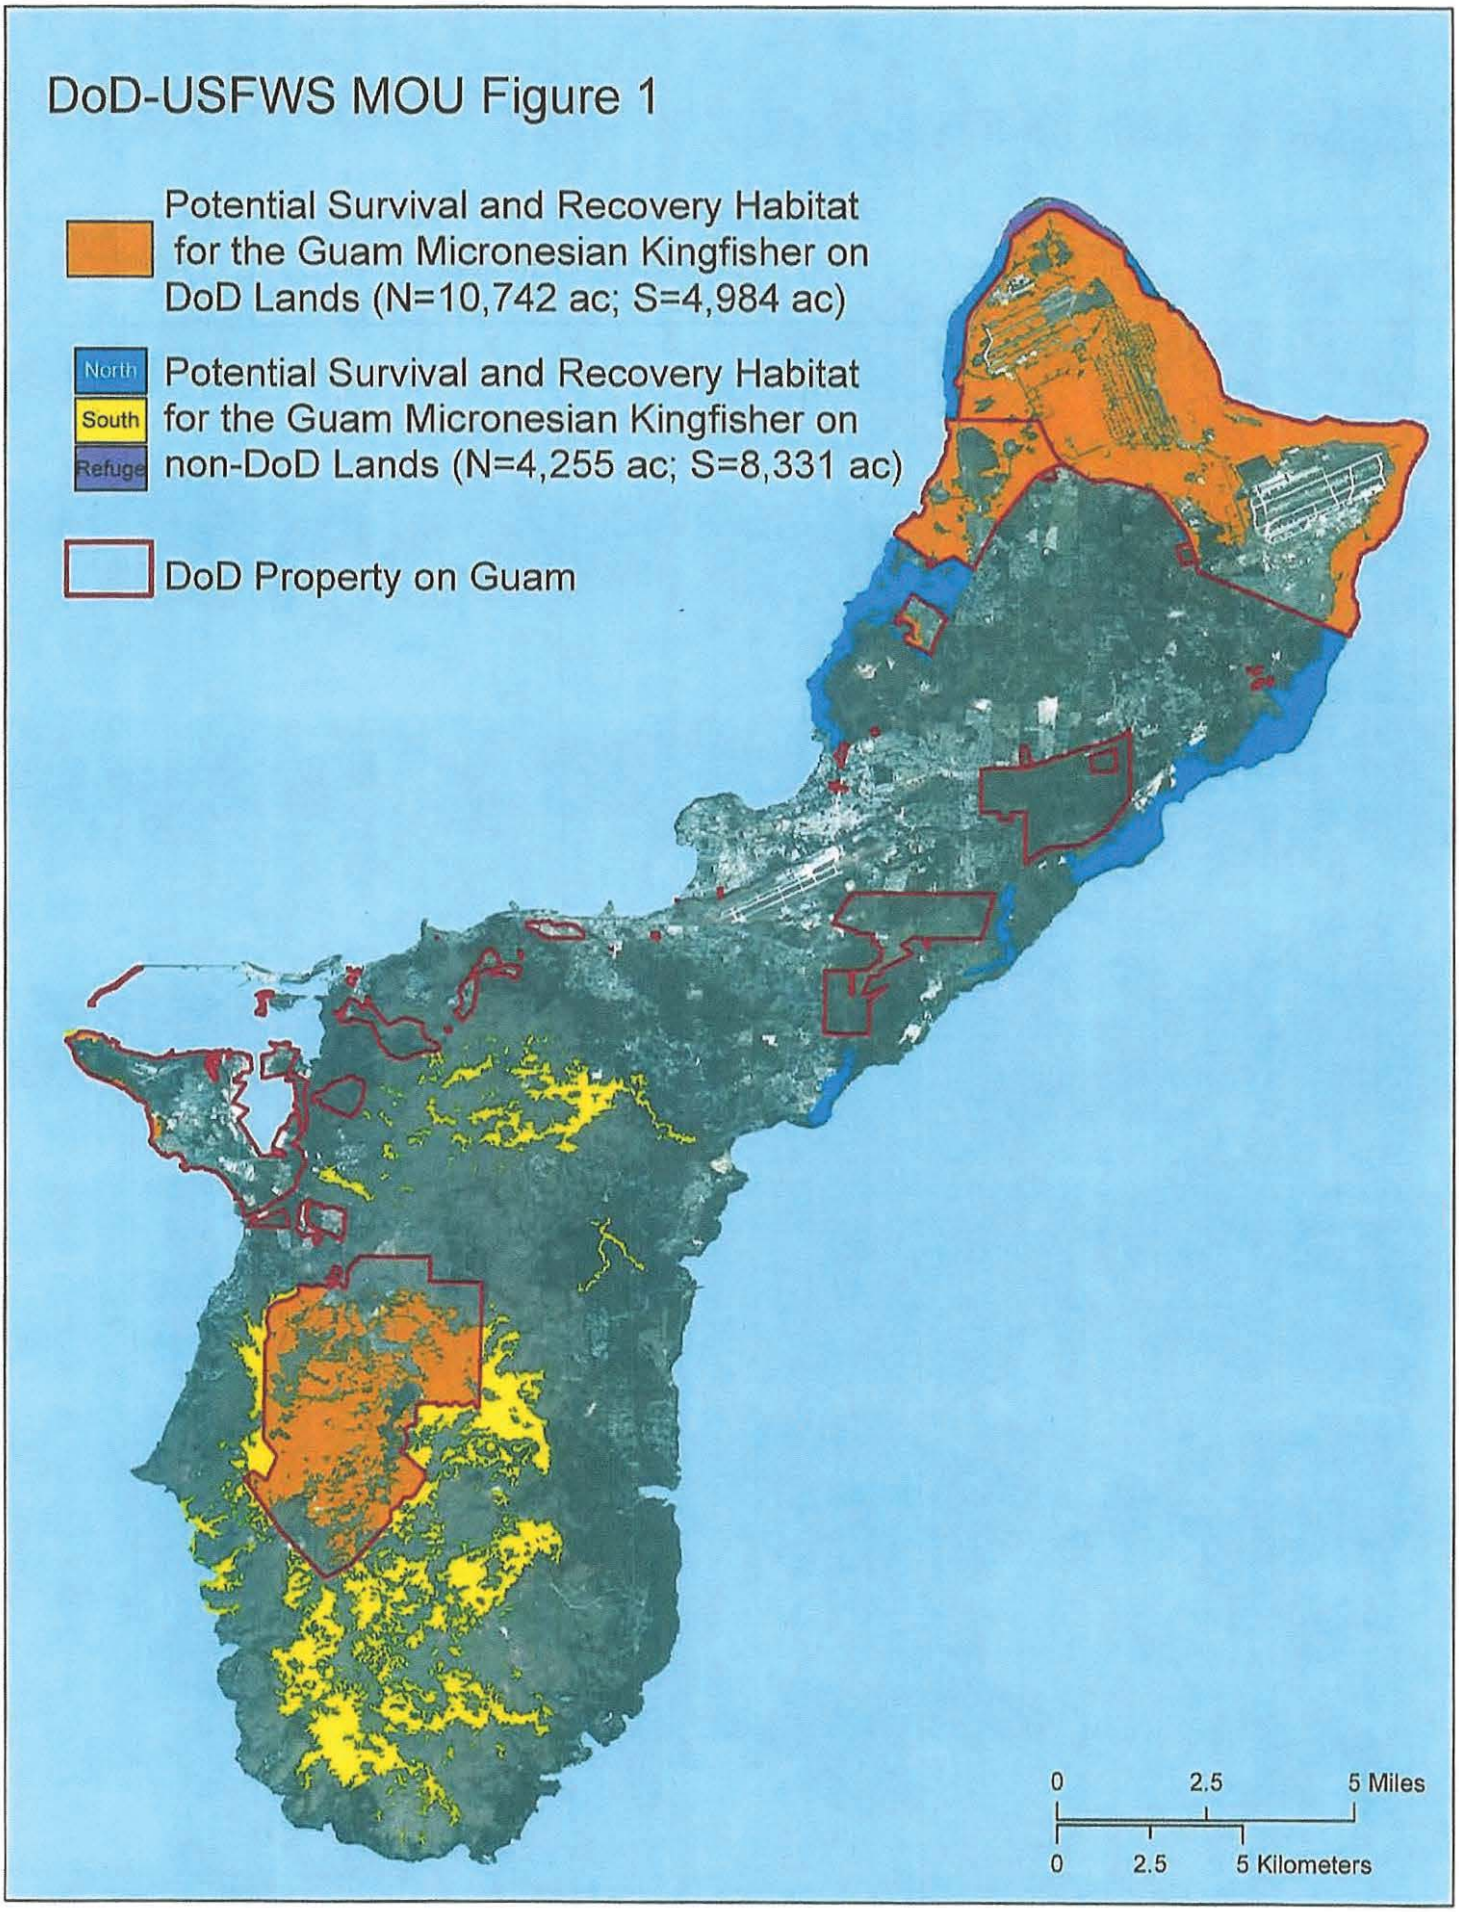
A. Changes and/or modifications to this MOA may be made at any time upon mutual written consent of the Parties. With regard to both Parties, no oral statement by any person and no written statement by anyone other than the undersigned, or an authorized representative as designated in writing, shall be interpreted as modifying or otherwise affecting the terms of this MOA.

B. This MOA shall be deemed null and void in its entirety if any one of the following events occurs: 1) Both Parties revoke the agreement in writing; 2) the DON does not sign a ROD with the currently identified preferred alternative in the Final Biological Assessment regarding the DON's proposed Guam Military Relocation as discussed in

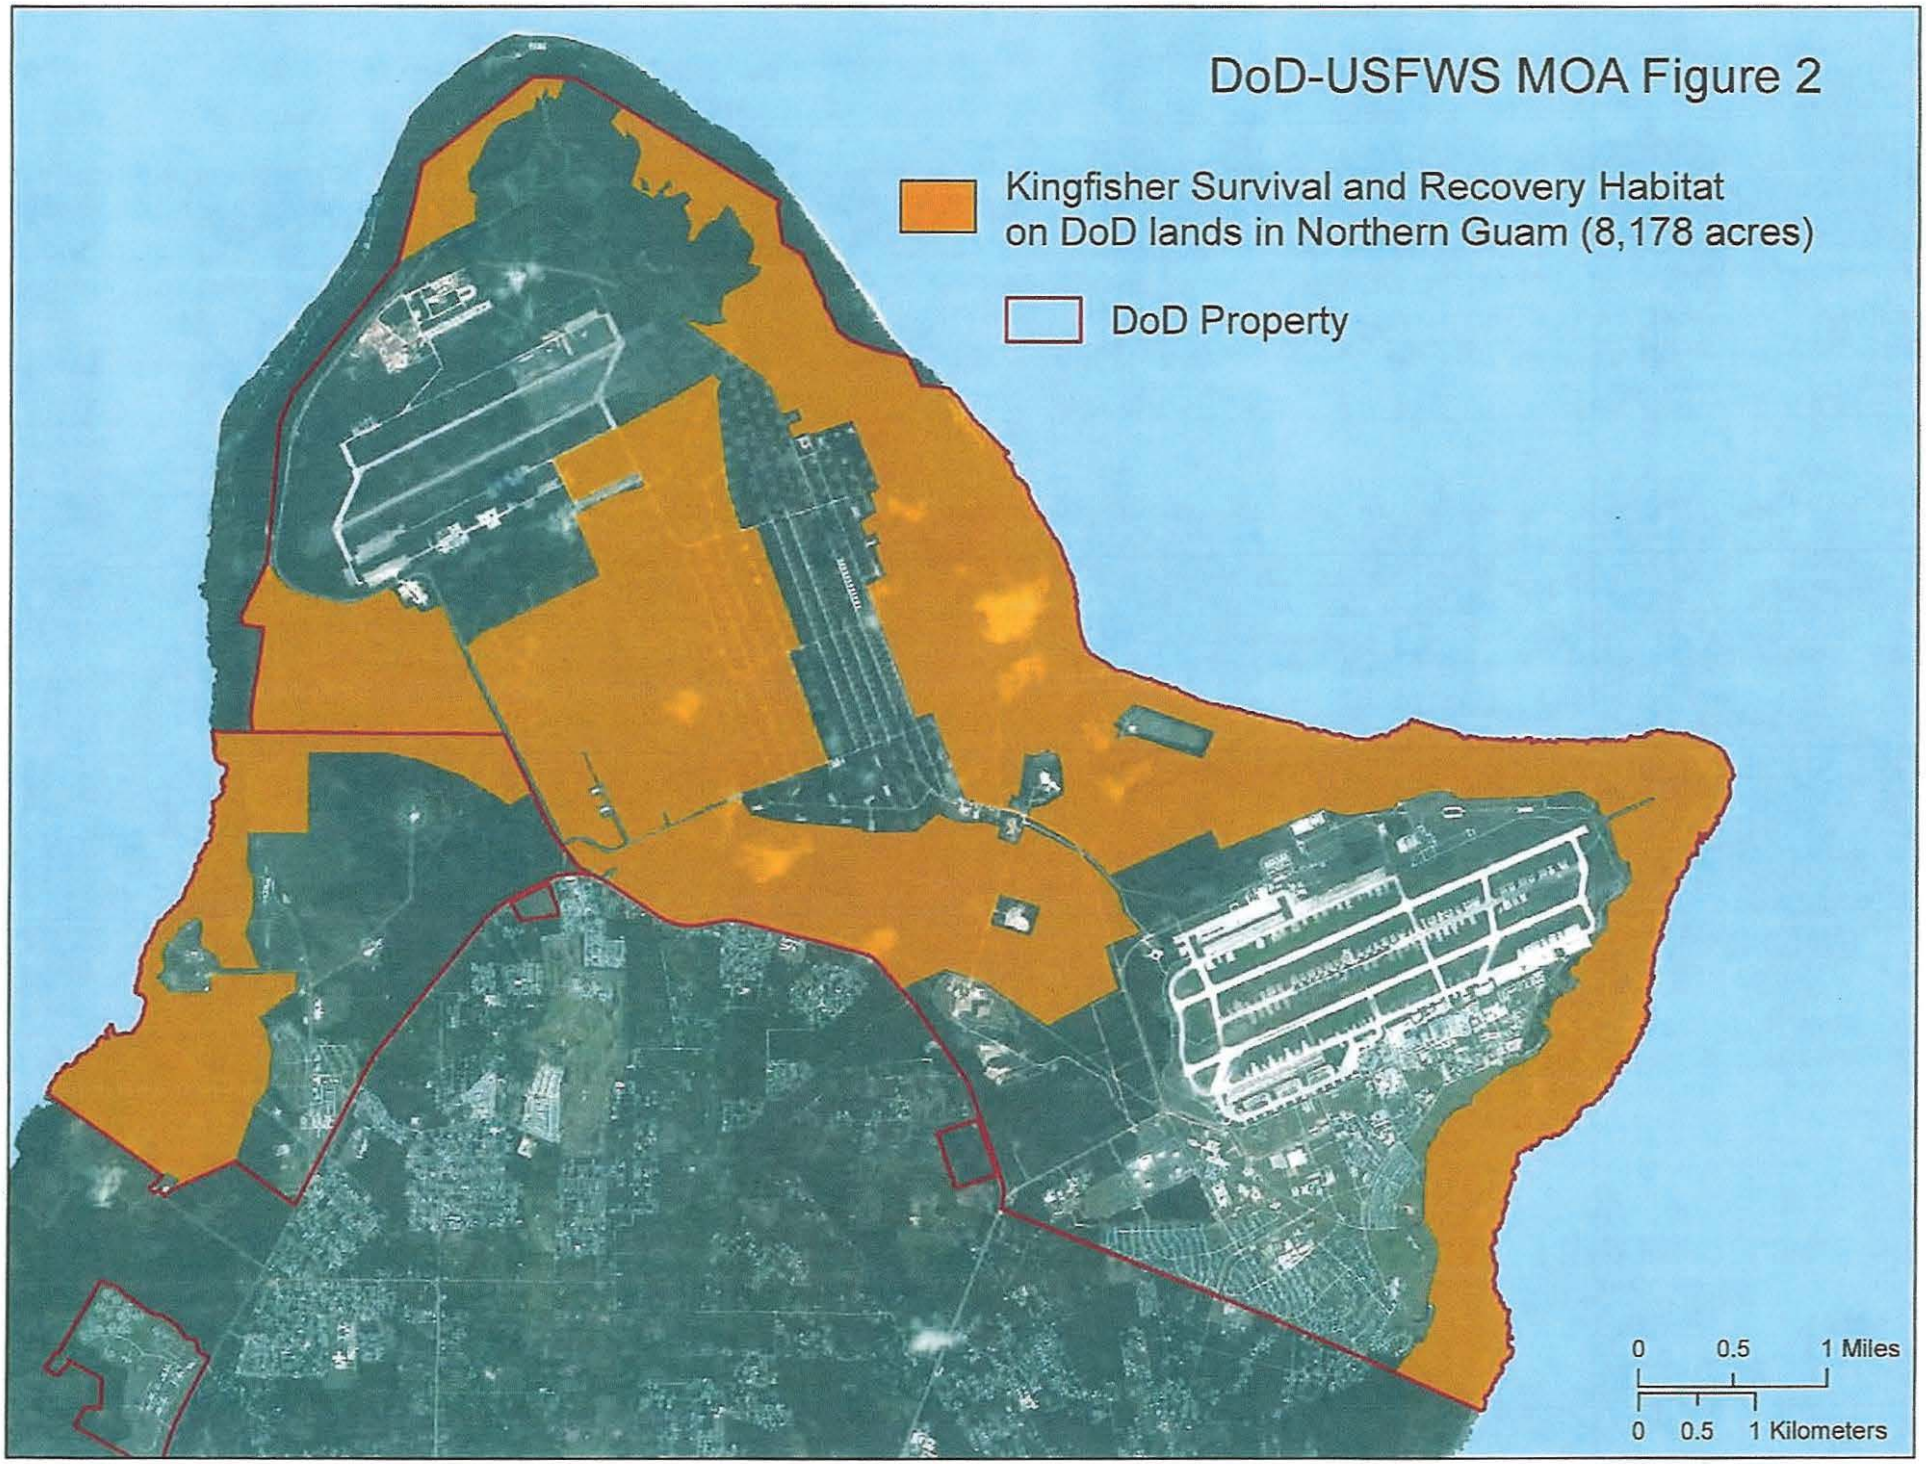
paragraph IV.E of this MOA; or 3) the USFWS determines that the kingfisher is no longer viable for reintroduction on Guam.

C. The Parties understand and agree that performance by the DON of any of the terms of this MOA is subject to the availability of appropriated funds. Nothing herein shall constitute nor be considered to constitute an obligation or expenditure of funds in advance of or in excess of a proper appropriation by the Congress of the United States or otherwise be in violation of the Anti-Deficiency Act, 31 U.S.C. § 1341 et seq.

D. This MOA shall not be construed to create any private right, privilege, remedy, claim or cause of action against the Parties for or by any person or entity.



VII. RESOLUTION OF DISAGREEMENTS



The Parties shall consult with one another to resolve issues at staff levels and elevate disputes through the respective organizational levels only if necessary. Notification of potential areas of disagreement by either agency should be in writing. If there is no resolution at the staff level, either agency may elevate the issue to the appropriate official within each agency or department.

Subject: Reinitiation of the 2015 Biological Opinion on the Department of the Navy's Relocation of U.S. Marine Corps from Okinawa to Guam and Associated Activities on Guam

Dear Commander Powell:

Enclosed is the US Fish and Wildlife Service's biological opinion for the proposed Marine Relocation from Okinawa to Guam. In accordance with section 7 of the Endangered Species Act of 1973, as amended, (16 U.S.C. 1531 et seq.) this concludes formal consultation for this project. Copies of the draft biological opinion were provided to your office for comments on June 2, 2017 with some errata corrections provided on June 6, 2017. We received your comments on June 19, 2017 and have incorporated corrections, additions and edits as appropriate. We appreciate your assistance and that of your team throughout this consultation. If you have any questions regarding this biological opinion, please contact Darren LeBlanc (Planning and Consultation Team manager) at 808-792-9403.

Sincerely,

Subject: Reinitiation of the 2015 Biological Opinion on the Department of the Navy's Relocation of U.S. Marine Corps from Okinawa to Guam and Associated Activities on Guam

Dear Commander Powell:

This document transmits the U.S. Fish and Wildlife Service's (Service[1]) Biological Opinion (BO) regarding effects on the 11 endangered or threatened species listed in **Table 1**, from the proposed action of relocating U.S. Marine Corps (USMC) personnel from Okinawa to Guam and related infrastructure construction and military training activities. The U.S. Department of the Navy (DON) is the designated lead Federal agency for this consultation. This BO is a partial reinitiation of the *Biological Opinion for the DON's Relocation of the U.S. Marine Corps from Okinawa to Guam* (2015 BO) (USFWS 2015a), finalized on July 31, 2015. On October 1, 2015, the Service listed 23 species located in Micronesia as endangered or threatened (80 FR 59424). Of these 23 species, 13 were found to occur adjacent to or within the proposed project areas (**Table 1**).

The action to relocate USMC personnel to Guam was first consulted on in January 2010 and a BO was signed on September 8, 2010 (2010 BO) (USFWS 2010). In October 2014, the DON requested reinitiation of the 2010 BO due to significant changes to the proposed action. The conclusion of that reinitiation resulted in the 2015 BO, which completely superseded the 2010 BO.

[1] A complete list of acronyms can be found in **Appendix A**.

This BO is a reinitiation of the 2015 BO for the Mariana fruit bat only and superceeds all information and analysis related to the Mariana fruit bat in the 2015 BO. Information and analysis in the 2015 BO for the Mariana crow (*Corvus kubaryi*), Guam Micronesian kingfisher (*Todiramphus cinnamominus cinnamominus*), Guam rail (*Gallirallus owstoni*), and *Serianthes nelsonii* remains binding. This BO also evaluates anticipated effects of the proposed action on 10 newly listed species that are known to occur within the project area and their terrestrial habitat. This BO was prepared in accordance with the requirements of section 7 of the Endangered Species Act (Act) of 1973 as amended (16 U.S.C. § 1531 *et seq*.).

Table 1. Endangered and threatened species addressed in this BO, their listing status in accordance with section 4 of the Act, and the effect determination made by DON.

Common Name	**Scientific Name**	**Listing Status**
May Affect, Likely to Adversely Affect Determination		
Mariana fruit bat	*Pteropus mariannus mariannus*	Threatened
Mariana eight spot butterfly	*Hypolimnas octocula marianensis*	Endangered
Humped tree snail	*Partula gibba*	Endangered
Guam tree snail	*Partula radiolata*	Endangered
Fragile tree snail	*Samoana fragilis*	Endangered
No Common Name (NCN)	*Bulbophyllum guamense*	Endangered
NCN	*Cycas micronesica*	Threatened
NCN	*Dendrobium guamense*	Threatened
NCN	*Heritiera longipetiolata*	Endangered
NCN	*Tabernaemontana rotensis*	Threatened
NCN	*Tuberolabium guamense*	Threatened
May Affect, Not Likely to Adversely Affect Determination		
NCN	*Eugenia bryanii*	Endangered
NCN	*Maesa walkeri*	Threatened
NCN	*Nervilia jacksoniae*	Threatened

On March 3, 2017, the DON also requested our concurrence with a determination that the proposed action may affect, but is not likely to adversely affect (MA,NLAA) the endangered plant, *E. bryanii* (DON 2017a). Subsequent email correspondence and discussions, that began on May 3, 2017 and concluded on May 17, 2017, resulted in the inclusion of the endangered plants, *M. walkeri* and *N. jacksoniae* to the DON's MA,NLAA concurrence request. Our review of these determinations and a concurrence with the DON's effect determinations for *E. bryanii, M. walkeri,* and *N. jacksoniae* is located in **Appendix B**.

This BO is based on information provided in your March 10, 2015 letter and Conference Assessment (DON 2015a), the subsequent Revised BA, email correspondences, discussions between the Service and DON, and information contained in our files. A complete administrative record for this consultation is in the Service's Pacific Islands Fish and Wildlife Office (PIFWO) in Honolulu, Hawaii.

Consultation History

March 10, 2015. The DON submitted a request for initiation of a Conference consultation on

seven federally proposed species (*B. guamense*, *C. micronesica*, *T. rotensis*, Mariana eight spot butterfly (*H. octocula marianensis*), humped tree snail (*P. gibba*), Guam tree snail (*P. radiolata*), and fragile tree snail (*S. fragilis*)) that may occur in the project action area. The DON determined that the proposed project MA,NLAA these federally proposed species. The DON conference assessment did not include *D. Guamense*, *P. malaspinae* and *T. guamense* in their analysis due to their initial review of these species and *no effect* determinations.

March 24, 2015. The Service informed the DON via a conference call that we did not concur with their no effect and MA,NLAA determinations on the proposed project's potential effects to federally proposed species within the action area.

March 25, 2015. The DON submitted proposed Conservation Recommendations to the Service, including: (1) DON's active participation in recovery committees for endangered or threatened species on Guam and DON's commitment to work with the Service to develop a re-introduction plan and supporting programmatic BO that ensures such re-introduction efforts are consistent with species recovery plans and the military mission on Guam; (2) developing a team to explore the establishment of potential conservation area(s) in the Mariana Islands as part of a broader consultation solution; (3) working with the Service, other Federal agencies, as appropriate, and Government of Guam to use their authorities to carry out programs for the conservation of threatened and endangered species; and, (4) incorporating habitat conservation areas and actions into the Joint Region Marianas (JRM) Integrated Natural Resource Management Plan (INRMP), because (a) INRMPs ensure military operations and natural resources conservation are integrated and consistent with stewardship and legal requirements; and, (b) INRMPs are planning documents that allow Department of Defense (DoD) installations to implement landscape-level management of their natural resources while coordinating with various stakeholders.

June 11, 2015. The Service and DON entered into an MOA (DON & USFWS 2015) to ensure that sufficient amounts of suitable survival and recovery habitat for the Guam Micronesian kingfisher would be conserved and managed within DoD lands in northern Guam.

July 31, 2015. The Service issued a BO (TAILS # 2015-F-0025) (2015 DON BO) to the DON for their Relocation of the Marine Corps from Okinawa to Guam and Associated Activities on Guam (USFWS 2015a). The Service's Pacific Northwest Regional Office notified the DON that work on the Conference Assessment for the proposed species would start in August and should be completed by November 30, 2015.

August 21, 2015. During a DoD/Service meeting in Hawaii, DoD provided the status of the Marine Corps Relocation project and how the schedule of the consultation related to the timelines of the action as one subset of multiple other military projects. September 3, 2015. The Service acknowledged receipt of the DON's March 10, 2015 letter and Conference Assessment dated February 26, 2015, requesting a Conference on the effects of the proposed project on the seven federally proposed species noted in their letter. The

Service noted the review of incoming documents was delayed because of PIFWO's substantial section 7 consultation workload. The Service also requested clarification on the DON's use of the term "maximum extent practicable" related to their proposed conservation measures (The Service noted that the "maximum extent practicable" standard applies to Section 10 permit actions and does not apply to Section 7 consultations; however, it was discussed during this process to characterize conservation measures); a re-evaluation of their species effects determinations; and, the status of surveys for the proposed species conducted within the project footprint, including areas to be used for training within the Naval Base Guam's Naval Munitions Site (NMS) that was discussed August 21, 2015.

September 15, 2015. The DON responded to the Service's September 3, 2015 letter acknowledging completed survey data for newly listed species and requested confirmation of any additional surveys available. The DON also requested formal Conference on the species included within their March 10, 2015 Conference Assessment.

September 22, 2015. The Service provides DON with a revised DoD consultation "stacking" schedule based on the discussions with DoD on August 21, 2015.

October 1, 2015. The final listing rule for 23 species was published in the Federal Register (80 FR 59424).

October 1 & 2, 2015. The DON and the Service held in-person meetings on Guam. DON provided an update on the implementation of the conservation measures detailed in the 2015 DON BO. The DON requested to reinitiate the consultation because of potential project effects to five of the newly listed species (Mariana eight spot butterfly, *B. guamense*, *C. micronesica*, *T. rotensis*, and *H. longipetiolata*). The DON provided a map of *B. guamense*, *T. rotensis*, *T. guamense*, *H. longipetiolata*, and *D. guamense* locations within the ungulate exclusion fence at Northwest Field (NWF), Andersen Air Force Base (AAFB). The Service requested the survey results, including the methods, for the newly listed plants within the action area and was told the surveys would not be completed for eight months. The Service indicated this information was needed to complete the status of the species in the action area and confirm the project effect determinations for the newly listed species. The DON stated they would submit a progress report for surveys (including methods and results) in northern Guam. The DON and the Service also discussed the information needs, the timeline for the reinitiated consultation, and the re-evaluation of the effect determinations per the Service's September 3, 2015 letter. The Service and DON discussed the likelihood and challenges for successfully translocating recovered host plants for the Mariana eight spot butterfly due to habitat restrictions.

October 2, 2015. The DON provided information via email on the status of the JRM's fiscal year 2014 project on the *C. micronesica* in Tinian as requested by the Service.

October 13, 2015. The DON requested that project activities for geotechnical borings be allowed to proceed within areas of Northwest Field (DON project P-715 area) and Finegayan

(DON project J-016 area). The DON submitted maps of the newly listed species within both areas for the Service's review.

October 14, 2015. The Service emailed the DON a reminder of the request for the survey results for the newly listed plants within the action area. The Service also stated an updated BA would not be required contingent upon the DON providing the missing information and clarifications requested in the Service's September 3, 2015 request letter.

October 14, 2015. The DON emailed a map of listed species locations within the ungulate eradication fence to the Service. In addition, the DON stated the final report for the newly listed species would not be completed for another eight months because the DON modified the cooperative agreement to add additional survey areas. However, the DON would submit a progress report.

October 26, 2015. The DON submitted a letter in response to the Service's September 3, 2015 letter requesting clarification. The letter confirmed the request for a section 7 consultation for the five newly listed species discussed at the October 1 and 2, 2015 meeting; a statement that the survey maps of recently completed surveys for the NWF area were provided to the Service on October 13, 2015; a statement that the proposed action would directly impact the Mariana eight spot butterfly, *T. rotensis*, and *H. longipetiolata*; a statement that no project impacts are anticipated for *B. guamense*, *C. micronesica*, humped tree snail, Guam tree snail, and fragile tree snail; a statement that no Marine Corps relocation related ground training would occur in the Naval Munitions Storage (NMS); and a list of best management practices (BMPs).

October 29, 2015. The DON and the Service discussed the October 26, 2015, letter stating that no project impacts were anticipated for *B. guamense*, *C. micronesica*, humped tree snail, Guam tree snail, and the fragile tree snail. The DON stated that the consultation should be formal for *B. guamense* and *C. micronesica* and informal for the three listed snails.

November 10, 2015. The DON provided the Service with the monthly status reports of plant surveys (October 2014 to August 2015) that were submitted to JRM. These surveys did not include sufficient data and maps to address the Service's request for the complete surveys.

November 20, 2015. DON met with University of Guam butterfly researchers/experts to discuss the recovery value and the feasibility or logistics of the proposed conservation measures for the Mariana eight spot butterfly. The Service staff was unable to attend at the last minute due to extreme weather events.

November 24, 2015, The DON submitted maps for the Service's review that included plant species of cultural importance (including newly listed speices and high value trees) within geotechnical boring project activity sites in the Northwest Field and Finegayan

December 1, 2015. The Service approved the request to initiate work on geotechnical borings within the P-175 area.

December 3, 2015. The Service emailed the DON requesting the DON's proposed conservation measures for the Mariana eight spot butterfly. The DON and the Service discussed re-scheduling the November 20, 2015 meeting since the majority of partners were unable to attend.

December 15, 2015. In a letter and enclosed map, the DON included the locations of *T. guamense* and *D. guamense* within the northern Finegayan area. The DON requested these two species be included in the section 7 consultation and concluded that the proposed action may affect, but was not likely to adversely affect *T. guamense* and *D. guamense*.

December 16, 2015. The DON and Service held a teleconference focused on the December 15, 2015 letter and the conservation measures proposed for the *T. guamense*, *D. guamense*, and the Mariana eight spot butterfly. December 17, 2015. The DON sent an email to the Service requesting the due date of the final consultation.

December 22, 2015. The DON and the Service agreed to a revision of the Guam Micronesian Kingfisher (GMK) Recovery Habitat Memorandum Of Agreement (MOA), which was originally signed on June 11, 2015. The modification identified a mutually agreed upon revised configuration for 5,234 acres of habitat for the recovery and survival of GMK in northern Guam.

January 11, 2016. The Service requested an update on geotechnical boring activities proceeding within the NWF (DON project P-715 area) and Finegayan areas (DON project J-016 area).

January 12, 2016. The Service requested the DON review the description of the proposed training activity at the NMS to ensure the accuracy of the proposed action.

January 21, 2016. In response to the Service's January 11, 2016 request for an update, the DON reported that the Route 3A geotechnical work was completed, and the geotechnical work within the LFTRC was currently in progress with biomonitors accompanying the geotech crew on site.

January 21, 2016. The DON and Service discussed the timeline for the completion of the formal consultation. The Service inquired about the status of the report on species surveys within the ungulate exclusion fencing at NWF. The Service advised the DON that if a BO is completed based on the information to date, formal consultation may need to be reinitiated if new information revealed effects not considered in the resulting BO. As a follow up to the December 16, 2015 meeting, the DON stated they would not salvage *T. guamense* and *D. guamense*.

January 26, 2016. The DON and the Service discussed finalization of the BO to include the newly listed species and agreed that the target due date would be the end of March 2016.

January 28, 2016. The DON and the Service discussed the language to describe a qualified biologist per implementation of conservation measures in the draft BO, status of the ungulate eradication fence relocation at NWF, review of the Consultation History section of the draft BO, and status of the informal consultation for the subject action. The DON stated that any salvage or translocation of *T. guamense* and *D. guamense* should be included as a conservation recommendation (i.e., not as a conservation measure) in the final BO.

January 31, 2016. The DON asked for a timeline to complete the draft BO and review the DON's comments and finalize the BO.

February 3, 2016. The Service stated that they would provide a signed BO within five business days after receiving DON's comments on the draft BO.

February 4, 2016. The DON sent a letter to the Service to confirm the timeline changes for completing the draft BO. The DON asked the Service to provide a draft BO by mid-March, followed by a review period, with an anticipated final BO due in mid-April. The letter also included new information identifying over 5,000 *T. guamense* and over 300 *D. guamense* at Finegayan that had to be incorporated into the effects analysis.

February 4-12, 2016. Emails were exchanged between the DON and the Service clarifying the number of *B. guamense*, *T. guamense*, and *D. guamense* individuals within the action area, the number of individuals that would be removed as a result of the proposed project activities, additional project details, and a reference for the information on environmental baseline conditions for *S. nelsonii*.

February 5, 2016. The Service acknowledged that sufficient information to reinitiate the subject formal consultation was received from the DON for the following species; Mariana eight spot butterfly, *B.guamense*, *C. micronesica*, *D. guamense*, *H. longipetiolata*, *T. rotensis*, and *T. guamense*. The Service stated that a draft BO would be completed on March 25, 2016 and a final BO would be completed by April 15, 2016. The Service also acknowledged an ongoing dialog about the increase in the population of the Mariana fruit bat and whether that might warrant a revision to the effects analysis in the July 31, 2015 BO.

February 6, 2016. The Service and DON discussed U.S. Marine Corps (USMC) training at the NMS. The DON stated that the Project Description would not include USMC training at the NM) and that no Marine relocation ground training was planned in the NMS area over the next 5 years. DON would re-initiate if the species were listed and there would be a potential to affect the species in the NMS.

February 17, 2016. The Service sent the DON a draft Consultation History section for review.

February 19, 2016. The Service emailed the DON requesting the inclusion of a conservation measure to salvage and relocate the listed orchids, specifically *T. guamense* that could not be avoided in the course of construction.

February 23, 2016. The DON emailed a report to the Service on the monitoring of Mariana fruit bat within the Habitat Management Unit (HMU) at (AAFB). The report documents observations in one area of up to 112 fruit bats within the HMU.

February 24, 2016. The Service requested information on the number of *T. rotensis* individuals that would be removed as a result of the action.

February 24, 2016. The DON sent a letter to the Service requesting to reinitiate consultation on Mariana fruit bat as part of the on-going Marine Relocation to Guam consultation.

February 24, 2016. The DON emailed a report entitled *Memorandum for File, Subject: Pre-Construction High Value Tree (HVT) Surveys of J-001B Utilities and Site Improvements Phase I, Naval Base Guam*. The initial surveys focused on plant species of cultural importance and included the following HVTs: *C. micronesica (*cycad*), Intsia bijuga* (ifit), *Elaeocarpus joga* (joga), *Artocarpus mariannensis* (seed breadfruit), and *Artocarpus altilis* (seedless breadfruit). Additional tree species observed include *Ficus prolixa* and *F. tinctoria* (banyan) and *Maytenus thompsonii.* The supplemental surveys focused on re-surveying the HVTs post-storm events. Incidental sightings of plant species that were listed on November 1, 2015 and host plants for the Mariana eight spot butterfly were also recorded during the supplemental surveys.

March 1, 2016. The DON provided the Service comments on the draft BO Consultation History.

March 2, 2016. The DON determined and provided the number of *T. rotensis* individuals that would be removed as a result of the action.

March 3, 2016. The Service asked DON to provide the report on the surveys for the Mariana eight spot butterfly that indicated this species occurs at the Mangilao golf course and Fadian Cove, as stated in the DON's conference assessment.

March 10, 2016. The DON sent an email to the Service stating that *T. guamense* and *D. guamense* would be salvaged within the action area to the maximum extent practicable.

March 14, 2016. The Service and the DON discussed by teleconference project activities that would adversely affect the Mariana eight spot butterfly and *T. guamense*. Clarification on the impacted area for the butterfly within the proposed Live-Fire Training Range Complex (LFTRC) and proposed conservation measures for these two listed species were also discussed. The Service stated their preliminary analysis on the project impacts of the DON's action indicated very serious deleterious consequences for *T. guamense* and Mariana eight spot butterfly. The Service indicated the seriousness of the concern could likely push back finalization of the draft BO scheduled for March 25. The Service asked if the DON could possibly avoid taking approximately 5,000 *T. guamense* plants from the Finegayan area. The Service also indicated that one firing range, as currently planned, would take one of nine known populations of Mariana eight spot butterflies, and asked if

the range could be altered to avoid the take. The DON stated it would seek clarification and evaluate possible options.

March 21, 2016. The DON indicated that the construction plans for the Finegayan area were not finalized, and they could not be specifically altered at the current time because neither the construction bids nor the geological analyses of the site suitability were completed. The DON maintained that construction would avoid the orchids to the "maximum extent practicable" and that they would re-insert the conservation measure to relocate individuals that could not be avoided. The Service made clear that the success of transplantation was unknown and had to be considered as such in the analyses, and offered that the effects would likely still be severe unless more plants could be avoided. The DON suggested that the host plants of the Mariana eight spot butterfly might not be in the impact zone of the live-fire training range, and offered to provide some more detailed maps to better indicate the location of the butterflies relative to the range.

March 22, 2016. The DON sent additional information on the number of individuals of *T. guamense* that occur within DoD land on Guam.

March 24, 2016. The DON sent the rare plant survey report, titled "Plant Surveys, Joint Region Marianas Interim Report" to the Service.

March 31, 2016. The DON reviewed and updated the draft conservation measures for the proposed project to include the Newly Listed Species: Mariana eight spot butterfly, *B. guamense, C. micronesica, D. guamense, H. longipetiolata, T. rotensis,* and *T. guamense*.

April 4, 2016. Service staff conducted site visits of the AAFB portion of north Finegayan area to assess general habitat and growth characteristics of *T. guamense* in the wild. The purpose of the visit was to look at the existing habitat that the orchids inhabited and document observations to assist in the effects analysis and development of conservation measures.

April 5, 2016. The DON and the Service discussed by phone the DON's current understanding of the number of *T. guamense* and the construction impact on the Mariana eight spot butterfly. The DON indicated they would only be able to avoid 838 *T. guamense* of the just over 5,000 in the Finegayan action area (of the over 7,000 then identified on Guam) and that they could still not identify exactly which 838 *T. guamense* individuals would be avoided. In addition, while the DON was confident about avoiding 300 individuals, they were less certain about their ability to avoid the other approximately 500 of the 838. The Service indicated that this would have a substantial effect on the orchid population. The Service also stated the location of the avoided *T. guamense* individuals would be important, since not all habitat is created equal, and stated concerns with fragmentation of the *T. guamense* population. The DON indicated it was not possible to move the firing range that was going to impact the Mariana eight spot butterfly habitat due to safety issues on other adjacent firing ranges. The Service requested Geographic Information System (GIS) shape files for the locations of both the butterflies and the orchids.

April 11, 2016. Service staff conducted site visits of the Finegayan area to assess general habitat and growth characteristics of *T. guamense* in the wild.

April 13, 2016. The DON and the Service discussed the status of the draft BO. The Service indicated they had received all needed information except for that anticipated from a field visit planned to the Finegayan action area. The DON confirmed that impact area around the firing range was still as mapped (i.e., including the demolition of six of the nine known host plant locations of the Mariana eight spot butterfly). The Service indicated again that the proposed action effects on *T. guamense* and the Mariana eight spot butterfly were sufficiently significant to potentially delay finalizing the BO and would likely require Service review above the Field Office level.

April 18, 2016. DON escorted the Service in the field to look at the clusters of orchids near the NE corner of Finagayan.

April 26–May 5, 2016. Through a series of calls, the Service and the DON discussed possible alternative minimization and conservation measures for *T. guamense* and the Mariana eight spot butterfly.

April 29, 2016. The DON emailed the Service with an adjustment (including map and description of the change to the proposed action) to the firing range construction that would allow the DON to avoid all nine known locations of the Mariana eight spot butterfly. The DON included a map with this email as well as a description of the change to the proposed action.

May 4, 2016. The DON emailed the Service proposing further adjustments to the Finegayan construction area which would avoid 3,485 *T. guamense* individuals and a commitment to transplant an additional 2,000 individuals with an estimated success rate of 50 percent for the translocations (i.e. 1,000 successfully translocated and surviving)

May 5, 2016. The Service requested a consolidated proposal that would describe these proposed changes to facilitate review so that the draft BO could be sent to the DON by the end of May.

May 11, 2016. The DON emailed a letter and attachments of the consolidated proposals for best management practices and conservation measures on *T. guamense* and the Mariana eight spot butterfly for the Marine Corps Relocation to Guam to the Service.

July 8, 2016. In-person meetings between DON and the Service discussed the status of the consultation analysis and release of the draft BO.

July 17, 2016. The Service provided the DON a preliminary working draft BO for review. The draft BO contained analysis of impacts to only two of 11 species contained in the scope of the consultation.

July 24-28, 2016. Three-day meeting in Portland between DoD-Service representatives to discuss next steps in the development of Marianas Archipelago Conservation Strategy (MACS) that supports Service conservation initiatives and the DoD mission in the Region, and the Conservation Recommendations in the July 2015 BO while also providing overarching benefits to affected jurisdictions.

August 3, 2016. Conference call between DON and Service to determine a meeting date and to discuss DON's questions regarding the preliminary draft BO.

August 23-24, 2016. Meeting in Hawaii between the Service and DON to discuss the preliminary work on the draft BO. The discussion centered on new known occurrences of *T. guamense*, edge effect analysis, and potential impacts to butterflies and the conservation measures that would address these impacts. Review of the conservation measures offered by DON was conducted and a discussion of "certainty of effectiveness" led to Service requesting DON to provide additional information.

October 28, 2016. Conference call between the DON and the Service to discuss summary points and action items from the August 23-24, 2016, meeting in Hawaii. Discussion topics included ungulate eradication fence at NWF, butterfly rearing data from Dr. Moore's (University of Guam) research, and a BO amendment for Mariana fruit bat. The Service requested a revised reinitiation package that would include all previously submitted information.

November 4, 2016. The DON provided Phase 1 Data submission (including the draft write up on *T. guamense*, maps, metadata, survey line transects) and references to the Service.

November 5, 2016. In person meeting on Guam with DON and Service to discuss forest enhancement concepts at Finegayan, NWF, and Andersen South

December 1, 2016. Teleconference discussion of *T. guamense* Phase I data submission, clarification of the definitions of primary and secondary limestone forests, and discussion of schedule of future calls and in-person meetings.

December 14, 2016. Teleconference discussion of the Service's review of the Phase 1 data submission and how the edge effect analysis would consider the new empirical data provided by the DON. The Service notified the DON that we were developing a white paper on their edge effect analysis for *T. guamense,* which would be provided to DON prior to the upcoming in-person meeting. The group identified topics for discussion at the January 2017 in-person meeting in Portland.

January 12, 2017. The DON provided a white paper to the Service titled “Psychotria Criteria Review and Evaluation” supporting the argument that federally endangered *Psychotria malaspinae* is not the species that is present within the planned footprint of the Live Fire Training Range Complex (LFTRC). According to the research, the species present within the planned footprint of the LFTR is *P. hombroniana.* The DON provided their revised final comments on the Service’s draft BO.

January 17-18, 2017. The DON and Service consultation team members met in Portland, Oregon. Topics discussed included the Service's preliminary analysis on edge effects (edge effects white paper), the DON's Phase 1 information submission concerning *T. guamense*, general comments on the working draft BO, format and scope of anticipated BO (amendment vs. full BO), fire management plan, exclusion of *P. malaspinae* from the consultation, corrections to the Intelligence, Surveillance, and Strike Capability Project (ISR-Strike) history and compliance as portrayed in the working draft BO, potential inclusion of a perimeter fence/ ungulate eradication around the LFTRC, the consultation schedule, and new species occurrence data for butterfly and host plants at Northwest Field.

January 24, 2017. The Service presented by teleconference the white paper on edge effect analysis based on occurrence data provided by DON. The DON expressed concern with the assumptions and purpose of the statistical analysis of the edge effect paper, pointing out that the data collected was not intended to be used as statistical analysis, and that only a very small subset of the data provided was used to support the Service analysis. In addition, conclusions on edge effect were being made solely on the manipulated distribution data, without taking into account any other factors of the environment and habitat. The DON recommended that the statistical analysis by DON represents only a view of occurrence distribution from existing edges and not a determination of edge effect. The Service took the DON's comments under advisement.

January 25, 2017. Conference call between the Service and DON to discuss edge effects; the Service stated that revisions to the edge effects papers are being considered, including adding more data and changing the title to a study on the distribution of species with regard to existing edge. The revised white paper would be provided to the DON when complete.

January 31, 2017. DON requested a waiver regarding implementation of Term & Condition #4 in the Relocation of the USMC from Okinawa to Guam and Associated Activities on Guam BO (2015-F-0025) since the subject fence would be addressed in the current consultation.

February 1, 2017. The DON and Service discussed butterfly related topics on a conference call. Topics included DON providing additional new host plant and butterfly occurrence data from Dr. Fiedler, University of Guam, to update butterfly and host plant occurrences since the Final Listing Rule was published. A review of conservation measures specifically related to the butterfly was discussed. The DON opened the discussion on potential Terms and Conditions for the butterfly. FWS suggested that all measures be included as Conservation Measures.

February 8, 2017. Conference call between the Service and DON during which the Service committed to providing a response by February 15, 2017 to the DON's letter requesting a waiver from the 2015 BO term and condition (2015-F-0025). Also discussed were the edge effect paper, the Mariana fruit bat amendment, the Makua BO for reference

regarding the fire management plan, and conclusion of the previously discussed ISR-Strike BO language.

February 21, 2017. The Service acknowledged (2017-TA- 0150) the DON's efforts to comply with Term and Condition #4 from the 2015 BO (2015-F-0025), and agreed to discuss DON's alternatives to the ISR-Strike fence location as part of the current consultation.

February 22, 2017. Conference call between the Service and DON to discuss any outstanding tasks and issues. The Service provided DON with the revised draft Edge Effect white paper, which focused only on *T. guamense*.

February 23, 2017. The DON and Service subject matter experts discussed the Mariana fruit bat amendment and clarified that the military relocation and the Habitat Management Unit (HMU) management are separate actions and require separate amendments, and clarified Fire Management Plan specifics.

March 3, 2017. The DON emailed a letter and enclosed BA requesting a re-initiation of formal section 7 consultation on the effects of the proposed project on the eleven federally listed species noted in their letter. The DON determined that the action may affect, but was not likely to adversely affect three species (*E. bryanii*, the fragile tree snail and the humped tree snail) and may affect, likely to adversely affect the remaining eight species (the Mariana eight spot butterfly, the Guam tree snail, *T. guamense*, *B. guamense*, *D. guamense*, *C. micronesica*, *T. rotensis*, and *H. longipetiolata*).

March 13-14, 2017. In person meeting between DON and the Service in Hawaii to review information presented in the March 3, 2017 BA. The Service informally identified some additional information needs from the BA.

March 24, 2017. The Services provided the DON a list of information and comments from the 2017 BA necessary to complete a BO.

April 5, 2017. DON and Service consultation call to discuss status updates.

April 11-13, 2017. DON and Service teleconferences to clarify questions in the BA especially related to the information needs identified in March 24, 2017 letter.

April 12, 2017. DON submitted responses to the information request and comments provided by the Service regarding the Marine Corps Relocation to Guam BA. DON also emailed GIS data, EndNote library, sample HACCP plan, Wildland Fire Plan for MCB Hawaii and COMNAVMAR INST 3500.4.

April 12, 2017. The Service acknowledged receipt of a complete consultation package with a consultation start date of March 3, 2017. The Service also acknowledged that the consultation will also include the Mariana fruit bat to address new information on the species status and DON's request for an amendment to the amount of take of Mariana fruit bat specified in the 2015 BO (2015-F-0025).

April 20, 2017. Service requested information on the draft Forest Enhancement Plan.

April 21, 2017. DON and Service teleconference to discuss monitoring plans and specific details for all out-planting vegetation restoration activities mentioned in the Revised BA.

April 25, 2017. In person meeting on Guam with DON, Service and species experts to discuss monitoring concepts for the Mariana eight spot butterfly and the three listed snail species, especially those recently observed at Andersen South.

April 27-28, 2017. DON and Service conducted in-person site-visits on Guam to examine the project footprint areas and listed species habitat, including: LFTRC; Andersen South; Haputo ERA; Finegayan; and, other listed species locations. The Service identified and made DON aware of a discrepancy with the GPS location of the mature *S. nelsonii* and proposed Multipurpose Machine Gun Range (MPMG) range. The Service also indicated to DON that the 5 year review on *S. nelsonii* was recently completed and that the status for the species in the wild on Rota declined by 73% from the 1992 baseline. The Service recommended that DON should re-consult due to the significant wild population decline. May 4, 2017. DON confirmed that any project activities would not be within 100 feet of the *S. nelsonii* tree since prior maps misidentified the exact location of the tree and identified construction within this 100ft boundary.

May 11, 2017. The DON provided information clarifying Table 6 in the BA, relating to the population of *B. guamense*.The Service requested information on Forest Enhancement site establishment, monitoring, and proposed success criteria.

May 12, 2017. The Service recommended to the DON that *M. walkeri* and *N. jacksoniae* be included in the consultation with an effect determination of MA,NLAA due to DON proposing actions that will avoid or minimize effects to these two listed species within the NMS.

May 16, 2017. DON provided the Service with their identified measures related to out-planting the listed plant species. A draft vegetation map of the forest enhancement areas used to develop more site specific enhancement plans/targets was also provided.

May 17, 2017. DON verbally agreed to include *M. walkeri* and *N. jacksoniae* as MANLAA in the current consultation since DON intends to identify the area with these two species as a "No Training Area" to restrict access to the areas with these two plants in order to avoid the potential for effect. DON also stated that they were not interested in adding *S. nelsonii* to the current BO. The Service also received information on Forest Enhancement site establishment, monitoring, and proposed success criteria.

June 2, 2017. The Service provided a draft BO to DON.

June 19, 2017. The DON provided written comments to the Service on the draft BO.

June 22, 2017. The DON and Service consultation team members met in Hawaii to discuss DON comments on the draft BO

July 14 and 17, 2017. Conference calls between the DON and the Service to discuss the revised draft Incidental Take Statement.

BIOLOGICAL OPINION

Description of the Proposed Action

The DON proposes to relocate USMC personnel from Okinawa, Japan to Guam; construct and operate a Main Cantonment area and separate Family Housing; construct and operate a LFTRC; and conduct military training activities on Guam. Project activities will occur on land administered by the (DoD). The proposed action includes activities described in the 2015 BO addressing effects to the species in **Table 1** (above).

Minor non-substantive clarifications and organizational changes have been made to the description of the proposed action included in this BO and therefore this section differs from the 2015 BO. The only component actions not included in this BO are five roadway and bridge work projects (USFWS 2015a, p. 35), as majority of these projects have been completed, or occur within previously developed areas of Guam such as residential and commercial areas (**Table 2**). Where appropriate, effects from completed roadway projects are included in the Environmental Baseline section. In addition, 50 individual road projects have been proposed but would occur in urban areas and would be the responsibility of the Government of Guam or the Federal Highway Administration (FHWA). Where appropriate, these projects are included in the Cumulative Effects section. Finally, new details from DON have been included to describe proposed conservation measures within the two Forest Enhancement Sites (North Finegayan and Finegayan) and ungulate fencing and eradication activities surrounding the LFTRC in the Northwest Field (NWF). The conservation measures specific to these areas amend the measures described in the 2015 BO (USFWS 2015a, p. 37-38).

Table 2. Five roadway and bridge work projects included in the 2015 BO that have since been completed or initiated.

#	Description	Status
1	Route 1 and Route 8 intersection and improvement (Hagåtña) ("Guam Road Network" GRN1) – (Part of Hagåtña Bridge Replacement Project Scope)	Completed
2	Route 1 and Route 3 intersection and roadway improvements (Dededo) (GRN2)	Under Construction
3	Replacement of Hagåtña (Agaña) Bridge #1 with reinforced concrete (GRN3)	Completed
4	Route 11 roadway improvements from the port to Route 1, including pavement strengthening (GRN4)	Completed
5	Widening of the Route 1 and Route 11 intersection, adding a second left turn lane and pavement strengthening (GRN5)	Completed

The proposed action is divided into ten components listed below and described in detail in subsequent sections. The locations for these project components are shown in **Figure 1 (**all Figures are located in **Appendix C)**.

1. Relocation of approximately 5,000 USMC personnel and 1,300 dependents from Japan to Guam;
2. Utilities and Site Improvement Activities within DON-administered lands;
3. Construction of the Main Cantonment at the Naval Base Guam Telecommunications Site (NBGTS), Finegayan;
4. Construction of Family Housing at AAFB;
5. Construction and Operation of the LFTRC at the NWF and the establishment of an associated Surface Danger Zone (SDZ);
6. Construction and Operation of a hand grenade range at Andersen South as part of the LFTRC;
7. Training Activities and Aircraft Operations within AAFB;
8. Training Activities and Aircraft Operations within Naval Base Guam;
9. Training Activities and Aircraft Operations within the Naval Munitions Site (NMS) Southern Land Navigation Area; and
10. Conservation Measures to avoid or minimize project impacts.

Relocation of U.S. Marine Corps Personnel and Dependents

In furtherance of an agreement with the Government of Japan, the DON plans to relocate 5,000 USMC personnel and 1,300 dependents from Okinawa to Guam. The most recent population estimate for Guam is approximately 174,000 residents (UN 2015). The proposed action would temporarily increase Guam's population by approximately 10,000 (DON 2015b, p. ES-4) or 7.1 percent by 2021 (UN 2015). This number will decrease to about 7,400 additional residents after construction is completed by 2032 (DON 2015b, p. ES-4) or a 4.6 percent overall increase (DON 2017a, p. 14). All construction projects and training activities listed under project components would be conducted in support of or as a result of USMC relocation to Guam.

An estimated maximum number of 1,227 workers from Guam and up to 3,227 workers from off-island would work on construction projects related to the proposed action (DON 2015b, p. 4-136). It is anticipated that the majority of off-island construction workers would be H-2B visa holders or temporary non-agricultural workers from the Philippines and other Pacific Islands. In 2011, construction of the Ukudu Workforce Village (Village) in urban Dos Amantes, Guam was completed. The Village is designed to be scalable in support of the proposed action. The Village's first phase includes accommodations for 2,000 tenants. At full capacity, the 252-acre complex would include a fire station, medical clinic, recreational spaces and other residential amenities necessary to house up to 14,000 temporary residents (Montvel-Cohen 2011). During the later years of construction (2025-2026), it is anticipated that more workers from Guam than from off-island would work on construction projects related to the proposed project (DON 2015b, p. 4-136).

Utilities and Site Improvements

The proposed action includes approximately 100 separate construction projects identified as Utilities and Site Improvements (U&SI) that would occur prior to large-scale vertical construction (**Figure 2**). These projects include clearing, grubbing, grading, earthwork (such as digging, trenching, drilling, boring and/or cut and fill), processing and stockpiling of green waste, erosion and sediment control, temporary construction fencing, perimeter or security fencing, landscaping and other activities to prepare the area for vertical construction. Additionally, the effort will likely require removal of unexploded ordnance (UXO) and munitions and explosives of concern (MEC), seismic fault, and geotechnical/geophysical and/or topographic surveys in preparation for vertical construction. Conservation measures including contractor education, inspection of construction equipment and supplies to ensure they are free of invasive species, and biological monitoring to ensure project impacts to listed species are minimized and impacts to their habitats do not occur outside of the designated project footprint, are described in more detail in the Conservation Measures section of this project description. U&SI activities include installation of electrical, water, and sanitary sewer systems. The following sections describe in detail all U&SI projects included in the proposed action.

Clearing, Grading, and Earthwork

Clearing and grubbing U&SI projects, conducted at specific project sites, include removal of vegetation, stripping limestone rock, and removal and stockpiling of reusable topsoil. U&SI projects would permanently convert 1,219 ac (493 ha) from limestone forest habitat, and 613 ac (248 ha) from herbaceous scrub forest to developed land (**Table 3**). Clearing and grubbing site work preparation would occur prior to mass grading of the site.

Table 3. Amount of vegetation type or substrate that would be permanently modified to support the construction of the cantonment, family housing, and LFTRC facilities, as well as utility system preparatory work to connect the facilities to existing or new electrical, water, and sanitary sewer systems.

Project Site	**Existing Vegetation or Substrate**		
	Limestone Forest[1]	Herbaceous Scrub	Developed/Barren Land
Finegayan, Main Cantonment	683 ac (276 ha)	115 ac (46 ha)	394 ac (159 ha)
AAFB, Family Housing	12 ac (5 ha)	0.13 ac (0.05 ha)	488 ac (197 ha)
LFTRC	187 ac (76 ha)	49 ac (20 ha)	70 ac (28 ha)
AAFB, South	212 ac (86 ha)	80 ac (32 ha)	115 ac (47 ha)
Naval Base Guam	86 ac (35 ha)	358 ac (145 ha)	2, 106 ac (852 ha)
Water Wells and Sanitary Sewer Systems[2]	39 ac (16 ha)	11 ac (4 ha)	48 ac (19 ha)
TOTAL	1,219 ac (493 ha)	613 ac (248 ha)	3,221 ac (1,303 ha)

[1]Includes both primary and secondary limestone forest habitat, characterized by limestone karst and native vegetation.

[2]Majoriity of electrical system infrastructure would be installed along existing roadways or occur within the Main Cantonment footprint (DON 2017a, p. 17).

Grading and earthwork U&SI projects include major earth moving of large contiguous areas (mass grading) and limited fine grading along the roadway corridors and drainage systems. The cut and fill quantities associated with this mass grading effort would provide for a building pad for future vertical construction, which anticipates further import of structural fill material. Grading for construction of the cantonment and family housing areas and associated infrastructure, comprising the Finegayan and AAFB components would include 3,732,871 yd^3 (2,853,984 m^3) of cut (excavation) and 2,958,469 yd^3 (2,261,911 m^3) of fill, resulting in a net of 774,402 yd^3 (92,072 m^3) of cut material available for use as needed (DON 2015b, p. 2-50). The cut and fill quantities also assume a two foot deep road pavement section, including compacted base and pavement surfacing.

Grading to provide a clear zone for perimeter security fencing is included. In accordance with USMC Order 5530.1A, a 15 ft. (4.6 m) wide gravel perimeter road would be constructed on the inside of all perimeter fence lines, and a 20 ft. clear zone would be provided on the outside of the perimeter fence line.

If soil testing and/or geotechnical recommendations indicate native material excavated on site is not suitable for reuse as fill material, then importation of fill material may be required. Contractors are required to obtain aggregate/soil from contractors/vendors who have local permits. Imported sand and other quarried products from abroad are subject to inspection by the Guam Department of Agriculture which issues an importation permit. All sand and aggregate material imported will be accompanied by official records indicating chemical composition, pest-free certification, treatment certificate, and certificate of origin. Treatment (disinfection) would be conducted at the point of origin.

Processing of Green Waste and Construction Debris

Green waste processing and demolition debris generated during construction will be handled by contractors at designated laydown areas, in accordance with the *Comprehensive Construction and Demolition and Solid Waste Management Plan* (DON 2010). Contractors will be required to process the generated green waste as part of their assigned contract requiring 100 percent diversion of the green waste into mulch (trees and stumps) and compost (leaves and grass), and 60 percent minimum diversion of construction and demolition debris waste into reusable material, including but not limited to, concrete crushing and reuse as base material. Green waste would be processed in accordance with Marine Corps Activity Guam (MCAG) management procedures to prevent and reduce the spread of the invasive coconut rhinoceros beetle (*Oryctes rhinoceros*) and little fire ant (*Wasmannia auropunctata*) (DON 2016). The DON subject matter experts will review the contractor's green waste processing and composting facility operations plan to ensure that it meets industry and regulatory standards. The contractor would be responsible for obtaining the solid waste facility permit issued by Guam Environmental Protection Agency (GEPA) prior to commencing activities. Construction and demolition debris and green waste that cannot be recycled or reused, as well as waste that is prohibited at Layon Landfill in Southern Guam, would be disposed of at the Naval Base Guam Landfill and other permitted private hard fill facilities (DON 2015b).

Removal of Unexploded Ordnance, Munitions and Explosives of Concern

Any earthwork or excavation for building foundations, roads, underground utilities, and other infrastructure could encounter unexploded military munitions in the form of UXO, discarded military munitions (DMM), and/or material potentially presenting an explosive hazard (MPPEH). To reduce the potential hazards related to the exposure to MEC, in accordance with DoD Directive 6055.9, Ammunition and Explosive Safety Standard (ESS) and Naval Ordnance Safety and Security Activity Instruction 8020.15D, ESS documentation would be prepared that outlines specific measures that would be implemented to ensure the safety of workers, the public and avoid adverse effects to natural/cultural resources. UXO that is identified during construction of facilities that requires open detonation in-place may require an emergency permit from GEPA. UXO that is safe to transport would be taken to the AAFB Hazardous Waste Management Facility – Explosive Ordnance Disposal (EOD) Permitted Facility to be safely detonated. Depending on the location and the nature of the UXO, it may be taken to either the AAFB permitted facility or to the NBG Magazine for detonation as part of an emergency response under the Military Munitions Rule.

Electrical and Communication Systems

The proposed action is estimated to require a minimum of 5.7 megawatts of electrical power annually, in addition to DON's existing power needs, with increases primarily occurring as a result of the Main Cantonment and family housing projects (DON 2015b, p. 3-19). Because no refurbishing/reconditioning of any combustion turbines would be required, a supplemental major stationary source impact concentration analysis was not performed. Various upgrades to existing substations would not exceed the existing facility footprint. In addition, a new substation equipped with two 15 megavolt ampere, 34.5 kV – 13.8 kV transformers would be constructed in the Main Cantonment area, south of the main gate. A new 34.5 kV transmission line from the Harmon Substation, connecting Finegayan to AAFB would be placed underground (**Figure 2**).

Proposed Information Technology/Communications (IT/COMM) systems would require inter-base connections between the proposed Main Cantonment, the proposed LFTRC, AAFB, Andersen South, and other existing bases. These hardwired connections would consist of up to eight 6-inch conduits buried approximately 3 ft (0.9 m) deep. Off-site conduits would be encased in concrete and would have lockable manholes for security. Because redundant off-island communication paths are needed, an additional connection to the Tata Communications Cable Termination Facility (in Piti, Guam) from AAFB may be required. Off-site conduits would follow existing roads and rights-of-way between the facilities.

AAFB Well Field and Associated Water System

In order to support the proposed action, approximately 11 new water supply wells are proposed to be installed at AAFB, as well as several well-refurbishment projects and upgrades to DON's existing water system. When complete, the proposed water well area would total an estimated 45.2 ac (18.3 ha), including up to 7.6 ac (3.1 ha) for the test wells and approximately 11 production wells (each 200 ft [61 m] in diameter), approximately 28 ac (11.3 ha) for the water

lines and access roads that would connect the wells, and approximately 9.6 ac (3.9 ha) for a well field water storage tank, pumps, and treatment system (**Figure 2**). The new potable water distribution pipes would be installed underground at least three feet (0.9 m) deep. The width of the trench to install the pipes would be about 1.5 ft (0.5 m) to 4 ft (1.2 m), for 6-inch (15.2 cm) to 24-inch (61 cm) pipelines. The specific number and locations of wells would be determined during well development and would consider updated water system information. The estimated long-term increase in potable water demand to the Guam Waterworks Authority (GWA) potable water system would peak during construction around year 2021 at 0.84 million gallons per day (Mgal/d) (3.18 million liters per day [ML/d]) as a result of the proposed action (DON 2015b, p. 4-111). This estimate does not include forecasted organic civilian growth.

Based on conservative estimates, it is anticipated that to locate one well of sufficient yield to support production, approximately three test wells would be required. The well field area can accommodate approximately 22 test wells, 11 production wells and associated equipment. However, the actual footprint of the wells and the access roads to each is not known at this time, but is anticipated not to exceed 90 ac (36.4 ha) of cleared vegetation (DON 2017a, p. 24).

Prior to the start of drilling, efforts would be made by the design contractor to minimize disturbance to the limestone forest by inspecting the area with a DON biologist and identifying previously disturbed areas to the extent possible, for use as water well sites (DON 2017a, p. 23). In addition, the following actions would be implemented:

- Where disturbed areas cannot be identified, for each well location, a 14-ft (4.3 m) path will be created for the drill rig, trucks/vehicles and other equipment to get to the test well locations.
- An approximately 100 ft by 100 ft (or 0.23 ac [0.1 ha]) work area will be required to set up the equipment at each test well location.
- For each test well, an 8-inch to 12-inch (21 cm to 30.5 cm) borehole will be drilled to a depth of approximately 500 ft to 600 ft (152 m to 183 m) below ground surface. A submersible pump will be placed at the bottom of the well, and pump test and water sampling conducted. Based on the results of the pump test and water sampling, the well will either be abandoned or identified as a potential production well. For test wells identified as a potential production well, GIS survey coordinates will be taken and a stake placed at the test well site.
- A production well consists of well casing (approximately 10-inch to 12-inch [25 cm to 30.5 cm] in diameter), screen, gravel pack, submersible well pump, pump motor housing, and surface/borehole seal. At each well station the following will be provided: well housing, discharge piping, and flow meter. Each well head will have electrical lines, water transmission pipes, and feeders to each well.
- Locations of the water transmission and feeder lines will follow already disturbed areas made during test well drilling (path made by the drill rig/vehicles/equipment). A 20 ft to 30 ft (6 m to 9.1 m) wide strip will be required for construction of the pipelines, and manholes, valves, bends, anchor blocks, etc. as well as backfill material. The main transmission lines, ranging from 8 inches to 16 inches (20.3 cm to 40.6 cm) in width, will connect the well field storage tank facility to feeder lines. The individual well feeder lines, approximately 6 inches (15.2 cm) in width, will connect the wells to the main transmission lines.

- In the well field storage tank facility area, there will be a booster pump, water treatment storage tank, electrical room, and central emergency backup generator and fuel storage tank. In addition to the 14 ft (4.3 m) wide path for cranes/vehicles/equipment, an approximately 550 ft x 650 ft area (8.2 ac) will be disturbed during construction of the water storage tank and associated facilities.
- Unless cuttings or excavation materials are deemed contaminated or unacceptable as fill material, cuttings will be placed back into a borehole or trench. Unacceptable fill material or excess cuttings/excavation material will be removed from the site.
- The DON will be responsible for tracking and ensuring that 90 ac (36.4 ha) of cleared area is not exceeded during water well pre-construction, construction, and operation. When 68 ac (27.5 ha) or 75 percent of the allowed disturbance area is reached, the construction contractor will stop work and re-evaluate to determine if 90 ac (36.4 ha) could be exceeded, upon which time the DON will notify USFWS (DON 2017a, p. 24).

During well testing, only those wells with good water quality and capacity will be identified as production well sites. Test wells deemed unsuitable will be filled and capped and left in place, restored or converted to monitoring wells for management of the Northern Guam Lens Aquifer (NGLA).

Total average daily water extraction from the NGLA from all sources (the DoD water system, the GWA water system, and a few private wells) is estimated to be 47.0 Mgal/d (177.9 ML/d) by year 2028 (USGS 2013). USGS developed a numerical groundwater model to estimate the regional effects to groundwater availability from various withdrawal and recharge scenarios that include the increased withdrawal due to the proposed action and all other known future DoD actions, as well as organic growth of the Guam civilian population. The results from the model assist water resource managers in planning, designing, and managing water systems that will produce a sustainable and reliable freshwater supply (USGS 2013). The results of the USGS study confirm the recharge rate of the NGLA used in a 1992 Government of Guam study, but indicate that increased withdrawal from the NGLA may result in higher levels of chloride concentrations as compared to the 2010 base year scenario (DON 2015b, p. 4-112). The model indicates that these chloride concentration spikes would be a localized phenomenon, in which simulated salinity levels (i.e., measured by chloride concentration) in three wells (two GWA and one DoD) in the Finegayan basin moved into the cautionary classification. However, by redistributing withdrawal rates among the extraction wells, it would be possible to meet the water demands and maintain acceptable salinities over all existing and proposed GWA and DoD wells (DON 2015b, p. 4-112).

Sanitary Sewer System

The proposed wastewater collection system for the Main Cantonment and Family Housing would connect to the existing GWA collection system along Route 3 and Route 9 (**Figure 2**). The proposed wastewater collection system would include a network of gravity mains, manholes; two wastewater pump stations, force mains, and refurbishment of existing wastewater pump stations. Upgrades to existing GWA pump stations would connect to GWA's Supervisory Control and Data Acquisition (SCADA) system at the central monitoring station in Mangilao, Guam.

Wastewater would be conveyed to the Northern District Wastewater Treatment Plant (WWTP) in Dededo for treatment and disposal.

DON anticipates a monthly maximum wastewater flow of up to 4.77 Mgal/d (17.8 ML/d) from Cantonment/Family Housing, USMC personnel and other DoD, or project-related contractors. These levels would represent a 36 percent increase from the baseline (DON 2015b, p. 4-114).

The Northern District WWTP currently requires upgrades to meet the National Pollutant Discharge Elimination System (NPDES) permit standards of secondary treatment and the Guam Water Quality Standards, including those for nutrients (DON 2015b, p. 4-115). Until the required upgrades are operational, additional projected wastewater flows from the proposed action and all other sources would be treated to only primary treatment standards before discharge into coastal waters that are located south of Tanguisson Point on the northern shoreline of Guam (EPA 2013). In order to bring the Northern District WWTP into compliance, in August 2016 DoD awarded GWA $55.3M for: 1) the GWA Interceptor Sewer Refurbishment; 2) the Northern District Wastewater Treatment Plant Upgrade; and 3) the Northern Guam Lens Aquifer Monitoring System Expansion and Rehabilitation (GWA 2017). Timelines for completion of these projects are unknown and would depend on a variety of factors.

Construction and Operation of the Main Cantonment at Finegayan

The proposed Main Cantonment development includes base operations and support facilities constructed within 1,213 ac (491 ha) at Finegayan (DON 2017a, p. 18). A security fence approximately 27,900 ft (8,504 m) in length will be constructed around the Main Cantonment perimeter. The components of the Main Cantonment and support facilities are listed below, followed by examples of buildings for each category.

- Command Core: Marine expeditionary brigade headquarters and command buildings.
- Unit Operations: 3rd Marine Expeditionary Brigade Command Element, 4th Marines; 9th Engineer Support Battalion; ground combat element infantry battalions; artillery battalion; combat logistics battalion; and combat engineer battalion, including explosive ordnance disposal.
- Base Operations: Base administration, fire station, public works, vehicle fueling, base auto shop, kennel, corrosion prevention and control, and security.
- Housing: Bachelor enlisted quarters (BEQ) and bachelor officer quarters (BOQ).
- Community Support: Dining facility, fitness center, recreation areas, education center, auditorium/theater, branch exchange, bank/credit union, food court/amusement center, medical/dental clinic, and post office.
- Training: Battle training center, individual combat skills course.

Unit Operations and Base Operations will have the most intensive land use equivalent or similar to activities found in light industrial zoned areas. Activities in the Command Core, BEQ/BOQ, Community Support, and Training areas will have activities that are equivalent to residential or commercial zoned areas. Individual projects for follow-on vertical work will be implemented in accordance with function-specific criteria pertaining to civil, architectural, structural, mechanical, electrical and other engineered features of work.

Construction and Operation of Family Housing at AAFB

The Family Housing facilities will be located on 510 ac (206.4 ha) of developed or disturbed land on AAFB. Family housing includes residences for accompanied permanent USMC personnel and their dependents, and support and recreational facilities. Unaccompanied USMC personnel would stay at the Main Cantonment during their shorter-term (approximately six month) assignment to Guam. The new housing density at AAFB would be 5.5 units per acre. The family housing area would be accessed by the existing family housing gate (the Santa Rosa Gate) at the northern end of Route 15, or from the AAFB Main Gate off Route 9. The existing family housing would be demolished and 912 family housing units would be constructed as replacements for the existing AAFB housing, in addition to the 535 family housing units required for USMC families. All of the 1,447 family housing units would be integrated into one large housing pool where all eligible personnel and families would reside.

Expansion of existing community support facilities, such as the child development center, youth center, and temporary lodging facility may be required. New facility construction may include a temporary lodging facility, a community center, and a family support center.

The existing capacity of utilities at AAFB is adequate for the Family Housing project. The increase in the number of housing units and facilities would be minimal compared to the current number of housing units and facilities. Additionally, the new facilities would implement energy and water efficient features meeting Leadership in Energy and Environmental Design (LEED) silver or greater standards, which would reduce utility requirements.

Construction and Operation of the LFTRC and Associated Surface Danger Zone

The proposed LFTRC at AAFB NWF would consist of five individual ranges, range support buildings, range towers, range access roads, and a perimeter fence, removal of portions of the Ritidian Ungulate Fence (USFWS 2006) and the establishment of a Surface Danger Zone (SDZ) over NWF and the existing Guam National Wildlife Refuge (GNWR) (**Figure 3**). Repairs to Route 3A would also be part of the project. The LFTRC would require construction of electrical, telecommunication, wastewater, and water lines or facilities configured to operate with the existing utility infrastructure of AAFB NWF (DON 2017a, p. 19). The individual ranges are described below:

- *Known Distance (KD) Rifle Range*. The KD Rifle Range would have 50 firing points for 5.56-millimeter (mm) weapons. The range would be 534 ft (163 m) wide and 1,500 ft (457 m) from the farthest firing line to the target line. The target line would be flush with the ground, and there would be level ground from the 600 ft (183 m) firing line to the target line. The range would include a 25 ft (8 m) tall impact berm behind the target line. The range footprint would encompass approximately 18.5 ac (7.5 ha). The berm will be vegetated in accordance with the DON's landscape guidelines.
- *KD Pistol Range*. The KD Pistol Range would provide 25 firing points for training with 9-mm and 0.45-caliber (cal) weapons. The range would be 123 ft (37.5 m) wide by 150 ft (46 m) long with level ground from the firing line to the target line. The range would

include a 12 ft (4 m) tall impact berm behind the target line and 12 ft (4 m) lateral berms. The range footprint would encompass approximately 0.4 ac (0.2 ha).

- *Non-Standard Small Arms (NSSA) Range*. The NSSA Range would provide 25 firing points, and be used for training with 5.56-mm weapons. The range would be 204 ft (62.3 m) wide by 328 ft (100 m) long with level ground from the 300 ft (91 m) firing line to the target line. There would be a 16 ft (5 m) tall impact berm behind the target line and 16 ft (5 m) lateral berms on each side. The NSSA range footprint would encompass approximately 1.5 ac (0.6 ha).
- *Modified Record of Fire (MRF) Range*. The MRF Range would have 16 firing points for use by 5.56-mm weapons. This live-fire range area would be 525 ft (160 m) wide by 657 ft (200 m) in length with a 25 ft (8 m) tall impact berm at the far end of the range. The range footprint would encompass approximately 7.9 ac (3.2 ha).
- *Multipurpose Machine Gun (MPMG) Range*. The MPMG Range would have eight stationary firing lanes to support training with 5.56-mm, 7.62-mm, and 0.50-cal weapons, as well as 40-mm inert training rounds (i.e., nonexplosive). The range would be 525 ft (160 m) wide at the firing line, expanding to 1,050 ft (320 m) wide at the far end of the range. The range would be 3,281 ft (1,000 m) long and would include a 25 ft (8 m) tall impact berm at the far end of the range. The MPMG range footprint would encompass approximately 59 ac (24 ha).

Specific support buildings in the LFTRC NWF would include three range observation towers, target-storage and maintenance shed, ammunition issue points, covered bleachers, portable toilets, safety signage and lighting, and parking.

The range footprints would be entirely cleared of vegetation and the ranges would be designed with perimeter berms to contain expended rounds of ammunition within the range footprint. The MPMG range would include more uneven terrain with some vegetation. The purpose of the MPMG range is to simulate a more natural environment. Vegetation on the ranges would be designed using the Guam Landscaping Guidelines (DON 2011) and use appropriate or non-invasive species in order to reduce potential impacts associated with non-native vegetation.

Lighting will be designed to meet minimum safety, sustainable, antiterrorism, and force protection requirements. “Night-adapted lights” will be installed in the briefing and bleacher areas at NWF. Night-adapted lighting includes bulbs in red or other spectrums that allow a person’s eyes to remain adapted to low light or night conditions while still providing enough light for work and safety. Illumination of the coastline or beach will be kept to an absolute minimum including the shielding of lights and directing lighting away from the forest or other wildlife habitat (see Conservation Measures section).

LFTRC Construction Phase

Development of the LFTRC is anticipated to occur in two phases: Phase-1 would include the construction of the smaller ranges and repair/improve Route 3A; and, Phase-2 would include the construction of the larger MPMG Range. Due to the uneven limestone rock substrate prevalent throughout the NWF, construction of the LFTRC would involve the use of heavy machinery including, but not limited to the following: tractors, cranes, scrapers, jackhammers, pile drivers,

excavators, dozers, backhoes, and crane clam shovels (DON 2015b, p. 3-26). Blasting or the use of dynamite material will not be authorized. Approximately 212 ac (86 ha) would be cleared as a result of the construction of the LFTRC (DON 2014). Construction timelines are subject to availability of funding (DON 2017a, p. 21). Grading requirements for construction of the ranges and associated infrastructure would include 2,047,295 cubic yards (yd^3) (1,565,270 cubic meters [m^3]) of cut and 1,932,392 yd^3 (1,477,420 m^3) of fill, resulting in a net of 114,903 yd^3 (87,850 m^3) of cut (DON 2017a, p. 21). However, any grading and other earthwork required during facility construction at any of the ranges would be implemented to balance cut and fill on-site to the extent possible. If off-site fill material were needed, it would be obtained from a permitted source.

LFTRC Operational Phase

Range use would depend on the number of personnel required to complete annual individual training events, the duration of each event, and the training capacity of each range. The live-fire operations at the LFTRC would occur between 7:00 a.m. and 7:00 p.m. for up to 39 weeks (273 days) per year, and night operations (estimated to occur two nights per week over 39 weeks per year) would occur between 7:00 p.m. and 10:00 p.m. or 6:00 a.m. to 7:00 a.m. Training at the LFTRC would typically occur during weekdays but periodic weekend use could also occur as needed. Night training is estimated to occur twice per week during the associated qualification periods and would require consecutive firing days.

When operational, an estimated 6,719,190 rounds of various ammunition types are expected to be expended at the LFTRC NWF annually, by USMC and non-USMC personnel (**Table 4**) (DON 2017a, p. 22). Each range would also be required to have an emergency response vehicle. The actual number of emergency response vehicles would vary depending on the proximity of individual active ranges to each other. Transportation to and from the range is generally not expected to occur during peak travel hours.

Noise levels from training at the LFTRC would be impulse noise with very intense sounds of short duration (e.g., the discharge of a weapon). Firing noise from single shots merged in bursts, machine gun burst, and concurrent firing of multiple weapons would result in short periods of intense firing followed by periods of silence. Live-fire operations may occur for hours at a time, for five days a week, or not occur for multiple weeks in a row. The most widely used metric for noise is the day-night average sound level (DNL). The DNL represents energy-averaged sound levels measured by summation and averaging of sound exposure level (SEL) values during a 24-hour period. Noise levels at the LFTRC are estimated using the A-weighted DNL (ADNL), which is used to describe noise from transportation sources (e.g., vehicles, aircraft) and from other continuous sources (e.g., generators). The noise levels at LFTRC are estimated within the immediate and adjacent areas and would range from 55 ADNL to greater than 85 ADNL, depending on the zone or area (DON 2014, p. 68).

All operations of the LFTRC would adhere to the Marine Corps Ground Range Certification and Recertification Program (Marine Corps Order 3550.9, June 2004), Range Safety (Marine Corps Order 3570.1C, February 2012) and policies and procedures for range and training area management (Marine Corps Order P3550.10, July 2005). The Marine Corps Range and Training

Area Management Program is used to track ordnance expenditures and training area usage in order to remain in compliance with mandated government reporting requirements and environmental and safety policies.

Table 4. Annual amount of ammunition estimated to be expended at the LFTRC, NWF.

Range	Weapon	Ammunition Type	Estimated Annual Ammunition Usage		
			Day	Night	Total
USMC Usage					
KD Rifle Range	M16/M4	5.56 mm	1,533,300	322,800	1,856,100
	M249 SAW	5.56 mm	59,200	39,664	98,864
KD Pistol Range	M9	9 mm	324,956	19,328	344,464
Non-standard Small Arms Range	M16/M4	5.56 mm	569,356	403,500	972,856
	M249 SAW	5.56 mm	152,736	34,900	187,636
MRF Range	M16/M4	5.56 mm	304,920	62,820	367,740
	M249 SAW	5.56 mm	59,200	17,760	76,960
MPMG Range	M249 SAW	5.56 mm	377,104	0	377,104
	M40/M110	7.62 mm	13,824	4,104	17,928
	M240	7.62 mm	576,716	141,336	718,052
	M107	0.50 cal	3,520	0	3,520
	M2	0.50 cal	190,756	6,180	196,936
	MK19	40 mm inert	84,480	8,448	92,928
	M-203/M-32 Grenade Launcher	40 mm inert	24,940	2,580	27,520
Total Estimated USMC Use =			**4,275,008**	**1,063,420**	**5,338,608**
Joint Use (non-USMC)					
Total Estimated Joint Use =			**1,104,466**	**276,116**	**1,380,582**
Grand Total					
USMC + Joint Use			***5,379,474***	***1,399,536***	***6,719,190***

*SAW = Squad Automatic Weapon.

LFTRC Surface Danger Zone

The proposed action includes the establishment of a SDZ within the NWF and the GNWR. The SDZ would delineate areas that fired ammunition fragments or ricochets may land, forming the outermost limit of the LFTRC. The DoD standard for risk acceptance on ranges is a 99.9999 percent level of containment, which means the probability of munitions (for inert ordnance) or a hazardous fragment (for live ordnance) escaping the SDZ is one in a million. The SDZ projects north and outward over the GNWR-administered fee simple land and submerged lands. The DON would demarcate the SDZ beyond the shoreline through navigation map updates to alert maritime traffic of the potential hazard. For the land-based perimeter of the SDZ, perimeter access roads (KD and MPMG), perimeter fencing, or signage would indicate its boundaries for personnel and public safety. Approximately 3,701 ac (1,498 ha) of lands and submerged lands are required to support the SDZ. This includes approximately 142 ac (57.5 ha) of the Ritidian

Point Unit (fee simple land) of the GNWR and 3,059 ac (1,238 ha) of the submerged lands of the Philippine Sea.

Although most of the SDZ area can be seen with binoculars from the observation towers at Ritidian Point at NWF, ground patrols within the GNWR would ensure that the area under the SDZ is cleared of people prior to the operations of the LFTRC. Patrols would be conducted on the beach prior to the operations of the LFTRC, which will operate daily up to 39 weeks per year. The purpose of the access is to ensure the water portion of the SDZ is clear of people. The Range Safety Specialist (RSS) would conduct a ground survey of three locations (**Figure 4**); however they may only access one or two of these locations to clear the water portion of the SDZ. The RSS will access the location by using an all-terrain vehicle (ATV) (2 or 4 passenger Gator-type vehicle). The RSS will get out of the ATV and move to an area where the water portion of the SDZ can be seen (not on the beach). The RSS will use a pair of binoculars to clear the water portion of the SDZ. The RSS will walk back to the ATV and drive out the same trail taken to get to the access locations. Once the SDZ has been cleared, the RSS would notify Range Control and depart the area. The ground survey would last approximately 20 minutes.

Training Activities and Aircraft Operations within Andersen South

The proposed action at Andersen South would include the following: construction and operation of a Hand Grenade (HG) Range as part of the LFTRC; construction and operation of military training in an Urban Terrain Training Area (a portion of which will be a modular unit and another will be reconstructed from the existing unit); a logistics and administration area; a convoy course; an advanced motor vehicles operators course; an aviation training landing zone; an aviation and maneuver area landing zone; Pioneer Road; other range roads; a perimeter fence; main, secondary, and range road gates at Andersen South (**Figure 1**).

Construction and Operation of a Hand Grenade Range

The HG Range would include an approximately 0.9 ac (0.4 ha) area developed as a hand grenade training complex for the M67 fragmentation grenade that will be connected to existing utility infrastructure where available. The following features would be developed within the hazard zone: a holding shelter for four persons, four throwing positions with grenade sumps, a range observation tower with ballistic glass, and a grenade "dudded" impact area. A grenade house would be collocated with the grenade throwing pits. A concrete munitions storage (i.e., magazine) surrounded on three sides by earthen berms would be used for the temporary storage of hand grenades during training events.

In addition to the live-fire area, there would be a 1.0 ac. (0.4 ha) non-live-fire training area developed adjacent to the range and outside of the HG Range SDZ. The training area would consist of a demonstration area with bleachers, an open practice throwing field with various targets and throwing positions, portable toilets, and a parking area. Inert practice grenades would be used at this training area to provide familiarization training prior to proceeding onto the live-fire area of the range (DON 2017a, p. 24-25).

Other Activities at Andersen South

Convoy operations, maneuver training for military operations in urban terrain, and general maneuver and air-ground operations would vary, but may occur up to five days per week, 45 weeks per year, day and night. Up to 250 to 300 USMC personnel would participate in maneuver training at Andersen South each week, for a total annual throughput of approximately 11,250 to 13,500 personnel. Convoy operations would typically consist of 7 to 10 vehicles (e.g., high mobility multipurpose wheeled vehicles) traveling in tandem along an established course. Military operations in urban terrain includes transporting units to Andersen South by helicopter or vehicle, maneuvering toward the military operations in the urban terrain complex on foot or by vehicle, and engaging in integrated training at the urban terrain complex. Military operations in urban terrain at the reconstructed training area (also referred to as the Urban Embassy Component) will consist of 24 or more, multi-story concrete structures to simulate at least four city blocks.

The modular military operations in urban terrain (also referred to as the Rural Military Operations in Urban Terrain) would consist of movable components that can be stacked and grouped into a number of configurations to present tactical situations to be overcome by training units. This modular military operations in urban terrain will consist of shipping containers that will be assembled on site to simulate a more rural village or set of suburban buildings located outside the core urban area. Forklifts or cranes would be used to reconfigure the modules of the military operations in urban terrain to add variety and diversity to training. The military operations in urban terrain complex would include live-fire ranges, including a breacher and shooting house that will be used for forced-entry training, and the HG Range and storage shed. These training areas would be suitable for units or organizations of up to 800 USMC personnel at a time, and will be used daily by 40 to 750 personnel. The military operations in urban terrain will operate day and night; night operations will comprise an estimated 15 percent of all operations. The military operations in urban terrain will be used by organizations based on Guam, transients, and visiting regional allied forces. Units using the military operations in urban terrain may bivouac in the vicinity, or arrive and depart daily.

Typically, dry runs and individual skills training would occur prior to the military operations in urban terrain exercises, which will involve fire teams (smallest unit of infantry, typically four or fewer individuals), and squad drills (a group of 8 to 12 individuals). Types of weapons that will be authorized for use at the military operations in urban terrain will include M16, M4, M249, and M240. Blanks, simulators, smoke grenades, diversionary devices (improvised explosive devices and booby traps that release smoke when activated), special effects small arms marking system (similar to paintball), and a multiple integrated laser engagement system (small laser receivers scattered over the uniform of an individual soldier, which detect when the soldier has been shined by another soldier's firearm laser) are used in place of ammunition and explosives that would be used in a real combat situation.

Tactical motor vehicle operator training is a continuous requirement for USMC units. The advanced motor vehicle operations course would consist of a route along which a series of obstacles would be placed for driver trainees to negotiate. This would include obstacles simulating terrain features such as narrow bridges, serpentine courses, brake modulation blocks,

river crossing, side slope, pot holes, curb and ditch crossing, humps (similar to moguls on a ski slope), and narrow urban driving. The obstacles are connected with unpaved roads. The capacity of the advanced motor vehicle operations course facility will range from 25 to 60 personnel and will be used for individual, section, squad, or platoon training. An estimated 20 drivers per week would train at the advanced motor vehicle operations course, primarily with high mobility multipurpose wheeled vehicles. At two drivers per vehicle, an estimated 10 high mobility multipurpose wheeled vehicles would use the course during training events.

Convoy training consists of simulated threats and tactical scenarios to train in various defensive techniques. This area of Andersen South is currently used by the Air Force for expeditionary airfield and military operations in urban terrain training, which has similarities to the maneuver area training. The convoy training course is 2.5 mi (4 km) and would use existing and new roadways (see Andersen South construction area, **Figure 1**) within areas identified for the maneuver training space. All existing roads would be open to motor vehicle use associated with maneuver area training; this will primarily be wheeled vehicles, but occasionally a tracked vehicle may be used in maneuver area training at Andersen South. The area will continue to support Air Force training, while also accommodating Marine Corps training requirements. Access to the site would be by vehicle or air lift. Air lifts would typically involve two to four CH-53 helicopters dropping off and picking up personnel twice a week.

Andersen South would support landing zones for aviation training and include helicopter support team training for ground units. Personnel will be trained in rappelling from the helicopter and procedures that will be used in inserting and extracting troops via helicopter at combat locations. The air operation events associated with this air-ground training will typically consist of a pass for orientation, followed by a downwind approach, hovering at 30 ft (9 m) above ground level for approximately one minute at a designated landing zone and a departure. Since the maneuver area aviation training operations will be a component of training to meet the aviation training requirements, they are also described as aviation training. Helicopter-insertion extraction activities include fast rope, rappelling, helocasting, and parachute operations. Helicopter insertion-extraction training operations would involve one pass for landing zone orientation, followed by an approach of the landing zone, hovering at approximately 30 ft (9 m) above ground level for approximately one minute, and then departing the landing zone. During each training event, approximately three helicopter insertion-extraction operations would be conducted at one or more closely located landing zones. Approximately 114 helicopter insertion-extraction events would occur at Andersen South per year. Confined area landing, external loads, and maneuver lift (see descriptions above) training would also occur on Andersen South at a frequency of 125, 63, and 720 events per year, respectively.

Shooting house operations, which are to be located in Andersen South, are conducted in an enclosed structure and provide training in close-quarter skills, like room clearing and hallway navigation. Live-fire training operations with the 5.56-mm rifle will be authorized within the facility.

<u>Training Activities and Aircraft Operations within AAFB</u>

The main base at AAFB comprises about 11,500 ac (4,654 ha). Mass grading for construction of the Air Combat Element facilities addressed under the 2010 BO, has been completed as of May 2017. There are two airfields on AAFB, the north ramp and the south ramp runways. The facilities constructed at AAFB north and south ramps will be used by 12 permanently stationed MV-22 Ospreys and will accommodate the loading of additional transient aircraft. These aircraft will be used to conduct training and operational flights, including the following components: field carrier landing practice, familiarization-instrument, Marine air-ground task force, tactical air operations center, and routine operations to occur in association with the Air Mobility Command and the Air Combat Element (ACE). A training event consists of one aircraft performing a take-off, a training evolution, and a landing. These aircraft training operations (**Table 5**) would occur at existing airfields.

Table 5. Anticipated total flight operations at AAFB resulting from previous projects with the addition of the proposed action (Czech and Kester 2008).

Aircraft Type	**Anticipated Total Aircraft Operations per Year at Andersen Air Force Base**			
	Previously Addressed	Proposed Project	Total	% Increase
Helicopter	19,029	19,489	38,518	102%
Jet/Propeller	25,697	6,424	32,121	25%

The ACE facilities would be used for aircraft operations, maintenance of MV-22 tilt rotor aircraft, and training and support functions. The ACE facilities would also be used for USMC air control group training. The USMC air control group training involves coordination of air command, control, and defense units and the tactical air operations center. Training entails the set-up and operation of air traffic control radar and radio frequency emitters and facilities consisting of shelters, a portable tower, and electrical power sources. Tactical air operations center training involves the establishment and dismantling of these facilities within a 96-hour period. Training includes use of various emitters and sensors which need to be de-conflicted with other electronic equipment operating in the area. The ACE bed-down facilities will operate 24 hours per day and seven days per week. Staffing levels will be contingent on surge and operational requirements of the ACE facilities. Traffic would include government-owned vehicles, personal-owned vehicles, and shuttle buses from the proposed Main Cantonment area.

Approximately 1,000 annual field carrier landing practice and 79 annual familiarization-instrument flight events are proposed for AAFB. Field carrier landing practice operations entail one or more aircraft flying at a low altitude in almost circular patterns and involves landing on a simulated aircraft carrier during the day and, using night-vision goggles, at night. Familiarization-instrument training, including autorotation and simulated engine-out approaches will occur on the improved airfields with the support of aircraft rescue and firefighting facilities. Rotary-wing aircraft operations will occur at the AAFB airfields and in various proposed training areas on Guam. Fixed-wing aircraft operations will occur only in the immediate airfield environment of AAFB. Aircraft would then leave this area to conduct activities within established training areas of the Mariana Islands Training and Testing (MITT) program or other locations as described under MITT (USFWS 2015b). Air traffic at the ACE bed-down and the

north ramp will include helicopter, vertical lift aircraft, fixed-wing, and unmanned aircraft arrivals and departures.

In addition, the new Air Embarkation Facility was completed in June 2015 to serve as the passenger terminal for AAFB and temporary cargo storage. Air embarkation and disembarkation refers to the loading and unloading of passengers or cargo to and from aircraft. The passenger facilities are comparable to those of a small airport: luggage handling, waiting area, and ticket and documentation area. Cargo is staged for loading to aircraft or disbursement to warehouses or individual commands. The Air Embarkation Facility will operate 24 hours per day and seven days per week.

Training Activities and Aircraft Operations within Naval Base Guam

Naval Base Guam (NBG) is located along the southern side of Apra Harbor on the western coast of Guam. Relocation of the USMC to Guam would result in frequent embarkation operations supporting amphibious transportation of Guam-based Marines and other transiting amphibious forces for potential contingency, humanitarian, and exercise operations in the Pacific theater. In-water ship berthing and embarkation areas, staging areas, an amphibious craft laydown area, a military working dog kennel, a medical and dental clinic, wash down facilities, brown tree snake (BTS) barriers, and quarantine areas will be developed and operated at NBG. In addition, a U.S. Coast Guard (USCG) berthing and crew support building will be relocated to an area that is not currently forested. The military working dog kennel relocated from its existing site to a new site on NBG, within an existing laydown area for base maintenance with existing access roads and utility tie-ins.

The Apra Branch Medical and Dental Clinic will be built on a previously disturbed area that is currently vacant. The Morale, Welfare, and Recreation area will be developed to provide food and beverage booths, seating for 500 people, 40 phone bank seats, 100 stalls for visitor and rental car parking, portable restrooms, laundry facilities, temporary lighting, and trash dumpsters.

All facilities will have security lights mounted on buildings or steel poles. Lighting along the wharves will consist of 1,000-watt high pressure sodium floodlights mounted on new or existing poles. Lighting will be shielded and aimed such that the majority of the illumination will be directed towards the wharf deck, extending over water approximately 100 ft (30.5 m). All actions related to development and improvement of waterfront facilities will occur in currently paved or landscaped areas. All utility distribution lines and ductwork will be located underground, generally within existing utility corridors.

The DON will develop permanent and temporary wash down, quarantine, and inspection sites at arrival areas at Apra Harbor (ship and amphibious vehicle loading and unloading) (USFWS 2015a, p. 31-33) as follows.

1. A wash down, quarantine, and inspection facility will be built at Apra Harbor within 600 ft (183 m) of Victor Wharf to reduce the risk of exposure to invasive species after leaving the clean, biosecure area. During construction, invasive species and debris will be removed from the site. Prior to operation, the biosecure area will be inspected

to ensure the area is free of invasive species. These facilities will provide for vehicle cargo quarantine, inspection, and storage. The areas will use BTS barriers and active trapping for BTS will occur. The facilities will include a pre-wash down area, vacuum equipment, wash racks (raised platforms with ramps at either end that facilitate cleaning and inspection of undercarriages), an inspection building, and fenced area that will meet the requirements for the use of inspection dogs and a cargo loading and inspection area. Specifically, these facilities will be built in a designated paved area with a wash down area and sufficient space for segregating "clean" from "dirty" equipment, cargo, and vehicles. The areas will be surrounded by BTS barriers following specifications received from the Service: The barriers will be 4.5 ft (1.4 m) tall; made from pre-cast concrete with an outward projecting lip to deter snakes; the barriers will have only two gates providing one-way flow of traffic through the site; each gate made from sliding chain-link with fabric barriers or comparable materials to prevent BTS ingress and egress.

2. When in Apra Harbor, the vehicles and equipment unloaded or loaded onto a ship will be inspected and receive a wash down on arrival and departure to prevent introduction of any pest or invasive species that may present a potential threat to agriculture, public health, or the natural resources of Guam or other Pacific Islands. All wash downs will be conducted and supervised by trained personnel in accordance with Armed Forces Pest Management Board, Technical Guide No. 31 (2017). Personnel from USDA may participate in inspections and BTS inspections will be conducted with involvement of USDA Animal and Plant Health Inspection Service (APHIS) personnel. Vehicles will be inspected (internally and externally) prior to passing into the biosecure area. The water used to wash vehicles will be captured and circulated through filters to prevent pests from spreading. All waste on board ships will continue to be steam sterilized prior to disposal in regulated landfills in accordance with base operating procedures.
3. Supplies for the USCG Cutters are delivered to the wharves from existing DON supply warehouses where all supplies and material have undergone required USDA inspections upon arrival and before being transferred out of the warehouse and onto a USCG ship. The USCG ships do not offload supplies onto Guam from other locations.
4. Truck traffic at the NBG wharf will be required to re-supply ships. Trucks may be from DON Supply or direct from commercial vendors. Equipment to move cargo will be brought to the wharf as needed. When an aircraft carrier is not berthed, the Port Operations building will be used for storage. All equipment and cargo will go through inspection procedures prior to being brought into "clean" areas or being loaded on to ships, regardless of vendor.
5. A wash down, quarantine, and inspection facility will also be built at the amphibious vehicle laydown area in Apra Harbor to reduce the risk of exposure to invasive species after leaving the clean, biosecure area. This facility will be adjacent to the shore so that amphibious craft can drive into the wash down, quarantine, and inspection facility. This facility will be built to the specifications described above for Victor Wharf with modifications to accommodate amphibious vehicles, specifically: the laydown area will have dedicated ramps for landing craft air cushion and amphibious assault vehicles in the quarantine area.

6. Typically, the Amphibious Task Force will arrive fully supplied to meet all training requirements or will be replenished as needed prior to training in the CNMI. If cargo is loaded or unloaded, inspection is required as described above for Victor Wharf. Cargo will be loaded and unloaded in the laydown area which will be of sufficient size to segregate "clean" from "dirty" cargos. If there is a training mission on Guam, the trucks will drive off the ships' stern ramps (and be inspected as described above). Other cargo may be offloaded by mobile crane. After inspection, cargo may be temporarily stored in a "clean" material handling equipment area at the waterfront.
7. For all facilities, the DON will attempt to include USDA APHIS at the earliest possible time to plan for BTS inspections. Planning for cargo storage will include considerations of the length of time for storage, risk of BTS or other invasive species, and origin and destination of cargo.

All amphibious (i.e., on water) training operations and conservation measures are assessed under the MITT BO (USFWS 2015b). Though new facilities would be constructed due to the proposed project, no additional amphibious training will occur in undisturbed areas, and no new or increased frequency of training is anticipated under the proposed action. Therefore, amphibious training will not be analyzed in this BO.

New aviation training for external loads will occur at Orote Airfield on NBG. The training requires access to pre-positioned cargo for practice, and ground access is needed for ground support team personnel. External loads cannot be carried across public roads or populated areas. External load training operations will involve one pass for landing zone orientation, followed by an approach of the landing zone, hovering approximately 30 ft (9 m) above ground level for approximately one minute while the ground support team attaches a load (e.g., concrete block, items in a cargo net, or a vehicle), departure of the landing zone vicinity with the load in tow, flying with the load in an arc, then returning to the landing zone with the load, and hovering for approximately 30 seconds while the ground support team retrieves the equipment, and then departing the landing zone vicinity. During each event, these operations will typically involve five repeated attachments and detachments of external loads at the same landing zone where the ground support team is positioned. Ground support teams will include up to 40 personnel at one time and will support landing zone operations. Approximately 10 to 12 wheeled vehicles (e.g., high mobility multipurpose wheeled vehicles) will be used by these teams.

Training Activities and Aircraft Operations within the Naval Munitions Site

The Naval Munitions Site (NMS) is approximately 8,646 ac (3,499 ha) with ground-training activities occurring in the Southern Land Navigation Area consisting of 3,357 ac (1,359 ha) and the Northern Land Navigation Area consisting of 508 ac (206 ha) (**Figure 1**). The NMS is comprised of primarily savanna, ravine forest and limestone forest vegetation communities. Company-level patrolling, jungle training, land navigation, and air-ground operations will occur on five to seven consecutive days, 12 weeks per year, day and night, for a total annual throughput at the NMS of 1,440 Marines. Sixteen events are authorized under the MITT BO (USFWS 2015b). The number of days and weeks described above represent an increase of training events per year due to the proposed action (revised total of 28 events per year). This site is rural and rugged, supporting land-navigation training primarily for Special Forces personnel.

Access to the NMS for training will occur via aircraft transport operations at proposed landing zones. Approximately eight CH-53 (heavy-lift transport helicopter) lifts will be required for a company-level training event. Personnel, hand-carried supplies, and equipment will typically be airlifted to the site on a Monday and lifted out on Friday of the same week. No other roads will be established and no vehicles will be used within the training site. The access road will have an associated parking area that will be periodically mowed to allow for parking and to reduce fuel loading and potential for fires. Foot trails will be established within the Southern Land Navigation Area of the NMS due to repeated use during maneuver training.

Terrain flight, ground threat reaction, defensive maneuvering, confined area landing, and external load training will occur at the NMS. Terrain flights require a route with varying terrain at 50 ft to 200 ft (15 m to 61 m) above ground level. Training for terrain flights will occur only within the southern portion of the NMS, south of the southern extent of Fena Reservoir. Aircraft will leave AAFB and transit to southern Guam using standard military flight procedures (i.e., greater than 1,000 ft. [305 m] above ground level). Aircraft may fly over land or over water on their way to the NMS. A typical training event may involve an aircraft leaving AAFB, moving to the east over the ocean, traveling along the coast at an altitude greater than 1,000 ft (305 m) until approximately the Talofofo River, and then flying up the river to the NMS still at an altitude equal to or greater than 1,000 ft (305 m). Flights may go up the Ugum River at altitudes of 1,000 ft (305 m) or greater above ground level until they reach 9,843 ft (3,000 m) from the mouth of the river at Highway 4 and then flights may conduct low-level terrain flights. Once aircraft cross into the NMS below Fena Reservoir (training restriction line), pilots will then be authorized to conduct low-level 50 ft to 200 ft (15 m to 61 m) above ground level terrain flights within the southern NMS. Low-level flights will not occur over munition bunkers, the main NMS, the area to the east of the munition bunkers, over Fena Reservoir, or over the Almagosa Springs.

Ground threat reaction training requires a tactical flight maneuver area or route (similar to terrain flight routes) where ground-based electromagnetic radiation threat simulators may be placed. Defensive maneuvers are also conducted along a route over land or water. Differing helicopter types (AH-1, CH-53E, UH-1) and the MV-22 tilt rotor aircraft, will be used to conduct terrain flights, ground threat reaction, and defensive maneuver training; however, terrain flight training operations are low altitude tactics and the ground threat reaction and defensive maneuver training are conducted more in a tactical navigation area than along a route. Ground threat reaction is also low-altitude training like terrain flights, while defensive maneuver training is higher in altitude (equal to or greater than 1,000 ft [305 m] above ground level). Approximately 100 terrain flights, 94 ground threat reaction flights, 94 defensive maneuvers, and 1,104 maneuver lift flights per year will occur in the NMS.

Confined area landing training operations will also occur at the NMS. Confined area landing training consists of one pass of the landing zone for orientation, a downwind approach, followed by the landing, and takeoff. To meet qualification requirements, confined area landing training events typically will have five associated operations. Typically, a number of different, closely located landing zones will be used during the training event. There will be approximately 125 confined area landing training operations per year at the NMS. Approximately 63 external load training operations per year will also occur at the NMS originating from NBG.

Conservation Measures to Avoid or Minimize Project Impacts

The project's conservation measures are designed to avoid or minimize project effects to listed species and their habitats or to contribute to the recovery of a listed species. The Conservation Measures in the 2015 BO (USFWS 2015a, p. 36-46) remain intact and binding unless noted below. Conservation measures are considered part of the proposed action and are vital to determining the scope of the proposed action.

Implementation of conservation measures is required under the terms of the proposed action. The Service's effects analyses and determinations assume proposed project conservation measures will be implemented in full. Any changes to, modifications of, or failure to implement these conservation measures may result in a need to reinitiate this consultation. Modifications to certain aspects of a conservation measure, described herein, may be substituted for those provided in this BO, so long as such modifications provide protection equal to or greater than the protection afforded by the measure, as it is proposed and analyzed in this BO, and the Service's written concurrence is given. All conservation measures must be implemented prior to or concurrent with construction, unless otherwise stated.

After the conservation measures have been fully implemented, the long-term management of the species addressed in this consultation within the project areas, must be incorporated into the final JRM INRMP.

The proposed action's conservation measures are organized into five categories listed below and described in subsequent sections.

- Measures to contribute to the recovery of listed species;
- Measures to minimize the effects of construction;
- Measures to minimize the effects of invasive species;
- Measures to minimize the effects of fire; and
- Measures to minimize the effects of training.

<u>Conservation Measures that will Contribute to the Recovery of Listed Species</u>

This subsection is organized into general measures, core measures, species specific targets, and a conceptual implementation plan. General measures are designed to protect listed species during construction and operation phases of the proposed action.

These general measures are as follows, and are also referred to in subsequent paragraphs that discuss specific species conservation measures (DON 2017a, pp. 34-36):

1. *Fencing of the Haputo Ecological Reserve Area (ERA) Access Trail, Signage, and Education*. The DON will fence the Haputo ERA access trail to manage access in order to assist in maintaining the characteristics and integrity of the ERA. The fencing will prevent overuse by military and civilian personnel and potential damage to terrestrial biological resources within the ERA. These measures are consistent with the goals and objectives of the Haputo ERA Management Plan (NAVFACMAR 2010). In addition, in

accordance with the Haputo ERA Management Plan, the DON will develop and install informational and educational signage on the cliff line above the Haputo ERA. The educational materials will educate military and civilian personnel on the sensitive biological resources within the Haputo ERA, and monitor and document visitor use of the area, and prevent overuse and potential damage to terrestrial biological resources.

2. *Pre-construction Surveys, General Listed Plant Salvage and Translocation*. The DON will conduct pre-construction surveys to identify all listed plant species prior to the commencement of construction activities. If pre-construction surveys identify a listed plant species present in the construction area and the individuals cannot be avoided or translocated, then healthy plant material will be salvaged or available seeds will be collected, and such material will be housed in the Native Plant Nursery or directly transplanted into protected habitat or Forest Enhancement Sites (**Figure 5**). The ability to salvage the plants or collect seeds would be dependent on the health of the plant and whether or not it would survive transplantation or whether the plant produces seed. An authorized biologist would make the determination of "health." Transplantation timing will be site specific. Plants that cannot be immediately transplanted shall be stored at the DON Native Plant Nursery.
3. *Native Plant Nursery*. The DON is developing a Native Plant Nursery within the proposed Main Cantonment (**Figure 5**), for the storage and propagation activities of native and listed plant species, associated with the proposed action. Temporary locations adjacent to the Forest Enhancement Sites may also be developed in order to assist in the hardening off process for plants as they transition from the long-term Nursery to Forest Enhancement Sites or other protected areas.
4. *Authorized Biologist Qualifications and Propagation/Translocation Authorization Process*. All authorized biologists shall be considered agents of the DON and the Service for the purposes of conducting Conservation Measures described in this BO. Authorized biologists shall report directly to DON regarding all compliance issues or questions; this includes all draft and final reports of noncompliance (DON 2017a, p. 35). Prior to commencing translocation of the Mariana eight spot butterfly, Guam tree snail, humped tree snail, fragile tree snail, *T. guamense*, *B. guamense*, *D. guamense*, *T. rotensis*, *C. micronesica*, or *H. longipetiolata* the DON shall submit a statement of qualifications for potential biologists to the Service. The Service will provide a response (either concurrence or a detailed explanation of why the person may not meet the qualifications) no later than 30 calendar days after the statement is sent. If after 30 calendar days there is no response from the Service, DON will assume concurrence from the Service. The qualifications to work with the aforementioned species include the following:
    a. A bachelor's degree with an emphasis in botany, horticulture, ecology, or a related science;
    b. At least 100 documented hours of experience conducting propagation, translocation, transplantation, pest control, and monitoring of the aforementioned species or a closely related species; and
    c. Applicant must provide contact information of three references familiar with their work related to b (above).
5. *Annual Reporting of Conservation Measures*. The authorized biologist shall record each observation of each species handled in annual monitoring reports. The authorized

biologist will also include the type of activities (e.g., propagation, translocation) being conducted on each species and if relocated to another area, provide the location.

6. *Avoidance of Listed Orchid Species in a Small Location at Finegayan*. The DON will not construct within the area designated as "No Construction Area" within the proposed Main Cantonment because the location is not suitable for construction (**Figure 5**). The area is known to contain approximately 816 *T. guamense* and one *D. guamense*.

Forest Enhancement Sites, Ungulate Eradication Areas, and BTS Exclusion Fences

The core of DON's conservation measures that are intended to contribute to the recovery of listed species are focused on two Forest Enhancement Sites (North Finegayan and Finegayan), the NWF Ungulate Control Area, and two BTS Exclusion Fences (North Unit and South Unit) (**Figure 5**). The BTS Exclusion Fences would be located within the Forest Enhancment Sites. The DON's primary goal is to take an ecosystem approach to restoring, enhancing, and managing the limestone forest on DoD lands in support of range sustainment efforts on Guam (DON 2017b).

Forest Enhancement Sites

As stated in the 2015 BO (USFWS 2015a, p. 37), the DON will implement a forest enhancement project to enhance a minimum of 1,000 acres (404.7 ha) in Finegayan. The total minimum size of the Forest Enhancement Sites was determined under the 2015 BO in order to offset the loss of recovery habitat for the Guam Micronesian kingfisher, Mariana crow, Guam rail, and Mariana fruit bat (USFWS 2015a, p. 107).

Since 2015, the DON has refined the Forest Enhancement Conservation Measure to identify the sites and include the following:

1. The North Finegayan Forest Enhancement Site is approximately 650 ac (263 ha) and will be fully enclosed by an ungulate exclusion fence (**Figure 5**) that will be maintained and monitored throughout the life of the project.
2. The Finegayan Forest Enhancement Site (also referred to as the Finegayan Outplanting Site) is approximately 455 ac (184 ha) and will be located within the Main Cantonment area of Finegayan. This entire site will include ungulate control and be enclosed with a permanent fence (**Figure 5**) that will be maintained and monitored throughout the life of the project. Signage and other educational measures would be implemented to limit access to the Finegayan Outplanting Site.

Forest Enhancement activities will include the following:

- Installation of ungulate exclusion fences around approximately 1,000 acres (404.7 ha);
- Active removal of ungulates (i.e., trapping, snaring, shooting) with the goal of eradication within the fenced areas;
- Invasive plant removal; and
- Propagation, planting, and establishment of dominant and rare species characteristic of native limestone forest habitats (e.g., *A. mariannensis*, *B.*

> *guamense*, *D. guamense*, *E. calcareum*, *G. mariannae*, *F. prolixa*, *M. citrifolia*, *C. micronesica*, *W. elliptica*, *S. nelsonii*, *H. longipetiolata*, *P. pedunculata*, *T. rotensis*, and *T. guamense*).

The Conservation Measure has been modified from the 2015 BO (USFWS 2015a, p. 37) to allow for the translocation and outplanting of *T. guamense*, *D. guamense*, *B. guamense*, and Mariana eight spot butterfly host plants, *P. pedunculata* and *E. calcareum* within the Forest Enhancement Sites.

The process for initiating Forest Enhancement activities remains unchanged from the 2015 BO, "when a DON-related project is initiated that results in clearing of habitat that could aid int the recovery of listed species, a commensurate amount of forest enhancement will begin. The exact amount of recovery habitat that will be cleared will depend on final design specifications. The DON's Forest Enhancement project will enhance at least the same number of acres of recovery habitat as that cleared by the proposed action. The DON expects that approximately 1,000 acres of forest will need to be enhanced as part of the Project Description. The timeline for initiation of Forest Enhancement projects will be based on the construction timeline for the proposed action. The first construction project that will clear recovery habitat will trigger the initiation of forest enhancement. The sequence of forest enhancement will be: (1) ungulate exclusion fence, (2) ungulate removal, (3) invasive plant control, and (4) native plant establishment (USFWS 2015a, p. 37).

An overview of the DON's general process for forest enhancement and restoration activities is outlined below (DON 2017b):

1. Identify forest restoration/enhancement blocks.
2. Map the proposed forest restoration/enhancement area boundaries.
3. Receive authorization for specific area of forest to be restored or enhanced and vegetation clearance approach for permanent ungulate fences, access-grid trails, and temporary cross fencing.
4. Obtain clearance for any ground disturbing activities from UXO specialist.
5. Perform forest inventory for species density and dominance.
6. Construct permanent ungulate exclusion fence around perimeter of the enhancement site.
7. When fencing is complete, begin ungulate removal program.
8. Monitor ungulate removal program. Based on ungulate monitoring results, implement further ungulate control activities to achieve ungulate eradication.
9. Develop an invasive plant removal and native plant species outplanting and establishment plan based on the forest inventory.
10. Once ungulates are eradicated from the enhancement site, begin invasive species removal.
11. During the wet season, implement the out-planting of the enhancement site(s).
12. Annually, conduct vegetation and ungulate monitoring and if necessary, repair fencing, implement further ungulate removal activities, invasive plant removal and outplanting.
13. If a typhoon occurs during the forest enhancement process, fences will be inspected, repaired and if fences have been breached, conduct necessary ungulate control.

The DON understands that restoration/enhancement of a forest is a long-term program, requiring a sustained effort for 30 or more years (DON 2017b, p.1). Ongoing projects and management efforts will be coordinated and integrated with future management efforts to achieve the long-term goal of restoring and enhancing habitats for native species, including listed species.

Brown Tree Snake Exclusion Fences

The DON has initiated support for large-scale, long-term efforts to refine methods for BTS control that will reduce the BTS population on a landscape level more cost effectively and increase the efficacy of capturing BTS in low-density situations. In early 2012, the DON coordinated with the Service, USDA, and USGS on priority BTS projects. The development of a bait formulation for BTS suppression was determined to be the highest priority project need. The USDA National Wildlife Research Center (NWRC) was funded for a multi-year project by the DON at the start of fiscal year 2013 to implement the bait formulation project.

The DON will implement selected projects identified as priorities in the BTS Technical Working Group Strategic Plan that is compatible with the military mission on Guam for up to 10 years from the start of Main Cantonment construction, subject to Congressional funding guidelines and restrictions. DON and the Service acknowledge financial support is subject to the availability of funds, and no provision herein shall be interpreted to require obligation of payment of funds, in accordance with the Anti-Deficiency Act of 1982 (31 U.S.C. §§1341).

The DON's purpose for BTS control projects is to identify and use successful technology to severely suppress or eradicate BTS. To accomplish this goal, DON will install a BTS barrier surrounding the South Unit (**Figure 5**), to exclude BTS from approximately 160 acres (65 ha). Construction of the South Unit-BTS Exclusion Fence would begin after current experimental BTS suppression activities are deemed successful. Experimental BTS suppression activities, conducted by USDA Wildlife Services (USFWS 2011a, 2011b) are occurring within the existing 136-acre (55 ha) Habitat Management Unit (HMU) (**Figure 5**). The HMU is enclosed by a BTS exclusion fence. The Service and DON biologists are working closely to evaluate progression of experimental BTS suppression activities within the HMU.

Upon demonstrated reduction of BTS within the South Unit, the DON will initiate the construction of the North Unit- BTS Exclusion Fence, to exclude BTS from approximately 300 ac (121 ha). If landscape scale experimental BTS suppression activities are unsuccessful at any stage and as a result, large BTS Exclusion Fences would be ineffective, then DON would not construct new BTS Exclusion Fences and instead would manage those areas as Forest Enhancement Sites.

In response to decreased BTS densities, the rodent and feral cat populations are expected to increase. In order to address this anticipated increase the DON will implement rodent and feral cat control within necessary areas of DoD property.

Northwest Field (NWF) Ungulate Control Area

The DON will construct an ungulate exclusion fence to exclude feral ungulates from the LFTRC in the NWF (**Figure 5**). The ungulate exclusion fence would be approximately 3.69 kilometers (2.3 mi) in length and would tie-in to topographic barriers (i.e., cliffs) on each end. The DON is proposing to construct the LFTRC in the last remaining contiguous primary limestone forest habitat on Guam; therefore by constructing the NWF Ungulate Fence, habitat not within the proposed range footprint would be protected from ungulates. Approximately 218 ac (88.2 ha), 66.7 ac (27.0 ha), and 97.1 ac (39.3 ha) of primary limestone forest, secondary limestone forest, and herbaceous scrub, respectively would be protected from ungulates over the life of the project.

Ungulate control in the LFTRC may occur prior to NWF Ungulate Fence construction. All ungulate control and eradication activities, including those occurring in Finegayan may use any number of established ungulate control/eradication techniques: Ground Hunting by professional sharpshooters; Aerial Hunting; Recreational Hunters; Ungulate Control Specialists; Hunting with Dogs; Live trapping (including corrals); Snares; Lethal Baits; Nontoxic Baits to Attract Target Species; Divider Fencing; Radiotelemetry (Judas animals); and Fertility Control. The DON's objective of constructing the ungulate exclusion fences is to eradicate all ungulates within the fence.

In addition, the DON will adhere to the following 2015 BO Conservation Measures (USFWS 2015a, p. 38):

- The NWF Ungulate Control Fence will be completed within two years of awarding the contract for construction of the portion of LFTRC that removes the existing Ritidian Ungulate Fence (**Figure 3**).
- The DON will remove all ungulates from the NWF Ungulate Control Area within six months after completing the NWF Ungulate Fence (**Figure 5**).

Conservation Measures for Specific Species

Mariana eight spot butterfly

The DON will conduct pre-construction surveys to identify any stages of the Mariana eight spot butterfly prior to the commencement of construction activities. If any life stage of the Mariana eight spot butterfly (e.g., eggs, caterpillar, and chrysalis) is located within a project footprint during pre-construction surveys, it will be relocated onto an appropriate host plant (e.g., relocate pre-diapause larvae to *Procris pedunculata* or *Elatostema calcareum*) within similar sites away from the project footprint. This can be conducted by clipping the host plant and grafting the plant to another plant outside the project footprint (Cook and Delisle 2010). This method has been conducted successfully for the Sacramento Mountains checkerspot butterfly (*Euphydryas anicia cloudcrofti*) (USWFS 2002a, 2002b).

The DON will plant the Mariana eight spot host plants (*P. pedunculata* and *E. calcareum*) within the Forest Enhancement Sites and on the backside of the earthen berms of LFTRC ranges. The primary objective is to provide habitat corridors for the Mariana eight spot butterfly. The number of host plants that will be planted would be commensurate with the amount of Mariana eight spot host plants that are removed within the footprint of the LFTRC.

Guam tree snail, fragile tree snail, and the *humped tree snail*

The DON will conduct pre-construction surveys to identify any Guam tree snail, fragile tree snail, or humped tree snail within the project footprint prior to the commencement of construction activities. If any listed snail is found, the authorized biologist will translocate the listed snail away from the project footprint and into suitable habitat.

Mariana fruit bat

For projects within or in the vicinity of suitable Mariana fruit bat habitat, surveys following the Service-recommended JRM protocol (USFWS 2009) will be conducted one week prior to the onset of work (USFWS 2015a, p. 40). If a Mariana fruit bat is present within 492 ft (150 m) of the project site, the work will be postponed until the bat has left the area. The measure is intended to prevent, avoid and minimize potential effects to fruit bats, and will be implemented during pre-construction and construction activities.

Listed Plant Species

DON expects that six endangered or threatened plant species (*B. guamense*, *C. micronesica*, *D. guamense*, *H. longipetiolata*, *T. rotensis*, and *T. guamense*) would be affected by the proposed action. Effects are expected to be in the form of entire habitat removal (i.e., clearing of vegetation and grading). The DON will conduct conservation measures specifically designed to address each listed plant species (**Table 6**). Healthy listed plants located within a project footprint will be transplanted into Forest Enhancement Sites or other suitable protected areas (e.g., NWF Ungulate Control Area) prior to clearing. The ability to salvage the plants would be dependent on the health of the plant and whether or not it would survive transplantation. An authorized biologist will make the determination of "health." If DON is not able to meet the minimum percent survival ratio with whole plants or viable seeds from within the project footprint, then DON will pursue seed collection, tissue germination, and plant division and/or stem cuttings, as suitable to the species, from other sources outside the project footprint to provide seedlings to meet out-planting success targets (**Table 6**).

Table 6. Conservation measures for listed plant species, including out-planting site selection, monitoring and success criteria (DON 2017c).

Scientific Name	No. of Plants Subject to Removal	% Survival Ratio of Salvaged Material[1]	Targeted No. of Plants to Survive[2]	Out-planting Site Selection Criteria	Maintenance	Monitoring
Bulbophyllum guamense	3	50%	2	1. Wind: reduce wind influence by planting in forest with intact canopy; 2. Host: native host trees, large trees (*Heritiera* spp., *Ficus* spp.); 3. Sunlight/moisture: lower branches of canopy tree in disturbed forests, higher branches of canopy tree in high humidity microclimates; 4. Orientation on host branch/trunk: top of horizontal/wide lateral branches in lower/mid-canopy of large host trees; 5. Stage of life: adult/large specimens can be affixed to bark of branches directly and secured; and 6. Habitat: disturbed limestone forest.	One year of maintenance (e.g., supplemental watering, hand-weed removal, pest removal, treatments with insecticide, installation of fence protectors; etc.) after transplantation to ensure a minimum of 50% survivorship.	One year of monitoring for growth and establishment shall be conducted regularly to determine the status of the species, at least monthly and more frequently depending on the conditions of the out-planted plants.

Scientific Name	No. of Plants Subject to Removal	% Survival Ratio of Salvaged Material[1]	Targeted No. of Plants to Survive[2]	Out-planting Site Selection Criteria	Maintenance	Monitoring
Cycas micronesica	3,191	50%	1,596	1. Wind: reduce wind influence by planting in forest gaps; 2. Sunlight: half day sunlight, in forest gaps and along western forest edges that receive less wind flow; 3. Spacing: place in groupings (groves) with ~10 ft. between trunk centers; 4. Culture methods: adult trees, remove fruit, old fronds, reduce new frond length by half for remainder of fronds, or remove all fronds if tree is infested with cycad scale; and 5. Habitat: limestone forest, coastal limestone.	One year of maintenance (e.g., supplemental watering, hand-weed removal, pest removal, treatments with insecticide, installation of fence protectors; etc.) after transplantation to ensure a minimum of 50% survivorship.	One year of monitoring for growth and establishment shall be conducted regularly to determine the status of the species, at least monthly and more frequently depending on the conditions of the out-planted plants.

Scientific Name	No. of Plants Subject to Removal	% Survival Ratio of Salvaged Material[1]	Targeted No. of Plants to Survive[2]	Out-planting Site Selection Criteria	Maintenance	Monitoring
Dendrobium guamense	18	50%	9	1. Wind: able to withstand exposed positions in tree canopies; 2. Orientation on host branch/trunk: top of horizontal/wide lateral branches, branch crotches and on upright branches in mid to upper canopy of large host trees; 3. Host: native host trees, large trees (*Heritiera* spp., *Ficus* spp.); 4. Sunlight: Require dappled to direct sunlight of upper tree canopy; 5. Stage of life: adult clumps can be removed as a clump and affixed to branch of tree directly and secured, juvenile specimens should be affixed on branch with moss around roots to prevent desiccation; and 6. Habitat: degraded/disturbed native limestone forest.	One year of maintenance (e.g., supplemental watering, hand-weed removal, pest removal, treatments with insecticide, installation of fence protectors; etc.) after transplantation to ensure a minimum of 50% survivorship.	One year of monitoring for growth and establishment shall be conducted regularly to determine the status of the species, at least monthly and more frequently depending on the conditions of the out-planted plants.

Scientific Name	No. of Plants Subject to Removal	% Survival Ratio of Salvaged Material[1]	Targeted No. of Plants to Survive[2]	Out-planting Site Selection Criteria	Maintenance	Monitoring
Heritiera longipetiolata	7	50% viable seed	4	1. Sunlight: require half day sunlight, in forest gaps and along western forest edges that receive less wind flow; 2. Spacing: should have 10-15 ft. of growing room for adequate sunlight exposure. Due to large mature size should be spaced at a minimum of 50-ft. apart if planting more than one specimen in the same plot; 3. Habitat: Disturbed limestone forest; cliff sides, terraces, coastal limestone.	One year of maintenance (e.g., supplemental watering, hand-weed removal, pest removal, treatments with insecticide, installation of fence protectors; etc.) after transplantation to ensure a minimum of 50% survivorship.	One year of monitoring for growth and establishment shall be conducted regularly to determine the status of the species, at least monthly and more frequently depending on the conditions of the out-planted plants.
Tabernaemontana rotensis	217	50% viable seed	109	1. Wind: can withstand moderate wind exposure; 2. Sunlight: requires high sunlight levels; 3. Spacing: place in groupings (groves) with ~10-ft. between trunk centers; and 3. Habitat: disturbed limestone forest, gaps, edges, terraces.	One year of maintenance (e.g., supplemental watering, hand-weed removal, pest removal, treatments with insecticide, installation of braces; etc.) after transplantation to ensure a minimum of 50% survivorship.	One year of monitoring for growth and establishment shall be conducted regularly to determine the status of the species, at least monthly and more frequently depending on the conditions of the out-planted plants.

Scientific Name	No. of Plants Subject to Removal	% Survival Ratio of Salvaged Material[1]	Targeted No. of Plants to Survive[2]	Out-planting Site Selection Criteria	Maintenance	Monitoring
Tuberolabium guamense	4,922[3]	50%	1,000	1. Wind: plant in forest with intact canopy; 2. Host: native host trees, large trees (*Heritiera* spp., *Ficus* spp.); 3. Sunlight/moisture: lower branches of canopy tree in disturbed forests, higher branches of canopy tree in high humidity microclimates; 4. Orientation on host branch/trunk: top of horizontal/wide lateral branches in lower/mid-canopy of large host trees; 5. Stage of life: adult/large specimens can be affixed to bark/branches; 6. Habitat: disturbed limestone forest.	One year of maintenance (e.g., supplemental watering, hand-weed removal, pest removal, treatments with insecticide, installation of fence protectors; etc.) after transplantation to ensure a minimum of 50% survivorship.	One year of monitoring for growth and establishment shall be conducted regularly to determine the status of the species, at least monthly and more frequently depending on the conditions of the out-planted plants.

[1]Salvaged material from plants of the Orchid family (Orchidaceae) will be in the form of whole plants, whereas salvaged material from *H. longipetiolata* and *T. rotensis* will be in the form of seeds, and *C. micronesica* will be in form of whole plants or basal suckers, known as cycad pups.
[2]Survived is defined for Orchidaceae species as the documented observation of new root growth after transplantation into a protected area, or for *H. longipetiolata, T. rotensis*, and *C. micronesica* 'survived' is defined as the documented observation that the plant is ready to set fruit or flower.
[3]The DON has committed to relocating as many individuals of *T. guamense* as is feasible; however a minimum of 1,000 *T. guamense* individuals will survive.

Conservation Measures to Minimize the Effects of Construction

Construction activities would range from simple improvements to extensive clearing and earthmoving activities. For this reason, specific conservation measures have been designed to minimize the effects of construction:

1. *Contractor Education Program*. The DON will implement a contractor education program to ensure that construction contractor personnel are informed of the biological resources in the project area, including invasive species, special-status species, avoidance measures, and reporting requirements. The measure is intended to prevent inadvertent effects to terrestrial biological resources due to lack of awareness of resource presence, habitat requirements, and protective measures. The measure will be implemented during preconstruction and construction.
2. *Contractor Plans and Specifications*. DON will ensure that all construction activities will occur within the limits of construction shown in the plans and specifications. This measure is intended to prevent additional habitat loss. The measure will be implemented during pre-construction and construction.
3. *Access and Location Constraints*. Construction of the Main Cantonment components will take place on the upper plateau area of Finegayan and will not occur in the Haputo Ecological Reserve Area (ERA). Construction personnel are issued base passes for official business only within construction areas; these restrictions are specified in construction contracts.
4. *Guam Landscaping Guidelines*. Appropriate or non-invasive species will be planted in all new landscapes. This measure is intended to promote habitat for native species, reduce water consumption, and reduce the need for fertilizers. The measure will be implemented during construction.
5. *LFTRC Range Berm Controls*. LFTRC range berms will contain native or non-invasive herbaceous vegetation, and other measures as appropriate for listed species (see Conservation Measures to Contribute to the Recovery of Listed Species). This measure will help to manage storm water runoff and control erosion, and the berm will minimize the number of bullets in certain ranges that may fall outside the range footprint. The measure will be implemented during construction.
6. *Lighting Installations*. Lighting will be designed to meet minimum safety, sustainability, antiterrorism, and force protection requirements. Hooded-lights will be used to the maximum extent practicable at all new roads and facilities within known sea turtle land habitat and Mariana fruit bat roost areas. Either hooded or "night-adapted" lights will be installed at the LFTRC. Illumination of forest, coastline, or beach will be consistent with range safety and security requirements and kept to an absolute minimum including the shielding of lights and directing lighting away from the forest, shorelines and other wildlife habitat areas. This measure will be implemented during pre-construction, construction, and during all DON operations.
7. *Monitoring Construction Contractors*. The DON will be responsible for oversight of avoidance, minimization, and conservation measures implementation by the contractors for projects associated with the proposed action. The DON shall ensure that construction remains within the limits of construction and that sensitive resources are avoided, unless

otherwise specified in this Project Description. This measure will be implemented during pre-construction, construction, and operations.

Conservation Measures to Minimize the Effects of Invasive Species

To reduce the spread of invasive species and encourage a more holistic approach to managing invasive species including their pathways and other vectors, as part of the proposed action the DON funded the development of a Regional Biosecurity Plan (RBP) for Micronesia and Hawaii (formerly referred to as the Micronesia Biosecurity Plan). The RBP was completed in March 2015 with various contributions from government agencies, organizations, and individuals (DON 2015c). The goal of the RBP is to provide stakeholders in Micronesia and Hawaii with a platform for coordination and integration of interagency invasive species management efforts such as control, interdiction, eradication, and research. Several of the RBP recommendations are incorporated into this Project Description as best management practices (DON 2017a, p. 31-32). These best management practices include:

1. *Vegetation Waste Management Procedures*. Green waste will be handled by the contractors at designated onsite laydown areas within the limits of construction. Contractors will be required to divert all green waste. The larger-sized green waste consisting of trees and stumps will be processed into mulch and the smaller sized green waste will be processed into compost. Green waste would be processed in accordance with MCAG management procedures to prevent and reduce the spread of the invasive coconut rhinoceros beetle and little fire ant (DON 2016). A proposed green waste processing facility at NBG Landfill may also be used to process green waste generated during construction. The DoD will seek permit authorization from the GEPA for the proposed green waste processing facility.
2. *Implementation of Landscaping Guidelines*. The DON has developed an instruction manual providing landscaping design guidelines specific to appropriate plant selection and establishment for all the DON construction activities on Guam (DON 2011). This manual implements required DON policies including, but not limited to:
   - use of native regional plants for landscaping;
   - design, use, and promoting construction practices that minimize adverse effects on natural habitat;
   - pollution prevention by reducing fertilizer and pesticide use, integrated pest management practices, recycling green waste (composting), and minimizing runoff;
   - implementing efficient water practices; and
   - preventing the introduction of invasive species.

   The above measure is intended to reduce potential effects associated with non-native vegetation, promote habitat for native species, reduce water consumption, and reduce the need for fertilizers.
3. *Biosecurity Outreach and Education*. The DON has initiated and will continue to implement a targeted, comprehensive outreach and education program for DoD and civilian populations for biosecurity education focused on prevention. As a starting point, the DON initiated a contract for the development of biosecurity outreach and education materials. The contractor has designed and produced an activity booklet, a two-sided, tri-fold, educational brochure with an associated poster that differentiates native from

introduced species, defines invasive species, describes the known impacts of invasive species on native species and ecosystems, and what can be done to prevent and control invasive species. The DON will develop additional informational videos, expand the radio public service announcement (PSA) broadcasts, and other print media as well as active public outreach concurrent with the arrival of the first major influx of USMC personnel anticipated in 2020 and continue the educational outreach at this level for an additional 5 years.

4. *HACCP Planning*. Hazard Analysis Critical Control Point (HACCP) planning is a site specific pathway management tool implemented by the DON that provides a comprehensive method to identify risks and focus procedures to prevent spread of species through likely pathways. Construction work could unintentionally spread non-target (potentially invasive) species. These non-targets could hitchhike on construction equipment or be included in shipments of materials and supplies from locations outside of Guam. The pathways used by invasive species to move into new locations are not always obvious. Many problematic species, diseases, and parasites have been transferred to new locations as undetected (and unplanned) hitchhikers. Understanding pathways and developing plans to reduce non-target species and prevent biological contamination is necessary to avoid unintended spread of species. To achieve this goal, the DON will conduct the following steps related to HACCP planning:
    a. All construction contracts will contain a requirement to develop a HACCP Plan which will identify risks and potential pathways for non-native species and will outline procedures for controlling and removing risks identified. Construction contractors are required to provide documentation that supports prevention, worker awareness training, and control of non-native invasive and pest species in the project area and efforts to prevent the movement of non-native invasive species to areas outside the project area, whether in a purposeful or inadvertent manner. The contractor is responsible for ensuring that employees receive applicable environmental and occupational health and safety training and are up to date on all regulatory requirements for specific training for the type of work to be conducted onsite.
    b. Construction contracts will contain a requirement for inspections and proper re-use or disposal of vegetation to avoid contributing to the further spread of the coconut rhinoceros beetle. The construction contractors are to identify and implement control measures to prevent the inadvertent movement of non-native, invasive species to Guam and to and from the project site to other locations on Guam. The contractor is required to establish appropriate facilities that comply with all environmental laws and regulations, provide training for proper vehicle hygiene, and promptly take corrective and preventative actions for noncompliance. This includes thorough vehicle wash down and inspection for soil and other materials prior to leaving or entering a new project site.
    c. All HACCP planning and implementation related to the proposed action will be the responsibility of the awarded project contractor(s) to ensure that proper control measures are used throughout the construction activities to prevent the inadvertent movement of invasive species from one location to the project site, and/or from the project site to other locations. It will be the responsibility of DON to review and

concur with the development phase of the HACCP planning process to ensure proper compliance by contractors.

d. HACCP plans will be approved and inspected by the DON.

5. *Monitoring to Evaluate Effectiveness of HACCPs*. The DON shall provide training, review, and technical guidance on HACCP plan development, implementation, and revision during the construction phase of the buildup on Guam. The HACCP planning covers Guam-related rapid response actions. The DON contracted a baseline ecosystem monitoring study for projects on AAFB in 2011. Transects were focused on areas where newly introduced species were most likely to occur. The intent of the project was to establish a baseline of both native and non-native plants present prior to the beginning of planned construction activities. The baseline will serve as a reference for subsequent monitoring efforts conducted concurrently with construction in order to aid in evaluating the success of implemented HACCP plans. The baseline and subsequent monitoring efforts will help to determine whether any non-native plant species detected during surveys are newly introduced or were present prior to the beginning of construction. The AAFB project was completed in December 2012.

   To document the effectiveness of HACCP implementation at construction sites, the DON has developed and will implement a long-term monitoring program for terrestrial vegetation. For any clearing of vegetation that is adjacent to or contiguous with recovery habitat, the perimeter and 98.4 ft (30 m) into the habitat will be surveyed to identify vegetation community species composition. This survey will be repeated six months and one year after vegetation removal to ensure effectiveness of the HACCP implementation (clean equipment, supplies, and materials) during construction activities. If new non-native, invasive species are detected, the DON will notify the Service and the DON will develop and implement an eradication plan or control effort to prevent infestation. The DON will develop an early detection and rapid response component to be implemented immediately when an incipient invasive species is discovered in the proposed action area.

6. *Brown Tree Snake Interdiction*. The JRM has established a comprehensive BTS interdiction program to ensure that military activities, including the transport of civilian and military personnel and equipment to and from Guam, do not contribute to the spread of the BTS to other islands or regions. The BTS interdiction requirements are specified in DoD instructions (i.e., *36 Wing Instruction 32-7004, BTS Control Plan and JTREGMARIANASINST 5090.10A, BTS Control and Interdiction*). The proposed action will continue to comply with these established procedures:

   a. The DON will fund any increase of current federally funded BTS interdiction measures (in Guam, CNMI, and Hawaii) where the need for the increase is to address direct or indirect effects related to the USMC relocation to Guam. The fiscal year (FY) 2010 level of funding for the Federal interagency BTS interdiction effort on Guam, CNMI, and Hawaii and 2010 transportation levels associated with outbound cargo from Guam for the U.S. or U.S. territories will be used as the baseline. The Service agrees that it is not DON's responsibility to fund increased interdiction measures that are identified more than one year after the end of the fiscal year in which the USMC relocation construction activities have ended and permanent non-transient USMC military units have completed their relocation to Guam. For the

purposes of this Project Description, interdiction is defined as: "to hinder, prohibit, or prevent the BTS from becoming established in new locations by conducting inspection and suppression processes." Since 2010, the DON has worked with USDA and the Service to determine BTS interdiction cost increases. To date, there has been no measurable increase in interdiction costs according to the USDA.

b. *Coordination with the USGS.* Close coordination between USGS and DON will continue to occur in support of the BTS Research Closed Population Facility at NWF (located adjacent to the LFTRC and within the SDZ). The DON will ensure through briefings or information packages that the personnel using the LFTRC know the importance of the facility and maintain the integrity of the fence. Standard operating procedures will be developed and incorporated into the Range Management Plan (RMP) for the LFTRC to ensure protection of the USGS BTS Closed Population Facility fence and require immediate notification to the proper authorities in the event that the fence is accidentally damaged, to allow for a quick repair.

Conservation Measures to Minimize the Effects of Fire

The DON will prepare a Range Fire Management Plan (RFMP) and provide the RFMP to the Service prior to LFTRC operations. The RFMP will include protocols for monitoring fire conditions and adjusting training as needed (e.g., certain types of training will be restricted under certain fire conditions) and include the location and management protocols for fire breaks, firefighting roads, and a firefighting water-system. In addition, military units undergoing training will be briefed on requirements suitable to the conditions of the day and protocols should a fire occur (e.g., fire suppression protocols and capabilities, and the priority of habitat protection in relation to all other factors considered in the plan).

Fire management is a key component of range management. The DON goal is to reduce the effects of fires by limiting their frequency, size, and severity while still allowing the USMC to maintain a high level of combat readiness. In order to avoid or minimize impacts to listed species or recovery habitat, the RFMP will include the following elements of fire management (DON 2017a, p. 33-34):

1. *Implementation of a Fire Danger Rating System*. A Fire Danger Rating System will be tailored to specific military uses (i.e., training activities) at the LFTRC and the local weather and fuel conditions will be established. Weather readings will be taken every hour by remote automated weather stations (RAWS) on the installation. This information is immediately available to Range Control, who will use the output from the remote automated weather stations to determine the level of fire danger. This, in turn, determines any restrictions placed on military training for that hour. Restrictions are relayed to troops in the field via radio transmission. By restricting highly fire prone activities during periods of high fire danger, the likelihood of a fire start is reduced. Additionally, fires that are ignited are more likely to occur during periods of low or moderate fire danger, making them easier to control and extinguish.
2. *Fuels Management*. All available fuel management techniques will be considered for fire break and fuel break maintenance, as well as fuel management control. Standard on-the-ground application is limited to mechanical cutting, herbicide application, and prescribed fire. If herbicide is to be applied, care will be taken to ensure there is no overspray into adjacent forested areas.

3. *Locations and Standards of Fire Breaks and Fuel Breaks*. Fire breaks are similar to four-wheel drive roads and are cleared of all vegetation to mineral soil. Fuel breaks are swaths of cut, burned, grazed or otherwise modified vegetation so that a fire's behavior is reduced. The fuel break widths are determined by fuels, topography, and prevailing winds. Fuel management corridors will be established and maintained providing areas through which fire will not carry. These corridors will provide several distinct areas where fire may be contained in order to prevent a catastrophic fire event. Each corridor will be approximately 328 ft to 985 ft (100 m to 300 m) wide, although terrain, safety concerns, or protected resources may constrain the width in some areas. Fire breaks and fuel breaks shall be established immediately adjacent to the forest edge, along the outer perimeter of each range, so that there is no herbaceous vegetation along the edge of the forest.

   Fuel specifications within the corridor require that canopy cover not exceed 20 percent. Cover of fuel within the fuel management corridors will be measured at a scale of 33 ft (10 m). Within the fuel management corridors, no 33 ft x 33 ft (10 m x 10 m) area will have greater than 20 percent cover of fuel. Cover 'starts/stops' at the edge of a plant clump's canopy. The clump includes the dead herbaceous fuel on the ground. The frequency of a fuel break's upkeep is dependent on the speed of regrowth and/or colonization. If the vegetation within the range footprint is less than 3 ft (1 m) tall, then no active management would be needed to maintain fuels below 3 ft (1 m) in height, within the 131 ft to 197 ft (40 m to 60 m) wide fuel break area.
4. *Standard Operating Procedures*. Standard Operating Procedures (SOPs) outline responsibilities for fire prevention, Fire Danger Rating System usage, staffing levels, equipment caches, fuel modifications, proper fire suppression actions, and post-fire reports. The SOPs also include fire prevention briefings to be given to range users prior to commencement of training, notification lists in case of fire, operational decision charts for fires, and maps of protected resources, fuels, fire breaks, and Fuel Management Areas.
5. *Range Control Approval and Guidance*. Prior to firing all pyrotechnics (including tracers), Range Control approval and guidance must be obtained. Fire Department and Range Control personnel will have the authority to stop live-fire training for non-compliance with any training regulation and/or SOPs.
6. *Fire Suppression*. Water trucks (pickup truck with a tank in the back) will be on-site as a first responder vehicle. Water trucks may be supported by a fire truck or helicopter, as warranted. All locations for fire suppression activities will be prioritized in order to minimize or prevent fire effects to listed species.
7. *USFWS Review*. The Service will be provided a 30-day review period, from the date of receipt of the Draft RFMP, to provide comments and recommendations for the DON's consideration. The RFMP will be finalized for the LFTRC prior to operation of the first range at the LFTRC.

Conservation Measures to Minimize the Effects of Training

1. *Aviation Training in NMS* (see NMS Operations). All aviation training will be conducted so that aircraft approach the southern portion of the NMS over the Talofofo River watershed and Fena Reservoir at heights of 1,000 ft (305 m) or greater above ground

level. Flights may go up the Ugum River at altitudes of 1,000 ft (305 m) or greater above ground level until they reach 9,843 ft (3,000 m) from the mouth of the river at Highway 4 and then aircraft may conduct low level terrain flights. Low-level training flights will be restricted to the southernmost portion of the NMS where Mariana swiftlets are not commonly present.

2. *Ground Training in NMS* (see NMS Operations). The DON will maintain 328 ft (100 m) 'No Training Buffers' around the known Mariana swiftlet nesting caves (*e.g.*, Mahlac Cave, Fachi Cave, Maemong Cave) in the NMS. This measure is intended to avoid and minimize effects to Mariana swiftlets, and will be implemented during operations.
3. *Designated No Wildlife Disturbance Areas.* The DON will ensure that military training units work in close coordination with JRM MITT to clearly define authorized training restrictions, and where appropriate, designate No Wildlife Disturbance (NWD) areas or other designations to prohibit training in sensitive sites. The DON will work closely with DON Biologists to identify new NWD areas, consistent with USMC combat readiness and training requirements. Proper designation of NWD areas will ensure that bivouacs do not cause additional disturbance to endangered species or tree snails.

Term of the Proposed Action

The DON will be using an adaptive management approach to adjust the schedule for construction and implementation of the various project components in order to reduce the peak workforce population, ensure conservation measures are initiated prior to or concurrently with specific project impacts, and allow the DON to adhere to contract and fiscal constraints. This approach precludes the need for a specific construction schedule that is difficult to estimate. All construction projects are anticipated to be completed by 2032 or within 15 years of signing of this Opinion. Maintenance, operations and monitoring measures may continue indefinitely. The Service anticipates that the long-term management of the species addressed in this consultation within the project areas, must be incorporated into the final JRM INRMP. Refer also to section 15, Reinitiation Closing Statement.

Action Area

The term "action area" is defined in the implementing regulations for section 7 at 50 C.F.R. §402.02 as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action." In delineating the action area, we evaluated the farthest reaching physical and biotic effects of the action on the environment, including all DON facilities, infrastructure and training activities, as well as conservation measures described in the Project Description.

The action area for this consultation is the island of Guam (**Figure 1**). The specific areas likely to be affected directly or indirectly by the proposed action are discussed in detail in the Revised 2017 BA (DON 2017a). In addition to what is detailed in the Revised 2017 BA, the following effects from the action may be Guam-wide: 1) effects from introduction of invasive species by the proposed action could spread throughout the whole island of Guam and 2) the population increase resulting from the proposed action will cause additional human disturbance throughout the island, including at recreation sites, hunting areas, traffic along roads, etc.

ANALYTICAL FRAMEWORK FOR THE JEOPARDY AND DESTRUCTION/ADVERSE MODIFICATION OF CRITICAL HABITAT ANALYSIS

Jeopardy Determination

In accordance with policy and regulation, the jeopardy analysis of this BO relies on four components: (1) Status of the Species, which evaluates the range-wide condition of the Mariana fruit bat, Mariana eight spot butterfly, Guam tree snail, humped tree snail, fragile tree snail, *B. guamense*, *C. micronesica*, *D. guamense*, *H. longipetiolata*, *T. rotensis*, and *T. guamense* and the factors responsible for that condition, and the survival and recovery needs of each species; (2) the Environmental Baseline, which evaluates the current condition of the species in the action area, the factors responsible for that condition, and the relationship of the action area to the survival and recovery of each affected species; (3) the Effects of the Action, which determines the direct and indirect effects of the proposed Federal action, along with any interrelated or interdependent effects, on these species; and (4) Cumulative Effects, which evaluates the effects of future, non-Federal activities in the action area on the species.

In accordance with policy and regulation, the jeopardy determination is made by evaluating the effects of the proposed Federal action in the context of the Mariana fruit bat, Mariana eight spot butterfly, Guam tree snail, humped tree snail, fragile tree snail, *B. guamense*, *C. micronesica*, *D. guamense*, *H. longipetiolata*, *T. rotensis*, and *T. guamense* current status, taking into account any cumulative effects, to determine if implementation of the proposed action is likely to cause an appreciable reduction in the likelihood of both the survival and recovery of the Mariana fruit bat, Mariana eight spot butterfly, Guam tree snail, humped tree snail, fragile tree snail, *B. guamense*, *C. micronesica*, *D. guamense*, *H. longipetiolata*, *T. rotensis*, and *T. guamense* in the wild.

The jeopardy analysis in this BO places an emphasis on consideration of the range-wide survival and recovery needs of the Mariana fruit bat, Mariana eight spot butterfly, Guam tree snail, humped tree snail, fragile tree snail, *B. guamense*, *C. micronesica*, *D. guamense*, *H. longipetiolata*, *T. rotensis*, and *T. guamense* and the role of the action area in the survival and recovery of these species as the context for evaluating the significance of the effects of the proposed Federal action, taken together with cumulative effects, for purposes of making the jeopardy determination.

Adverse Modification Determination

Past designations of critical habitat have used the terms “primary constituent elements” (PCEs), “physical or biological features” (PBFs) or “essential features” to characterize the key components of critical habitat that provide for the conservation of the listed species. The new definition of destruction or adverse modification of critical habitat was published as a final rule on February 11, 2016 (81 FR 7214) and discontinues the use of the terms PCEs or essential features, and relies exclusively on use of the term PBFs because that term is contained in the Act. However, the shift in terminology does not change the approach used in conducting a “destruction or adverse modification” analysis, which is the same regardless of whether the

original designation identified PCEs, PBFs or essential features. The only species addressed in this BO with designated critical habitat is the Mariana fruit bat. The adverse modification analysis for Mariana fruit bat critical habitat was conducted on the proposed Federal action in the 2015 BO (USFWS 2015a, pp. 103-104 and pp. 144-145). This analysis and the information used in the analysis remain unchanged and are referred to by reference in appropriate sections of this consultation.

STATUS OF THE SPECIES

Status of the Mariana fruit bat

Species Description

The Mariana fruit bat (fanihi in Chamorro) was listed as endangered in 1984, but was downlisted to threatened on January 6, 2005 when it was determined that all fruit bats on Guam and throughout the Commonwealth of the Northern Mariana Islands (CNMI) comprise a single subspecies (70 FR 1190). The Mariana fruit bat is the only fruit bat species under U.S. jurisdiction. In 2004, critical habitat for the fruit bat was designated at the GNWR in the Ritidian Unit (69 FR 62944).

The Mariana fruit bat is a medium-sized fruit bat in the family Pteropodidae, and weighs between 0.73 lb to 1.27 lb (331 g to 577 g). Male Mariana fruit bats are slightly larger than females. The underside (abdomen) is black to brown with gray hair interspersed that creates a grizzled appearance. The shoulders (mantle) and sides of the neck are bright golden brown, but may be paler in some individuals. The head varies from brown to dark brown. The well-formed, rounded ears and large eyes give the face a canine appearance (USFWS 2009 p. 4).

The paleotropical genus *Pteropus* is represented by approximately 63 species distributed across the Indian Ocean, Southern Asia, Australia, and in Oceania as far east as the Cook Islands (Almeida et al. 2014 p. 83). Most species in the genus *Pteropus* occur on islands or in coastal areas (Almeida et al. 2014 p. 84). Four species in the genus *Pteropus* are extinct and 38 species (60 percent of the genus) are considered critically endangered, endangered, threatened, near threatened, or vulnerable under the definitions of the IUCN (IUCN 2017). One of the four extinct species, *Pteropus tokudae,* occurred only on Guam and has not been detected since 1968 (Bonaccorso et al. 2008; USFWS 2009).

Flannery (1995) and Simmons (2005) consider the Mariana fruit bat as one of two subspecies of fruit bats restricted to the Mariana Archipelago, with the Mariana fruit bat inhabiting the islands from Guam to Saipan and *P. mariannus paganensis* occurring on Pagan and Alamagan islands. However, subsequent genetic analysis conducted by Brown et al. (2011) indicate no genetic differentiation among islands within the Mariana Archipelago and that the bats on these islands, currently classified as two subspecies, should be managed as a single subspecies, *P. mariannus mariannus* (p. 940). In addition to the Mariana fruit bat, there are several other subspecies of *P. mariannus* endemic to other archipelagos, including the Caroline Islands and the Palau Archipelago (Brown et al. 2011 p. 934).

Critical Habitat Description

Approximately 376 ac (152 ha) were designated as critical habitat for the Mariana fruit bat on Guam (USFWS 2004, 46 pp). Critical habitat was identified using the guidelines provided by the Mariana fruit bat recovery plan (1990). Although the current population of Mariana fruit bats on Guam is small, and most Mariana fruit bats roost in a limited area, the foraging behavior and diverse diet of the Mariana fruit bats cause them to use most of the island for foraging (Wiles et al. 1995). Thus, all of the designated critical habitat for this species is used for foraging and/or roosting and is considered occupied.

Guam Critical Habitat Unit

The Guam critical habitat unit consists of approximately 376 ac (152 ha) of land in the fee simple portion of the GNWR. The vegetation in this unit consists of coastal, limestone, and secondary limestone forests, composed of native and introduced plant species and contains the full range of physical or biological features needed for the conservation of the Mariana fruit bat. This area is important because it contains areas used for foraging by the last known Mariana fruit bat colony (currently abandoned) on Guam. This area also contains roosting and foraging sites historically and currently used by Mariana fruit bats (USFWS 2004, p. 62951; J. Schwagerl, Service, pers. comm. 2015). This unit also encompasses essential conservation areas identified in the Mariana fruit bat recovery plan (USFWS 1990b). The draft revised recovery plan (USFWS 2009d) does not contain specific areas for recovery.

Current threats to Guam critical habitat unit include habitat loss, degradation, and fragmentation due to development, military training, and fire, human disturbance, introduced ungulates, invasive plants, and non-native predators. Actions that exacerbate these threats or result in new threats, individually or in combination, may result in appreciably decreasing habitat value or quality of habitat necessary for the recovery and survival of Mariana fruit bats on Guam.

Recent conservation actions in the Guam critical habitat unit include construction of a multi-species enclosure fence at the GNWR at Ritidian Point, BTS trapping and ungulate removal within the enclosure fence; and out-planting of native plants including *S. nelsonii*.

Physical or Biological Features

The physical or biological features required by the Mariana fruit bat for the biological needs of foraging, sheltering, roosting, and rearing of young are found in areas supporting limestone, secondary, ravine, swamp, agricultural, and coastal forests composed of native and introduced plant species. These forest types provide the physical or biological features of:

- Plant species used for foraging, such as *Artocarpus* spp., *Carica papaya*, *Cycas micronesica*, *Ficus* spp., *Pandanus tectorius*, *Cocos nucifera*, and *Terminalia catappa*; and
- Remote locations, often within 328 ft. (100 m) of cliff lines that are 260 to 590 ft. (80 to 180 m) tall, with limited exposure to human disturbance and that contain mature *Ficus* spp., *Mammea odorata*, *Casuarina equisetifolia*, *Macaranga*

thompsonii, *Guettarda speciosa*, *Neisosperma oppositifolia*, and other tree species that are used for roosting and reproductive activity.

Life History

Mariana fruit bats, similar to other bats in the Pteropodidae family, do not use laryngeal echolocation, instead relying primarily on vision and smell to avoid obstacles and locate food sources (Almeida et al. 2014) . Mariana fruit bats vocalize readily within colonies and when roosting. The diet of the Mariana fruit bat is comprised of fruits, nectar, pollen, and some leaves from at least 45 different plant species (Mildenstein & Johnson 2017) . Rapid digestion and metabolism of such foods makes these animals reliant on forest habitat with diverse food resources available throughout the year (USFWS 2009 p. vi). Mariana fruit bats use several forest types for foraging, roosting, and breeding, including native primary and secondary limestone forest, volcanic (or ravine) forest, old coconut plantations, and groves of *Casuarina equisetifolia* (Rice & Taisacan 1988; Worthington et al. 2001 p. 137; Wiles & Johnson 2004 p. 589,591). Most Mariana fruit bats roost during the day in maternity colonies at sites to which they show a high level of fidelity (unless disturbed). A small proportion of Mariana fruit bats, usually males, roost alone or in small groups called bachelor colonies. Within colonies, Mariana fruit bats typically group themselves into harems (one male and 2-15 females) or bachelor groups (predominantly males) (Wiles 1987).

Population Dynamics

Population demographic information for the Mariana fruit bat is limited. Based on three-years of field observations on Guam similar to other Pteropodidae species, female Mariana fruit bats rear up to one pup annually (USFWS 2009) and likely have a gestation period of approximately 4.6 to 6.3 months (Pierson & Rainey 1992 pp. 1–17). Many *Pteropus* species typically do not give birth until 18 months of age (Pierson & Rainey 1992 pp. 1–17; McIlwee & Martin 2002 p. 76). Lifespan of substantially larger species, *P. alecto*, in Australia is four to five years, with a maximum of eight years (Vardon & Tidemann 2000).

Based on this demographic information, several authors have suggested that *Pteropus* bats have a low maximum population growth rate and thus a slow rate of recovery when a population is diminished (Pierson & Rainey 1992 p. 76; McIlwee & Martin 2002). **Table 7** provides current population sizes per island and other demographic data (Mildenstein & Johnson 2017 p. 20).

Table 7. Mariana fruit bat population sizes and density by island.

Island	Forest Habitat (ha)	No. of Bats	Density
Guam	25,711	45	0.00
Rota	6,663	4,149	0.62
Aguiguan	302	50	0.17
Tinian	6,481	< 25	0.00
Saipan	5,355	< 50	0.01
Farallon de Medinilla	< 1	< 5	--
Anatahan	N/A[2]	150	--

Sarigan	169	157	0.93
Guguan	170	226	1.33
Alamagan	485	86	0.18
Pagan	1,971	1,017	0.52
Agrihan	2,336	858	0.37
Asuncion	316	573	1.81
Maug	48	11[1]	

[1]Insufficient data available.

Status and Distribution

The Mariana fruit bat is endemic to the Mariana Archipelago (**Figure 6**). The Mariana Archipelago extends across 459 nautical miles (nmi) (850 km) and is comprised of the U.S. Territory of Guam and 14 islands constituting the CNMI. The Mariana fruit bat is found on all 15 islands within the Marianas, except for Uracas, the northernmost island (Wiles et al. 1989 p. 69). The Mariana fruit bat is currently thought to be extirpated from Tinian (USFWS 2014 p. 3). A single Mariana fruit bat was photographed on Farallon de Medinilla on two occasions, in 1996 and in 2008 (DON 2013 pp. 4–123).

Mariana fruit bats in general are strong fliers and highly mobile and small groups have been observed flying over the ocean between islands (Wiles & Glass 1990 p. 2; Wiles & Johnson 2004 p. 593). Distances between are: Guam to Rota, 32.3 nmi (60 km); Rota to Aguijan, 42.1 nmi (78 km); Aguijan to Tinian, 4.9 nmi (9 km); Tinian to Saipan, 2.7 nmi (5 km); Saipan to Farallon de Medinilla, 45.9 nmi (85 km); and Saipan to Anatahan, 64.3 nmi (119 km). In the remaining northern Marianas, interisland distances range from 15.7 nmi to 54.0 nmi (29 km to 100 km). All islands have a maximum elevation ranging from 551 ft to 3,166 ft (168 m to 965 m) with the exception of Farallon de Medinilla, which has a maximum elevation of 266 ft (81 m). All islands are visible in clear weather from the tops of adjacent islands (Wiles & Glass 1990 p. 1).

Distribution of occupied Mariana fruit bat roost sites have fluctuated sharply in the southern islands and are thought to be due to variations in survey methods, coverage, and movements of Mariana fruit bats between islands (USFWS 2009 p. 9). Initial observations of Mariana fruit bats in the southern islands (Aguiguan, Tinian, and Saipan) in 1983 and 1984 revealed populations of less than 25 to 50 Mariana fruit bats on each island. Mariana fruit bat numbers increased to about 75 to 100 individuals on Saipan in 1986 and to about 300 individuals on Aguiguan by 1988 (Wiles & Glass 1990 p. 2). Mariana fruit bats on Rota are believed to move periodically among the southern islands, and thus Rota is considered to be important to the long-term stability of the species in the southern part of the Marianas (Wiles & Glass 1990 p. 2; Wiles et al. 1995). Historic numbers of Mariana fruit bats on Guam have been between 400 and 800 since 1984, but have since been decreasing. By the early 1980s nearly all Mariana fruit bats on Guam lived in Northern Guam in a single colony, which occasionally divided into several smaller aggregations (Wiles & Glass 1990 p. 2; Mildenstein & Johnson 2017 p. 25).

Survey data in the northern islands (Anatahan, Sarigan, Guguan, Alamagan, Pagan, and Agrihan; excluding Asuncion and Maug, which were not surveyed during this time period), indicate a 40

percent decline in Mariana fruit bat numbers between 1983 and 2000 (USFWS 2009 p. 11). In the 2014 5-year review, Mariana fruit bats were found to be stable or declining throughout most of their range; the only exception being on Rota where populations were increasing since 2008 due to increased enforcement of wildlife reguations (USFWS 2014). Approximately 42 percent and 58 percent of the entire Mariana fruit bat population resides in the northern and southern islands, respectively (**Figure 6**; (Mildenstein & Johnson 2017)).

Threats

Illegal hunting, loss of native forest, predation by the BTS on Guam, and the increased risk of extirpation or extinction faced by small, fragmented populations are the most significant threats to the survival of the Mariana fruit bat (USFWS 2014). These current known and potential threats are discussed below.

Threats:

- Loss or Degradation of Habitat:
    - Human development is a factor in habitat loss on all inhabited southern islands and on northern islands with military activity.
    - Feral ungulates and Philippine sambar deer (*Rusa marianna*) degrade habitat on many of the Mariana Islands. The successful eradication of feral ungulates from Sarigan and Anatahan suggests that similar projects may succeed on other islands. However, once grazing and browsing pressure is removed, the potential invasion of native forest by alien plants may be a more difficult and long-term recovery issue.
- Human Disturbance:
    - Illegal hunting is a threat to Mariana fruit bats throughout its range. Although law enforcement activity has increased since 2009 (CNMI -DLNR 2008; CNMI-DLNR 2009a, 2009b, 2010), illegal hunting of Mariana fruit bats on Rota continues and will likely resume to historical levels unless consistent, effective law enforcement efforts in tandem with education and outreach programs continue. Mariana fruit bats appear to be declining on Tinian, Saipan and Guam, and illegal hunting is thought to have greatly contributed to the decimation or decline of those populations (Wiles & Payne 1986; Wiles & Glass 1990; Sheeline 1991; Stinson & Glass 1992; Esselstyn et al. 2006). As with Rota, recovery of the Mariana fruit bat on human-inhabited islands will not likely be possible without strong education programs combined with effective control of illegal hunting.
- Nonnative Snake Predation:
    - Brown tree snakes prey on non-volant young left at the roost during the night, thus preventing the recruitment of young bats into the breeding population. Effective control of BTS must be achieved before the Mariana fruit bat population on Guam can recover. The interdiction, control, and ultimate eradication of BTS in the archipelago are the focus of major, ongoing projects, and the Mariana fruit bat is likely to benefit from these efforts in the long term. This prognosis would change drastically if the BTS were to become established widely throughout the archipelago.
- Stochastic Events:

- Typhoons and volcanic eruptions result in mortality, reduced population viability, and habitat loss. Natural disasters can be especially damaging to the viability of smaller Mariana fruit bat populations (e.g., on Guam, Saipan, Aguiguan, and Maug). The significant loss of habitat on Anatahan after the volcanic eruption in 2003 resulted in the loss of a substantial Mariana fruit bat population that has not yet recovered.

Mariana Fruit Bat Recovery Criteria

A draft revised recovery plan for the Mariana fruit bat (USFWS 2009d) addressed actions needed for the survival and recovery needs of the Mariana fruit bat. Since publication of the draft revised recovery plan, new information on the Mariana fruit bat has resulted in changes to how we look at recovery for the species. We now consider recovery in terms of stable or increasing subpopulations of sufficient size distributed across Guam and the Mariana Islands. To meet recovery objectives, stable or increasing fruit bat subpopulations should at a minimum be distributed on the islands that currently have extant populations (USFWS 2009d). Actions that reduce or eliminate the potential for self-sustaining populations of resident Mariana fruit bats on Guam may hamper or preclude recovery of the species. The reduction or elimination of this potential may take many forms: degradation or loss of habitat and resources required by the fruit bat for foraging, roosting, and reproduction; increased exposure of fruit bats to illegal hunting and other sources of human disturbance; and introduction of non-native predators that prey upon fruit bats. In order for the Mariana fruit bat's population to recover on Guam, sufficient amounts of functional habitat will need to be protected and restored on Guam (USFWS 2009d).

Guam contains a large proportion of the remaining native limestone forest in the southern inhabited Mariana Islands, and most of that habitat is located within DoD lands. Habitat loss and degradation, illegal hunting, predation by non-native predators, and human disturbance currently impact fruit bats within the action area. If threat levels increase within Mariana fruit bat habitat in the action area, it may further inhibit the potential for the species to recover.

Survival and Recovery Needs

Before the Mariana fruit bat is considered for delisting, the Service proposes that stable or increasing populations should exist on three of the five southern islands (Saipan, Tinian, Aguiguan, Rota, and Guam), and six of the northern islands where Mariana fruit bats have persisted historically (Anatahan, Sarigan, Guguan, Alamagan, Pagan, Agrihan, Asuncion, and Maug; (USFWS 2009 pp. 40–41). Of the six northern islands that require stable or increasing numbers, two of these must include Pagan, Anatahan, or Agrihan. Since publication of the draft revised recovery plan in 2009 (USFWS 2009), new information on the Mariana fruit bat has resulted in changes to how we look at recovery for the species. We now consider recovery in terms of stable or increasing subpopulations of sufficient size distributed across Guam and the Mariana Islands. To meet recovery objectives, stable or increasing Mariana fruit bat subpopulations should at a minimum be distributed on the islands that currently have extant populations (USFWS 2009). The final version of the Mariana fruit bat recovery plan is currently in review, and recovery criteria stated here may change upon completion of the final plan.

Of the six northern islands, the only evidence for a possibly increasing population is on Asuncion (USGS 2010 p. 33). Of the five southern islands, only Rota has achieved an increasing population. Although a conservation area containing some important habitat for Mariana fruit bats was established on Rota (USFWS 2011 p. 1), there is not currently enough protected Mariana fruit bat habitat on Rota, Guam, Tinian, or Saipan to support substantial population recovery on any of those islands. Even if sufficient habitat is set aside in conservation to support recovery of populations, controlling illegal hunting may continue to be a challenge that limits recovery of the species (USFWS 2014 p. 5).

Status of the Mariana eight spot butterfly

Species Description

The Mariana eight spot butterfly (abbabang in Chamorro, or libweibwogh in Carolinian) was federally listed as endangered under the Act on October 1, 2015 (80 FR 59423). No critical habitat has been designated for this species. A recovery plan for the Mariana eight spot butterfly has not been completed.

The Mariana eight spot butterfly is a medium-sized butterfly in the Nymphalidae family (Schreiner & Nafus 1997 p. 28). The Mariana eight spot butterfly was originally described by Butler in 1869 and is recognized as a distinct taxon in Swezey (1942 p. 35), the most recent and accepted taxonomy for this subspecies. In addition to the Mariana eight spot butterfly, there are several other subspecies endemic to specific archipelagos, including New Caledonia, Vanuatu, and Palau (Samson 1986 p. 16; Schreiner & Nafus 1997 p. 36).

Like most nymphalid butterflies, orange and black are the two primary colors exhibited by Mariana eight spot butterfly. Unlike other species in the genus *Hypolimnas*, male and female Mariana eight spot butterflies are similar and exhibit no sexual dimorphism (Schreiner & Nafus 1996 p. 36; Campora & Lee 2009 p. 5). The larvae of Mariana eight spot butterfly maintains a black head through all instars, and their spines are more red than orange (Schreiner & Nafus 1997 p. 36). This characteristic sets them apart from larvae of the non-native *H. bolina* from New Zealand and *H. anomala* from Malaysia, both which occur on Guam. All three species (*H. bolina*, *H. anomala*, and the Mariana eight spot butterfly) have larvae that look similar in appearance during their immature stages (Schreiner & Nafus 1997 p. 36; Campora & Lee 2009 p. 4; Lindstrom & Benedict 2014 p. 18).

Life History

The Mariana eight spot butterfly undergoes seven life stages before pupating into a reproductive adult (**Table 8**) (Schreiner & Nafus 1996 pp. 3–5). Large sixth instar caterpillars of the Mariana eight spot butterfly often travel farther distances in search of food and will find a cryptic location for pupation (Schreiner & Nafus 1996 p. 3). As a result, the length of time spent as a pupa and longevity of adults is unknown (Moore 2014 p. B17). Adult Mariana eight spot butterflies are most abundant between December and February (Moore 2014 p. B16). These months include the end of the rainy season and the beginning of the dry season on Guam.

Butterflies in general require sufficient food resources to support various stages of growth. Larval feeding first supports growth of the larval insect, and at subsequent instar stages, growth stops and accumulated larval nutrients are stored for proper adult growth (Boggs & Freeman 2005 p. 353). Boggs and Freeman (2005) found that restricting the food intake at the larval stage decreased adult longevity and female fecundity levels (p. 359).

Table 8. Estimated life stages of the Mariana eight spot butterfly and mortality rates at each stage, based on a year-long study at a single site on Guam.

Stage	Duration (days)	No. Found	No. Found After Hatching / Molting to Next Stage	Percent Recovered
Egg	6	445	45	10
1st Instar	2.4 ± 0.6	47	21	44
2nd Instar	2.0 ± 0.7	37	21	57
3rd Instar	2.5 ± 0.8	36	32	88
4th Instar	2.9 ± 0.8	46	30	65
5th Instar	3.7 ± 1.0	46	33	72
6th Instar	6.1 ± 1.5	51	15	29

Population Dynamics

Little is known about the factors affecting population dynamics of the Mariana eight spot butterfly. However, recently Rubinoff (2016) suggested that Mariana eight spot butterflies show metapopulation dynamics (pp. 4-5). Because most insects are short-lived in the adult stage, and cryptic in other stages, detection and assessment of minimum viable habitat size may require repeated visits over multiple years to properly assess occupied patches that may depend on varying environmental conditions or site characteristics (Eiben & Rubinoff 2014 p. 1077). Some sites on Guam are used occasionally by populations of the Mariana eight spot butterfly or may be used to support connectivity across the landscape (Rubinoff 2016 p. 5).

Within a population, Schreiner and Nafus (1996; Table 11) found that mortality rates are high in the juvenile stages. The Mariana eight spot butterfly occurs in low numbers (Moore 2014 pp. B7-16) likely in response to habitat loss and fragmentation that has reduced the distribution and abundance of host plants, and reduced the connectivity between extant, but discrete local populations. For example, over a year-long survey on Guam across 12 different sites, a maximum total of six adult Mariana eight spot butterflies were observed in one day (Schreiner & Nafus 1996 p. 2). If the distribution and abundance of host plants and the connectivity between Mariana eight spot butterfly populations continue to decline and they become increasingly isolated in distribution, the distance between patches of suitable habitat may become too great to sustain the species (Rubinoff 2016 p. 6).

Status and Distribution

The Mariana eight spot butterfly is endemic to Guam and Saipan (Lindstrom & Benedict 2014 p. 9). The Mariana eight spot butterfly is likely extirpated from Saipan (Schreiner & Nafus 1997 p. 36; Moore 2014 pp. B7–B10). In 2014, *H. octocula marianensis* was known from six locations on Guam: Orote Point, Hilaan, Tweed's Cave area, Pagat Cave area, Mangilao golf course and

Fadian cove (Lindstrom & Benedict 2014 p. 9). Other locations have also been reported by Dr. Curt Fiedler (pers comm 2017). Dr. Fiedler has reported observations in four additional locations: (1) east and (2) west of the GNWR headquarters along the base of the cliff at sea level, (3) patches of host plants near Taguan (1,000 steps trail), and (4) large patches of host plants inland at Faifai beach (northern edge of Tumon Bay). An estimate of a one-kilometer buffer is used to distinguish between subpopulations and represents maximum butterfly flight distance, based on similar species under similar conditions (Hill et al. 1996 p. 730).

The Mariana eight spot butterfly appears to be constrained by available host plants. Larvae of Mariana eight spot butterfly feed on two native plants: *Elatostema calcareum* and *Procris pedunculata* (Campora & Lee 2009 p. 1; Moore 2014 p. B16). Both host plants are from the family Urticaceae and occur in wet, native forest areas with exposed limestone karst. Schreiner and Nafus (1996) noted a close association in the occurrence of the butterfly's life stages with the presence of host plants (p. 2). On Guam, multi-year surveys show that *E. calcareum* and *P. pedunculata* are rare and usually are observed in small patches irregularly distributed almost exclusively along the cliff edges, or embedded in tall towers of karst along the shore or in forested areas, where nonnative ungulates cannot reach them easily (Moore 2014 p. B22).

Threats

The following list of factors influencing the current condition of the Mariana eight spot butterfly are based on the findings reported by (Lindstrom & Benedict 2014 pp. 34–35; Moore 2014 pp. B21-21; Rubinoff 2016 p. 4):

- Loss and Degradation of Habitat (especially host plants):
    - Urban and agricultural development, ungulates, military training, urbanization, the spread of nonnative plants that displace native plants, and inadvertent damage to host plants by humans (e.g., coconut crab hunters who deploy traps near host plants) – all contribute to the loss of habitat for *H. octocula marianensis*.
    - Loss or degradation of habitat causes the loss of important habitat corridors that function to support gene flow and maintain population connectivity.
- Predation from Non-native Species:
    - Two genera of parasitic wasps (*Ooencyrtus* sp. and *Telenomus* sp.) have been documented to cause mortality of *H. octocula marianensis* eggs.
    - Species of nonnative ants have also been documented predating on eggs and larvae.
- Stochastic Events:
    - Typhoons result in mortality, reduced population viability, and habitat loss. Natural disasters can be especially damaging to the viability of already fragmented populations.

Survival and Recovery Needs

The range-wide population of the Mariana eight spot butterfly is comprised of up to 10 known local populations. All of these local populations are small, geographically restricted, and subject to further decline due to habitat loss and predation from non-native species. The likelihood of this species surviving and recovering is dependent on ensuring a functional metapopulation of

Mariana eight spot butterflies. Given the current status of this species, achieving that condition requires maintaining and enhancing the viability of all ten known populations and the reestablishment of additional populations in forest habitat patches that facilitate connectivity between Mariana eight spot butterfly local populations. Avoiding or effectively offsetting adverse effects to butterfly-occupied habitat is critical to maintaining the diminished resiliency of the entire Mariana eight spot butterfly population during this population bottle-neck.

More specifically, the conservation needs of the Mariana eight spot butterfly are as follows:

1. Protection, restoration, and enhancement of interconnected patches of high quality butterfly habitat (containing host plants) that are distributed across the landscape of Guam within the flight range of dispersing Mariana eight spot butterflies is essential to its conservation. Based on best available information on the conservation biology of nymphalid butterflies (Bonebrake et al. 2010 pp. 1831–1841) and consideration of the basic principles of conservation biology (Groom et al. 2006 pp. 15–19), the Service finds that a minimum of six discrete populations that are spatially distributed to accommodate a sufficient degree of connectivity between populations are needed to sustain a persistent population of the Mariana eight spot butterfly on Guam. Habitat protection is essential to the Mariana eight spot butterfly. Habitat should be contiguous and include both nectar and known host plants, with the protection of occupied host plants given the highest priority (A. Moore, UOG, pers. comm. 2016; M. Richardson, USFWS, pers. comm. 2016.). Because the Mariana eight spot butterfly is dependent on two rare host plant species (*E. calcareum* and *P. pedunculata*), the Mariana eight spot butterfly is at a high risk of extinction on Guam from ongoing habitat loss and destruction. Because the population is currently small and geographically restricted, it is vulnerable to loss of genetic diversity, catastrophic environmental events, and random fluctuations in demographic parameters. Expansion of the existing metapopulation and reestablishment of populations in unoccupied suitable habitat is essential to protect this species against these threats.
2. Given its highly degraded and vulnerable status in the wild, a timely and effective captive propagation and reintroduction program for the Mariana eight spot butterfly is needed.
3. A high priority should be placed on the timely gathering of additional life history information on the Mariana eight spot butterfly, especially in terms of understanding the metapopulation structure and needs of the overall population. Maintaining adequate connectivity between and among habitat patches and local populations is essential to both its survival and recovery. If host plant populations continue to decline and become further isolated, the distance between patches may become too great to sustain the species (Rubinoff 2016 p. 6).
4. The exclusion of feral ungulates from, and the reintroduction of larval host plants to, limestone forest areas is a very important and promising conservation measure (Moore 2014 p. B22).
5. Control of non-native plants, ants, and slugs is also important for the Mariana eight spot butterfly's survival and recovery in the wild.

Status of the Partulid Snails

The family Partulidae consists of approximately 120 species of snails in three genera (*Eua*, *Samoana* and *Partula*) across the Pacific Islands, many of which are restricted to a single island. *Partula* is the most diverse genus with approximately 92 species described; there are 23 *Samoana* species and four *Eua* species (Lee et al. 2014). Partulid snails are endemic to the high islands of Oceania (i.e., islands with sufficient elevation to generate their own precipitation and support rain forest formation). Of the six partulid snail species described from the Mariana Islands, only three extant species remain: the Guam tree snail (*P. radiolata*), humped tree snail (*P. gibba*), and the fragile tree snail (*S. fragilis*).

Endemic Partulids have become increasingly exposed to continental predators as human settlement and globalization have facilitated these introductions. Some degree of biotic isolation that can be maintained can provide refuge for these tree snails and will contribute to the increased survival of species in their native habitats (Lee et al. 2014).

The Guam tree snail, humped tree snail, and fragile tree snail share similar life history characteristics described below and co-occur within extant populations. Species in the Partulidae family are predominantly nocturnal, arboreal, herbivorous and are relatively long-lived. They are also slow reproducing, ovoviviparous (give birth to live young), and cross- or self-fertilizing hermaphrodites (Cowie 1992). The life-expectancy of partulids can be greater than 5 years and reproduction of up to 18 young per year begins within the first year through the entire life-span (Cowie 1992).

Status of the Guam tree snail

Species Description

The Guam tree snail (akaleha or denden in Chamorro), is a member of the Partulidae family, was federally listed as endangered under the Act on October 1, 2015 (80 FR 59423). No critical habitat has been designated for this species. A recovery plan for the Guam tree snail has not been completed. The species was also listed as endangered by the Government of Guam in 2009.

Guam tree snail shells are dextral with an obtuse spire, and five whorls. The peristome is simple thin and white. The background color is pale straw with darker axial rays and brown lines. Adult length is 0.5 in to 0.7 in (13 mm to 18.5 mm), and 0.3 in to 0.5 in width (8 mm to 12 mm) (Smith et al. 2008). Juveniles can be mistaken for the fragile tree snail.

Life History

Little is known about the life history of the Guam tree snail. This species is found in bushes on the undersides of leaves. The preferred habitat is cool, shaded forest habitat with high humidity and reduced air movement that prevents excessive water loss. Increased mobility is associated with snails in habitats with greater humidity and precipitation. Partulids feed primarily on a range of living, dead or decaying plant material (Cowie 1992 p. 167) and there is no clear obligate relationship with any particular type of tree or bush. Guam tree snail populations showed a very low degree of genetic heterogeneity among all surveyed populations indicating some degree of population specific genetic diversity, there was no discernible colony specific/geographic patterns (Lindstrom & Benedict 2014).

Population Dynamics

The historic population size of the Guam tree snail is unknown; however, more than 2,000 individuals were collected across 37 sites in the 1920s (Crampton 1925). Lindstrom and Benedict (2014) indicated that the Guam tree snail was not found in many sites surveyed in 1989 (Hopper & Smith 1992). However, in both 1989 and 2013, the Guam tree snail was both the most widespread and common Partulid snail on Guam (Hopper & Smith 1992; Moore 2014). At the time of listing in 2015, there were no more than 26 colonies of Guam tree snails, with between 10 and 150 individuals per colony.

Surveys in 2013 on Guam provide the most complete population information that is currently available. On DoD property, 328 Guam tree snails were found in two locations (Lindstrom & Benedict 2014). In addition, a total of 38 live snails were documented in Anderson South in February 2017 (**Figure 10**). Outside of DoD property, more than 363 Guam tree snails were documented during timed searches in 11 different locations (Lindstrom & Benedict 2014).

Status and Distribution

The Guam tree snail is endemic to the island of Guam and is the most commonly encountered Partulid snail on the island. Historically, Guam tree snails occurred across the island in suitable and widely available strand vegetation, forested river borders and lowland and highland forests. The Guam tree snail has been found in coconut forests, similar to the humped tree snail; however, the Guam tree snail's range also includes range into scrub forests and limestone forests, especially those dominated by *O. oppositifolia*. They have been found on a wide variety of plants including both natives and nonnatives (Lindstrom & Benedict 2014).

Threats

The following threats to the species contributed to its listing or were identified subsequent to listing and continue to to be an issue in the ability of the species to recover.

- Loss or degradation of habitat
    - Ungulates not only graze upon snail host plant species (both native and nonnative), but cause profound changes to the understory of forest habitats, which in turn affect tree snail populations (Smith et al. 2008; Smith 2013).
    - *Leucaena leucocephala*, an introduced shrub or tree, grows quickly and forms dense thickets that crowd out native canopy trees. This transition has created a drier understory which is likely less suitable for the Guam tree snail and other listed tree snails (Hopper & Smith 1992).
    - Human development, urbanization and military activity threaten all Partulid populations on both inhabited and uninhabited islands as they result in a loss, fragmentation and/or degradation of native forest habitat and the plants on which the tree snails live.
- Low population numbers

    - The low degree of genetic heterogeneity throughout the island makes the species less resilient evolutionarily and more prone to extinction pressures
    - Stochastic events (i.e. typhoons, disease) are likely to have disproportionate effects on small populations and/or those with little to no genetic diversity
- Nonnative species predation
    - The alien carnivorious flatworm (i.e. manokwari flatworm), predatory snails (i.e. rosy wolf snail and *Gonaxis* spp.) and rats significantly threaten tree snail persistence.
- Direct human impact
    - The collection of snail shells for trade may contribute to additional decline of the Guam tree snail.

Survival and Recovery Needs

The eradication of ungulates from occupied sites, as well as sites that previously contained the Guam tree snail (Crampton 1925; Hopper & Smith 1992), will serve both to enhance conditions for populations already present and contribute to additional habitat that may become occupied.

Predation rates and sources of predation must be assessed in order to minimize their impact when possible and effectively manage Partulid snail populations on Guam. It is necessary to further characterize the impact of the flatworm, by assessing their activity patterns, habitat and dietary preferences, distribution and reproductive capacity in order to reduce predation by the nonnative species.

Comprehensive studies are needed on the basic biology of the Guam tree snail. Relatively little is known about their life history and much needs to be learned before their conservation can be effectively addressed. There is very little knowledge about basic biological requirements, reproductive output, survival rates, longevity, predation risks, activity patterns, feeding behavior, and seasonal patterns of abundance.

Additional surveys focused in locations that have not yet been adequately surveyed should be prioritized. Surveys are needed to examine locations that are isolated and physically difficult to access on Guam, or determine the presence and status of populations on other Mariana Islands. However, conducting repetitive exploratory surveys in the same locations on Guam at the expense of general biological studies and protecting current occurrence locations could divert resources away from where they are needed most.

Status of the Humped Tree Snail

Species Description

The humped tree snail (akaleha or denden in Chamorro) was federally listed as endangered on October 1, 2015 (80 FR 59423). No critical habitat has been designated for this species. A recovery plan for the humped tree snail has not been completed. The species was also listed as endangered by the Government of Guam in 2009. The species is part of the Partulidae family, as described above.

Humped tree snail shells are primarily dextral with an acute spire, 4 to 4 ½ whorls with the last whorl gibbous. Humped tree snail whorls are various shades of white or brown with the background color variable, chestnut brown to whitish-yellow, and purple. Adult length is 14 to 18 mm, and width 10 to 14 mm (Smith et al. 2008).

Life History

Little is known about the life history of the humped tree snail. Humped tree snails are generally an arboreal species, found in the sub-canopy of mixed native forests with good understory and ground cover (Hopper & Smith 1992; Smith et al. 2008; Hadfield 2010). There is no particular obligate relationship with any particular type of tree or bush; however, they are most often found on the endemic *Piper guamensis*. They are also commonly found on coconut palms and ferns, including *Microsorium punctatum*, on Guam. Compared to the Guam tree snail, humped tree sanils were generally observed on fewer host species (Hopper & Smith 1992).

Increased mobility is associated with snails in habitats with greater humidity and precipitation. Humped tree snails feed primarily on a wide range of living, dead or decaying plant material (Cowie 1992 p. 167). The humped tree snail has also been observed consuming Mariana fruit bat ejecta (Berry 2016).

Population Dynamics

Partulid snails face a significant conservation crisis across the Pacific, as seen by declines in abundance and a number of extinctions (Lydeard et al. 2004). In 1992, Hopper and Smith described their concern for the apparent drastic loss of humped tree snails since the initial 1920 survey (Crampton 1925). At the time of listing in 2015, the population of humped tree snails on Guam declined to approximately 100 individuals and today, the humped tree snail is only found at one location, Haputo Beach (Lindstrom & Benedict 2014). The humped tree snail is the least common of the three listed tree snail species on Guam. By 2008, no humped tree snails were found on Rota, Tinian, or Aguiguan potentially due to extensive deforestation and agriculture (Smith et al. 2008; Hadfield 2010). Population decline of humped tree snails has been reported on most islands of the CNMI; however, population estimates on the islands are unknown (CNMI-DLNR 2015).

Status and Distribution

The humped tree snail was the first *Partula* described from the Mariana Islands in 1821 and was distributed across the archipelago (Kerr 2013). The range of the humped tree snail includes Guam, Rota, Aguiguan, Tinian, Saipan, Anatahan, Sarigan, Alamagan, and Pagan (Kurozumi 1994; Smith et al. 2008). Current comprehensive surveys have not been conducted, however data indicate that the humped tree snail is declining across its range but may still be common on some northern islands, such as Pagan and Sarigan (Kerr 2013).

In 1920, humped tree snails were initially observed on Guam in at least 39 sites. By 1989, the humped tree snail was known from only one location, Haputo Beach which was not originally

identified as an occupied site (Hopper & Smith 1992). At the time of listing in 2015, humped tree snails were no longer found on Anatahan, possibly due to volcanic activity and were also not found on Aguiguan.

Threats

The following threats to the species contributed to its listing and continue to be an issue in the ability of the species to recover.

- Loss or degradation of habitat
    - Ungulates not only graze upon the host plant species, but cause profound changes to the understory of forest habitats, which in turn affect tree snail populations (Smith et al. 2008; Smith 2013).
    - *Leucaena leucocephala*, an introduced shrub or tree, grows quickly and forms dense thickets that crowd out native canopy trees. This transition has created a drier understory which is likely less suitable for the humped tree snail and other listed tree snails (Hopper & Smith 1992).
    - Human development, urbanization and military activity threaten all Partulid populations on both inhabited and uninhabited islands as they result in a loss, fragmentation and/or degradation of native forest habitat and the plants on which the tree snails live.
- Low population numbers
    - A single humped tree snail colony with few individuals likely exhibits little to no genetic diversity and is thus at extreme risk of extirpation as it is less resilient evolutionarily and more prone to extinction pressures.
    - Stochastic events (i.e. typhoons, disease) are likely to have disproportionate effects on small populations and/or those with little to no genetic diversity
- Nonnative species predation
    - The alien carnivorious flatworm (i.e. manokwari flatworm), predatory snails (i.e. rosy wolf snail and *Gonaxis* spp) and rats significantly threaten tree snail persistence.
- Direct human impact
    - The collection of snail shells for trade may contribute to additional decline of the humped tree snail.

Survival and Recovery Needs

The eradication of feral ungulates from sites that contain tree snails, as well as those that previously contained them, will serve both to enhance conditions for populations already present, and contribute to additional habitat that may become occupied. Tarague Basin was reported by Crampton in 1925 to have had all three snail species present. The area is still occupied by the Guam tree snail and may be a suitable habitat for the humped tree snail, as well as the fragile tree snail if ungulates are removed from the area (Crampton 1925; Lindstrom & Benedict 2014).

Predation rates and sources of predation must be assessed in order to minimize their impact when possible and effectively manage Partulid snail populations on Guam. It is necessary to further

characterize the impact of the flatworm, by assessing their activity patterns, habitat and dietary preferences, distribution and reproductive capacity in order to reduce predation by the nonnative species.

Comprehensive studies on the basic biology of the fragile tree snail are needed. Relatively little is known about their life history, and more needs to be learned before their conservation can be effectively addressed. There is very little knowledge about basic biological requirements, reproductive output, survival rates, longevity, predation risks, activity patterns, feeding behavior, and seasonal patterns of abundance. Thoroughly quantified population assessments of the humped tree snail across the range are needed to understand population trends.

Additional surveys focused in locations that have not yet been adequately surveyed should be prioritized. Surveys are needed to examine locations that are isolated and physically difficult to access on Guam, or determine the presence and status of populations of species on other Mariana Islands. However, conducting repetitive exploratory surveys in the same locations on Guam at the expense of general biological studies and protecting current occurrence locations could divert resources away from where they are needed most.

Status of the Fragile tree snail

Species Description

The fragile tree snail (akaleha or denden in Chamorro) was federally listed as endangered under the ESA on October 1, 2015 (80 FR 59423). No critical habitat has been designated for this species. A recovery plan for the fragile tree snail has not been completed. The species was also listed as endangered by the Government of Guam in 2009. The fragile tree snail is a member of the Partulidae family as described above.

The *Samoana* genus has a disjunct distribution: extensively distributed throughout Samoa to the Marquesas Islands in Polynesia. However, the fragile tree snail is the solitary western species, the only *Samoana* species to occur outside of southeastern Polynesia, 5,000 kilometers from its nearest congener in Fiji (Lee et al. 2014). It is now believed that the evolutionary origin of the *Samoana* genus is in the far western portion of the range. In the portion of the range, the fragile tree snail is only one of 22 species in the genus which can still be found (Lee et al. 2014). One hypothesis for the absence of the genus *Samoana* from much of the Western range of the genus may stem from (as yet unidentified) ecological factors that have driven original populations to extinction and prevented rare long-distant migrants from reestablishing new populations (Lee et al. 2014).

Fragile tree snail shells are dextral and pellucid with a conic spire, and four whorls. The peristome is thin but well expanded. The background color is buff with narrow darker maculations and whitish banding. Adult length is 12 to 16 mm, and width 10 to 12 mm. (Smith et al. 2008). Adults can be mistaken for juvenile Guam tree snails.

Life History

The life history of Mariana partulids is unknown. Cool, shaded forest with high humidity and reduced air movement that prevents excessive water loss is the preferred habitat. They live on subcanopy vegetation. Increased mobility is associated with snails in habitats with greater humidity and precipitation. Partulids feed on a range of living, dead or decaying plant material (Cowie 1992) and there is no clear obligate relationship with any particular type of tree or bush. However, the fragile tree snail was found on a smaller number of plants (approximately five) compared to the Guam tree snail (found on approximately 30 different plants) during one survey (Hopper & Smith 1992).

Thie fragile tree snail is unique among Mariana partulids in that the eggs are large (4.2 mm × 3.3 mm) and encapsulated by a calcareous shell. Further, the fragile tree snail reaches sexual maturity before growing a reflexed peristome, a trait not reported for any other partulid species (Crampton 1925).

Population Dynamics

Populations of the fragile tree snail have not been extensively quantified but are thought to be in decline compared to originally rare population sizes. Approximately 20 fragile tree snails were found in the two occurrences during recent surveys (Lindstrom & Benedict 2014). It was not possible to determine the maturity of individuals in the colony because of the unique characteristic of this species to reach maturity before the formation of the varical lip (Smith et al. 2008). In 1996, one colony of the fragile tree snail was found on the southern edge of the Sabana with unknown quantitative estimates of the number of individuals in the colony (Bauman 1996). The species has not been observed on Rota since 1996.

Status and Distribution

The fragile tree snail is endemic to Guam and Rota (Kerr 2013). Fragile tree snails are the only *Samoana* species to occur outside of southeastern Polynesia. Fragile tree snails are more commonly found in limestone forest habitat, but have also been found in beach back strand vegetation, generally dominated by the trees *Hernandia* spp. and *Cordia* spp., or in riverine forest where *Hibiscus tiliaceus* is predominant (Kerr 2013).

Historically, the fragile tree snail was known from 13 populations in northern Guam and one on Rota. It was originally described as rare and low in number (Crampton 1925; Easley 1970). In 1989, fragile tree snails were found only in the presence of the Guam tree snail and in only 6 of 26 surveyed sites distributed across Guam (Hopper & Smith 1992). By 2013, only two colonies were known on Guam (Pagua Point and Lost Pond) (Lindstrom & Benedict 2014) and one colony on Rota, but in a different location from the original colony (Bauman 1996). No genetic heterogeneity was found between the two fragile tree snail populations on Guam (Lindstrom & Benedict 2014).

Threats

The following threats to the species contributed to its listing or were identified subsequent to listing and continue to be an issue in the ability of the species to recover.

- Loss or degradation of habitat
    - Ungulates not only graze upon host plant species (both native and nonnative), but cause profound changes to the understory of forest habitats, which in turn affect tree snail populations (Smith et al. 2008; Smith 2013).
    - *Leucaena leucocephala*, an introduced shrub or tree, grows quickly and forms dense thickets that crowd out native canopy trees. This transition has created a drier understory which is likely less suitable for the fragile tree snail and other listed tree snails (Hopper & Smith 1992).
    - Human development, urbanization and military activity threaten all Partulid populations on both inhabited and uninhabited islands as they result in a loss, fragmentation and/or degradation of native forest habitat and the plants on which the tree snails live.
- Low population numbers
    - The two colonies of fragile tree snails showed no genetic heterogeneity, which is indicative of a small population that has recently undergone a population bottleneck and is isolated from other colonies. The lack of genetic diversity throughout the island makes the species less resilient evolutionarily and more prone to extinction pressures.
    - Stochastic events (i.e. typhoons, disease) are likely to have disproportionate effects on small populations and/or those with little to no genetic diversity.
- Nonnative species predation
    - The alien carnivorious bipaliid flatworm (*P. manokwari*), predatory snails (i.e., rosy wolf snail and *Gonaxis* spp.) as well as rats, significantly threaten tree snail persistence.
- Direct human impact
    - The collection of snail shells for trade may contribute to additional decline of the fragile tree snail.

Survival and Recovery Needs

The eradication of feral ungulates from sites that contain tree snails, as well as those that previously contained them, will serve both to enhance conditions for populations already present, and contribute to additional habitat that may become occupied. Tarague Basin was reported by Crampton in 1925 to have had all three snail species present. The area is still occupied by the Guam tree snail and may be a suitable habitat for the humped tree snail, as well as the fragile tree snail if ungulates are removed from the area (Crampton 1925; Lindstrom & Benedict 2014).

Predation rates and sources of predation must be assessed in order to minimize their impact when possible and effectively manage Partulid snail populations on Guam. It is necessary to further characterize the impact of the flatworm, by assessing their activity patterns, habitat and dietary preferences, distribution and reproductive capacity in order to reduce predation by the nonnative species.

Comprehensive studies on the basic biology of the fragile tree snail are needed. Relatively little is known about their life history, and more needs to be learned before their conservation can be effectively addressed. There is very little knowledge about basic biological requirements, reproductive output, survival rates, longevity, predation risks, activity patterns, feeding behavior, and seasonal patterns of abundance. Thoroughly quantified population assessments of the fragile tree snail across the range are needed to understand population trends.

Additional surveys focused in locations that have not yet been adequately surveyed should be prioritized. Surveys are needed to examine locations that are isolated and physically difficult to access on Guam, or determine the presence and status of populations of species on other Mariana Islands. However, conducting repetitive exploratory surveys in the same locations on Guam at the expense of general biological studies and protecting current occurrence locations could divert resources away from where they are needed most.

Status of the *Bulbophyllum guamense*

Species Description

Bulbophyllum guamense (siboyas hålum tåno in Chamorro) was federally listed as threatened under the Act on October 1, 2015 (80 FR 59423). No critical habitat has been designated for this species. A recovery plan for *B. guamense* has not been completed. *Bulbophyllum* is the largest genus in the Orchidaceae with an estimated 2,000 polymorphic epiphytes (growing on other plants), lithophytes (growing on rocks), or rarely terrestrial (growing on the ground) orchids (Costion & Lorence 2012).

Bulbophyllum guamense is an epiphytic orchid which occurs in large mat-like formations high on branches of big trees, as well as on smaller trees of coastal lowland/limestone forests. The pseudobulbs form a thick clump connected by very short rhizomes. *Bulbophyllum guamense* has leaves that are oblong, elliptic, 10 - 15 cm long and 2.6 - 3.8 mm wide (Stone 1970 p. 155). Flowers are single, fleshy, and greenish-yellow in color (Raulerson & Rinehart 1992 p. 90). The sepals are the most conspicuous part of the flower, while the yellow-green lip with its wine markings is hinged and extremely mobile (Raulerson & Rinehart 1992 p. 90).

Life History

Little is known about the life history of *B. guamense*. *Bulbophyllum guamense* is epiphytic and grows on trees within limestone forest type ecosystems. On Guam, *B. guamense* was found in the lower canopy of closed forests (about 10 feet {3 m}or less) (Zarones et al. 2015). On Rota, the species has been found at elevations greater than 984 ft (300 m) in the Sabana tableland, Sabana slopes and water cave regions, within tall and short limestone forest and secondary pandanus forest on emergent trees (Zarones et al. 2015). *Bulbophyllum guamense* has been observed in many native and non-native host tree species including: *Hernandia labyrinthica*, *Elaeocarpus joga, Premna serratifolia, Heritiera longipetiolata, Pisonia umbellifera*, *Persea Americana, Vitex parviflora, Areca catechu, Eugenia* spp., *Ficus* spp., *Dypsis* spp. or *Pandanus tetorius,* as well as in dead trees (Zarones et al. 2015; JRM 2016; DON 2017).

Typical to orchids in this genus, *B. guamense* has a carrion-like scent (Raulerson & Rinehart 1992 p. 90), and it is almost ever-blooming, as one flower drops, another replaces it until one is pollinated. The ovary then enlarges to form a ribbed capsule about five cm by one cm, where the dust-like seeds develop (Raulerson & Rinehart 1992 p. 90). *Bulbophyllum guamense* has a sympodial growth habit that form sequential pseudobulbs (with determinate growth). Research is currently being conducted to determine if the numbers of orchids can be increased vegetatively by division within a nursery environment (J. McConnell 2016).

Population Dynamics

At the time of listing in 2015, approximately 500 *B. guamense* individuals were identified throughout the species range, with approximately half on Guam and half on Rota, representing a population decline. There is limited information on the population structure on Guam. On Rota, approximately 200 *B. guamense* individuals were found with a population structure consisting of seedlings, juveniles, and flowering adults in a specialized niche habitat within the forest ecosystem (Zarones et al. 2015).

Status and Distribution

Bulbophyllum guamense is endemic to Guam and Rota and is widely-distributed (Raulerson & Rinehart 1992 p. 90). Historically, *B. guamense* was recorded on Guam from clifflines encircling the island, and on the slopes of Mt. Lamlam and Mt. Almagosa. In 1992, this species was reported to occur in large mat-like formations on trees "all over the island," (Guam) (Raulerson & Rinehart 1992 p. 90). At the time of listing in 2015, there were 12 known occurrences, three on Guam and nine on Rota, along Rota's Sabana tableland and slopes above 980 ft (300 m) elevation (Zarones et al. 2015).

Threats

The following threats to the species contributed to its listing or were identified subsequent to listing and continue to to be an issue in the ability of the species to recover.

- Loss or degradation of habitat
    - Ungulates grazing upon forest plant species impact many native plants resulting in profound changes to the forest habitat. In the absence of ungulates, healthier and more pristine forest habitats contain a broader species composition and structure on which epiphytic orchids depend.
    - Nonnative plants can degrade forest habitats. *B. guamense* has been found on both native and nonnative trees; however, the health and persistence of the orchid on native and nonnative trees is unknown.
    - Urbanization and development as well as natural or incidental fire, directly impact and reduce habitat availability for epiphytic orchids.
    - Edge effects due to disturbance and fragmentation have been shown to negatively impact orchids in cloud forests (Parra Sánchez et al. 2016).

- Stochastic Events, primarily typhoons degrade forest. Affected forest areas may require several years to become reestablished and this can be exacerbated if habitats are reduced or degraded.

Survival and Recovery Needs

In order to ensure the survival of *B. guamense*, wild populations and habitat needs to be protected and maintained on Guam and Rota. Control of nonnative ungulates will help restore native forest habitat and host trees for the species.

Status of the *Dendrobium guamense*

Species Description

Dendrobium guamense (no common name) was federally listed as threatened on October 1, 2015 (80 FR 59423). No critical habitat has been designated for this species. A recovery plan for *D. guamense* has not been completed.

Dendrobium guamense is an epiphyte in the orchid family (Orchidaceae). This orchid usually occurs on tree branches in forests in filtered sunlight. Stems are crowded and up to 60 cm long (Stone 1970). Leaves are arranged alternately in two opposite vertical rows, are up to 10 cm long and 7-15 mm wide (Stone 1970). Two small white flowers emerge between two leaves, and are open only one day, appearing as balls on the second day.

Life History

Dendrobium orchids typically produce large numbers of very small and easily dispersed seeds. These seeds contain almost no food reserves. Seedlings must quickly form mycorrhizal associations with appropriate fungi to supply them with needed nutrition as they develop (Lavarack et al. 2000). As an epiphytic orchid, *D. guamense* are supported by trunk and thick lower branches, sometimes in small twigs in the top of the canopy of trees. They cling strongly onto their hosts with a developed root system and use the moisture and organic debris caught in the crevices and bark of the host for nourishment. The humid tropical air is absorbed for additional moisture and nutrients. In northern Guam, individuals of *D. guamense* were observed mostly on *Ficus* spp. proximal about 10 ft. to 25 ft. (3 m to 7.6 m) high in the canopy (JRM 2016 p. 7). *Dendrobium* species take advantage of the microclimate, which are found on the trunk, lower branches, under the canopy, and prefer shade or moderate light. In the Naval Magazine in southern Guam, *D. guamense* was observed at all elevations along rivers and on ridges and plateaus, and on numerous tree species (JRM 2016).

Population Dynamics

Dendrobium guamense was identified as the most abundant of the three epiphytic orchids federally listed as threatened in 2015 and was found to be the most abundant of the three listed orchids on Rota (Zarones et al. 2015). Given the recent discovery of *D. guamense* on Aguiguan, it is possible that the species could be found on other northern islands of the CNMI if more

extensive surveys were done. In the 1980s, this species was common in trees on Guam and Rota, with more than 12 occurrences on Guam and 17 occurrences on Rota (Raulerson & Rinehart 1992 p. 98; Thomas & Rock 2015). At the time of listing in 2015, at least 21 locations totaling approximately 1,250 individuals were reported on Guam (4), Rota (15), Tinian (1) and Aguiguan (1).

On Guam, the four occurrences contain approximately 250 individuals, primarily in the Naval Magazine area and Andersen Air Force Base (Quinata 1994 p. 8). Three individuals were also found in Anao Pt. and Ipan outside of DoD property since the time of listing (GPEPP 2015). On Rota, a survey team reported more than 700 individuals of *D. guamense* on the western third of Rota, represented by seedlings, juveniles, and flowering adults (Zarones et al. 2015). The presence of multiple generations in a healthy population structure indicates that the status of *D. guamense* on Rota is better than previously known.

Status and Distribution

Dendrobium guamense occurs in the forest ecosystem on Guam, Rota, Saipan (historically), and Tinian, and recently recorded for the first time on Aguiguan (Raulerson & Rinehart 1992; Quinata 1994; Costion & Lorence 2012; Zarones et al. 2015). As recently as the 1980s, this species was common in trees on Guam and Rota, with more than 12 occurrences on Guam and 17 occurrences on Rota (Raulerson & Rinehart 1992; Thomas & Rock 2015).

Threats

The following threats to the species contributed to its listing or were identified subsequent to listing and continue to to be an issue in the ability of the species to recover.

- Loss or degradation of habitat
    - Ungulates graze upon forest plant species impacting many native plants resulting in profound changes to the forest habitat. In the absence of ungulates, healthier and more pristine forest habitats contain a broader species composition and structure on which epiphytic orchids depend.
    - As numbers of cattle and ranchers increase on Tinian, there may be a greater risk of cattle potentially escaping and becoming feral. Both feral and domestic cattle can drastically alter the landscape (Wiles et al. 1990 pp. 176, 177), and depending on the location and amount of land designated as pasture land for domestic cattle, negative impacts to the forest ecosystem may be observed in the future, minimizing the available habitat.
    - Nonnative plants can degrade forest habitats. *D. guamense* has been found on both native and nonnative trees; however, the health and persistence of the orchid on nonnative trees is unknown.
    - Urbanization and development as well as natural or incidental fire, directly impact and reduce habitat availability for epiphytic orchids.
    - Edge effects due to disturbance and fragmentation have been shown to negatively impact orchids in cloud forests

- Stochastic events, primarily typhoons degrade forest. Affected forest areas may require several years to become reestablished and this can be exacerbated if habitats are reduced or degraded.

Survival and Recovery Needs

In order to recover *T. guamense*, individuals of this species in the wild and their habitat need to be protected on islands throughout their range. Reducing or eliminating nonnative ungulates will help restore native forest habitat and host trees for the species.

Status of the *Tuberolabium guamense*

Species Description

Tuberolabium guamense (no common name) was federally listed as threatened under the Act on October 1, 2015 (80 FR 59423). No critical habitat has been designated for this species. A recovery plan for *T. guamense* has not been completed.

The genus *Tuberolabium* consists of 17 epiphytic orchid species. *T. guamense* has roots that elevate the leaves and flowers away from the tree trunk. Leaves are leathery, oblong, about 13 cm long and 1.5 cm wide. Small white flowers are on a rachis about 3.5 cm long (Raulerson & Rinehart 1992 p. 127).

Life History

Similar to other epiphytic orchids, *T. guamense* grows slowly and requires specific microclimates, which are found on the trunk, lower branches, and under the forest canopy. *Tuberolabium guamense* clings onto their host trees with a strong developed root system and uses the moisture in the air and organic debris caught in the crevices and bark of the host for nourishment (Tibbs 2008).

There is limited information on the life history and habitat preferences of *T. guamense*. The age of maturity and the lifespan of the species are unknown. However, McConnell (2016) indicated *T. guamense* grows slowly and is a long-lived plant. In addition, *T. guamense* exhibits a monopodial growth habit in which the stem may continue to grow indefinitely (McConnell 2016). Monopodial orchids lack pseudobulbs, which store water. They rely on high humidity in the air for water. Observations of *T. guamense* indicate that this species is associated with the native orchid *Taeniophyllum mariannense* (worm orchid) and moss on host trees. *T. guamense* has primarily been found in the shade of the forest canopy at a range of heights from one to 20 feet (JRM 2016). On Guam, *T. guamense* has been observed on a wide variety of host trees, both native and nonnative (more than 19 species) as well as on dead branches and trees. The majority have been found on *Vitex parviflora* and *Pandanus tectorius* depending on the dominant vegetation (JRM 2016; DON 2017).

On Rota, the *T. guamense* population occurs within a specialized niche of limestone forest within tall and short limestone forest and secondary pandanus forest at elevations greater than 300

meters of the Sabana region (Zarones et al. 2015). Forests located within the Sabana are often shrouded in clouds and mist, and some areas include healthy growths of epiphytes (Falanruw 1989 p. 6). *Tuberolabium guamense* has been found on seven native host plants: primarily *Hernandia labyrinthica*, *Premna obtusifolia, and Elaeocarpus joga* with fewer occurrences on: *Pipturus argenteus*, *Ficus prolixa*, *Macaranga thompsonii*, and *Pisonia umbellifera* (Zarones et al. 2015).

Population Dynamics

In 1992, Raulerson and Rinehart (p. 87) stated that although *T. guamense* may appear abundant on the limestone ridges, the habitats are limited and in reality these orchids are rare on Rota and Guam (1992). For example, the Rota *T. guamense* population occurs in clusters within limestone forest in the Sabana region. At the time of listing in 2015, *T. guamense* was known from seven occurrences: one occurrence of one individual on Guam and six occurrences of 239 individuals on Rota, in the forest ecosystem (80 FR 59423). On Guam, surveys since the time of listing conducted by DON identified over 12,800 individuals, a substantial increase in the known population size. (DON 2017). Because individuals were defined as a single plant, regardless if it was part of a large cluster or clump, more research should be done to determine if this is an effective measure to distinguish an individual of *T. guamense* to avoid over counting during surveys. Winker et al. (2009) suggests that epiphytic orchid clusters be defined as inhabiting a single tree, and that within each tree only reproductive individuals be counted for monitoring purposes (pp. 997-1003).

Status and Distribution

Tuberolabium guamense is predominantly known from the islands of Guam and Rota, with a few scattered historical occurrences on Tinian and Aguiguan (Raulerson & Rinehart 1992 p. 127; Thomas & Rock 2015). Most orchids are narrowly distributed in specific habitats (Cribb et al. 2003). In 1992, *T. guamense* was found in "trees and shrubs all over the island" (Raulerson & Rinehart 1992 p. 127), and the Consortium of Pacific Herbaria has records of 22 collections from Guam, five collections from Rota, 15 collections from Tinian, and three collections from Aguiguan (Thomas & Rock 2015). *Tuberolabium guamense* individuals are also not distributed uniformly throughout the forests; and where they occur, are often present in clusters.

Threats

The following threats to the species contributed to its listing or were identified subsequent to listing and continue to to be an issue in the ability of the species to recover.

- Loss or degradation of habitat
  - Ungulates graze upon forest plant species impacting many native plants resulting in profound changes to the forest habitat. In the absence of ungulates, healthier and more pristine forest habitats contain a broader species composition and structure on which epiphytic orchids depend.
  - Nonnative plants can degrade forest habitats. Invasive vines such as *Coccinia grandis* (ivy gourd) and *Antigonon leptopus* (chain of love) are aggressive invaders of

disturbed or edge habitat, and can form dense blankets that cover individuals of *T. guamense* (Space & Falanruw 1999).

- *Tuberolabium guamense* has been found on both native and nonnative trees; however, the health and persistence of the orchid on nonnative trees is unknown.
- Urbanization and development as well as natural or incidental fire, directly impact and reduce habitat availability for epiphytic orchids.
- Stochastic events, primarily typhoons degrade forest. Affected forest areas may require several years to become reestablished and this can be exacerbated if habitats are reduced or degraded.

Survival and Recovery Needs

In order to recover *T. guamense*, individuals of this species in the wild and their habitat need to be protected on islands throughout their range. Reducing or eliminating nonnative ungulates will help restore native forest habitat and host trees for the species.

Status of the *Cycas micronesica*

Species Description

Cycas micronesica (fadang in Chamorro) was federally listed as threatened under the ESA on October 1, 2015 (80 FR 59423). No critical habitat has been designated for this species. A recovery plan for *C. micronesica* has not been completed.

Cycas micronesica is part of the Cycadaceae family which contains only one genus, *Cycas*, a very ancient genus of trees dating back to the Jurassic period. Ninety-eight *Cycas* species are described, and 75 species (77 percent of the genus) are considered critically endangered, endangered, threatened, near threatened, or vulnerable under the definitions of the (IUCN 2017). All *Cycas* species are restricted to the equatorial regions.

Cycas micronesica is a palm-like plant, usually unbranched tree with a thick trunk. Adult stem lengths reach 8m, rarely to 12m, and 14-25 cm in diameter with pinnate leaves 150-180 cm long (Hill 1994).

Life History

Cycas micronesica is the only native gymnosperm in the Mariana Islands. Cycads are dioecious, and both sexes bear reproductive structures that are relatively massive amongst gymnosperms (e.g. conifers). *Cycas micronesica* occurs in limestone forests in Guam and Rota, with fewer occurrences in volcanic soils typical of southern Guam (Stone 1970 p. 65; Hill 1994). Few studies exist that describe cycad natural history and ecology in the Mariana Islands, and much of the current literature is focused on its decline and effects from introduced pests. However, *C. micronesica* (identified as *C. circinalis* at the time) is a food source for the Mariana fruit bat (*P. mariannus mariannus*), which feed on its fruits (Wiles & Fujita 1992 p. 27), as well as for the Chamorro people, who process the fruits to rid the naturally-occurring toxins (Whiting 1963). *Cycas micronesica* emits chemical cues to attract specialist insects for pollination (Schneider et

al. 2002); however, there is also evidence of wind as a pollen vector in open areas or forested areas with some wind on Guam (Terry et al. 2009 p. 96; Hamada et al. 2015).

Population Dynamics

At the time of listing, there were fewer than 516,000 individuals on Guam (Marler 2013). This number does not distinguish between successfully reproducing adults and juveniles (Marler 2013), which, because of the effects of the cycad aulacaspis scale (*Aulacaspis yasumatsui*), implies that the number of extant individuals that can successfully reproduce is much lower. Within Guam's AAFB, over 257,000 individuals were documented in July 2013; however, the population structure was dominated by adults with little recruitment and declining reproductive success (Marler 2014). In a separate survey, an unquantified number of *C. micronesica* individuals were found at 11 sites across Guam, some of which were on AAFB (Harrington et al. 2012). Between March 2015 and January 2017, natural resources personnel from the MCAG P&D office conducted surveys which identified 19,852 mature individuals (DON 2017). On Rota, fewer than 111,500 individuals are present across the four occurrences (Marler 2013). Nearly 300,000 *C. micronesica* trees were documented on Yap (Marler 2013). The number of *C. micronesica* across Palau is the smallest with approximately 2,500 individuals (Marler 2013). As of February 2016, the total outplanted population on Tinian was 903, half of which were small and required continued maintenance (NAVFACMAR 2016).

Status and Distribution

Cycas micronesica is known historically from Guam, Rota, Palau (politically the independent Republic of Palau) and Yap (geographically part of the Caroline Islands; politically part of the Federated States of Micronesia (Hill 2004; Hill et al. 2004) and has also been out-planted on Tinian (NAVFACMAR 2016). It was the most abundant tree on Guam forest inventory surveys in 2002 with over 1.5 million trees identified (Donnegan et al. 2004 p. 16) and was similarly common on Rota. At the time of listing in 2015, there were a total of 15 to 20 occurrences of *C. micronesica* with 900,000 to 950,000 individuals on Guam, Rota, Yap, and Palau (80 FR 59423). The number of occurrences per island (or group of islands) was as follows: four fragmented occurrences on Guam, three of which were in the north; four on Rota; three on the Yap islands; and four across Palau (80 FR 59423).

Threats

The following threats to the species contributed to its listing or were identified subsequent to listing and continue to to be an issue in the ability of the species to recover.

- Loss or degradation of habitat
    - Loss and degradation of habitat from development, urbanization, agriculture, as well as wild or incidental fire.
    - Exotic plants, trees, shrubs, and vines have all been found to compete with *C. micronesica* for space, reducing available habitat.
    - The presence of nonnative ungulates degrades remaining forest habitats through herbivory and physical damage impeding their ability to survive.

- Low population number
    - A lack of recruitment into the population which on Guam is currently dominated by adults increases the vulnerability of the species to maintain a population structure which can maintain or promote the population.
- Nonnative pest species
    - *Cycas micronesica* is severely affected by multiple pest species, with *A. yasumatsui*, an introduced cycad specialist armored scale insect, being the most significant threat (Marler & Muniappan 2006 p. 3). The cycad aulacaspis scale is causing rapid mortality of all life stages of the plant (Marler 2014). As of January 2013, *C. micronesica* mortality reached 92 percent on Guam, and cycads on Rota are experiencing a similar fate from the cycad aulacaspis scale (Marler 2013). *Aulacaspis yasumatsui* has also invaded Palau; however the effects of the invasion on *C. micronesica* have not yet been determined. All seedlings of *C. micronesica* in a study area were observed to die within 9 months of infestation by *A. yasumatsui* (Marler & Muniappan 2006 p. 3; Marler & Lawrence 2012 p. 233; WPTRC 2012 p. 4). A specialist scale predator beetle, *Rhyzobius lophanthae*, was introduced purposefully to treat the *A. yasumatsui* outbreak with some positive results (Marler & Lawrence 2012 pp. 234–238). However, a number of other insects, including cycad blue butterfly (*Chilades pandava*) and a native longhorn beetle that bores cycad stems (*Dihammus marianarum*), also contribute to declining health and mortality in Guam cycad populations (Marler & Muniappan 2006 p. 3; Marler & Lawrence 2012 pp. 238–240).
    - In the absence of subsequent disturbances (i.e. typhoons) a healthy *C. micronesica* plant is resilient to typhoon damage (Hirsh & Marler 2002). However, the poor health status of remaining trees indicates that the natural resilience of this taxon to typhoon effects has been decreased by the chronic *A. yasumatsui* damage.

Survival and Recovery Needs

In order to recover *C. micronesica*, individuals of this species need to be protected throughout its range. *Cycas micronesica* populations should have age structures consisting of seedlings, juveniles, and adult plants. Expanded trials with biocontrol, especially targeting *A. yasumatsui*, should be considered to help stabilize the population (Marler & Lawrence 2012 p. 240). In addition, future invasions from other pests must be prevented (Marler & Lawrence 2012 p. 240). Feral pigs and introduced deer are also threats through herbivory and physical damage, further compounding effects from insects (Marler & Lawrence 2012 p. 238); therefore, ungulate control and fencing restoration sites are also crucial steps in managing cycad populations.

Status of the *Heritiera longipetiolata*

Species Description

Heritiera longipetiolata (ufa halomtano in Chamorro) was federally listed as endangered under the Act on October 1, 2015 (80 FR 59423). No critical habitat has been designated for this species. A recovery plan for *H. longipetiolata* has not been completed.

Heritiera longipetiolata is part of the hibiscus family, Malvaceae, which are flowering plants. The family contains 244 genera with over 4,000 species. There are two *Heritiera* species on Guam (Stone 1970). *Heritiera longipetiolata* is a stout, medium-sized tree and the trunk is often twisted. The alternate ovate-oblong leaves are large (15-30 cm long and 8-15 cm wide) and borne on long petioles that are abruptly enlarged at the base of the leaf blade. The upper leaf surface is dark green and slightly glossy. Flowers are yellowish-tan in color. The fruits are brown, woody and about the size of a Brazil nut, with thick walls (Stone 1970; Raulerson & Rinehart 1991 p. 94).

Life History

Little is known about the life history of *H. longipetiolata*. This species can be propagated by seeds. It is never found in riverine or coast strands instead, it occurs rooted in crevices in dissected limestone slopes and plateaus in the Marianas (Costion & Lorence 2012). Stone (1970) reported that *H. longipetiolata* was rarely found in flower or fruit; however, 70percent of a population on Saipan was observed with flowers or fruit buds (EFC & Services 2002) On Guam, *H. longipetiolata* occurs mostly on limestone cliffs.

Population Dynamics

In 1997, there were about 1,000 individuals on Guam, several hundred on Tinian, and fewer than 100 on Saipan, with no known remaining individuals on Rota (Wiles 1998). At the time of listing in 2015, *H. longipetiolata* was known from 10 occurrences totaling approximately 200 individuals, on Guam, Saipan, Tinian, and Rota, all within the forest ecosystem (80 FR 59423). The total population of *H. longipetiolata* on Guam was approximately 90 individuals; on Tinian, there were between 30 and 40 individuals, and possibly more in forest areas; on Saipan, *H. longipetiolata* was known from three occurrences, totaling at least 53 individuals, with several hundred seedlings beneath the trees; and on Rota, more recent information indicates that there was at least one individual of *H. longipetiolata* (80 FR 59423).

Surveys since the time of listing documented 255 *H. longipetiolata* at four different DoD locations on Guam (DON 2017). Additionally, during surveys in 2014 and 2015, 1,816 individuals were tagged at five locations outside of DoD property on Guam, 149 of which were mature trees (GPEPP 2015).

Status and Distribution

Historically, *H. longipetiolata* is endemic to the islands of Guam, Rota, Saipan, and Tinian and the only location outside of the Mariana Islands is in Pohnpei (Stone 1970; Raulerson & Rinehart 1991; Costion & Lorence 2012).

Threats

The following threats to the species contributed to its listing or were identified subsequent to listing and continue to to be an issue in the ability of the species to recover.

- Loss or degradation of habitat
  - Incremental habitat loss due to wild fire, urbanization, and agricultural development is increasingly threatening the availability of habitat.
  - The presence of nonnative plants and other nonnative ungulates (pigs, goats, and water buffalo), and Philippine deer, is likely to further degrade remaining forest habitats, thus impeding their ability to survive.
  - The spatial distribution is a major concern, as so many individuals are growing in close proximity throughout AAFB. This aggregated pattern increases the vulnerability of the population, especially to the threat of habitat loss and is exacerbated by the fact that most individuals on AAFB are located in sites with less than 15percent slope, which is also terrain suitable for human development.
- Low population number
  - A small number of individuals in the population increases the likelihood of reduced genetic diversity, vulnerability to stochastic events (i.e. typhoons or disease) and ultimately extinction pressure.

Survival and Recovery Needs

In order to recover *H. longipetiolata*, the remaining populations or occurrences of this species need to be protected throughout its range. *Heritiera longipetiolata* populations should have age structures consisting of seedlings, juveniles, and adult plants. Ungulate control should be implemented throughout its range, especially on Guam since the majority of the rangewide population exists on the island. In addition, control of nonnative plants and invasive insects and outplanting of *H. longipetiolata* in protected areas are critical for its recovery. Restoration works should focus on outplanting saplings within protected and ungulate-free areas.

Status of the *Tabernaemontana rotensis*

Species Description

Tabernaemontana rotensis (no common name) was listed as threatened under the Act on October 1, 2015 (80 FR 59423). No critical habitat has been designated for this species. A recovery plan for *T. rotensis* has not been completed.

Tabernaemontana rotensis is in the dogbane family, Apocynaceae, which includes trees, shrubs, herbs, stem succulents, and vines. The family contains 366 genera, and the *Tabernaemontana* genus consists of 103 species (The Plant List 2013). *Tabernaemontana rotensis* is a small to medium-sized (8-10 m tall) tree with leaves that are thin, light green, opposite, and 15-30 cm long (Stone 1970). Flowers are white, elongate, slender, and branch from the tree. *Tabernaemontana rotensis* produce conspicuous orange fruit that are twinned or single and beaked (UOG 2007 p. 6; GPEPP 2015 p. 22).

Life History

Tabernaemontana rotensis occurs in forests with crevices of rough limestone (Raulerson & Rinehart 1991 p. 94) and are able to colonize sites that occur in full sun or in deep shade (UOG

2007 p. 16). The species has primarily been found in areas of little to no slope (<15%) (UOG 2007; JRM 2016). *Tabernaemontana rotensis* has been found in forest habitats most often co-occurring with *C. micronesica*; however, *T. rotensis* were not found in areas that were dominated by alien tree species (UOG 2007).

Tabernaemontana rotensis populations typically flower in August through October, followed by the production of immature or orange fruit (UOG 2007 p. 23). During this time period, 40 to 80 percent of trees were found to have at least some flowering occur every month (cite). The fruit of *T. rotensis* reaches full size approximately 30 to 35 days after flowering. Fruit color changes from bright green to dull green in subsequent months, and a dull orange color break occurs in 50 to 60 days after flowering (UOG 2007 p. 24).

Seed dispersal of *T. rotensis* is dependent on birds and therefore a lack of frugivore bird species on Guam has resulted in limited spatial distribution of *T. rotensis*. Today, *T. rotensis* is generally found clumped within confined areas, as seedling establishment is restricted to within the vicinity of the parent tree (UOG 2007). This phenomenon does not support seedling recruitment, as seedlings develop in extreme competition with one other, and many of them become stunted and die (UOG 2007 pp. 14, 22).

In typhoon conditions, *T. rotensis* develops a synchronized pulse of flowering about one month after the typhoon. This pulse of flowering leads to mast seeding event about four months after a typhoon (UOG 2007 p. 29). This species may behave like a pioneer species since germination and seedling emergence have been shown to be maximized in full sun conditions (i.e., after typhoon damage) (UOG 2007).

Population Dynamics

In a study specific to AAFB, the species occurred in clumped patches within 256 sites across the base (UOG 2007). The population structure of over 21,000 individuals included emerging seedlings, young juveniles, and reproductive mature individuals with an extensive canopy size. The species was observed in Northern Guam in the following areas: Ritidian Point, Pati Point, HMU, and central and southeast edge of AAFB (UOG 2007; JRM 2016). At least five individuals of *T. rotensis* also occur within the GNWR. At the time of listing, *T. rotensis* was known from six occurrences on Guam and nine individuals on Rota (80 FR 59423). Individuals on Rota varied in size between 0.5 m and 6 m (1.6 ft. to 19.7 ft.) spread across the western, southern, and eastern parts of the island (CNMI-DLNR 2015).

Since the time of listing, additional surveys have identified and tagged 196 total individuals (88 of which were mature) at two locations outside of DoD property (GPEPP 2015). A total of 23,325 individuals have been identified at six locations on DoD property, over 85percent of which are on AAFB (Department of Navy 2017).

Status and Distribution

Tabernaemontana rotensis is endemic to Guam and Rota and was suggested to be restricted to limestone forest habitat (Stone 1970). It was originally noted as very rare needing seed cultivation or cuttings to assure the existence of the species (Stone 1970).

Threats

The following threats to the species contributed to its listing or were identified subsequent to listing and continue to to be an issue in the ability of the species to recover.

- Loss or degradation of habitat
  - Incremental habitat loss due to wild fire, urbanization, and agricultural development is increasingly threatening the availability of habitat.
  - The presence of nonnative plants and other nonnative ungulates (pigs, goats, and water buffalo), and Philippine deer, is likely to further degrade remaining forest habitats, thus impeding their ability to survive.
  - The spatial distribution is a major concern, as so many individuals are growing in close proximity throughout AAFB. This aggregated pattern increases the vulnerability of the population, especially to the threat of habitat loss and is exacerbated by the fact that most individuals on AAFB are located in sites with less than 15percent slope, which is also terrain suitable for human development.
- Population recruitment
  - The lack of dispersal by birds restricts the spatial extent of the populations on Guam. Clustered populations can exhibit less genetic diversity becoming less resilient evolutionarily and more vulnerable to stochastic events causing a disproportionate effect (extreme events or disease) and thus prone to extinction pressures.
  - Typhoons will continue to degrade forest and the affected forest areas may require several years to regenerate. Typhoons may actually open canopy space to germinate *T. rotensis* seeds and promote the population; however, in order for successful regeneration following thyphoons is dependent on a viable seed bank and if there is regeneration, it will likely result in clustered spatial distribution (UOG 2007).

Survival and Recovery Needs

In order to recover *T. rotensis*, the remaining individuals of this species need to be protected on Guam and Rota. *Tabernaemontana rotensis* populations should have age structures consisting of seedlings, juveniles, and adult plants. Ungulate and invasive species control should be implemented throughout its range. On Guam, restoring areas with this species' natural dispersers (*e.g.*, native frugivore birds) would expand the distribution of *T. rotensis* population into new habitat niches, niches that would have likely been naturally occupied by the *T. rotensis* population prior to the loss of seed dispersal on Guam. Outplanting or relocation of wild seedlings within protect areas would help increase their abundance and distribution on Guam and Rota.

ENVIRONMENTAL BASELINE

General Environmental Baseline

A general overview of the status of, and threats to, limestone forest habitat within the action area, followed by species-specific environmental baseline sections, are presented below. This overview reflects the important role of forest habitat in the conservation of all the listed species addressed in this BO.

Overview of Guam

Guam is the largest and southernmost island of the Marianas Archipelago. It is almost 30 mi (50 km) long and from 4.3 mi to 9.3 mi (7 km to 15 km) wide. The northern part of Guam is a limestone plateau interrupted by a few low hills that are volcanic in nature and other hills that are exclusively coralline (formed from coral). The original forest on limestone was of large trees, with a thick canopy overhead (see below for further description). The northern part of the island gently slopes to the southward from about 656 ft (200 m) to about 328 ft (100 m) at the narrow waist of the island. There is no surface water in the northern part of the island (Fosberg 1960, pp. 51-52). Only in the southern and central parts of Guam are there permanent streams (Stone 1970, p. 12). The central part of Guam includes a mixture of volcanic and limestone substrate. The southern part of Guam is hilly, largely of volcanic origin (*e.g.*, basalts) but in several places the hills are capped with a layer of limestone (Stone 1970, p. 12). The southern half of the island is made up of deeply weathered volcanic material with patches of limestone and numerous streams (Fosberg 1960, p. 52). Forest habitat is broken up by ridges and flats covered by grass. The forests in these areas tend to resemble that on limestone; however, the forest is thicker and is dominated by lower stature trees (Fosberg 1960, p. 53; Stone 1970, p. 18). At lower elevations, forest occurs primarily in ravines, valley bottoms, and on steep slopes.

Limestone Karst Forests on Guam

Limestone karsts are sedimentary rock outcroppings consisting primarily of calcium carbonate and are recognized as important ecosystems with high species diversity (Mueller-Dombois and Fosberg 1998, p. 217; Clements et al. 2006, pp. 733-734). The high species diversity on karst arises from the numerous ecological niches created by complex terrains and variable micro-climatic conditions (Clements et al. 2006, p. 734). On Guam, karst is found on an uplifted plateau located on the northern half of the island and on uplifted weathered volcanic terrain in the southern half (Fosberg 1960, p. 54; Stone 1970, p. 12; Mueller-Dombois and Fosberg 1998, p. 241). The limestone soils of north and south Guam were historically forested (Stone 1970, p. 14; Mueller-Dombois and Fosberg 1998, p. 270; Guam Department of Agriculture 2010, p. 7), and limestone forest on Guam is composed primarily of mature growth of native trees and plants with a moderately dense canopy 33 ft to 98 ft (10 m to 30 m) in height (DAWR 2006, p. 19). We define primary limestone forest as forest with vegetation that was never cleared and is dominated by native species (Fosberg 1960, p. 56; DAWR 2006, p. 218).

Primary limestone forests are critically important to Guam's native flora and fauna (Stone 1970, p. 22; USFWS 2005a, p. iv; DAWR 2006, p. 28; DON 2014b, p. 3-40). They retain key functional components of native forests such as large native trees and high canopy cover (Fosberg 1960, p. 56; Mueller-Dombois and Fosberg 1998, p. 217 and 270; DON 2014b, p. 3-40), and are necessary for the recovery of Guam's terrestrial native species (DAWR 2006, p. 27; Jenkins 1983, p. 22; Michael 1987; Morton et al. 1999, p. 22). Intact primary limestone forests harbor greater tree species diversity than degraded habitat (Stone 1970, p. 22) and provide habitat for a broad diversity of wildlife. These forests are also highly productive and often store more carbon than degraded forests (Caves et al. 2013, p. 7). The primary limestone forest on AAFB is considered some of the highest quality native limestone forest left on Guam to serve as habitat for listed species (Morton 1996, p. 69).

Threats to Guam's Limestone Forests

Over the past several centuries, Guam has lost much of the native forest to agriculture, a growing human population, economic development, and military activities (Mueller-Dombois and Fosberg 1998, p. 270; USFWS 2009d, p. 27). The distribution of primary limestone forest on Guam has been steadily declining (Fosberg 1960, p. 54; DAWR 2006, p. 28). Although little is known about the nature of Guam's vegetation before World War II, progressive alteration of the island's vegetation clearly began with human colonization (Fosberg 1960, p. 54). On limestone soils, native forest was cleared and replaced by coconut plantations, open fields and gardens, pasture, and secondary forest (Mueller-Dombois and Fosberg 1998, p. 242). During World War II, large areas were cleared and some habitat was destroyed during heavy fighting (Fosberg 1960, p. 54).

Currently, the remaining limestone forests on Guam face numerous threats including habitat fragmentation and loss, lack of management, introduced ungulates, invasive species, typhoons, forest conversion, and loss of seed dispersers (USFWS 2005a, p. 27; DAWR 2006, p. 28; USFWS 2008a, p. 17-18). These combined threats are degrading the habitat quality of remaining limestone forests and limiting the acres of high quality primary limestone forest habitat available to recover listed species on Guam. Currently, forested areas cover approximately 48 percent of Guam (DAWR 2006, p. 31). Of this, about 13 percent consists of limestone forest habitat (Brown 2005 as cited in DAWR 2006, p. 28).

Forest Habitat Fragmentation, Degradation, and Loss

Habitat fragmentation is a change in habitat configuration caused by clearing, development, invasive species, typhoons, and ungulates that result in the remaining habitat to occur in patches intermixed with areas of non-habitat (Noss et al. 2006, p. 213). Habitat fragmentation creates edges that have different properties than the habitat itself. For example, edges often have different microclimate patterns that are drier, less shaded, and warmer than forest interiors. They are often areas with increased predation and serve as entry points into native habitats for invasive vegetation, pests, and pathogens (Noss et al. 2006, p. 228). The effects of edges that are caused by habitat fragmentation can occur up to 492 ft (150 m) into the forest (Murcia 1995, p. 59). Habitat fragmentation and edges can result in localized extirpations of species, shifts in community composition, increases in invasive species, increased predation, and in suitable

habitat becoming unsuitable due to pollution, invasive species, physical size, or barriers blocking access to habitats (Groom and Vynne 2006, p. 174; Noss et al. 2006, 38 pp). Habitat fragmentation has been implicated in reduced species richness, avian abundance, productivity, and food supply (Blake and Karr 1987, VanderWerf 1993, Burke and Nol 1998, Trine 1998, Porneluzi and Faaborg 1999). Overall, edges may have adverse effects to some wildlife populations and ecological processes (Murcia 1995, p. 58; Laurance 2000, p. 134) and may affect forests at larger landscape scales (Laurance 2000, p. 134).

Habitat degradation and loss on Guam has been caused by various human activities including agriculture, mining, forestry, fires, infrastructure development, military training, urbanization, industry, pollution (including light, noise, and toxic chemicals), and changes in community and ecosystem structure due to invasive species (Groom and Vynne 2006, p. 164; USFWS 2008a, p. 17). Habitat loss and degradation from human activities is a threat to the recovery of many listed species on Guam (USFWS 2008a, p. 17; USFWS 2012c, p. 3).

Feral Ungulates

Feral ungulate species that occur on Guam include pigs (*Sus scrofa*), Philippine deer (*Rusa marianna*), and the Asiatic water buffalo (*Bubalis bubalis*) and are not native to the island. Feral ungulates have caused severe damage to Guam's forests by browsing on plants, causing erosion, inhibiting plant growth and regeneration, and facilitating the establishment of invasive plants, which can impede forest regeneration by displacing or smothering native species (USFWS 2009d, p. 27). For example, deer and pigs foraging on fallen fruits and seedlings of the native breadfruit (*Artocarpus mariannensis*), an important Mariana fruit bat food, in combination with impacts from typhoons, have resulted in a decline in the number of native breadfruit trees on Guam (Wiles 2005, p. 509).

Feral pigs are extremely destructive and have both direct and indirect effects on native plant communities. While rooting in the soil in search of invertebrates and plant material, pigs directly affect native plants by disturbing and destroying vegetative cover and trampling plants and seedlings. They may also reduce or eliminate plant regeneration by damaging or eating seeds and seedlings. Pigs are a major vector for the establishment and spread of competing invasive non-native plant species, by dispersing plant seeds on their hooves and coats as well as through the spread of their feces (Matson 1990, p. 245; Siemann et al. 2009, p. 547). Feral pigs feed preferentially on the fruits of many non-native invasive plants, spreading the seeds of these species through their feces as they travel in search of food. In addition, rooting pigs contribute to erosion by clearing vegetation and creating large areas of disturbed soil, especially along hillsides (Smith 1985, pp. 190, 192, 196, 200, 204, 230–231; Stone 1985, pp. 254–255, 262–264; Medeiros et al. 1986, pp. 27–28; Scott et al. 1986, pp. 360–361; Tomich 1986, pp. 120–126; Cuddihy and Stone 1990, pp. 64–65; Aplet et al. 1991, p. 56; Gagne and Cuddihy 1999, p. 52).

On Guam, feral pigs were introduced in the 1600's, established a population by 1772, and were distributed island-wide by the early 1900's (Conry 1988, p. 26). As documented in other locations, wallowing, rooting, and trampling are common in most forested areas and can be locally severe (Conry 1988, p. 27). A large complex of wallows and feeding sites in Tarague Basin on AAFB measured over 5.7 ac (2.3 ha), and was stripped of all ground cover with no tree

regeneration (Conry 1988, p. 27). On AAFB, densities of Philippine deer and feral pigs were estimated at 0.8 deer per acre (1.8 deer per hectare) and 0.2 pigs per acre (0.4 pigs per hectare), which are some of the highest densities recorded in the world (Knutson and Vogt 2003, unpubl. manuscript).

Philippine deer were introduced to Guam in the 1770's (Safford 1905, p. 76), and are distributed throughout the island (Conry 1988, p. 27). Heavy browsing pressure has been documented and browse lines are common (Conry 1988, p. 27). Deer populations in the 1990s appeared to be expanding (Wiles et al. 1999, p. 193), and may be the largest in Micronesia (p. 200). Philippine deer have caused significant changes in forest structure and species composition in native ecosystems on Guam, and are not considered compatible with conservation of native ecosystems and recovery of endangered species (Wiles et al. 1999, p. 193).

The Asiatic water buffalo was introduced to Guam in the 1600's from the Philippines (Conry 1988, p. 27). High densities, and the gregarious habits of Asiatic water buffalo, have resulted in habitat damage such as mud wallows, broad trails, vegetation trampling, and tracks, with some areas so heavily trampled that ground cover has been denuded and soil erosion scars and slumping are evident (Conry 1988, pp. 27-28). The Asiatic water buffalo occurs primarily on the Ordnance Annex and surrounding non-Navy lands in southern Guam, with a population estimated at 50-60 animals (USFWS 2008a, p. 18).

Conversion of Forest to Savanna in Southern Guam

Savanna areas in southern Guam are enlarging into previously forested areas as a result of human-caused wildfires and grazing (Stone 1970, p. 14; Mueller-Dombois and Fosberg 1998, p. 242). To estimate the rate of historical forest conversion to savanna, Greenlee (2010) delineated areas that were dominated by forest vegetation in 1975 using aerial photographs and compared these areas to recent infrared imagery. Based on this analysis, approximately 1,119 ac (453 ha) of forest has been converted to savanna in southern Guam since 1975; this estimate indicates the average rate of forest loss in southern Guam is approximately 37 ac/year (15 ha/year) (Greenlee 2010).

Habitat Destruction and Modification by Typhoons

Guam has been affected by typhoons in 37 of the last 50 years (USFWS 2005a, p. 32). Super-typhoons (with wind gusts of over 150 mi (240 km) per hour) occur approximately once every five years (the last one, Pongsona, occurred in 2002). Typhoons destroy native vegetation by opening the canopy and modifying the availability of light, and create disturbed areas conducive to invasion by non-native pest species (Asner and Goldstein 1997, p. 148; Harrington et al. 1997, pp. 539-540). Typhoons also can cause defoliation (loss of leaves), uprooting of trees, and breakage of stems, branches, and trunks of trees depending on the severity and duration of the storm and its point of impact (Brokaw and Walker 1991, p.442). Super-typhoons fragment and decrease the suitability of existing habitat, and exacerbate the effects of introduced plants and ungulates (USFWS 2005a, p. 34). Climate models indicate that typhoons in the northwestern Pacific are expected to increase in intensity, frequency, and duration by 2200 (Emanuel et al. 2008, p. 360).

Loss of Pollinators, Seed Dispersers, and Frugivores

The loss of forest birds on Guam caused by BTS predation has caused a disruption in the ecosystem services provided by birds as pollinators, seed dispersers, and frugivores (Mortenson et al. 2008, p. 2146; Caves et al. 2013, p. 7). Seeds are dispersed significantly farther from parent trees on islands with birds compared to Guam, and seed ingestion by birds doubles to quadruples the chance of germination for plant species (Rogers 2011, p. 2). The combination of loss of seed dispersal and reduced germination can produce major changes in the spatial pattern, abundance, and diversity of Guam's forests (Rogers 2011, p. 2). In addition, seed set and seedling recruitment were significantly higher on Saipan (where BTS is absent) than Guam for bird pollinated trees (Mortensen et al. 2008, p. 2146). These studies concluded that the loss of ecosystem services provided by birds will result in the loss of species diversity, distribution, and abundance; slow regeneration of degraded forests; and a reduction of plant species recruitment (Mortensen et al. 2008, p. 2146 and 2153; Rogers 2011, p. 2; Caves et al. 2013, p. 5).

Human Disturbance

The listed species on Guam are also threatened by disturbance from human activities including, but not limited to, noise from military training (aircraft, munitions, firing ranges, vehicles, etc.), noise from recreational pursuits (hiking, and hunting), and construction noises. These disturbances not only negatively affect species, but reach into forested interiors and degrade the quality of habitat for listed species. The Mariana fruit bat is sensitive to human disturbance, and as development continues on Guam, disturbance-free forested habitats are increasingly rare on Guam.

Land Management on DoD Lands

The majority of remaining limestone forests on Guam occurs on DoD lands at AAFB and the NBG's NMS. As noted above, the primary limestone forest on AAFB is considered some of the best native limestone forest remaining that provides habitat for threatened and endangered species (Morton 1996, p. 69). The Service and the DoD (USAF, DON, and JRM) have worked together over the past 20 years to manage DoD lands for threatened and endangered species. In 1994, a Cooperative Agreement (Agreement) was established between the USAF, DON, and the Service for purposes of establishing and managing the GNWR Overlay on DoD lands (USFWS 1994). The GNWR includes approximately 376 ac (152 ha) of fee simple Service-owned land and 22,501 ac (9,106 ha) of Overlay Refuge areas on land owned by DoD. The Agreement, which is still in effect, affirms the signatory parties commitment for a "coordinated program centered on the protection of endangered and threatened species and other native flora and fauna, maintenance of native ecosystems, and the conservation of native biological diversity in cooperation with the Guam's DAWR, consistent with the national defense mission of the Navy." Notably, all signatory parties to agreed that DON lands included within the GNWR shall be managed and administered, consistent with the national defense mission of the DON and the requirements of section 7(a)(2) of the Act, and other laws as applicable.

Management of listed species habitat on DoD lands has occurred with some success. The approximately 180 ac (73 ha) Haputo ERA and the 30 ac (12 ha) Orote Point ERA, both on NBG are two examples. Both were established in 1984, prior to the Agreement, as mitigation for the Kilo Wharf project. The 133 ac (54 ha) Habitat Management Unit (HMU) on AAFB was developed as a conservation measure under the 2006, informal consultation on the Beddown of Training and Support Initiative at the NWF (USFWS 2006c, p. 2), and currently serves as an experimental site for BTS research and control.

Environmental Baseline for the Mariana Fruit Bat

Other than a few isolated periods of increase, Mariana fruit bats have been declining on Guam since the early 1900s (Wiles 1987b, p. 1; USFWS 2009d, pp. 6 & 7 and references cited therein). Although the decline of the Mariana fruit bat was likely initiated by the introduction of firearms and increased hunting efficiency in the early 1900s, predation by BTS has contributed to the continued decline (Wiles et al. 1987, p.148; Lemke 1992, p. 137; Wiles et al. 1995, p. 32; Janeke 2006, p. 3; Brooke 2008, p. 2; USFWS 2009d, p. 19, 30). By 1995, nearly all of Guam's remaining Mariana fruit bats were located on AAFB (Wiles et al. 1995, p. 39). In 2006, the only known maternity colony on Guam was located on AAFB at Pati Point and had less than 100 individuals (Janeke 2006, p. 4). By 2010 the Pati Point colony no longer existed, and no other colonies were known to exist on Guam (SWCA 2012, p. 20, DON 2014c, p. 2).

In December 2015, Mariana fruit bats were observed within the HMU at AAFB. Preliminary estimates were 30 to 50 Mariana fruit bats present within the HMU (D. Lujan, AAFB, pers. comm. 2016). Since that time, Mariana fruit bats have been regularly using the forest of the HMU for foraging and roosting. According to direct observation and indirect evidence of Mariana fruit bat presence (e.g., excrement, discarded fruits with bat-teeth markings), the Mariana fruit bats appear to be using most of the interior forested area in the HMU. Four different Mariana fruit bat roosting locations were identified during three perimeter and eight interior surveys of the HMU in 2016. The largest group of Mariana fruit bats counted in one area was 112 bats (Mildenstein 2016, p. 1). Mariana fruit bats were also observed flying from and to adjacent areas outside of the HMU (Mildenstein 2016, p. 2).

As described below, individual Mariana fruit bats have been detected at multiple locations on Guam in the past eight years.

Mariana fruit bat detections in northern Guam (GNWR, AAFB, Finegayan, and Haputo):

- In December 2015-February 2016, bats were observed within the HMU on AAFB. It is estimated that 112 bats were present within a colony at the HMU. This represents greater than a 200 percent increase in the estimated Mariana fruit bat population on Guam in early 2015. The increase in the Guam bat population is evidence of the periodic movement of bats between Guam and Rota.
- In July 2014, a large-scale survey throughout AAFB resulted in an estimate of 8-21 bats (DON 2014c, p. 2). Annual base-wide surveys on AAFB have been conducted in 2014, 2015, 2016 and 2017 (A. Brooke, DON, pers. comm 2017).
- Surveys on AAFB in 2012 recorded 50 detections of Mariana fruit bats at 84 stations, some of which could have been the same individuals. Mariana fruit bats were primarily

recorded along the cliff line extending from above the Combat Arms Training and Maintenance (CATM) Range east to Pati Point, in the MSA, and in the vicinity of the HMU (SWCA 2012, p. 58).

- In 2011, three Mariana fruit bats were observed flying west along the beach in front of the headquarters at GNWR (Schwagerl, pers. comm., 2015).
- Extensive surveys throughout AAFB from December 2010 to December 2011 resulted in a conservative estimate of approximately 25 Mariana fruit bats (DON 2014c, p. 48).
- From 2010-2013, a single Mariana fruit bat was observed flying across Route 3A on six occasions; four observations of a Mariana fruit bat flying into the HMU from Finegayan, and two observations of a Mariana fruit bat flying out of the HMU into Finegayan in the late afternoon (J. Schwagerl, USFWS, pers. comm. 2015). Mariana fruit bats from AAFB may use forested areas of Finegayan for foraging and roosting.
- During 10 observation days in 2008, one fruit bat was observed in the Haputo ERA and one in the northeastern portion of Finegayan (Brooke 2008, p. 1). The Haputo ERA contains some of the best remaining fruit bat habitat on the DON-managed lands (Brooke 2008, p. 2; DON 2010c).

Mariana fruit bat detections at Naval Magazine, Naval Base Guam, and in Southern Guam:

- In August 2014, two observations of a Mariana fruit bat in flight occurred at Fena Reservoir within the NMS (L. Takano, USFWS, pers. comm. 2014).
- In May and June of 2012 seven detections were recorded during surveys on six separate occasions at four locations on the NMS; it could not be determined whether observations were of a single individual or multiple individuals (DON 2014a, p. 48).
- In 2012, Mariana fruit bat surveys were conducted within the NMS and at a site on private land located in southern Guam (DON 2013b). Seven observations were recorded of a solitary Mariana fruit bat in flight at NMS, but it could not be determined if these observations represent one, or multiple individuals (DON 2013b, p. 11). These observations supplement Mariana fruit bat sightings previously documented in the vicinity of the NMS where foraging and roosting habitat is present (Brooke 2008, pp 1-2). No observations were recorded at the private lands site where suitable Mariana fruit bat roosting and foraging habitat is limited. However, known food plants of the Mariana fruit bat are present in the vicinity and this area may be used for roosting, foraging, and other activities (DON 2013b, p. 12).
- One Mariana fruit bat was sighted on NBG lands in 2008 during 90 hours of surveys at 14 survey locations on or near NBG lands. (DON 2014a, p. 48).

Threats to the Mariana Fruit Bat within the Action Area

In addition to the threats described in the General Environmental Baseline section, the following threats also affect Mariana fruit bat populations on Guam.

Hunting

Humans have been using Mariana fruit bats as a food source since human arrival in the Marianas. Consumption of Mariana fruit bats represents a significant Chamorro cultural tradition (Lemke 1992, p. 135; Sheeline 1991, p. 14). Demand for Mariana fruit bats for human

consumption is demonstrated by the large commercial trade in Mariana fruit bats that existed in the Marianas in the late 1960s until it became illegal through the Convention on International Trade of Endangered Species of Wild Fauna and Flora (CITES) (Wiles and Payne 1986, p. 143; Stinson et al. 1992, p. 63-66; Wiles et al. 1997, p. 204; CITES 2015). It is estimated that approximately 221,000 Mariana fruit bats were imported to Guam between 1975 and 1989 (Wiles 1992, p. 54). Illegal hunting appears to be the key reason for the Mariana fruit bat's dramatic decline on Guam (Wiles 1987b, p. 154; Wiles and Brooke 2009; USFWS 2009d, p. vii).

Even though Mariana fruit bats are protected by Guam and Federal law, they are likely still hunted opportunistically on private property when they transit the island and by hunters on AAFB (GNWR, unpublished data, 2005). For example, in 2007, reports were made of construction workers illegally hunting Mariana fruit bats at the Pati Point colony. The number of Mariana fruit bats at the colony declined from 55 (summer 2007) to 21 (December 4, 2008 survey) (PEER 2009). A recreational public ungulate hunting program has been in effect on AAFB since 1964 (D. Lujan 2015, pers. comm.), and is managed by a small group of hunters known as the Volunteer Conservation Officers (VCOs). The public is authorized to hunt on weekends in designated areas, and VCOs may hunt after regular working hours during the week. All hunting effort is documented by the VCOs. Currently, archery-only hunting is allowed in four areas (D. Lujan 2015, pers. comm.) and shotgun and muzzle loading hunting is prohibited. Elimination of shotgun and muzzle-loading hunting likely reduced the chance of illegal hunting of Mariana fruit bats on AAFB; however, it is possible that they are still hunted opportunistically on AAFB. SWCA (2012, p. 58) reported that roosting Mariana fruit bats were approached by observers as close as 16 ft (5 m), and suggested that hunters could, without difficulty, shoot and kill a roosting Mariana fruit bat.

Noise

Air traffic is the primary source of noise disturbance for Mariana fruit bats on Guam (SWCA 2008, p. 2-3; SWCA 2012, p. 23, 37). The first known study examining the effects of aircraft overflights on Mariana fruit bats on AAFB was conducted at Pati Point, where a colony of approximately 400 Mariana fruit bats roosted (Morton 1996). During this study, roosting Mariana fruit bats responded to some low-altitude aircraft overflights with distress and flushing, which increased time spent in alert, aggression, and maintenance behaviors. Four-engine carriers and bombers generally elicited a greater response from roosting Mariana fruit bats than fighter aircraft. Morton (1996, p. iii) suggested that higher levels of air-traffic volume would result in increased energy expenditure and perhaps roost abandonment by some or all of the Mariana fruit bats present at AAFB.

In 2006, the effects on Mariana fruit bats from noise resulting from increased jet aircraft and helicopter use at AAFB were analyzed in the ISR-Strike BO (USFWS 2006b). In that consultation, noise effects were expected to adversely affect the Mariana fruit bat to the extent that the nearby Pati Point colony would be abandoned, and Mariana fruit bats would relocate from Pati Point to other, less-protected areas on the island (USFWS 2006b, p. 49). In the ISR-Strike BO, we concluded that Mariana fruit bats on Guam would be taken as a result of the proposed action, but that action would not jeopardize the continued overall existence of the Mariana fruit bat (USFWS 2006b, pp. 49-52).

In 2007-2008, another study was conducted to document potential effects of aircraft noise on fruit bats at AAFB (SWCA 2008). During this period, the number of fruit bats at the Pati Point colony had decreased from 55 to 21 by the end of the surveys (PEER 2009). Aircraft noise affected the Mariana fruit bats by increasing alertness behaviors, preventing Mariana fruit bats from resting and sheltering in place, compared to surveys with no overflight occuring. However, the proportion of bats displaying alertness behaviors following an overflight was variable. Overflights did not appear to affect active thermoregulation. Six percent of overflights resulted in flushing events, and all flushing events were at noise levels exceeding 106 dBc, the highest reading being 122.6 dBc (SWCA 2008, pp. 2-3).

In 2010, another study was was funded to assess the effects of aircraft noise on Mariana fruit bats at AAFB (SWCA 2012); however, the colony at Pati Point no longer existed. Although up to eight individual Mariana fruit bats were observed roosting there at any one time, most departed the site by the end of each sampling period, indicating the site was no longer used as a colonial roost (SWCA 2012, p. 2). Increases in active thermoregulation (32 percent), maintenance (14 percent), locomotion (74 percent), and alertness (62 percent) were recorded during aircraft overflights. All flush events were at recorded peak noise levels above 90 dBA/101 dBc; the highest reading at 124.9 dBA/125.5 dBc (two F-15 aircraft). The observed flush events were associated with fighter, bomber, transport, and helicopter aircraft overflights (SWCA 2012, p. 23, 37).

Observations suggest that Mariana fruit bats may also be affected by small arms noise at the existing CATM Range at Tarague (J. Quitugua, DAWR, pers. comm. 2015). When the Mariana fruit bat colony was still roosting at Pati Point, a DAWR wildlife biologist observed Mariana fruit bats avoiding the firing range area as they left the roost to fly to their foraging grounds. Some flew away from land over the ocean, and returned to land by the Tarague beach area. Others flew up to the cliff line heading towards the ISR-Strike area. These observations occurred while the firing range was active on two different days. During the time period between the two observations, the number of Mariana fruit bats in the colony dropped from approximately 40 to less than 20 individuals. When the firing range was inactive, Mariana fruit bats were observed to fly along the cliff line near the range (J. Quitugua, DAWR, pers. comm. 2015).

Typhoons

Mariana fruit bats evolved in the presence of typhoons, the principal natural disturbance in the archipelago, but today these storms are a threat to the species because they can exacerbate the effects of the anthropogenic threats listed above (USFWS 2009d, p. 34). Evidence from Rota suggests that typhoons may not be a substantial source of direct mortality for Mariana fruit bats (Stinson et al. 1992, p. 65; Esselstyn et al. 2006, p. 536). However, the synergistic effect of illegal hunting and severe storms on Mariana fruit bats is documented on Rota (e.g., Stinson et al. 1992; Esselstyn et al. 2006). Severe storms can alter Mariana fruit bats foraging and roosting behavior by decimating food resources, removing protective foliage cover, temporarily modifying forest structure, and changing vegetation composition, especially by facilitating encroachment of non-native species. Loss of food resources can drive Mariana fruit bats to forage on the ground, during daylight hours, and closer to areas of human activity; thereby

increasing their vulnerability to illegal hunting (Stinson et al. 1992, p. 65; Esselstyn et al. 2006, p. 532).

Mariana Fruit Bat Survival and Recovery Habitat

Although Mariana fruit bats have been observed in a variety of habitat types, they are more likely to occur in native primary or secondary limestone forest (see Status of the Species above). Mariana fruit bat populations that have been subject to intense hunting pressure (e.g., populations on Saipan, Tinian, Rota, and Guam) are sensitive to human presence, and in recent history, maternity roosts are not known to occur in close proximity to areas inhabited by humans (Wiles 1987b, p. 151; J. Boland, unpublished data 2008-2014). However, Mariana fruit bats may forage on or near human-inhabited lands, in spite of hunting pressure (Wiles 2006, pers. comm. as cited in USFWS 2006b; Boland 2008-2015, pers. obs.). Therefore, for this BO, we assume that all areas identified as limestone and ravine forests on the 2006 Forest Service landcover maps (Liu and Fisher 2006a) are potential habitat for the fruit bat on Guam. We then updated the amount of available habitat on Guam by removing all forested areas cleared since the landcover map was completed using 2011 satellite imagery of Guam (Metevier 2014, unpubl. data). Although primary limestone forest is higher quality habitat that secondary limestone forest habitat, we did not account for habitat quality in these calculations due to our inability to differentiate between these forest categories using imagery alone. Similarly, we were unable to account for other aspects of habitat quality such as hunting and predation threats. As such, our estimate of available survival and recovery habitat (hereafter, referred to as habitat) on Guam is likely an oversetimate.

Using the methods above, the total area of Mariana fruit bat habitat on Guam was estimated to be 27,096 ac (10,965 ha) (**Figure 7**). Based on our estimate of 27,096 ac (10,965 ha) of existing survival and recovery habitat for the Mariana fruit bat (Metevier 2014, unpubl. data), the estimated carrying capacity for Mariana fruit bats on Guam is 19,847 bats (DON 2013d, p. 26, 45). In order for native limestone forest to serve as habitat for the Mariana fruit bat, it will need to be managed to reduce threats to the species, including the BTS, illegal hunting, invasive plant species, and feral ungulates (USFWS 2009a, pp. 42-43). Only 576 ac (233 ha) of this habitat is designated for the purposes of conservation. Most of the lands set aside for conservation are not currently managed to reduce threats. Therefore, it is important to protect and manage Guam's forest habitat to allow for recovery of the Mariana fruit bat. If habitat continues to be degraded, it may no longer provide the appropriate attributes necessary to support the Mariana fruit bat.

Environmental Baseline for the Mariana Eight Spot Butterfly

The Mariana eight spot butterfly relies on the limestone forest and thus is affected by the same stressors within the action area threatening Guam's limestone forest habitat, described above. The DoD lands affected by the proposed action encompass six of 10 host plant populations used by Mariana eight spot butterflies on Guam (Rubinoff 2016, p. 6). Within the action area, Mariana eight spot butterflies of all life stages were always found in close proximity to their two host plant species, *E. calcareum* and *P. pedunculata* (Rubinoff 2011, in litt.; Rubinoff 2013). Both of the host plant species are rare in their range and are susceptible to feral ungulate grazing, based upon observations that the plants occur only in the extremely rugged limestone karst that is

inaccessible by most feral ungulates (Rubinoff 2013, in litt.). The amount of total suitable habitat for the Mariana eight spot butterfly within the action area has not been quantified.

In northern Guam, the Ritidian and Haputo areas are important sites because they include the most current and consistent observations of Mariana eight spot butterfly adults and their other life stages. Extensive host plant patches and five occurrences with adult or larval butterflies were documented within the Ritidian Point, NWF area (DON 2016, p. 3). All adult and larva observations were near the cliff line in the area of the proposed MPMG Range. Host plant patches and observations of Mariana eight spot butterflies, caterpillars and eggs also occur within the Haputo ERA (Rubinoff 2016, attachment). It is likely that protection from feral ungulates and the presence of large stands of host plants support these important, larger populations and result in greater population persistence (Rubinoff 2016).

The host plants for the Mariana eight spot butterfly are also present at AAFB Golf Course, AAFB Pati Point, and AAFB Tarague (USFWS 2012a; Globteck and HDR 2012; Rubenoff 2013; Lindstrom and Benedict 2014, DON 2015; Rubinoff 2016). These three areas are situated west of Ritidian Point, along the northern plateau around to the south. Mariana eight spot butterflies, or their life stages, have been observed using these areas (USFWS 2012a; Globteck and HDR 2012; Rubenoff 2013; Lindstrom and Benedict 2014, DON 2015; Rubinoff 2016). A sixth area with host plants and butterflies, Spanish Steps/Orote, is within an ERA; this area is located the furthest south. The Mariana eight spot butterfly has likely been able to survive in this area because feral ungulate access is limited due to steep topography and is surrounded by cliff line and ocean. In total, surveys in the action area, while not comprehensive, have documented 2,310 individual host plants of *E. calcareum* and *P. pedunculata.*

Figure 9 shows all locations where Mariana eight spot butterflies were documented within the action area. An estimate of a 1-kilometer buffer is used to distinguish between subpopulations and represents maximum Mariana eight spot butterfly flight distance, based on similar species under similar conditions (Hill et al. 1996, p. 730). However, recent comprehensive surveys have not been conducted within the action area to verify persistence of these subpopulations.

Since reintiation of this consultation, in 2016, the GNWR and Guam Plant Extinction Prevention Program (GPEPP) began propagating host plants (*E. calcareum and P. pedunculata*) successfully in their nurseries, for future outplanting and forest restoration activities.

Environmental Baseline for the Partulid Snails: Humped Tree Snail, Guam Tree Snail, and Fragile Tree Snail

Tree snails rely on primary and secondary limestone forest habitat and thus are affected by the same stressors within the action area threatening Guam's limestone forests, described above. Tree snails prefer cool, dense, shaded native forest communities, with high humidity and reduced air movement to conserve moisture (USFWS 2012a, 2012b). The humped tree snail, Guam tree snail, and the fragile tree snail were all reported in 1989 within the Haputo ERA (Hopper and Smith, 1992). A 2008 survey found two colonies within the Haputo ERA, one known historically at Haputo Beach and another further north at Pugua Point, but still within Haputo ERA. The Pugua Point site contained fragile tree snails and Guam tree snails, while the Haputo Beach site

contained humped tree snails and Guam tree snails (Smith et al., 2008). During surveys conducted in 2011, one colony of Guam tree snails and fragile tree snails were observed in back strand and *Neisosperma* forest vegetation at the east end of Tarague basin (DON, 2013d), north of the project footprint on AAFB. In surveys conducted in 2011 and 2013, no tree snails were observed in the NWF area (DON, 2013d; UOG 2014). Although tree snails were not found within the project footprint of the LFTRC, potential tree snail habitat does occur within the areas subject to clearing for the LFTRC (DON 2017a, p. 44).

Surveys conducted in 2013 found approximately 245 individual Guam tree snails, 112 humped tree snails, and three fragile tree snails within the Haputo ERA (UOG 2014). There are no records of tree snails within the Finegayan impacted areas. No tree snails have been reported from the support areas on AAFB and adjacent lands.

On NBG, Lindstrom and Benedict (2014) reported three populations of Guam tree snails on one of the 47 transects. A colony of 10 individuals of Guam tree snails was detected near Apra (Lindstrom and Benedict 2014). Two other populations of Guam tree snails were also identified along the same transect (Lindstrom and Benedict 2014). The second population consisted of five individuals observed in a one person-hour search and individuals were found on leaves less than 16.4 ft (5 m) high on a large *Annona reticulata* tree, approximately 49 ft (15 m) tall. Both of the populations were found within 65.6 ft (20 m) of a small freshwater stream. The third population of Guam tree snails, 68 individuals in total, was observed on *Morinda citrifolia* trees in a one person-hour search and this population was no less than 164 ft (50 m) from a freshwater source. No other colonies of tree snail species were observed in NBG (Lindstrom and Benedict 2014).

Guam tree snails were sighted in August 2016 in the Anderson South area and again in November 2016. Confirmation that these sightings were Guam tree snails were provided by subject matter experts at the University of Guam (Megan Volsteadt and Dr. Curt Fiedler) (Gosnell, 2017, personal communication). Surveys in the same area by USDA Wildlife Services personnel reported three live snails in 2016, DON personnel returned to the locations where these snails were sighted and confirmed presence of 35 live snails (and 51 snail shells) in February 2017 (Olmsted, 2017, personal communication). A total of 38 live snails were documented in the Andersen South project location (**Figure 10**).

Below is a summary of Partulid snail detections on non-DoD properties within the action area (Lindstrom and Benedict 2014):

- Hagåtña Springs, Hagåtña River and Asan Beach Memorial Park were all visited to conduct targeted searches in July 2013. At Hagåtña Springs, 11 Guam tree snails were documented during a timed search, but many other individuals were observed subsequently in that location away from the area searched. At Hagåtña River, at least 17 Guam tree snails were documented. At Asan Beach Memorial Park, 119 Guam tree snails were documented during a one person-hour search, with many others observed in that general location outside of the timed search period.
- Pigo Cemetary, Namo River, and Sella Bay were visited in July 2013. Pigo Cemetery was found to have four Guam tree snails, Namo River had 10 Guam tree snails, and at Sella Bay, eight Guam tree snails were observed. Ritidian Point was the site of a targeted

search on July 17, 2013 and 20 Guam tree snails were documented (but many more observed).

- The Lost Pond area was visited on July 20, 2013, and 118 Guam tree snails were recorded.
- On July 23, 2013, at the Ylig River, 22 Guam tree snails were observed. At Fua Bay on July 25, 2013, 74 Guam tree snails were observed and on July 26, 2013, at Cetti Bay, 30 Guam tree snails were documented (Lindstrom and Benedict 2014). Fragile tree snails were recorded during the wet season at Pugua Point and Lost Pond (Hilaan) during targeted searches. It was thought that some snails from other locations were also fragile tree snails, DNA samples from these individuals indicated they were actually juvenile Guam tree snails. Tarague Basin was reported to have sightings of fragile tree snails; however, surveys by Lindstrom and Benedict observed only Guam tree snails. Since some Guam tree snails have very similar color patterns to fragile tree snails, particularly as juveniles (Hopper & Smith, 1992), the previous identifications may have resulted in juvenile Guam tree snails being misidentified as fragile tree snails. The humped tree snail is only found at one location, Haputo Beach (Lindstrom & Benedict 2014). As stated in the Status section, the humped tree snail is the least common of the three listed tree snail species on Guam.

Environmental Baseline for the Orchids (Orchidacea): *Bulbophyllum guamense*, *Dendrobium guamense*, and *Tuberolabium guamense*

Orchids are known for their specialized niches and often, specific pollinators (Williams 1973). *Bulbophyllum guamense*, *D. guamense*, and *T. guamense* are not exceptions to the need for specialized conditions, which include certain requirements for humidity, air circulation, and sunlight. However, more research is needed to delineate the specific abiotic and biotic factors that are needed for each of these orchids, to understand what is required to maintain viable populations of each, and to determine the amount of habitat available for recovery throughout their ranges. The number of individuals of each listed orchid species presented below is based on botanical surveys. The majority of surveys were conducted or funded by the DON on DoD administered lands and results are not comprehensive island-wide, thus the number of plants within the action area is considered a conservative value.

As noted above in the General Baseline section, habitat loss, fragmentation and degradation associated with urban development, ungulates, invasive species, and typhoons continue to negatively impact forests on Guam. *Bulbophyllum guamense*, *D. guamense*, and *T. guamense* are also at risk from herbivory by nonnative invertebrates such as slugs.

Environmental Baseline for *Bulbophyllum guamense*

Approximately 148 individuals of *B. guamense* are present within the action area (**Figure 11**) (DON 2017a). Of this amount, 127 occur within the NMS. *Bulbophyllum guamense* forms mat-like formations made of many bulbs on branches. We define an individual here as the entire mat-like formation because of the difficulty in delineating within the formation. The action area supports 36 percent of the range-wide population.

Environmental Baseline for *Dendrobium guamense*

Approximately 264 individuals of *D. guamense* are present within the action area. The greatest concentration of *D. guamense* occurs within the NMS (**Figure 12**). Approximately 17 individuals of *D. guamense* are present in the area proposed for the Main Cantonment at Finegayan and 41 individuals are present in the proposed LFTRC area (DON 2017a). *Dendrobium guamense* grows in large clumps on branches. However, we use individual to represent each unique orchid clump. The action area supports 31 percent of the range-wide population.

Environmental Baseline for *Tuberolabium guamense*

Tuberolabium guamense is present in the areas that include the proposed Main Cantonment at Finegayan, LFTRC, the HMU at NWF, and the NMS. During survey efforts, a total of 12,607 *T. guamense* individuals or occurences were identified within the action area (DON 2017a). Of these plants, 6,924 *T. guamense* were identified in Finegayan, 3,078 on NWF, and 2,314 on the main portion of AAFB (**Figure 13**). For some occurrences, over 100 individual *T. guamense* were found on a single tree. *Tuberolabium guamense* has been observed growing as a solitary individual and as a large cluster. When possible the survey counts represent an individual plant.

Surveys found *T. guamense* to occur within secondary limestone forests (82 percent of occurrences) and primary limestone forest (17 percent of occurrences). *T. guamense* is found in small numbers within other vegetation community types, such as ravine forests, coconut plantation, herbaceous-scrub, and savanna vegetation types (these vegetation community types accounted for one percent of occurrences.

The highest densities of *T. guamense* are seen in secondary forests (14.8 plants per ac, or 36.56 plants per ha) and primary limestone forests (5.9 plants per ac, or 14.49 plants per ha). Across all vegetation community types where this species is found, *T. guamense* occurs in an approximate density of 10.2 *T. guamense* per ac (25.2 *T. guamense* per ha). The action area supports 98 percent of the range-wide population.

Environmental Baseline for *Cycas micronesica*

Cycas micronesica relies on a healthy limestone forest and thus is affected by the same stressors within the action area threatening Guam's limestone forest habitat, described in the General Baseline section above. During surveys conducted on AAFB in 2012-2013, 12,770 living and 12,425 dead *C. micronesica* were tallied (Marler 2014, pp. 89). During 2014-2015, surveys were conducted at Ritidian Point and NWF, containing the proposed LFTRC footprint. *Cycas micronesica* was reported as occurring in high densities with few scale infestations (JRM 2014). JRM (2016) reported at least 3,561 mature *C. micronesica* are present within the proposed NWF Ungulate Control Area, and little scale infection was noted at Ritidian Point. Most cycads had dark leaves and many healthy fronds (JRM 2016, p. 6). Because of the high numbers documented throughout forest and edge areas of AAFB, it is highly likely that a large number of cycads, both infested and relatively healthy, are located within the proposed project footprint,

much of which is within AAFB. The proposed footprint for the Main Cantonment area in Finegayan is comprised of approximately 500 ac (202 ha) of similar limestone forest habitat (DON 2014, p. 96) which, based on numbers from nearby AAFB, likely contain high numbers of cycads. In addition, corridors for utilities and other development under this action are located throughout northern Guam with likely occurrences of *C. micronesica*. Updated surveys conducted in 2015 through 2017, reported a total of 19,852 *C. micronesica* plants (both mature and juvenile) within the action area (DON 2017a, p. 82). **Figure 14** shows all locations where *C. micronesica* were documented within the action area. The action area supports five percent of the range-wide population of *C. micronesica*.

Despite the relatively high numbers of *C. micronesica* within the action area, the health of *C. micronesica* subpopulations are poor and subpopulations are declining, due largely to invasive insect damage (Marler and Lawrence 2012, p. 240). Over a five-year survey period, Marler and Muniappan (2006) recorded 10 invasive insect species on Guam predating on *C. micronesica* plants, including four records of invasive insects new to Guam (**Table 8**).

The Cycad aulacaspis scale is among the most damaging threat to *C. micronesica* within the action area. This scale, native to Thailand and unintentionally introduced to Guam in 2003, attacks all age classes and major plant parts of *C. micronesica*. A six-year study that surveyed 687 *C. micronesica* plants in one area before and after Cycad aulacaspis scale infestation, found all *C. micronesica* seedlings were killed within 9 months and all juvenile *C. micronesica* plants were killed within 30 to 50 months after initial scale exposure (Marler and Lawrence 2012, p. 233). By the end of the study, Marler and Lawrence (2012) estimated a 92 percent mortality rate for *C. micronesica* once exposed to the Cycad aulacaspis scale (p. 233) and the loss of 75 percent of mature trees (p. 238), due to Cycad aulacaspis scale damage. Other invasive insects, such as the Cycad leaf miner and stem borer species (**Table 8**) compound effects of the Cycad aulacaspis scale, as the leaf miner further damages the naturally long-lived leaves of *C. micronesica* and the stem borers preferentially attack already stressed plants, contributing to their mortality (Marler and Lawrence 2012, p. 238).

A biological control agent, *Rhyzobius lophanthae* that naturally predates on the Cycad aulacaspis scale was introduced to Guam in 2004 with limited success. The *R. lophanthae* scale predator has extended the life of many mature *C. micronesica* plants, however the size differential between *R. lophanthae* and *A. yasumatsui* limits ongoing efficacy of biocontrol efforts, as the Cycad aulacaspis scale is able to find locations on *C. micronesica* plants that the predator cannot access (Marler and Lawrence 2012, p. 238). As a result of ongoing invasive insect damage, no new wild seedlings have been observed within the action area since 2008, and recruitment appears to be severely limited for the *C. micronesica* Guam subpopulation (Marler and Terry 2011, p. 778).

Table 8. Summary of invasive insect species on Guam and the type of damage caused to *C. micronesica* plants (Adapted from Marler and and Muniappan 2006, p. 3).

Common name	Scientific name	Order	Family	Damage to leaf	Stem	Cone
Cycad leaf miner	*Erechthias* sp. *	Lepidoptera	Tineidae	X		
Cycad aulacaspis scale	*Aulacaspis yasumatsui**	Hemiptera	Diaspididae	X	X	X
Armored scale	*Lepidosaphes* sp. near *rubrovittata*	Hemiptera	Diaspididae	X		
Indian wax scale	*Ceroplastes ceriferus*	Hemiptera	Coccidae	X		
Hemisperical scale	*Saissetia coffeae*	Hemiptera	Coccidae	X		
Stem borer	*Dihammus marianarum*	Coleoptera	Cerambycidae		X	X

Stem borer	*Dasyses rugosella**	Lepidoptera	Tieneidae		X	
Cycad male cone borer	*Anatrachyntis* sp.*	Lepidoptera	Cosmopterigidae			X
Oriental flower beetle	*Protaetia orientalis*	Coleoptera	Scarabaeidae			X

*New records for Guam

Environmental Baseline for *Heritiera longipetiolata*

Heritiera longipetiolata is found rooted in crevices in limestone slopes and plateaus within the action area (Costion and Lorence 2012, p. 79). Approximately 404 individuals of *H. longipetiolata* are present on Guam (DON 2017a, p. 110; GPEPP 2015). The 82 individuals in northern Guam represent over 20 percent of the known population on the island (**Figure 15**). The factors limiting the *H. longipetiolata* subpopulation within the action area include heavy predation on seeds by deer and the browsing of seedlings by deer and pigs (Wiles et al. 1995, p. 43). The action area supports 83 percent of the range-wide population of *H. longipetiolata*.

Environmental Baseline for *Tabernaemontana rotensis*

Tabernaemontana rotensis on Guam was once thought to be extremely rare, but recent surveys have found thousands of individuals along forest margins and open patches. It should be noted that some of the clusters of *T. rotensis* included one adult plant and numerous seedlings. **Figure 16** shows the known locations for all *T. rotensis* within the action area. The factors limiting the *T. rotensis* subpopulation within the action area include lack of frugivores and natural seed dispersers, and browsing of seedlings by feral ungulates (UOG 2007). Approximately 22,413 *T. rotensis* plants occur within the action area (DON 2017a, p. 110; GPEPP 2015), which supports approximately 99 percent of the range-wide *T. rotensis* population.

Previous Consultations in the Action Area

The following section 7 consultations have been conducted within the action area of this BO.

- In October 2006, the Service issued a non-jeopardy BO on the ISR-Strike Project on AAFB, Guam (ISR BO; USFWS 2006) and effects to the Mariana Crow and the Mariana fruit bat. The incidental take statement accompanying the ISR-Strike BO authorized the take of up to one Mariana fruit bat foraging territory in the form of harm as result of clearing and construction of the Aircraft Staging Area Facility. In addition, the take of two Mariana fruit bat colonies and 21 Mariana fruit bats on Guam and 36 Mariana fruit bats from Rota (or six premature migrations to Rota) in the form of harassment and death as a result of aircraft disturbance associated with overflights and subsequent illegal hunting impacts was authorized throughout the duration of the proposed action. The conclusion relied on provisions in the proposed action to monitor the status of Mariana fruit bats observed to ensure no additional take occurred due to construction activities, as well as minimizing, avoiding and/or offsetting the impacts of increased aircraft operations on the species. The measures would offset the impacts of incidental take and provide a net conservation benefit to the species as a whole.
- In September 2010, the Service issued a non-jeopardy BO on the Joint Guam Program Office (JGPO) Relocation of the USMC from Okinawa to Guam and Associated Activities on Guam and Tinian (JGPO BO; Service File #2010-F-0122) and effects to the Mariana fruit bat, Guam Micronesian kingfisher, Guam rail, Mariana common moorhen, Mariana crow, Mariana swiftlet, Micronesian megapode, Green sea turtle and Hawksbill sea turtle. The incidental take statement accompanying the JGPO BO authorized up to 10 of the remaining Mariana fruit bats at the Pati Point natural area colony to be taken in the form of harassment due to loud aircraft noise resulting from the proposed action. To minimize impacts of incidental take of the Mariana fruit bat, DON would minimize the level of incidental take occurring as a result of aircraft operations on Guam by developing measures to control BTS, restore or enhance Mariana fruit bat habitat, reduce ungulates, restore forest habitat, manage four ecological reserve areas, reduce poaching by adding conservation law enforcement officers and fund research to fill knowledge gaps of Mariana fruit bat demography, movements, and phylogeography. DON would also monitor and report the number of Mariana fruit bats occupying all known roost sites on AAFB from one year prior to and one year after the proposed overflight increases were fully implemented.
- In February 2015, the Service issued a non-jeopardy BO on the MITT Program (MITT BO; USFWS 2010) and effects to the Mariana fruit bat and Micronesian megapode. The MITT BO included an incidental take statement which authorized one fruit bat to be killed every five years on Farallon de Medinilla (FDM) as a result of bombing, gunnery and missile exercises conducted under the program. The non-jeopardy conclusion included measures to monitor the impacts of take of Mariana fruit bat caused by the MITT program.
- In July 2015, the Service issued a non-jeopardy BO on the DON's Relocation of the USMC from Okinawa to Guam and Associated Activities on Guam (2015 BO; USFWS 2015) and effects to the Mariana fruit bat, Mariana crow, Guam Micronesian kingfisher, as well as designated critical habitat for these three species. The 2015 BO allowed up to 30 Mariana fruit bats at AAFB and Finegayan (the current population size at the time) to be repeatedly taken in the form of harassment leading to injury from loud aircraft noise, operation of the LFTRC, construction noise, and other human disturbance resulting from the proposed action. Mortality was not anticipated from the proposed action. The non-

jeopardy conclusion relied on the following conservation measures: postpone construction activities if a Mariana fruit bat was present within 492 ft (150 m) of the site, use hooded lighting, provide education materials and survey for maternity colonies. On February 14, 2016, the DON informed the Service that up to 112 Mariana fruit bats were found within the HMU on AAFB during surveys, and that based on this finding, the DON requested an increase in the amount of take authorized in the form of harassment. DON's request for an increase in Mariana fruit bat take is addressed in this BO.

The remaining 10 species addressed in this BO are newly listed and therefore no previous consultations have been conducted on those species.

EFFECTS OF THE ACTION

Exposure Analysis Approach

The Service has developed an analysis framework for section 7 consultations that incorporates the general structure, primary concepts, and nomenclature of the U.S. Environmental Protection Agency's ecological risk assessment framework (USFWS 2005c). Factors causing adverse effects are called "stressors" and beneficial effects are called "benefits." Under this approach, the Service determines the effects of the action on listed species and critical habitat by evaluating the location, timing, duration, frequency, and intensity of listed species or critical habitat exposure to each stressor and benefit, and the likely effects of such exposure on the reproduction, numbers, and distribution of the listed species and on the recovery support function of critical habitat. The only species addressed in this BO with designated critical habitat is the Mariana fruit bat. The analysis of effects on Mariana fruit bat critical habitat was conducted on the proposed Federal action in the 2015 BO (USFWS 2015a, pp. 103-104 and pp. 144-145). This analysis and the information used in the analysis remain unchanged and are therefore not included in this consultation.

The proposed action's stressors include and are limited to:

- Habitat modification due to vegetation clearing and grubbing;
- Topsoil excavation and loss of karst substrate;
- Cut and fill earthmoving;
- Water well boring/drilling;
- Trenching and grading;
- Stockpiling of green waste;
- Disturbance from lighting systems;
- Aircraft traffic, including DoD aircraft;
- Vehicle traffic, including both civilian and military;
- Military training, including all ground maneuvers, munitions and firearm use; and
- Aviation training, including low-level terrain flights and external load training.

The proposed action's benefits include and are limited to:

- Enhancement and protection of limestone forest habitat;
- Control and eradication of ungulates in the Forest Enhancment Sites and the LFTRC;
- Creation of BTS exclosures and suppression of the BTS within the exclosures; and

- Landscape scale invasive species planning and prevention.

For purposes of this analysis, the term of effects of the proposed action associated with the permanent destruction of listed species habitat caused by earthmoving and vegetation clearing activities and degradation of listed species habitat associated with the operation of the training areas are considered to be indefinite.

General Effects of the Action

Habitat Loss and Fragmentation (All Affected Listed Species)

The proposed action is likely to cause forest habitat loss and fragmentation as a result of vegetation clearing and earthmoving activities. Definitions and descriptions of habitat fragmentation are described above in the Environmental Baseline section. The further loss, degradation, and fragmentation of forest habitat, is likely to decrease the amount of suitable habitat for recovery of all terrestrial listed species on Guam. Habitat suitable for the survival and recovery of the Mariana fruit bat has been delineated on Guam (Amidon in litt., 2015). Because *C. micronesica* has been considered one of the dominant trees within the forests on Guam and occurs within all Mariana fruit bat foraging habitat, we used the number of Mariana fruit bat habitat acres affected by the proposed action to estimate the amount of habitat loss for *C. micronesica*. Based on known species ranges and survey reports, the remaining nine species (the Mariana eight spot butterfly, Guam tree snail, fragile tree snail, humped tree snail, *B. guamense*, *D. guamense*, *T. guamense*, *H. longipetiolata*, and *T. rotensis*) co-occur or prefer similar habitat conditions, such as primary and secondary limestone forests; therefore the loss of those habitat types are used to represent the loss of habitat for the nine species affected by the proposed action. Habitat is defined as both occupied and unoccupied suitable habitat. The amount of habitat relied upon by the 11 listed species, which will be lost as a result of the proposed action is shown in **Table 9**.

Table 9. Anticipated loss of habitat relied upon by the affected listed species, resulting from implementation of the proposed action.

Project	**Habitat Cleared** acres (hectares)	
	Mariana fruit bat & *C. micronesica*	Mariana eight spot butterfly, Guam tree snail, fragile tree snail, humped tree snail, *B. guamense*, *D. guamense*, *T. guamense*, *H. longipetiolata*, and *T. rotensis*
Finegayan, Main Cantonment	449 ac (182 ha)	683 ac (276 ha)
AAFB Main, Family Housing	180 ac (73 ha)	12 ac (5 ha)
LFTRC	168 ac (68 ha)	79 ac (32 ha)
AAFB South	2 ac (1 ha)	212 ac (86 ha)
Naval Base Guam	5 ac (2 ha)	86 ac (35 ha)
Water Wells and Sanitary Sewer Systems	77 ac (31 ha)	51 ac (21 ha)
Utilities & Site	38 ac (15 ha)	30 ac (12 ha)

Improvements		
TOTAL	919 ac (372 ha)	1,153 ac (467 ha)

The largest effects on listed species habitat in terms of habitat fragmentation will be on AAFB near Ritidian Point from construction of the LFTRC. This area currently contains a large expanse (over 350 ac {142 ha}) of high-quality primary limestone forest that serves as occupied habitat for the Mariana fruit bat, Mariana eight spot butterfly, *B. guamense*, *D. guamense, Tuberolabium guamense*, *C. micronesica*, *H. longipetiolata*, and *T. rotensis*, and unoccupied habitat for the Guam tree snail, fragile tree snail, and humped tree snail (DON 2017a, p. 44). This primary limestone forest is also contiguous with GNWR, providing an even larger forested area serving as habitat for the above eleven listed species. In total, approximately 78 ac (32 ha) of primary limestone forest and 109 ac (44 ha) of secondary limestone forest would be permanently cleared for construction of the LFTRC.

In addition to LFTRC clearing activities, the proposed action will create a Surface Danger Zone (SDZ) over approximately 68 percent of the GNWR at Ritidian Point during operation of the LFTRC. The SDZ will cover the GNWR access road, visitor center, offices, and other facilities and thereby limit access to the GNWR while firing occurs at the LFTRC. Any entry into GNWR will require scheduling with and approval by LFTRC Range Control personnel. The limited access that GNWR staff will have to the refuge property during the estimated 39 weeks per year the LFTRC is active will limit the amount of habitat management that can occur at the GNWR. This could have an adverse effect on listed species by: 1) limiting maintenance of the predator exclusion fence at the GNWR, 2) limiting maintenance of native out-plantings, 3) limiting invasive plant control, and 4) limiting effective ungulate control. Per Section 2822 (Establishment of surface danger zone, Ritidian Unit, GNWR) in the 2015 National Defense Authorization Act, the Service and the DON may enter into an agreement to establish and operate a SDZ over the GNWR. The agreement may include relocation and reconstruction of GNWR facilities, mitigation for impacts to wildlife species, and use of DoD personnel to complete GNWR conservation actions; however, this agreement is not yet in place. Therefore, in this analysis we assume that the operation of the LFTRC will have an adverse effect on listed species by preventing the management, research, and monitoring that would have otherwise occurred at GNWR.

In summary, a total of 1,219 ac (493 ha) of limestone forest habitat will be cleared and permanently lost as a result of the proposed action. The loss of Guam's limestone forests and habitat for listed species furthers the long-term trajectory of loss of native forested habitat on Guam, and without the full implementation of conservation measures, may affect recovery of listed species on Guam. Given the small amount of habitat left on Guam, off-setting measures are provided to restore or protect the remaining limestone forest and listed species habitats. Such measures are important in terms of the conservation needs of affected listed species and the recovery support function of affected critical habitat. The effects of habitat loss are further discussed in the species-specific sections below.

Edge Effects (All Affected Listed Species)

Based on the approximately 187 ac (76 ha) of listed species habitat (primary and secondary limestone forest) that will be cleared for the LFTRC, approximately 6.2 mi (10 km) of new edge will be created. As discussed in the Environmental Baseline section above, edge effects can cause adverse effects to wildlife populations and ecological processes (Murcia 1995, p. 58; Laurance 2000, p. 134) not adapted to habitat edge conditions. Abiotic edge effects may include changes in microclimate, soil conditions, and wind. Biotic edge effects include increased predation, competition, disease, and parasitism (Ewers and Didham, 2006; Harper, et al., 2005). Microclimate effects include changes in light, temperature, and relative humidity (Kapos 1989; Kapos et al. 1993; Carmago and Kapos 1995). Soil changes due to edge effects may include changes in temperature, moisture, and nutrient cycling (Kapos 1989; Carmago and Kapos 1995; Grilli et al. 2011). Edge effects also tend to increase in severity with larger areas of disturbance. For example, large clearings, such as those proposed for the LFTRC and Main Cantonment provide a larger area to accumulate heat from the sun or a longer fetch in which wind speed can accelerate (Laurance et al. 2002; Laurance and Curran 2008; Laurance et al. 2011).

Edge effect responses by listed plant species may include mortality, reduced seedling recruitment, and reduced or stunted growth rates (Harper et al. 2005). The Mariana fruit bat and Mariana eight spot butterfly are also vulnerable to edge effect due to the alteration of available foraging and breeding habitat.

Fire Effects (All Affected Listed Species)

The proposed action may result in wildfires burning listed species habitat. Fires could start from live-fire training (including use of tracers), bivouacking with campfires, arson, barbeques, debris burning, cigarette smoking, aircraft mishaps, and vehicular malfunctions. Between 1991 and 2002, an average of 28 fires per year burned on DON lands on Guam (DON 2013e, p. 4-8), with 429 ac (174 ha) burned on average per year. Most of the area burned was savanna grasslands (DON 2013e, p. 4-8). This is approximately double the average annual number of fires on DON lands from 1979 to 1989, though the burned acreage on DON lands was similar (425 ac per year or 172 ha per year). Arson and debris burning account for approximately 70 percent of fires, and 87 percent of area burned, on DON lands from 1979 to 2002. Smoking (eight percent), unknown (three percent), and miscellaneous causes (including children, campfires, and equipment) account for approximately four percent of fires on DON lands on Guam (Nelson 2009, Ch. 3 p. 4).

Fires can lead to a variety of direct and indirect affects to wildlife and their habitats. Fire can burn habitat resulting in habitat loss, fragmentation, and degradation, and loss of foraging and breeding habitat. Fires could expose Mariana fruit bats to smoke, resulting in respiratory distress or abandonment of habitat.

Range Fire Management Plan

To minimize adverse effects to listed species resulting from fires, the DON proposes to develop and implement a Range Fire Management Plan (RFMP) for the LFTRC. The RFMP will be prepared, among other purposes, to minimize fire threat to surrounding habitat and listed species, specifically *B. guamense, D. guamense, T. guamense, C. micronesica, H. longipetiolata, T.*

rotensis, and habitat and host plant species for the Mariana fruit bat, Mariana eight spot butterfly, Guam tree snail, humped tree snail, and the fragile tree snail. The RFMP will be developed and implemented to ensure that any fire sparked during training will not spread beyond the firing range and into forested habitat. Because the LFTRC is surrounded by listed species habitats, the development and implementation of the RFMP will be critical to insure that the listed species and their habitat near firing ranges are not lost due to training activities.

Because a comprehensive RFMP will be reviewed by the Service and conservation measures implemented, as described above, we anticipate that no additional habitat will be lost due to wildfires igniting as a result of the proposed action. Although the DON's comprehensive RFMP may also minimize fire impacts on non-DoD lands on Guam by instituting fire prevention, detection, and suppression programs as well as implementing landscape-level fuel modifications in the NMS, the beneficial effects of this DON action to threatened and endangered species are difficult to assess because the RFMP has not been completed at this time.

Invasive Species (All Affected Listed Species)

Implementation of the proposed project is likely to increase the risk of introducing or spreading non-native terrestrial and aquatic invasive species including plants, animals, and microbes. Pathways associated with anthropogenic activities have a relative risk of introducing and dispersing non-native or invasive species. Hulme et al. (2008) described three broad mechanisms for non-native species introductions: importation as a commodity (e.g., purposeful importation as biocontrol, pet trade), arrival via transport vector, and natural dispersal. Of these mechanisms, Hulme et al. (2008) further described a framework for introductions that is supported by six principal pathways, of which two could potentially occur via the implementation of the DON's proposed action: contaminantion of a specific commodity and stowaway (independent of a commodity, like ballast water or airfreight). The pathways of contaminants and stowaways include, but are not limited to species transported via: construction equipment, personal protective equipment, and delivery of supplies, materials, goods, foot traffic, vehicles or vessel traffic. Invasive species introduced as contaminants and stowaways could occur as a result of inadequate sanitation and inspection during and prior to the movement of equipment, supplies, personnel, or vehicles. The repeated or routine movement of equipment and people increases the risk of introduction and establishment of a non-native and/or invasive species.

It is important to understand that the "risk" of introduction and establishment of invasive species is highly variable across taxa and habitats. Identifying and analyzing risk for all the species that could be moved via DON-related activities is not practicable. Instead, a more efficient approach is to identify pathways where numerous species from different taxa may be inadvertently introduced and implement prescriptive measures to control risks from those pathways. A pathway risk assessment will provide a structure for assessing where the greatest "risk" for a non-native species introduction occurs and locations where managing ingress or egress of these species is most efficient for control. Pathways must be controlled because repetition of an action has a direct effect on propagule pressure which as stated above increases the likelihood of a species to become established.

To address pathways and encourage a more holistic approach to managing invasive species, the DON funded the development of the Regional Biosecurity Plan (RBP) for Micronesia and Hawaii (formerly referred to as the Micronesia Biosecurity Plan). Individual activities for various species will continue, but the DON and others agree it is more efficient to manage pathways and prescribe corrective measures for a suite of species that will be monitored at discrete control points over time. The RBP will provide stakeholders in Micronesia and Hawaii with a platform for coordination and integration of inter-agency invasive species management efforts such as control, interdiction, eradication, and research. Several of the recommendations of the RBP are incorporated into the proposed action and are detailed in the Conservation Measures section. For example, to control points along potential invasive species pathways, the DON's HACCP program has been established for construction which includes control measures as well as baseline and follow on surveys to evaluate the effectiveness of the program (e.g., inspection of all DON related equipment or materials entering or leaving the action area, implementation of vehicle wash down procedures).

The DON is also committed to a comprehensive BTS interdiction program, also detailed in the Conservation Measures section, to ensure that military activities, including the transport of civilian and military personnel and equipment to and from Guam, do not contribute to the spread of the BTS (DON 2014a, p. 38). Brown tree snake interdiction requirements (e.g., trapping and inspections at ports, cargo facilities; and aircraft inspections of household goods, and biosecurity plans for training events) are specified in DoD instructions (i.e., 36 Wing Instruction 32-7004, BTS Control Plan and COMNAVMAR Instruction 5090.10A, BTS Control and Interdiction Plan) as well as the annual Work Financial Plan that is developed in cooperation with USDA Wildlife Services (DON 2014a, pp. 38-39).

In addition, the DON will fund any increase of current federally funded BTS interdiction measures (in Guam, CNMI, and Hawaii) where the need for the increase is to address direct or indirect effects related to the proposed action. The fiscal year (FY) 2010 level of funding for the Federal interagency BTS interdiction effort on Guam, CNMI, and Hawaii and 2010 transportation levels associated with outbound cargo from Guam to the U.S. or U.S. territories will be used as the baseline. The Service agrees that it is not DON's responsibility to fund increased interdiction measures that are identified more than one year after the end of the fiscal year in which the USMC relocation construction activities have ended and permanent non-transient USMC military units have completed their relocation to Guam. However, the Service understands the DON will continue to provide a baseline level of interdiction funding related to the direct, indirect, and induced-growth effects of its proposed action beyond one year.

Because of the DON's commitment to the RBP and BTS interdiction and with full implementation of the biosecurity measures described above, we anticipate that the proposed action will reduce the introduction and spread of invasive species both within the action area and beyond the borders of Guam.

Beneficial Effects of the Proposed Action (All Affected Listed Species)

In addition to the above measures that will minimize the risk of fire and spread of invasive species, the proposed action also includes other measures which will provide beneficial effects to all affected listed species.

- Enhancement and protection of two Forest Enhancement Sites in Finegayan totaling 1,108 ac (448 ha) of limestone forest habitat. In 2016, the DON conducted a vegetation survey (MCAG 2016) to determine the vegetation composition baseline prior to the commencement of forest enhancement activities (**Figure 17**). A majority of the current vegetation in the Forest Enhancement Sites consists of non-native *Vitex parviflora* (476 ac, 192.6 ha) or is comprised of grassland and disturbed limestone forest gaps (354 ac, 143.3 ha) (**Table 10**).
- Enhancement and protection of approximately 218 ac (88.2 ha), 66.7 ac (27.0 ha), and 97.1 ac (39.3 ha) of primary limestone forest, secondary limestone forest, and herbaceous scrub, respectively, by constructing an ungulate fence, creating an Ungulate Control Area in the Northwest Field, and eradicating ungulates within this area surrounding the LFTRC.
- Fencing of the Haputo Ecological Reserve Area (ERA) and providing signage and educational materials along the access trail to minimize human disturbance in the area and assist in maintaining the characteristics and integrity of the ERA. The fencing will prevent overuse by military and civilian personnel and potential damage to terrestrial biological resources.

Table 90. Vegetation-type totals within the North Finegayan Forest Enhancement Site and the South Unit BTS Exclusion Fence (MCAG 2016). General field classifications were used and overlap may exist.

	Total	
Dominant Vegetation	**Acres**	**Hectares**

Total Area Surveyed	830	335.8

Conservation measures with specific effects are described in species specific sections below.

Direct and Indirect Effects of the Action on the Mariana Fruit Bat

In addition to the general and beneficial effects of the action discussed above, a species-specific effects analysis for the Mariana fruit bat is provided below.

The Service's draft recovery criteria for the Mariana fruit bat proposes that recovery of the Mariana fruit bat will require subpopulations on each island where they are currently extant, and those subpopulations must be of sufficient size to avoid genetic and demographic risks associated with small populations (USFWS 2009a, p. 9). The Mariana fruit bat subpopulation within the action area fluctuates due to periodic movements between Rota and Guam. For example, in February 2016, 112 Mariana fruit bats were documented within the AAFB HMU area on Guam. This connectivity between Rota and Guam is important to allow access to available food resources and ensure genetic flow between islands. Resilience of the Mariana fruit bat population on Guam is expected to be low given the critically small starting population, the species' slow reproductive rate (USFWS 2009a, p. 17 and references therein), infrequent and unpredictable immigration from other islands (DON 2013d, p. 78), and abundant, widespread, and uncontrolled threats (USFWS 2009a, p. 19-33 and references therein). Based on our estimate of 27,096 ac (10,965 ha) of existing survival and recovery habitat for the Mariana fruit bat (Amidon in litt., 2015), the estimated carrying capacity for Mariana fruit bats on Guam is 19,847 bats (DON 2013d, p. 26, 45).

Given the small population of Mariana fruit bats remaining on Guam, recovery will likely depend on immigration or translocation of Mariana fruit bats from Rota (Esselstyn et al. 2006, p. 531) and long-term conservation and maintenance of Mariana fruit bat habitat on Guam. The Mariana fruit bat has high energetic demands associated with flight and year-round breeding, and as such depends on a steady and ample supply of fruiting and flowering plants that are distributed patchily through space and time (Wiles and Fujita 1992, pp. 26-31; USFWS 2009d, p. vi; Amitai et al. 2010, p. 2693; Downs et al. 2012, p. 344). To meet requirements for breeding, feeding, and sheltering, a self-sustaining population of Mariana fruit bats will rely on threat-managed, native limestone forest habitat containing diverse food resources that are available throughout the year.

Noise Effects

The proposed action will generate noise from the use of a variety of vehicles and machinery (construction and engineering equipment, fixed-wing aircraft, helicopters, and other convoy vehicles) and munitions (small arm firing and projectile detonations). Noise resulting from weapons training and construction on Guam will affect areas occupied by the Mariana fruit bat and reduce the quality of Mariana fruit bat habitat within disturbance range of the noise. Increased jet and helicopter aircraft traffic throughout Guam and especially at AAFB will regularly expose the Mariana fruit bat to high levels of noise.

Upon operation of the LFTRC, live-fire operations would occur between 7:00 am and 7:00 pm for up to 39 weeks per year, plus night operations (two nights per week over 39 weeks per year) would occur between 7:00 pm to 10:00 pm or 6:00 am to 7:00 am. The noise disturbance from the training will be impulse noise with very intense sounds of short duration (e.g., the discharge of a weapon). Firing noise from single shots merged in bursts, machine gun burst, and concurrent firing of multiple weapons would result in short periods of intense firing followed by periods of silence. Live-fire operations may occur for hours at a time, for five days a week, or not occur for multiple weeks in a row.

Peak noise level measures sound from a single event (e.g., grenade detonation or firing of a small arms weapon) received at a defined location, and is often referred to as sound pressure level (SPL). The average daily noise level (ADNL) sound metric accounts for not only the maximum SPL, but also the duration and temporal variation of the sound exposure (US Army 2008, p. 3-61). The DON provided the Service with estimated ADNL noise levels for all activities of the proposed action, including operation of the LFTRC, aircraft overflights within the action area, and operation of the hand-grenade training range at AAFB South **(Figure 18)**. The DON conducted a noise study at AAFB at three sampling sites near the LFTRC and found that ambient noise was never below 50 dB, and on some days was above 65 dB almost 100 percent of the time (DON 2014a, p. 66). The DON provided ADNL levels for areas surrounding the LFTRC (DON 2014a, p. 68). In the areas closest to the training ranges in operation the estimated ADNL would increase approximately 20 to 25 dB over baseline conditions, with average daily sound levels rising above 85 dB.

Hall and Richards (2000, p. 38) reported that flying foxes had peak sensitivity at 11 kHz but could hear between 2-40 kHz. Given the sensitivity of Mariana fruit bats to noise and human disturbance on Guam, and because of the reaction of Mariana fruit bats to hunting disturbance (i.e. gunshots), we anticipate that Mariana fruit bats will avoid the LFTRC and surrounding areas while it is in operation. For this reason, we have conservatively chosen a 65 dB threshold for noise disturbance of Mariana fruit bats that would preclude them from using habitat for breeding, foraging, or sheltering. The 65 dB threshold is based on the high-end of current ambient noise levels; we can reasonably expect that all habitats with noise louder than 65 dB would be avoided by Mariana fruit bats given the level and type of noise (i.e., gunshots). Therefore based on GIS mapping of areas where noise levels above 65 dB are expected to occur, we anticipate that approximately 1,817 ac (735 ha) of Mariana fruit bat habitat will be lost or degraded in northern Guam (AAFB and LFTRC) due to noise effects from military training and aircraft flights (**Figure 19**).

The proposed construction of the Main Cantonment at Finegayan will increase human presence and noise in the area. The cantonment is near the Haputo ERA, which contains high-quality Mariana fruit bat habitat, where fruit bats have been observed in the past. Increased use of the Haputo ERA by humans could deter Mariana fruit bats from using these areas for foraging or roosting.

Training will also occur at the NMS in southern Guam, where Mariana fruit bats are routinely observed. Training will include air-ground operations on five to seven consecutive days, 12 weeks per year, day and night, for a total annual throughput at the NMS of 1,440 Marines. Training at the NMS will also include terrain flight, ground threat reaction, defensive maneuvering, confined area landing, and external load training. These training activities will result in an increase in temporary noise and other human disturbance at the NMS. Solitary Mariana fruit bats flushed as a result of project noise may travel to another area where the likelihood of poaching or harassment is greater overall than it is on DoD lands. Flight restrictions will limit low-level flights over much of the NMS and this will minimize, but not completely avoid, adverse noise impacts to the Mariana fruit bat in this area. Therefore, we anticipate that approximately 319 ac (129 ha) of Mariana fruit bat habitat will be degraded in Southern Guam due to noise effects from military aircraft training flights (**Figure 20**).

Species Response

Stress reactions caused by human disturbance can have an adverse effect on Mariana fruit bats by increasing energetic demands, disrupting hormonal balance, and forcing relocation to lower quality habitat (Klose et al. 2006, p. 347, and references therein; CNMI 2010, p. 7). All of these factors can lead to reduced time foraging, sheltering, or breeding and adversely affect survival. When a disturbance is experienced by a Mariana fruit bat colony, individuals may disperse on their own or in smaller groups (CNMI 2010, p.6). In some cases, the degree of colony dispersal (i.e., how many individuals leave the main colony) may be related to the degree and/or type of human disturbance. When Mariana fruit bats are forced to disperse from colonies as a result of human disturbance, infant mortality may increase because dependent, non-volant pups that are too big for the mother to carry are likely abandoned. Forced dispersal may also negatively affect the reproductive potential of the population because access to mates is compromised (CNMI 2010, p. 7). Even without dispersal, high levels of stress from any disturbance can disrupt reproductive cycles and/or lead to miscarriage (Wingfield et al. 1998, p. 192-193, Heideman 2000, pp. 169-199, Klose et al. 2006, p. 347).

The following reactions to aircraft noise have been reported:

- Mariana fruit bats have been reported to flush at noise levels exceeding 106 dBC (SWCA 2008, pp. 2-3) and at peak noise levels above 90 dBA/101 dBc (SWCA 2012, p. 23, 37).
- Mariana fruit bats at a maternity colony on Rota flushed when a helicopter was within 656 ft (200 m) and a military jet aircraft (type unknown) flew overhead within 984 ft (300 m) (J. Boland, pers. obs., 2009 and 2010).
- Successive launches of F-14 aircraft repeatedly flushed 50 Mariana fruit bats from a roost site and F-14s (95 dBA to 106 dBA) also caused agitated Mariana fruit bat vocalization and flushing (Grout 1993 in Morton 1996, p. 67).
- Increases in active thermoregulation (32 percent), maintenance (14 percent), locomotion (74 percent), and alertness (62 percent) of Mariana fruit bats were recorded after aircraft overflights (SWCA 2012, p. 23, 37).

Mariana fruit bats in the vicinity of construction could be disturbed or harassed by noise and human presence. In order to avoid disturbance to Mariana fruit bats in the vicinity of construction, the DON will conduct surveys for Mariana fruit bats one week prior to onset of construction in areas within or in the vicinity of Mariana fruit bat habitat. If a Mariana fruit bat is present within 492 ft (150 m) of the project site, the work will be postponed until the bat has left the area (DON 2014a, p. 33). The DON clarified that this conservation measure does not mean that work will halt if a Mariana fruit bat enters the vicinity of a construction site while construction is on-going (C. Cobb, DON, 2015, pers. comm.). In general, Mariana fruit bats are likely to avoid construction sites due to human presence and noise disturbance, and seek other locations to roost and forage. If a fruit bat is present near a construction site and not seen (for example, roosting below a cliff line) then it will likely be harassed or harmed by the proposed action.

Noise from construction of the proposed action would be temporary and intermittent. Construction noise reaching fruit bat habitat may rise above the disturbance threshold for the

Mariana fruit bat; however, this noise will be short-term in duration and will not lead to a permanent reduction in the capability of the habitat to serve as suitable habitat for Mariana fruit bats.

Most Mariana fruit bats will depart from roost sites to foraging areas from one hour before to one hour after sunset (J. Boland unpublished data, 2008-2011). Therefore the range will be operational when bats can be expected to be commuting to foraging areas. We expect that any Mariana fruit bats that are able to hear the LFTRC in operation will avoid the area and seek out a less disturbed area. While bats are capable of flying outside the disturbance zone, bats seeking alternate commuting corridors and/or foraging areas may be forced into lower quality habitat or exposed to increased risks of poaching and harassment. In addition, bats in the vicinity of the LFTRC when firing begins will likely flush and leave the area. As mentioned above, if reproductive females are exposed to stressors that cause flushing and dispersal, it can disrupt reproductive cycles, cause miscarriage, or cause abandonment of non-volant young (Wingfield et al. 1998, p. 192-193, Heideman 2000, pp. 169-199, Klose et al. 2006, p. 347).

A colony of bats may periodically roost within the HMU on AAFB. These bats forage within AAFB and are likely to be further harassed from the increase in aircraft overflights associated with the proposed action.

Mariana fruit bats are suspected to migrate from Rota to Guam periodically following typhoons, and the migrants are suspected to return to Rota when the effects of the storm have subsided (Wiles and Glass 1990, p. 3; Esselstyn et al. 2006, p. 536). Migrants from Rota are thought to have occupied the Pati Point roost site on Guam in the past (Esselstyn et al. 2006, pp. 535-536; Wiles and Glass 1990, p. 2-3). We suspect that if Rota migrants are subjected to high levels of noise disturbance from increased air traffic at AAFB, it may cause them to return to Rota prematurely. A premature return to Rota under post-typhoon conditions may expose Mariana fruit bats to high levels of hunting and decreased food and habitat availability.

It is also possible that the increased noise near Pati Point, and on AAFB in general, will limit the establishment and growth of the Mariana fruit bat colony in northern Guam. If the Mariana fruit bat population on Guam were to increase, individuals and colonies are not likely to establish roost sites in areas with high levels of human foot, vehicular, or aircraft traffic, due to hunting-induced sensitivities to human-presence (i.e., humans are predators), and sensitivity to loud noise and vibration from aircraft (see data presented above and in the Species Status section).

Habitat Conservation and Protection

The DON's protection and management of 5,234 ac (2,118 ha) of Guam Micronesian kingfisher habitat in northern Guam, in accordance with the GMK MOA (**Figure 21**), will have a beneficial effect on the survival and recovery of the Mariana fruit bat on Guam because these two species use similar habitat.

As part of the proposed action, the DON proposes to create two Forest Enhancement Sites at Finegayan, in low-quality secondary limestone forest, to benefit listed species, including the Mariana fruit bat. The DON has proposed the enhancement of the sites to include installation of

ungulate exclusion fences protecting a minimum of 1,000 ac (405 ha) and the creation of two BTS-free enclosures totaling 460 ac (186 ha), according to the schedule described in the Conservation Measures section, with the goal of ungulate eradication within the fenced areas; invasive plant removal; and the propagation, planting, and establishment of dominant and rare species characteristic of native limestone forest habitats. Although this site would not fully compensate for the loss of primary limestone forest in northern Guam, the enhancement of forest and protection of the site is expected to provide benefits to the Mariana fruit bat.

Summary

The proposed action is likely to adversely affect the Mariana fruit bat on Guam. Noise from, aircraft, operation of the LFTRC, and other military training activities will harm and harass Mariana fruit bats in the vicinity of the project activities. In total, 2,136 ac (864 ha) of Mariana fruit bat habitat will be lost, or degraded at least 75 percent of the time, due to noise effects of the proposed action (**Figure 13 & 14**). This loss or degradation of Mariana fruit bat habitat represents 8 percent of the existing Mariana fruit bat habitat on Guam.

While the maximum number of Mariana fruit bats seen at one time within the action area was estimated at 112 individuals, the number of Mariana fruit bats in Guam is unknown, but is believed to flunctuate as a result of migrations between Guam and Rota. The Guam population of Mariana fruit bats may forage throughout the action area in search of food resources and suitable roosting sites. Mariana fruit bats will avoid or be flushed from habitat areas with excessive noise above the ambient level, such as weapon fire or aircraft flights, as evidenced by documented observations. This disturbance, combined with existing threats to the Mariana fruit bats in the action area (as described in the Environmental Baseline), will make reestablishment of a Mariana fruit bat colony at Pati Point in northern Guam, unlikely. Increased human disturbance in northern Guam and in the NMS area may alter Mariana fruit bat behavior, increase stress reactions, or preclude use of high-quality foraging areas. Based on the increased disturbance throughout AAFB, where Mariana fruit bats have been historically detected, it is likely that individual bats may be harassed by the proposed action. Mortality to Mariana fruit bats as a result of the proposed action is unlikely. As part of the proposed action, the DON protect and management of 5,234 ac (2,118 ha) of Mariana fruit bat habitat in northern Guam, including 3,271 ac (1,324 ha) of occupied or suitable Mariana fruit bat habitat away from noise effects (**Figure 13**).

The areas of Mariana fruit bat habitat that will be permanently cleared are areas which, in the absence of the project and in the foreseeable future, would have remained intact to provide habitat for the species. Although this loss will not preclude the survival or recovery of the Mariana fruit bat, it will reduce the total number of bats the island can support. The proposed action will reduce the current estimate for the carrying capacity of Mariana fruit bats on Guam (see Environmental Baseline above) by approximately 1,559 bats.

Effects to Mariana Fruit Bat Critical Habitat

The proposed action may affect Mariana fruit bat critical habitat and its primary constituent elements (USFWS 2004). Although the current population of Mariana fruit bats on Guam is

small, the foraging behavior and diverse diet of the fruit bats cause them to use most of the island for foraging, as documented by Wiles et al. (1995). Thus, all of the designated critical habitat for this species is used for foraging and/or roosting and is considered occupied. Recent sightings of Mariana fruit bats at the GNWR within the critical habitat unit confirm this. Actions that affect the ability of the critical habitat unit to provide the conservation function for which it was designated (serving as habitat for roosting and foraging bats) may adversely affect critical habitat, regardless of whether the habitat features are actually physically altered.

The proposed project will not clear any designated critical habitat for the Mariana fruit bat. However, the proposed action will create disturbance that may affect the PCE (described above) requiring remote locations on clifflines with limited exposure to human disturbance. As described below, this primary constituent element will be adversely affected by the proposed action.

Construction

Construction of the MPMG range will take place over approximately three years beginning in 2021. Construction equipment will include standard heavy equipment including bulldozers, graders, haulers, large trucks. No blasting or use of dynamite will occur as part of the proposed project. The use of heavy equipment can reach noise levels of 96 dB (USFWS 2006a, p. 15). Noise levels within critical habitat, at the base of the cliff below the MPMG firing range, are anticipated to be 5 to 15 dB less than that above the cliff line (personal communication, M. Downing, Blue Ridge Research and Consulting, February 2014 in DON 2014b, p. 5-230). Therefore, we anticipate that noise from construction of the LFTRC would range between 81-91 dB within the critical habitat unit (without accounting for noise attenuation due to vegetation, humidity or other factors). Ambient noise within the critical habitat unit will depend on wind and surf conditions, and distance from the ocean. Based on ambient noise studies conducted above the cliff line at AAFB (DON 2014a, p. 66), we expect that ambient noise within the critical habitat unit is at least 60 to 65 dB. Therefore, noise from the construction of the MPMG firing range on AAFB may reach between 16 to 26 dB above ambient conditions in the critical habitat unit.

Noise from construction will not be heard within the entire critical habitat unit. While it is difficult to estimate what portions of the critical habitat unit will be affected, we assume that the noise above ambient levels would be heard in the portions of critical habitat immediately below the MPMG cliff line. In a conservative scenario, construction noise may be heard in a 100 ac (41 ha) portion of the 376 ac (152 ha) critical habitat unit (or 27 percent of the critical habitat unit). Noise from construction of the MPMG would be temporary and intermittent. Noise reaching the critical habitat unit would likely only come from construction activities at the MPMG range, which might occur for a few years of the total construction time.

Construction noise within the critical habitat (81-91 dB) will rise above the disturbance threshold for Mariana fruit bats (described in the Effects of the Action – Mariana Fruit Bat section). This noise will be short-term in duration and will not lead to a permanent reduction in the capability of the critical habitat unit to support recovery of the Mariana fruit bat. However, during construction, the critical habitat unit will not serve as a remote location with limited exposure to

human disturbance and this will limit the fruit bat's use of the clifflines for roosting or reproductive activity. Construction noise at this time, and for a period of time after while fruit bats still avoid the area, may have an adverse effect on the critical habitat unit serving as a remote location.

Operation of the LFTRC and aircraft overflights

Noise disturbance from the LFTRC and aircraft overflights could expose the critical habitat unit to increased human disturbance and preclude Mariana fruit bat roosting and reproductive activity. Based on the noise data shown in **Figure 17**, approximately two acres of fruit bat critical habitat, along a cliffline, will be exposed to noise levels above 65 dB. This includes approximately 150 linear meters (492 linear ft) of cliffline. There are approximately 2,500 m (6,652 feet) of cliffline within the critical habitat unit. Therefore, the amount of cliffline critical habitat precluded from use by the Mariana fruit bat is small.

In addition, based on the map of noise contours for aircraft at AAFB from the 2010 DON EIS (DON 2010b, Vol. 2, p. 6-25), we do not expect aircraft noise over the critical habitat unit to rise above ambient conditions.

Direct and Indirect Effects of the Action on the Mariana Eight Spot Butterfly

In addition to the general effects of the action discussed above, a species-specific effects analysis for the Mariana eight spot butterfly is provided below.

NOTE: In light of limited available empirical information on the biology and ecology of the Mariana eight spot butterfly, in the following analysis we have relied on information for other well-studied butterfly species in the same family (Nymphalidae). The Mariana eight spot butterfly appears to exhibit much of the same behavior, life history, and patchy distribution as other well-studied species in the family Nymphalidae. The Nymphalidae are the largest family of butterflies with about 6,000 species distributed throughout most of the world. These are usually medium-sized to large butterflies. Most species have a reduced pair of forelegs and many hold their colorful wings flat when resting. Many butterflies in this family exhibit a similar patchy distributional pattern because they exist as metapopulations [i.e., at any given point in time, butterflies may be using some areas and not others (Hanski and Gilpin 1991)]. Suitable habitat within the range of a species that exists as a metapopulation can play a pivotal role in maintaining natural metapopulations, especially for butterflies like the Mariana eight spot butterfly that may have limited dispersal abilities.

Habitat Loss

One of the most important factors likely influencing the status of butterfly species' populations in general and the Mariana eight spot butterfly population in particular is the distribution and abundance of nutritional resources, primarily food plants for larvae and nectar for adults. In many cases, the plant species providing nectar and those providing larval food are different, but grow together in the same habitat patches (Ehrlich 1984). The host plants for the Mariana eight spot butterfly are distributed in patches, and there is a strong association between the occurrence

of the species and its host plants. Schreiner and Nafus (1996) reported that at all locations where host plants were present, at least one of the life stages of the Mariana eight spot butterfly occurred. Recent surveys have shown that the Mariana eight spot butterflies are rarely observed except in close proximity to host plants.

Under the proposed action, 350 ac (142 ha) of high quality limestone forest habitat containing nectar and host plants known to be used by foraging Mariana eight spot butterflies and larvae within and surrounding the proposed LFTRC at Ritidian Point will be removed or degraded as a result of the construction and operation of this facility. The proposed action will directly and permanently remove 140 individual host plants (*E. calcareum* and *P. pedunculata*) for the Mariana eight spot butterfly on 187 ac (76 ha) within the proposed MPMG and Non-Standard Small Arms (NSSA) ranges at the LFTRC.

The Ritidian Point area is an important site for the Mariana eight spot butterfly due to interconnected patches of host plants within primary and secondary limestone forest habitat. Mariana eight spot butterflies have consistently been observed occupying this area. For example, during surveys, seven of the 140 individual host plants within the proposed project footprint were found to be occupied by Mariana eight spot butterfly larvae or chrysalis (DON 2017a, pp. 121-122). Permanent removal of host plants would decrease the number of suitable egg-laying sites by female Mariana eight spot butterflies. In addition, larvae of the Mariana eight spot butterfly will have a reduced amount of available food resources. The permanent removal of 350 ac (142 ha) of limestone forest habitat in this portion of the butterfly's range is likely to decrease the carrying capacity of the Ritidian Point area for the butterfly and cause a temporal decrease in the use of the area by Mariana eight spot butterflies.

However, this loss of habitat will be partially offset by the permanent fencing and removal of ungulates within an area of 284.7 ac (115.2 ha) of existing primary limestone and secondary limestone forest adjacent to the LFTRC in the Ritidian Point area. It is likely that with the installation of fencing and removal of ungulates, the host plants for the Mariana eight spot butterfly will be able to establish and thrive and Mariana eight spot butterflies will expand into this protected area.

Habitat Fragmentation

Many butterfly species exhibit metapopulation structure in which populations colonize new patches as previously occupied patches are vacated, leading to an on-off temporal patchwork of localized occupation and extirpation during certain times of the year or over several years (Rubinoff 2016, pp. 4-5). Connectivity of host plants and patch sizes are expected to influence the suitability of habitat for the Mariana eight spot butterfly. Given what we know about butterflies in this family, we suspect that on Guam, as habitat has been lost, the remaining patches have become smaller and more isolated. As habitat patches have become more isolated, the amount of intervening unsuitable areas between the suitable habitat patches have likely exceeded an individual's movement or dispersal capability and heighten vulnerability to the overall metapopulation.

Based on vegetation and butterfly surveys, our current understanding of the distribution and connectivity of suitable butterfly habitat on Guam, while not optimum, has allowed the Mariana eight spot butterfly metapopulation to persist within the action area. We believe the current distribution of butterfly habitat is a result, in part, of ungulates not being able to reach butterfly host plants due to the rugged terrain along cliff faces and the loss of habitat from other sources (e.g., development). As such, controlling existing threats such as ungulates is necessary in order to preserve existing locations of and expand habitat for Mariana eight spot butterfly host plant species.

The construction of the LFTRC will convert a portion of the limestone forest where Mariana eight spot butterflies occur from contiguous primary limestone karst forest to fragmented habitat. Habitat fragmentation may be one of the most challenging ecological issues to address (Dobson et al 1999). For example, Warren (1993) found that key butterfly species have been disappearing even from protected areas and concluded that, if site protection alone is not enough to maintain butterfly populations in the long-term, more emphasis should be placed on creating and maintaining habitat links at a landscape scale. In the absence of functioning habitat links, habitat fragmentation leads to isolation of populations, loss of genetic heterozygosity within populations, disruption of metapopulation, and local extinctions (Wilson et al. 2009, p. 1421). The long-term conservation of most butterfly species requires the protection of its metapopulation in a closely linked network of high quality habitat patches (Thomas et al. 2001, p. 1791).

Under the proposed action, conservation measures involving ungulate-proof fencing and ungulate removal as well as development of a focused fire management plan to minimize the frequency and size of fires caused by live-fire exercises are likely to provide for butterfly habitat in the Ritidian Point area that is better quality than is currently available.

Maintenance of the suitable habitat in a particular landscape is the most fundamental factor determining the presence of a species in a particular area (Thomas et al. 2001). In this context, stepping-stone habitat patches are important for butterflies. Maintaining habitat patches can help ensure and speed up the re-colonization of unoccupied sites that contain suitable habitat. The more isolated a habitat patch is, the less likely it is to be occupied, similarly the greater the gap between habitat patches the longer it takes for the vacant patch to be colonized. In general, the smaller the gap between habitat patches the quicker the vacant patch can be colonized (Thomas et al. 1992).

The network of host plant habitat patches at Ritidian Point is not currently contiguous and is situated between two occupied Mariana eight spot butterfly areas at Haputo and Tarague. As a result of the proposed action, areas of butterfly habitat will be permanently removed, potentially fragmenting habitat by creating gaps that could limit butterfly movement or dispersal between habitat patches within the Ritidian Point area and potentially between the two neighboring areas. Furthermore, because host plants for the Mariana eight spot butterfly are restricted in distribution, occurring in tower karst (Rubinoff 2016, 9 pp), populations of the Mariana eight spot butterfly could easily become isolated, since many tropical forest butterflies are unlikely to fly through open terrain (Laurance et al. 2002).

However, the permanent protection and maintenance of the proposed ungulate-proof fenced area discussed above is likely to provide the Mariana eight spot butterfly with a large block of suitable habitat that when restored, will provide better quality habitat than is currently available in the area. We also note, that while the firing range will not have a durable conservation easement per se, there would be no development or construction in adjacent areas of suitable butterfly habitat due to safety concerns (e.g., live fire exercises). Additionally, the mandatory development of a fire management plan (i.e., implementation of fire prevention measures) will minimize the impact of fires that may ignite within the areas adjacent to the firing range from the use of live munitions. This land use configuration will ensure that the areas of suitable butterfly habitat adjacent to the LFTRC are permanently protected from direct (development) and indirect (fire) loss of habitat, which would effectively benefit the Mariana eight spot butterfly.

Human Disturbance

Although we did not find any studies that evaluated the specific effects of construction activity and the operation of an active firing range on butterflies, a study on the effects of human recreational activities on butterflies found that oviposition events were concentrated on host plants furthest from the trail, suggesting that breeding habitat was constrained by recreational activities (Bennett et al. 2013, pp. 1783-1798). Minimum breeding areas or habitat patches for various butterflies have been calculated and range from 1.2 ac (0.5 ha) to over 123 ac (50 ha), but these areas should be considered within the metapopulation structure (Spalding 2005, p. 4). It is unknown what the minimum breeding area is for the Mariana eight spot butterfly.

Construction activity and firing range operation would disturb Mariana eight spot butterflies using host plants that remain on the edge of the clearing of the MPMG range, and in the absence of adequate buffers, may no longer provide suitable habitat for egg-laying female butterflies. While we do not know the extent of disturbance caused by the proposed action on the Mariana eight spot butterfly, we estimate the exposure of some, small areas adjacent to the LFTRC to human disturbance would be tempered by the beneficial effect of permanently protecting suitable butterfly habitat adjacent to the LFTRC from development or other land use activities due to firing range safety concerns.

In addition to the Ritidian Point area, the proposed action will also affect two subpopulations of Mariana eight spot butterflies located in the Finegayan-Haputo ERA and NMS. The Haputo ERA is an important site for Mariana eight spot butterflies because of the amount of high-quality host plants available. The proposed action includes construction and operation of a 1,213 ac (492 ha) Main Cantonment on the upper plateau above the Haputo ERA. The DON has addressed the potential for increased military and civilian access to the shoreline and into Haputo ERA by fencing the Haputo ERA and providing for educational signage and materials, as part of the proposed action. The NMS, Southern Land Navigation Area contains a single site where the Mariana eight spot butterfly was observed over multiple occasions in the last 10 years in primary limestone forest habitat. Ground maneuvers planned for the Southern Land Navigation Area may disturb this subpopulation of Mariana eight spot butterflies. The NMS, Northern Land Navigation Area also contains eight butterfly-unoccupied locations of individual host plants (*E. calcareum* and *P. pendunculata*).

Habitat Conservation and Minimization Measures

The adverse effects of the proposed action discussed above to the Mariana eight spot butterfly would be minimized, in part, by the DON's proposed conservation measures. The following is a summary of those conservation measures that may affect the Mariana eight spot butterfly:

- Implementation of fire prevention measures will decrease the risk of wildfire and destruction of habitat for the Mariana eight spot butterfly located adjacent to the LFTRC and within the Naval Munitions Site.
- Pre-construction surveys within a project footprint will be conducted to identify all stages of the Mariana eight spot butterfly, prior to construction. If any life stage of the Mariana eight spot butterfly (e.g., eggs, caterpillar, and chrysalis) is located within a project footprint during pre-construction surveys, it will be relocated onto an appropriate host plant (e.g., relocate pre-diapause larvae to *Procris pedunculata* or *Elatostema calcareum*) in similar sites away from the project footprint. This can be conducted by clipping the host plant and grafting the plant to another plant outside the project footprint (Cook and Delisle 2010), but within an occupied area of Mariana eight spot butterflies. The translocation of butterflies using the host plant grafting method in not likely to be 100 percent successful; however, if translocation is done in accordance with accepted protocols (Cook and Delisle 2010) and harm resulting from the relocation would be exempted from take prohibitions. The objective of this conservation measure is to minimize the amount of impact to the species by re-locating individuals out of harm's way and into existing suitable habitat. Movement of the individuals is better for the species than leaving them in habitat that will be destroyed by construction actions as long as actions are sensitive enough to protect the various different life stages.
- The DON will out-plant a minimum of 140 individual host plants of either *P. pedunculata* or *E. calcareum*, commensurate with the amount of each plant species that is removed as a result of construction activities associated with the proposed action. Out-planted host plants will be located in protected areas, including the two Forest Enhancement Sites at Finegayan and within the new ungulate exclusion fence surrounding the LFTRC.
- In addition to the 140 host plants to be out-planted in protected areas, the DON will out-plant host plants of either *P. pedunculata* or *E. calcareum* on the backside of LFTRC range berms that have no likelihood of encountering munitions. This conservation measure will enhance the suspected habitat corridor along the cliff face to ensure connectivity of nearby locations of Mariana eight spot butterflies. When feasible, but no less than annually, the DON will document the status of Mariana eight spot butterfly host plants on the backside of the earthen berms and any presence of the Mariana eight spot butterfly, in order to evaluate the efficacy of this conservation measure.
- The DON will construct an ungulate exclusion fence and remove ungulates within the NWF Ungulate Control Area, surrounding the LFTRC. This conservation measure will protect and enhance 284.7 ac (115.2 ha) of existing primary limestone and secondary limestone forest habitat that is occupied by the Mariana eight spot butterfly.

The planting of butterfly host plants at the Finegayan Forest Enhancement Sites will increase the number of host plants available for the Mariana eight spot butterfly. However, it is unknown

whether this site would be naturally colonized by Mariana eight spot butterflies or whether there would be suitable conditions to allow breeding at this site. The Finegayan Forest Enhancement Sites include mostly *Vitex* sparse canopy and mixed limestone plateau/secondary limestone forest which is a different vegetation community than the vegetation community found in the Haputo ERA and Ritidian Point area where Mariana eight spot butterflies have been observed. Though rearing of Mariana eight spot butterflies in captivity has been successful, successful full-scale propagation or breeding the species in captivity and subsequent reintroduction into previously unoccupied areas, requires additional research and refinement (C. Cobb, DON, pers. Comm 2017). The DAWR has funded a captive breeding project at the University of Guam, with planning underway (D. Vice, DAWR, pers. Comm. 2016).

Although butterfly habitat is limited within the NWF Ungulate Control Area, fencing and removal of ungulates will protect and enhance 284.7 ac (115.2 ha) of existing primary limestone and secondary limestone forest habitat for the Mariana eight spot butterfly. Once ungulates are removed, this permanent protection will greatly assist in improving butterfly habitat and connectivity. Habitat connectivity and patch sizes influence the suitability of habitat. When habitat is lost, the remaining patches become smaller and more isolated. As habitat patches become more isolated, the amount of intervening unsuitable areas between the suitable habitat patches can exceed an individual's movement or dispersal capability and heighten its vulnerability. Therefore, connectivity between patches of suitable habitat is necessary to facilitate daily and seasonal movements, and dispersal to increase the likelihood of long-term viability of Mariana eight spot butterfly populations. Because of long-term commitments to habitat protection through fencing and removal of ungulates, this conservation measure is likely to effectively expand the amount of suitable butterfly habitat beyond its current distribution along the cliff faces. As a result of the proposed fencing and removal of ungulates, host plants and other associated forest plants are expected to develop and be maintained within the 284.7 ac (115.2 ha) area for the foreseeable future.

Summary

The known distribution of Mariana eight spot butterfly populations is disjunct. This suggests that, historically, butterfly habitat was likely less fragmented and provided much greater connectivity to facilitate butterfly movement and dispersal. The proposed action will remove 350 ac (142 ha) of butterfly habitat, including approximately 140 host plants of *P. pedunculata* or *E. calcareum*, which represents 6.1 percent of all currently known host plants range-wide. However, the conservation measures proposed as part of the action (e.g., out-planting of 140 host plants, installation of ungulate-proof fencing, ungulate removal, fire management, and translocation of individual butterflies) in conjunction with natural expansion of host plants within the fenced area will not only minimize impacts of the action, but also restore additional butterfly habitat within areas that are currently unsuitable.

The Ritidian Point area includes occupied habitat and other suitable habitat that is important for sheltering, breeding, and foraging Mariana eight spot butterflies. The restoration of habitat under the proposed action is likely to allow for butterfly population expansion and provide additional habitat connectivity above what is currently available. In addition, this area includes a network of host plant patches with consistent observations of Mariana eight spot butterfly occupancy that

will be retained with implementation of the proposed action. The area is situated between two other Mariana eight spot butterfly habitat areas, and is therefore likely important in maintaining the connectivity of populations for this species.

Implementation of the proposed action, inclusive of the conservation measures, is likely to result in a net loss of limestone forest habitat and adverse impacts to the Mariana eight spot butterfly and its habitat, but will ultimately assist in the restoration of butterfly food plants that will benefit the metapopulation by increasing habitat connectivity. When the fencing in the Ritidian Point area is complete and ungulates are removed, we anticipate these actions will be effective in facilitating the establishment and maintenance of butterfly host plants and other associated forest vegetation within the 284.7 ac (115.2 ha) fenced area for the foreseeable future. Collectively, these conservation actions are likely to temper the loss and fragmentation of limestone forest and butterfly habitat caused by the proposed action to an extent that does not deepen the current degraded baseline for the Mariana eight spot butterfly on Guam.

Direct and Indirect Effects of the Action on the Partulid Snails: Humped Tree Snail, Guam tree snail, and Fragile tree snail

In addition to the general effects of the action discussed above, a species-specific effects analysis for the Partulid snails is provided below.

For partulid snails, the analysis considers the number of known snails within project footprints, existing vegetation cover, historical records of partulid snails within the action area, and mark-recapture survey data from long-surveyed populations of endemic tree snails elsewhere in the Pacific. The most severe impact to listed partulid snails is expected to occur within Anderson South, where up to 212 ac (86 ha) of disturbed secondary limestone forest snail habitat is expected to be permanently removed. In 2016, the DON opportunistically found a site of Guam tree snails within this 212 ac (86 ha) area at Anderson South that had not been known previously. In 2016 and 2017, the DON conducted transect surveys to count the number of listed partulid snails within the project site. The DON focused survey efforts on the most suitable and likely habitat to be occupied by partulid snails and expanded survey efforts outwards from that area. Due to the vegetation and substrate, not all vegetation within the 212 ac (86 ha) area at AAFB South could be surveyed. Based on the survey method we estimated a conservative transect buffer area of 9.8 ft (3 m), to represent the area searched along a transect. Based on the transect buffer area, a total of 153 ac (62 ha) were surveyed within the area of suitable snail habitat in AAFB South. Within the area surveyed, the DON found 38 live Guam tree snails, along with 51 dead Guam tree snail shells (DON 2017a, p. 45).

No other species of listed partulid snails were found at Anderson South. At the time of listing in 2015, the humped tree snail on Guam declined to approximately 100 individuals and was only found at one location, Haputo Beach, alongside the Guam tree snail and fragile tree snail (Smith et al. 2008). The DON will construct an ungulate fence and limit military and civilian recreational activities within the Haputo Beach ERA in order to minimize effects to listed partulid snails, as part of the proposed action. The entire Haputo ERA ungulate fence will be approximately 2.8 mi (4.6 km) in length, tying into steep cliffs on each end. Since 1989, the fragile tree snail was found only in the presence of the Guam tree snail (Hopper & Smith 1992),

and adult fragile tree snails are often mistaken for juvenile Guam tree snails. Based on the co-occuring nature of these species and the inability to accurately differentiate fragile tree snails from Guam tree snails, the effects analyses for the listed partulid snails are evaluated collectively.

While suitable habitat exists within the Main Cantonment and LFTRC areas proposed for clearing, the DON surveys have resulted in no sightings of listed partulid snails in these areas. No historical sites of listed partulid snails are known within the Main Cantonment and LFTRC areas proposed for clearing.

Partulid snails are found on the tops and undersides of various types of vegetation and do not exhibit a preference for a particular host plant species, rather they can be found in beach back strand vegetation and primary and seconday limestone forest habitat. Their cryptic nature can make detection challenging. Based on a 5-year dataset surveying listed Hawaiian tree snails of similar shape and size in a forested habitat enclosure where a known number of snails were translocated into the enclosure, timed-count monitoring efforts found that during subsequent surveys for tree snails on average only 30 percent of the actual number of tree snails present, are detected by human observers (U.S. Army 2015, Appendix 3-1; US Army 2016, p. 167; Hall et al. 2010, pp. 67-80).

Based on listed partulid surveys conducted within the action area, with consistent one-person hour searches in over 15 different sites, oberservers were able to detect and count 433 Guam tree snails or fragile tree snails (DON 2017a, p. 45; Lindstrom and Benedict 2014). Due to similar color patterns, surveyors were unable to reliably distinguish fragile tree snails from juvenile Guam tree snails (DON 2017a, p. 45; Lindstrom and Benedict 2014). Based on an average detection rate of 30 percent, the Guam tree snail and fragile tree snail population within the action area is approximately 1,400 snails. Approximately 100 humped tree snails were detected in the Haputo ERA, which is the only location in which they are known to occur. However, all three listed partulid snail species co-occur in similar habitat.

However, because the tree snails are located in terrain that is difficult to survey and the individuals are small and cryptic and can easily be missed during a survey, the Service is using the amount of impacted habitat (212 ac {86 ha}) as a surrogate to evaluate the effects to the Guam, fragile, and humped tree snails.

Habitat Conservation and Minimization Measures

In order to reduce effects to partulid snails, the DON has committed to conduct pre-construction surveys to locate partulid snails within the project footprint, prior to construction or any vegetation clearing activities. The pre-construction surveys will be conducted with the objective of locating, removing, and translocating listed snails out of the project footprint and into suitable protected habitat. Snails would be moved to similar suitable, protected habitat (i.e., habitat not subject to further anthropogenic effects or ungulate damage) and alongside other conspecifics.

In addition, the DON has committed to protect and enhance a total of 1,393 ac (564 ha) of suitable partulid snail habitat in primary and seconday limestone forest in the Finegayan and Ritidian areas.

Summary

The proposed action will adversely affect the Guam tree snail and possibly the fragile tree snail. While the humped tree snail and fragile tree snail are not known to occur within the project footprint, all three species co-occur and are found within the Haputo ERA. The DON will fence the Haputo ERA to reduce civilian and military access and minimize degradation to sensitive snail habitat. Historically, all three species shared similar habitat throughout the action area. Therefore, the likelihood that DON pre-construction surveys may detect individuals of the humped or fragile tree snail in the future cannot be discounted.

The proposed action will result in harm or harass of all Guam tree snails, fragile tree snails or humped tree snails in the 212 ac (86 ha) of limestone forest habitat to be impacted at Anderson South. The DON will conduct pre-construction surveys within the 212 ac (86 ha) of habitat and move all tree snails found to host plants in suitable tree snail habitat outside of the construction footprint. Pacific tree snail translocation techniques have been successful when conducted on similar species (U.S. Army 2015, Appendix 3-1). As long as the DON follows these translocation techniques, any effects to individual snails that occur as a result of translocation from the project footprint to protected habitat will be exempt from take prohibitions. In addition, the DON has committed to protect and enhance a total of 1,393 ac (564 ha) of suitable partulid snail habitat in primary and seconday limestone forest in the Finegayan and Ritidian areas. Therefore, the effect of the DON's action is qualitative, where the relocation of tree snails is considered in context of the amount of habitat impacted within the project footprint and the importance of this habitat to overall snail recovery. Based on the full implementation of the DON's proposed conservation measures, we expect the populations of Guam tree snail, humped tree snail and fragile tree snail to be maintained within the action area.

Direct and Indirect Effects of the Action on the Orchids (Orchidacea): *Bulbophyllum guamense*, *Dendrobium guamense*, and *Tuberolabium guamense*

In addition to the general effects of the action discussed above, a species-specific effects analysis for the affected listed orchids is provided below.

Direct and Indirect Effects on *Bulbophyllum guamense*

The proposed project will result in the removal of three individuals of *B. guamense* in order to clear forests to construct utilities, buildings, structures, and the LFTRC. The DON has proposed to conduct pre-construction surveys for *B. guamense* within the project construction footprint. After pre-construction surveys are completed and if individuals of *B. guamense* are present within the construction footprint and cannot be avoided, the DON has proposed to salvage healthy individuals of *B. guamense* and relocate individuals to other protected areas away from the project footprint or temporarily house the *B. guamense* individuals at the DON Nursery until a suitable translocation site can be found. Individuals would be relocated by a qualified biologist

and into protected forest habitat or the forest enhancement sites at Finegayan. Please refer to the conservation measures section for more detail.

The DON's conservation measures, to salvage and relocate orchids, are intended to prevent the mortality of individuals of *B. guamense* as a result of the proposed construction activities. However, removing orchids from the wild may result in injuries to the plants. Salvaged individuals may sustain injury from the uprooting, bruising, broken bulbs and leaves (William 1894, p. 15). The DON's measure to hire a qualified biologist would minimize this effect.

Translocation programs, which include moving orchids into new sites (assisted migration) or augmenting wild populations, have been used as tools for orchid conservation (Zettler and McInnis 1992). However, in devising conservation strategies, particularly assisted migration to new safe sites, it is important to consider the orchid's life history traits that may have an impact on long-term survival (Dixon et al. 2003, p. 4). In addition, effective conservation of orchids includes understanding natural migration routes and the functionality of biotic partners (mycorrhizas and pollinators). Orchids are also acutely susceptible to changes in ecosystem equilibria involving organic content, light availability, hydrology and competition that can affect both adult survival and the ability of seedlings to germinate and survive to maturity. We expect the DON will consider these factors in choosing adequate recipient sites for *B. guamense*.

Genetic differences between and among populations also should be considered in the relocation of orchids (Swarts and Sinclair 2008, Duffy et al. 2009). Because little is known about the life history traits of *B. guamense*, the success of relocating individuals of *B. guamense* back into the wild is unknown. However the DON is committed to ensure that a minimum of two *B. guamense* individuals survive and exhibit new root growth at a new protected site. If the DON is unable to successfully salvage all three *B. guamense* individuals then the DON will seek sources outside the project footprint for tissue culture and propagation of *B. guamense*. Since orchids are relatively slow-growing plants, it will require anywhere from several months to more than a year for a newly planted specimen on the tree to become securely attached. The DON has committed to monitoring the success of *B. guamense* translocations that will allow for appropriate adaptive management measures to be implemented in order to reach success targets, defined in **Table 6**.

In addition to the three *B. guamense* individuals known to occur within the project footprint, if any other *B. guamense* individuals are found during pre-construction surveys the DON will seek to translocate all healthy *B. guamense* individuals found.

Habitat Conservation and Minimization Measures

The largest concentration of *B. guamense* occurs within the NMS, which contains at least 127 *B. guamense* individuals within primary and secondary limestone forest habitat. The DON will implement avoidance measures including signage restricting access into sensitive areas of orchid habitat and minimization measures to reduce the risk of fire from training activities that would severely impact *B. guamense* habitat. By adhering to all conservation measures, effects to *B. guamense* will be minimized significantly.

The DON will also protect and enhance a minimum of 1,000 ac (405 ha) of occupied suitable *B. guamense* habitat, according to the schedule described in the Conservation Measures section, with the goal of ungulate eradication within the fenced areas; invasive plant removal; and the propagation, planting, and establishment of dominant and rare species characteristic of native limestone forest habitats. In addition, the DON will protect 285 ac (115 ha) of existing primary limestone and secondary limestone forest habitat surrounding the LFTRC in northern Guam.

Summary

The proposed action will adversely affect *B. guamense*. The proposed action will result in harm, injury, or mortality to three *B. guamense* individuals that occur in the Finegayan and Ritidian areas. In consideration of the DON's commitment to insure that of the three individuals of *B. guamense* removed, at least two *B. guamense* will survive; the proposed action will result in the loss of 0.2 percent (1 of 407) of the known range-wide population of *B. guamense* and 0.6 percent (1 of 148) of the known population within the action area. Although surveys within the construction footprint have been conducted, surveys may have missed *B. guamense*. The DON has proposed pre-construction surveys. Because *B. guamense* are confined to limited areas and their distribution is not uniform across the landscape, we expect a few additional *B. guamense* to be located near the individuals found in the Finegayan area and the seven occurrences within and surrounding the LFTRC. In addition, as detailed above and in the General Effects section, the proposed action will result in the fragmentation of habitat and will cause ecological degradation that extends beyond the proposed vegetation clearing due to edge effects.

We estimate that that the proposed action would negatively impact less than one percent of the known *B. guamense* population range-wide. Although edge effects, and most notably fragmentation, of forest habitat would occur within the action area in northern Guam, the majority of the population of *B. guamense* occurs at the NMS in southern Guam and these individuals and habitat would be avoided. In addition, if orchids are salvaged, kept in captivity and relocated back into the wild successfully, these methods coupled with the current research being conducted to propagate *B. guamense*, potentially could be used for augmenting existing populations in efforts to recover the species. Based on the full implementation of the DON's conservation measures, we expect the population of *B. guamense* to be maintained within the action area.

Direct and Indirect Effects on *Dendrobium guamense*

In addition to the general effects of the action discussed above, a species-specific effects analysis for *D. guamense* is provided below.

The proposed project will result in the removal of 18 individuals of *D. guamense* in order to clear areas of vegetation to construct utilities, buildings, structures, and the LFTRC. The DON has proposed to conduct pre-construction surveys for *D. guamense* within the project construction footprint. After pre-construction surveys are completed and if individuals of *D. guamense* are present within the construction footprint and cannot be avoided, the DON has proposed to salvage all healthy individuals of *D. guamense* that are feasible to relocate to other protected areas away from the project footprint or temporarily house the *D. guamense* individuals at the

DON Nursery until a suitable translocation site can be found. Individuals would be relocated by a qualified biologist and into protected forest habitat or the forest enhancement sites at Finegayan. Please refer to the conservation measures section for more detail.

The DON's conservation measures, to salvage and relocate orchids, are intended to prevent the mortality of individuals of *D. guamense* as a result of the proposed construction activities. However, removing orchids from the wild may result in injuries to the plants. Salvaged individuals may sustain injury from the uprooting, bruising, broken bulbs and leaves (William 1894, p. 15). The DON's measure to hire a qualified authorized biologist would minimize this effect. As stated in the Effects of the Action for *B. guamense*, translocation programs have been used as tools for orchid conservation (Zettler and McInnis 1992). However, in devising conservation strategies, it is important for biologist and conservation planners to be fully aware of the orchid's life history traits that may have an impact on long-term survival (Dixon et al. 2003, p. 4). In addition, effective conservation of orchids includes understanding natural migration routes and the functionality of biotic partners (mycorrhizas and pollinators). Orchids are also acutely susceptible to changes in microclimate; including humidity, temperature and moisture, as well as organic content, and the presence of other competitors that can affect both adult survival and the ability of seedlings to germinate and survive to maturity. We expect the DON will consider these factors in choosing adequate recipient sites for *D. guamense*. Genetic differences between and among populations also should be considered in the relocation of orchids (Swarts and Sinclair 2008, Duffy et al. 2009).

Because little is known about the life history of *D. guamense*, the likelihood of success of relocating individuals of *D. guamense* back into the wild is unknown. However, the DON is committed to ensure that at a minimum nine *D. guamense* individuals survive and exhibit new root growth at a new protected site. If the DON is unable to successfully salvage all nine *D. guamense* individuals then the DON will seek sources outside the project footprint for tissue culture and propagation of *D. guamense*. The DON has committed to monitoring the success of *D. guamense* translocations that will allow for appropriate adaptive management measures to be implemented in order to reach success targets, defined in **Table 6**.

In addition, to the 18 *D. guamense* individuals known to occur within the project footprint, if any other *D. guamense* individuals are found during pre-construction surveys the DON will seek to translocate all healthy *D. guamense* individuals found.

Habitat Conservation and Minimization Measures

The largest concentration of *D. guamense* occurs within the Naval Munitions Site (NMS), which contains at least 201 *D. guamense* individuals within primary and secondary limestone forest habitat. The DON will implement avoidance measures including signage restricting access into sensitive areas of orchid habitat and minimization measures to reduce the risk of fire from training activities that would severely impact *D. guamense* habitat in the NMS. By adhering to all conservation measures, effects to *D. guamense* will be minimized significantly.

The DON will also protect and enhance a minimum of 1,000 ac (405 ha) of occupied suitable *D. guamense* habitat, according to the schedule described in the Conservation Measures section,

with the goal of ungulate eradication within the fenced areas; invasive plant removal; and the propagation, planting, and establishment of dominant and rare species characteristic of native limestone forest habitats. In addition, the DON will protect 285 ac (115 ha) of occupied primary limestone and secondary limestone forest habitat surrounding the LFTRC in northern Guam.

Summary

The proposed action will adversely affect *D. guamense*. The proposed action will result in impacts to 18 *D. guamense* individuals that occur in the Finegayan, LFTRC, and Anderson South areas. In consideration of the DON's commitment to insure that nine of the 18 individuals of the relocated *D. guamense* will survive; the proposed action will result in the loss of one percent (9 of 837) of the known range-wide population of *D. guamense* and 3.4 percent (9 of 264) of the known population within the action area. Because *D. guamense* are confined to limited areas and their distribution is not uniform across the landscape, we expect a few additional *D. guamense* to be located near the individuals found in the Finegayan area and the 41 occurrences within and surrounding the LFTRC.

We estimate that that the proposed action would negatively impact less than three percent of the known *D. guamense* population range-wide. Although edge effects, and most notably fragmentation, of forest habitat would occur within the action area in northern Guam, the majority of the population of *D. guamense* occurs at the NMS in southern Guam and these individuals and habitat would be avoided. In addition, if orchids are salvaged, kept in captivity and relocated back into the wild successfully, these methods coupled with the current research being conducted to propagate *D. guamense*, potentially could be used for augmenting existing populations in efforts to recover the species. Based on the full implementation of the DON's conservation measures, we expect the population of *D. guamense* to be maintained within the action area.

Direct and Indirect Effects on *Tuberolabium guamense*

In addition to the general effects of the action discussed above, a species-specific effects analysis for *T. guamense* is provided below.

The proposed action will result in adverse effects to *T. guamense* as a result of the removal of 4,922 individuals of *T. guamense* in order to clear areas of forest for the construction of buildings, structures, utilities and roads in the Finegayan and Ritidian areas. The 4,922 individuals of *T. guamense* represent 39 percent (4,922 of 12,607) of the known population on Guam, and 38.3 percent (4,922 of 12,846) of the total known population of *T. guamense* range-wide.

The DON has proposed to conduct pre-construction surveys for *T. guamense* within the project construction footprint. After pre-construction surveys are completed and if individuals of *T. guamense* are present within the construction footprint and cannot be avoided, the DON has proposed to salvage healthy individuals of *T. guamense* and relocate individuals to other protected areas away from the project footprint or temporarily house the *T. guamense* individuals at the DON Nursery until a suitable translocation site can be found. Individuals would be

relocated by a qualified biologist and into protected forest habitat or the forest enhancement sites at Finegayan. Please refer to the conservation measures for more detail.

The DON's conservation measures, to salvage and relocate orchids, are intended to prevent the mortality of individuals of *T. guamense* as a result of the proposed construction activities. However, removing orchids from the wild may result in injuries to the plants. Salvaged individuals may sustain injury from the uprooting, bruising, broken bulbs and leaves (William 1894, p. 15). The DON's measure to hire a qualified authorized biologist would minimize this effect.

As stated in the Status of the Species section of this BO, *T. guamense* does not occur uniformly within the forest; but instead grows in more humid areas where moss is present on trees and other epiphytic growth including ferns and other native orchids occur. Local site conditions may have a large impact on population dynamics of orchid species, and differences in populations may be due to variables relating to seed germination, such as availability of suitable fungi to promote seed germination, or suitable organic content, moisture, and temperature levels (Perkins 1995, Jersakova and Malinova 2007, Jacquemyn 2010). Therefore, it is important to conserve habitats in which remaining large populations of rare orchids occur, in order to save such species from extirpation (Cozzolino et al. 2003).

The Finegayan area contains the largest and most robust known population of *T. guamense*; the majority or 56 percent of the known range-wide population occurs within the proposed Main Cantonment at Finegayan. The proposed action would negatively impact the Finegayan population by reducing it by at least 70 percent (from 6,924 to 2,070 orchids) and by removing the largest known cluster of this orchid species in the wild. However, this reduced population is not expected to be more vulnerable to extirpation because nearly all remaining *T. guamense* orchids would be contained within the two Forest Enhancement Sites. The DON will enclose these areas with ungulate-proof fences and eradicate ungulates within these enclosures, as well as conduct common native and listed species out-planting efforts to enhance these areas for protection of limestone forest habitat. These measures taken together are expected to protect and allow natural augmentation of the remaining Finegayan population of *T. guamense*.

The area within and adjacent to the proposed LFTRC at Ritidian represents the best remaining primary limestone forest habitat on Guam. Approximately 3,078 individuals of *T. guamense* are present within the Ritidian area. Based on current surveys, the proposed action will result in the removal of 68 *T. guamense* individuals as a result of construction of the LFTRC. The proposed action is also expected to result in fragmentation of *T. guamense* habitat within the Ritidian area.

Habitat Conservation and Minimization Measures

As a conservation measure to minimize the above adverse effects, the DON will salvage all healthy *T. guamense* found during pre-construction surveys where feasible, with the objective of translocating the *T. guamense* individuals to protected areas or temporarily house the specimens at the DON's Nursery until a suitable site can be found. The DON has committed to ensure that a minimum of 1,000 *T. guamense* individuals are translocated or outplanted successfully into protected areas. Because little is known about the life history of *T. guamense*, the likelihood of

success of relocating individuals of *T. guamense* back into the wild is unknown. If the DON is unable to successfully salvage at least 1,000 *T. guamense* individuals from within the project footprint, then the DON will seek sources outside the project footprint for tissue culture and propagation of *T. guamense*. The DON has committed to monitoring the success of *T. guamense* translocations that will allow for appropriate adaptive management measures to be implemented in order to reach success targets, defined in **Table 6**.

The salvaging and relocation of *T. guamense* are intended to prevent the mortality of *T. guamense*. However, in devising conservation strategies, it is important for biologist and conservation planners to be fully aware of the orchid's life history traits that may have an impact on long-term survival (Dixon et al. 2003, p. 4). In addition, effective conservation of orchids includes understanding natural colonization routes and the functionality of biotic partners (mycorrhizas and pollinators). Orchids are also acutely susceptible to changes in microclimate; including humidity, temperature and moisture, as well as organic content, and the presence of other competitors that can affect both adult survival and the ability of seedlings to germinate and survive to maturity. We expect the DON will consider these factors in choosing adequate recipient sites for *T. guamense*. Genetic differences between and among populations also should be considered in the relocation of orchids (Swarts and Sinclair 2008, Duffy et al. 2009).

The DON will also protect and enhance a minimum of 1,000 ac (405 ha) of occupied suitable *T. guamense* habitat, according to the schedule described in the Conservation Measures section, with the goal of ungulate eradication within the fenced areas; invasive plant removal; and the propagation, planting, and establishment of dominant and rare species characteristic of native limestone forest habitats. In addition, the DON will protect 285 ac (115 ha) of occupied primary limestone and secondary limestone forest habitat surrounding the LFTRC in northern Guam.

Summary

The proposed action will adversely affect *T. guamense*. The proposed action will result in adverse affects to at least 4,922 individuals of *T. guamense* that occur in the Finegayan and LFTRC areas. In consideration of the DON's commitment to insure that of the amount removed, at least 1,000 *T. guamense* will survive; the proposed action will result in the loss of 30.5 percent (3,922 of 12,846) of the known range-wide population of *T. guamense* and 31.1 percent (3,922 of 12,607) of the known population within the action area. In view of the fact that comprehensive *T. guamense* surveys were focused only within and adjacent to the proposed project footprints, the proposed project's impact to the range-wide population of *T. guamense* is a conservative estimate. Based on the status of Guam's remaining forest habitat and current botanical surveys, it is likely that the Finegayan and Ritidian areas constitute the best habitat for *T. guamense* range-wide.

The proposed action will negatively impact the Finegayan subpopulation by reducing it by at least 70 percent (from 6,924 to 2,070 orchids) and by removing the largest known cluster of this orchid species in the wild. However, this reduced population is not expected to be more vulnerable to extirpation because nearly all remaining known *T. guamense* orchids would be contained within the two Forest Enhancement Sites. The DON will enclose these areas with ungulate-proof fences and eradicate ungulates within these enclosures, as well as conduct

common native and listed species out-planting efforts to restore these areas for protection of limestone forest habitat. These measures taken together are expected to provide 1,000 ac (405 ha) of protected occupied *T. guamense* habitat and allow natural augmentation of the remaining Finegayan population of *T. guamense*. In addition, the DON will also control and eradicate ungulates within the Ungulate Control Area in the NWF, surrounding the LFTRC. The Ungulate Control Area will provide 285 ac (115 ha) of occupied primary limestone forest habitat for *T. guamense*. Overall restoration efforts are likely to offset the loss of 30 percent of the *T. guamense* population range-wide. With conservation measures in place, we expect the *T. guamense* population to increase within the Finegayan Forest Enhancement Sites and within the Ungulate Control Area at Ritidian within 10 years.

Direct and Indirect Effects of the Action on *Cycas micronesica*

In addition to the general effects of the action discussed above, a species-specific effects analysis for *C. micronesica* is provided below.

The proposed project will result in the removal of 3,191 individuals of *C. micronesica* in order to clear forest to construct the LFTRC ranges at Ritidian Point and the Main Cantonment at Finegayan. The remaining 3,177 individuals within the Ritidian Point area will be subject to edge effects, habitat fragmentation, and increased susceptibility to the introduced cycad scale insect, *A. yasumatsui*. Once infected with the cycad scale insect, *C. micronesica* plants monitored have had a 90 percent mortality rate over several years, especially in heavily degraded habitat (JRM 2016).

The largest concentration of *C. micronesica* (18,620 in total) occurs within primary limestone forest habitat within the Ritidian area. *Cycas micronesica* relies on a healthy limestone forest; therefore the loss of 1,219 ac (493 ha) of limestone forest habitat will adversely affect the population of *C. micronesica* on Guam.

Habitat Conservation and Minimization Measures

The DON has proposed to conduct pre-construction surveys for *C. micronesica* within the project construction footprint. After pre-construction surveys are completed and if individuals of *C. micronesica* are present within the construction footprint and cannot be avoided, the DON attempt to translocate any healthy mature individuals and basal suckers (i.e., cycad pups) found. Healthy basal suckers of *C. micronesica* found during pre-construction surveys would be temporarily housed at the DON Nursery until a suitable translocation site can be found. Any cycad pups salvaged may need to be hardened and grown to a suitable size prior to translocation. Individuals of *C. micronesica* would be relocated by an authorized biologist into protected forest habitat (e.g., NWF Ungulate Control Area or lands within the MOA). Refer to the conservation measures section for more detail.

The DON's conservation measures are intended to reduce effects to *C. micronesica* as a result of the proposed construction activities. The relocation of basal suckers of *C. micronesica* has been successful (USFWS 2016, in litt.). Of the 3,191 known *C. micronesica* individuals within the construction footprint, the DON has committed to insuring that 1,596 *C. micronesica* individuals

are maintained and survive into maturity. However, due to predation by invasive insect species, detailed in the Environmental Baseline section, the number of extant individuals that can successfully reproduce is unknown. These 1,596 *C. micronesica* individuals that the DON commits to manage will either be translocated as a whole plant, a basal sucker from the impacted mature plant, or sourced from stock outside the project footprint and propagated in the DON Nursery. The priority is to salvage the maximum amount of genetic stock from the impacted mature *C. micronesica* plants in the Ritidian area. Prior to out-planting into a protected area, the DON will ensure that the *C. micronesica* individual is of sufficient size and durability to withstand the change in environment and will likely need to be hardened off in a temporary location close to the out-planting site. The DON understands the time commitment involved in the growth of cycad plants from basal suckers.

Although the remaining 3,177 mature *C. micronesica* indivduals in the vicinity of the LFTRC would be subject to habitat fragmentation, 34 of these mature trees would be enclosed within the Ungulate Control Area surrounding the LFTRC, and as a result these plants and their offspring would be protected from ungulate damage.

Summary

The proposed action will adversely affect *C. micronesica*. The proposed action will result in harm, injury, or mortality to 3,191 *C. micronesica* individuals that occur in the Finegayan and LFTRC areas. In consideration of the DON's commitment to insure that of the 3,191 individuals of *C. micronesica* removed, at least 1,596 *C. micronesica* will survive; the proposed action will result in the loss of 0.4 percent (1,595 of 421,802) of the minimum known range-wide population of *C. micronesica* and 0.8 percent (1,595 of 19,852) of the known population within the action area.

We estimate that the proposed action would negatively impact less than one percent of the known *C. micronesica* population range-wide. At Ritidian, the loss and fragmentation of high quality limestone forest habitat will have immediate adverse impacts to *C. micronesica*, as well as other native and listed species that rely on *C. micronesica*. However, based on the full implementation of the DON's conservation measures, including translocation and propagation efforts of *C. micronesica* beginning concurrently or prior to forest clearing activities, we expect the population of *C. micronesica* to be temporarily reduced within the action area.

Direct and Indirect Effects of the Action on *Heritiera longipetiolata*

In addition to the general effects of the action discussed above, a species-specific effects analysis for *H. longipetiolata* is provided below.

The proposed project will result in the removal of seven individuals of *H. longipetiolata* in order to clear forest to construct the Multi-Purpose Machine Gun (MPMG) and Non-Standard Small Arms (NSSA) ranges for the LFTRC at Ritidian. The remaining 21 mature trees in the vicinity of the LFTRC will be subject to edge effects and habitat fragmentation. In addition, in the event of a severe wind storm, with the removal of forest vegetation that would otherwise have acted as a buffer from strong winds or typhoons, structural damage or injury to the remaining *H.*

longipetiolata mature trees are likely, especially since *H. longipetiolata* trees are the tallest canopy trees in the area (JRM 2016, pp. 5-6).

The largest concentration of *H. longipetiolata* (223 in total) occurs within remnant coastal plateau secondary limestone forest habitat at Naval Base Guam and AAFB. These areas are outside the construction project footprints and are not expected to be impacted.

Habitat Conservation and Minimization Measures

The DON has proposed to conduct pre-construction surveys for *H. longipetiolata* within the project construction footprint. After pre-construction surveys are completed and if individuals of *H. longipetiolata* are present within the construction footprint and cannot be avoided, the DON would record any mature trees. If any mature trees within the project footprint are found to be seeding, the DON would make every attempt to collect viable seeds from a mature *H. longipetiolata* tree prior to removal. Please refer to the conservation measures section for more detail.

The DON's conservation measures are intended to reduce effects to *H. longipetiolata* as a result of the proposed construction activities. Of the seven known *H. longipetiolata* trees within the construction footprint, the DON has committed to insuring that four *H. longipetiolata* plants are maintained and survive into maturity. These four *H. longipetiolata* individuals will be propagated from seed collected from the seven impacted mature trees, or sourced from seed outside the project footprint and propagated from seed. The priority is to salvage the genetic stock from the impacted mature trees. Prior to out-planting into a protected area, the DON will ensure that the *H. longipetiolata* individual is of sufficient size and durability to withstand the change in environment and will likely need to be hardened off in a temporary location close to the out-planting site. The DON understands the time commitment involved in the growth of hardwood trees from seed. The DON will construct an ungulate fence enclosing 285 ac (115 ha) of occupied primary limestone and secondary limestone forest habitat surrounding the LFTRC in northern Guam. This area and other areas on GMK MOA designated land will be used as *H. longipetiolata* outplanting sites.

Although the remaining 21 mature trees outside the LFTRC footprint at Ritidian would be subject to habitat fragmentation, 18 of these mature trees would also be enclosed within the Ungulate Control Area surrounding the LFTRC, and as a result these trees and their saplings would be protected from ungulate damage.

Summary

The proposed action will adversely affect *H. longipetiolata*. The proposed action will result in harm, injury, or mortality to 7 *H. longipetiolata* mature trees that occur in the LFTRC area. In consideration of the DON's commitment to insure that of the 7 individuals of *H. longipetiolata* removed, at least four *H. longipetiolata* individuals will be propagated from seed and maintained to maturity; the proposed action will result in the loss of 0.6 percent (3 of 488) of the minimum known range-wide population of *H. longipetiolata* and 0.7 percent (3 of 404) of the known population within the action area.

Considering the temporal delay, resulting from the DON's proposal to collect only *H. longipetiolata* seed and propagate to maturity, we estimate that that the proposed action will negatively impact 1.4 percent of the known *H. longipetiolata* population range-wide. The largest concentration of *H. longipetiolata* (223 in total) occuring within remnant coastal plateau secondary limestone forest habitat at Naval Base Guam will not be affected by the proposed action. Based on the full implementation of the DON's conservation measures, we expect the population of *H. longipetiolata* to be maintained within the action area.

Direct and Indirect Effects of the Action on *Tabernaemontana rotensis*

In addition to the General effects of the action discussed above, a species-specific effects analysis for *T. rotensis* is provided below.

The proposed project will result in the removal of 217 individuals of *T. rotensis* in order to clear forest to construct utilities, buildings, and structures, within AAFB Main and AAFB South, including the LFTRC at Ritidian. The remaining 189 mature trees in the vicinity of the LFTRC area will be subject to edge effects and habitat fragmentation. In addition, in the event of a severe wind storm, with the removal of forest vegetation that would otherwise have acted as a buffer from strong winds or typhoons, structural damage or injury to the remaining *T. rotensis* trees is likely.

The largest concentration of *T. rotensis* (16,366 in total) occurs within limestone forest habitat at AAFB in northeast Guam. The majority of these trees are outside the construction project footprints, however these trees occur adjacent to areas proposed for roads or utility infrastructure and therefore are expected to be indirectly impacted by project effects in the form of edge effects and habitat fragmentation.

Habitat Conservation and Minimization Measures

The DON has proposed to conduct pre-construction surveys for *T. rotensis* within the project construction footprint. After pre-construction surveys are completed and if individuals of *T. rotensis* are present within the construction footprint and cannot be avoided, the DON would record any mature trees. If any mature trees within the project footprint are found to be seeding, the DON would make every attempt to collect viable seeds from a mature *T. rotensis* tree prior to removal. Refer to the conservation measures section for more detail.

The DON's conservation measures are intended to reduce effects to *T. rotensis* as a result of the proposed construction activities. Of the 217 known *T. rotensis* trees within the construction footprint, the DON has committed to insuring that 109 *T. rotensis* trees are maintained and survive into maturity. These 109 *T. rotensis* trees that the DON commits to manage will be propagated from seed collected from the impacted mature tree, or sourced from seed outside the project footprint and propagated from seed. The priority is to salvage the genetic stock from the impacted mature tree. Prior to out-planting into a protected area, the DON will ensure that the *T. rotensis* individual is of sufficient size and durability to withstand the change in environment and will likely need to be hardened off in a temporary location close to the out-planting site. The

DON understands the time commitment involved in the growth of hardwood trees from saplings or seed. The DON has committed to monitoring the success of *T. rotensis* outplanted individuals to allow for appropriate adaptive management measures to be implemented in order to reach success targets, defined in **Table 6**. The DON will construct an ungulate fence enclosing 285 ac (115 ha) of occupied primary limestone and secondary limestone forest habitat surrounding the LFTRC in northern Guam and protect and enhance two Forest Enhancement Sites in Finegayan totaling 1,108 ac (448 ha) of occupied limestone forest habitat. This area and other areas on GMK MOA designated land will be used as *T. rotensis* outplanting sites.

Although the remaining 189 mature trees outside the LFTRC footprint at Ritidian would be subject to habitat fragmentation, 34 of these mature trees would be enclosed within the Ungulate Control Area surrounding the LFTRC, and as a result these trees and their saplings would be protected from ungulate damage.

Summary

The proposed action will adversely affect *T. rotensis*. The proposed action will result in harm, injury, or mortality to 217 *T. rotensis* individuals that occur in the LFTRC and AAFB South areas. In consideration of the DON's commitment to insure that of the 217 individuals of *T. rotensis* removed, 109 *T. rotensis* individuals will be propagated from seed and maintained to maturity; the proposed action will result in the loss of 0.5 percent (108 of 22,422) of the known range-wide population of *T. rotensis* and 0.5 percent (108 of 22,413) of the known population within the action area.

Considering the temporal delay, resulting from the DON's proposal to collect only *T. rotensis* seed and propagate to maturity, we estimate that that the proposed action will negatively impact one percent of the known *T. rotensis* population range-wide. The largest concentration of *T. rotensis* trees (19,319 in total) occur in secondary limestone and primary limestone forest habitat suounding Andersen Air Force Base, and will not be affected by the proposed action. Based on the full implementation of the DON's conservation measures, we expect the population of *T. rotensis* to be maintained within the action area.

CUMULATIVE EFFECTS

Cumulative effects include the effects of future State, tribal, local or private actions that are reasonably certain to occur in the action area considered in this BO. Future Federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the Act.

The extent to which future development is addressed as a cumulative effect in the following analysis excludes any such future development that will have a federal nexus, such as federally-funded roads, or is likely to be caused by other Federal actions. Such actions will be addressed in future section 7 consultations.

Future state, local, or private actions that are reasonably certain to occur in the action area are listed below.

- A private developer has initiated steps to build the Pago Bay Ocean Resort, residential condominiums. The planned footprint of the resort is three ac (1.2 ha) on the southern side of Pago Bay. Surveys for listed partulid tree snails have not been conducted within the project footprint; however, one ac (0.4 ha) of the project footprint may be suitable habitat for any of the federally listed tree snail species.
- Guam Waterworks Authority will be upgrading the Northern District Wastewater Treatment Plant in Dededo. The upgrade will consist of increasing the capacity of the current plant and provide for secondary treatment of wastewater. The upgrade will impact approximately 10 ac (4 ha). Surveys for listed partulid tree snails have not been conducted on this land, however based on tree snail habitat preferences, the species may be present.
- The Guam International Raceway Park in Yigo will be completing site improvements and a raceway expansion. The current footprint of the raceway is 253 ac (102 ha) and the improvements and expansion are anticipated to impact an additional 70 ac (28 ha). There is a potential to impact the following listed species that may be present in the area based on habitat suitability: Mariana eight spot butterfly, *C. micronesica*, and *H. longipetiolata*.

Natural Resource Management Projects

Most natural resource management projects that would benefit the listed species covered in this BO will be federally funded. However, small scale projects may occur funded by the territorial or local governments. These projects may benefit listed species; however, their scale is likely to be insignificant compared to the loss of habitat from the proposed action.

Species-Specific Cumulative Effects

In northern Guam, habitat for these species may be lost as a result of cumulative effects from civilian development. Because we are still learning about the life histories and habitat requirements of the newly listed species addressed in this consultation, we are unable to estimate the specific number of acres that would be lost as a result of cumulate effects from civilian development. However, many of the newly listed species addressed in this consultation occur in limestone forest habitat. We anticipate at least a few hundred acres would be developed in the absence of the proposed action by 2035.

In southern Guam, habitat for the listed orchids at issue in this consultation may be lost as a result of cumulative effects from wildfire. However, since the trend in annual area burned has been declining, and we anticipate it will continue to decline as a result of ongoing and future Federal support of the development of local fire suppression resources, the amount of habitat lost to wildfire should decline. In addition, the listed orchids are present in ravine forests in southern Guam and the threat of wildfire may not be as high for ravine forests, which are located closer or adjacent to rivers.

CONCLUSION

After reviewing the current status of the listed species addressed in this BO, the environmental baseline, the effects of the proposed action and the cumulative effects, it is the Service's biological opinion that the action, as proposed is not likely to jeopardize the continued existence of the Mariana fruit bat, Mariana eight spot butterfly, the humped tree snail, Guam tree snail, fragile tree snail, *B. guamense*, *D. guamense*, *T. guamense*, *C. micronesica*, *H. longipetiolata*, and *T. rotensis*; and is not likely to destroy or adversely modify Mariana fruit bat critical habitat. The Service reached these conclusions based on the findings for each species presented below.

Mariana Fruit Bat

The proposed action will adversely affect the Mariana fruit bat on Guam due to increased noise and human disturbance. Approximately 1,817 ac (735 ha) in the LFTRC and AAFB in northern Guam and 319 ac (129 ha) at the NMS in southern Guam will be affected by increased disturbance to the level that would result take in the form of harm or harass that may preclude successful breeding, foraging and sheltering by the Mariana fruit bat. About 7.8 percent of the Mariana fruit bat habitat on the island will be degraded as a result of the proposed action, and although this impact will not preclude the recovery of the Mariana fruit bat, it may reduce the total number of bats that the island can support. The noise and disturbance to the Mariana fruit bats from construction and operation of project facilities will generally be intermittent and of short duration.

The DON's protection and management of 5,234 ac (2,118 ha) of Mariana fruit bat habitat in northern Guam, including the protection and enhancement of 3,271 ac (1,324 ha) of occupied and suitable Mariana fruit bat habitat away from noise effects will help off-set the disturbance of Mariana fruit bat habitat from the proposed action, and will help insure that Mariana fruit bat habitat in the near term, will be available for survival and recovery of the species on Guam. In addition, the DON's biosecurity conservation measures including landscape-level BTS eradication/control, recommendations from the Regional Biosecurity Plan, HACCP planning, and BTS interdiction program, will be beneficial to the Mariana fruit bat because it will reduce the snake population on Guam and also help prevent spread of the BTS to Rota and other Mariana islands. Based on the full implementation of the DON's proposed conservation measures, including pre-construction surveys, protection and enhancement of 3,271 ac (1,324 ha) of occupied and suitable Mariana fruit bat habitat, and BTS control, we expect the population of Mariana fruit bats to be maintained in the action area. In addition, the DON's two Forest Enhancement Sites at Finegayan, including the creation of 460 ac (162 ha) of BTS-free habitat will facilitate future recolonization or reintroduction of the Mariana fruit bat into Finegayan. Furthermore, the DON's BTS interdiction and control work will help prevent the spread of BTS to other Mariana Islands that support the Mariana fruit bat.

On the basis of these findings, the Service concludes that the effects of the subject action, taken together with cumulative effects, is not likely to appreciably reduce the likelihood of both the survival and recovery of the Mariana fruit bat in the wild because sufficient habitat and populations are likely to persist throughout its range at levels that retain the potential for recovery of this species.

<u>Mariana fruit bat critical habitat</u>

The Guam critical habitat unit for the Mariana fruit bat consists of approximately 376 ac (152) ha of land in the fee simple portion of the GNWR. The critical habitat unit is currently occupied, and is located at the base of the cliff below the LFTRC. Upon operation of the LFTRC, noise from gunshots will reach a small portion (approximately two acres) of the critical habitat unit. This noise may preclude the Mariana fruit bat from using this area for roosting as a remote place free of human disturbance. However, because only two acres will be affected, this noise is unlikely to diminish the value of the critical habitat for the conservation of the species in the long-term. Therefore, we determine that the proposed action will not result in the destruction or adverse modification of the Guam critical habitat unit for the Mariana fruit bat.

Mariana Eight Spot Butterfly

The range-wide population of the Mariana eight spot butterfly is comprised of at least 10 known local populations. All of these local populations are small, geographically restricted, and subject to further decline due to loss of their native host plants, habitat degradation, and mortality caused by two genera of parasitic wasps (*Ooencyrtus* spp. and *Telenomus* spp.), which predate on Mariana eight spot butterfly eggs. The likelihood of this species surviving and recovering is dependent on restoring a functional metapopulation of Mariana eight spot butterfly. Given the current status of this species, avoiding or effectively offsetting adverse effects to butterfly-occupied habitat is critical to maintaining the resiliency of the Mariana eight spot butterfly metapopulation in the action area.

The proposed action will result in the removal of 350 ac (142 ha) of butterfly habitat, including 140 host plants of *P. pedunculata* or *E. calcareum*, which represents 6.1 percent of all known host plants range-wide. The proposed action will also result in habitat fragmentation and edge effects to limestone forest habitat within the action area, which may reduce its potential to be used by the Mariana eight spot butterfly in the future.

The DON has proposed conservation measures to minimize, the adverse effects of the proposed action on the butterfly in the form of forest habitat restoration, propagation and out-planting efforts to augment existing habitat of *P. pedunculata* and *E. calcareum* host plants, and the commitment to conduct pre-construction surveys to identify all stages of the Mariana eight spot butterfly, prior to construction. If any life stage of the Mariana eight spot butterfly (e.g., eggs, caterpillar, and chrysalis) is located within a project footprint during pre-construction surveys, it will be relocated onto an appropriate host plant (e.g., relocate pre-diapause larvae to *P. pedunculata* or *E. calcareum*) in similar sites away from the project footprint. This has been successfully carried out by clipping the host plant and grafting the plant to another plant outside the project footprint (Cook and Delisle 2010) but within an occupied area of butterfly habitat. These conservation measures will not preclude effects to the species but will minimize effects as a result of vegetation clearing activities. Overall, implementation of the proposed action is likely to temporarily degrade the quality of habitat for the survival of the Mariana eight spot butterfly. In order to prevent permanent degradation of Mariana eight spot butterfly habitat, the DON will place a high priority on creating and protecting quality butterfly habitat in the Haputo ERA and remaining locations within the Ritidian Point area, but outside LFTRC range operations. The

creation and protection of this high quality Mariana eight spot butterfly habitat should occur without delay.

On the basis of these findings, the Service concludes that the effects of the proposed action, taken together with cumulative effects, is not likely to appreciably reduce the likelihood of both the survival and recovery of the Mariana eight spot butterfly in the wild because effects of the action will be minimized significantly and sufficient habitat and populations are likely to persist throughout its range at levels that retain the potential for recovery of this species.

Partulid Snails: Guam tree snail, humped tree snail, and the fragile tree snail

The proposed action will adversely affect Guam tree snail and possibly the fragile tree snail. While humped tree snail and fragile tree snail are not known to occur within the project footprint, all three species occur within the Haputo ERA. The DON will fence the Haputo ERA to reduce civilian and military access and minimize degradation to sensitive snail habitat. Historically, all three species co-occurred and shared similar habitat throughout Guam. Therefore, the likelihood that DON pre-construction surveys will detect individuals of humped tree snail and fragile tree snail cannot be discounted.

The proposed action will result in harm or harass to all Guam, fragile, or humped tree snails located in the 212 ac (86 ha) of occupied Partulid snail habitat in Anderson South that will be permanently removed. Not all vegetation within the 212 acres has been surveyed. The area that will be cleared is disturbed secondary limestone forest habitat. The DON will conduct a biological survey of a minimum of two-person hours (e.g., 4-persons at 30 minutes each or 2-persons at one hour) at least three days prior to construction at Anderson South for the purpose of locating and removing listed snails within the project footprint that would be impacted by construction activities. The DON will work with the Service and experienced malacologists for appropriate refinement of translocation methods and selection of receiving sites. All detected Partulid snails will be translocated into a protected area with suitable habitat which would allow the translocated Partulid snails to thrive. In addition, the DON will protect and enhance 1,393 ac (564 ha) of suitable Partulid snail habitat in primary and seconday limestone forest in the Finegayan and Ritidian areas. The DON will also fence the Haputo ERA to reduce civilian and military access and minimize degradation to sensitive snail habitat.

On the basis of these findings, the Service concludes that the effects of the subject action, taken together with cumulative effects, is not likely to appreciably reduce the likelihood of both the survival and recovery of Guam tree snail, humped tree snail and fragile tree snail in the wild because effects of the action will be minimized significantly and sufficient habitat and populations are likely to persist throughout its range at levels that retain the potential for recovery of this species.

Orchids*: Bulbophyllum guamense, Dendrobium guamense,* and *Tuberolabium guamense*

The proposed action will adversely affect three *B. guamense* individuals that occur in the Finegayan and Ritidian areas. In consideration of the DON's commitment to insure that of the three individuals of *B. guamense* relocated, at least two *B. guamense* will survive; the proposed

action will result in the loss of 0.5 percent of the known range-wide population of *B. guamense*. The majority of the population of *B. guamense* occurs at the NMS in southern Guam and these individuals and habitat would be avoided.

The proposed action will result in relocation of 18 individuals of *D. guamense* that occur in the Finegayan, LFTRC, and Anderson South areas. Translocation efforts will require at least nine *D. guamense* to survive and exhibit new root growth at a new protected site. Therefore, the proposed action will result in the impacts to 2.2 percent of the known range-wide population of *D. guamense*.

The population of *T. guamense* on Guam comprises 98 percent of its known range-wide population. The loss of 4,922 individuals of *T. guamense* as a result of the proposed action would represent a decrease of the Guam population by 39 percent (4,922/12,607) and in the range-wide population by 38.3 percent, and reduce the largest known subpopulation of this species on Guam. In consideration of the DON's commitment to insure that of the amount removed, at least 1,000 *T. guamense* will survive and exhibit new root growth at a new protected site; the proposed action will result in the loss of 30 percent of the known range-wide population of *T. guamense*.

With the listed orchids being salvaged, kept in captivity and relocated back into the wild, instead of being destroyed, these methods coupled with the current research being conducted to propagate *B. guamense*, *D. guamense,* and *T. guamense* could potentially be used for augmenting existing populations in efforts to recover the species. The DON will protect and enhance a minimum of 1,000 ac (405 ha) of suitable limestone forest habitat in the Forest Enhancement Sites, with the goal of ungulate eradication within the fenced areas; invasive plant removal; and the propagation, planting, and establishment of dominant and rare species characteristic of native limestone forest habitats. These protected areas will provide suitable habitat for translocation efforts and future recovery efforts for *B. guamense, D. guamense,* and *T. guamense*. In addition, the DON will protect 285 ac (115 ha) of existing primary limestone and secondary limestone forest habitat surrounding the LFTRC in northern Guam.

On the basis of these findings, the Service concludes that the effects of the subject action, taken together with cumulative effects, is not likely to appreciably reduce the likelihood of both the survival and recovery of *B. guamense, D. guamense,* and *T. guamense* in the wild because effects of the action will be minimized significantly and sufficient habitat and populations are likely to persist throughout its range at levels that retain the potential for recovery of this species.

Cycas micronesica

The proposed action would result in adverse effects to *C. micronesica* and loss of over 1,000 acres of occupied habitat for this species. The proposed action will result in adverse effects to at least 3,191 individuals of *C. micronesica* that occur in the Ritidian and Finegayan areas.

Range-wide, the total population of *C. micronesica* is approximately 420,000 individuals and the 3,191 individuals represent 0.8 percent of the known population. Of the total individuals affected, the DON will insure that at least 50 percent, or 1,596 *C. micronesica* will survive relocation efforts, initially as basal suckers and then be out-planted into protected areas to allow

survival into maturity. Based on this conservation measure, the proposed action will result in the loss of 0.4 percent of the known range-wide population of *C. micronesica*. The largest concentration of *C. micronesica* (18,620 in total) occurs within primary limestone forest habitat throughout northern Guam.

Considering the status and environmental baseline of *C. micronesica*, and the effects of the action, taken together with cumulative effects, the proposed action is not likely to reduce appreciably the likelihood of the survival and recovery of *C. micronesica* in the wild.

Heritiera longipetiolata

The proposed action would result in adverse effects to at least seven individuals of *H. longipetiolata* and loss of over 1,000 acres of unoccupied habitat that occurs in the Ritidian Point area. The range-wide population of *H. longipetiolata* is approximately 339 individuals and the seven individuals at Ritidian represent two percent of the known population. In consideration of the DON's commitment to insure that at least four *H. longipetiolata* will survive to maturity; the proposed action will result in the loss of one percent of the known range-wide population of *H. longipetiolata*.

On the basis of these findings, the Service concludes that the effects of the subject action, taken together with cumulative effects, is not likely to appreciably reduce the likelihood of both the survival and recovery of *H. longipetiolata* in the wild because effects of the action will be minimized significantly and sufficient habitat and populations are likely to persist throughout its range at levels that retain the potential for recovery of this species.

Tabernaemontana rotensis

The proposed action would result in adverse effects to at least 217 individuals of *T. rotensis* and loss of over 1,000 acres of occupied habitat for this species in the Ritidian Point area. The range-wide population of *T. rotensis* is approximately 21,000 individuals and the 217 individuals to be impacted at AAFB and Anderson South represent one percent of the known population. In consideration of the DON's commitment to insure that at least 109 *T. rotensis* will survive to maturity; the proposed action will result in the loss of 0.5 percent of the known range-wide population of *T. rotensis*.

On the basis of these findings, the Service concludes that the effects of the subject action, taken together with cumulative effects, is not likely to appreciably reduce the likelihood of both the survival and recovery of *T. rotensis* in the wild because effects of the action will be minimized significantly and sufficient habitat and populations are likely to persist throughout its range at levels that retain the potential for recovery of this species.

INCIDENTAL TAKE STATEMENT

Section 9 of the Act and Federal regulations pursuant to section 4(d) of the Act prohibit the take of endangered or threatened species, respectively, without special exemption. Take is defined as harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in

any such conduct. Harm is further defined by the Service to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavioral patterns, including, breeding, feeding, or sheltering. Harass is defined by the Service as intentional or negligent actions that create the likelihood of injury to listed species to such an extent as to significantly disrupt normal behavior patterns which include, but are not limited to, breeding, feeding or sheltering.

Incidental take is defined as take that is incidental to, and not the purpose of, carrying out an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking that is incidental to and not intended as part of the agency action is not considered a prohibited taking under the Act provided that such taking is in compliance with the terms and conditions of this Incidental Take Statement.

The measures described below are non-discretionary, and must be undertaken by DON for the exemption in section 7(o)(2) to apply. The DON has a continuing duty to regulate the activity covered by this incidental take statement. If DON (1) fails to assume and implement the terms and conditions or (2) fails to require contractors to adhere to the terms and conditions of the incidental take statement through enforceable terms that are added to contract documents, the protective coverage of section 7(o)(2) may lapse. In order to monitor the impact of incidental take, DON must report the progress of the action and its impact on the species to the Service as specified in this incidental take statement [50 CFR 402.14(i)(3)].

Take of listed plants are not covered under this incidental take statement because sections 7(b)(4) and 7(o)(2) of the Act do not apply to listed plant species. The Act provides protection for endangered plants by prohibiting removal and reduction to possession or the malicious damage of such plants on areas under Federal jurisdiction, or the destruction of endangered plants on non-Federal areas in violation of State law or regulation or in the course of any violation of a State criminal trespass law. Exceptions to these prohibitions are described in 50 C.F.R. 17.61, 17.62, 17.71, and 17.72.

Amount or Extent of Take Anticipated

Determining with accuracy the anticipated incidental take for a specific number of individuals of the Mariana fruit bat, Mariana eight spot butterfly, Guam tree snail, humped tree snail, and fragile tree snail is difficult because the subject species are small, cryptic in nature (butterfly and snails), two species are similar in appearance in their juvenile forms (Guam and fragile tree snail), definitive population estimates are lacking (all species), and the natural population fluctuations of these species remain undescribed (all species).

Under these circumstances, monitoring of take impacts in terms of individuals of the affected listed species is problematic. As a consequence of these compounded uncertainties, the Service finds that a habitat surrogate is a practical alternative to expressing and monitoring the anticipated extent of take of these five species because (1) the causal link between the surrogate and take is described above in the *Effects of the Action* section of this BO; (2) we have also explained above why it is not practical to express the amount or extent of take or monitor take impacts in terms of individuals; and (3) below we provide a clear standard for determining when the level of anticipated take has been exceeded. The habitat surrogate represents the area of habitat in which

the listed species is known occur, or where suitable habitat exists but has not been surveyed, within the construction and operation footprint of the proposed action and where the biological impacts of the action on the species are likely to conform to the statutory and regulatory definition of take.

Based on the analysis presented in this BO, the Service anticipates the following take is likely to occur as a result of the proposed action:

1. Over the term of the proposed action, all Mariana fruit bats using 2,136 ac (864 ha) of suitable roosting and foraging habitat surrounding the construction and operation footprint of the proposed action (**Figure 13**) are likely to be taken in the form of harm or harass due to exposure to loud aircraft noise, and to noise, light, and human disturbance associated with construction and operation of the LFTRC. This includes approximately 1,817 ac (735 ha) in northern Guam and approximately 319 ac (129 ha) in southern Guam due to noise effects from military aircraft flights and training exercises. The biological impact of the taking on the fruit bat is likely to cause a significant disruption of their breeding, feeding, and sheltering behavior to an extent that creates the likelihood of injury, but not death, of the affected bats. This take level is based on the analyses presented in the *Effects of the Action* section above, which included consideration of the following factors:
    a. The population of the Mariana fruit bat on Guam fluctuates due to periodic migrations of Mariana fruit bats between Guam and Rota;
    b. The Mariana fruit bat population within the action area has been concentrated in northern Guam within AAFB and Finegayan;
    c. Mariana fruit bats have also been noted using the NMS in southern Guam;
    d. In the last 17 years, Mariana fruit bat breeding colony survey counts have reported an average of 113.75 Mariana fruit bats in total on Guam (119 and 179 Mariana fruit bats reported from two separate island-wide efforts in 2000; 40 Mariana fruit bats in 2008; and 112 Mariana fruit bats in 2016);
    e. When Mariana fruit bats are forced to disperse from colonies as a result of human disturbance, infant mortality may increase because dependent, non-volant pups that are too big for the mother to carry are likely abandoned. Forced dispersal may also negatively affect the reproductive potential of the population because access to mates is compromised (CNMI 2010, p. 7). Even without dispersal, high levels of stress from any disturbance can disrupt reproductive cycles and/or lead to miscarriage;
    f. The action area contains approximately 27,096 ac (10,965 ha) of suitable Mariana fruit bat habitat. The proposed action will result in the loss or degradation of 7.9 percent of Mariana fruit bat habitat due to noise disturbance; and,
    g. Mariana fruit bats traverse large areas in search of food and shelter and therefore are likely to be exposed to stressors caused by the proposed action (aircraft noise, construction and operation of the proposed action) multiple times during their life-span;
2. The Service anticipates that, over the term of the proposed action, all life stages of the Mariana eight spot butterfly (i.e., egg cluster, caterpillar, chrysalis, and butterfly) found on identified host plants within 350 ac (142 ha) of occupied habitat within the

LFTRC construction footprint are likely to be subject to take in the form of capture and re-location out of "harm's" way. In addition, all Mariana eight spot butterfly life stages that remain within the 350 ac (142 ha) after host plant translocation occurs are likely to be taken in the form of harm or harass caused by vegetation clearing activities during construction of the LFTRC. The biological impact of the taking on the Mariana eight spot butterfly is likely to be negligible due to the relocation of all identified host plants. Any hram occurring to any Mariana eight spot butterfly life stage during the relocation process would be exempted from take prohibitions as long as translocation protocols are being followed. This take level is based on the analyses presented in the *Effects of the Action* section above, which included consideration of the following factors:

a. The locations of Mariana eight spot butterflies (of all life stages) are closely associated with the occurrence of their host plants, *E. calcareum* or *P. pedunculata*. Both of these plant species are rare within the action area;
b. Due to the cryptic nature of Mariana eight spot butterfly larvae, eggs, and chrysalides and their dependence on these host plants, it is reasonable to use Mariana eight spot butterfly host plants as a surrogate for Mariana eight spot butterfly presence; and
c. The DON has identified 140 individual host plants for the Mariana eight spot butterfly on 187 ac (76 ha) within the LFTRC construction footprint. Of these host plant locations, 11 were documented to contain Mariana eight spot butterfly larvae.

3. The Service anticipates that, based on the pre-development estimate of 176 listed tree snails occurring within the 212 acres of occupied, or potentially occupied, habitat in the Anserson South area, that about 53 Guam tree snail are likely to be detected, based on a 30 percent searcher efficiency, and subject to take in the form of capture and relocation out of harm's way. Although not found within the 212 acres on previous surveys, take in the form of capture and relocation out of harm's way may also occur to any individuals of the humped tree snail or fragile tree snail. Any hram occurring to tree snails during the relocation process would be exempted from take prohibitions as long as translocation protocols are being followed. In addition, all individuals of the Guam tree snail, humped tree snail, or the fragile tree snail remaining on the 212 ac of suitable habitat after removal and relocation efforts are completed may be taken in the form of harm or harass as a result of vegetation clearing activities during construction, operation, and military training activities at AAFB South. This take level is based on the analyses presented in the *Effects of the Action* section above, which included consideration of the following factors:

a. Guam's listed partulid snails are found on the tops and undersides of various types of vegetation and do not exhibit a preference for a particular host plant species, rather they can be found in coastal strand vegetation and primary and secondary limestone forest habitat;
b. Due to their habitat and behavior, listed partulid snails are difficult to detect. Based on a 5-year dataset surveying listed Hawaiian tree snails of similar shape and size in a forested habitat enclosure where a known number of snails were translocated into the enclosure, timed-count monitoring efforts found that during subsequent surveys for tree snails, on average only 30 percent of the

actual number of tree snails present, are detected by human observers (U.S. Army 2015, Appendix 3-1);

c. While the DON has documented only the Guam tree snail within the construction footprint at Anderson South, all three federally listed species (the Guam tree snail, humped tree snail, and the fragile tree snail) co-occur, share similar habitat, and have similar appearances in their juvenile stages; and
d. The DON has detected 38 Guam tree snail individuals within the AAFB South construction footprint; this number reflects 0.83 snails per acre. Based on this information, we expect that up to a total of 127 listed partulid snails are likely present within the 153 ac (62 ha; 0.83 snails per ac x 153 ac = 127 snails) surveyed area. A total of approximately 59 ac (24 ha) of suitable snail habitat at AAFB South was not surveyed. Based on the density of 0.83 snails per acre, calculated from the surrounding surveyed area at AAFB South, we expect that up to 49 snails occur within the unsurveyed 59 ac (24 ha) area of disturbed secondary limestone forest habitat. Therefore, we estimate a total of 176 snails (127 snails + 49 snails) occur within the AAFB South area proposed for construction and operation. While we expect that listed partulid snail density is not uniform in a habitat area, incorporating the highest density estimate to calculate the number of snails likely to be impacted provides a conservative estimate to describe the maximum amount of impact to these species as a result of construction and operation activities at AAFB South.

Effect of the Take

As described in the accompanying BO,the Service determined that this level of anticipated take is not likely to result in jeopardy to the Mariana fruit bat, Mariana eight spot butterfly, Guam tree snail, humped tree snail, or the fragile tree snail.

Reasonable and Prudent Measures

Reasonable and Prudent Measures serve to minimize the impacts of anticipated take on listed species, and to establish (through terms and conditions) the requirements for the monitoring of take levels to ensure timely reinitiation of consultation if anticipated take levels are exceeded. The Service believes the following Reasonable and Prudent Measures are necessary and appropriate to minimize and monitor the impacts of incidental take on the Mariana fruit bat, Mariana eight spot butterfly, Guam tree snail, humped tree snail, and the fragile tree snail:

1) The DON shall monitor the level of incidental take of the Mariana fruit bat, Mariana eight spot butterfly, Guam tree snail, fragile tree snail, and the humped tree snail using a habitat-based surrogate because it is not practical to detect or monitor the take of individuals that are: (1) exposed to excessive noise levels or other human disturbance; and (2) small and cryptic. The amount of habitat subject to excessive noise levels and to clearing for project construction can be monitored to ensure that these amounts are not exceeded as the proposed action is implemented. The causal link between the habitat surrogate and take of listed species was established for each of these species in the *Effects of the Action* section of the biological opinion.
2) The DON shall prioritize the enhancement and protection of high quality Mariana eight spot butterfly habitat (e.g., forest enhancement areas, Haputo ERA trail and

NWF Ungulate Control Area), including outplanting of *P. pedunculata* and *E. calcareum* host plants into these protected areas prior to or commensurate with vegetation clearing activities that remove butterfly habitat.

Terms and Conditions

In order to be exempt from the prohibitions of section 9 of the Act, the DON must comply with the following Terms and Conditions, which implement the Reasonable and Prudent Measures, described above and specify reporting requirements. These terms and conditions are non-discretionary.

In order to implement the reasonable and prudent measures above, the following terms and conditions apply:

1) The DON shall implement the Conservation Measures in the Project Description of this BO. We reiterate this requirement here for convenience and clarity.
2) To minimize the level of incidental take of the Mariana fruit bat, Mariana eight spot butterfly, Guam tree snail, humped tree snail, and the fragile tree snail, the DON shall:
    a. Halt construction if a Mariana fruit bat is present within 492 ft (150 m) of a construction site, at any point during the construction cycle, until the bat leaves the area of its own accord.
    b. Use hooded lighting within 482 ft (150 m) of all potential Mariana fruit bat roost habitat.
    c. Provide educational materials regarding Mariana fruit bat appearance, behavior, and biology to all pertinent DON personnel so that they can correctly identify any Mariana fruit bats near or within the proposed action. If a Mariana fruit bat is sighted down range, in the line of fire, during operation of the LFTRC, all use of the range shall cease until the Mariana fruit bat has left the area of its own accord.
    d. Implement systematic searches for Mariana fruit bat maternity colonies, on a semi-annual basis, in all areas of suitable habitat within AAFB that could be affected by the proposed action including; 1) all Mariana fruit bat habitat within the 65 dB noise contour surrounding the LFTRC and AAFB shown on **Figure 13**; and 2) all Mariana fruit bat habitat that will be subject to increased noise levels from aircraft overflights. Searches shall begin one year prior to the operation of the LFTRC and one year prior to the proposed overflight increases. Surveys shall proceed on a semi-annual bases for the first five years, then conducted annually for the length of the project. If a Mariana fruit bat maternity colony is found the Service shall be notified within one week of the finding.
    e. Monitor all known Mariana fruit bat roost sites, in all areas of AAFB that could be affected by the proposed action including; 1) all Mariana fruit bat habitat within the 65 dB noise contour surrounding the LFTRC and AAFB shown on **Figure 13**; and 2) all Mariana fruit bat habitat that will be subject to increased noise levels from aircraft overflights at a minimum of once a quarter, from one year prior to and one year after the proposed overflight increases are fully

implemented and during all years in which operation of the LFTRC is active. The monitoring methodology shall, at a minimum, include direct counts of Mariana fruit bats using a spotting scope at an appropriate distance to avoid disturbance impacts to the bats.

f. Conduct a noise study at the GNWR and at Ritidian Point upon operation of the MPMG range at the LFTRC. The noise study shall occur during the first year of operation of the LFTRC. Multiple stations shall record noise levels during operation of the MPMG at the GNWR and at Ritidian Point. The monitoring stations shall be approved by the Service in coordination with the DON. Noise monitoring shall occur during day and night activities over multiple days (minimum of 10 days) at least once a quarter to address seasonal and climatic changes. Weather conditions during monitoring shall be closely recorded including temperature, humidity, and wind direction. Results of the after-action noise study, combined with Mariana fruit bat survey data, will continue to inform analyses of noise effects on Mariana fruit bats and assist in refinement of minimization measures, if needed.

g. Conduct a biological survey, involving a minimum of one-person hour, at least three days prior to construction at AAFB South, for the purpose of locating and removing listed partulid snails (Guam tree snail, humped tree snail, and fragile tree snail) within the project footprint or that would be impacted by construction activities, and translocate any listed snails to protected, suitable habitat. The DON shall work with the Service for appropriate refinement of translocation methods and selection of receiving sites.

h. Conduct a biological survey, no less than annually, for the purpose of evaluating the use of sites where host plants with life stages of the Mariana eight spot butterfly (e.g., eggs, caterpillar, and chrysalis) were relocated onto an appropriate host plant (e.g., relocate pre-diapause larvae to *Procris pedunculata* or *Elatostema calcareum*) away from the project footprint.

3) DON shall complete the NWF Ungulate Control Fence within two years of awarding the contract for construction of the portion of LFTRC that removes the existing Ritidian Ungulate Fence.
4) DON shall remove all ungulates from the NWF Ungulate Control Area within six months after completing the NWF Ungulate Fence.
5) In order to monitor the impact of incidental take, the DON shall annually report the progress of the action and its impact on the species, to the Service. A Take Monitoring Plan (Plan) for the Mariana fruit bat, Mariana eight spot butterfly, Guam tree snail, humped tree snail, and the fragile tree snail shall be prepared by the DON in close coordination with and the approval of the Service within 60 days of the date of issuance of the BO accompanying this incidental take statement. The Plan shall include a schedule for the submittal of reports detailing the extent of listed species habitat subject to excessive noise levels or clearing for construction and operation activities to ensure the limits of take exemption have not been exceeded during implementation of the proposed action.

If, during the course of the action, the extent of incidental take is exceeded or occurs for reasons other than described in the BO (above) or the project description or timing changes, such

incidental take represents new information requiring reinitiation of consultation and a new determination(s) of compliance with section 7(a)(2) of the Act. The DON must immediately provide an explanation of the causes of the taking and review with the Service the need for reinitiation of formal consultation.

In summary, the Service anticipates that, over the term of the proposed action, all Mariana fruit bats using 2,136 ac (864 ha) of suitable roosting and foraging habitat surrounding the construction and operation footprint within the action area (**Figure 13**) are likely to be subject to take in the form of harass due to their exposure to noise levels above 65 decibels caused by the proposed action. The Service anticipates that, over the construction phase of the proposed action, all Mariana eight spot butterflies of different life stages (i.e., egg cluster, caterpillar, chrysalis, and butterfly) found on identified host plants in 350 ac (142 ha) of occupied habitat within the LFTRC construction footprint are likely to be subject to take in the form of capture and re-location. The Service anticipates that, over the construction phase of the proposed action, all individuals of the Guam tree snail, humped tree snail, or the fragile tree snail on 212 ac (86 ha) of occupied or potentially occupied habitat (187 ac sureveyd + 59 ac that has not been surveyed), are likely to be subject to take in the form of capture due to capture and relocation and harm due to project clearing and construction.

The incidental take exempted under this incidental take statement will be exceeded if:

1) Effects of the action cause take of the Mariana fruit bat in the form of harm (involving actual death or injury) due to habitat modification (i.e., excessive noise levels) within the 2,136 (864 ha) acres of bat roosting and foraging habitat; or any effects of the action are likely to cause take of the bat in the form of harm or harass outside of the 2,136 ac (864 ha) acres of roosting and foraging habitat discussed above; and/or
2) Mariana eight spot butterfly host plants are found in areas outside of the 350 ac (142 ha) discussed above, and these additional areas would be impacted by the project construction to an extent likely to cause take of the butterfly; and/or
3) Listed tree snails are found in habitat outside of the 212 ac (86 ha) discussed above and subject to project construction impacts causing take in the form of harm.

Conservation Recommendations

Section 7(a)(1) of the Act directs Federal agencies to utilize their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species, to help implement recovery plans, or to develop information. The recommendations provided relate only to the proposed action and do not necessarily represent complete fulfillment of the DON's section 7(a)(1) responsibilities for the species. In order for the Service to be kept informed of actions minimizing or avoiding adverse effects or benefiting listed species or their habitats, the Service requests notification of the implementation of any conservation recommendations.

Conservation Recommendations for the Mariana fruit bat

Our conservation recommendations for the Mariana fruit bat include (adapted from USFWS 2014, pp. 5-6):

- Ungulate monitoring and control:
    - Decrease habitat loss by eradicating feral ungulates on islands where ungulates exist, and prevent their introduction on other islands where Mariana fruit bat recovery is desired.
    - Decrease habitat loss by controlling feral deer in areas of high-quality Mariana fruit bat habitat.
- Habitat and natural process management and restoration:
    - Improve habitat through support of native forest restoration, especially on Guam, Saipan, and Tinian.
    - Set aside enough high-quality habitat areas, including in-perpetuity protection of conservation areas that support the recovery of Mariana fruit bat populations on three of the five southern islands.
- Human interaction monitoring and management:
    - Limit military training in areas occupied by Mariana fruit bats to activities that will not disturb Mariana fruit bats or their habitat.
    - Limit urban development in areas occupied by or potentially used for roosting and foraging by Mariana fruit bats.
- Continue and increase efforts to prevent introduction of BTS on other Mariana Islands.
- Predator / herbivore monitoring and control:
    - Develop and implement large-scale, long-term methods for BTS control that will reduce the BTS population on a landscape level on Guam.

Conservation Recommendations for the Mariana eight spot butterfly

Future conservation actions needed for the Mariana eight spot butterfly are listed below. The following actions reflect findings presented in Lindstrom and Benedict (2014, pp. 34-35), Moore (2014, pp. B21-21), and Rubinoff (2016, p.4):

- Develop and implement standardized surveys for the Mariana eight spot butterfly within suitable habitat across Guam.
    - Survey results and location information should be kept current and compiled (i.e., stored in an electronic database) and available to our conservation partners.
- Eradicate or control feral ungulates to allow Mariana eight spot butterfly host plants to expand their range onto less rugged karst, consequently increasing their availability to the butterfly.
- Determine seasonal habitat use, movement, and population dynamics of the butterfly.
    - Identify nectar plants for adult Mariana eight spot butterflies.
- Research the basis for host plant use and possible oviposition preferences of female Mariana eight spot butterflies.
- Augment existing subpopulations or populations of the Mariana eight spot butterfly, provided that studies or data indicate such augmentation is likely to be effective. Augmentation should be conducted under a plan that fully considers the principles of metapopulation and conservation biology principles.

- Reintroduce captive-reared Mariana eight spot butterflies within suitable, but currently unoccupied, habitat to bolster the function and viability of the metapopulation. Female Mariana eight spot butterflies would be collected from an existing local population(s) and allowed to oviposition in captivity. The larvae would then be reared in captivity, and larvae or pupae would be returned back into the wild at new, protected sites.
- Designate Mariana eight spot butterfly reserves or conservation areas that provide host and nectar plants within contiguous habitat at spatial scales that reflect the metapopulation behavior of the overall Mariana eight spot butterfly population.
- Propagate host plants in a nursery and out-plant host plants in protected areas.
    - Conduct research to determine optimal conditions for out-planted host plants and to determine ideal location of out-plantings that increases the likelihood of butterfly use and occupancy.
- Remove invasive vines that are encroaching on Mariana eight spot butterfly host plants.
- Develop standard operating procedures for the proper collection and relocation of eggs and larvae that may be at risk due to projects, including potential future development.
- Develop and initiate an effective public education and outreach focused on the conservation of the Mariana eight spot butterfly.

Conservation Recommendations for B. guamense, D. guamense, and T. guamense

Future management actions which would benefit *B. guamense D. guamense, and T. guamense* include:

- Ungulate control throughout *B. guamense, D. guamense, and T. guamense* range would contribute to the protection of the species and habitat.
- Monitoring the status of *B. guamense, D. guamense, and T. guamense* to determine rate of population change and determine population threshold that triggers additional conservation action
- Determine life history and habitat preferences, including conditions that support healthier and more reproductively viable individuals.
- Identify areas that if protected, could provide additional habitat for the conservation of *B. guamense, D. guamense, and T. guamense*.
- Determine the best methods in augmenting populations and relocating and/or reintroducing *B. guamense, D. guamense, and T. guamense* into protected areas within its historic range.

Conservation Recommendations for Cycas micronesica

Recommended management actions to help recover the species include:

- Conduct bio-control trials to control damage by insect pests such as the native beetle *D. marianarum* and the invasive *A. yasumatsui*
- Protection from predation and damage by invasive ungulates by use of fencing and population control measures
- Prevention of new invasive pest species which may further threaten the status of *C. micronesica*
- Protection of existing habitat, primarily existing limestone forest

Conservation Recommendations for Heritiera longipetiolata

The following recommendations (adapted from DAWR 2006, p. 120) include future management actions to help recover *H. longipetiolata*. This includes:

- Collect seeds from fruiting trees and develop a nursery of seedlings for outplanting in protected areas throughout its range.
- Outplant or relocate wild seedlings/saplings to increase the species distribution.
- The eradication of ungulates from current and potential habitat will serve both to enhance conditions for populations already present, and contribute to promoting additional habitat that may become occupied naturally or via outplanting.
- Install enclosures around trees to protect seeds and seedlings from ungulate.

Conservation Recommendations for Tabernaemontana rotensis

The following are recommended conservation actions that would assist in reaching recovery of *T. rotensis*:

- Continue monitoring and survey efforts for *T. rotensis*. Information about the health and reproductive status of individuals will create a more complete understanding of the species on these islands and will inform conservation actions to protect the species.
- Collect seeds from fruiting trees and develop a nursery of seedlings for outplanting in protected areas throughout its range.
    - *Tabernaemontana rotensis* responds to typhoons with a synchronized flowering pulse (UOG 2007, p. 6). Conservation efforts should ensure harvest of the mast seeding that occurs about four months after the passage of a typhoon (UOG 2007, pp. 22, 29).
- Outplant or relocate wild seedlings to increase their distribution.
    - *Tabernaemontana rotensis* seedlings typically occur in a cluster near the parent tree. The seedlings compete with one another for light and other resources, and not all seedlings survive. Resource managers would benefit from transplanting some of these seedlings prior to their death (UOG 2007, p. 22). This approach also would thin out crowded seedlings and possibly ensure more of them remain alive (UOG 2007, p. 23).
- The eradication of ungulates from current and potential habitat will serve both to enhance conditions for populations already present, and contribute to promoting additional habitat that may become occupied naturally or via outplanting.
- Prevent establishment of introduced invasive species (*e.g.*, insect pests).
- Install enclosures around trees to protect seeds and seedlings from ungulate.

Reinitiation – Closing Statement

This concludes the Service's formal consultation on the action outlined in the DON's formal consultation request. As provided in 50 CFR § 402.16, reinitiation of formal consultation is required and shall be requested by the Federal agency or by the Service, where discretionary Federal involvement or control over the action has been retained or is authorized by law and: (1) If the amount or extent of incidental take is exceeded; (2) If new information reveals effects of the action that may affect listed species or critical habitat in a manner or to an extent not previously considered; (4) If the identified action is subsequently modified in a manner that causes an effect to the listed species or critical habitat that was not considered in the biological

opinion; or (5) If a new species is listed or critical habitat designated that may be affected by the identified action. In instances where the amount or extent of incidental take is exceeded, any operations causing such take must cease immediately pending reinitiation.

Thank you for your ongoing efforts to conserve listed species. If you have questions, please contact Jacqueline Flores, Mariana Islands Team Manager, at (671) 989-6744 or via email at jacqueline_flores@fws.gov or Darren LeBlanc, Planning and Consultation Team Manager, at (808) 792-9403 or via email at darren_leblanc@fws.gov . In future communications with us regarding this project, please refer to this project by these reference numbers, 01EPIF00-2015-F-0025 and 01EPIF00-2016-F-0185.

Sincerely,

Mary Abrams
Field Supervisor
Pacific Islands Fish and Wildlife Office

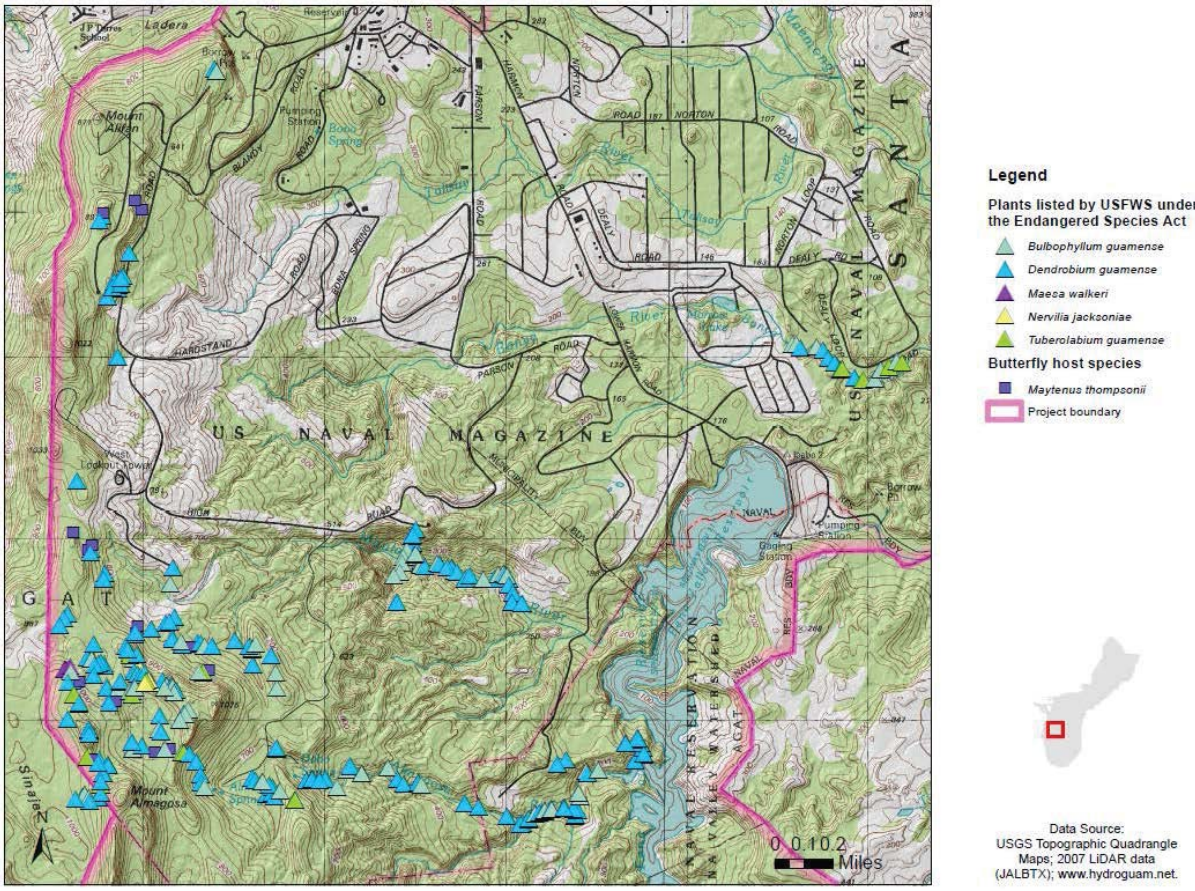
Commander Jeffrey S. Powell
Director, Pacific Programs Office
Office of the Assistant Secretary of the Navy (OASN)
Energy, Installations and Environment (EI&E)
1000 Navy Pentagon
Washington, DC 20350-1000

Dear Commander Powell:

The U.S. Fish and Wildlife Service (Service) received your request on May 18, 2017, requesting our concurrence with your determination that the Marine Corps relocation from Okinawa to Guam, including the construction of the Live Fire Training Range Complex (LFTRC), the Marine Cantonment, and use of lands within the Naval Munitions Site (collectively known as Project) may affect, but is not likely to adversely affect three newly listed plant species pursuant to section 7 of the Endangered Species Act (ESA) of 1973, as amended (16 U.S.C 1531 et seq.). This consultation addresses the impact of the project on the federally threatened plants *Maesa walkeri* and *Eugenia bryanii*, and the federally endangered plant *Nervilia jacksoniae*.

The DON's proposed Project includes the relocation of 5,000 USMC personnel and 1,300 dependents from Okinawa to Guam. To support this relocation effort, the DON plans to construct and operate a main cantonment area, including family housing; construct and operate an LFTRC; and conduct training activities on Guam. Project activities will occur on land administered by the Department of Defense and the Government of Guam (for road and bridge work). This consultation addresses actions that will take place within the Northwest Field (NW Field) for the construction of the LFTRC and within the Naval Munitions Site (NMS), in both the Northern Land Navigation Area and the Southern Land Navigation Areas. For a complete description of the Project, along with maps of the action area, please see the Description of the Proposed Action section of the accompanying 2017 USMC Relocation BO.

Maesa walkeri (no common name) is a shrub in the primrose family (Primulaceae) found only in the Mariana Islands within the forest ecosystem (USFWS, 2015). At the time of listing, *M.*



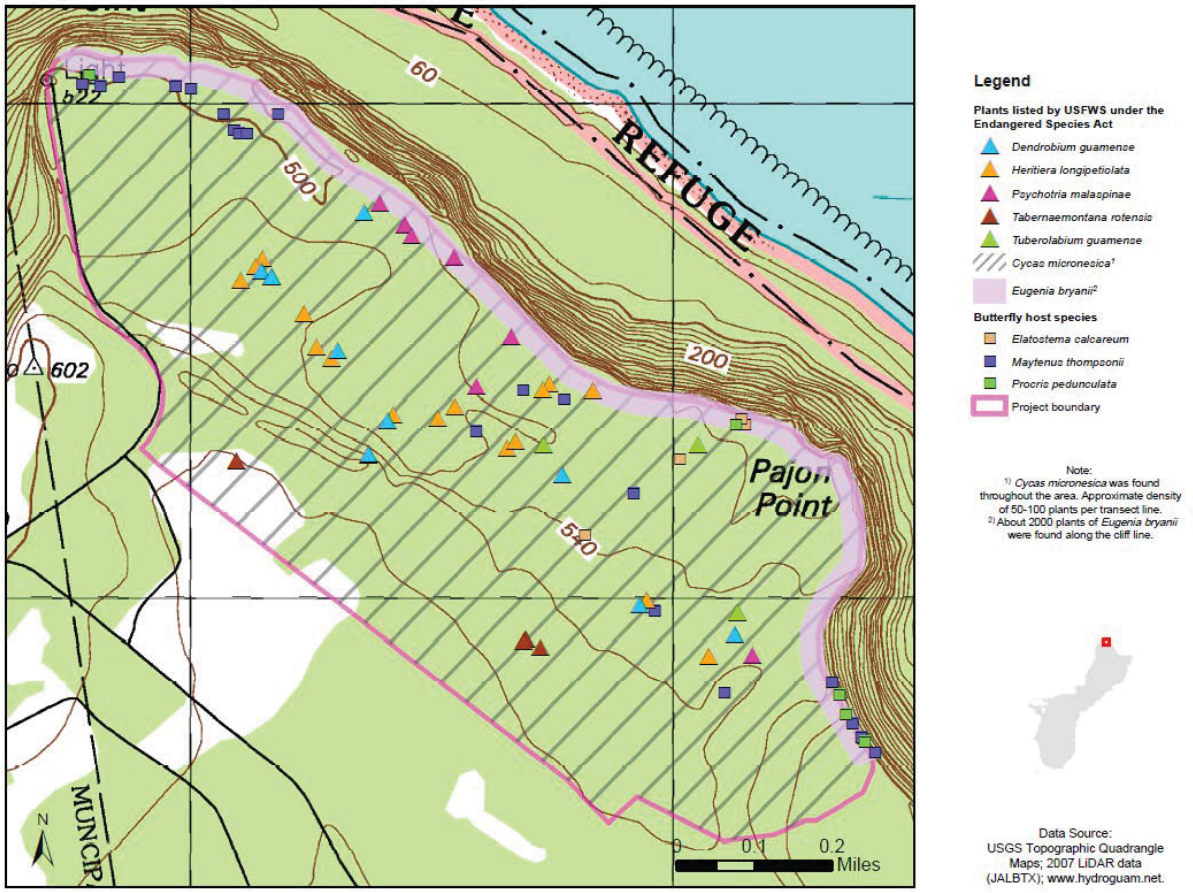
walkeri was known from five occurrences on Guam and Rota, totaling at least 686 individuals. On Rota, there are 684 individuals spread out across the Sabana with a population structure consisting of seedlings, juveniles, and adults (USFWS, 2015) and only two individuals were known on Guam. Subsequent surveys on Mt. Lamlam discovered 45 individuals (GPEPP, 2015). Recent surveys in the Naval Munitions have discovered a total of seven mature adults, but no recruitment was noted (JRM, 2016). **Figure 1** shows the known distribution of *M. walkeri* within the NMS.

Nervilia jacksoniae (no common name) is a small herb in the orchid family (Orchidaceae), and is found only in the Mariana Islands. It typically grows in shady areas from a small subterranean tuber. It remains dormant for a portion of the dry season. Flowers open in June or July and only remain open for a short period. The seed capsule takes a month to mature. Leaves are small (about 5 x 3 centimeters), kidney-shaped, and emerge as the seed capsule is developing (Raulerson and Rinehart, 1992). Threats to *N. jacksoniae* include habitat loss and destruction from development as well as damage due to ungulates (wallows, digging, and browsing) as well as predation from invasive slugs, and damage from fire events. At the time of listing, it was known from two occurrences totaling fewer than 200 individuals on Guam and 13 occurrences of 320 individuals on Rota (USFWS, 2015). Recent surveys on NMS have discovered 204 mature individuals within the river valleys (JRM, 2016). Surveys of the limestone forest in the NMS to determine the full extent of the species have not been completed. **Figure 1** shows the known distribution of *N. jacksoniae* within the NMS.

Eugenia bryanii (no common name) is a small perennial shrub in the Myrtle family (Myrtaceae), and is known only from Guam. *E. byranii* is a multi-stemmed shrub with small elliptical leaves. Flowers are short with four white petals and numerous stamens. Fruits are round and bright red, with edible pulp surrounding one or two seeds (Raulerson and Rinehart, 1991). *Eugenia bryanii* primarily occurs on limestone clifflines along the west and east coasts of Guam (Raulerson and Rinehart, 1991). At the time of listing only five occurrences were known with approximately 420 individuals (USFWS, 2015). Surveys by DOD have since discovered large numbers of individuals along the cliffline at Ritidian Point. Approximately 2,000 individuals were discovered within the ungulate fenced area along the cliffline (JRM, 2016). Threats to *E. bryanii* include habitat loss and destruction from development as well as damage due to ungulates (browsing) as well as predation from invasive slugs, and damage from fire events. **Figure 2** shows the distribution of *E. bryanii* within the proposed LFTRC lands on the island of Guam.

Maesa walkeri and *N. jacksoniae* populations occur within the NMS. Potential physical disturbance includes trampling by soldiers or vehicles, destruction by the creation of roads and trails, or placement of bivouacs. DON will ensure that military training units work in close coordination with Joint Region Mariana's Mariana Island Range Complex (MIRC) to clearly define authorized training restrictions, and where appropriate, designate No Wildlife Disturbance (NWD) areas or other designations to prohibit training in sensitive areas. DON will work closely with DON Biologists to identify new NWD areas, consistent with USMC combat readiness and training requirements. Proper designation of NWD areas will ensure that bivouacs do not cause additional disturbance to endangered species (USFWS, 2017).

Figure 1: Locations of M. walkeri and N. jacksoniae within the NMS (JRM, 2016)



Eugenia bryanii occurs along the cliffline at the northernmost edge of the LFTRC complex footprint. As all individuals occur within 50 meters of the cliffline no direct loss is expected from the construction of the LFTRC. One individual plant occurs within the footprint of the LFTRC, but occurs over the cliff edge and is not expected to be affected by construction (DON, 2017). Habitat fragmentation is expected to be minimal. The primary benefit to the species will be the removal and restriction of ungulates from the area to relieve browsing pressure (DON, 2017). Specific measures to enhance the conservation of *E. bryanii* are listed in the DON BA (2017). These measures include prioritization of fire suppression activities in areas known to contain ESA-listed species; creation of an ungulate management fence and removal of ungulates; as well as translocation and propagation of individuals. These conservation measures are expected to provide a beneficial effect by primarily removing ungulate herbivory as a constraint to recovery.

Based on the information and analysis above, we agree with your determination that the proposed projects effects to the three listed plant species would not exceed insignificant or discountable levels. Therefore, we concur with your determination that the proposed project may affect, but is not likely to adversely affect the three listed plant species *E. bryani, M. walkeri* and *N. jacksoniae* pursuant to section 7 of the ESA. Our basis for this conclusion is that the DON will implement the proposed actions and conservation measures specified in the accompanying 2017 USMC Relocation BO, and herein. Actions other than those specified in the Marine

Relocation BO and in this informal consultation have the potential to result in harm to listed species and therefore may require reinitiation of section 7 consultation. In addition, if new information reveals that the proposed project may affect listed species in a manner or to an extent not considered, or a new species or critical habitat is designated that may be affected by the proposed action, reinitiation of consultation pursuant to section 7 of the ESA may be necessary.

Figure 2: Distribution of E. bryanii along the cliffline within NW Field (DON, 2017).

Thank you for your ongoing efforts to conserve listed species. If you have questions, please contact Jacqueline Flores, Mariana Islands Team Manager (phone: (671) 989-6744, email: jacqueline_flores@fws.gov). In future communications with us regarding this project, please refer to this project by these reference numbers, 01EPIF00-2015-F-0025 and 01EPIF00-2016-F-0185.

Sincerely,

MARY ABRAMS

Subject: Formal Consultation for Divert Activities and Exercises at the Saipan International Airport, Commonwealth of the Northern Mariana Islands

Dear Mr. Aoyama:

This document represents the U.S. Fish and Wildlife Service's (Service) Biological Opinion on the U.S. Air Force's (USAF) proposed Divert Activities and Exercises (Divert) at the Saipan International Airport (GSN) in accordance with section 7 of the Endangered Species Act (ESA) of 1973, as amended (16 U.S.C 1531 et seq.). This Biological Opinion addresses the potential impacts of Divert on the endangered nightingale reed-warbler (*Acrocephalus luscinia)*. Your request for formal consultation was received on September 10, 2012. An informal consultation addressing potential impacts to the endangered Mariana moorhen (*Gallinula chloropsis guami*), Mariana swiftlet (*Aerodramus bartschi*), and threatened green sea turtle (*Chelonia mydas*), is found in Appendix 1.

Overall island-wide effects to the nightingale reed-warbler are addressed through the October 23, 2008, *Programmatic Biological Opinion Regarding the Reestablishment, Management, and Use of the Saipan Upland Mitigation Bank, Saipan* (2008-F-0033) (Programmatic Biological Opinion). The Programmatic Biological Opinion addressed the creation of the Saipan Upland Mitigation Bank (SUMB) to protect and manage 419 hectares of land on Saipan in perpetuity for the nightingale reed-warbler. The findings and recommendations in this consultation are based on: (1) the USAF Biological Assessment for Divert received on September 10, 2012; (2) phone calls, meetings, and emails between Rachel Rounds (Service) and the USAF and its contractors; (3) the SUMB Programmatic Biological Opinion and; (4) other information available to us. A complete administrative record is on file in our office.

CONSULTATION HISTORY

June 17, 2013. The USAF and the Service agree upon final language for the invasive species conservation measures.

May 9, 2013. The Service provided the USAF with proposed edits to the invasive species section of conservation measures.

April 10, 2013. The USAF provided the Service with a re-written rapid response conservation measure which is acceptable to both agencies.

March 13, 2013. The USAF and Service had a phone call to further discuss the rapid response conservation measure in the draft Biological Opinion.

February 27, 2013. The Service provided USAF with revised invasive species conservation measures for their review.

February 26, 2013. The Service (Rachel Rounds and Domingo Cravalho) had a phone call with USAF and U.S. Navy staff and contractors (William Grannis, Kurt Rautenstrauch, Steve Pyle, Carol Gaudette, Lieutenant Colonel Alves, Steve Mosher, Lance Laughmiller, Mark Cruz, Edward Lynch, Mark Petersen) to discuss invasive species conservation measures.

February 14, 2013. The USAF provided the Service with comments on the draft Biological Opinion.

February 1, 2013. The Service provided the USAF with a draft Biological Opinion for review.

January 25, 2013. William Grannis (USAF) provided Rachel Rounds (Service) with an updated project description.

January 14, 2013. William Grannis (USAF) called Rachel Rounds (Service) to notify the Service that the USAF would like to purchase 17 credits in the SUMB to offset impacts to the nightingale reed-warbler.

December 12, 2012. The Service (Rachel Rounds, Earl Campbell, Brand Phillips, and Domingo Cravalho) had a phone call with USAF staff and contractors (William Grannis, Kurt Rautenstrauch, Shannon Cauley, Steve Pyle, Carol Gaudette, Mark Ingoglia, and Lieutenant Colonel Alves) had a conference call to discuss invasive species conservation measures.

November 16, 2012. William Grannis (USAF) sent Rachel Rounds (Service) a revised project description.

October 18, 2012. Kurt Rautenstrauch (HDR) provided Rachel Rounds (Service) with maximum noise estimates for four aircraft types and 10 locations around GSN.

October 11, 2012. Rachel Rounds (Service) and USAF staff and contractors (William Grannis, Daniel Robinson, Dale Clark, Steve Pyle, Julie Hong, Major Toves, Kurt Rautenstrauch, Tanya Perry) had a phone call to discuss the timeline for re-initiation of the Biological Opinion, the noise disturbance analysis, and joint military training exercises.

October 1, 2012. Rachel Rounds and Domingo Cravalho (Service) and USAF staff and contractors (William Grannis, Major Toves, Kurt Rautenstrauch, Shannon Cauley, Steve Pyle, and Edward Lynch) had a phone call to discuss SUMB credit purchases, Biological Opinion timeline, and brown treesnake conservation measures.

September 20, 2012. Rachel Rounds (Service) and USAF staff and contractors (William Grannis, Julie Hong, Major Toves, Bernie Marcos, Shannon Cauley, and Kurt Rautenstrauch) had a phone call to discuss conservation measures, SUMB credit purchases, monitoring projects, and the Divert training schedule.

September 18, 2012. Rachel Rounds (Service) sent William Grannis (USAF) a list of questions on the Divert Biological Assessment.

September 10, 2012. The Service received the Final Biological Assessment from the USAF.

July 26, 2012. Rachel Rounds (Service) and USAF staff and contractors (William Grannis, Edward Lynch, Stephen Pyle, Shannon Cauley) had a phone conversation to discuss Service comments on the draft Biological Assessment.

July 19, 2012. The USAF submitted a draft Biological Assessment to the Service for review.

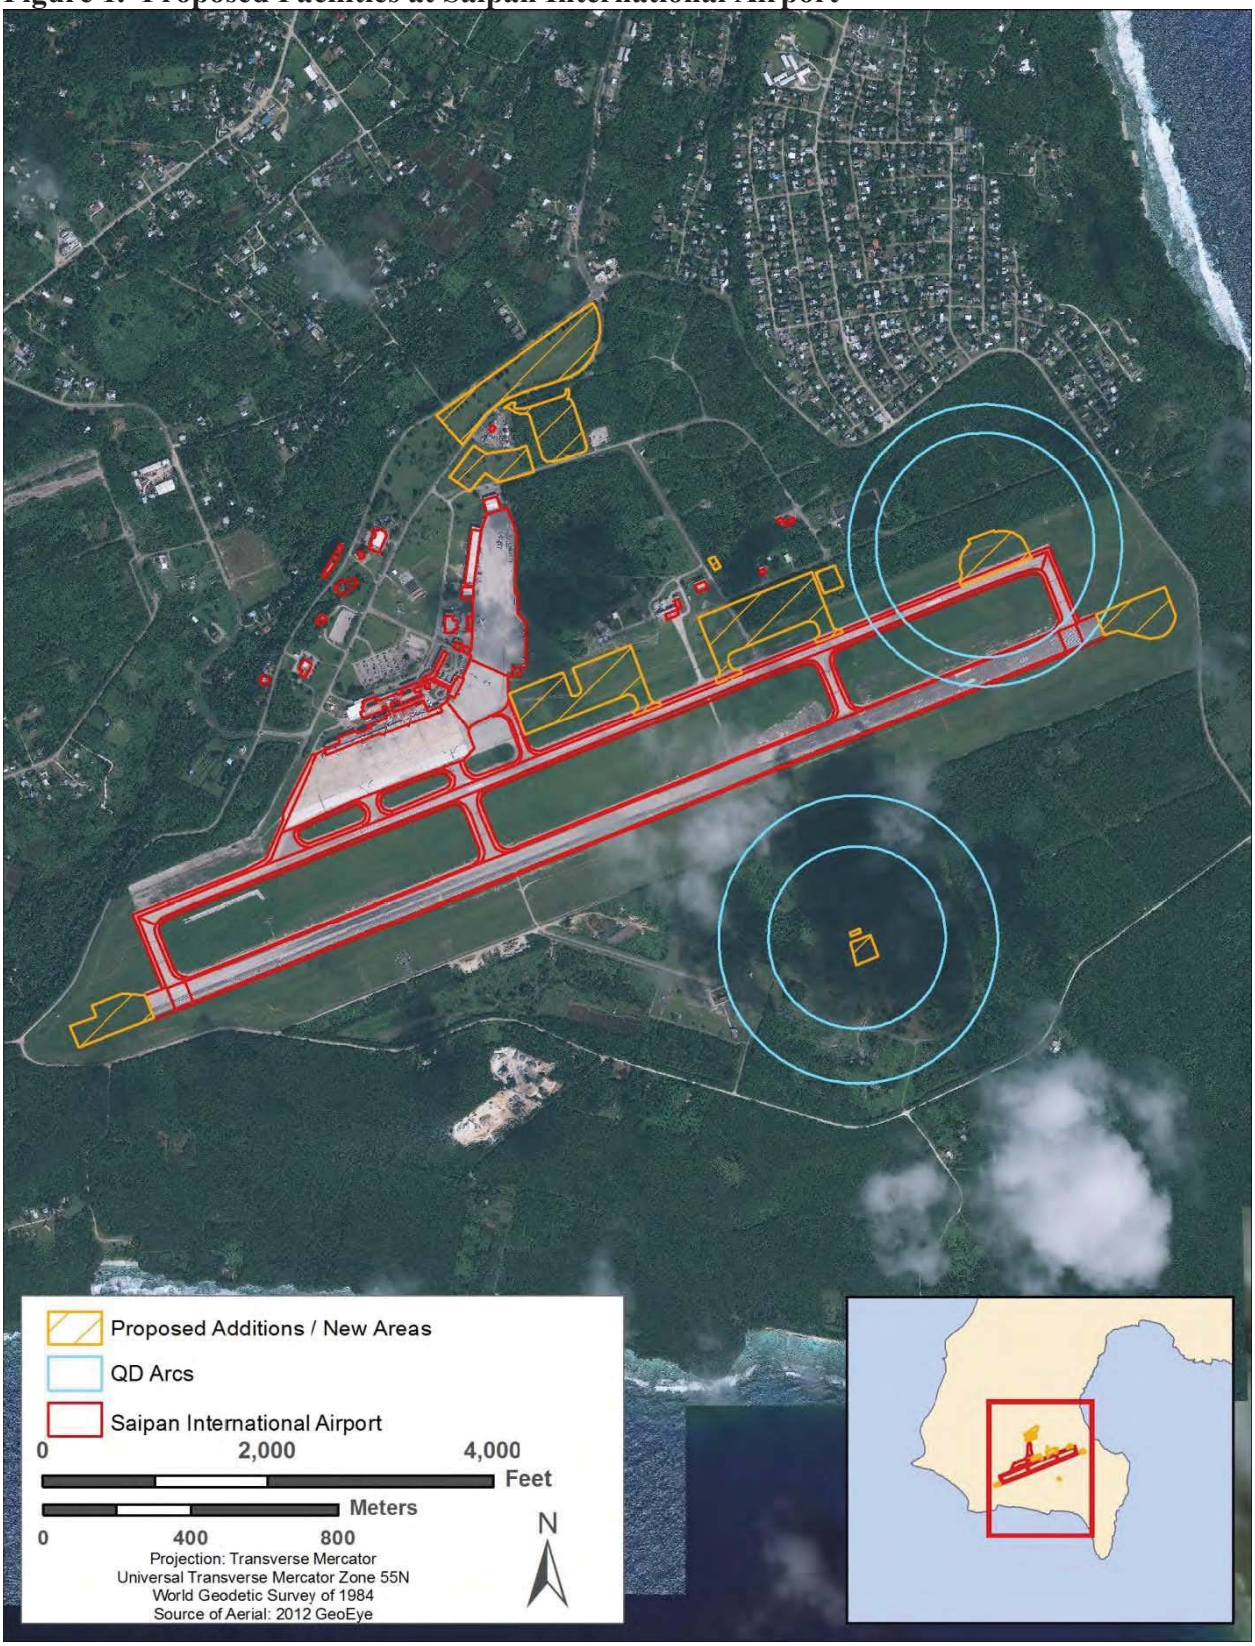
May 31, 2012. The USAF and its contractors (Kurt Rautenstrauch, William Grannis, Mark Ingoglia, Edward Lynch, Mark Petersen, Shannon Cauley, and Major Pete Toves) and Service staff (Rachel Rounds and Earl Campbell) met to discuss the results of threatened and endangered species surveys at the Saipan International Airport and the section 7 consultation process.

July 15, 2011. USAF and its contractors (Edward Lynch, Carol Gaudette, William Grannis, Shannon Cauley, Julie Hong, and Mark Ingoglia) presented to the Service (Loyal Mehrhoff, Earl Campbell, Annie Marshall, Steve Miller, Fred Amidon, Domingo Cravalho, and Rachel Rounds) initial information regarding the Divert Project, discussed threatened and endangered species in the potential project areas, and discussed the section 7 consultation process.

ACTION AREA

The action area for the proposed project is the airport and surrounding areas (Figure 1), the seaport (Figure 2), and the Saipan Upland Mitigation Bank Conservation Area, which will be used for mitigation actions.

Figure 1. Proposed Facilities at Saipan International Airport



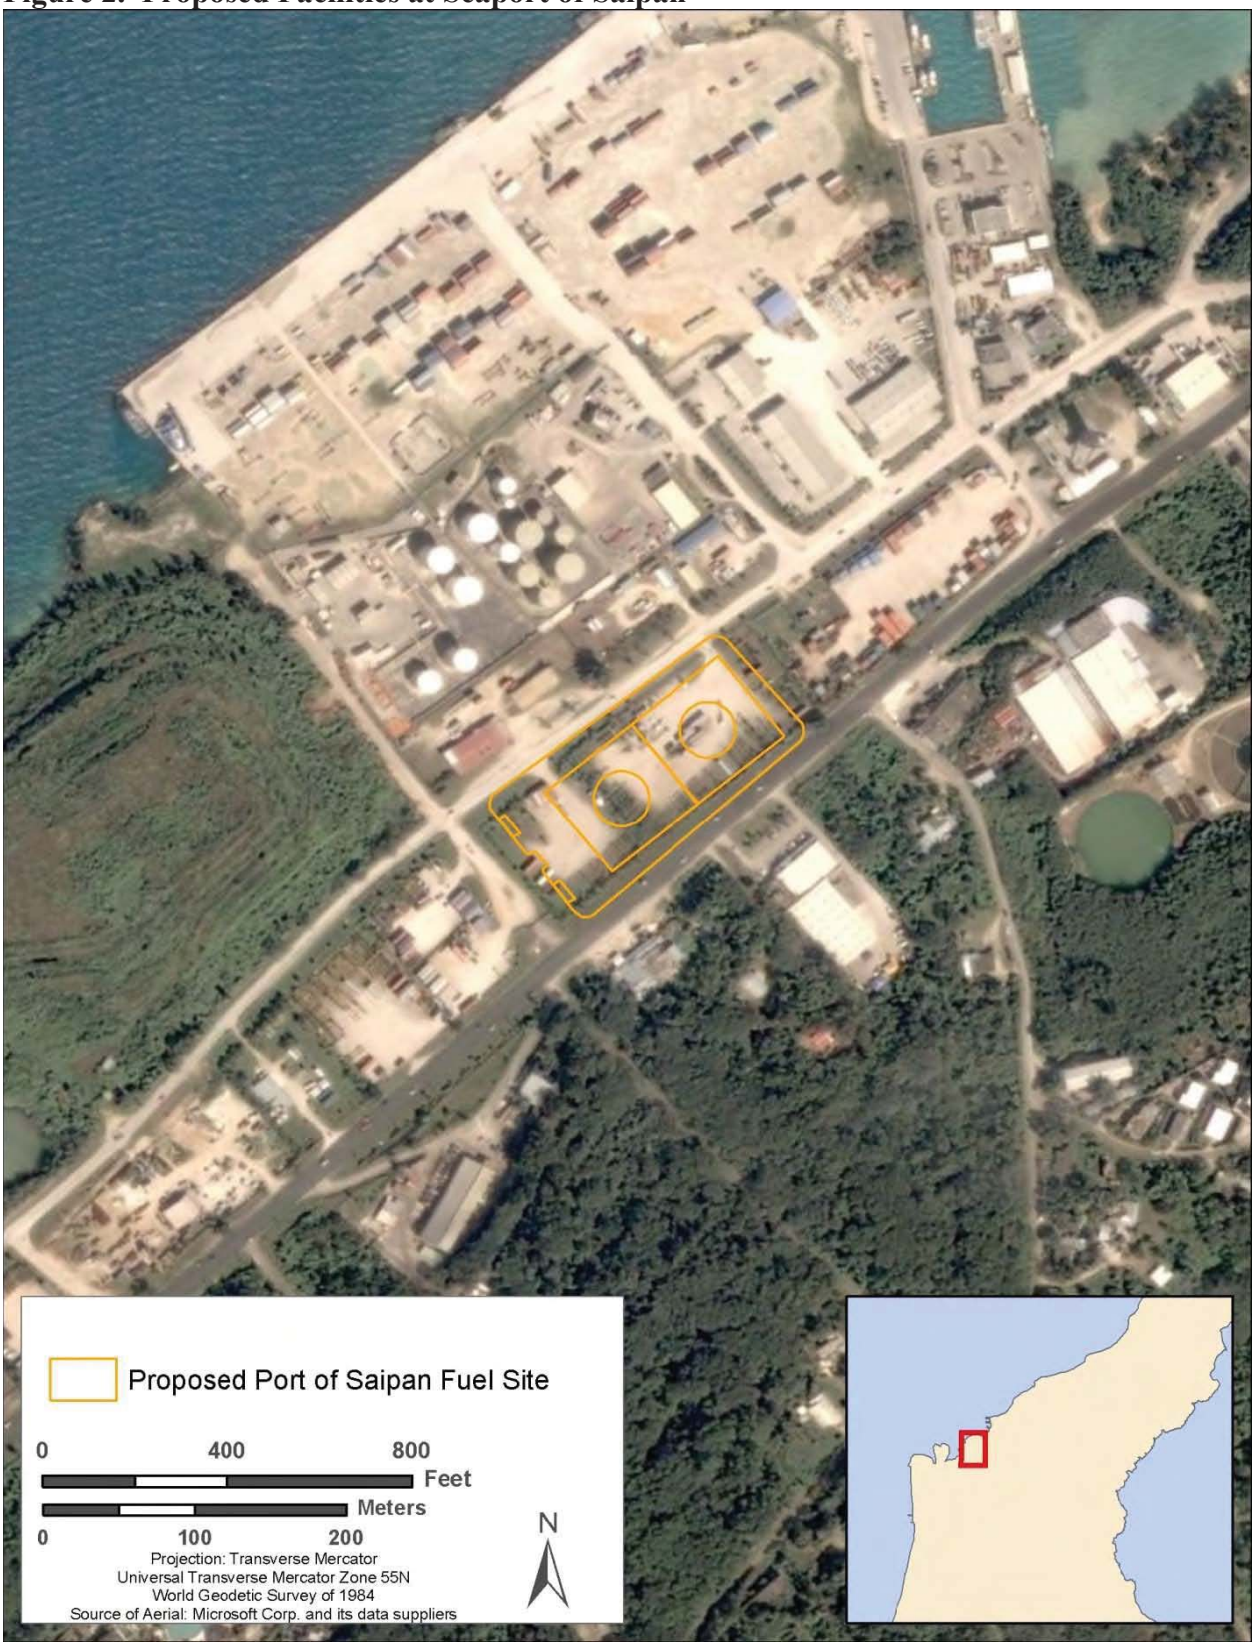


Figure 2. Proposed Facilities at Seaport of Saipan

DESCRIPTION OF THE PROPOSED ACTION

The Biological Assessment for Headquarters Pacific Air Forces Divert Activities and Exercises in Saipan fully describes the proposed construction and implementation of the Divert Project and is incorporated by reference herein. A brief description of the proposed action is provided below. This Biological Opinion will include effects from construction, training, joint military exercises, and humanitarian exercises for the lifetime of the Divert action. The purpose of the Divert project is to establish divert activity capabilities to support and conduct current, emerging, and future exercises, while ensuring the capability to meet mission requirements in the event that access to Andersen Air Force Base on Guam, or other western Pacific locations, is limited or denied. The need for humanitarian assistance can arise suddenly and without warning, such as disaster response in Japan during the 2011 earthquake and tsunami. Because of the proximity to forward-deployed forces in the western Pacific, the Marianas provides the best alternative for forward-deployed U.S. forces to train on U.S.-owned lands and to develop the proposed additional divert capabilities.

Construction

Saipan International Airport

The USAF proposes to construct and expand facilities at GSN. New facilities could include an expanded runway; associated pavement markings and lighting; parking aprons; a temporary munitions storage area; a hazardous cargo aircraft parking pad; an arm/disarm pad; an aircraft hangar; a maintenance facility; a jet fuel receiving, storage and distribution system; and navigational aids. Temporary billeting facilities for up to 700 personnel may also be developed adjacent to the airport. The total size of the facilities, if they are all constructed, would be about 24 hectares (59 acres).

Seaport of Saipan

Two hectares (approximately five acres) would be developed at the Port of Saipan for construction of fuel storage tanks. Two aboveground 2.1-million gallon tanks and associated piping would be constructed near the seaport on federally leased land. The site is located adjacent to the U.S. Army Reserve Center between Beach Road and Middle Road. Existing infrastructure at the port would be used to offload fuel from vessels. The site is in an industrial area that has been previously developed.

The timeline of Phase 1 construction is expected to be 24 to 36 months with geotechnical surveys beginning in 2013. The construction schedule for Phase 2 construction is not yet established.

Implementation

After completion of facility construction, the USAF would use GSN periodically and temporarily for ground and air activities, aircraft support activities, and other airfield ground support activities. A mix of joint cargo, tanker, fighter, and other aircraft could be diverted to or fly from the airfield. Implementation activities conducted might include, but are not limited to, divert landings and take-offs, joint military exercises, jet fueling and storage, humanitarian assistance and disaster relief airlift staging including non-combatant evacuation operations, and billeting. Implementation activities are expected to begin in 2016 or 2017.

Joint military exercises at GSN may include scheduled joint, combined, and unit-level military training activities and exercises, as described and analyzed in the Mariana Island Range Complex Environmental Impact Statement (EIS) (U.S. Navy 2010) and Biological Opinion (USFWS 2010). Aircraft and personnel participating in these combined exercises would be temporarily located at and operate from GSN for a combined total of about 60 days (eight weeks) per year. An exercise could last approximately two weeks. No more than 700 personnel would participate in exercises at GSN at any given time. Humanitarian and divert exercises would be short-term events.

A mix of joint fighter, cargo, and tanker aircraft, not to exceed the airport parking capacity could be diverted to or exercised from GSN. A maximum of six tankers or 12 fighters, or a mix of those aircraft, could operate from GSN if one parking apron is constructed. If the second parking apron is constructed, a total of 12 tankers, or 24 fighters, or a mix of those aircraft, could operate from GSN. The exact mixture of aircraft used during implementation will vary depending on mission requirements. Aircraft that would be used for joint military exercises include cargo, air mobility, and refueling aircraft such as the KC-135, and tactical or fighter aircraft such as the F-16, and F-22. The maximum capacity of aircraft anticipated to be used at GSN at any one exercise or Divert event is 24 fighters or 12 tankers, based on the construction of two parking aprons. Military exercises are anticipated to occur no more than eight weeks per year, such as in four, two-week exercises; however, longer exercises of up to four weeks could occur. The on-going joint military exercises, including joint multi-carrier strike group and joint combined exercises, could constitute four of the eight weeks of training under Divert. To model worst-case noise for an average busy day during a military exercise event, the USAF estimated that each aircraft would complete four operations per day (two arrivals and two departures). The USAF assumed that 90 percent of aircraft operations would occur during the day (7 a.m. to 10 p.m.) and 10 percent at night (10 p.m. to 7 a.m.).

In the Divert Draft EIS (USAF 2012), the USAF modeled baseline, low, medium, and high scenarios for military exercises. The USAF anticipates that the Divert military exercises covered by this Biological Opinion will fall in the range of the low and medium scenarios presented in the Draft EIS. In the baseline scenario (current conditions) approximately 140 flights operate out of GSN on a daily basis. The mix and type of aircraft assumed for each modeled scenario is based on construction of two parking aprons and could result in 12 KC-135 under the low scenario, 6 KC-135, 8 F-16, and 4 F-22 under the medium scenario, and 12 F-16 and 12 F-22 under the high scenario. Under the low scenario the number of tanker/cargo aircraft flights (a flight is a take-off and landing) per day would increase to 152 (an increase of 12 flights). Under the medium scenario the number of flights per day would increase to 164 (an increase of 24 flights). Under the high scenario the number of flights per day would increase to 202 (an increase of 62 flights).

Conservation Measures

The following conservation measures, developed in coordination with the Service, will avoid or minimize effects to the nightingale reed-warbler. They are considered part of the project description. Any changes to, modifications of, or failure to implement these conservation measures may result in a need to reinitiate this consultation.

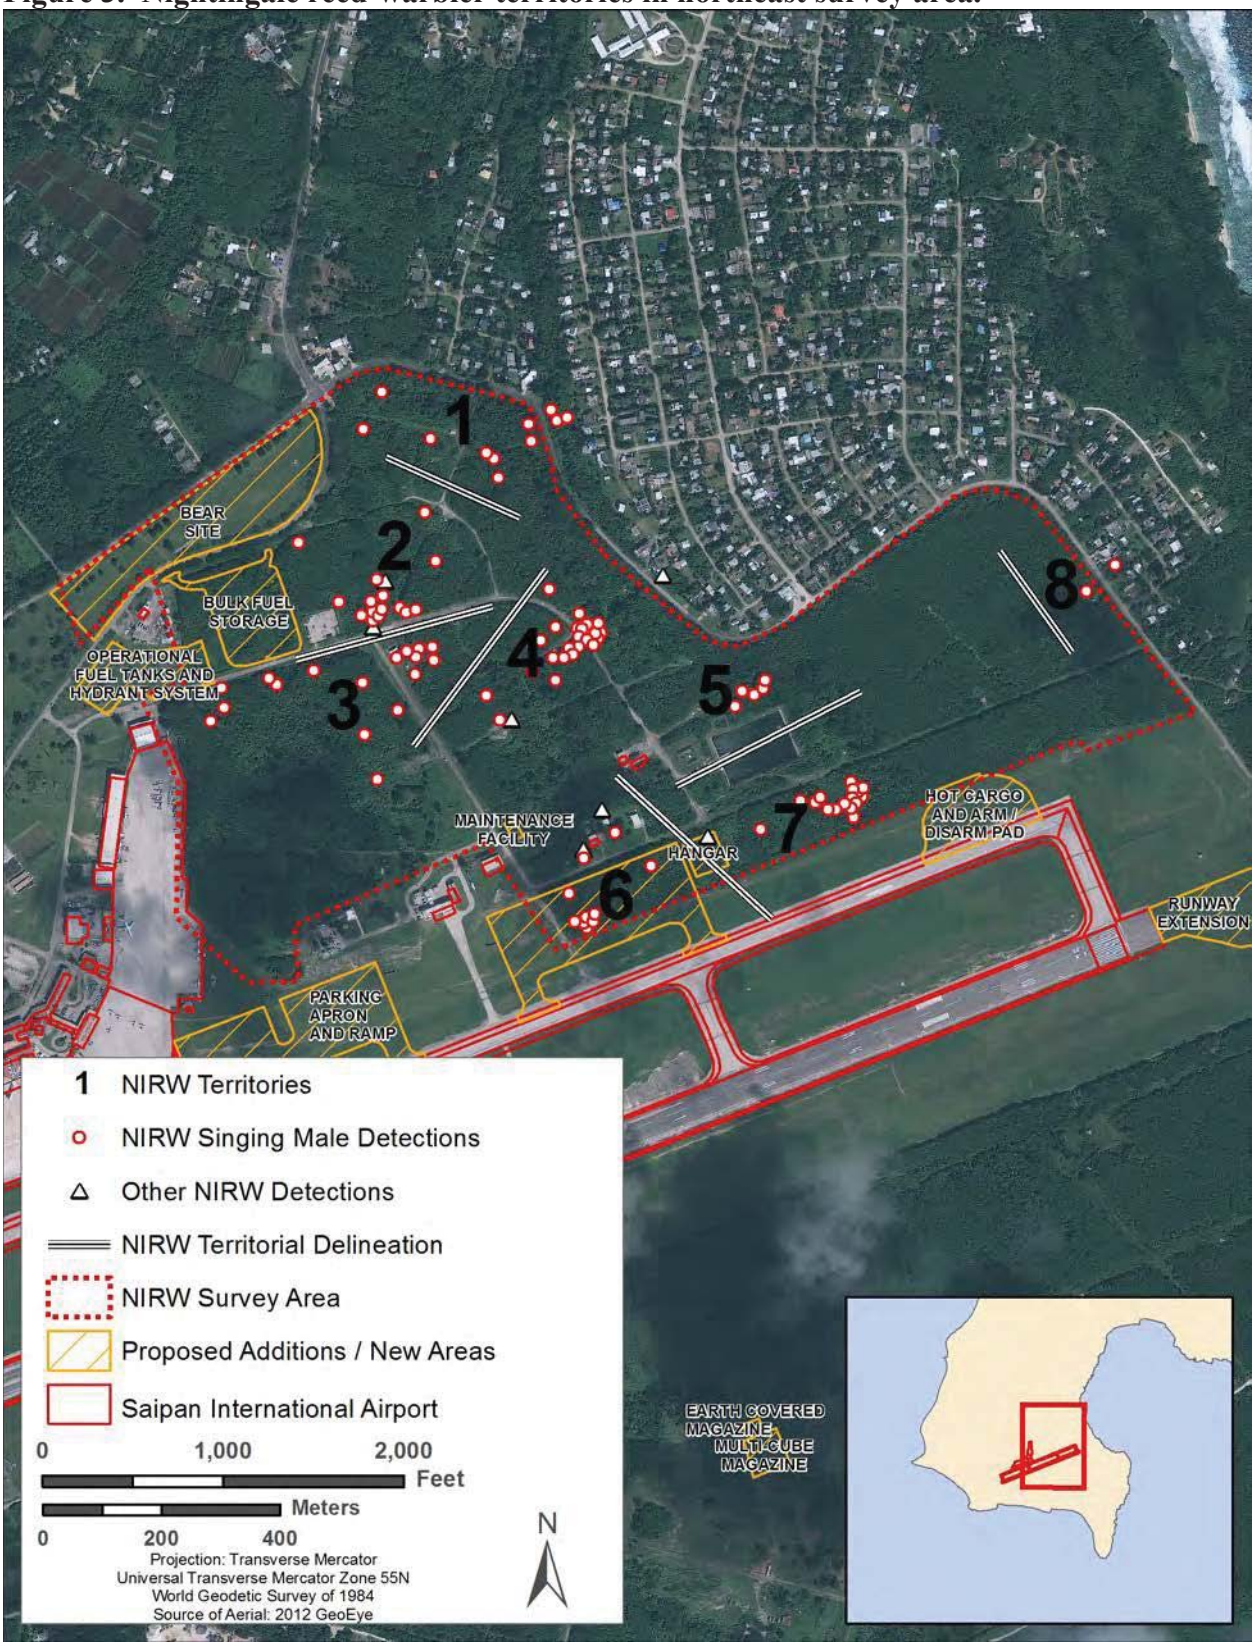
Construction

1. The USAF will purchase one credit in the Saipan Upland Mitigation Bank prior to any construction of the east parking apron (Figure 3). If a credit for Territory Six (see Figure 3) has already been purchased for implementation actions (fighter jet flights) then a credit for Territory Six will not need to be purchased a second time. In accordance with the Nightingale Reed-Warbler Programmatic Consultation and Saipan Upland Mitigation Bank Agreement and Addendum, the agreed-upon credit purchase will be as follows:
    a. Prior to the start of any vegetation clearing or earth-moving activities at the East Parking Apron, the USAF shall purchase one credit at the Saipan Upland Mitigation Bank, which is intended to provide 1.75 nightingale reed warbler territories within the Bank boundary.
    b. Upon written notification that the credit has been purchased (i.e., the CNMI government has received and deposited the funds required to purchase the credit, specified under 1.a. above, within the Commonwealth Mitigation Bank Revolving Fund authorized under CNMI P.L. 10-84 and a receipt is sent to the Service documenting the deposit), the Service will provide a letter to the USAF indicating that the credit purchase obligation has been fulfilled and on-site project activities may begin as outlined within the project description above and the remainder of the conservation measures listed below.

2. Clearing of vegetation at the east parking apron will only occur between October through December or April through June, when nightingale reed-warbler nesting activity is not at its peak.

3. The USAF will not locate a laydown yard or other temporary construction facilities in nightingale reed-warbler habitat or within a 50-meter buffer zone around reed-warbler territories.

4. When possible, the use of very noisy (greater than 60 decibels A-weighted (dBA)) heavy machinery should be limited to the non-active or non-peak breeding seasons or temporary noise barriers or buffer zones should be installed to protect nightingale reed-warblers using buffer zones or areas of connectivity.



5. Adequate plastic construction fencing will be placed and maintained around any habitat that is to be avoided (including buffer areas and adjacent parcels) to prevent impacts to habitat from construction equipment and personnel.

6. All on-site construction personnel will receive instructions regarding the presence of listed species and the importance of avoiding and minimizing impacts to these species and their habitat.

7. All on-site personnel will receive instruction regarding the brown treesnake (*Boiga irregularis*) and what to do immediately in case of a sighting.

8. The USAF will ensure that no unauthorized take of nightingale reed-warbler or destruction of their habitat occurs. The USAF will have the authority to stop all activities that may

Figure 3. Nightingale reed-warbler territories in northeast survey area.

result in such take or destruction until appropriate corrective measures have been completed. The USAF will report immediately any unauthorized impacts to the Service and CNMI DFW.

9. A litter-control program will be implemented during construction. All tools, gear, and construction scrap will be removed upon completion of work in order to prevent the attraction of non-native pests (e.g., rats). All workers will ensure their food scraps, paper wrappers, food containers, cans, bottles, and other trash from the project area are deposited in covered or closed trash containers. The trash containers shall be removed from the project area and disposed of off-site at an approved landfill at the end of each working day.

10. A brief summary report will be provided to the Service within 30 days of construction implementation to document implementation of any fencing, buffer zones, and minimization measures.

Implementation

To offset impacts from noise disturbance and habitat degradation resulting from implementation of joint military exercises as proposed in the Divert EIS, the USAF will purchase seventeen credits in the SUMB. These credits will be purchased prior to initiation of any proposed Divert exercises out of GSN that use fighter-type jet aircraft. It is expected that proposed Divert exercises will begin in 2016 or 2017. If a credit for Territory Six, which will be cleared for the east parking apron, has already been purchased then a credit for Territory Six will not need to be purchased a second time. In accordance with the Nightingale Reed-Warbler Programmatic Consultation and Saipan Upland Mitigation Bank Agreement and Addendum, the agreed-upon credit purchase will be as follows:

a. Prior to the start of proposed Divert exercises out of GSN that use fighter-type jet aircraft, the USAF shall purchase seventeen credits at the Saipan Upland Mitigation Bank, which is intended to provide 29.75 nightingale reed warbler territories within the Bank boundary.
b. Upon written notification that the credit has been purchased (i.e., the CNMI government has received and deposited the funds required to purchase the credit, specified under 1.a. above, within the Commonwealth Mitigation Bank Revolving Fund authorized under CNMI P.L. 10-84 and a receipt is sent to the Service documenting the deposit), the Service will notify the USAF indicating that the credit purchase obligation has been fulfilled and on-site project activities may begin as outlined within the project description above and the remainder of the conservation measures listed below.

Invasive Species Interdiction and Control

The USAF will be responsible for oversight of avoidance, minimization, and mitigation implementation by the construction contractors for projects associated with the proposed Divert activities. In addition, the USAF will be responsible for oversight of training, review, and guidance on Hazard Analysis and Critical Control Point (HACCP) plan development, implementation and revision during the construction phase of the project. The HACCP plans will incorporate measures to ensure invasive species, including the brown treesnake, are not transported to the CNMI from Guam via project vehicles, materials and equipment. The USAF

will be responsible for assuring that any HACCP plans are implemented by construction contractors to prevent the inadvertent movement of non-native, invasive species from other locations to the project site. The USAF will coordinate development of HACCP plans with the Service, including, but not limited to, annual meetings and reports to ensure the actions to eliminate or reduce risk are sufficient and on-going during construction activities.

Brown Treesnake Interdiction and Control

1. Per Public Law 110-417, [Division A], title III, Section 316, October 14, 2008, 122 Statute 4410 and per DoD Defense Transportation Regulations, Chapter 505 protocols, the USAF, with support from Joint Region Marianas (JRM), commits to implementing 100 percent inspection of all outgoing cargo and aircraft that are leaving from Guam associated with the Divert project. Inspections will be performed with trained quarantine officers and dog detection teams, which could be supplemented by other pest control expertise (with appropriate U.S. Department of Agriculture-Wildlife Services (USDA-WS) brown treesnake detection training and oversight) to meet 100 percent inspection goals for training activities, as required by Joint Region Marianas Instruction 5090.4. As a stakeholder, the Service will have input on the USAF protocols for implementing brown treesnake interdiction and control strategies. The USAF will work cooperatively with JRM, the Service, and USDA-WS to seek information in development of protocols for implementation of interdiction and control methods aimed at controlling brown treesnake as related to Divert training activities. On an as needed basis, the Service, USDA-WS, and USAF may request meetings to discuss interdiction and control method protocols as related to Divert military exercises.

   a. In the event military units, vehicles, and equipment accidentally leave Guam without inspection, as soon as possible, the USAF will notify: (1) USDA-WS and (2) the point of destination port or airport authorities and work with the destination port to resolve the issue. Urgency of notification is a priority so that rapid response or other actions can be implemented to reduce risk.

   b. In addition, the USAF will route inbound personnel and cargo for tactical approach exercises or humanitarian operations (that require an uninterrupted flow of events) directly to CNMI training locations to avoid Guam seaports and airfields. If Guam cannot be avoided, the USAF, in cooperation with USDA-WS and the Service, shall identify, and USAF will implement appropriate interdiction methods that may include redundant inspections (see 1c) or other interdiction methods as agreed to by the Service, USDA-WS, USAF and JRM. Additionally, tactical approach exercises will involve only cargo equipment that has not originated from areas containing a brown treesnake population or will be 100 percent inspected by certified brown treesnake canine programs. If the USDA-WS develops performance standards for this activity, the USAF will adopt those standards, provided they are compatible with military mission.

   c. The USAF is committed to implementing 100% redundant inspections after discussions with appropriate stakeholders. Redundant inspections include inspections on Guam and at the receiving jurisdiction for administrative and logistical movements that do not require a tactical approach to complete the training requirements. It is anticipated that

redundant inspections to the extent possible would utilize existing quarantine and inspection protocols at receiving ports, but in the event that there is inadequate inspection coverage the USAF will coordinate with the USDA-WS to provide additional canine inspection teams that will augment quarantine and inspection protocols at the receiving ports. Appropriate stakeholders include, but are not limited to: the Service to ensure the inspections are adequate to reduce risks to trust resources, USDA-WS, receiving jurisdictions and their supporting agencies with expertise in invasive species control, and other inspection authorities as needed to ensure inspection methods are current and revised as new techniques, technology, or data become available.

2. The USAF will also establish snake-free quarantine areas (barriers) for cargo traveling from Guam to CNMI and other brown treesnake-free areas. These barriers will be subject to: (1) multiple day and night searches with appropriately trained interdiction canine teams that meet performance standards under 1b; (2) snake trapping; and (3) visual inspection for snakes. In lieu of permanent barriers, temporary barriers may be preferable to permanent exclosures because of the variable sizes needed to handle different cargo amounts for the various training activities. The USAF will produce standard operating procedures for temporary barrier construction and use within two years of the issuance of this Biological Opinion. Standard operating procedures will ensure that temporary barriers will be constructed and maintained in a manner that assures the efficacy of the barrier and that staff maintaining and constructing the temporary barriers will receive training related to this activity prior to construction. The construction and maintenance of temporary barriers utilized for cargo traveling from Guam to CNMI and other brown treesnake-free areas must be approved by the Service prior to use. During the construction phase of this project, the existing permanent snake-free quarantine area at the Saipan seaport should be utilized for surface cargo following relevant CNMI and DoD regulations. Standard operating procedures will be developed in cooperation with the Service, U.S. Geological Survey, Fort Collins Science Center, Invasive Species Science Branch, and the USDA-WS to ensure risk to trust resources is adequately minimized. If risks are not adequately minimized, additional recommendations will be provided for incorporation into the protocols until the USAF and Service mutually agree the risk has been minimized. The Service, USAF, and other appropriate parties will meet, if necessary, to resolve concerns such that the protocols ensure risk is adequately minimized.

3. The USAF, in conjunction with the Service and JRM, will develop procedures and protocols specific to Divert training events that will support a rapid response action in the event of a brown treesnake sighting resulting from Divert activities. Divert activities and exercises will be varied in the number of aircraft and personnel, and each event will have differing logistics support capabilities depending on the nature of the event. The type and amount of logistic support will be agreed to prior to each major event. Logistic support will include consideration of both in-kind assistance through air transport, shared billeting, security detail, food, materials, and ground transportation, and financial compensation for agreed-to response actions that could not be supported by in-kind assistance, including compensation for performance of services to support the deployment and execution of rapid response search teams.

4. The USAF, working in collaboration with the Service, and USDA-WS, will decide how best to implement the Brown Treesnake Control Plan (BTS TWG 2009, 37 pp.) relevant to Divert activities. The USAF and Service must mutually agree on the Brown Treesnake Control Plan implementation.

5. The USAF will provide invasive species awareness training for all military and contractor personnel prior to all training activities. This would include a mandatory viewing of a brown treesnake educational video, distribution of pocket guides with brown treesnake information and personal inspection guidelines to be carried at all times, and assurance that brown treesnake awareness extends from the chain of command to the individual military service member

6. Due to limited availability of inspectors, trained dogs, and quarantine facilities and equipment on Guam and the CNMI, the USAF will coordinate closely with the Service, U.S. Department of Agriculture, CNMI Department of Land and Natural Resources, and Joint Region Marianas staff responsible for managing their brown treesnake program, on planning for training activities on Saipan. The USAF, along with cooperating agencies, will identify the inspection and interdiction requirements for the Divert training, including the number of trained quarantine officers and dog detection teams required. The USAF will coordinate and consult with the Service on the inspection and interdiction requirements identified by the USAF, and the Service must concur with these requirements prior to the implementation of the exercise or training activity. The USAF, along with the cooperating agencies, will develop plans to ensure that inspection personnel are available and that all requirements can be met, and will identify the support that the USAF will need to provide for the inspections. Planning for training exercises generally begins months prior to implementation of an exercise, and planning for complex training that would require a substantial number of inspectors, quarantine areas, or other personnel or equipment for control and interdiction generally begins more than a year in advance. If adequate resources, such as trained inspectors and dog teams, are not available during training activities, training will not occur until resources are available.

<u>Prevention of Invasive Species Introductions and Spread</u>

1. All personnel involved in Divert training will adhere to DoD Instruction 5090.10A and the 2005 Brown Treesnake Control and Interdiction Plan, which calls for individual troops to conduct self-inspections to avoid potential transport of brown treesnakes. Troops will inspect all personal gear and clothing (e.g., boots, bags, weapons, pants), hand-carried equipment and supplies and tent canvas. The intent of this measure is to minimize the potential risks and subsequent effects associated with transport of troops and personnel from Guam to the CNMI and other areas that do not have brown treesnakes.

2. In addition to self-inspections, each training action will undergo a pathway risk analysis as a tool to improve programmatic efficiency while preventing the spread and introduction of invasive species. Actions at risk of transporting invasive species will have prevention tasks identified and implemented to reduce risk. Methods employed such as HACCP planning

development and implementation by the USAF may be utilized to conduct pathway analysis. Pathway risk analysis must be completed prior to each training action being implemented.

3. The USAF is a participating agency in the development of the Micronesia Biosecurity Plan. The Micronesia Biosecurity Plan is intended to coordinate and integrate inter-agency invasive species management efforts such as control, interdiction, eradication, and research. Once completed, any portions of the Micronesia Biosecurity Plan determined to be applicable to Divert construction and training activities, will be implemented when such procedures do not unduly interfere with military training. The USAF will continue to work cooperatively with the Service and U.S. Department of Agriculture in development of protocols for implementation of interdiction and control methods in accordance with recommendations contained in the Micronesia Biosecurity Plan identified as being tied to USAF actions.

STATUS AND ENVIRONMENTAL BASELINE OF THE SPECIES

A complete Status of the Species for the nightingale reed-warbler can be found in the October 23, 2008, *Programmatic Biological Opinion Regarding the Reestablishment, Management, and Use of the Saipan Upland Mitigation Bank, Saipan* (2008-F-0033). The nightingale reed-warbler was federally listed as an endangered species in 1970 (Service 1970, p. 18321). No critical habitat has been designated for this species. The main threats currently facing the nightingale reed-warbler are: (1) habitat loss and degradation *(e.g.,* wetland destruction, upland forest conversion, habitat destruction by feral ungulates, and habitat degradation by non-native invasive plant species); (2) potential for the establishment of the brown treesnake on Saipan; and, (3) predation by introduced animals such as rats *(Rattus* spp.), cats *(Felis catus),* and possibly monitor lizards *(Varanus indicus).* Island-wide surveys for the nightingale reed-warbler were completed on Saipan in 1982, 1997, and 2007 (Engbring et al. 1986, USFWS 1998a, Camp et al. 2009). These data indicate nightingale reed-warbler populations on Saipan declined by approximately 61 percent from 1982 to 2007. While we do not have updated population information for the last 5 years, we assume that the population has continued to decline as threats to the species have not changed. Habitat loss through development has continued and predator control has not been implemented. However, most habitat loss has been permitted through use of the Saipan Upland Mitigation Bank which will have a long-term benefit to the species. The population of nightingale reed-warblers in the Saipan Upland Mitigation Bank Conservation Area has not been surveyed since 2008. From 1999 to 2008 the population fluctuated yearly but tended to remain stable over the 10-year period (CNMI DFW, unpublished data, 2013).

Environmental Baseline

Micronesian Environmental Surveyors, a contractor for the USAF, conducted avian surveys around GSN in February and March of 2012. Surveys were conducted on the northeast side of the airport where most facilities would be constructed and an area south of the runway slated for the munitions storage facility (Figure 4). Eight nightingale reed-warbler territories were defined in the northeast survey area (see Figure 3). No nightingale reed-warblers were detected south of the runway.

Figure 4. Nightingale reed-warbler survey areas

Additional nightingale reed-warbler territories are likely present in areas surrounding the airport that were not surveyed as part of the proposed project. These territories would not be subjected to construction disturbance, but are within areas that will have increased noise due to additional overflights. There is potential nightingale reed-warbler habitat in As Gonno to the northwest of the airport, east and west of the runway, and south of the runway near Obyan. Comprehensive nightingale reed-warbler surveys were not conducted in these areas, but roadside point-counts were conducted three times at east and west ends of the runway. A nightingale reed-warbler was heard at the west end of the runway, and potential habitat was observed at both ends. In addition, surveys conducted in 2007 by the Service and CNMI DFW detected two nightingale reed-warblers near the west end of the runway, confirming that there are reed-warblers in the area. It is assumed, therefore, that nightingale reed-warbler territories are present at both ends of the runway.

Using vegetation mapping, existing CNMI DFW and USFWS unpublished survey data, and information from Camp et al. (2009), we have estimated the potential number of nightingale reed-warbler territories in the non-surveyed areas around the airport. The two areas that will have the loudest noise from Divert training are the east and west ends of the runways (see Figure 4).

We estimate there are potentially four nightingale reed-warbler territories at the east and west ends of the runway. Nightingale reed-warblers are also present in habitats to the north and south of the airport. We estimate that there are potentially thirteen nightingale reed-warbler territories within approximately 500 meters north and south of the runways that may experience noise disturbance from Divert training activities.

The most recent data indicates there are approximately 229 nightingale reed-warblers in the Saipan Upland Mitigation Bank Conservation Area (CNMI DFW unpublished data 2008). There are no nightingale reed-warblers located at or adjacent to the seaport site (see Figure 2).

EFFECTS OF THE ACTION

Construction

Evaluation under the SUMB Programmatic Biological Opinion

The proposed project will clear 2.6 hectares of nightingale reed-warbler habitat for construction of the east parking apron. Project activities will include clearing vegetation and use of heavy equipment. Project impacts are assessed by determining the number of territories directly and indirectly affected by the action. Due to vegetation clearing for construction of the east apron, one nightingale reed-warbler territory will be subject to direct impacts including habitat loss, fragmentation and degradation. Indirect impacts to this territory and potential adjacent territories include increased noise during clearing and increased risk of non-native invasive species. Under the SUMB Programmatic Biological Opinion, project impacts are assessed by determining the number of territories directly and indirectly affected by the action. For habitat clearing for the east apron, impacts to nightingale reed-warblers will be minimized by purchasing one credit in the Saipan Upland Mitigation Bank commensurate with the direct and indirect impacts associated with the project, and by implementing conservation measures.

Implementation

The implementation of Divert will cause an increase in noise levels around GSN and in surrounding nightingale reed-warbler habitats. The effects analysis for implementation of Divert will therefore focus on potential noise impacts to nightingale reed-warblers from the increase in flights at GSN. This section will first review existing knowledge and literature regarding the impacts of noise on avian species, with an emphasis on military noise and its impacts on songbirds. The noise review is followed by an overview of potential impacts to nightingale reed-warblers from Divert, and then an assessment of the level of take that is expected from Divert.

Noise review

Studies on the impacts of aircraft overflights to wildlife have been primarily limited to work on ungulates (e.g., Krausman et al. 1998; Maier et al. 1998; Frid 2003; Landon et al. 2003; Krausman et al. 2004; Lawler et al. 2005), birds of prey (e.g., Andersen et al. 1989; Watson 1993; Trimper et al. 1998; Delaney et al. 1999; Palmer et al. 2003), and waterbirds (e.g. Ward et al. 1999; Conomy et al. 1998 a,b; Komenda-Zehnder et al. 2003). These studies report a wide range of reactions to overflights depending on the biology of the species, its previous exposure to overflights, whether the species is breeding, the type of aircraft, the altitude of the aircraft, and the lateral distance between aircraft and the species. The variability in these reactions and their specific circumstances make it difficult to be certain how a particular species, such as the nightingale reed-warbler, will react to aircraft overflights.

Avian behavioral responses to noise may range from flushing and body shifting to physiological responses such as an increase in heart rate or hormone balance (Brown 2000, p. 11; Barber et al. 2010, p. 181). Specific reactions will vary by species and by an individual's previous exposure to noise disturbance (Manci 1998, p. 15). Individuals with previous exposure to aircraft overflights may display less reaction to overflights then individuals without previous exposure (Andersen et al. 1989, Conomy et al. 1998b). This reduced reaction is believed to be a sign of habituation; however, the habituation may be individual or species specific. For example, Conomy et al. (1998b) found that black ducks (*Anas rubripes*) did not become habituated to noise. Larkin (1996, p. 1) in a review of noise impacts on wildlife, reported that decreased responsiveness from wildlife after repeated noise is frequently observed and attributed to habituation. However, the degree of disturbance to which a species can habituate may be limited (National Park Service 1994, p. 5.17). Francis et al. (2011a, pp. 6-7) state that overall most species, even urban-adapted species, respond negatively to noise.

Whether a bird moves away from a site of disturbance or stays on site will be dependent on the quality of the current site, the distance to other suitable sites, the relative risk of predation or density of competitors at different sites, and the investment an individual has made to a site (i.e. establishing a territory) (Gill et al. 2001, p. 266). A bird with suitable habitat nearby may avoid disturbance because it has alternative sites to go to, but a bird with no suitable habitat nearby will be forced to remain onsite despite the disturbance, regardless of whether or not this will affect survival or reproductive success (Gill et al. 2001, p. 266). The cost of moving to a new site for a territorial species could be high (Gill et al. 2001, p. 266).

Habitat Degradation

There are multiple ways for anthropogenic noise to cause habitat degradation including noise pollution, masking of avian acoustic signals, changes in predation risk, and reduction in reproductive success. Noise pollution is defined as undesirable human noise, and has increased in most environments over the last century (Ortega 2012, p. 7). Noise pollution can affect birds in numerous ways including physical damage to ears; stress, fright and avoidance responses; changes in reproductive success and in vocal communication; and interference with ability to hear predators and other sounds (Ortega 2012, p. 8). Anthropogenic noise could be a factor driving bird species out of urban areas, even when other habitat requirements are still sufficient (Slabbekoorn and Ripmeester 2007, p. 73).

Most studies on habitat degradation from noise have focused on highway and gas drilling compressor pads, and these studies demonstrate that habitat near a noise source is less suitable than habitat farther away. Francis et al. 2011b (p. 1269 and 1278) found that compressor noise at gas wells caused a five percent lower occupancy of avian species near the pads. Bayne et al. 2008 (p. 1190) found that passerine density was significantly influenced by chronic anthropogenic noise from gas compressors, and that noise levels from compressor stations affected birds up to 700 meters into the surrounding forest. Ovenbirds (*Seiurus aurocapilla*) were found to have lower pairing success near compressor pad sites compared with noiseless well pads (Habib et al. 2007, p. 176). Foppen and Deuzeman (2007; reported in Slabbekoorn and Ripmeester 2007, p. 9) found that great reed warblers (*Acrocephalus arundinaceus*) had higher densities of territories in a wetland near a busy road during two years when the road was closed, compared to years both before and after the road closure. Kuitunen et al. 1998 (p. 297) found that land bird density was lower closer to highways, but this was not the case for the only *Acrocephalus* species in the study area, *Acrocephalus schoenobaenus* (p. 299). The willow warbler (*Phylloscopus trochilus*) had a much lower density of territorial males within 0-200 meters from a highway compared to habitat farther away, yearling males were found 50 percent more often in the road zone, and the study indicated that the road zone probably serves as a sink for young males due to reduced habitat quality from noise (Foppen and Reijnen 1994, p. 99). These studies generally show that noise pollution can cause habitat degradation.

Masking

Anthropogenic noise that drowns out vocal communication between birds is called masking. Masking can have serious consequences because birds communicate vocally to attract mates and defend territories (Ortega 2012, p. 10; Slabbekoorn and Ripmeester 2007, p. 1; Barber et al. 2010, p. 180). Masking of communication necessary for territory defense and mate attraction may have a negative impact on reproductive success and exclude birds from otherwise suitable habitat (Halfwerk et al. 2011, p. 210). Halfwerk et al. (2011, pp. 217-218) suggest four mechanisms related to masking that could reduce avian reproductive success: (1) female birds interpret male songs masked by high noise as of lower quality and put less energy into the breeding cycle; (2) a noisy territory may be perceived of as being a lower quality and avoided, reducing the number of available territories for breeding; (3) increased noise levels cause physiological stress due to reduced foraging opportunities if prey are less easy to detect or because the bird has to spend more time scanning for predators; and, (4) noise could have a negative impact on parent-offspring communication.

Anthropogenic noise is typically loud and low in pitch (Slabbekoorn and Ripmeester 2007, p. 1). Birds with low-frequency signals are more likely to abandon noisy areas (Francis et al. 2011a, p. 7), including noisy roads (Slabbekoorn and Ripmeester 2007, p. 1), and birds inhabiting noisy areas may sing at a higher frequency to reduce masking by noise (Francis et al. 2011a, p. 6; Barber et al. 2010, pp. 185-186; Slabbekoorn and Ripmeester 2007, p. 3). How well a species can survive in urban and other noisy environments may depend on how well they can adjust the frequency of their vocal communication (Slabbekoorn and Ripmeester 2007, p. 3). *Luscinia megarhynchos*, an urban nightingale in Berlin, was found to sing at higher sound levels in noisy locations and raised their song volumes in response to traffic noise by singing louder on weekday mornings than weekends (Brumm 2004, pp. 434-435). Slabbekoorn and Peet (2003, p. 267) found that urban great tits (*Parus major*) at noisy locations sang with a higher frequency. Males singing at higher vocal amplitudes may be at a disadvantage due to increased energetic costs of singing loudly (Brumm 2004, p. 439). Noise pollution can also inhibit a bird's ability to detect predators (Habib et al. 2007, p. 181; Ortega 2012, pp. 13-14) or drown out alarm calls warning of approaching predators (Barber et al. 2010, p. 182 and 184).

The Service does not have data on the frequency of the nightingale reed-warbler song (Marshall 2012, pers. com.). Few songbird species rely just on low frequencies but one species that does is the great reed-warbler, and other nightingale species are known to use a wide range of frequencies, including very low ones (Slabbekoorn and Ripmeester 2007, p. 9).

Breeding

Anthropogenic noise can have negative effects on avian breeding (Halfwerk et al. 2011, p. 210; Slabbekoorn and Ripmeester 2007, p. 2; Ortega 2012, p. 10). Noise may affect egg production, incubation, brooding and nest abandonment (Ortega 2012, p. 10). Halfwerk et al. (2011, p. 210) found that females laid smaller clutches in noisier areas, and that noise recorded in April had a negative effect on the number of great tit fledglings independent of clutch size, compared to noise in March. High noise levels could lead females to breed later, allocate less energy to care of eggs and chicks, and cause communication difficulties between parents and offspring (Halfwerk et al. 2011, pp. 217-218).

Habib et al. (2007, p. 176) found that ovenbird pairing success was reduced, and more inexperienced birds were breeding for the first time, near noisy compressor sites compared to noiseless sites. This reduction in ovenbird pairing success near compressor sites was likely caused by noise interfering with a male's song, thereby inhibiting communication with females and reducing pair success (Habib et al. 2007, p. 176). Foppen and Reijnen (1994, p. 95) found that the zones nearest to a highway served as a sink for male willow warblers, and that the proportion of successful yearling males was 50 percent lower in the road zones compared to zones farther away from the highway.

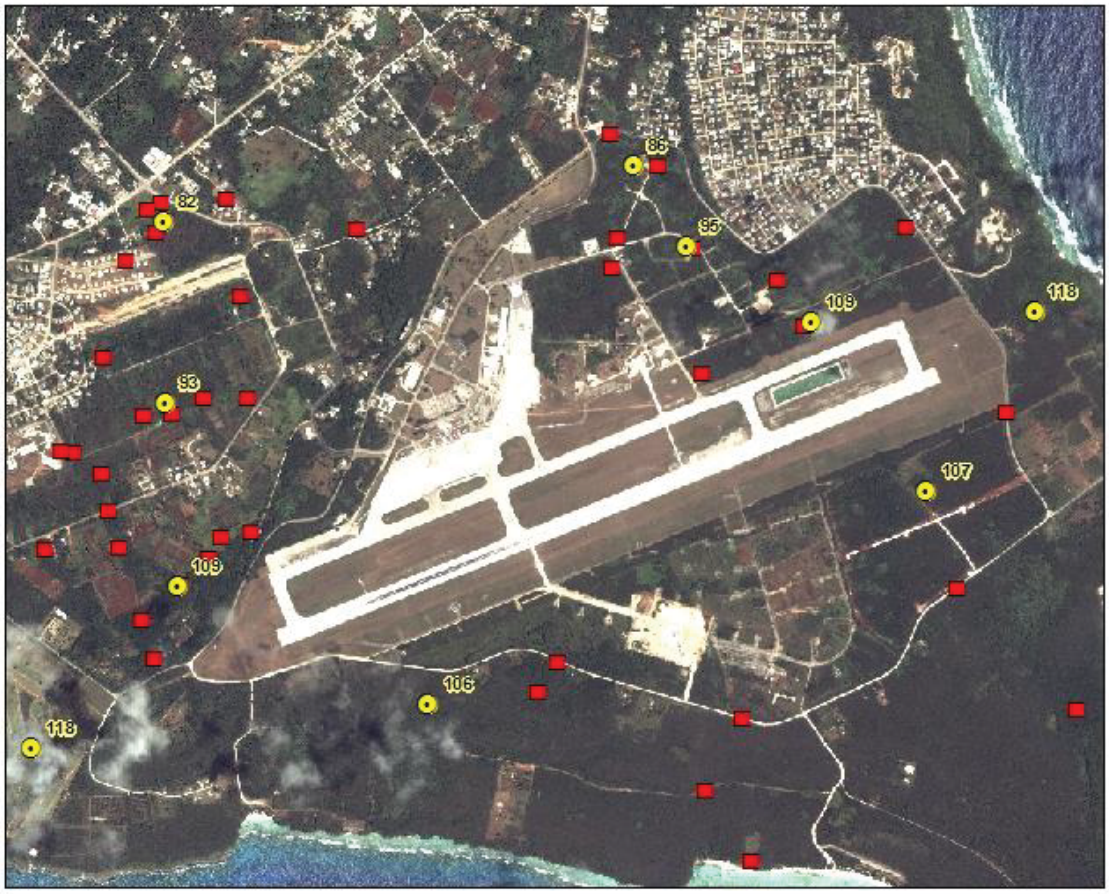
There may be differences between the effects of chronic noise and intermittent loud noise in the responses of breeding birds. Birds that select nest sites with chronic noise may "accept" the noisy conditions and not abandon nests in response to the noise. However, birds that select nest sites during quiet times, and then become disturbed by noisy conditions later, may abandon nests (Ortega 2012, p. 10).

In a study of the effects of helicopter noise from the Marine Corps Air Station Miramar (MCAS) on California gnatcatcher (*Polioptila california californica*) reproduction, Hunsaker and Rice (2006, p. 101) found that noise levels at MCAS did not affect reproductive success. California gnatcatchers found and inhabited suitable nesting sites in spite of the noise environment, and the factors affecting nest success were habitat, topography, and rainfall. Awbrey and Hunsaker (1997, p. 3177) found that fixed-wing aircraft noise at Naval Air Station Miramar was correlated with fewer California gnatcatcher nest attempts and eggs laid, but that once a nest was established with eggs in it, military aircraft noise had no detectable influence on reproductive success. In Hawaii, Vanderwerf (2000, p. 9) studied the response of Oahu elepaio (*Chasiempis sandwichensis ibidis*) at eight nests to military noise (artillery blasts ranging from 89-116 dB). No elepaio flushed from a nest in response to artillery noise. A mild response was only observed twice by the same incubating male who raised his head and scanned the area after an artillery blast then resumed preening after 1-2 seconds (Vanderwerf 2000, p. 38). Delaney et al. (2002, p. 54) found that the nesting success of red-cockaded woodpeckers (*Picoides borealis*) near Fort Stewart, Georgia, was not significantly affected by experimental and passive military training noise. However, red-cockaded woodpeckers did flush from their nests repeatedly due to nearby (less than 100 meters) artillery and blank fire events, but returned to their nests quickly and without impact to nesting success (Delaney et al. 2002, p. 59). The effects of aircraft noise on Oahu elepaio or red-cockaded woodpeckers were not tested in either study.

Birds may also suffer physical damage to their ears from loud noise (Barber et al. 2010, p. 181). Damage can occur from single blasts (>140 dBA), multiple blasts (>125 dBA) or continuous exposure to noise at greater than 110 dBA (Ortega 2012, p. 9; Dooling and Popper 2007, p. 23). Birds are able to regenerate the sensory cells of the inner ear providing a way for them to recover from physical damage to the ear from loud noise, and so do not suffer permanent hearing loss like mammals (Dooling and Popper 2007, p. 5 and p. 25). However, in their review, Dooling and Popper (2007, p. 27) state that the effects of short, intermittent, and high intensity sounds on avian hearing are much less known than that from highway noise.

Effects of Aircraft Overflight Noise on Nightingale Reed-Warblers

Upon implementation of Divert, military training flights would occur up to eight weeks a year at GSN. Exact training exercises are not defined at this time. Humanitarian operations occurring outside the eight week training time may also occur but are not expected to significantly disturb nightingale reed-warblers above current baseline conditions at the airport. The focus of this section will be the effects of increased noise from aircraft overflights on nightingale reed-warblers from eight weeks of joint military exercises at GSN.



The noise disturbance from the training will be short-term, high-intensity, repeated single pulse, and intermittent. In the areas closest to the runway the average daily noise (DNL), as presented in the medium scenario in the DEIS (USAF 2012), would increase approximately 20 to 25 dBA over baseline conditions, with average daily sound levels not rising above 83 dBA. However, the maximum noise from each individual aircraft overflight will increase from baseline conditions between 10 to 29 dBA for F-22 (or similar fighter jet) training flights, depending on proximity to the airport runways (Table 1, Figure 5). The loudest noise would occur at the east and west ends of the runway where noise from F-22 training flights could reach 118 dBA for each take-off or landing. The maximum number of F-22 flights per day would be 48, and the

noise event would last less than 60 seconds, with the maximum sound level occurring only briefly. Flights from KC-135, and similar aircraft, will also occur; however noise from these flights does not rise above current conditions and therefore no adverse effect is expected from operation of these planes.

Table 1. Noise levels (in dBA) from current aircraft operations and proposed military operations for ten points surrounding GSN in occupied or potential nightingale reed-warbler (NIRW) habitat.

	Current	Proposed Military		
Location	**767**	**KC-135**	**F-16**	**F-22**
East end of runway	89.4	95.2	115.9	118.1
West end of runway; east golf course pond	92.6	97.3	115.8	117.7
Occupied NIRW territory north of runways	85.4	79.1	105.7	108.7
As Gonno farm area; occupied NIRW territories	84.1	81.2	99.1	108.7
Obyan area south of runways	85.2	76.5	103.5	106.4
Obyan area south of runways	83.8	78.0	104.8	106.5
Occupied NIRW territory north of runways	76.5	64.7	85.7	94.5
Koblerville; occupied NIRW territories	73.3	60.0	83.3	93.0
Occupied NIRW territory north of runways	76.4	55.7	78.8	86.3
Koblerville; occupied NIRW territories	68.3	45.4	73.1	82.2

The nightingale reed-warblers that have territories surrounding GSN may be habituated to current airport noise levels, along with noise from vehicular traffic and rural residential areas. The most frequent aircraft flying currently out of GSN is the Piper Cherokee (a single-engine aircraft) with 113 daily flights, followed by the Cessna 441 (13 daily flights), the 747-200 (6 flights), and the 767-300 (6 flights) (USAF 2012, p. 3-4). The 767 is the loudest aircraft currently operating out of GSN, and is similar in noise level to the 747. Noise from 767 and 747 takeoffs and landings range from approximately 75 dBA to 93 dBA 12 times a day in areas surrounding GSN (see Table 1).

Male nightingale reed-warblers have high site-fidelity to their established territories, remaining in the same location for multiple years (Craig 1992; Mosher 2006; Johnson 2003). It is not known what levels of disturbance or habitat degradation would cause a male reed-warbler to abandon an established territory. However, as described above, some birds may be forced to stay in habitat made unsuitable by noise disturbance because suitable habitat is limited elsewhere. The nightingale reed-warbler is a strongly territorial species (Mosher 2006, USFWS 1998b) and could appear habituated to airport noise but actually be maintaining territories in the area due to habitat limitations not habituation, and may suffer fitness costs due to this. Habitat loss is considered one of the primary threats to the nightingale reed-warbler (USFWS 1998b), and this, combined with territoriality, may mean that some pairs are forced into lower-quality habitat. There are no studies comparing reproductive success of reed-warblers in undisturbed versus disturbed habitats, so it is unknown if the birds near GSN suffer fitness costs because of the noise disturbance in the area.

Nightingale reed-warblers have been observed to be tolerant of noise disturbance (Rounds pers. com. 2012). They have been observed in urban areas of Garapan, on the edges of residences, farms, and industrial areas where use of heavy equipment and construction occurs, and successfully nested with heavy equipment operating 75 meters away at a quarry site (Rounds pers. com. 2012; Gourley and Johnson 2002). While there have been no comprehensive studies of reed-warbler response to noise, it does appear that the species is tolerant to some levels of noise disturbance.

For eight weeks a year, both the noise level and frequency of aircraft flights will increase under Divert. During the non-breeding season, nightingale reed-warblers could be disturbed by military training flights while foraging or roosting. In these cases responses may include startling, fight-or-flight responses, and/or flushing. Since the noise is of short-duration, it is not expected that these responses would significantly disrupt foraging or roosting and most likely the birds will quickly return to what they were doing. Nightingale reed-warbler communication may be disrupted in the short-term if aircraft noise exceeds reed-warbler song frequency.

Eight weeks of military training during the nightingale reed-warbler breeding season could have adverse effects on breeding success for pairs with territories near the airport. The adverse effects are most likely to occur during the territory formation, nest building, egg-laying, and early incubation stages (see Awbrey and Hunsaker 1997). If military training occurred during these early stages it is possible that a pair could abandon a territory or a nest due to the new noise disturbance (Ortega 2012, p. 10). What seemed high-quality suitable habitat without the noise disturbance may degrade to unsuitable habitat after military training begins.

Incubating or brooding birds may flush off nests as with red-cockaded woodpeckers (Delaney et al. 2002, p. 55) or may stay on the nest similar to the Oahu elepaio (Vanderwerf 2000, p. 38). Because no studies have monitored reed-warbler nests during disturbance events, it is unknown how incubating or brooding nightingale reed-warblers will react to F-22s or other fighter jets flying overhead. Once a nest is established it is less likely that the pair will abandon the nest or the territory and the noise disturbance at this point is less likely to reduce reproductive success. Begging calls from nestlings or juveniles could be temporarily masked by the loud noise but because the noise is of short-duration it is unlikely to affect provisioning rates.

The noise pollution from the military training could lead to overall habitat degradation around the airport. It is possible that during training events birds could abandon territories and look for new less-disturbed habitats for breeding. Once the training session is over the habitat will become quiet again, and the same pairs, or new ones, could move back in. In a worst-case scenario a cycle could be repeated of birds abandoning and reestablishing territories and the area could become a sink for nightingale reed-warbler breeding (see Halfwerk et al. 2011, Ortega 2012, Habib et al. 2007).

Predation is a primary cause of nightingale reed-warbler nest failure (Mosher 2006; USFWS 1998b). Feral cats or rats stalking a nightingale reed-warbler are likely to prey on the birds regardless of noise. Predation from Micronesian starlings (*Aplonis opaca*) or collared kingfishers (*Todiramphus chloris*) on nightingale reed-warbler nests is possible, though not documented in the literature (Mosher 2006, p. 60). If noise disturbance causes a nightingale reed-warbler to flush from incubating or brooding at a nest it is possible an avian predator more tolerant of noise could take advantage of the absence and prey upon the nest, but again, a cat or rat is likely to predate regardless of the noise. Overall, it is not expected that noise from Divert training will cause an increase in nightingale reed-warbler predation because the noise disturbance will be intermittent and short in duration.

As described above, hearing damage from single, repeated loud noises typically occurs at noise levels greater than 125 dBA. Noise from the Divert training is not expected to rise above 120

dBA in nightingale reed-warbler habitat. Therefore, we do not expect hearing damage from the proposed training activities.

Take assessment

Guidance on potential effects of noise on endangered wildlife and when disturbance rises to the level of take was taken from USFWS (2006), Pater et al. (2009), and Dooling and Popper (2007). While nightingale reed-warblers may be disturbed by many human activities, we anticipate that such disturbance rises to the level of harassment under a limited range of conditions. For the Divert project, we are assuming that harassment may occur when nightingale reed-warblers demonstrate behavior suggesting that the safety or survival of the individual is at significant risk, or that a reproductive effort is potentially lost or compromised. Examples of this behavior include, but are not limited to:

- An adult is repeatedly flushed from a nest during the incubation, brooding, or fledging period, that potentially results in egg failure or reduced juvenile survival.
- An adult is repeatedly flushed from a nest resulting in increased energetic costs.
- An adult or juvenile abandons a territory.

The amount of incidental take of the nightingale reed-warbler that will occur is difficult to quantify because the effects of noise on nightingale reed-warblers is not well studied, and it is unknown how frequently joint military exercises will occur during the nightingale reed-warbler breeding season. For this Biological Opinion, we quantified take using the best available data on effects of noise on songbirds (described above), our knowledge of nightingale reed-warbler behavior, and best estimates of joint military exercises training schedules provided by the USAF.

We estimate that there are potentially four nightingale reed-warbler territories at the west and east ends of the runway where the loudest noise will occur. These territories will be subject to noise levels up to 118 dBA from F-22, or similar fighter jets, overflights. The maximum number of F-22 (or similar fighter jet) flights per day would be 48 and the best estimate of a training event is two weeks. This level of training and noise disturbance could cause nightingale reed-warblers to abandon territories or nests, especially if the training occurred immediately prior to or at the beginning of a nesting attempt. Birds may also have startle responses and/or flush from nests. Nightingale reed-warblers may suffer increased energetic costs due to repeated loud noises and flushing. The increased energetic costs could adversely affect reed-warblers by decreasing the energy available to them for foraging and reproduction. The noise levels in these areas could cause these four territories to become unsuitable habitat for reed-warblers, though they may still occupy the area, and breed successfully, during quiet times.

Adults displaced by habitat degradation will attempt to establish new territories in areas that may already be occupied by other nightingale reed-warblers. Since the nightingale reed-warbler is territorial, neighboring pairs are likely to aggressively confront the displaced adults. A frequently observed pattern of intra-specific passerine bird territorial behavior is that the bird defending its territory is more aggressive than an intruder and is usually successful at driving the intruder away (Van Tyne and Berger 1976). The confrontation could disrupt the neighboring pairs' normal nesting behavior patterns by taking adults away from nests during the breeding season to defend their territories. However, this disruption is unlikely to rise to the level of take.

Nightingale reed-warblers are also present in habitats to the north and south of the airport runways in areas that will experience periodic noise up to 110 dBA from military training events. These areas, within approximately 500 meters of the runways, may support up to 13 nightingale reed-warbler pairs (based on survey data for Divert and habitat estimations). In our opinion it is less likely that birds will abandon territories in these areas, but birds could flush from nests if they are startled, especially during early training events before they are habituated to the noise. The noise disturbance will increase to over 20 dBA greater than ambient nesting conditions in these areas, and that has been used by the Service as a threshold for disturbance reaching the level of take (USFWS 2006). However, the birds in these areas currently experience daily noise, from take-offs and landings of commercial aircraft, that reaches up to 90 dBA. We feel that the noise disturbance may cause increased energetic costs for nightingale reed-warblers flushed from nests due to joint military exercise; however, we do not expect this disturbance to result in reduced reproductive success. Therefore, we expect a low level of take of nightingale reed-warblers, in the form of harassment and increased energetic costs from flushing, in the 13 territories that will experience increased noise (but below 110 dBA) from joint military exercises.

Evaluation under SUMB Programmatic Biological Opinion

Due to noise disturbance from implementation of Divert military exercises, four nightingale reed warbler territories will be subject to direct impacts including habitat loss and degradation and thirteen nightingale reed-warbler territories will be subject to direct impacts of habitat degradation. Under the SUMB Programmatic Biological Opinion project impacts are assessed by determining the number of territories directly and indirectly affected by the action. For noise disturbance, ESA responsibilities will be addressed by the purchase of 17 credits and by implementing associated conservation measures.

Biosecurity

To reduce the risk of introduction and spread of non-native, invasive species via Divert activities, the USAF has proposed to implement a variety of conservation measures throughout the action area. Effective interdiction of brown treesnakes on Guam and the CNMI is critical to preventing the spread of this species. The USAF has committed to snake inspection (100% as a goal), construction of snake barriers and brown treesnake rapid response to support military training. In addition, the USAF has committed to the establishment of a biosecurity program during construction and implementation of the proposed project. Successful implementation of the biosecurity program will prevent adverse effects to listed species, and other native wildlife, from introduction of non-native species.

CUMULATIVE EFFECTS

Cumulative effects include the effects of future non-Federal actions that are reasonably certain to occur within the area of action subject to consultation. Future Federal actions will be subject to the consultation requirements established in section 7 of the ESA and, therefore, are not considered cumulative for the proposed action. Sustenance farming, clearing, and burning are ongoing and are likely to continue to be implemented on the island of Saipan. However, use of the SUMB to off-set impacts from authorized habitat clearing will limit adverse effects to nightingale reed-warblers from habitat loss. Unauthorized clearings are also likely to continue on Saipan, further reducing the amount and quality of nightingale reed-warbler habitat. Natural disasters, such as typhoons, also occur regularly on Saipan further damaging habitat. Persecution of nightingale reed-warblers by people resentful of ESA restrictions has also been reported, and may continue in the future.

CONCLUSION

The Service anticipates that the direct and indirect effects of the proposed action will result in take of the nightingale reed-warbler in the form of harassment from noise disturbance and harm from habitat clearing. Adverse effects of the proposed actions on nightingale reed-warblers will be minimized by avoidance and minimization measures. For the nightingale reed-warbler, the Service has determined that the proposed action conforms with the SUMB Programmatic Biological Opinion based upon the nature of the action and the incorporation of avoidance, minimization, and offsetting measures as described in that document. Additionally, the status, baseline, and potential project impacts are current and consistent with those evaluated within the SUMB Programmatic Biological Opinion. After reviewing the current status, the environmental baseline, the effects of the proposed action, and the cumulative effects, it is the Service's biological opinion that implementation of the proposed action discussed herein is not likely to jeopardize the continued existence of the nightingale reed-warbler.

INCIDENTAL TAKE STATEMENT

Section 9 of the ESA and Federal regulations promulgated pursuant to section 4(d) of the ESA prohibit the take of endangered or threatened species, respectively, without special exemption. Take is defined as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct. Harm is further defined by the Service to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing behavior patterns which include, but are not limited to, breeding, feeding, or sheltering. Harass is defined by the Service as intentional or negligent actions that create the likelihood of injury to listed species to such an extent as to significantly disrupt normal behavior patterns which include, but are not limited to, breeding, feeding or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, carrying out an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2) of the ESA, taking that is incidental to and not intended as part of the agency action is not considered a prohibited taking under the ESA provided that such taking is in compliance with the terms and conditions of this Incidental Take Statement.

The measures described below are non-discretionary, and must be undertaken by the USAF so that they become binding conditions of any grant, permit, or permissions issued by the USAF, as appropriate, for the exemption in section 7(o)(2) to apply. The USAF has a continuing duty to regulate the activity covered by this incidental take statement. If the USAF (1) fails to assume and implement the terms and conditions or (2) fails to require the adherence to the terms and conditions of the incidental take statement through enforceable terms that are added to the permit, grant document, or other permissions, the protective coverage of section 7(o)(2) may lapse. In order to monitor the impact of incidental take, the USAF must report the progress of the action and its impact on the species as specified in the Incidental Take Statement.

AMOUNT OR EXTENT OF TAKE

Based on the proposed project description and the analysis of the effects of the proposed action provided above, the Service anticipates that construction and implementation of Divert on Saipan may cause take of the nightingale reed-warbler. The Service is tracking the loss of the nightingale reed-warbler and its habitat permitted under the SUMB Programmatic Biological Opinion, and we evaluate each project to ensure that continued implementation will not result in unacceptable effects to the listed species. The conservation measures appropriate to avoid, minimize and offset project impacts as identified in the SUMB Programmatic Biological Opinion have been included within the project description above. We estimate the following forms of incidental take will occur from construction and implementation of Divert training:

1. One nightingale reed-warbler territory will be cleared for construction of the east parking apron resulting in harm of up to two adults and up to four juveniles.

2. Four nightingale reed-warbler territories could be abandoned due to habitat degradation from repeated and loud noise from fighter jet training resulting in harassment of up to eight adults and up to sixteen eggs, chicks, or juveniles.

3. Thirteen nightingale reed-warbler territories will suffer habitat degradation from noise disturbance from fighter jet training resulting in periodic, but rare, harassment of up to twenty-six adults.

Effect of the Take

The level of Incidental Take anticipated from this project is consistent with the SUMB Programmatic Biological Opinion and will not jeopardize the survival or recovery of the nightingale reed-warbler.

Reasonable and Prudent Measures

The reasonable and prudent measures given below, with their implementing terms and conditions, are designed to minimize the impacts of incidental take that might otherwise result from the proposed actions. If, during the course of the action, the level of incidental take is exceeded, such incidental take represents new information requiring reinitiation of consultation and review of the reasonable and prudent measures provided. In addition, the action that caused the taking must cease; the action agency must immediately provide an explanation of the causes of the taking; and must review with the Service the need for possible modification of the

reasonable and prudent measures. The following reasonable and prudent measures are necessary and appropriate to minimize the effect of take on the nightingale reed-warbler. The measures described below are non-discretionary and must be implemented.

1. The USAF shall minimize the potential for harassment, harm, or mortality of nightingale reed-warblers.

Terms and Conditions

In order to be exempt from the prohibitions of section 9 of the ESA, the USAF must ensure compliance with the following terms and conditions, which implement the reasonable and prudent measure described above. These terms and conditions are nondiscretionary.

The following terms and conditions implement reasonable and prudent measure number one.

1(a) To the extent practicable, consistent with national security and contingency requirements, and military safety and security requirements, the USAF will notify the Service on an annual basis of upcoming Divert training events at GSN including timing and description of the joint military exercises.

1(b) The USAF will submit annual reports to the Service on the first of December of each year beginning in 2014. The purpose of the annual report is to discuss successes and failure of all avoidance, minimization, and conservation measures, and terms and conditions listed in this biological opinion in relation to the anticipated and observed impacts and incidental take. The report will include details regarding invasive species control and interdiction including which cargo/flights were inspected or non-inspected, potential level of risk associated with each cargo/flight type, and where the cargo/flights originated from for training related actions only. The reports should include explanations if specific inspections were missed and document all snake detections or other high risk incidents and the method used for the detection for training related actions only. The report will also include the number of brown treesnake kills during training actions.

The annual report will also include a description of all actions that occurred at GSN related to Divert (including humanitarian operations, flight diversions, and joint military exercises).

1(c) The USAF will convene an annual coordination meeting or conference call prior to 28 February of each year, starting in 2015, to discuss findings within the compliance report and adapt avoidance, minimization, and conservation measures to further reduce incidental take.

CONSERVATION RECOMMENDATIONS

Section 7(a)(1) of the ESA directs Federal agencies to utilize their authority to further the purposes of the ESA by carrying out conservation programs for the benefit of endangered and threatened species. The term "conservation recommendations" has been defined as suggestions

from the Service regarding discretionary measures to minimize or avoid adverse effects of a proposed action on listed species or critical habitat or regarding the development of information. The recommendations provided here relate only to the proposed action and do not necessarily represent complete fulfillment of the agency's 7(a)(1) responsibilities for these species.

1. The USAF should implement a monitoring project, using qualified avian biologists, when joint military exercises begin operating out of GSN (anticipated in 2016 or 2017). The monitoring project could occur in habitats experiencing noise above 100 dBA from take-off and landings of fighter jets (see Figure 3). The monitoring project could be used to:
   - Determine noise levels in nightingale reed-warbler territories surrounding the airport when fighter jets take-off and land at GSN.
   - Determine if take-off and landing of fighter jets from GSN cause a behavioral response (i.e. startle, alert, flushing, stress, etc.) in nightingale reed-warblers.
   - Determine the effect of take-off and landing of fighter jets from GSN on nightingale reed-warbler breeding success in areas surrounding the airport.
   - Determine population trends and territory fidelity of nightingale reed-warblers surrounding the airport.

2. The USAF should implement rat and/or cat control at nightingale reed-warbler territories, and monitor nightingale reed-warbler nest success, to determine how predator control affects breeding success.

REINITIATION-CLOSING STATEMENT

This concludes formal consultation on this action. As required in 50 CFR § 402.16, reinitiation of consultation is required where discretionary Federal agency involvement or control over the action has been retained (or is authorized by law) and if: (1) the amount or extent of incidental take is exceeded; (2) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion; (3) the agency action is subsequently modified in a manner that causes an effect to the listed species or critical habitat not considered in this opinion; or (4) a new species is listed or critical habitat designated that may be affected by the action. In instances where the amount or extent of incidental take is exceeded, any operation causing such take must cease pending reinitiation.

As stated in the Conclusion (above), the Service's finding of non-jeopardy is based in large part on the conservation measures. Should there be a failure to carry out any or all of the described measures, or if the measures are not effective, or if these measures are modified in any way without Service coordination, reinitiation of consultation will be required. If you have any questions regarding this Biological Opinion, please contact Rachel Rounds at (808) 792-9400.

Sincerely,

for Loyal Mehrhoff
Field Supervisor

Appendix 1. Not Likely to Adversely Affect Determination for the Mariana Common Moorhen, Mariana Swiftlet, and Green Sea Turtle

This Appendix is in response to your request for our concurrence with your determination that the Divert Project, as described above, will not adversely affect the endangered Mariana common moorhen, Mariana swiftlet, or green sea turtle. The findings and recommendations in this consultation are based on: (1) your Biological Assessment dated August, 2012; and (2) other information available to us. A complete administrative record is on file in our office. This response is in accordance with section 7 of the Endangered Species Act of 1973 (Act), as amended (16 U.S.C. 1531 *et seq.*).

Mariana common moorhen

Listing Status

The Mariana common moorhen was federally listed as an endangered species in 1984 (USFWS 1984). The recovery plan for the Mariana common moorhen was finalized in 1991 (USFWS 1991a, 55 pp.). A five-year status review completed in 2009 determined that the Mariana common moorhen still meets the definition of endangered (USFWS 2009, p. 9).

Historic and Current Distribution

The Mariana common moorhen is currently found on Saipan, Tinian, Rota, and Guam. The Mariana common moorhen is believed to be extirpated from Pagan due to the volcanic eruption in May, 1981, and destruction of vegetation by feral ungulates (Stinson et al. 1991, pp. 41–42). In 2004, it was estimated that there were approximately 90 Mariana common moorhen on Guam, 154 on Saipan, 41 on Tinian, and only two individuals on Rota (Takano and Haig 2004, p. 247 (Table 9)). On Guam, the number of Mariana common moorhens has recently decreased at the Fena Valley Reservoir potentially due to the loss of *Hydrilla verticillata,* a wetland plant used as a nesting substrate, as a result of eutrophication of the lake after a typhoon (Brooke and Grimm 2008, p. 2). While it is possible that the Fena Reservoir birds moved to other wetlands and the Guam population has not declined overall, comprehensive surveys on Guam would be needed to determine the impact of the loss of habitat at Fena Lake to the overall population. Moorhen surveys are conducted by the CNMI Division of Fish and Wildlife at 22 wetland sites on Saipan. Data from these surveys shows that population numbers were stable on Saipan from 2007-2010 (CNMI DFW 2010).

Ecology and Life History

The Mariana common moorhen prefers wetlands with diverse, non-persistent, emergent vegetation containing deep and shallow water areas with equal areas of vegetation cover and open water (Ritter and Savidge 1999, p. 286; Stinson et al. 1991, p. 39). Primary habitats (as defined in the recovery plan) include: Agana marsh, Fena Valley reservoir, and the Naval Station Marsh, Guam; Lake Hagoi on Tinian; and Lake Susupe, Puntan Muchot, and Garapan wetlands on Saipan (USFWS 1991a, pp. 4–16). Several secondary wetland habitats were identified on Guam and Saipan; only one secondary wetland (Magpo) on Tinian was considered important for the recovery of the species (USFWS 1991a, pp. 4–16).

Mariana common moorhens feed on plant and animal matter in or near wetlands (USFWS 1991a). Seale (1901, p. 31) found grass, insects, and larvae in the stomachs of the Mariana

common moorhen on Guam. Pratt et al. (1987, p. 128) reported that Mariana common moorhen eat mollusks and plants. Little is known about the reproduction of the Mariana common moorhen (USFWS 1991a, p. 17). Nests have been constructed in *Scirpus litoralis*, *Panicum muticum*, and *Cyperus* spp. (Ritter 1994, p. 128; USFWS 1996, p. 7). Birds often nest multiple times in a year and juveniles from early broods are known to stay on their natal territory and help rear siblings from later broods (Ritter 1994, p. 130; Takano 2003, pp. 4–5).

Threats

Currently, the main two threats to the Mariana common moorhen are: (1) loss and degradation of wetland habitat, including filling, alteration of hydrology, invasion of habitat by non-native plants, and unrestricted grazing of domestic and feral ungulates; and 2) predation by introduced species (USFWS 1991a, p. 19; USFWS 1996, pp. 11–12).

Conservation Needs

Only interim recovery objectives were identified in the recovery plan due to a lack of data necessary to fully understand the needs of viable populations of this species (USFWS 1991a, p. 21). The primary task is to promote the survival of the species by providing stable, productive habitat throughout the historical Mariana common moorhen range. This entails 1) securing and managing all primary habitats to maximize the habitat conditions; 2) maintaining the secondary habitats as wetlands or creating new wetlands for those that are lost; and 3) minimizing mortality from predation, poaching, and other factors including human disturbance.

Environmental baseline

In 2001, an island-wide survey produced an estimate of 154 Mariana moorhens on Saipan (Takano and Haag 2004, p. 245). The CNMI Division of Fish and Wildlife conducts quarterly surveys at 22 wetlands on Saipan. From 2007 to 2010 the total number of moorhens detected at these sites has remained stable between 70 to 80 moorhens per survey (CNMI DFW 2010, p. 44).

Surveys conducted from January to March of 2012 by USAF contractors detected a single adult Mariana common moorhen at the Coral Ocean Point golf course east pond. No moorhens were detected at the GSN water catchment basin or the Coral Ocean Point golf course west pond, and no other potential moorhen habitat is located within the action area. The Coral Ocean Point golf course east pond has an impervious lining that inhibits the growth of shoreline vegetation. The moorhen was observed roosting and taking cover under a *Bougainvillea spectabilis* plant along the northeastern shoreline. Mariana common moorhens have also been detected repeatedly at the Coral Ocean Point golf course east pond by the CNMI DFW during quarterly waterbird surveys. Due to the lack of vegetation around the golf course pond, suitable habitat for Mariana common moorhen breeding is not present, and Mariana common moorhen have not been observed nesting at either golf course pond. There are no moorhens located near the Saipan port facilities or the Saipan Upland Mitigation Bank.

Not Likely to Adversely Affect: Mariana common moorhen

The Coral Ocean Point golf course east pond is located approximately 650 meters from the southern edge of GSN and from the nearest potential construction site. Noise from construction of Divert facilities is unlikely to disturb Mariana common moorhens at the east pond because moorhens at this pond would be habituated to noise disturbance from the airport, golf course

operations, and a nearby helicopter launching pad. Mariana moorhens are not found close enough to airport runways to be at risk of a bird strike.

However, increased aircraft operations at GSN under Divert operations will cause an increase in ambient noise at the east pond. Operation of civilian 767 at GSN result in a noise level of approximately 93 dBA from at the east pond (Table 1) from take-offs and landings. Under implementation of the Divert Project, noise levels at the east pond will rise to approximately 118 dBA with take-off and landings of F-22 or similar fighter jets.

There have been numerous studies on the impacts of aircraft overflights to wildlife including studies of waterbirds (e.g., Ward, et al. 1999; Conomy, et al. 1998 a,b; Komenda-Zehnder, et al. 2003). These studies report a wide range of reactions to overflights depending on the biology of the species, its previous exposure to overflights, whether the species is breeding, the type of aircraft, the altitude of the aircraft, and the lateral distance between aircraft and the species. The variability in these reactions and their specific circumstances make it difficult to be certain how a particular species, such as the Mariana moorhen, will react to aircraft overflights.

Individuals with previous exposure to aircraft overflights may display less reaction to overflights than individuals without previous exposure (Andersen et al. 1989, Conomy et al. 1998b). This reduced reaction is believed to be a sign that these individuals have habituated to these overflights. This habituation, however, may be individual or species specific. For example, Conomy and others (1998b) found that black ducks (*Anas rubripes*) became habituated to aircraft noise with continued exposure while wood ducks (*Aix sponsa*) did not.

Given that Mariana common moorhens have been using the east pond for at least a decade, it can be assumed that these individuals have habituated to the current level of aircraft overflights. There is no moorhen habitat near Andersen Air Force Base on Guam to use as a comparison airport with high aircraft overflights. Moorhens on Saipan have also been found in other highly disturbed and noisy locations, including the flooded parking lot of an abandoned garment factory at a busy intersection on Saipan (Rounds 2012, pers com). On Guam, Mariana common moorhens nest in a pond immediately adjacent to a busy parking lot at an industrial fuel facility (Rounds 2012, pers com.). Use of these sites indicates that moorhens can tolerate high levels of human disturbance.

There will be a long-term and permanent increase in aircraft operations from the proposed Divert Project, and noise levels from aircraft overflights will increase with F-22 and other figher jets operating out of GSN. Moorhens do not breed at the east pond so disturbance of nesting birds will not occur. Moorhens using the east pond may notice the increase in noise levels from aircraft overflights. However, given their tolerance of human disturbance and habituation to current noise levels, we do not believe this disturbance will rise to the level of harass or harm as defined by the ESA. Therefore, we have determined it is discountable that a Mariana common moorhen would be adversely affected by increased aircraft overflights at GSN given that moorhens are not breeding at the site, appear tolerant of some levels of human disturbance, and are habituated to the current noise levels from GSN.

Because comprehensive biosecurity measures, including HACCP planning and redundant brown treesnake inspections, will be implemented by the USAF to keep brown treesnakes, and other invasive species, off of Saipan, we do not expect adverse effects to Mariana moorhens from introduction of invasive species.

Mariana swiftlet

Listing Status

The Mariana swiftlet was federally listed as endangered on August 27, 1984 (USFWS 1984). A five-year status review was completed in 2010 (USFWS 2010) and a recovery plan for the Mariana swiftlet was completed in 1991 (USFWS 1991b).

Historic and Current Distribution

The Mariana swiftlet is endemic to Guam and the four southern islands of the CNMI (Cruz et al. 2008, p. 233). A population also became established on Oahu, Hawaii, between 1962 and 1965 (Wiles and Woodside 1999, p. 57). Most historical information on the species comes from Guam, where it was reported as being common and the third most abundant species seen during roadside counts, but declined to approximately its current levels by the late 1970s (USFWS 1991b, p. 7). The total number of Mariana swiftlets occurring within its historical range is currently over 6,000 individuals and it currently occurs on Guam (in three known caves within the Naval Munitions Site), Aguiguan (in nine known caves), and Saipan (ten known caves), and is considered extirpated from Tinian and Rota (CNMI DFW 2010, pp. 45-46; Navy 2011, p. 4; USFWS 1991b, pp. 8, 13–14; Engbring et al. 1986, pp. 58–59). Long-term data from swiftlet surveys at 10 caves on Saipan shows that swiftlet numbers have been steadily increasing, to a total count of over 5,500 individuals in 2010 (CNMI DFW 2010).

Ecology and Life History

The Mariana swiftlet nests and roosts in limestone caves with the following characteristics: entrances typically a minimum of 2 m (6.2 ft) high; chambers with dark zones; and fresh air (USFWS 1991b, p. 2). Most birds leave their cave at dawn and return at sunset, but often return from foraging to roost in caves during the day. Swiftlets navigate through the darkest portions of caves using echolocation (Vogt and Williams 2004).

Mariana swiftlets capture prey while flying, and foraging has been observed to occur over a wide variety of habitat types, including cleared and forested areas, but they appear to favor ridge crests and open grassy savanna areas (USFWS 1991b, p. 6). Large flocks have been reported to form in the evening with birds congregating and feeding close to the ground until it is dark (Chantler and Driessens 1995, p. 130). An analysis of swiftlet guano collected from occupied caves on Saipan found that the remains of flying ants (*Formicidae*) were common, as were the remains of beetles (*Coleoptera*) (Kershner et al. 2007).

Eggs are laid in cup-shaped nests made of moss and saliva attached to cave walls or ceilings. A single egg is laid, usually between January and July, which is incubated for approximately 23 days with fledging occurring after 47 days (Reichel et al. 2007). Both adults care for the nestling which is, on average, fed by each adult 1.8 times a day (Morton and Amidon 1996).

Threats to the Mariana Swiftlet

The restricted distribution of Mariana swiftlets, along with its small population size and dependence on caves, makes the species vulnerable to threats. The causes for the decline of Mariana swiftlets are mostly unknown, but human disturbance, predation, pesticides, and disease have all been hypothesized as having a role. Swiftlets have been documented to flush or fail to enter their caves when humans are near or within their caves (Wiles and Woodside 1999, pp. 57, 61). Swiftlet sensitivity to human presence has resulted in injuries to chicks and adults and could result in damage to eggs (Wiles and Woodside 1999, p. 61). Sources of human disturbance have included Japanese soldiers during World War II, guano mining, hunters, hikers, and vandalism.

While the introduction of brown treesnake is known to have caused the extirpation of many bird species in Guam and CNMI, it is not known whether it has significantly affected swiftlets. Brown treesnake predation on Mariana swiftlets is considered to be a regular event and only those birds able to find nest or roost sites on high, smooth walls and ceilings are able to avoid snake predation. In August, 2011, seven brown treesnakes were observed climbing the walls of the Mahlec cave on Guam (Mosher 2011, pers. com.). The use of pesticides such as DDT has been suspected of causing the decline of swiftlet populations on Guam (Diamond 1984, p. 452), but the concentrations of pesticide residues found in swiftlet guano have not supported this hypothesis (Grue 1985, p. 301). On Saipan, non-native cockroaches are known to destroy swiftlet nests by consuming the saliva that holds the nests to the walls or ceilings (Cruz et al. 2008, p. 242). Savidge (1986, p. 9) investigated the role of disease in the decline of birds on Guam and found that there is no evidence that it has played a significant role. The typhoons that frequently occur in the area may cause periodic declines in swiftlet populations, but are not expected to threaten the species as a whole since the species has survived numerous such events during its evolutionary history (USFWS 1991b, p. 22).

Conservation Needs

The primary threats to the species continue to be predation by the brown treesnake and disturbance at nesting caves. However, other introduced predators and introduced insect species also may have negative impacts to the species. Efforts to minimize disturbance and control snakes and other predators at some nesting colonies have been undertaken. However, additional efforts are needed to help recover the species.

Ongoing Conservation Actions

Brown treesnake trapping occurs at the three occupied swiftlet caves on Guam on the Naval Munitions Site. No predator trapping currently occurs at caves on Saipan or Aguiguan. Quarterly swiftlet departure counts are conducted on Saipan and Guam to monitor swiftlet population numbers.

Environmental Baseline

Swiftlets have been detected foraging over most areas of Saipan, though they are less frequently detected in urban areas (Marshall 2011, pers. comm.). Ten caves are known in Saipan, in the central portion of the island; however, swiftlets are regularly seen foraging in areas where no caves have been found. The nearest swiftlet cave to GSN is more than three kilometers (2 miles) away and the nearest cave to the Saipan port is approximately 1,200 meters away (0.75 mile). There are no known caves in the Saipan Upland Mitigation Bank, though swiftlets frequently

forage there. No Mariana swiftlets were detected during bird surveys at GSN for the proposed project. Island-wide surveys conducted by the Service and CNMI DFW on established transects on Saipan detected swiftlets primarily in the central parts of the island, but swiftlets were also detected in the vicinity of GSN (USFWS 2008).

Not Likely to Adversely Affect: Mariana swiftlet

There are no Mariana swiftlet caves near the Saipan airport or seaport, and no adverse impacts to swiftlet caves from the Divert project are expected. Mariana swiftlets are not detected frequently in the vicinity of GSN. If construction noise or noise from aircraft overflights disturbs swiftlets, they will easily be able to avoid the disturbance and forage elsewhere. The clearing of 4.5 ha of second-growth forest for the Divert Project would also not adversely affect the availability of foraging habitat in the area, or on Saipan. There have been no reports of aircraft striking Mariana swiftlets and the chance of such a strike is discountable given the distance from Mariana swiftlet caves and low presence of swiftlets in the area. Mariana swiftlets may forage near the Saipan seaport; however, this is an industrial port and the low-level of construction noise from the Divert Project in this area is unlikely to adversely affect a Mariana swiftlet. Mariana swiftlets commonly forage in the Saipan Upland Mitigation Bank. Mitigation actions, such as habitat restoration and invasive species removal, for the nightingale reed-warbler that occur in the SUMB will also beneficially affect the Mariana swiftlet. Overall, effects from the proposed project are discountable. Therefore, the project may affect, but will not adversely affect, the Mariana swiftlet, and mitigation actions may benefit the species.

Because comprehensive biosecurity measures, including HACCP planning and redundant brown treesnake inspections, will be implemented by the USAF to keep brown treesnakes, and other invasive species, off of Saipan, we do not expect adverse effects to Mariana swiftlets from introduction of invasive species.

Green sea turtle

The following section summarizes sea turtle biology based on the information in recovery plans and five-year status reviews developed by the NMFS and Service (NMFS and USFWS 1998, 95 pp.; 2007, 105 pp.). Sea turtles are highly migratory, globally distributed, and generally found in tropical and subtropical waters along continental coasts and islands between 30° north and 30° south latitude and, to a lesser extent, in subtropical waters with temperatures above 20° C. The geographic range of sea turtles includes the Caribbean Sea, Atlantic, Pacific, and Indian Oceans and associated bodies of water.

Sea turtles bury their eggs in the sand in upper areas of oceanic beaches. Reproductive maturity occurs at ages ranging from 20 to 50 years and varies by species. Female sea turtles have high site fidelity to their hatching (natal) beaches, returning close to their own hatching site to lay their nests. Females may nest multiple times over a given nesting season. Nesting seasons typically occur at semi-regular intervals, with inter-nesting intervals ranging between two to more than five years depending on the species. Hatchlings emerge 45 to 90 days after a nest is laid. Emerging hatchlings navigate toward the water using visual cues; they move toward the brighter horizon and away from darker silhouettes formed by dune line, tree lines, or cliff walls (Tuxbury and Salmon 2005, p. 312). In addition to nesting, green sea turtles may also use

beaches to haul out and bask, although this behavior has never been documented in Guam or the CNMI (Kelly, 2009, pers. comm.; Wusstig 2009, pers. comm.).

Numbers of breeding green sea turtle populations in Hawaii, Australia, and Japan are increasing (Chaloupka et al. 2008, p. 299; NMFS and Service 2007, p. 13) and numbers of turtles nesting on Guam have been stable (NMFS and Service 2007, p. 13). Approximately 1,000 to 2,000 green turtles inhabit island reef areas in Guam and the southern CNMI (Kolinski et al. 2004, pp. 98, 111). In 1995 and 2001 (Tinian), 1999 (Saipan), and 2003 (Rota), the majority of individuals observed in the surrounding waters were juveniles or sub adults (Kolinski et al. 2001, pp. 59, 66; Kolinski et al. 2004, p. 107; Kolinski et al. 2006, pp. 514, 517; Pultz et al. 1999, p. 92).

In CNMI, green turtle nesting occurs from March to August with some year round nesting documented. The CNMI DFW Sea Turtle Program has monitored green sea turtle nesting activity on Saipan since 1999, and has documented 4 to 18 nests laid per year (CNMI DFW unpublished annual reports). There are two nesting beaches found within the action area: Obyan beach and Coral Ocean Point beach.

Not Likely to Adversely Affect: Green sea turtle

No green sea turtle nesting beaches will be impacted by construction of Divert facilities. Hatchlings or nesting adult females may be exposed to noise from aircraft overflights on Obyan or Coral Ocean Point beaches. Obyan beach is located approximately 1,000 meters from GSN and in the worst-case scenario would have noise levels from aircraft overflights reaching 65-70 dBA. Coral Ocean Point beach is located approximately 900 meters from GSN, and noise levels from aircraft overflights could reach 70-85 dBA in a worst-case scenario. Noise contour lines under baseline conditions do not reach either beach, indicating that current noise levels are below 65 dBA.

Given the small number of green sea turtles nesting on Saipan, and the short period of time that hatchlings or adult female green sea turtles spend on beaches, there is only a small chance that aircraft overflights, which would occur for a maximum of 8 weeks a year, reaching 85 dBA (at Coral Ocean Point) would occur at the same time a hatchling turtle or adult turtle were on the beach. Based on observations of adult green sea turtles at Obyan beach and their reactions to aircraft overflights, it is not expected that the turtles would be adversely affected by a temporary increase in noise (Summers 2012, pers. com.). Therefore, the Divert Project may affect, but will not adversely affect, green sea turtles.

Subject: Amendment to the Biological Opinion for Development of Divert Capabilities and Conducting Divert Activities and Exercises, Saipan and Tinian, Commonwealth of the Northern Mariana Islands (01EPIF00-2012-F-0445)

Dear Mr. Grannis:

This letter acknowledges the U.S. Fish and Wildlife Service's (Service) receipt of your July 8, 2015, letter requesting our concurrence with your determination that extending aircraft Divert capabilities and conducting Divert activities and exercises on Tinian, Commonwealth of the Northern Mariana Islands (CNMI), is not likely to adversely affect the threatened green turtle (*Chelonia mydas*) and the endangered hawksbill sea turtle (*Eretmochelys imbricata*) pursuant to section 7 of the Endangered Species Act (ESA) of 1973, as amended (16 U.S.C. 1531 et seq.). You met with us on August 21, 2015 and you provided us with additional information about the project via email on September 14, 2015, by phone on September 22, 2015, and via email on October 6, 2015. On June 27, 2013, we completed a Biological Opinion addressing Divert activities at Saipan International Airport (Divert Biological Opinion; 01EPIF00-2012-F-0445) to satisfy operational requirements for humanitarian assistance, disaster response, and joint exercises in the Pacific in the event that airfield access at Andersen Air Force Base or other western Pacific airfields is limited. The revised proposed action modifies the Divert project to move some or all Divert capabilities and activities to Tinian International Airport.

The Divert Biological Opinion addressed potential adverse project effects to the endangered nightingale reed-warbler (*Acrocephalus luscinia*) and we concurred with the Department of the Air Force's determination the proposed actions on Saipan were not likely to adversely affect the endangered Mariana common moorhen (*Gallinula chloropus guami*), Mariana swiftlet (*Aerodramus bartschi*), and the green turtle. Your September 14, 2015, email, attached herein as Appendix 1, details modifications to the Divert project on Saipan. The extent of Divert construction at Saipan International Airport and Seaport has been reduced and fighter aircraft have been removed from the proposed action on Saipan. Construction disturbance on Saipan has been reduced from the 59 acres addressed in the Divert Biological Opinion to 31 acres. Fewer than 6.6 acres of tangantangan, habitat for the nightingale reed-warbler, will be cleared, down

COPY

from the 11 acres addressed in the Divert Biological Opinion. The Divert Biological Opinion addressed the loss, fragmentation, and degradation of one occupied nightingale reed-warbler territory due to construction of the east parking ramp and the purchase of one credit in the Saipan Upland Mitigation Bank to compensate for the loss of that breeding territory. The Divert Biological Opinion also addressed the habitat loss and degradation of 17 occupied nightingale reed-warbler breeding territories due to fighter aircraft noise disturbance and compensatory mitigation in the form of purchase of 17 credits in the Saipan Upland Mitigation Bank. Because the updated action does not entail construction of the east parking ramp or loss or degradation of any other habitat occupied by the nightingale reed-warbler from the fighter aircraft, the action no longer entails purchase of credits in the Saipan Upland Mitigation Bank.

All other components of the proposed action on Saipan, as detailed in Appendix 1, remain the same as described in the Divert Biological Opinion. Accordingly, these modifications to Divert actions on Sapian do not warrant reinitiation of formal consultation because the effects of the remaining, reduced, actions were addressed in the Divert Biological Opinion. The remaining proposed Divert actions on Saipan will be conducted in conformance with the Divert Biological Opinion, and the effects of those actions will be consistent with the analysis in that Biological Opinion. The Incidental Take Statement, Reasonable and Prudent Measures, Terms and Conditions, and Conservation Recommendations in the Divert Biological Opinion remain in effect. We are providing this Amendment to the Divert Biological Opinion to document these modifications to proposed Divert actions on Saipan and to address effects of new proposed Divert actions on Tinian.

REVISED PROJECT DESCRIPTION - TINIAN

Construction Activities on Tinian

The Divert project will entail development of infrastructure to support up to 12 KC-135 or similar large-bodied aircraft, or a mix of these large aircraft and up to 24 smaller fighter or tactical aircraft, at Tinian International Airport. Figure 1 details the proposed construction of runway, cargo, parking, fueling, and maintenance facilities within and adjacent to existing facilities at Tinian International Airport. No wetlands or limestone forest are within or adjacent to the proposed construction areas. To minimize potential impacts to turtle nesting beaches, Department of Defense policies, will be followed to minimize erosion and sedimentation during construction and to manage storm water runoff after construction.

Page 1 of "Assessment of Potential Effects to Threatened, Endangered, and Proposed Species from Developing Divert Capabilities and Conducting Activities and Exercises on Tinian" (Assessment) indicates a fuel pipeline from the Tinian Seaport to the airport may be constructed. On September 22, 2015, you confirmed this fuel pipeline had been removed from the Divert project.

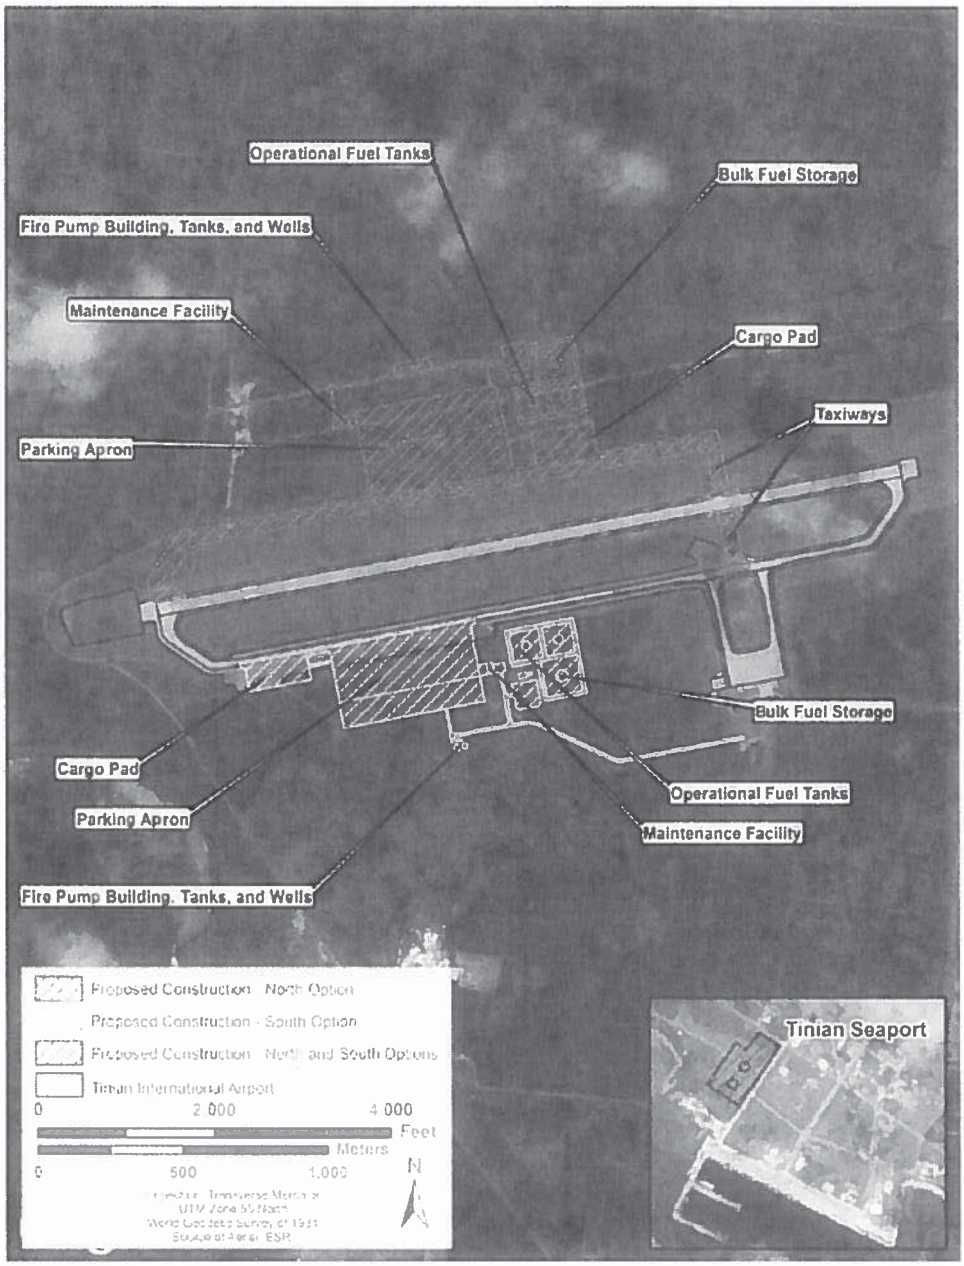

Figure 1. Construction footprint at Tinian Airport.

Divert Operations on Tinian

Divert aircraft training and operations will occur at Tinian Airfield when other locations in the western Pacific, such as Andersen AFB, are unavailable, due to emergencies such as natural disasters and for other operational reasons for a period of up to eight weeks per year. In limited instances such as disasters and humanitarian responses, operations may extend beyond the eight week per year time period. A mix of cargo, tanker, fighter, and other aircraft could be diverted to the Tinian airfield. Activities will include aircraft take-offs, staging, and landings, jet fueling and storage, humanitarian assistance including disaster relief airlift staging including non-combatant evacuation operations and billeting. Personnel and members of the public

accompanying the aircraft on Tinian could number up to 265 during Divert training and operations. These people will be billeted in existing hotel and other accommodations.

Biosecurity Measures to be Implemented During Divert Construction and Operations on Tinian

Invasive Species Interdiction and Control

The U.S. Air Force (USAF) will be responsible for oversight of avoidance, minimization, and mitigation implementation by the construction contractors for projects associated with the proposed Divert activities. In addition, the USAF will be responsible for oversight of training, review, and guidance on Hazard Analysis and Critical Control Point (HACCP) plan development, implementation and revision during the construction phase of the project. The HACCP plans will incorporate measures to ensure invasive species, including the brown treesnake, are not transported to the CNMI from Guam via project vehicles, materials and equipment. The USAF will be responsible for assuring that any HACCP plans are implemented by construction contractors to prevent the inadvertent movement of non-native, invasive species from other locations to the project site. The USAF will coordinate development of HACCP plans with the Service, including, but not limited to, annual meetings and reports to ensure the actions to eliminate or reduce risk are sufficient and on-going during construction activities.

Brown Treesnake Interdiction and Control

1. Per Public Law I 10-417, [Division A], title Ill, Section 316, October 14, 2008, 122 Statute 4356 and per DoD Defense Transportation Regulations, Chapter 505 protocols, the USAF, with support from Joint Region Marianas (JRM), commits to implementing 100 percent inspection of all outgoing cargo and aircraft that are leaving from Guam associated with the Divert project. Inspections will be performed with trained quarantine officers and dog detection teams, which could be supplemented by other pest control expertise (with appropriate U.S. Department of Agriculture-Wildlife Services (USDA-WS) brown treesnake detection training and oversight) to meet 100 percent inspection goals for training activities, as required COMNAVMARIANASINST 5090.10A and 36 Wing Instruction 32-7004. As a stakeholder, the Service will have input on the USAF protocols for implementing brown treesnake interdiction and control strategies. The USAF will work cooperatively with JRM, the Service, and USDA-WS to seek information in development of protocols for implementation of interdiction and control methods aimed at controlling brown treesnake as related to Divert training activities. On an as needed basis, the Service, USDA-WS, and USAF may request meetings to discuss interdiction and control method protocols as related to Divert military exercises.

    a. In the event military units, vehicles, and equipment accidentally leave Guam without inspection, as soon as possible, the USAF will notify: (1) USDA-WS and (2) the point of destination port or airport authorities and work with the destination port to resolve the issue. Urgency of notification is a priority so that rapid response or other actions can be implemented to reduce risk.

    b. In addition, the USAF will route inbound personnel and cargo for tactical approach exercises or humanitarian operations (that require an uninterrupted flow of events) directly to CNMI training locations to avoid Guam seaports and airfields. If Guam cannot

be avoided, the USAF, in cooperation with USDA-WS and the Service, shall identify, and USAF will implement appropriate interdiction methods that may include redundant inspections or other interdiction methods as agreed to by the Service, USDA-WS, USAF and JRM. Additionally, tactical approach exercises will involve only cargo equipment that has not originated from areas containing a brown treesnake population or will be 100 percent inspected by certified brown treesnake canine programs. If the USDA-WS develops performance standards for this activity, the USAF will adopt those standards, provided they are compatible with military mission.

c. The USAF is committed to implementing 100% redundant inspections after discussions with appropriate stakeholders. Redundant inspections include inspections on Guam and at the receiving jurisdiction for administrative and logistical movements that do not require a tactical approach to complete the training requirements. It is anticipated that redundant inspections to the extent possible would utilize existing quarantine and inspection protocols at receiving ports, but in the event that there is inadequate inspection coverage the USAF will coordinate with the USDA-WS to provide additional canine inspection teams that will augment quarantine and inspection protocols at the receiving ports. Appropriate stakeholders include, but are not limited to: the Service to ensure the inspections are adequate to reduce risks to trust resources, USDA-WS, receiving jurisdictions and their supporting agencies with expertise in invasive species control, and other inspection authorities as needed to ensure inspection methods are current and revised as new techniques, technology, or data become available.

2. The USAF will also establish snake-free quarantine areas (barriers) for cargo traveling from Guam to CNMI and other brown treesnake-free areas. These barriers will be subject to: (1) multiple day and night searches with appropriately trained interdiction canine teams that meet performance standards under 1b; (2) snake trapping; and (3) visual inspection for snakes. In lieu of permanent barriers, temporary barriers may be preferable to permanent exclosures because of the variable sizes needed to handle different cargo amounts for the various training activities. The USAF will produce standard operating procedures for temporary barrier construction and use within two years of the issuance of this Biological Opinion. Standard operating procedures will ensure that temporary barriers will be constructed and maintained in a manner that assures the efficacy of the barrier and that staff maintaining and constructing the temporary barriers will receive training related to this activity prior to construction. The construction and maintenance of temporary barriers utilized for cargo traveling from Guam to CNMI and other brown treesnake-free areas must be approved by the Service prior to use. During the construction phase of this project, the existing permanent snake-free quarantine areas at both the Saipan and Tinian seaports should be utilized for surface cargo following relevant CNM I and DoD regulations. Standard operating procedures will be developed in cooperation with the Service, U.S. Geological Survey, Fort Collins Science Center, Invasive Species Science Branch, and the USDA-WS to ensure risk to trust resources is adequately minimized. If risks are not adequately minimized, additional recommendations will be provided for incorporation into the protocols until the USAF and Service mutually agree the risk has been minimized. The Service, USAF, and other appropriate parties will meet, if necessary, to resolve concerns such that the protocols ensure risk is adequately minimized.

3. The USAF, in conjunction with the Service and JRM, will develop procedures and protocols

specific to Divert training events that will support a rapid response action in the event of a brown treesnake sighting resulting from Divert activities. Divert activities and exercises will be varied in the number of aircraft and personnel, and each event will have differing logistics support capabilities depending on the nature of the event. The type and amount of logistic support will be agreed to prior to each major event. Logistic support will include consideration of both in-kind assistance through air transport, shared billeting, security detail, food, materials, and ground transportation, and financial compensation for agreed-to response actions that could not be supported by in-kind assistance, including compensation for performance of services to support the deployment and execution of rapid response search teams.

4. The USAF, working in collaboration with the Service, and USDA-WS, will decide how best to implement the Brown Treesnake Control Plan (BTS TWG 2009, 37 pp.) relevant to Divert activities. The USAF and Service must mutually agree on the Brown Treesnake Control Plan implementation.

5. The USAF will provide invasive species awareness training for all military and contractor personnel prior to all training activities. This would include a mandatory viewing of a brown treesnake educational video, distribution of pocket guides with brown treesnake information and personal inspection guidelines to be carried at all times, and assurance that brown treesnake awareness extends from the chain of command to the individual military service member.

6. Due to limited availability of inspectors, trained dogs, and quarantine facilities and equipment on Guam and the CNMI, the USAF will coordinate closely with the Service, U.S. Department of Agriculture, CNMI Department of Lands and Natural Resources, and JRM staff responsible for managing their brown treesnake program, on planning for training activities on Tinian. The USAF, along with cooperating agencies, will identify the inspection and interdiction requirements for the Divert training, including the number of trained quarantine officers and dog detection teams required. The USAF will coordinate and consult with the Service on the inspection and interdiction requirements identified by the USAF, and the Service must concur with these requirements prior to the implementation of the exercise or training activity. The USAF, along with the cooperating agencies, will develop plans to ensure that inspection personnel are available and that all requirements can be met, and will identify the support that the USAF will need to provide for the inspections. Planning for training exercises generally begins months prior to implementation of an exercise, and planning for complex training that would require a substantial number of inspectors, quarantine areas, or other personnel or equipment for control and interdiction generally begins more than a year in advance. If adequate resources, such as trained inspectors and dog teams, are not available during training activities, training will not occur until resources are available.

Prevention of Invasive Species Introductions and Spread

1. All personnel involved in Divert training will adhere to COMNAVMARIANASINST 5090.10A and the 2005 Brown Treesnake Control and Interdiction Plan, which calls for individual troops to conduct self-inspections to avoid potential transport of brown treesnakes. Troops will inspect all personal gear and clothing (e.g., boots, bags, weapons, pants), hand-carried equipment, and supplies and tent canvas. The intent of this measure is to minimize the potential risks and subsequent effects associated with transport of troops and personnel from Guam to the CNMI and other areas that do not have brown treesnakes.

2. In addition to self-inspections, each training action will undergo a pathway risk analysis as a tool to improve programmatic efficiency while preventing the spread and introduction of invasive species. Actions at risk of transporting invasive species will have prevention tasks identified and implemented to reduce risk. Methods employed such as HACCP planning development and implementation by the USAF may be utilized to conduct pathway analysis. Pathway risk analysis must be completed prior to each training action being implemented.

The USAF is a participating agency in the development of the Micronesia Biosecurity Plan. The Micronesia Biosecurity Plan is intended to coordinate and integrate inter-agency invasive species management efforts such as control, interdiction, eradication, and research. Once completed, any portions of the Micronesia Biosecurity Plan determined to be applicable to Divert construction and training activities, will be implemented when such procedures do not unduly interfere with military training. The USAF will continue to work cooperatively with the Service and U.S. Department of Agriculture in development of protocols for implementation of interdiction and control methods in accordance with recommendations contained in the Micronesia Biosecurity Plan identified as being tied to USAF actions.

ANALYSIS OF EFFECTS OF THE ACTION

Your letter indicates you have determined the proposed actions on Tinian will have no effect to the endangered Mariana fruit bat (*Pteropus mariannus mariannus*), Mariana common moorhen (*Gallinula chloropus guami*), Micronesian megapode (*Megapodius laperouse*), and the proposed species *Heritiera longipetiolata*, *Dendrobium guamense*, and humped tree snail (*Partula gibba*) (these species were listed under the Act on October 1, 2015; 80 FR 59423). The Tinian monarch (*Monarcha takatsukasae*) was delisted in 2004 (69 FR 56367).

To conclude a proposed action is not likely to adversely affect listed species, the Service must find that the effects of the proposed action are expected to be insignificant, discountable, or beneficial. Insignificant effects relate to the size of the impact and should never reach the scale where take occurs, discountable effects are those that are extremely unlikely to occur, and beneficial effects are positive effects without any adverse effects. We applied this standard, as well as consideration of the probable duration, frequency, and severity of potential project stressors in our analysis of effects of the proposed action on the green turtle and hawksbill sea turtle.

Green and hawksbill turtles forage offshore of Tinian (Pultz et al. 1999; Kolinski et al. 2001; Maison et al. 2010) and a small population of green sea turtles nests on most beaches on Tinian (Pultz et al. 1999, NAVFAC 2014). One hawksbill sea turtle nest was found on the northeastern

shore of Tinian (more than two miles from Tinian International Airport) during monthly surveys of beaches conducted 1999 through 2012 (NAVFAC 2015, Table 3.9-3), and nesting by this species on Tinian is uncommon (Pultz et al. 1999; NAVFAC 2014, 2015).

According to your letter, and confirmed by our review of available GIS Tinian imagery GIS analysis of Tinian digital imagery (cnmi_tinian_wv2_08082010_rgb_ps_8bit_lut_v1.sid) no sandy beaches suitable for green turtle or hawksbill sea turtle nesting occur within the loudest areas under the takeoff and landing flight path at Tinian International Airport because the coast is steep and rocky. The turtle nesting beaches Unai Barcinas and Unai Leprosarium (DON 2010, Section 3.8.2.2.1) are located 0.3 to 0.8 miles south to southwest of the TNI runway where they will be exposed to loud noise during takeoff and landing of aircraft (Figure 2). Ninety percent of aircraft operations will occur during the day.

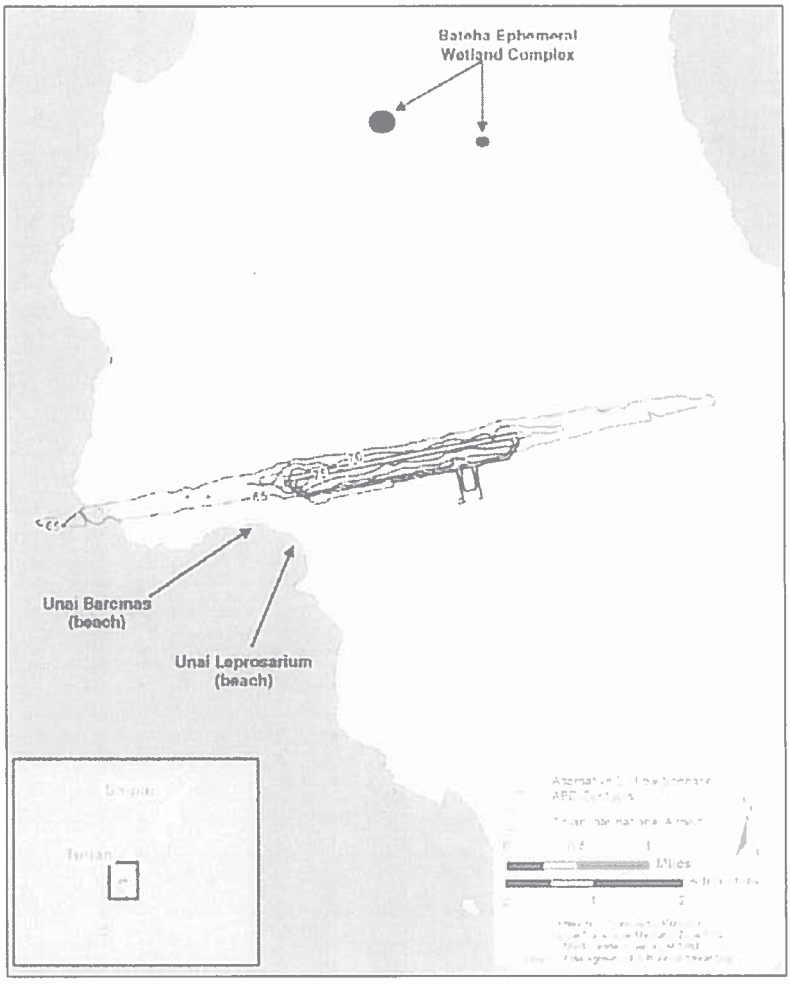

Figure 2. Noise contours (dBA day-night level) during an average busy day at Tinian International Airport for 48 KC-135 operations per day provided in your July 8, 2015, letter.

Your September 14, 2015, email indicates maximum noise levels during takeoff of the loudest aircraft associated with the proposed action could reach 79 dB at Unai Barcinas and 70 dB at Unai Leprosarium. Aircraft noise is below 200 Hz (Hodgdon et al 2007). Nesting and hatching green turtles could therefore be exposed to aircraft noise.

The sea turtle ear appears to be adapted for hearing in water, but on land sea turtle hearing is comparable to that of a person with moderate to severe hearing loss (Ridgway et al 1969, Lenhardt 1994, and Magyar 2009, Lin et al 2011). Findings by Mabyar (2009) indicate that although hatchlings in water are very responsive to noise, displaying agitated behavior, abrupt body movements, and startle responses, on land, airborne experimental and beachside nightclub noise did not elicit a measureable response or affect nestling direction of movement from the nest to the ocean. The shell and bones may conduct noise through the turtle's body to its ears, which are enclosed within soft tissue in its head (Dow Piniak et. al. 2012).

Studies indicate green turtles don't hear airborne sounds unless the sound level intensities are above 50 db (at 200 Hz) and 92 dB (at 50 Hz) (Ridgway et al 1969, Lenhardt 1994, and Magyar 2009). This level of hearing is comparable to a human with moderate (at 200 Hz) to severe (at 50 Hz) hearing loss. For reference, the decibel sound pressure level scale is calibrated at zero to the limits of human hearing (U.S. DOT FHA 2006), whereas predators can hear airborne sounds in the -20 dB range. Therefore, although higher frequency portion of the anticipated 70 – 79 dB aircraft takeoff and landing airborne noise will be audible to green turtles at Unai Barcinas and Unai Leprosarium, the noise is not expected to elicit a measurable response or affect nesting behavior of turtles on these beaches. In addition, because the majority of flights will be during the day, when turtles are not expected to be on the beaches, exposure of turtles to noise related to aircraft takeoff and landing will be minimal. Therefore, effects of the proposed action to sea turtles are expected to be insignificant.

CONSERVATION RECOMMENDATIONS

We are concerned about potential project impacts to the Tinian monarch, a species delisted in 2004. This endemic bird only occurs on Tinian and the population has declined 38 percent between 1996 and 2008. Project activities may result in noise disturbance, habitat loss, and other impacts to Tinian monarchs. We recommend project impacts, including clearing vegetation suitable for Tinian monarch use, be avoided. In 2013, we received a petition requesting that the Tinian monarch be listed as threatened or endangered under the ESA. We are in the process of reviewing the petition.

CONCLUSION

Based on the description of the proposed action and on the best information available to describe the behaviors and biological needs of the species considered here, the Service concurs with your determination that the proposed action on Tinian is not likely to adversely affect the green turtle and the hawksbill sea turtle. In addition, we conclude that activities described in the revised project description for Saipan are within the scope of the project described in the Divert Biological Opinion, and therefore the effects of those actions will be consistent with the analysis in that Biological Opinion.

REINITIATION STATEMENT

Should project plans change, or if monitoring efforts by the Air Force, contractors, or the CNMI, indicate that project components are having an effect on listed species not anticipated in this

consultation, please contact us immediately so we may assist you in ensuring continued project compliance with the ESA.

This concludes section 7 consultation on this action. As required in 50 CFR § 402.16, reinitiation of consultation is required where discretionary Federal agency involvement or control over the action has been retained (or is authorized by law) and if: (1) the amount or extent of incidental take is exceeded; (2) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion; (3) the agency action is subsequently modified in a manner that causes an effect to the listed species or critical habitat not considered in this opinion; or (4) a new species is listed or critical habitat designated that may be affected by the action. In instances where the amount or extent of incidental take is exceeded, any operation causing such take must cease pending reinitiation.

If you have any questions or concerns about this consultation or the consultation process in general, please feel free to email Jacqueline Flores at jacqueline_flores@fws.gov or contact her at (671) 989-6744.

Sincerely,

David Tessler
Acting Field Supervisor

Evaluation of Requirements for Reinitiation of Formal Consultation for Planned Divert Activities and Exercises on Saipan

The U.S. Pacific Air Forces (PACAF) and U.S. Fish and Wildlife Service (USFWS) completed consultation as required by Section 7 of the Endangered Species Act (ESA) in June 2013 for planned divert activities and exercises at the Saipan International Airport (GSN). Since June 2013, PACAF has modified their plans for activities on Saipan, and has therefore considered whether consultation should be re-initiated for their planned activities. As summarized in this paper, and based on the requirements in 50 CFR 402.16, re-initiation of consultation is not required for activities now planned to occur on Saipan. This paper also identifies the conservation measures specified in the 2013 Biological Opinion (BO) that are applicable to activities currently proposed on Saipan. This analysis was based on the alternative or combination of activities currently being considered in the Revised Draft Environmental Impact Statement that would have the greatest effect on listed species (e.g., the largest facility footprints, the maximum number of flight events).

2013 Consultation – PACAF prepared a Biological Assessment (BA) and requested formal consultation in September 2012 to consider effects to the endangered nightingale reed-warblers from planned activities and exercises for the Divert proposed project on Saipan. Planned activities considered in the BA (and subsequently in the 2013 BO) included the following.

- Disturbance of up to 59 acres at GSN and 4 acres at the Port of Saipan, including the clearing of 11.0 acres of tangantangan forest at GSN.
- Training activities at GSN for up to eight weeks per year and involving:
    - Joint fighter, cargo, and tanker aircraft, not to exceed 24 fighters, or 12 cargo/tanker aircraft, or a mix of those aircraft.
    - Up to 700 personnel participating in an exercise.
    - On-site, temporary billeting of personnel during some exercises.
    - Up to about 72 takeoffs and landings of military aircraft per day during exercises, totaling up to about 1,920 per year.
- Emergency and other unplanned divert landings of military aircraft.

PACAF concluded that the proposed activities would not affect Mariana fruit bats and Micronesian megapodes, and that those activities may affect, but would not be likely to adversely affect Mariana common moorhens, Mariana swiftlets, and nesting green sea turtles. They also concluded that the project is likely to adversely affect the nightingale reed-warbler.

The BA and BO considered the following effects to nightingale reed-warblers.

- Habitat loss, fragmentation, and degradation, leading to the destruction of one nightingale reed-warbler territory from clearing of 6.4 acres of habitat for the east parking ramp.
- Indirect effects to other nightingale reed-warbler territories from increased noise during construction.
- Increased noise from aircraft overflights, possibly causing:
    - Habitat loss or degradation, harassment, increased energetic costs, abandonment of territories or other adverse modifications of behavior, nest abandonment, decreased ability to communicate, and adverse physiological effects from the operation of joint fighter aircraft. Up to 13 nightingale reed-warbler pairs could be affected.
    - No adverse effects from the operation of KC-135 and similar aircraft.
- Increased risk of the introduction and spread of non-native invasive species during construction and implementation.

Current Planned Activities at Saipan – Based on public and agency input into the Draft EIS for divert activities and exercises, the USAF removed numerous elements from their planned activities on Saipan including:

- Runway extension
- Navigational aids
- Aircraft hanger
- Temporary munitions storage
- Arm/disarm pad
- Tent billeting (lodging)
- Fighter aircraft operations.

PACAF currently is planning to implement the following activities at Saipan that could affect listed species (**Table 1**).

- Disturbance of up to 31 acres at GSN and 4 acres at the Port of Saipan, including the clearing of 6.6 acres of tangantangan forest.
- Training activities at GSN for up to eight weeks per year involving:
  - Operation of KC-135 tankers or similar aircraft, but no fighter aircraft, from GSN.
  - Up to 265 personnel participating in an exercise (but no onsite billeting/tent lodging).
  - A typical exercise of 2 to 4 KC-135 aircraft, with each aircraft taking off and landing twice per day.
  - About 720 tanker operations per year. (An operation is considered one take-off, or one landing).
- Emergency and other unplanned divert landings of military aircraft.

These activities will have the following effects on nightingale reed-warblers, which would be similar to or less than those considered during the completed consultation.

1. Loss of habitat from clearing of 6.4 acres of tangantangan forest. The east parking ramp would not be constructed and the territory there would not be directly affected.
2. Indirect effects to nightingale reed-warbler territories from increased noise during construction.
3. Noise from aircraft overflights, leading to:
   - No adverse effects from the operation of KC-135 and similar aircraft
4. Increased risk of the introduction and spread of non-native invasive species during construction and implementation.

Table 1. Comparison of Previously Planned and Currently Planned Divert Activities and Exercises on Saipan.

	2013 Planned Activities	Current Planned Activities
Total acres to be disturbed	**59**	**31**
Acres of tangantangan	**11.0**	**≤6.6**[1]
Fighter aircraft	**Yes**	**No**
Maximum number of personnel per exercise	**700**	**265**
Number of aircraft per day	**12–24**	**2–4**
Maximum of operations per day	**72**	**16**
Operations per year	**1,920**	**720**
Emergency landings	**Yes**	**Yes**

[1] Amount of acreage to be disturbed would be less under hybrid modified alternative discussed at 21 Aug 15 meeting.

Requirements for Reinitiation of Consultation – The implementing regulations for Section 7 of the ESA at 50 CFR 402.16 identify four conditions that would require reinitiation of formal consultation.

1. Exceed the amount of taking – The project has not been implemented and no take has occurred.

2. New information is available that identifies effects of the action not previously considered – No new information is available about potential effects.

3. Modification of the action that would cause an effect that was not previously considered – Planned activities will cause the same types of effects as considered in the 2013 BO, but those effects will be of a lesser magnitude.

4. A new species is listed or critical habitat is designated – Six species that could occur on Saipan have been proposed for listing since completion of consultation in 2013. The USFWS has confirmed that none of these species would occur in the tangantangan forest or disturbed/ developed areas that would be used for planned activities GSN (letter from R. Rounds, USFWS, to W. Grannis, AFCEC, 22 January 2015); thus, there will be no adverse effects to those species.

50 CFR 402.16 Reinitiation of formal consultation.

Reinitiation of formal consultation is required and shall be requested by the Federal agency or by the Service, where discretionary Federal involvement or control over the action has been retained or is authorized by law and:

(a) If the amount or extent of taking specified in the incidental take statement is exceeded:

(b) If new information reveals effects of the action that may affect listed species or critical habitat in a manner or to an extent not previously considered:

(c) If the identified action is subsequently modified in a manner that causes an effect to the listed species or critical habitat that was not considered in the biological opinion; or

(d) (d) If a new species is listed or critical habitat designated that may be affected by the identified action.

Conclusion – Based on this analysis, it is concluded that none of the four requirements in 50 CFR 402.16 are applicable; therefore, PACAF does not need to reinitiate formal consultation for planned divert activities and exercises on Saipan.

Conservation Measures – Table 2 lists the conservation measures that PACAF plans to implement to comply with the requirements of the BO if planned divert activities and exercises are conducted on Saipan. These are the same measures identified in the BO, with the following clarifications:

- No credit will be purchased from the Saipan Upland Mitigation Bank for construction of the east parking apron, as that facility will not be constructed. All other effects during construction would be similar to or less than those considered in the BO, and in accordance with that document, implementing those other construction activities do not require the purchase of a credit to compensate for direct or indirect effects to nightingale reed-warblers or their habitat.

- No credits will be purchased for the loss of nightingale reed-warbler territories caused by noise from operating fighter aircraft. PACAF now plans to operate only KC-135 aircraft, which (as concluded in the BO) would not result in adverse effects to nightingale reed-warblers.

TABLE 2. SAIPAN NATURAL RESOURCE MITIGATION MEASURES DEFINED IN SEC 7 CONSULT

NO.	MITIGATION MEASURES FROM DIVERT BIOLOGICAL OPINION, SAIPAN	SOURCE OF REQUIREMENT	DUE	Modified Saipan Alternative	COMMENTS/CONSIDERATIONS
1	Purchase credit in SUMBA prior to construction of Eastern Parking Ramp	Conservation measure considered part of project description	prior to construction of east parking apron	Not Applicable	East Parking Ramp is no longer part of the proposed action.
2	Clearing vegetation only during Oct-Dec or Apr-Jun	Conservation measure considered part of project description	Construction	Applicable	
3	No laydown yard or temp construction area within nightingale reed warbler habitat or 50 meter buffer zone around reed-warbler territories.	Conservation measure considered part of project description	Construction	Applicable	
4	When possible, the use of very noisy (greater than 60 decibels A-weighted (dBA)) heavy machinery should be limited to the non-active or non-peak breeding seasons or temporary noise barriers or buffer zones should be installed to protect nightingale reed-warblers using buffer zones or areas of connectivity	Conservation measure considered part of project description	Construction	Applicable	
5	Adequate plastic construction fencing will be placed and maintained around any habitat that is to be avoided (including buffer areas and adjacent parcels) to prevent impacts to habitat from construction equipment and personnel.	Conservation measure considered part of project description	Construction	Applicable	
6	All on-site construction personnel will receive instructions regarding the presence of listed species and the importance of avoiding and minimizing impacts to these species and their habitat.	Conservation measure considered part of project description	Construction	Applicable	
7	All on-site personnel will receive instruction regarding the BTS and what to do immediately in case of a sighting.	Conservation measure considered part of project description	Construction	Applicable	
8	The USAF will ensure that no unauthorized take of nightingale reed-warbler or destruction of their habitat occurs. The USAF will have the authority to stop all activities that may result in such take or destruction until appropriate coiTective measures have been completed. The USAF will report immediately any unauthorized impacts to the Service and CNMI DFW.	Conservation measure considered part of project description	Construction/ Implementation	Applicable	
9	Litter control (see BO for details)	Conservation measure considered part of project description	Construction	Applicable	
10	Reporting to USFWS within 30 days of construction implementation to document implementation of any fencing, buffer zones, and minimization measures.	Conservation measure considered part of project description	Within 30 days of construction start	Applicable	
11	Pay SUMBA for 17 Nightingale Reed Warbler Territories if using Fighters	Conservation measure considered part of project description	Implementation Phase: prior to flying fighters	Not applicable	No fighters will be used during Divert exercises and activities.
12	Develop Hazard Analysis and Critical Control Point (HACCP) plans for construction and coordinate development with the Service	Conservation measure considered part of project description	prior to construction activities	Applicable	
13	Brown Tree Snake Inspections for 100% of outgoing vessels from Guam to Saipan (see BO for details). Will be performed with trained quarantine officers and dog detection teams	Conservation measure considered part of project description	Construction/ Implementation	Applicable	Inspection is already in place and this is a normal course of action.
14	Avoid routing flights through Guam for exercises	Conservation measure considered part of project description	Implementation Phase	Applicable	
15	100% redundant inspections after discussions with appropriate stakeholders. Redundant inspections include inspections on Guam and at the receiving jurisdiction for administrative and logistical movements that do not require a tactical approach to complete the training requirements.... in the event that there is inadequate inspection coverage the USAF will coordinate with the USDA-WS to provide additional canine inspection teams that will augment quarantine and inspection protocols at the receiving ports.	Conservation measure considered part of project description	Construction/ Implementation	Applicable	
16	Establish Snake-Free Quarantine Areas for cargo traveling from Guam to CNMI and other brown treesnake-free areas (see BO for details)	Conservation measure considered part of project description	Construction/ Implementation	Applicable	The existing quarantine area at Saipan Port may suffice for shipments. If HACCP determines it is insufficient, temporary barriers may be necessary. JRM is developing a standard design using shade cloth with stakes. At the airport, the temporary barriers are what is recommended by USFWS.

TABLE 2. SAIPAN NATURAL RESOURCE MITIGATION MEASURES DEFINED IN SEC 7 CONSULT

NO.	MITIGATION MEASURES FROM DIVERT BIOLOGICAL OPINION, SAIPAN	SOURCE OF REQUIREMENT	DUE	Modified Saipan Alternative	COMMENTS/CONSIDERATIONS
17	The USAF, in conjunction with the Service and JRM, will develop procedures and protocols specific to Divert training events that will support a rapid response action in the event of a brown treesnake sighting resulting from Divert activities. USAF will agree on the type and amount of logisitical support in advance of a training event and will provide agreed-to support for a rapid response resulting from Divert activities (see BO for details)	Conservation measure considered part of project description	Construction/ Implementation	Applicable	
18	The USAF, working in collaboration with the Service, and USDA-WS, will decide how best to implement the Brown Treesnake Control Plan (BTS TWG 2009, 37 pp.) relevant to Divert activities. The USAF and Service must mutually agree on the Brown Treesnake Control Plan implementation.	Conservation measure considered part of project description	Construction/ Implementation	Applicable	
19	The USAF will provide invasive species awareness training for all military and contractor personnel prior to all training activities.	Conservation measure considered part of project description	Construction/ Implementation	Applicable	
20	USAF will coordinate with the Service, U.S. DOA, CNMI DLNR and JRM on planning for training activities on Saipan. The USAF, along with cooperating agencies, will identify the inspection and interdiction requirements for the Divert training, including the number of trained quarantine officers and dog detection teams required. The USAF will coordinate and consult with the Service on the inspection and interdiction requirements identified by the USAF, and the Service must concur with these requirements prior to the implementation of the exercise or training activity. The USAF, along with the cooperating agencies, will develop plans to ensure that inspection personnel are available and that all requirements can be met, and will identify the support that the USAF will need to provide for the inspections... if adequate resources, such as trained inspectors and dog teams, are not available during training activities, training will not occur until resources are available.	Conservation measure considered part of project description	Implementation	Applicable	
21	Troop self-inspections IAW DoD Instruction 5090.IOA and the 2005 Brown Treesnake Control and Interdiction Plan.	Conservation measure considered part of project description	Implementation	Applicable	
22	Perform pathway risk analysis for each training action	Conservation measure considered part of project description	Implementation	Applicable	
23	Once completed, any portions of the Micronesia Biosecurity Plan determined to be applicable to Divert construction and training activities, will be implemented when such procedures do not unduly interfere with military training.	Conservation measure considered part of project description	Construction/ Implementation	Applicable	The Micronesia Biosecurity Plan is now final as the "Regional Biosecurity Plan for Micronesia and Hawaii." Determination on what is applicable has not yet been made.
24	Monitor and report take as specified in Incidental Take Statement	Incidental Take Statement	Construction/ Implementation	Applicable	During construction the monitor and report must be by the environmental monitor. After construction, the BOS contract must take this over.
25	One nightingale reed-warbler territory will be cleared for construction of the east parking apron resulting in harm of up to two adults and up to four juveniles.	Incidental Take Statement	Construction	Not applicable	Only applicable if east parking ramp were constructed. This ramp is not part of the proposed action for the revised project.
26	Four nightingale reed-warbler territories could be abandoned due to habitat degradation from repeated and loud noise from fighter jet training resulting in harassment of up to eight adults and up to sixteen eggs, chicks, or juveniles.	Incidental Take Statement	Implementation	Not applicable	
27	Thirteen nightingale reed-warbler territories will suffer habitat degradation from noise disturbance from fighter jet training resulting in periodic, but rare, harassment of up to twenty-six adults.	Incidental Take Statement	Implementation	Not applicable	
28	The USAF shall minimize the potential for harassment, harm, or mortality of nightingale reed-warblers	Reasonable and Prudent Measures	Construction/ Implementation	Applicable	
29	To the extent practicable, consistent with national security and contingency requirements, and military safety and security requirements, the USAF will notify the Service on an annual basis of upcoming Divert training events at GSN including timing and description of the joint military exercises.	Terms and Conditions	Implementation	Applicable	

TABLE 2. SAIPAN NATURAL RESOURCE MITIGATION MEASURES DEFINED IN SEC 7 CONSULT

NO.	MITIGATION MEASURES FROM DIVERT BIOLOGICAL OPINION, SAIPAN	SOURCE OF REQUIREMENT	DUE	Modified Saipan Alternative	COMMENTS/CONSIDERATIONS
30	Annual report to USFWS	Terms and Conditions	1 Dec, beginning in 2014	Applicable	Report was provided to Service at end of 2014; reports will continue and will contain details required per terms and conditions as project is approved and proceeds.
31	The USAF will convene an annual coordination meeting or conference call prior to 28 February of each year, starting in 2015, to discuss findings within the compliance report and adapt avoidance, minimization, and conservation measures to further reduce incidental take.	Terms and Conditions	prior to 28 Feb each year, starting in 2015		Not done in 2015 as project was on ice at that time. Recommend we agree it will not be done until the ROD that selects location is signed and design/construction activity begins.
32	Monitoring of fighter noise effects on NRW for fighters only	Conservation Recommendation	Implementation	Not applicable	
33	Conservation Recommendation: rat/cat control measures	Conservation Recommendation	Construction/ Implementation	Applicable

National Marine Fisheries Service
Endangered Species Act Section 7 Consultation
Biological Opinion and Conference Report

Agencies:	United States Navy[1] National Marine Fisheries Service
Activities Considered:	U.S. Military Mariana Islands Training and Testing Activities; and The National Marine Fisheries Services' promulgation of regulations and issuance of a letter of authorization pursuant to the Marine Mammal Protection Act for the U.S. Navy to "take" marine mammals incidental to Mariana Islands Training and Testing activities from August 2015 through August 2020
Consultation Conducted by:	Endangered Species Act Interagency Cooperation Division of the Office of Protected Resources, National Marine Fisheries Service
Approved by:	Donna S. Wieting Director, Office of Protected Resources
Date:	JUN 12 2015
PCTS Tracking Number:	FPR-2014-9070

This document is the National Marine Fisheries Service (NMFS) Office of Protected Resources biological opinion (Opinion). The consulting agency for these proposals is NMFS Office of Protected Resources - Endangered Species Act Interagency Cooperation Division. This opinion has been prepared in accordance with section 7 of the Endangered Species Act of 1973, as

---

[1] The Navy is the executive agent for Mariana Islands Training and Testing (MITT) activites which include all Navy, US Air Force (USAF), and US Coast Guard (USCG) activities as outlined in the MITT Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS). This Biological Opinion (BO) supports Navy, USAF, and USCG actions.

amended (16 U.S.C. 1531 et seq.). The Public Consultation Tracking System number for this consultation is FPR-2015-9111.

BIOLOGICAL OPINION

1 Introduction 1
1.1 Consultation History 2
2 Description of the Action 3
2.1 Mariana Islands Training Activities 5
2.1.1 Anti-Air Warfare (AAW) 5
2.1.2 Amphibious Warfare (AMW) 6
2.1.3 Strike Warfare (STW) 7
2.1.4 Anti-Surface Warfare (ASUW) 7
2.1.5 Anti-Submarine Warfare (ASW) 8
2.1.6 Electronic Warfare (EW) 9
2.1.7 Mine Warfare (MIW) 10
2.1.8 Naval Special Warfare 11
2.1.9 Major Training and Other Training Activities 11
2.2 Mariana Islands Testing Activities 12
2.2.1 Naval Air Systems Command Testing Activities 13
2.2.2 Naval Sea Systems Command Testing Activities 14
2.2.3 Other Naval Sea System Command Testing Activities 15
2.2.4 Office of Naval Research and Naval Research Laboratory Testing Activities 16
2.3 Sonar, Ordnance, Targets, and Other Systems Used in Training and Testing 17
2.3.1 Sonar and Other Non-impulsive Sources 17
2.3.2 Ordnance and Munitions 18
2.3.3 Defense Countermeasures 18
2.3.4 Mine Warfare Systems 18
2.3.5 Mine Neutralization Systems 19
2.4 Proposed Training Activity Levels 19
2.5 Proposed Testing Activity Levels / Naval Air Systems Command 23
2.6 Proposed Testing Activity Levels - Naval Sea Systems Command 24
2.7 Office of Naval Research and Naval Research Laboratory Testing Activities 25
2.8 U.S. Navy Proposed Mitigation 25

2.9 NMFS' Promulgation of Regulations Pursuant to the Marine Mammal Protection Act (MMPA) 30
2.9.1 PART 218—REGULATIONS GOVERNING THE TAKING AND IMPORTING OF MARINE MAMMALS 31
2.10 NMFS' Issuance of Letters of Authorization (LOA) Pursuant to the MMPA Regulations 51
2.11 Interrelated and Interdependent Activities 51
2.12 Action Area 52
2.12.1 MITT Action Area 52
2.12.2 Mariana Islands Range Complex 54
2.12.3 Ocean Operating Areas Outside the Bounds of the Mariana Islands Range Complex 66
2.12.4 Pierside Locations and Apra Harbor 67
2.12.5 Nearshore Training and Testing Areas 67
3 Approach to the Assessment 69
3.1 Overview of NMFS' Assessment Framework 69
3.2 "Take" and Threatened Species 70
3.3 Defining "Significance" 70
3.4 Evidence Available for the Consultation 71
3.4.1 Consideration of new literature and pending Acoustic Guidance on the Effects of Anthropogenic Sound on Marine Mammals 72
3.4.2 The U.S. Navy's Exposure Estimates 75
3.4.3 Navy Marine Species Density Database (NMSDD) 79
3.4.4 Differences Between Navy Modeling Considered in Previous Biological Opinions and this Biological Opinion 80
3.4.5 Discussion of Finneran and Schlundt 2010 and 2011 Dolphin Studies in the Context of Phase II Modeling 81
3.4.6 Post Processing. Avoidance Behavior and Mitigation Measures as Applied to Sonar and Active Acoustic Sources 83
3.5 Treatment of "Cumulative Impacts" (in the sense of NEPA) 85
4 Status of Listed Resources 86
4.1 Species and Designated Critical Habitat Not Considered Further in this Opinion 90
4.1.1 Olive Ridley Sea Turtle 91
4.1.2 Acropora retusa 92
4.1.3 *Seriatopora aculeata* 94

4.2 Listed Species Considered Further in this Opinion 97
4.2.1 Blue Whale 98
4.2.2 Fin Whale 106
4.2.3 Humpback Whale 113
4.2.4 Sei Whale 123
4.2.5 Sperm Whale 129
4.2.6 Green Sea Turtle 139
4.2.7 Hawksbill Sea Turtle 148
4.2.8 Leatherback Sea Turtle 153
4.2.9 Loggerhead Sea Turtle 164
4.2.10 Scalloped Hammerhead Shark – Indo-West Pacific DPS 173
4.2.11 Acropora globiceps 177
5 Environmental Baseline 181
5.1 Climate Change 181
5.2 Coastal development and pollution 184
5.2.1 Light Pollution 186
5.3 Marine Debris 186
5.4 Fisheries 187
5.4.1 Bycatch 189
5.4.2 Directed Fisheries 190
5.5 Whaling 192
5.6 Ongoing U.S. Military Training and Testing Activities in the Action Area 195
5.7 Other U.S. Military Activities in the MITT Action Area 196
5.7.1 Guam and CNMI Military Relocation 196
5.7.2 X-Ray Wharf Improvements 197
5.7.3 Surveillance Towed Array Sensor System Low Frequency Active Sonar 197
5.7.4 Divert Activities and Exercises 203
5.7.5 Dredging, Filling and Explosive Clearing 203
5.8 Commercial and Private Marine Mammal Watching 204
5.9 Vessel Strike 205
5.10 Ocean Noise 208
5.10.1 Potential population-level impacts of anthropogenic noise 209
5.11 Invasive Species 209

5.11.1 Diseases 210
5.11.2 Habitat Impacts 210
5.12 Scientific Research and Permits 211
5.13 Conclusion on the Impact of the Baseline on Listed Resources 212
6 Effects of the Action on Species and Critical Habitat 213
6.1 Stressors Associated with the Proposed Action 214
6.2 Risk Assessment Framework – Marine Mammals 219
6.2.1 Direct Injury of Marine Mammals From Acoustic Stressors 219
6.2.2 Primary Blast Injury and Barotrauma 220
6.2.3 Auditory Trauma 220
6.2.4 Acoustic Resonance 221
6.2.5 Bubble Formation (Acoustically Induced) 221
6.2.6 Nitrogen Decompression 222
6.2.7 Hearing Loss 223
6.2.8 Auditory Masking 226
6.2.9 Physiological Stress 228
6.2.10 Behavioral Reactions 230
6.2.11 Repeated Exposures of Marine Mammals 243
6.2.12 Stranding 246
6.2.13 Long-term Consequences to the Individual and the Population 249
6.2.14 Criteria for Predicting Acoustic and Explosive Impacts – Marine Mammals 253
6.3 Risk Assessment Framework - Sea Turtles 268
6.3.1 Primary Blast Injury and Barotrauma 269
6.3.2 Auditory Trauma 269
6.3.3 Hearing Loss 270
6.3.4 Auditory Masking 270
6.3.5 Physiological Stress 271
6.3.6 Behavioral Reactions 272
6.3.7 Repeated Exposures of Sea Turtles 273
6.3.8 Criteria for Predicting Acoustic and Explosive Impacts – Sea turtles 275
6.4 Risk Assessment Framework – Scalloped Hammerhead Shark 283
6.4.1 Direct Injury of Scalloped Hammerhead Sharks from Non-Impulsive Acoustic Stressors 283
6.4.2 Primary Blast Injury and Barotrauma 285

6.4.3 Hearing Loss 286
6.4.4 Auditory Masking 290
6.4.5 Physiological Stress 292
6.4.6 Behavioral Reactions 293
6.4.7 Repeated Exposures of Fish 296
6.5 Delineation of Individuals of *Acropora globiceps* 297
6.6 Marine Species Density Estimates 299
6.6.1 Marine Mammal Density Estimates 299
6.6.2 Sea Turtle Density Estimates 300
6.7 Stressors Not Likely to Adversely Affect ESA-listed Species 301
6.7.1 Effects of Weapons Firing, Launch and Impact Noise 301
6.7.2 Effects of Aircraft Noise 302
6.7.3 Effects of Vessel Noise 303
6.7.4 Effects of Fiber Optic Cables, Guidance Wires, and Decelarators/Parachutes from Entanglement 307
6.7.5 Effects of Munitions and Other Military Expended Materials from Ingestion 309
6.7.6 Effects of Electromagnetic Devices 309
6.7.7 Effects of In-water Devices from direct physical strikes 312
6.8 Stressors That Are Likely to Adversely Affect ESA-Listed Species 313
6.8.1 Effects of Collisions with Vessels 314
6.8.2 Overview of Effects of Acoustic Stressors 319
6.8.3 Effects of Non-Impulsive Acoustic Stressors - Cetaceans 324
6.8.4 Effects of Non-Impulsive Acoustic Stressors - Sea Turtles 342
6.8.5 Effects of Non-Impulsive Acoustic Stressors - Scalloped Hammerhead Shark – Indo-Pacific DPS 346
6.8.6 Effects of Non-Impulsive Acoustic Stressors – *Acropora globiceps* 348
6.8.7 Effects of Impulsive Acoustic Stressors – Cetaceans 348
6.8.8 Effects of Impulsive Acoustic Stressors - Sea Turtles 353
6.8.9 Effects of Impulsive Acoustic Stressors - Scalloped Hammerhead Shark – Indo-West Pacific DPS 356
6.8.10 Effects of Impulsive Acoustic Stressors and Military Expended Materials 360
6.9 Cumulative Effects 374
7 Integration and Synthesis Of Effects 374
7.1.1 Blue Whale 376

7.1.2 Fin Whale 379
7.1.3 Humpback Whale 381
7.1.4 Sei Whale 383
7.1.5 Sperm Whale 385
7.1.6 Sea Turtles 386
7.1.7 Scalloped Hammerhead Shark – Indo-West Pacific DPS 395
7.1.8 Acropora globiceps 396
8 Conclusion 398
9 Incidental Take Statement 399
9.1 Amount or Extent of Take 400
9.1.1 Take Incidental to Mariana Islands Training and Testing Activities and Issuance of the MMPA Rule and Letters of Authorization 400
9.2 Effects of the Take 404
9.3 Reasonable and Prudent Measures 404
9.3.1 Monitoring 404
9.3.2 Reporting 405
9.4 Terms and Conditions 405
10 Conservation Recommendations 407
11 Reinitiation of Consultation 408
12 Information Quality Act 408
13 References 408

USW	Undersea Warfare

1 INTRODUCTION

Section 7(a)(2) of the Endangered Species Act of 1973, as amended (ESA; 16 U.S.C. 1536(a)(2)) requires each Federal agency to insure that any action they authorize, fund, or carry out is not likely to jeopardize the continued existence of any endangered or threatened species or result in the destruction or adverse modification of critical habitat of such species. When a Federal agency's action "may affect" a protected species, that agency is required to consult formally with the National Marine Fisheries Service (NMFS) or the U.S. Fish and Wildlife Service, depending upon the endangered species, threatened species, or designated critical habitat that may be affected by the action (50 CFR § 402.14(a)). Federal agencies are exempt from this general requirement if they have concluded that an action "may affect, but is not likely to adversely affect" endangered species, threatened species, or designated critical habitat and NMFS or the U.S. Fish and Wildlife Service concurs with that conclusion (50 CFR § 402.14(b)).

In this biological opinion (Opinion), the action agencies are the U.S. Department of Defense (DoD) and U.S. Coast Guard (USCG) (since the Navy is the lead action agency for this consultation, these agencies are collectively referred to as the "Navy" throughout this Opinion), which undertakes military training and testing activities and NMFS's Office of Protected Resources, Permits and Conservation Division, which is (1) promulgating regulations under the Marine Mammal Protection Act (MMPA) governing the U.S. Navy's "take" of marine mammals incidental to those military readiness activities which will be in effect from August 2015 through August 2020 and (2) proposing a Letter of Authorization (LOA) pursuant to the regulations that authorizes the U.S. Navy to "take" marine mammals incidental to those military readiness activities through August 2020. The consulting agency for these proposals is NMFS's Office of Protected Resources, Endangered Species Act (ESA) Interagency Cooperation Division.

This biological opinion was prepared by NMFS's Endangered Species Act Interagency Cooperation Division in accordance with section 7(b) of the Endangered Species Act (ESA) of 1973, as amended (16 U.S.C. 1531, et seq.), and implementing regulations at 50 CFR § 402. This document is NMFS's final biological opinion (Opinion) on the anticipated effects of these actions on endangered and threatened species and critical habitat that has been designated for those species, and supercedes previous biological opinions on Mariana Islands training described in more detail below, which is incorporated by reference.

This biological opinion is based on information provided in the March 2014 U.S. Navy request for ESA consultation package which included the September 2013 Mariana Islands Training and Testing Draft Environmental Impact Statement/Overseas Environmental Impact Statement (DEIS/OEIS); the Biological Evaluation; the Mariana Islands Training and Testing Endangered Species Act Section 7 Consultation Supplemental Information; NMFS Permits Division's 28 January 2015 request for Section 7 consultation under the ESA; and the proposed Federal regulations under the MMPA specific to the proposed activities (78 FR 7050). We also considered later versions of the Final EIS/OEIS and other supplemental information as they were made available to us. Also considered were the draft or final recovery plans for the endangered

or threatened species that are considered in this document, and publications that we identified, gathered, and examined from the public scientific literature.

The Navy proposes to conduct training and testing activities within the Mariana Islands Training and Testing (MITT) Study Area. Military training and testing activities have been ongoing in the same general geographic area for several decades. Ongoing activities that are analyzed in previous section 7 consultations are assessed in this Opinion as part of the *Environmental Baseline* in the Action Area.

1.1 Consultation History

- On March 7, 2014, the U.S. Navy requested section 7 formal consultation based on their determination that MITT activities may affect and are likely to adversely affect humpback whale (*Megaptera novaeangliae*), sei whale (*Balaenoptera borealis*), fin whale (*Balaenoptera physalus*), blue whale (*Balaenoptera musclus*), sperm whale (*Physeter macrocephalus*), green sea turtle (*Chelonia mydas*), hawksbill sea turtle (*Eretmochelys imbricata*), Olive ridley sea turtle (*Lepidochelys olivacea*), loggerhead sea turtle (*Caretta caretta*), leatherback sea turtle (*Dermochelys coriacea*), and conference on the proposed listing of 43 species of coral.

- On April 16, 2014, we responded to the U.S. Navy's 7 March 2014 request indicating that we had received sufficient information to initiate formal consultation. We also determined that NMFS Permits and Conservation Division's proposed action of promulgating a rule in accordance with the MMPA and subsequently issuing a LOA authorizing take of marine mammals incidental to U.S. Navy MITT activities are inter-dependent and interrelated to the U.S. Navy's proposed action and therefore must be included in the consultation. Due to the complexity of the proposed action and extent of species potentially affected, we proposed an extended consultation timeline with a final opinion issued no later than April 2015.

- On August 19, 2014, the U.S. Navy provided supplemental information to the biological evaluation provided on 7 March. The U.S. Navy determined that the Indo-West Pacific DPS of scalloped hammerhead shark is present in the MITT Study Area and upon their review of the pertinent biology literature combined with consideration of proposed Navy training and testing activities in MITT, reached a "may affect" determination for the Indo-West Pacific DPS of scalloped hammerhead shark.

- On September 22, 2014, the U.S. Navy's Pacific Fleet provided a minor change to the action consisting of a reduction from the originally-proposed 20 pound (lb) charges/net explosive weight (NEW) to be used in underwater detonations (UNDETS) to the currently-used 10 lb charge NEW in Apra Harbor, Guam and to request that the biological opinion cover the five listed species of coral found in the MITT study area (*Acropora globiceps*, *Acropora retusa*, *Acropora tenella*, *Pavona diffluens* and *Seriatopora aculeata*) in place of the previous request for conference opinion covering forty-three species of corals that were proposed for listing.

- On October 14, 2014, NMFS provided the draft Opinion along with questions to the Navy. NMFS received responses to questions on 6 November 2014 and comments on the draft Opinion on 10 November 2014.

- On December 5, 2014, the U.S. Pacific Fleet released a naval message to all subordinate commands, requiring mitigation for all hammerhead sharks prior to underwater detonations in the same manner employed for marine mammals and sea turtles.

- On April 7, 2015, NMFS and the Navy decided to include analyses for the proposed endangered Central-West Pacific DPS of green sea turtles, resulting in this Biological/Conference Opinion.

- On April 15, 2015, NMFS provided the final draft Opinion to the Navy and NMFS's Permits and Conservation Division for review.

- On April 30, 2015, NMFS reveived comments on the draft Opinon from the Navy.

- On May 1, 2015, the Navy provided supplemental information on the effects of training and testing activities on corals in Apra Harbor, Guam.

- On May 5, 2015, NMFS and the Navy held a teleconference to discuss alternate approaches to the coral risk analysis. The Navy also provided supplemental information on coral sightings around Guam and Farallon De Medinilla.

- On May 12, 2015, the Navy provided supplemental information on the impacts of munitions at Farrallon De Medinilla including estimates of seafloor impacted by munitions.

2 DESCRIPTION OF THE ACTION

"Action" means all activities or programs of any kind authorized, funded, or carried out, in whole or in part, by Federal agencies. Interrelated actions are those that are part of a larger action and depend on the larger action for their justification. Interdependent actions are those that have no independent utility apart from the action under consideration. This opinion addresses three interdependent actions as proposed by the U.S. Navy and NMFS's Permits Division.

This opinion addresses three interdependent actions as proposed by the U.S. Navy and NMFS's Permits Division: (1) the U.S. Navy's proposed military training and testing activities (i.e., readiness activities) conducted in the MITT Study Area; (2) NMFS's Permits Division's proposal to promulgate regulations pursuant to the MMPA governing the U.S. Navy's "take" of marine mammals incidental to the Navy's military readiness activities from August 2015 through August 2020; and (3) NMFS's Permits Division's proposal to issue an LOA pursuant to the regulations that authorize the U.S. Navy to "take" marine mammals incidental to military readiness activities in the MITT Study Area through August 2020.

The purpose of the activities the U.S. Navy conducts in the MITT Study Area is to meet the requirements of the U.S. Navy's Fleet Response Training Plan and allow Navy personnel to remain proficient in anti-submarine warfare and mine warfare skills (i.e., military readiness activities). The purpose of the MMPA regulations and the Permits and Conservation Division's LOA is to allow the U.S. Navy to "take" marine mammals incidental to military readiness activities in the MITT Study Area conducted through August 2020 in a manner that is consistent with the requirements of the MMPA and implementing regulations.

NMFS recognizes that while Navy training and testing requirements change over time in response to global or geopolitical events and other factors, the general types of activities addressed by this consultation are expected to continue into the reasonably foreseeable future, along with the associated impacts. Therefore, as part of our effects analysis, we assumed that the activities proposed for the remainder of the five year period of the MMPA Rule would continue into the reasonably foreseeable future at levels similar to that assessed in this Opinion and described in the 2015 MITT FEIS/OEIS and MMPA rule.

The tempo of training within the MITT Study Area is subject to variation within the scope of the activities described in the Navy's MITT FEIS/OEIS and this Opinion. Annual variation in the number of training events and quantities of authorized sonar systems and explosive training could occur. Given the inherent uncertainty and potential variation within the training spectrum due to unforeseen world events, the Navy stated that it cannot predict exact annual system use for the period.

Notwithstanding this analysis, however, NMFS would fully take into account all of the best available science and any change in the status of the species when and if the Navy applies for a new MMPA incidental take authorization upon expiration of the five-year regulations considered in this opinion. The Navy would also need to initiate a new ESA consultation at that time.
The Navy, U.S. Air Force, U.S. Marine Corps, and U.S. Coast Guard routinely train in the Action Area in preparation for national defense missions. Typical training and testing activities and exercises covered in this Opinion are briefly described in the following sections. Each military training activity described meets a requirement that can be traced ultimately to requirements set forth by the National Command Authority.

The Navy and other services have been conducting military readiness activities in the Action Area for decades. The tempo and types of training and testing activities have fluctuated because of the introduction of new technologies, the evolving nature of international events, advances in warfighting doctrine and procedures, and changes in force structure (organization of ships, weapons, and military personnel). Such developments influence changes in the frequency, duration, intensity, and location of required training and testing activities. The Navy categorizes training and testing activities into functional warfare areas called primary mission areas. Most training and testing activities analyzed in this Opinion fall into the following eight primary mission areas:

- Anti-air warfare
- Amphibious warfare
- Strike warfare
- Anti-surface warfare
- Anti-submarine warfare
- Electronic warfare
- Mine warfare
- Naval special warfare

Not all activities can be categorized in one of these areas. The research and acquisition community (i.e., testing community) also categorizes some, but not all, of its testing activities under these primary mission areas. Testing activities analyzed in this Opinion are categorized into the following areas:

- Life Cycle Activities
- Shipboard Protection Systems and Swimmer Defense Testing
- New Ship Construction
- Naval Research

U.S. Navy proposed training and testing activities and annual activity levels are summarized in this opinion. Specific details regarding each mission area can be found in the *Mariana Islands Training and Testing Final Environmental Impact Statement/Overseas Environmental Impact Statement (FEIS/OEIS)*, May 2015.

Also, NMFS' Permits Division proposes to issue five-year regulations and a LOA to the U.S. Navy, pursuant to section 101(a)(5)(A) of the Marine Mammal Protection Act of 1972, as amended (MMPA; 16 U.S.C. 1361 *et seq.*), for taking marine mammals incidental to conducting training and testing activities in the MITT Study Area. The MMPA regulations would be effective from August 2015 to August 2020.

2.1 Mariana Islands Training Activities

The following sections describe the training activities occurring in the MITT study area.

2.1.1 Anti-Air Warfare (AAW)

The mission of anti-air warfare is to destroy or reduce enemy air and missile threats (including unmanned airborne threats) and serves two purposes: to protect U.S. forces from attacks from the air and to gain air superiority. Anti-air warfare also includes providing U.S. forces with adequate attack warnings, while denying hostile forces the ability to gather intelligence about U.S. forces. Table 1 provides summaries of training activities in support of AAW.

Aircraft conduct anti-air warfare through radar search, detection, identification, and engagement of airborne threats-generally by firing anti-air missiles or cannon fire. Surface ships conduct anti-air warfare through an array of modern anti-aircraft weapon systems such as aircraft detecting radar, naval guns linked to radar-directed fire-control systems, surface-to-air missile systems, and radar-controlled cannons for close-in point defense.

Table 1. Typical Anti-Air Warfare Training Exercises

Activity Name	Activity Description
Anti-Air Warfare (AAW)	
Gunnery Exercise (Surface-to-Air) (GUNEX [S-A]) – Large-caliber	Surface ship crews defend against threat aircraft or missiles with guns.
Gunnery Exercise (Surface-to-Air) (GUNEX [S-A]) – Medium-caliber	Surface ship crews defend against threat aircraft or missiles with guns.
Missile Exercise (Surface-to-Air) (MISSILEX [S-A])	Surface ship crews defend against threat missiles and aircraft with missiles.

2.1.2 Amphibious Warfare (AMW)

The mission of amphibious warfare is to project military power from the sea to the shore through the use of naval firepower and Marine Corps landing forces. It is used to attack a threat located on land by a military force embarked on ships. Amphibious warfare operations include small unit reconnaissance or raid missions to large-scale amphibious operations involving multiple ships and aircraft combined into a strike group. Table 2 provides summaries of training activities in support of AMW.

Amphibious warfare training ranges from individual, crew, and small unit events to large task force exercises. Individual and crew training include amphibious vehicles and naval gunfire support training. Small-unit training operations include shore assaults, boat raids, airfield or port seizures, and reconnaissance. Large-scale amphibious exercises involve ship-to-shore maneuver, naval fire support, such as shore bombardment, and air strike and close air support training.

Table 2. Typical Amphibious Warfare Training Exercises

Activity Name	Activity Description
Amphibious Warfare (AMW)	
Naval Surface Fire Support Exercise-Land Based Target (FIREX [Land])	Surface ship crews use large-caliber guns to fire on land-based targets in support of forces ashore.
Amphibious Rehearsal, No Landing	Amphibious shipping, landing craft, and elements of the Marine Air Ground Task Force rehearse amphibious landing operations without conducting an actual landing on shore.
Amphibious Assault	Forces move ashore from ships at sea for the immediate execution of inland objectives.
Amphibious Raid	Small unit forces move swiftly from ships at sea for a specific short-term mission. Raids are quick operations with as few Marines as possible.
Unmanned Aerial Vehicles Ops (UAV OPS)	Military units employ unmanned aerial vehicles to launch, operate, and gather intelligence for specified amphibious missions.

2.1.3 Strike Warfare (STW)

The mission of strike warfare is to conduct offensive attacks on land-based targets, such as refineries, power plants, bridges, major roadways, and ground forces to reduce the enemy's ability to wage war. Strike warfare employs weapons by manned and unmanned air, surface, submarine, and naval special warfare assets in support of extending dominance over enemy territory (power projection). Table 3 provides summaries of training activities in support of STW.

Strike warfare includes training of fixed wing attack aircraft pilots and aircrews in the delivery of precision-guided munitions, non-guided munitions, rockets, and other ordnance, including the high-speed anti-radiation missile, against land-based targets in all conditions. Not all strike mission training events involve dropping ordnance and instead the event is simulated with video footage obtained by onboard sensors.

Table 3. Typical Strike Warfare Training Exercises

Activity Name	Activity Description
Strike Warfare (STW)	
Combat Search and Rescue (CSAR)	CSAR units use helicopters, night vision and identification systems, and insertion and extraction techniques under hostile conditions to locate, rescue, and extract personnel.

2.1.4 Anti-Surface Warfare (ASUW)

The mission of anti-surface warfare is to defend against enemy ships or boats. In the conduct of anti-surface warfare, aircraft use cannons, air-launched cruise missiles or other precision guided munitions; ships employ torpedoes, naval guns, and surface-to-surface missiles; and submarines attack surface ships using torpedoes or submarine-launched, anti-ship cruise missiles. Table 4 provides summaries of training activities in support of ASUW.

Anti-surface warfare training includes surface-to-surface gunnery and missile exercises, air-to-surface gunnery and missile exercises, and submarine missile or torpedo launch events.

Table 4. Typical Anti-Surface Warfare Training Exercises

Activity Name	Activity Description
Anti-Surface Warfare (ASUW)	
Gunnery Exercise (Air-to-Surface) – Small-caliber	Fixed-wing and helicopter aircrews, including embarked personnel, use small-caliber guns to engage surface targets.
Gunnery Exercise (Air-to-Surface) – Medium-caliber	Fixed-wing and helicopter aircrews, including embarked personnel, use medium-caliber guns to engage surface targets.
Missile Exercise (Air-to-Surface) – Rocket (MISSILEX [A-S] – Rocket)	Fixed-wing and helicopter aircrews fire precision-guided and unguided rockets against surface targets.

Activity Name	Activity Description
Missile Exercise (Air-to-Surface) – Missile (MISSILEX [A-S] – Missile)	Fixed-wing and helicopter aircrews fire precision-guided missiles against surface targets.
Laser Targeting (at sea)	Fixed-winged, helicopter, and ship crews illuminate enemy targets with lasers.
Bombing Exercise (Air-to-Surface) (BOMBEX [A-S])	Fixed-wing aircrews deliver bombs against surface targets.
Torpedo Exercise (Submarine-to-Surface)	Submarine attacks a surface target using exercise or live-fire torpedoes.
Missile Exercise (Surface-to-Surface) (MISSILEX [S-S])	Surface ship crews defend against threat missiles and other surface ships with missiles.
Gunnery Exercise Surface-to-Surface (Ship) – Large-caliber (GUNEX-S-S [Ship])	Ship crews engage surface targets with ship's large-caliber guns.
Gunnery Exercise Surface-to-Surface (Ship) – Small- and Medium-caliber (GUNEX-S-S [Ship])	Ship crews engage surface targets with ship's small- and medium-caliber guns.
Sinking Exercise (SINKEX)	Aircraft, ship, and submarine crews deliver ordnance on a seaborne target, usually a deactivated ship, which is deliberately sunk using multiple weapon systems.
Gunnery Exercise Surface-to-Surface (Boat) (GUNEX-S-S [Boat])	Small boat crews engage surface targets with small- and medium-caliber weapons.
Maritime Security Operations (MSO)	Helicopter and surface ship crews conduct a suite of Maritime Security Operations (e.g., Vessel Search, Board, and Seizure; Maritime Interdiction Operations; Force Protection; and Anti-Piracy Operation).

2.1.5 Anti-Submarine Warfare (ASW)

The mission of anti-submarine warfare is to locate, neutralize, and defeat hostile submarine threats to surface forces. Anti-submarine warfare is based on the principle of a layered defense of surveillance and attack aircraft, ships, and submarines all searching for hostile submarines. These forces operate together or independently to gain early warning and detection, and to localize, track, target, and attack hostile submarine threats. Table 5 provides summaries of training activities in support of ASW.

Anti-submarine warfare training addresses basic skills such as detection and classification of submarines, and distinguishing between sounds made by enemy submarines and those of friendly submarines, ships, and marine life. More advanced, integrated anti-submarine warfare training exercises are conducted in coordinated, at-sea training events involving submarines, ships, fixed wing aircraft, and helicopters. This training integrates the full spectrum of anti-submarine

warfare from detecting and tracking a submarine to attacking a target using either exercise torpedoes or simulated weapons.

Table 5. Typical Anti-Submarine Warfare Training Exercises

Activity Name	Activity Description
Anti-Submarine Warfare (ASW)	
Tracking Exercise/Torpedo Exercise – Helicopter (TRACKEX/TORPEX – Helo)	Helicopter crews search, track, and detect submarines. Exercise torpedoes may be used during this event.
Tracking Exercise – Maritime Patrol Aircraft Extended Echo Ranging Sonobuoys	Maritime patrol aircraft crews search, detect and track submarines using explosive source sonobuoys or multistatic active coherent system.
Tracking Exercise/Torpedo Exercise – Maritime Patrol Aircraft (TRACKEX/TORPEX – MPA)	Maritime patrol aircraft crews search, detect, and track submarines. Recoverable air launched torpedoes may be employed against submarine targets.
Tracking Exercise/Torpedo Exercise – Surface (TRACKEX/TORPEX – Surface)	Surface ship crews search, track, and detect submarines. Exercise torpedoes may be used during this event.
Tracking Exercise/Torpedo Exercise – Submarine (TRACKEX/TORPEX – Sub)	Submarine crews search, detect, and track submarines and surface ships. Exercise torpedoes may be used during this event.

2.1.6 Electronic Warfare (EW)

The mission of electronic warfare is to degrade the enemy's ability to use their electronic systems, such as communication systems and radar, in order to confuse or deny them the ability to defend their forces and assets. Electronic warfare is also used to recognize an emerging threat and counter an enemy's attempt to degrade the electronic capabilities of the Navy. Table 6 provides summaries of training activities in support of EW.

Typical electronic warfare activities include threat avoidance training, signals analysis for intelligence purposes, and use of airborne and surface electronic jamming devices to defeat tracking and communications systems.

Table 6. Typical Electronic Warfare Training Exercises

Activity Name	Activity Description
Electronic Warfare (EW)	
Electronic Warfare Operations (EW OPS)	Aircraft, surface ship, and submarine crews attempt to control portions of the electromagnetic spectrum used by enemy systems to degrade or deny the enemy's ability to take defensive actions.
Counter Targeting – Flare Exercise (FLAREX) – Aircraft	Fixed-winged aircraft and helicopters crews defend against an attack by deploying flares to disrupt threat infrared (IR) missile guidance systems.

Activity Name	Activity Description
Counter Targeting Chaff Exercise (CHAFFEX) – Ship	Surface ships defend against an attack by deploying chaff, a radar reflective material, which disrupt threat targeting and missile guidance radars.
Counter Targeting Chaff Exercise (CHAFFEX) – Aircraft	Fixed-winged aircraft and helicopter crews defend against an attack by deploying chaff, a radar reflective material, which disrupt threat targeting and missile guidance radars.

2.1.7 Mine Warfare (MIW)

The mission of mine warfare is to detect, and avoid or neutralize mines to protect Navy ships and submarines and to maintain free access to ports and shipping lanes. Mine warfare also includes offensive mine laying to gain control of, or deny the enemy access to sea space. Naval mines can be laid by ships (including purpose-built minelayers), submarines, or aircraft. Table 7 provides summaries of training activities in support of MIW.

Mine warfare neutralization (destruction) training includes exercises in which ships, aircraft, submarines, or underwater vehicles search for mines. Personnel train to destroy or disable mines by attaching and detonating underwater explosives to the mine. Other neutralization techniques involve impacting the mine with a bullet-like projectile or intentionally triggering the mine to detonate.

Table 7. Typical Mine Warfare Exercises

Activity Name	Activity Description
Mine Warfare (MIW)	
Civilian Port Defense	Naval mine warfare activities conducted at various ports and harbors, in support of maritime homeland defense/security.
Mine Laying	Fixed-winged aircraft and vessel crews drop/launch non explosive mine shapes.
Mine Neutralization – Explosive Ordnance Disposal (EOD)	Personnel disable threat mines. Explosive charges may be used.
Limpet Mine Neutralization System/Shock Wave Generator	Navy divers place a small charge on a simulated underwater mine.
Submarine Mine Exercise	Submarine crews practice detecting mines in a designated area.
Airborne Mine Countermeasure (MCM) – Mine Detection	Helicopter aircrews detect mines using towed and laser mine detection systems (e.g., AN/AQS-20, Airborne Laser Mine Detection System).
Mine Countermeasure Exercise – Towed Sonar	Surface ship crews detect and avoid mines while navigating restricted areas or channels using towed active sonar.
Mine Countermeasure Exercise – Surface (SMCMEX)	Mine countermeasure ship crews detect, locate, identify, and avoid mines while navigating restricted areas or channels using active sonar.
Mine Neutralization – Remotely Operated Vehicle Sonar	Helicopter aircrews disable mines using remotely operated underwater vehicles.

Activity Name	Activity Description
Mine Countermeasure (MCM) – Towed Mine Neutralization	Ship crews and helicopter aircrews tow systems (e.g., Organic and Surface Influence Sweep, MK 104/105) through the water that are designed to disable and/or trigger mines.

2.1.8 Naval Special Warfare

The mission of naval special warfare is to conduct unconventional warfare, direct action, combat terrorism, special reconnaissance, security assistance, counter-drug operations, and recovery of personnel from hostile situations. Naval special warfare operations are highly specialized and require continual and intense training. Table 8 provides summaries of training activities in support of NSW.

Naval special warfare units utilize a combination of specialized training, equipment, and tactics, including insertion and extraction operations using parachutes, submerged vehicles, rubber boats, and helicopters; boat-to-shore and boat-to-boat gunnery; underwater demolition training; reconnaissance; and small arms training.

Table 8. Typical Naval Special Warfare Exercises

Activity Name	Activity Description
Naval Special Warfare (NSW)	
Personnel Insertion/Extraction	Military personnel train for covert insertion and extraction into target areas using helicopters, fixed-wing aircraft (insertion only), small boats, and submersibles.
Direct Action (Tactical Air Control Party [TACP]/Joint Tactical Air Control)	Military personnel train for controlling of combat support aircraft; providing target designation, airspace de-confliction, and terminal control for Close Air Support. Teams also train in use of small arms and mortars.
Underwater Demolition Qualification/Certification	Navy divers conduct training and certification in placing underwater demolition charges.
Intelligence, Surveillance, Reconnaissance (ISR)	Special Warfare units train to collect and report battlefield intelligence.
Underwater Survey	Navy divers train in survey of underwater conditions and features in preparation for insertion, extraction, or intelligence, surveillance and reconnaissance activities.

2.1.9 Major Training and Other Training Activities

Major training exercises provide multi-Service and Joint participation in realistic maritime and expeditionary training that is designed to replicate the types of events and challenges that could be faced during real-world contingency operations. Major training exercises also include providing training to submarine, ship, aircraft, and special warfare forces in mission tactics, techniques, and procedures. Table 9 provides summaries of Major Training and Other Training Activities.

Table 9. Major Training and Other Training Activities

Activity Name	Activity Description
Major Training Activities	
Joint Expeditionary Exercise	A 10-day at-sea and ashore exercise which brings different branches of the United States (U.S.) military together in a joint environment that includes planning and execution efforts as well as military training activities at sea, in the air, and ashore. More than 8,000 personnel may participate and could include the combined assets of a Carrier Strike Group and Expeditionary Strike Group, Marine Expeditionary Units, Army Infantry Units, and Air Force aircraft.
Joint Multi-Strike Group Exercise	A 10-day at-sea and ashore exercise in which up to three Carrier Strike Groups integrated with U.S. Air Force and U.S. Marine Corps forces would conduct at-sea training and STW exercises simultaneously.
Marine Air Ground Task Force Exercise (Amphibious) – Battalion	A 10-day at-sea and shore exercise which conducts over the horizon, ship to objective maneuver for the elements of the Expeditionary Strike Group and the Amphibious Marine Air Ground Task Force. The exercise utilizes all elements of the Marine Air Ground Task Force (Amphibious), conducting training activities ashore with logistic support of the Expeditionary Strike Group and conducting amphibious landings.
Special Purpose Marine Air Ground Task Force Exercise	A 10-day at-sea and ashore exercise similar to Marine Air Ground Task Force (Amphibious) – Battalion, but task organized to conduct a specific mission (e.g., Humanitarian Assistance, Disaster Relief, Non-combatant Evacuation Operations).
Other Training Activities	
Surface Ship Sonar Maintenance	In-port and at-sea maintenance of sonar systems.
Submarine Sonar Maintenance	In-port and at-sea maintenance of sonar systems.
Small Boat Attack	Small boats or personal watercraft conduct attack activities on units afloat.
Submarine Navigation	Submarine crews locate underwater objects and ships while transiting out of port.
Search and Rescue at Sea	United States Coast Guard and military personnel train with ships, fixed wing and rotary aircraft to locate and rescue missing personnel and vessels at sea.
Precision Anchoring	Releasing of anchors in designated locations.

2.2 Mariana Islands Testing Activities

The Navy's research and acquisition community engages in a broad spectrum of testing activities in support of the fleet. These activities include, but are not limited to, basic and applied scientific research and technology development; testing, evaluation, and maintenance of systems (e.g., missiles, radar, and sonar), and platforms (e.g., surface ships, submarines, and aircraft); and acquisition of systems and platforms to support Navy missions and give a technological edge over adversaries.

The individual commands within the research and acquisition community included in this Biological Opinion are Naval Air Systems Command, Naval Sea Systems Command, the Office of Naval Research, and the Naval Research Laboratory.

The Navy operates in an ever-changing strategic, tactical, and funding and time-constrained environment. Testing activities occur in response to emerging science or fleet operational needs. For example, future Navy experiments to develop a better understanding of ocean currents may be designed based on advancements made by non-government researchers not yet published in the scientific literature. Similarly, future but yet unknown Navy operations within a specific geographic area may require development of modified Navy assets to address local conditions. Such modifications must be tested in the field to ensure they meet fleet needs and requirements.

Some testing activities are similar to training activities conducted by the fleet. For example, both the fleet and the research and acquisition community fire torpedoes. While the firing of a torpedo might look identical to an observer, the difference is in the purpose of the firing. The fleet might fire the torpedo to practice the procedures for such a firing, whereas the research and acquisition community might be assessing a new torpedo guidance technology or to ensure that the torpedo meets performance specifications and operational requirements. These differences may result in different analysis and potential mitigations for the activity.

2.2.1 Naval Air Systems Command Testing Activities

Naval Air Systems Command testing activities generally fall in the primary mission areas used by the fleets. Naval Air Systems Command activities include, but are not limited to, the testing of new aircraft platforms, weapons, and systems before those platforms, weapons and systems are delivered to the fleet. In addition to the testing of new platforms, weapons, and systems, Naval Air Systems Command also conducts lot acceptance testing of weapons and systems, such as sonobuoys.

The majority of testing and development activities (Table 10) conducted by Naval Air Systems Command are similar to fleet training activities, and many platforms (e.g., Maritime Patrol Aircraft) and systems (e.g., sonobuoys) currently being tested are already being used by the fleet or will ultimately be integrated into fleet training activities. However, some testing and development may be conducted in different locations and in a different manner than the fleet and therefore, though the potential environmental effects may be the same, the analysis for those activities may differ. Training with systems and platforms delivered to the fleet within the timeframe of this document are analyzed in the training sections of the MITT EIS/OEIS.

Table 10. Typical NAVAIR Testing Activities

Testing Event	Description	Weapons/Rounds/ Sound Source
Anti-Surface Warfare (ASUW)		
Air-to-Surface Missile Test	This event is similar to the training event missile exercise (air-to-surface). Test may involve both fixed wing and rotary wing aircraft launching missiles at surface maritime targets to evaluate the weapons system or as part of another systems integration test.	Explosive missiles

Testing Event	Description	Weapons/Rounds/ Sound Source
Anti-Submarine Warfare (ASW)		
Anti-Submarine Warfare Torpedo Test	This event is similar to the training event torpedo exercise. The Test evaluates anti-submarine warfare systems onboard rotary wing and fixed wing aircraft and the ability to search for, detect, classify, localize, and track a submarine or similar target. Some tests from fixed-wing aircraft will involve releasing torpedoes and sonobuoys from high altitudes (approximately 25,000 feet [ft.]).	Exercise (Non-explosive) torpedoes
Anti-Submarine Warfare Tracking Test – Maritime Patrol Aircraft (Sonobuoy)	This event is similar to the training event ASW TRACKEX-Maritime Patrol Aircraft (MPA). The test evaluates the sensors and systems used by maritime patrol aircraft to detect and track submarines and to ensure that aircraft systems used to deploy the tracking systems perform to specifications and meet operational requirements.	DICASS active sonobuoys, IEER sonobuoys (2 detonations per IEER buoy), High Duty Cycle sonobuoys, various Signal Underwater Sound (SUS) devices, MAC sonobuoys
Electronic Warfare (EW)		
Flare Test	Flare tests evaluate newly developed or enhanced flares, flare dispensing equipment, or modified aircraft systems against flare deployment. Tests may also train pilots and aircrew in the use of newly developed or modified flare deployment systems. Flare tests are often conducted with other test events, and are not typically conducted as standalone tests.	Chaff and flares are expended

2.2.2 Naval Sea Systems Command Testing Activities

Naval Sea Systems Command testing activities are aligned with its mission of new ship construction, life cycle support, and weapon systems development. Each major category of Naval Sea Systems Command activities is described below:

2.2.2.1 New Ship Construction Activities

Ship construction activities include testing of ship systems, and developmental and operational test and evaluation programs for new technologies and systems. At-sea testing of systems aboard a ship may include sonar, acoustic countermeasures, radars, and radio equipment. At-sea test firing of shipboard weapon systems, including guns, torpedoes, and missiles, are also conducted. Table 11 provides summaries of testing activities in support of ship construction and maintenance.

Table 11. Typical New Ship Construction Activities

Activity Name	Activity Description
New Ship Construction	
Anti-Submarine Warfare Mission Package Testing	Ships and their supporting platforms (e.g., helicopters, unmanned aerial systems) detect, localize, and prosecute submarines.
Anti-Surface Warfare Mission Package Testing	Ships and their supporting platforms (e.g., helicopters, unmanned aerial vehicles) detect, localize, and prosecute surface vessels.
Mine Countermeasure Mission Package Testing	Ships conduct mine countermeasure operations.

2.2.2.2 Life Cycle Activities

Testing activities (Table 12) are conducted throughout the life of a Navy ship to verify performance and mission capabilities. Sonar systems testing occurs pierside during maintenance, repair, and overhaul availabilities, and at sea immediately following most major overhaul periods. Radar cross signature testing of surface ships is conducted on new vessels and periodically throughout a ship's life to measure how detectable the ship is to radar. Additionally, electromagnetic measurements of off-board electromagnetic signature are conducted for submarines, ships, and surface crafts periodically.

Table 12. Typical Life Cycle Activities in the Study Area

Activity Name	Activity Description
Life Cycle Activities	
Ship Signature Testing	Tests ship and submarine radars, electromagnetic, or acoustic signatures.

2.2.3 Other Naval Sea System Command Testing Activities

Numerous test activities and technical evaluations, in support of Naval Sea Systems Command's systems development mission, often occur in conjunction with fleet activities within the MITT Study Area. Tests within this category include, but are not limited to anti-submarine warfare and mine warfare tests using torpedoes, sonobuoys, and mine detection and neutralization systems. Pierside, swimmer detection systems will also be tested.

Unique Naval Sea Systems Command planned testing includes a kinetic energy weapon for Navy ships, which uses electromagnetic energy to propel a projectile at a surface, air, or ground target.

Table 13. Other Naval Sea System Command Testing Activities.

Activity Name	Activity Description
Anti-Surface Warfare (ASUW)/Anti-Submarine Warfare (ASW) Testing	
Kinetic Energy Weapon Testing	A kinetic energy weapon uses stored electromagnetic energy released in a burst to accelerate a projectile. Projectiles used for testing are either non-explosive or in-air explosive munitions.
Torpedo Testing	Air, surface, or submarine crews employ live/exercise torpedoes against submarines or surface vessels.
Countermeasure Testing	Various systems (e.g., towed arrays and defense systems) are employed to detect, localize, and track incoming weapons.
At-sea Sonar Testing	At-sea testing to ensure systems are fully functional in an open ocean environment.
Shipboard Protection Systems and Swimmer Defense Testing	
Pierside Integrated Swimmer Defense	Swimmer defense testing ensures that systems can effectively detect, characterize, verify, and engage swimmer/diver threats in harbor environments.

2.2.4 Office of Naval Research and Naval Research Laboratory Testing Activities

As the Navy's Science and Technology provider, Office of Naval Research and the Naval Research Laboratory provide technology solutions for Navy and Marine Corps needs. The Office of Naval Research's missions, defined by law, are to plan, foster, and encourage scientific research in recognition of its paramount importance as related to the maintenance of future naval power, and the preservation of national security. Further, the Office of Naval Research manages the Navy's basic, applied, and advanced research to foster transition from science and technology to higher levels of research, development, test and evaluation. The Ocean Battlespace Sensing Department explores science and technology in the areas of oceanographic and meteorological observations, modeling, and prediction in the battlespace environment; submarine detection and classification (anti-submarine warfare); and mine warfare applications for detecting and neutralizing mines in both the ocean and littoral environment. The Office of Naval Research activities include: research, development, test, and evaluation activities; surface processes acoustic communications experiments; shallow water acoustic communications experiments; sediment acoustics experiments; shallow water acoustic propagation experiments; and long range acoustic propagation experiments. Office of Naval Research testing is shown in Table 14.

Table 14. Typical Office of Naval Research Testing Activity in the Study Area

Activity Name	Activity Description
Office of Naval Research	
North Pacific Acoustic Lab Philippine Sea 2018–19 Experiment (Deep Water)	The experiment area encompasses international waters. The initial experiment was completed in May of 2011; an acoustic tomography array, a distributed vertical line array (DVLA), and moorings were deployed in the deep-water environment of the northwestern Philippine Sea. The acoustic tomography array and DVLA have remained in situ at the experiment site since that time, collecting oceanographic and acoustic data used to study deep-water propagation and to characterize the temperature and velocity structure in this oceanographically complex and highly dynamic region. In addition, data will be collected during two periods of intensive experimental at-sea operations in May and July of 2018. During fall 2018, data will be collected passively by remotely sensing seagliders. Research vessels, acoustic test sources, side scan sonar, ocean gliders, the existing moored acoustic tomographic array and distributed vertical line array, and other oceanographic data collection equipment will be used to collect information on the ocean environment. The final phases of the experiment will be completed during March through May 2019. The resulting analyses will aid in developing a more complete understanding of deep water sound propagation and the temperature-velocity profile of the water column in this part of the world.

2.3 Sonar, Ordnance, Targets, and Other Systems Used in Training and Testing

The Navy uses a variety of sensors, platforms, weapons, and other devices to meet its mission. Training and testing with these systems may introduce acoustic (sound) energy into the environment. This section describes and organizes sonar systems, ordnance, munitions, targets, and other systems to facilitate understanding of the activities in which these systems are used. Underwater sound is described as one of two types for the purposes of the Navy's application: impulsive and non-impulsive. Underwater detonations of explosives and other percussive events are impulsive sounds. Sonar and similar sound producing systems are categorized as non-impulsive sound sources.

2.3.1 Sonar and Other Non-impulsive Sources

Modern sonar technology includes a variety of sonar sensor and processing systems. The simplest active sonar emits sound waves, or "pings," sent out in multiple directions and the sound waves then reflect off of the target object in multiple directions. The sonar source calculates the time it takes for the reflected sound waves to return; this calculation determines the distance to the target object. More sophisticated active sonar systems emit a ping and then rapidly scan or listen to the sound waves in a specific area. This provides both distance to the target and directional information. Even more advanced sonar systems use multiple receivers to listen to echoes from several directions simultaneously and provide efficient detection of both direction and distance. The Navy rarely uses active sonar continuously throughout the listed activities. When sonar is in use, the pings occur at intervals, referred to as a duty cycle, and the signals themselves are very short in duration. Even when the Navy is "operating continuously" while conducting ASW training, the sonar sends out a ping nominally once every 50 seconds, it

does not ping continuously when it is in operation. Therefore, even when operating continuously sonar signals are only actively transmitting 2% of the time. The Navy utilizes sonar systems and other acoustic sensors in support of a variety of mission requirements. Primary uses include the detection of and defense against submarines (anti-submarine warfare) and mines (mine warfare); safe navigation and effective communications; use of unmanned undersea vehicles; and oceanographic surveys.

2.3.2 Ordnance and Munitions

Most ordnance and munitions used during training and testing events fall into three basic categories: projectiles (such as gun rounds), missiles (including rockets), and bombs. Ordnance can be further defined by their net explosive weight, which considers the type and quantity of the explosive substance without the packaging, casings, bullets, etc. Net explosive weight (NEW) is the trinitrotoluene (TNT) equivalent of energetic material, which is the standard measure of strength of bombs and other explosives. For example, a 12.7-centimeter (cm) shell fired from a Navy gun is analyzed at about 9.5 pounds (lb) (4.3 kilograms (kg)) of NEW. The Navy also uses non-explosive ordnance in place of high explosive ordnance in many training and testing events. Non-explosive ordnance munitions look and perform similarly to high explosive ordnance, but lack the main explosive charge.

2.3.3 Defense Countermeasures

Naval forces depend on effective defensive countermeasures to protect themselves against missile and torpedo attack. Defensive countermeasures are devices designed to confuse, distract, and confound precision guided munitions. Defensive countermeasures analyzed in this opinion include acoustic countermeasures, which are used by surface ships and submarines to defend against torpedo attack. Acoustic countermeasures are either released from ships and submarines, or towed at a distance behind the ship.

2.3.4 Mine Warfare Systems

The Navy divides mine warfare systems into two categories: mine detection and mine neutralization. Mine detection systems are used to locate, classify, and map suspected mines, on the surface, in the water column, or on the sea floor. The Navy analyzed the following mine detection systems for potential impacts to marine mammals:

- Towed or hull-mounted mine detection systems. These detection systems use acoustic and laser or video sensors to locate and classify suspect mines. Fixed and rotary wing platforms, ships, and unmanned vehicles are used for towed systems, which can rapidly assess large areas.

- Unmanned/remotely operated vehicles. These vehicles use acoustic and video or lasers to locate and classify mines and provide unique capabilities in nearshore littoral areas, surf zones, ports, and channels.

- Marine mammal systems. The Navy deploys trained Atlantic bottlenose dolphins (*Tursiops truncatus*) and California sea lions (*Zalopus californianus*) for integrated training involving two primary mission areas: to find objects such as inert mine shapes, and to detect swimmers or other intruders around Navy facilities such as piers. These systems also include one or more motorized small boats and several crew members for

each trained marine mammal. When not engaged in training, Navy marine mammals are housed in temporary enclosures either on land or aboard ships.

2.3.5 Mine Neutralization Systems

Mine neutralization systems disrupt, disable, or detonate mines to clear ports and shipping lanes, as well as littoral, surf, and beach areas in support of naval amphibious operations. The Navy analyzed the following mine neutralization systems for potential impacts to marine mammals:

- Towed influence mine sweep systems. These systems use towed equipment that mimic a particular ship's magnetic and acoustic signature triggering the mine and causing it to explode.

- Unmanned/remotely operated mine neutralization systems. Surface ships and helicopters operate these systems, which place explosive charges near or directly against mines to destroy the mine.

- Airborne projectile-based mine clearance systems. These systems neutralize mines by firing a small or medium-caliber non-explosive, supercavitating projectile from a hovering helicopter.

- Diver emplaced explosive charges. Operating from small craft, divers put explosive charges near or on mines to destroy the mine or disrupt its ability to function.

2.4 Proposed Training Activity Levels

The following table provides a summary of training activities (as described in Section 2.1 above) including tempo and quantities of inert and live munitions that the Navy plans to expend during training that were analyzed by the U.S. Navy. Munitions that contain explosives are shaded grey in the table to highlight activities that might have greater potential for impact to listed species.

Table 15. Training Activities Ocurring in the Action Area

Range Activity	No. of Activities (per year)	Ordnance (Number per year)	Location
Anti-Air Warfare			
Air Combat Maneuver (ACM)	4,800	None	Study Area > 12 nm from land: SUA
Air Defense Exercise (ADEX)	100	None	Study Area > 12 nm from land: SUA
Air Intercept Control (AIC)	4,800	None	Study Area > 12 nm from land: SUA
Gunnery Exercise (Air-to-Air) – Medium-caliber (GUNEX [A-A]) Medium-caliber	36	9,000 rounds	Study Area SUA > 12 nm from land
Missile Exercise (Air-to-Air) (MISSILEX [A-A])	18	36 explosive missiles	Study Area SUA > 12 nm from land
Gunnery Exercise (Surface-to-Air) – Large-caliber (GUNEX [S-A]) – Large-caliber	5	40 rounds	Study Area SUA > 12 nm from land

Range Activity	No. of Activities (per year)	Ordnance (Number per year)	Location
Gunnery Exercise (Surface-to-Air) – Medium-caliber (GUNEX [S-A]) – Medium-caliber	12	24,000 rounds	Study Area SUA > 12 nm from land
Missile Exercise (Surface-to-Air) (MISSILEX [S-A])	15	15 explosive missiles	Study Area SUA > 12 nm from land
Strike Warfare (STW)			
Combat Search and Rescue	80	None	MIRC
Bombing Exercise (Air-to-Ground) (BOMBEX [A-G])*	2,300	2,670 NEPM 6,242 explosive rounds	FDM
Gunnery Exercise (Air-to-Ground) (GUNEX [A-G])*	96	24,000 small-caliber rounds 94,150 medium-caliber rounds 17,350 explosive med.-caliber rounds 200 explosive large-caliber rounds	FDM
Missile Exercise (MISSILEX)*	85	2,000 explosive rockets 85 explosive missiles	FDM
Amphibious Warfare (AMW)			
Amphibious Rehearsal, No Landing – Marine Air Ground Task Force	12	None	Study Area and Nearshore
Amphibious Assault	6	Blanks; Simunitions	MIRC; Tinian; Guam
Amphibious Raid	6	Blanks; Simunitions	MIRC; Tinian; Guam; Rota
Anti-Surface Warfare (ASUW)			
Gunnery Exercise (Air-to-Surface) – Small-caliber (GUNEX [A-S]) – Small-caliber	242	48,040 rounds	Study Area SUA > 12 nm from land
Gunnery Exercise (Air-to-Surface) – Medium-caliber (GUNEX [A-S]) – Medium-caliber	295	36,650 (7,150 explosive)	Study Area SUA > 12 nm from land; Transit Corridor
Missile Exercise (Air-to-Surface) – Rocket (MISSILEX [A-S] – Rocket)	3	114 rockets (114 explosive)	Study Area SUA > 12 nm from land
Missile Exercise (Air-to-Surface) (MISSILEX [A-S])	20	20 explosive missiles	Study Area SUA > 12 nm from land
Laser Targeting (at sea)	600	None	Study Area SUA > 12 nm from land
Bombing Exercise (Air-to-Surface) (BOMBEX [A-S])	37	368 NEPM 184 explosive	Study Area > 50 nm from land

Range Activity	No. of Activities (per year)		Ordnance (Number per year)	Location
Torpedo Exercise (Submarine-to-Surface)	5		10 EXTORP	Study Area > 3 nm from land
Missile Exercise (Surface-to-Surface) (MISSILEX [S-S])	12		12 Missiles explosive	Study Area > 50 nm from land
Gunnery Exercise (Surface-to-Surface) Ship – Large-caliber (GUNEX [S-S] – Ship) Large-caliber	140		5,698 rounds (500 explosive)	Study Area SUA > 12 nm from land; Transit Corridor
Gunnery Exercise (Surface-to-Surface) Ship – Small- and Medium-caliber (GUNEX [S-S] – Ship) Small- and Medium-caliber	100		21,900 rounds (900 explosive)	Study Area SUA > 12 nm from land; Transit Corridor
Sinking Exercise (SINKEX) Representative ordnance. Actual ordnance used will vary (typically less than shown).	2		28 explosive Bombs 42 explosive Missiles 800 explosive Large-caliber rounds 2 MK-48 explosive 4 explosive Demolitions	Study Area > 50 nm from land and > 1,000 fathoms depth
Gunnery Exercise (Surface-to-Surface) Boat – Small and Medium-caliber (GUNEX [S-S] – Boat	Medium-caliber	10	2,100 (100 explosive)	Study Area SUA > 12 nm from land; Transit Corridor
	Small-caliber	40	36,000 rounds	Study Area > 3 nm from land; Transit Corridor
Maritime Security Operations (MSO)	40		200 G911 anti-swimmer grenade	Study Area; MIRC
Anti-Submarine Warfare (ASW)				
Tracking Exercise – Helicopter (TRACKEX – Helo)	62		None/ REXTORP	Study Area > 3 nm from land; Transit Corridor
Torpedo Exercise – Helicopter (TORPEX – Helo)	4		4 EXTORP	Study Area > 3 nm from land
Tracking Exercise – Maritime Patrol Advanced Extended Echo Ranging Sonobuoys	11		None	Study Area > 3 nm from land
Tracking Exercise – Maritime Patrol Aircraft (TRACKEX – Maritime Patrol Aircraft)	34		None/ REXTORP	Study Area > 3 nm from land
Torpedo Exercise – Maritime Patrol Aircraft (TORPEX – Maritime Patrol Aircraft)	4		4 EXTORP	Study Area > 3 nm from land
Tracking Exercise – Surface (TRACKEX – Surface)	CG/DDG-92 FFG-30 LCS-10		None/ REXTORP	Study Area > 3 nm from land

Range Activity	No. of Activities (per year)	Ordnance (Number per year)	Location
Torpedo Exercise – Surface (TORPEX – Surface)	3	3 EXTORP	Study Area > 3 nm from land
Tracking Exercise – Submarine (TRACKEX – Sub)	12	None	Study Area > 3 nm from land; Transit Corridor
Torpedo Exercise – Submarine (TORPEX – Sub)	10	40 MK-48 EXTORP	Study Area > 3 nm from land
Major Training Activities			
Joint Expeditionary Exercise	1	Note 1	Study Area; MIRC
Joint Multi-Strike Group Exercise	1	Note 1	Study Area; MIRC
Marine Air Ground Task Force Exercise (Amphibious) – Battalion	4	Note 1	Study Area to nearshore; MIRC; Tinian; Guam; Rota; Saipan; FDM
Special Purpose Marine Air Ground Task Force Exercise	2	Note 1	Study Area to nearshore; MIRC; Tinian; Guam; Rota; Saipan
Electronic Warfare (EW)			
Electronic Warfare Operations (EW Ops)	480	None	Study Area
Counter Targeting Flare Exercise (FLAREX) – Aircraft	3,200	25,600 cartridges	Study Area > 12 nm from land
Counter Targeting Chaff Exercise (CHAFFEX) – Ship	40	240 cartridges	Study Area > 12 nm from land
Counter Targeting Chaff Exercise (CHAFFEX) – Aircraft	3,200	25,600 cartridges	Study Area > 12 nm from land
Mine Warfare (MIW)			
Civilian Port Defense	1	Note 1	Mariana littorals; MIRC; Inner and Outer Apra Harbor
Mine Laying	4	480 mine shapes	MIRC Warning Areas
Mine Neutralization – Explosive Ordnance Disposal (EOD)	20	20 explosive charges	MIRC mine neutralization sites at Piti and Outer Apra Harbor site are 10 lb. NEW maximum and 20 lb NEW maximum at Agat Bay Mine Neutralization Site
Limpet Mine Neutralization System/Shock Wave Generator	40	40 charges	Mariana littorals; Inner and Outer Apra Harbor
Submarine Mine Exercise	16	n/a	Study Area; nearshore
Airborne Mine Countermeasure – Mine Detection	4	n/a	Study Area; nearshore

Range Activity	No. of Activities (per year)	Ordnance (Number per year)	Location
Mine Countermeasure Exercise – Towed Sonar (AQS-20, LCS)	4	n/a	Study Area
Mine Countermeasure Exercise – Surface (SMCMEX) Sonar (SQQ-32, MCM)	4	n/a	Study Area
Mine Neutralization – Remotely Operated Vehicle Sonar (ASQ-235 [AQS-20], SLQ-48)	4	4 explosive neutralizers	Study Area
Mine Countermeasure – Towed Mine Detection	4	n/a	Study Area
Naval Special Warfare (NSW)			
Personnel Insertion/ Extraction	240	None	MIRC; Guam; Tinian; Rota
Underwater Demolition Qualification/ Certification	30	30 explosive charges	MIRC underwater demolition sites, 20 lb. NEW maximum charge (except Piti 10 lb. NEW maximum)
Other			
Surface Ship Sonar Maintenance	42	None	Study Area > 3 nm from land; Inner Apra Harbor; Transit Corridor
Submarine Sonar Maintenance	48	None	Study Area > 3 nm from land; Inner Apra Harbor; Transit Corridor
Small Boat Attack	6	2,100 small-caliber rounds	Study Area > 3 nm from land
	12	4,000 blank rounds	Study Area
Submarine Navigation	8	None	Apra Harbor and Mariana littorals
Search and Rescue At Sea	40	None	Study Area
Precision Anchoring	18	None	Apra Harbor; Mariana Islands anchorages

Notes:
(1) Exercise is composed of various activities accounted for elsewhere within Table
(2) Discussed as an embedded training activity to CHAFFEX/FLAREX in MIRC EIS/OEIS Appendix D (Air Quality Calculations and Record of Non-Applicability).
(3) CHAFF = Chaff Exercise, EIS = Environmental Impact Statement, EOD = Explosive Ordnance Disposal, EXTORP = Exercise Torpedo, FDM = Farallon de Medinilla, FLAREX = Flare Exercise, lb. = pounds, LCS = Littoral Combat Ship, MIRC = Mariana Islands Range Complex, mm = millimeters, n/a = Not Applicable, NEPM = Non-explosive Practice Munitions, NEW = Net Explosive Weight, nm = nautical miles, OEIS = Overseas Environmental Impact Statement, REXTORP = Recoverable Exercise Torpedo, SUA = Special Use Airspace
*** Ordnance are dropped on land (FDM) but are included in this table as a very small percentage may miss or richochet and end up in the water.**

2.5 Proposed Testing Activity Levels / Naval Air Systems Command

The following table provides a summary of testing activities including tempo and quantities of inert and live munitions that the Naval Air Systems Command plans to expend during testing that were analyzed by the U.S. Navy. Munitions containing explosives are shaded grey in the table to highlight activities that may have greater potential for impacts to listed resources than inert materials.

Table 16. Proposed Naval Air Systems Command Testing Activities

Range Activity	Action		
	No. of activities (per year)	Ordnance (Number per year)	Location
Anti-Surface Warfare (ASUW)			
Air-to-Surface Missile Test	8	8 harpoon missiles (4 explosive)	Action Area > 50 nm from land
Anti-Submarine Warfare (ASW)			
Anti-Submarine Warfare Tracking Test – Maritime Patrol Aircraft (Sonobuoys)	188	240 IEER/MAC 553 SUS	Action Area > 3 nm from land
Anti-Submarine Warfare Torpedo Test	40	40 EXTORP	Action Area > 3 nm from land
Broad Area Maritime Surveillance (BAMS) Testing – MQ-4C Triton	10	None	Action Area
Electronic Warfare (EW)			
Flare Test	10	None	Action Area > 3 nm from land

Notes: EIS = Environmental Impact Statement, EXTORP = Exercise Torpedo, IEER = Improved Extended Echo Ranging, MAC = Multi-static Active Coherent, nm = nautical miles, OEIS = Overseas Environmental Impact Statement, SUS = Signal Underwater Sound

2.6 Proposed Testing Activity Levels - Naval Sea Systems Command

The following table provides a summary of testing activities including tempo and quantities of inert and live munitions that the Naval Sea Systems Command plans to expend during testing that were analyzed by the U.S. Navy. Munitions containing explosives are shaded grey in the table to highlight activities that may have greater potential for impacts to listed resources than inert materials.

Table 17. Proposed Naval Sea Systems Command Testing Activities

Range Activity	Action			
	No. of activities (per year)		Ordnance (Number per year)	Location
Life Cycle Activities				
Ship Signature Testing	17		None	Action Area
Anti-Surface Warfare (ASUW)/Anti-Submarine Warfare (ASW) Testing				
Kinetic Energy Weapon Testing	50		2,000 projectiles	MIRC > 12 nm from land
	1 event total		5,000 projectiles	
Torpedo Testing	2		20 torpedoes (8 explosive)	MIRC > 3 nm from land
Countermeasure Testing	2		56 torpedoes	Action Area
At-Sea Sonar Testing	20		None	Action Area
New Ship Construction				
ASW Mission Package Testing	33		None	Action Area
MCM Mission Package Testing	32		48 neutralizers (24 explosive)	Action Area
ASUW Mission Package Testing	Gun Testing – Small-caliber	4	2,000 rounds	Action Area; Warning Area > 12 nm from land

Range Activity	Action			
	No. of activities (per year)		Ordnance (Number per year)	Location
	Gun Testing – Medium-caliber (30 mm)	4	4,080 rounds (2,040 explosive)	
	Gun Testing – Large-caliber (57 mm)	4	5,600 rounds (3,920 in-air explosive)	
	Missile/ Rocket Testing	4	32 missiles/ rockets (16 explosive)	

Notes: IEER = Improved Extended Echo Ranging, MCM = Mine Countermeasure, MIRC = Mariana Islands Range Complex, mm = millimeters, nm = nautical miles

2.7 Office of Naval Research and Naval Research Laboratory Testing Activities

As the Department of the Navy's Science and Technology provider, Office of Naval Research and Naval Research Laboratory provide technology solutions for Navy and Marine Corps needs. The Office of Naval Research's mission, defined by law, is to plan, foster, and encourage scientific research in recognition of its paramount importance as related to the maintenance of future naval power, and the preservation of national security.

Further, Office of Naval Research manages the Navy's basic, applied, and advanced research to foster transition from science and technology to higher levels of research, development, test, and evaluation. The Ocean Battlespace Sensing Department explores science and technology in the areas of oceanographic and meteorological observations, modeling, and prediction in the battlespace environment; submarine detection and classification (anti-submarine warfare); and mine warfare applications for detecting and neutralizing mines in both the ocean and littoral environment. The Office of Naval Research events include research, development, test, and evaluation activities; surface processes acoustic communications experiments; shallow and deep water acoustic communications experiments; sediment acoustics experiments; shallow and deep water acoustic propagation experiments; and long-range acoustic propagation experiments.

2.8 U.S. Navy Proposed Mitigation

This section summarizes the Navy's mitigation measures, that were developed in close coordination with NMFS' Office of Protected Resources based on previous consultations and lessons-learned from employment during Phase I (2010 to 2015) training and testing activities. Table 19 provides a summary of the Navy's proposed mitigation measures. These measures are

also described in NMFS' proposed final rule in this opinion. The measures presented in the table are discussed in greater detail in the Final EIS/OEIS, May 2015.

Table 19. Summary of the U.S. Navy's Proposed Mitigation

Activity Category or Mitigation Area	Recommended Lookout Procedural Measure	Recommended Mitigation Zone and Protection Focus
Specialized Training	Lookouts will complete the Introduction to the U.S. Navy Afloat Environmental Compliance Training Series and the U.S. Navy Marine Species Awareness Training or civilian equivalent.	The mitigation zones observed by Lookouts are specified for each Mitigation Zone Procedural Measure below.
Low-Frequency and Hull-Mounted Mid-Frequency Active Sonar during Anti-Submarine Warfare and Mine Warfare	2 Lookouts (general) 1 Lookout (minimally manned, moored, or anchored)	Sources that can be powered down: 1,000 yd. (914 m) and 500 yd. (457 m) power downs and 200 yd. (183 m) shutdown for marine mammals (hull-mounted mid-frequency and low-frequency) and sea turtles (low-frequency only). Sources that cannot be powered down: 200 yd. (183 m) shutdown for marine mammals and sea turtles.
High-Frequency and Non-Hull Mounted Mid-Frequency Active Sonar	1 Lookout	200 yd. (183 m) for marine mammals (high-frequency and mid-frequency), sea turtles (bins MF8, MF9, MF10, and MF12 only)
Improved Extended Echo Ranging Sonobuoys	1 Lookout	600 yd. (549 m) for marine mammals and sea turtles Passive acoustic monitoring conducted with Navy assets participating in the activity.
Explosive Sonobuoys using >0.5–2.5 lb. NEW	1 Lookout	350 yd. (320 m) for marine mammals and sea turtles Passive acoustic monitoring conducted with Navy assets participating in the activity.
Anti-Swimmer Grenades	1 Lookout	200 yd. (183 m) for marine mammals and sea turtles
Mine Countermeasures and Mine Neutralization using Positive Control Firing Devices	General: 1 or 2 Lookouts (NEW dependent) Diver-placed: 2 Lookouts	NEW dependent for marine mammals, sea turtles, and hammerhead sharks
Mine Neutralization Activities Using Diver-Placed Time-Delay Firing Devices	4 Lookouts	Up to 10-minute time-delay using up to 20 lb. NEW: 1,000 yd. (914 m) for marine mammals, sea turtles, and hammerhead sharks.
Explosive and Non-Explosive Gunnery Exercises – Small- and Medium-Caliber Using a Surface Target	1 Lookout	200 yd. (183 m) for marine mammals and sea turtles

Activity Category or Mitigation Area	Recommended Lookout Procedural Measure	Recommended Mitigation Zone and Protection Focus
Explosive and Non-Explosive Gunnery Exercises – Large-Caliber Using a Surface Target	1 Lookout	Explosive: 600 yd. (549 m) for marine mammals and sea turtles Non-Explosive: 200 yd. (183 m) for marine mammals and sea turtles Both: 70 yd. (64 m) within 30 degrees on either side of the gun target line on the firing side for marine mammals and sea turtles Both: 350 yd. (320 m) for surveyed shallow coral reefs
Non-Explosive Missile Exercises and Explosive Missile Exercises (Including Rockets) up to 250 lb. NEW using a Surface Target	1 Lookout	900 yd. (823 m) for marine mammals and sea turtles 350 yd. (320 m) for surveyed shallow coral reefs
Explosive Missile Exercises (Including Rockets) from > 250 to 500 lb. NEW using a Surface Target	1 Lookout	2,000 yd. (1.8 km) for marine mammals and sea turtles 350 yd. (320 m) for surveyed shallow coral reefs
Bombing Exercises, Explosive and Non-Explosive	1 Lookout	Explosive: 2,500 yd. (2.3 km) for marine mammals and sea turtles Non-Explosive: 1,000 yd. (914 m) for marine mammals and sea turtles Both: 350 yd. (320 m) for surveyed shallow coral reefs
Torpedo (Explosive) Testing	1 Lookout	2,100 yd. (1.9 km) for marine mammals and sea turtles and jellyfish aggregations Passive acoustic monitoring conducted with Navy assets participating in the activity.
Sinking Exercises	2 Lookouts	2.5 nm for marine mammals and sea turtles and jellyfish aggregations. Passive acoustic monitoring conducted with Navy assets participating in the activity.
Vessel Movements	1 Lookout	500 yd. (457 m) for whales 200 yd. (183 m) for all other marine mammals (except bow riding dolphins)
Towed In-Water Device Use	1 Lookout	250 yd. (229 m) for marine mammals

Activity Category or Mitigation Area	Recommended Lookout Procedural Measure	Recommended Mitigation Zone and Protection Focus
Precision Anchoring	No Lookouts in addition to standard personnel standing watch	Avoidance of precision anchoring within the anchor swing diameter of shallow coral reefs, live hardbottom, artificial reefs, and shipwrecks Except at existing anchorages as well as at near-shore training areas around Guam and in Apra Harbor, the Navy will not conduct precision anchoring activities within the anchor swing diameter of surveyed shallow coral reefs, live hardbottom, artificial reefs, and shipwrecks.
Shallow Coral Reefs, Hardbottom Habitat, Artificial Reefs, and Shipwrecks	No Lookouts in addition to standard personnel standing watch	Except at existing anchorages as well as at near-shore training areas around Guam and in Apra Harbor, the Navy will not conduct precision anchoring within the anchor swing diameter, or explosive mine countermeasure and neutralization activities within 350 yd. (320 m) of surveyed shallow coral reefs, live hardbottom, artificial reefs, and shipwrecks. No explosive or non-explosive small-, medium-, and large-caliber gunnery exercises using a surface target, explosive or non-explosive missile exercises using a surface target, explosive and non-explosive bombing exercises, or at-sea explosive testing within 350 yd. (320 m) of surveyed shallow coral reefs

2.9 NMFS' Promulgation of Regulations Pursuant to the Marine Mammal Protection Act (MMPA)

On April 17, 2013, NMFS' Permits Division received an application from the U.S. Navy requesting regulations and a LOA for the take of 26 species of marine mammals incidental to Navy training and testing activities to be conducted in the MITT Study Area over 5 years. The Navy is requesting regulations that would establish a process for authorizing take, via a five-year LOA, of marine mammals for training and testing activities proposed to be conducted from August 2015 through August 2020.

The regulations establish a framework under the MMPA whereby the Navy may obtain authorization to "take" marine mammals only if the "take" occurs within the MITT Study Area incidental to the Navy's testing and training activities. The framework includes the following: (1) specific activity and geographical region where "take" make occur, (2) dates when "take" may occur, (3) permissible methods of taking, (4) prohibitions on taking of marine mammals, (5) mitigation required, (6) monitoring and reporting requirements, (7) how LOAs may be applied for, (8) specifics of LOAs, and (9) renewals and modifications of LOAs and adaptive management processes.

In order to promulgate the Final Rule, NMFS must determine that the incidental taking of marine mammals will have a negligible impact on the species or stock(s) and will not have an unmitigable adverse impact on the availability of the species or stock(s) for subsistence uses (where relevant). NMFS has defined negligible impact in 50 CFR 216.103 as "an impact resulting from the specified activity that cannot be reasonably expected to, and is not reasonably likely to, adversely affect the species or stock through effects on annual rates of recruitment or survival."

NMFS Permits Division determined that the Navy's proposed action (summarized above) would result in the take of ESA-listed species and that such take would be in the form of exposure to sound or pressure waves in the water and interactions with vessels. The specific activity and geographic region where take may occur, the dates when take may occur, and permissible method of taking that will be set by the proposed regulations are all consistent with the Navy's action described previously in this Opinion so they will not be reiterated here. The estimated take of ESA-listed marine mammals is presented in Table 20. NMFS Permits Division's proposed final rule is based on the information contained in the revised LOA application.

Marine mammals present in the Study Area may be exposed to sound from active sonar and underwater detonations. The Navy requested MMPA authorization to take individuals of ESA-listed, marine mammal species by Level B harassment.

Table 20. Species Specific Take Requests from Modeling Estimates of Impulse and Non-Impulse Source Effects for All Training and Testing Activities Pursuant to the MMPA

Species	Annually			Total Over the five-year MMPA Rule		
	Level B	Level A	Mortality	Level B	Level A	Mortality
Humpback Whale	860	0	0	4,300	0	0
Blue whale	28	0	0	140	0	0
Fin Whale	28	0	0	140	0	0
Sei Whale	319	0	0	1,595	0	0

Species	Annually			Total Over the five-year MMPA Rule		
	Level B	Level A	Mortality	Level B	Level A	Mortality
Sperm Whale	506	0	0	2,530	0	0

There are five marine mammal species under NMFS' jurisdiction included in the Navy's incidental take authorization request that are listed as threatened or endangered under the ESA with confirmed or possible occurrence in the Study Area. They are: blue whale, humpback whale, fin whale, sei whale, and sperm whale. We are consulting with NMFS' Permits Division pursuant to section 7 of the ESA, on the issuance of a rule and LOA under section 101(a)(5)(A) of the MMPA for MITT activities. We have also determined that NMFS Permit Division's actions are interdependent with MITT. Therefore, both actions are assessed in this Opinion. The proposed MMPA rule will amend 50 CFR §218. The proposed rule provides a five-year framework for authorizations including descriptions of the specified activity and specified geographical region (Sec. 218.80), effective dates and definitions (Sec. 218.81), permissible methods of taking (Sec. 218.82), prohibitions (Sec. 218.83), mitigation (Sec. 218.84), requirements for monitoring and reporting (Sec. 218.85), and procedures for applications for letters of authorization (Sec. 218.86), issuance of letters of authorization (Sec. 218.87), and Renewals and Modifications of Letters of Authorization and Adaptive Management (Sec. 218.88).

We provide excerpts from the proposed rule, including excerpts of the description of the activity (anticipated levels of activities), and permissible methods of taking and mitigation for the five-year period. Statements in the proposed rule regarding ESA-listed species are emphzised in bold.

2.9.1 PART 218—REGULATIONS GOVERNING THE TAKING AND IMPORTING OF MARINE MAMMALS

1. The authority citation for part 218 continues to read as follow: Authority: 16 U.S.C. 1361 et seq.

2. Subpart J is added to part 218 to read as follows:

2.9.1.1 Subpart J – Taking and Importing Marine Mammals; U.S. Navy's Mariana Islands Training and Testing (MITT)

§ 218.90 Specified activity and specified geographical region.
(a) Regulations in this subpart apply only to the U.S. Navy for the taking of marine mammals that occurs in the area outlined in paragraph (b) of this section and that occurs incidental to the activities described in paragraph (c) of this section.

(b) The taking of marine mammals by the Navy is only authorized if it occurs within the MITT Study Area, which includes the MIRC and areas to the north and west. The Study Area includes established ranges, operating areas, warning areas, and special use airspace in the region of the Mariana Islands that are part of the MIRC, its surrounding seas, and a transit corridor to the

Hawaii Range Complex. The Study Area also includes Navy pierside locations where sonar maintenance and testing may occur.

(c) The taking of marine mammals by the Navy is only authorized if it occurs incidental to the following activities within the designated amounts of use:

(1) Non-impulsive Sources Used During Training and Testing:
- (i) Low-frequency (LF) Source Classes:
  - (A) LF4 – an average of 123 hours per year.
  - (B) LF5 – an average of 11 hours per year.
  - (C) LF6 – an average of 40 hours per year.
- (ii) Mid-frequency (MF) Source Classes:
  - (A) MF1 – an average of 1,872 hours per year.
  - (B) MF2 – an average of 625 hours per year.
  - (C) MF3 – an average of 192 hours per year.
  - (D) MF4 – an average of 214 hours per year.
  - (E) MF5 – an average of 2,588 items per year.
  - (F) MF6 – an average of 33 items per year.
  - (G) MF8 – an average of 123 hours per year.
  - (H) MF9 – an average of 47 hours per year.
  - (I) MF10 – an average of 231 hours per year.
  - (J) MF11 – an average of 324 hours per year.
  - (K) MF12 – an average of 656 hours per year.
- (iii) High-frequency (HF) and Very High-frequency (VHF) Source Classes:
  - (A) HF1 – an average of 113 hours per year.
  - (B) HF4 – an average of 1,060 hours per year.
  - (C) HF5 – an average of 336 hours per year.
  - (D) HF6 – an average of 1,173 hours per year.
- (iv) Anti-Submarine Warfare (ASW) Source Classes:
  - (A) ASW1 – an average of 144 hours per year.
  - (B) ASW2 – an average of 660 items per year.
  - (C) ASW3 – an average of 3,935 hours per year.
  - (D) ASW4 – an average of 32 items per year.
- (v) Torpedoes (TORP) Source Classes:
  - (A) TORP1 – an average of 115 items per year.
  - (B) TORP2 – an average of 62 items per year.
- (vi) Acoustic Modems (M):
  - (A) M3 – an average of 112 hours per year.
  - (B) [Reserved]
- (vii) Swimmer Detection Sonar (SD):
  - (A) SD1 – an average 2,341 hours per year.

(2) Impulsive Source Detonations During Training and Testing:
- (i) Explosive Classes:
  - (A) E1 (0.1 to 0.25 lb NEW) – an average of 10,140 detonations per year.
  - (B) E2 (0.26 to 0.5 lb NEW) – an average of 106 detonations per year.
  - (C) E3 (>0.5 to 2.5 lb NEW) – an average of 932 detonations per year.
  - (D) E4 (>2.5 to 5 lb NEW) – an average of 420 detonations per year.

(E) E5 (>5 to 10 lb NEW) – an average of 684 detonations per year.
(F) E6 (>10 to 20 lb NEW) – an average of 76 detonations per year.
(G) E8 (>60 to 100 lb NEW) – an average of 16 detonations per year.
(H) E9 (>100 to 250 lb NEW) – an average of 4 detonations per year.
(I) E10 (>250 to 500 lb NEW) – an average of 12 detonations per year.
(J) E11 (>500 to 650 lb NEW) – an average of 6 detonations per year.
(K) E12 (>650 to 2,000 lb NEW) – an average of 184 detonations per year.

(ii) [Reserved]

2.9.1.2 § 218.91 Effective dates and definitions.

(a) Regulations are effective [INSERT DATE OF FILING] through [INSERT DATE FIVE YEARS AFTER DATE OF FILING].

(b) The following definitions are utilized in these regulations:

(1) *Uncommon Stranding Event (USE)* – A stranding event that takes place within an OPAREA where a Major Training Exercise (MTE) occurs and involves any one of the following:

(i) Two or more individuals of any cetacean species (not including mother/calf pairs), unless of species of concern listed in paragraph (b)(1)(ii) of this section found dead or live on shore within a 2-day period and occurring within 30 miles of one another.

(ii) A single individual or mother/calf pair of any of the following marine mammals of concern: beaked whale of any species, *Kogia* spp., Risso's dolphin, melon-headed whale, humpback whale, sperm whale, blue whale, fin whale, or sei whale.

(iii) A group of two or more cetaceans of any species exhibiting indicators of distress.

(2) *Shutdown* – The cessation of active sonar operation or detonation of explosives within 14 nautical miles of any live, in the water, animal involved in a USE.

2.9.1.3 § 218.92 Permissible methods of taking.

(a) Under a Letter of Authorization (LOA) issued pursuant to § 218.97, the Holder of the Letter of Authorization may incidentally, but not intentionally, take marine mammals within the area described in § 218.90, provided the activity is in compliance with all terms, conditions, and requirements of these regulations and the appropriate LOA.

(b) The activities identified in § 218.90(c) must be conducted in a manner that minimizes, to the greatest extent practicable, any adverse impacts on marine mammals and their habitat.

(c) The incidental take of marine mammals under the activities identified in § 218.90(c) is limited to the following species, by the identified method of take:

(1) Level B Harassment for all Training and Testing Activities:

(i) Mysticetes:

(A) Blue whale (*Balaenoptera musculus*) – 140 (an average of 28 annually)

(B) Bryde's whale (*Balaenoptera edeni*) – 1,990 (an average of 398 annually)

(C) Fin whale (*Balaenoptera physalus*) - 140 (an average of 28 annually)

(D) Humpback whale (*Megaptera novaeangliae*) – 4,300 (an average of 860 annually)

(E) Minke whale (*Balaenoptera acutorostrata*) – 505 (an average of 101 annually)

(F) Sei whale (*Balaenoptera borealis*) - 1,595 (an average of 319 annually)

(G) Omura's whale (*Balaenoptera omurai*) - 515 (an average of 103 annually)

(ii) Odontocetes:

(A) Blainville's beaked whale (*Mesoplodon densirostris*) – 22,130 (an average of 4,426 annually)

(B) Bottlenose dolphin (*Tursiops truncatus*) – 3,705 (an average of 741 annually)

(C) Cuvier's beaked whale (*Ziphius cavirostris*) – 112,705 (an average of 22,541 annually)

(D) Dwarf sperm whale (*Kogia sima*) – 71,085 (an average of 14,217 annually)

(E) False killer whale (*Pseudorca crassidens*) – 2,775 (an average of 555 annually)

(F) Fraser's dolphin (*Lagenodelphis hosei*) – 12,860 (an average of 2,572 annually)

(G) Gingko-toothed beaked whale (*Mesoplodon ginkgodens*) – 19,485 (an average of 3,897 annually)

(H) Killer whale (*Orcinus orca*) – 420 (an average of 84 annually)

(I) Longman's beaked whale (*Indopacetus pacificus*) – 9,620 (an average of 1,924 annually)

(J) Melon-headed whale (*Peponocephala electra*) – 10,425 (an average of 2,085 annually)

(K) Pantropical spotted dolphin (*Stenella attenuata*) – 64,055 (an average of 12,811 annually)

(L) Pygmy killer whale (*Feresa attenuata*) – 525 (an average of 105 annually)

(M) Pygmy sperm whale (*Kogia breviceps*) – 27,895 (an average of 5,579 annually)

(N) Risso's dolphin (*Grampus griseus*) – 2,525 (an average of 505 annually)

(O) Rough-toothed dolphin (*Steno bredanensis*) – 9,095 (an average of 1,819 annually)

(P) Short-finned pilot whale (Globicephala macrorhynchus) – 9,075 (an average of 1,815 annually)

(Q) Sperm whale (*Physeter macrocephalus*) – 2,530 (an average of 506 annually)

(R) Spinner dolphin (*Stenella longirostris*) – 2,945 (an average of 589 annually)

(S) Striped dolphin (*Stenella coerulealba*) – 16,490 (an average of 3,298 annually)

(2) Level A Harassment for all Training and Testing Activities:

(i) Odontocetes:

(A) Dwarf sperm whale (*Kogia sima*) – 205 (an average of 41 annually)

(B) Pygmy sperm whale (*Kogia breviceps*) – 75 (an average of 15 annually)

2.9.1.4 § 218.93 Prohibitions.

Notwithstanding takings contemplated in § 218.92 and authorized by an LOA issued under §§ 216.106 and 218.97 of this chapter, no person in connection with the activities described in § 218.90 may:

(a) Take any marine mammal not specified in § 218.92(c);

(b) Take any marine mammal specified in § 218. 92(c) other than by incidental take as specified in § 218.92(c);

(c) Take a marine mammal specified in § 218.92(c) if such taking results in more than a negligible impact on the species or stocks of such marine mammal; or

(d) Violate, or fail to comply with, the terms, conditions, and requirements of these regulations or an LOA issued under §§ 216.106 and 218.97.

2.9.1.5 § 218.94 Mitigation.

(a) When conducting training and testing activities, as identified in § 218.90, the mitigation measures contained in the LOA issued under §§ 216.106 and 218.97 of this chapter must be implemented. These mitigation measures include, but are not limited to:

(1) *Lookouts* – The following are protective measures concerning the use of lookouts.

(i) Lookouts positioned on surface ships will be dedicated solely to diligent observation of the air and surface of the water. Their observation objectives will include, but are not limited to, detecting the presence of biological resources and

recreational or fishing boats, observing mitigation zones, and monitoring for vessel and personnel safety concerns.

(ii) Lookouts positioned in aircraft or on boats will, to the maximum extent practicable and consistent with aircraft and boat safety and training and testing requirements, comply with the observation objectives described above in § 218.94 (a)(1)(i).

(iii) Lookout measures for non-impulse sound:

(A) With the exception of vessels less than 65 ft (20 m) in length and ships that are minimally manned, ships using low-frequency or hull-mounted mid-frequency active sonar sources associated with anti-submarine warfare and mine warfare activities at sea will have two lookouts at the forward position. For the purposes of this rule, low-frequency active sonar does not include surface towed array surveillance system low-frequency active sonar.

(B) While using low-frequency or hull-mounted mid-frequency active sonar sources associated with anti-submarine warfare and mine warfare activities at sea, ships less than 65 ft (20 m) in length and ships that are minimally manned will have one lookout at the forward position of the vessel due to space and manning restrictions.

(C) Ships conducting active sonar activities while moored or at anchor (including pierside testing or maintenance) will maintain one lookout.

(D) Surface ships or aircraft conducting high-frequency or non-hull mounted mid-frequency active sonar activities associated with anti-submarine warfare and mine warfare activities at sea will have one lookout.

(iv) Lookout measures for explosives and impulse sound:

(A) Aircraft conducting IEER sonobuoy activities and explosive sonobuoy exercises will have one lookout.

(B) Surface vessels conducting anti-swimmer grenade activities will have one lookout.

(C) During general mine countermeasure and neutralization activities using up to a 20-lb net explosive weight detonation (bin E6 and below), vessels greater than 200 ft (61 m) will have two lookouts, while vessels less than 200 ft (61 m) or aircraft will have one lookout.

(D) Mine neutralization activities involving positive control diver-placed charges using up to a 20-lb net explosive weight detonation will have two

lookouts. The divers placing the charges on mines will report all marine mammal sightings to their supporting small boat or Range Safety Officer.

(E) When mine neutralization activities using diver-placed charges with up to a 20-lb net explosive weight detonation are conducted with a time-delay firing device, four lookouts will be used. Two lookouts will be positioned in each of two small rigid hull inflatable boats. When aircraft are used, the pilot or member of the aircrew will serve as an additional lookout. The divers placing the charges on mines will report all marine mammal sightings to their supporting small boat or Range Safety Officer.

(F) Surface vessels or aircraft conducting small- or medium-caliber gunnery exercises against a surface target will have one lookout.

(G) Aircraft conducting missile exercises (including rockets) against surface targets will have one lookout.

(H) Aircraft conducting bombing exercises will have one lookout.

(I) During explosive torpedo testing, one lookout will be used and positioned in an aircraft.

(J) During sinking exercises, two lookouts will be used. One lookout will be positioned in an aircraft and one on a surface vessel.

(K) Surface vessels conducting explosive and non-explosive large-caliber gunnery exercises will have one lookout.

(v) Lookout measures for physical strike and disturbance:

(A) While underway, surface ships will have at least one lookout.

(B) During activities using towed in-water devices, that are towed from a manned platform, one lookout will be used.

(C) Non-explosive small-, medium-, and large-caliber gunnery exercises using a surface target will have one lookout.

(D) Non-explosive bombing exercises will have one lookout.

(E) Aircraft conducting non-explosive missile exercises against a surface target will have one lookout.

(2) *Mitigation Zones* – The following are protective measures concerning the implementation of mitigation zones.

(i) Mitigation zones will be measured as the radius from a source and represent a distance to be monitored.

(ii) Visual detections of marine mammals within a mitigation zone will be communicated immediately to a watch station for information dissemination and appropriate action.

(iii) Mitigation zones for non-impulse sound:

(A) When marine mammals are visually detected, the Navy shall ensure that low-frequency and hull-mounted mid-frequency active sonar transmission levels are limited to at least 6 dB below normal operating levels (for sources that can be powered down during the activity) if any visually detected marine mammals are within 1,000 yd (914 m) of the source (i.e., the bow).

(B) The Navy shall ensure that low-frequency and hull-mounted mid-frequency active sonar transmissions are limited to at least 10 dB below the equipment's normal operating level (for sources that can be powered down during the activity) if any detected marine mammals are sighted within 500 yd (457 m) of the source.

(C) The Navy shall ensure that low-frequency and hull-mounted mid-frequency active sonar transmissions (for sources that can be turned off during the activity) are ceased if any visually detected marine mammals are within 200 yd (183 m) of the sonar dome. Active transmission will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone; (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source; (3) the mitigation zone has been clear from any additional sightings for a period of 30 minutes; (4) the ship has transited more than 2,000 yd. (1.8 kilometers [km]) beyond the location of the last sighting; or (5) the ship concludes that dolphins are deliberately closing in on the ship to ride the ship's bow wave (and there are no other marine mammal sightings within the mitigation zone).

(D) If the source is not able to be powered down during the activity (e.g., low-frequency sources within bins LF4 and LF5), mitigation will involve ceasing active transmission if a marine mammal is sighted within 200 yd. (183 m). Active transmission will recommence if any one of the following conditions is met: (1) the animal is observed existing the mitigation zone; (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source; (3) the mitigation zone has been clear from any additional sightings for a period of 30 minutes; or (4) the ship has transited more than 400 yd. (366 m) beyond the location of the last sighting.

(E) With the exception of activities involving platforms operating at high altitudes, when marine mammals are visually detected, the Navy shall

ensure that high-frequency and non-hull-mounted mid-frequency active sonar transmission (for sources that can be turned off during the activity) is ceased if any visually detected marine mammals are within 200 yd (183 m) of the source. Active transmission will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, (3) the mitigation zone has been clear from any additional sightings for a period of 10 minutes for an aircraft-deployed source, (4) the mitigation zone has been clear from any additional sightings for a period of 30 minutes for a vessel-deployed source, (5) the vessel or aircraft has repositioned itself more than 400 yd. (366 m) away from the location of the last sighting, or (6) the vessel concludes that dolphins are deliberately closing in to ride the vessel's bow wave (and there are no other marine mammal sightings within the mitigation zone).

(iv) Mitigation zones for explosive and impulse sound:

(A) A mitigation zone with a radius of 600 yd (549 m) shall be established for IEER sonobuoys (bin E4). Mitigation would include pre-exercise aerial observation and passive acoustic monitoring, which would begin 30 minutes before the first source/receiver pair detonation and continue throughout the duration of the exercise. The pre-exercise aerial observation would include the time it takes to deploy the sonobuoy pattern (deployment is conducted by aircraft dropping sonobuoys in the water). Explosive detonations would cease if a marine mammal is sighted within the mitigation zone. Detonations would recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 30 minutes.

Passive acoustic monitoring would be conducted with Navy assets, such as sonobuoys, already participating in the activity. These assets would only detect vocalizing marine mammals within the frequency bands monitored by Navy personnel. Passive acoustic detections would not provide range or bearing to detected animals, and therefore cannot provide locations of these animals. Passive acoustic detections would be reported to lookouts posted in aircraft and on vessels in order to increase vigilance of their visual observation.

(B) A mitigation zone with a radius of 350 yd (320 m) shall be established for explosive sonobuoys using 0.5-2.5 lb net explosive weight (bin E3). Mitigation would include pre-exercise aerial monitoring during deployment of the field of sonobuoy pairs (typically up to 20 minutes) and

continuing throughout the duration of the exercise within a mitigation zone of 350 yd (320 m) around an explosive sonobuoy. Explosive detonations would cease if a marine mammal is sighted within the mitigation zone. Detonations would recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 10 minutes.

Passive acoustic monitoring would also be conducted with Navy assets, such as sonobuoys, already participating in the activity. These assets would only detect vocalizing marine mammals within the frequency bands monitored by Navy personnel. Passive acoustic detections would not provide range or bearing to detected animals, and therefore cannot provide locations of these animals. Passive acoustic detections would be reported to lookouts posted in aircraft in order to increase vigilance of their visual observation.

(C) A mitigation zone with a radius of 200 yd (183 m) shall be established for anti-swimmer grenades (bin E2). Mitigation would include visual observation from a small boat immediately before and during the exercise within a mitigation zone of 200 yd (183 m) around an anti-swimmer grenade. Explosive detonations would cease if a marine mammal is sighted within the mitigation zone. Detonations would recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on its course and speed and the relative motion between the animal and the source, (3) the mitigation zone has been clear from any additional sightings for a period of 30 minutes, or (4) the activity has been repositioned more than 400 yd (366 m) away from the location of the last sighting.

(D) A mitigation zone ranging from 350 yd (320 m) to 800 yd (732 m), dependent on charge size and if the activity involves the use of diver-placed charges, shall be established for mine countermeasure and neutralization activities using positive control firing devices. Mitigation zone distances are specified for charge size in Table 7 of the preamble.

During general mine countermeasure and neutralization activities, mitigation would include visual observation from one or more small boats or aircraft beginning 30 minutes before, during, and 30 minutes after (when helicopters are not involved in the activity) or 10 minutes before, during, and 10 minutes after (when helicopters are involved in the activity) the completion of the exercise within the mitigation zones around the detonation site.

For activities involving diver-placed charges, visual observation would be conducted by either two small boats, or one small boat in combination with one helicopter. Boats would position themselves near the mid-point of the mitigation zone radius (but always outside the detonation plume radius and human safety zone) and travel in a circular pattern around the detonation location. When using two boats, each boat would be positioned on opposite sides of the detonation location, separated by 180 degrees. If used, helicopters would travel in a circular pattern around the detonation location.

For both general and diver-placed positive control mine countermeasure and neutralization activities, explosive detonations will cease if a marine mammal is sighted within the mitigation zone. Detonations will recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on a determination of its course and speed and the relative motion between the animal and the source, (3) the mitigation zone has been clear from any additional sightings for a period of 30 minutes, when helicopters are not involved in the activity or (4) the mitigation zone has been clear from any additional sightings for a period of 10 minutes when helicopters are involved in the activity.

(E) A mitigation zone with a radius of 1,000 yd (914 m) shall be established for mine countermeasure and neutralization activities using diver-placed time-delay firing devices (bin E6). Mine neutralization activities involving diver-placed charges would not include time-delay longer than 10 minutes. Mitigation would include visual observation from small boats or aircraft commencing 30 minutes before, during, and until 30 minutes after the completion of the exercise within a mitigation zone of 1,000 yd (914 m) around the detonation site. During activities using time-delay firing devices involving up to a 20 lb net explosive weight charge, visual observation will take place using two small boats. Fuse initiation would recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 30 minutes.

Survey boats would position themselves near the mid-point of the mitigation zone radius (but always outside the detonation plume radius/human safety zone) and travel in a circular pattern around the detonation location. One lookout from each boat would look inward toward the detonation site and the other lookout would look outward away from the detonation site. When using two small boats, each boat would be positioned on opposite sides of the detonation location, separated by 180

degrees. If available for use, helicopters would travel in a circular pattern around the detonation location.

(F) A mitigation zone with a radius of 200 yd (183 m) shall be established for small- and medium-caliber gunnery exercises with a surface target (bin E2). Mitigation would include visual observation from a vessel or aircraft immediately before and during the exercise within a mitigation zone of 200 yd (183 m) around the intended impact location. Vessels would observe the mitigation zone from the firing position. When aircraft are firing, the aircrew would maintain visual watch of the mitigation zone during the activity. Firing would cease if a marine mammal is sighted within the mitigation zone. Firing would recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on its course and speed and the relative motion between the animal and the source, (3) the mitigation zone has been clear from any additional sightings for a period of 10 minutes for a firing aircraft, (4) the mitigation zone has been clear from any additional sightings for a period of 30 minutes for a firing vessel, or (5) the intended target location has been repositioned more than 400 yd (366 m) away from the location of the last sighting.

(G) A mitigation zone with a radius of 600 yd (549 m) shall be established for large-caliber gunnery exercises with a surface target (bin E5). Mitigation would include visual observation from a ship immediately before and during the exercise within a mitigation zone of 600 yd (549 m) around the intended impact location. Ships would observe the mitigation zone from the firing position. Firing would cease if a marine mammal is sighted within the mitigation zone. Firing would recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 30 minutes.

(H) A mitigation zone with a radius of 900 yd (823 m) around the deployed target shall be established for missile exercises involving aircraft firing up to 250 lb net explosive weight using and a surface target (bin E9). When aircraft are firing, mitigation would include visual observation by the aircrew or supporting aircraft prior to commencement of the activity within a mitigation zone of 900 yd (823 m) around the deployed target. Firing would recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 10 minutes or 30 minutes (depending on aircraft type).

(I) A mitigation zone with a radius of 2,000 yd (1.8 km) shall be established for missile exercises involving aircraft firing >250 to 500 lb net explosive weight using and a surface target (bin E10). When aircraft are firing, mitigation would include visual observation by the aircrew prior to commencement of the activity within a mitigation zone of 2,000 yd (1.8 km) around the intended impact location. Firing would cease if a marine mammal is sighted within the mitigation zone. Firing would recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 10 minutes or 30 minutes (depending on aircraft type).

(J) A mitigation zone with a radius of 2,500 yd (2.3 km) shall be established for bombing exercises (bin E12). Mitigation would include visual observation from the aircraft immediately before the exercise and during target approach within a mitigation zone of 2,500 yd (2.3 km) around the intended impact location. Bombing would cease if a marine mammal is sighted within the mitigation zone. Bombing would recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 10 minutes.

(K) A mitigation zone with a radius of 2,100 yd (1.9 km) shall be established for torpedo (explosive) testing (except for aircraft operating at high altitudes) (bin E11). Mitigation would include visual observation by aircraft immediately before, during, and after the exercise within a mitigation zone of 2,100 yd (1.9 km) around the intended impact location. Firing would cease if a marine mammal is sighted within the mitigation zone. Firing would recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 10 minutes or 30 minutes (depending on aircraft type).

In addition to visual observation, passive acoustic monitoring would be conducted with Navy assets, such as passive ships sonar systems or sonobuoys, already participating in the activity. Passive acoustic observation would be accomplished through the use of remote acoustic sensors or expendable sonobuoys, or via passive acoustic sensors on submarines when they participate in the proposed action. These assets would only detect vocalizing marine mammals within the frequency bands monitored by Navy personnel. Passive acoustic detections would not

provide range or bearing to detected animals, and therefore cannot provide locations of these animals. Passive acoustic detections would be reported to the lookout posted in the aircraft in order to increase vigilance of the visual observation and to the person in control of the activity for their consideration in determining when the mitigation zone is free of visible marine mammals.

(L) A mitigation zone with a radius of 2.5 nautical miles around the target ship hulk shall be established for sinking exercises (bin E12). Mitigation would include aerial observation beginning 90 minutes before the first firing, visual observations from vessels throughout the duration of the exercise, and both aerial and vessel observation immediately after any planned or unplanned breaks in weapons firing of longer than 2 hours. Prior to conducting the exercise, the Navy would review remotely sensed sea surface temperature and sea surface height maps to aid in deciding where to release the target ship hulk.

The Navy would also monitor using passive acoustics during the exercise. Passive acoustic monitoring would be conducted with Navy assets, such as passive ships sonar systems or sonobuoys, already participating in the activity. These assets would only detect vocalizing marine mammals within the frequency bands monitored by Navy personnel. Passive acoustic detections would not provide range or bearing to detected animals, and therefore cannot provide locations of these animals. Passive acoustic detections would be reported to lookouts posted in aircraft and on vessels in order to increase vigilance of their visual observation. Lookouts will also increase observation vigilance before the use of torpedoes or unguided ordnance with a net explosive weight of 500 lb or greater, or if the Beaufort sea state is a 4 or above.

The exercise would cease if a marine mammal is sighted within the mitigation zone. The exercise would recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 30 minutes. Upon sinking the vessel, the Navy would conduct post-exercise visual observation of the mitigation zone for 2 hours (or until sunset, whichever comes first).

(M) A mitigation zone with a radius of 70 yd (64 m) within 30 degrees on either side of the gun target line on the firing side of the vessel for explosive and non-explosive large-caliber gunnery exercises conducted from a ship. Firing would cease if a marine mammal is sighted within the mitigation zone. Firing would recommence if any one of the following conditions is met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on its

course and speed and the relative motion between the animal and the source, (3) the mitigation zone has been clear from any additional sightings for a period of 30 minutes, or (4) the vessel has repositioned itself more than 140 yd (128 m) away from the location of the last sighting.

(v) Mitigation zones for vessels and in-water devices:

(A) A mitigation zone of 500 yd (457 m) for observed whales and 200 yd (183 m) for all other marine mammals (except bow riding dolphins) shall be established for all vessel movement, providing it is safe to do so.

(B) A mitigation zone of 250 yd (229 m) shall be established for all towed in-water devices that are towed from a manned platform, providing it is safe to do so.

(vi) Mitigation zones for non-explosive practice munitions:

(A) A mitigation zone of 200 yd (183 m) shall be established for non-explosive small-, medium-, and large-caliber gunnery exercises using a surface target. Mitigation would include visual observation immediately before and during the exercise within a mitigation zone of 200 m around the intended impact location. Firing would cease if a marine mammal is visually detected within the mitigation zone. Firing would recommence if any one of the following conditions are met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on its course and speed and the relative motion between the animal and the source, (3) the mitigation zone has been clear from any additional sightings for a period of 10 minutes for a firing aircraft, (4) the mitigation zone has been clear from any additional sightings for a period of 30 minutes for a firing vessel, or (5) the intended target location has been repositioned more than 400 yd (366 m) away from the location of the last sighting and the animal's estimated course direction.

(B) A mitigation zone of 1,000 yd (914 m) shall be established for non-explosive bombing exercises. Mitigation would include visual observation from the aircraft immediately before the exercise and during target approach within a mitigation zone of 1000 yd (914 m) around the intended impact location. Bombing would cease if a marine mammal is visually detected within the mitigation zone. Bombing would recommence if any one of the following conditions are met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 10 minutes.

(C) When aircraft are firing, a mitigation zone of 900 yd (823 m) around the deployed target shall be established for non-explosive missile exercises (including rockets) using a surface target. Firing would cease if a marine mammal is visually detected within the mitigation zone. Firing would recommence if any one of the following conditions are met: (1) the animal is observed exiting the mitigation zone, (2) the animal is thought to have exited the mitigation zone based on its course and speed and the relative motion between the animal and the source, or (3) the mitigation zone has been clear from any additional sightings for a period of 10 minutes or 30 minutes (depending on aircraft type).

(3) Stranding Response Plan:

(i) The Navy shall abide by the letter of the "Stranding Response Plan for Major Navy Training Exercises in the MITT Study Area," to include the following measures:

(A) Shutdown Procedures – When an Uncommon Stranding Event (USE - defined in § 218.91) occurs during a Major Training Exercise (MTE) in the MITT Study Area, the Navy shall implement the procedures described below.

(*1*) The Navy shall implement a shutdown (as defined § 218.91) when advised by a NMFS Office of Protected Resources Headquarters Senior Official designated in the MITT Study Area Stranding Communication Protocol that a USE involving live animals has been identified and that at least one live animal is located in the water. NMFS and the Navy will maintain a dialogue, as needed, regarding the identification of the USE and the potential need to implement shutdown procedures.

(*2*) Any shutdown in a given area shall remain in effect in that area until NMFS advises the Navy that the subject(s) of the USE at that area die or are euthanized, or that all live animals involved in the USE at that area have left the area (either of their own volition or herded).

(*3*) If the Navy finds an injured or dead animal floating at sea during an MTE, the Navy shall notify NMFS immediately or as soon as operational security considerations allow. The Navy shall provide NMFS with species or description of the animal(s), the condition of the animal(s), including carcass condition if the animal(s) is/are dead, location, time of first discovery, observed behavior (if alive), and photo or video (if available). Based on the information provided, NFMS will determine if, and advise the Navy whether a modified shutdown is appropriate on a case-by-case basis.

(*4*) In the event, following a USE, that qualified individuals are attempting to herd animals back out to the open ocean and animals are not willing to leave, or animals are seen repeatedly heading for the open ocean but turning back to shore, NMFS and the Navy shall coordinate (including an investigation of other potential anthropogenic stressors in the area) to determine if the proximity of mid-frequency active sonar training activities or explosive detonations, though farther than 14 nautical miles from the distressed animal(s), is likely contributing to the animals' refusal to return to the open water. If so, NMFS and the Navy will further coordinate to determine what measures are necessary to improve the probability that the animals will return to open water and implement those measures as appropriate.

(*5*) Within 72 hours of NMFS notifying the Navy of the presence of a USE, the Navy shall provide available information to NMFS (per the MITT Study Area Communication Protocol) regarding the location, number and types of acoustic/explosive sources, direction and speed of units using mid-frequency active sonar, and marine mammal sightings information associated with training activities occurring within 80 nautical miles (148 km) and 72 hours prior to the USE event. Information not initially available regarding the 80-nautical miles (148-km), 72-hour period prior to the event will be provided as soon as it becomes available. The Navy will provide NMFS investigative teams with additional relevant unclassified information as requested, if available.

2.9.1.6 § 218.95 Requirements for monitoring and reporting.

(a) As outlined in the MITT Study Area Stranding Communication Plan, the Holder of the Authorization must notify NMFS immediately (or as soon as operational security considerations allow) if the specified activity identified in § 218.90 is thought to have resulted in the mortality or injury of any marine mammals, or in any take of marine mammals not identified in § 218.91.

(b) The Holder of the LOA must conduct all monitoring and required reporting under the LOA, including abiding by the MITT Monitoring Project Description.

(c) General Notification of Injured or Dead Marine Mammals – Navy personnel shall ensure that NMFS (regional stranding coordinator) is notified immediately (or as soon as operational security considerations allow) if an injured or dead marine mammal is found during or shortly after, and in the vicinity of, an Navy training or testing activity utilizing mid- or high-frequency active sonar, or underwater explosive detonations. The Navy shall provide NMFS with species or description of the animal(s), the condition of the animal(s) (including carcass condition if the animal is dead), location, time of first discovery, observed behaviors (if alive), and photo or video (if available). The Navy shall consult the Stranding Response Plan to obtain more specific reporting requirements for specific circumstances.

(d) Annual MITT Monitoring Program Report – (1) The Navy shall submit an annual report describing the implementation and results of the MITT Monitoring Program, described in § 218.95. Data standards will be consistent to the extent appropriate across range complexes and study areas to allow for comparison in different geographic locations. Although additional information will be gathered, the protected species observers collecting marine mammal data pursuant to the MITT Monitoring Program shall, at a minimum, provide the same marine mammal observation data required in § 218.95. (2) As an alternative, the Navy may submit a multi-range complex annual monitoring plan report to fulfill this requirement. Such a report would describe progress of knowledge made with respect to monitoring plan study questions across multiple Navy ranges associated with the ICMP. Similar study questions shall be treated together so that progress on each topic shall be summarized across all Navy ranges. The report need not include analyses and content that does not provide direct assessment of cumulative progress on the monitoring plan study questions. The report shall be submitted either 90 days after the calendar year, or 90 days after the conclusion of the monitoring year date to be determined by the Adaptive Management process.

(e) Sonar Exercise Notification – The Navy shall submit to NMFS (specific contact information to be provided in the LOA) either an electronic (preferably) or verbal report within 15 calendar days after the completion of any major exercise indicating:

(i) Location of the exercise.
(ii) Beginning and end dates of the exercise.
(iii) Type of exercise.

(f) Annual MITT Exercise and Testing Report – The Navy shall submit preliminary reports detailing the status of authorized sound sources within 21 days after the end of the annual authorization cycle. The Navy shall submit a detailed report 3 months after the anniversary of the date of issuance of the LOA. The detailed annual report shall contain information on Major Training Exercises (MTE), Sinking Exercise (SINKEX) events, and a summary of sound sources used, as described below. The analysis in the detailed report will be based on the accumulation of data from the current year's report and data collected from previous reports. The detailed report shall contain information identified in § 218.95 (e)(1-5).

(1) Major Training Exercises/SINKEX:

(i) This section shall contain the reporting requirements for Coordinated and Strike Group exercises and SINKEX. Coordinated and Strike Group Major Training Exercises include:
(A) Joint Multi-Strike Group Exercise (Valiant Shield).
(B) Joint Expeditionary Exercise
(ii) Exercise information for each MTE:
(A) Exercise designator.
(B) Date that exercise began and ended.
(C) Location (operating area).
(D) Number of items or hours (per the LOA) of each sound source bin (impulsive and non-impulsive) used in the exercise.
(E) Number and types of vessels, aircraft, etc., participating in exercise.

(F) Individual marine mammal sighting info for each sighting when mitigation occurred during each MTE:

(*1*) Date/time/location of sighting.

(*2*) Species (if not possible, indication of whale/dolphin).

(*3*) Number of individuals.

(*4*) Initial detection sensor.

(*5*) Indication of specific type of platform the observation was made from (including, for example, what type of surface vessel or testing platform).

(*6*) Length of time observers maintained visual contact with marine mammal(s).

(*7*) Sea state.

(*8*) Visibility.

(*9*) Sound source in use at the time of sighting.

(*10*) Indication of whether animal is <200 yd, 200 to 500 yd, 500 to 1,000 yd, 1,000 to 2,000 yd, or >2,000 yd from sound source.

(*11*) Mitigation Implementation – Whether operation of sonar sensor was delayed, or sonar was powered or shut down, and how long the delay was; or whether navigation was changed or delayed.

(*12*) If source in use is a hull-mounted sonar, relative bearing of animal from ship, and estimation of animal's motion relative to ship (opening, closing, parallel).

(*13*) Observed behavior – Watchstanders shall report, in plain language and without trying to categorize in any way, the observed behavior of the animal(s) (such as animal closing to bow ride, paralleling course/speed, floating on surface and not swimming, etc.) and if any calves present.

(iii) An evaluation (based on data gathered during all of the MTEs) of the effectiveness of mitigation measures designed to minimize the received level to which marine mammals may be exposed. This evaluation shall identify the specific observations that support any conclusions the Navy reaches about the effectiveness of the mitigation.

(iv) Exercise information for each SINKEX:

(A) List of the vessels and aircraft involved in the SINKEX.

(B) Location (operating area).

(C) Chronological list of events with times, including time of sunrise and sunset, start and stop time of all marine species surveys that occur before, during, and after the SINKEX, and ordnance used.

(D) Visibility and/or weather conditions, wind speed, cloud cover, etc. throughout exercise if it changes.

(E) Aircraft used in the surveys, flight altitude, and flight speed and the area covered by each of the surveys, given in coordinates, map, or square miles.

(F) Passive acoustic monitoring details (number of sonobuoys, area, detections of biologic activity, etc.).

(G) Individual marine mammal sighting info for each sighting that required mitigation to be implemented:

(*1*) Date/time/location of sighting.

(*2*) Species (if not possible, indication of whale/dolphin).

(*3*) Number of individuals.

(*4*) Initial detection sensor.

(*5*) Indication of specific type of platform the observation was made from (including, for example, what type of surface vessel or platform).

(*6*) Length of time observers maintained visual contact with marine mammal(s).

(*7*) Sea state.

(*8*) Visibility.

(*9*) Indication of whether animal is <200 yd, 200-500 yd, 500-1,000 yd, 1,000-2,000 yd, or >2,000 yd from the target.

(*10*) Mitigation implementation – Whether the SINKEX was stopped or delayed and length of delay.

(*11*) Observed behavior – Watchstanders shall report, in plain language and without trying to categorize in any way, the observed behavior of the animals (such as animal closing to bow ride, paralleling course/speed, floating on surface and not swimming, etc.), and if any calves present.

(H) List of the ordnance used throughout the SINEKX and net explosive weight (NEW) of each weapon and the combined NEW.

(2) Summary of Sources Used.

(i) This section shall include the following information summarized from the authorized sound sources used in all training and testing events:

(A) Total annual or quantity (per the LOA) of each bin of sonar or other non-impulsive source;

(B) Total annual expended/detonated rounds (missiles, bombs, etc.) for each explosive bin; and

(C) Improved Extended Echo-Ranging System (IEER)/sonobuoy summary, including:

(*1*) Total expended/detonated rounds (buoys).

(*2*) Total number of self-scuttled IEER rounds.

(3) Geographic Information Presentation – The reports shall present an annual (and seasonal, where practical) depiction of training exercises and testing bin usage geographically across the Study Area.

(4) 5-year Close-out Exercise and Testing Report – This report will be included as part of the 2020 annual exercise or testing report. This report will provide the annual totals for each sound source bin with a comparison to the annual allowance and the 5-year total for each sound source bin with a comparison to the 5-year allowance. Additionally, if there were any changes to the sound source

allowance, this report will include a discussion of why the change was made and include the analysis to support how the change did or did not result in a change in the FEIS and final rule determinations. The report will be submitted 3 months after the expiration of the rule. NMFS will submit comments on the draft close-out report, if any, within 3 months of receipt. The report will be considered final after the Navy has addressed NMFS' comments, or 3 months after the submittal of the draft if NMFS does not provide comments.

2.10 NMFS' Issuance of Letters of Authorization (LOA) Pursuant to the MMPA Regulations

Subsequent to promulgation of the MMPA Rule, NMFS' Permits Division proposes to issue an LOA for Navy training and testing activities for the five year period (August 2015 through August 2020). Once issued, the LOA will set forth:

(1) Permissible methods of incidental taking;

(2) Means of effecting the least practicable adverse impact on the species, its habitat, and on the availability of the species for subsistence uses (i.e., mitigation); and

(3) Requirements for mitigation, monitoring and reporting.

Issuance of the LOA is dependent on a on a determination that the total number of marine mammals taken by the activity as a whole will have no more than a negligible impact on the affected species or stock of marine mammals. Incidental take of marine mammals that will be authorized by the LOA is also provided in the MMPA Rule and thus may not exceed the levels published in the Rule and assessed in this Opinion. Mitigation requirements are the same as those described in the MMPA rule as provided in the previous section and as assessed in this Opinion. Any unforeseen changes in the incidental take authorization above what is authorized in the MMPA Rule and LOA, would require amending the Rule and reinitiation of section 7 consultation pursuant to the ESA.

Section 7(b)(4)(C) of the ESA provides that if an endangered or threatened marine mammal is involved, the taking must first be authorized by Section 101(a)(5) of the MMPA. Accordingly, the terms of this incidental take statement and the exemption from Section 9 prohibitions of the ESA become effective only upon the issuance of MMPA authorization (i.e, five year regulations and LOA) to take the marine mammals in this Opinon. Absent such authorization, the incidental take statement is inoperative for marine mammals. The incidental take statement for sea turtles, fish, corals, and other non-marine mammal species will take effect immediately upon issuance of the LOA.

2.11 Interrelated and Interdependent Activities

Interrelated actions are those that are part of a larger action and depend on the larger action for their justification. Interdependent actions are those that have no independent utility apart from the action under consideration. NMFS determined that there are no interrelated and interdependent actions outside the scope of this consultation.

2.12 Action Area

Action Area means all areas affected directly, or indirectly, by the Federal action, and not just the immediate area involved in the action (50 CFR 402.02). The Action Area encompasses the MITT Study Area, transit corridor and area outsides of the study area where direct and indirect effects of stressors from Navy training and testing activities could be experienced.

2.12.1 MITT Action Area

The MITT Action Area is composed of the established ranges (at-sea ranges and land based training areas on Guam and CNMI), operating areas, and special use airspace in the region of the Mariana Islands that are part of the Mariana Islands Range Complex (MIRC) and its surrounding seas, and includes a transit corridor.[2] The MITT Action Area does not include the territorial waters of Palau or Micronesia. The transit corridor is outside the geographic boundaries of the MIRC and is a direct route across the high seas for Navy ships in transit between the MIRC and the HRC. The Proposed Action also includes pierside sonar maintenance and testing alongside Navy piers located in Inner Apra Harbor. The MITT Action Area is depicted in Figure 1.

[2] Vessel transit corridors are the routes typically used by Navy ships to traverse from one area to another. The route depicted in Figure 1 is a direct route between the MIRC and the HRC, making it a quick and fuel-efficient transit. The depicted transit corridor is notional and may not represent actual routes used. Actual routes navigated are based on a number of factors including, but not limited to, weather and training; however, the corridor represents the environment potentially impacted by the Proposed Action.

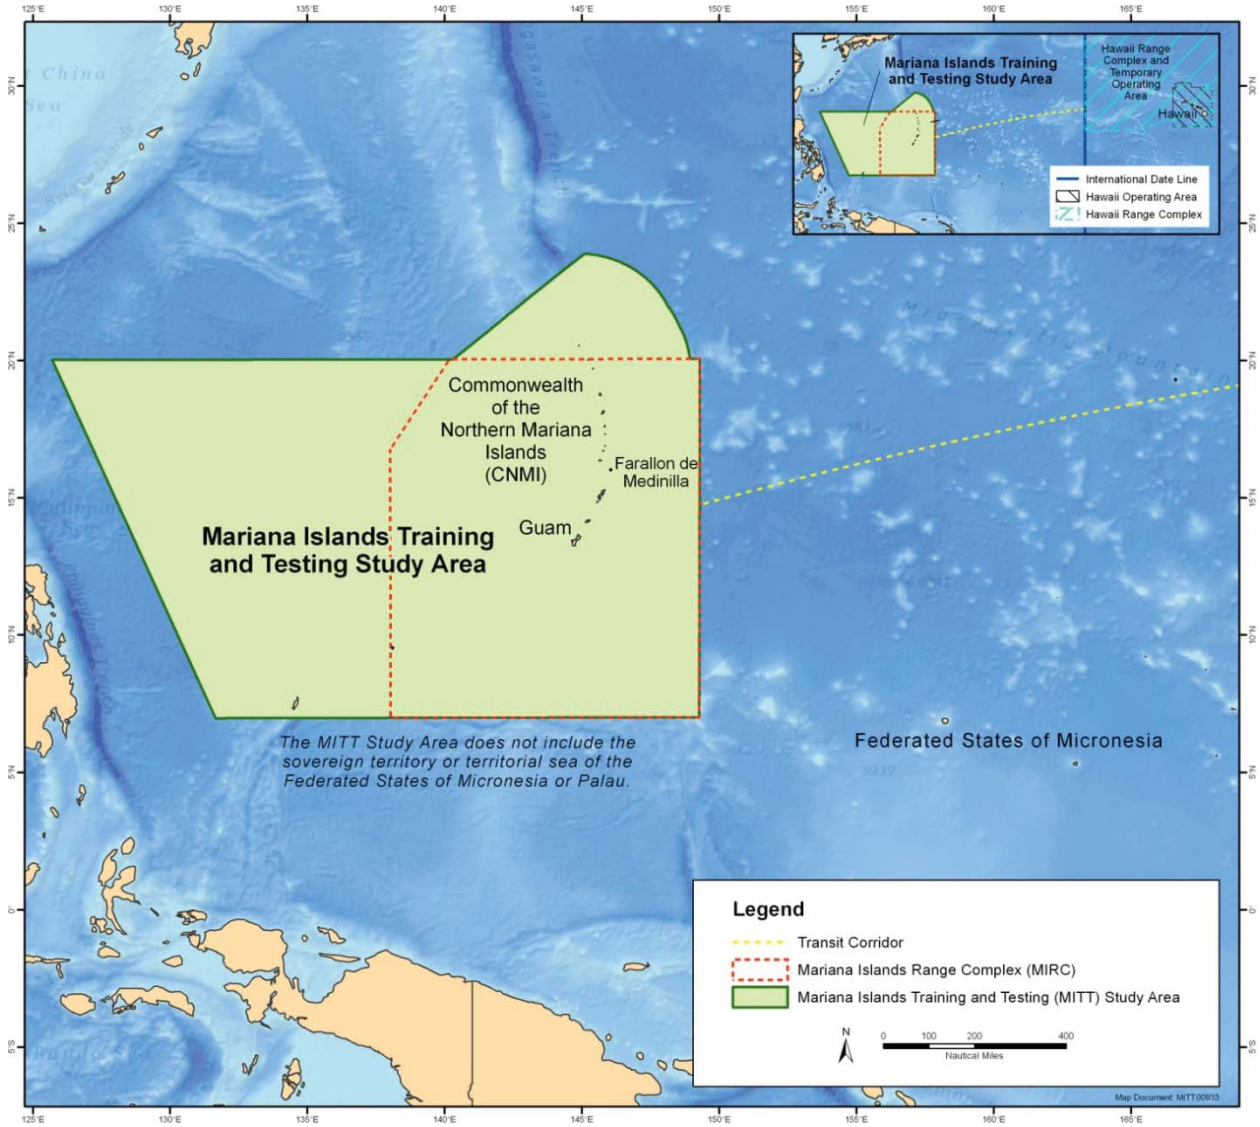

Figure 1.Mariana Islands Action Area with the Mariana Islands Range Complex and notional transit corridor

A range complex is a designated set of specifically bounded geographic areas that encompasses a water component (above and below the surface) and airspace, and may encompass a land component where training and testing of military platforms, tactics, munitions, explosives, and electronic warfare systems occurs. Range complexes include established ocean operating areas and special use airspace, which may be further divided to provide better control of the area and activities for safety reasons.

The MITT Action Area includes the MIRC land training areas and at-sea operating areas that were previously addressed in the MIRC EIS/OEIS (May 2010) with modifications to the special use air space that were addressed in the MIRC Airspace Environmental Assessment (EA)/Overseas EA (OEA) (U.S. Department of the Navy 2013), and the seaward extension of the northern and western edges of the MIRC study area, the transit corridor, and Navy pierside locations in the Apra Harbor Naval Complex.

2.12.2 Mariana Islands Range Complex

The MIRC includes land training areas, ocean surface and subsurface areas, and special use airspace. These areas extend from the waters south of Guam to north of Pagan (CNMI), and from the Pacific Ocean east of the Mariana Islands to the Philippine Sea to the west, encompassing 501,873 square nautical miles (nm^2) of open ocean.

2.12.2.1 Special Use Airspace and Air Traffic Controlled Assigned Airspace

The MIRC is anticipated to include approximately 70,000 nm^2 of special use airspace and ATCAA (once Federal Aviation Administration [FAA] rule-making and non-rule making airspace changes are complete[3]). As depicted in Figure 2 and Figure 3, this airspace is almost entirely over the ocean (except ATCAA 6 and W-13A) and includes warning areas, ATCAAs, and restricted areas.

[3] The MIRC Airspace EA/OEA tiered off from the MIRC EIS/OEIS; the Navy analyzed the potential impacts of redesignating ATCAAs in the MITT Study Area with Warning Areas and expanding the special use airspace around FDM. In that EA/OEA, no new training or testing events were proposed. The EA/OEA concluded that no significant impacts to the environment would occur as a result of the airspace redesignation and expansion. The FAA has rule-making and non-rule making authority for the airspace redesignation and expansion, and the MIRC Airspace EA/OEA supported the FAA in its rule-making and non-rule making process to establish special use airspace.

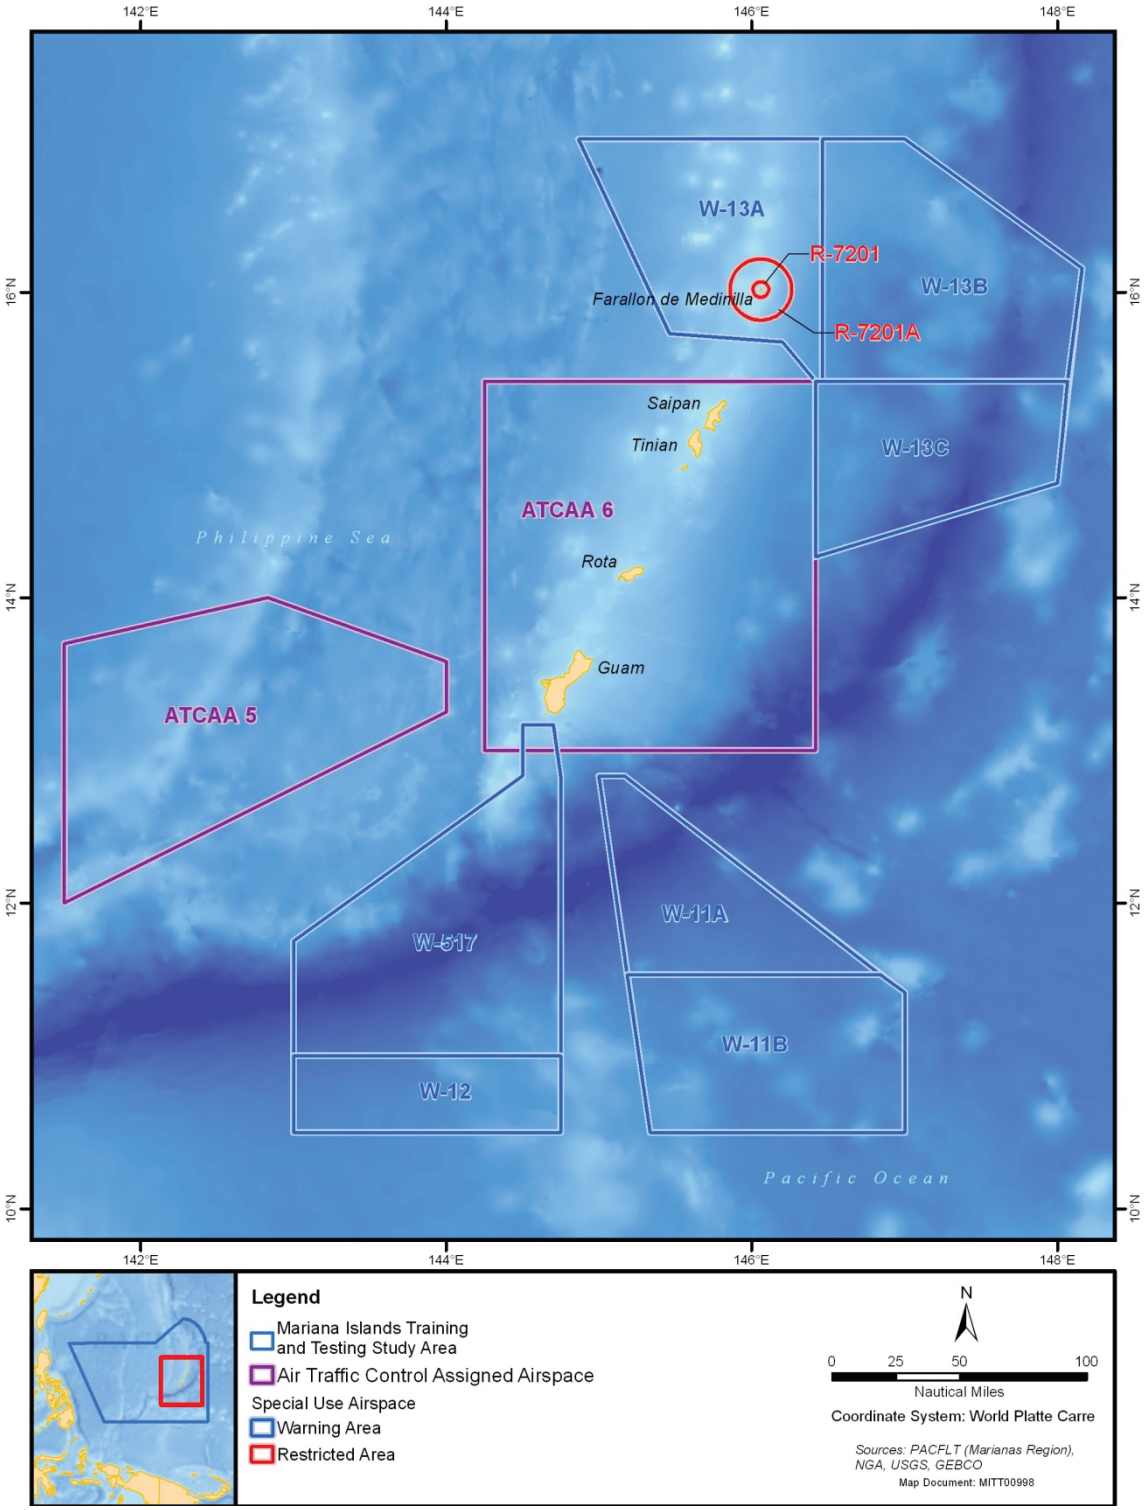

Figure 2.Mariana Islands Range Complex Airspace

Warning Area (W)-517 and W-12 include approximately 11,769 nm^2 of special use airspace; W-11 (A/B) is approximately 10,467 nm^2 of special use airspace, and W-13 (A/B/C) is approximately 13,752 nm^2 of special use airspace.

The ATCAAs of the MIRC account for more than 28,750 nm^2 of airspace and includes ATCAA 5 and ATCAA 6. (Figure 2)

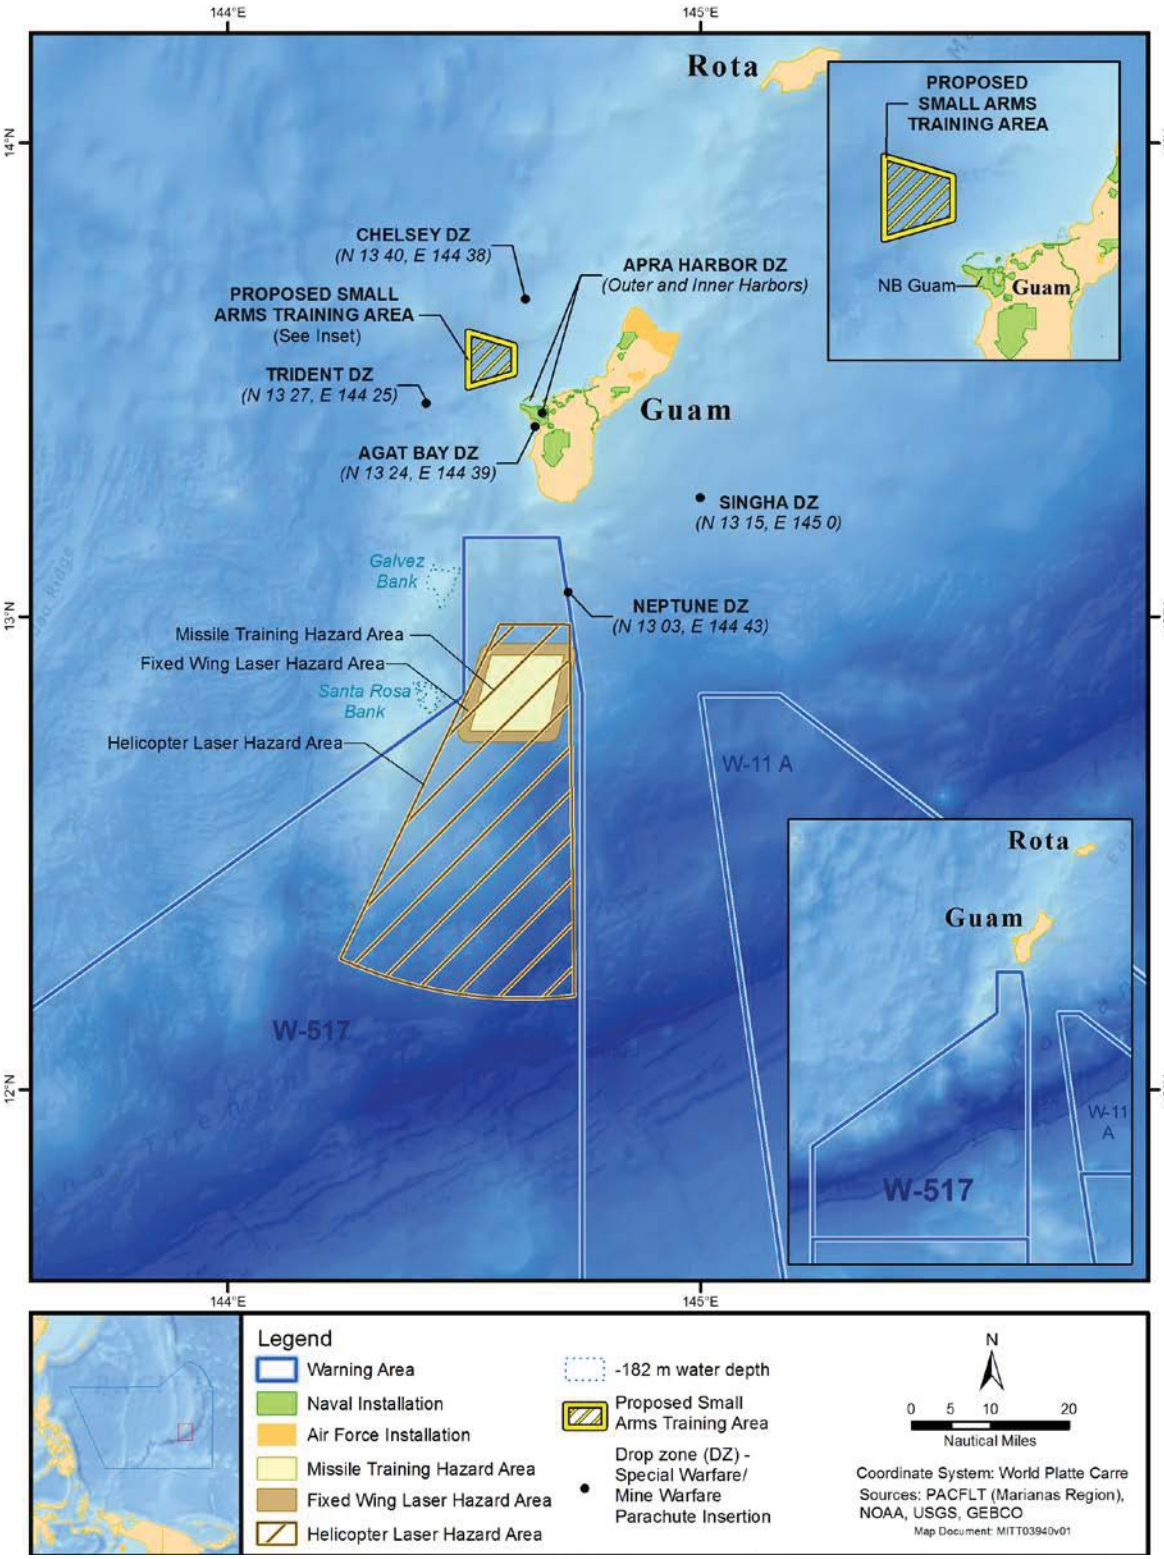

Figure 3.Mariana Islands Range Complex Airspace and Warning Area 517

The restricted area airspace over or near land areas within the MIRC makes up 452 nm^2 of special use airspace and includes restricted areas (R)-7201 and R-7201A which extends in a 12 nm radius around Farallon de Medinilla (FDM) (Figure 4).

2.12.2.2 Sea and Undersea Space

The MIRC includes the sea and undersea space from the ocean surface to the ocean floor. The MIRC includes designated sea and undersea space training sites to include designated drop zones, underwater demolition and floating mine exclusion zones, danger zones associated with live fire ranges, and training areas associated with military controlled beaches, harbors, and littoral areas.

W-517 (Figure 3) is special use airspace where the sea space underneath is also restricted from public access during hazardous training and testing events. Portions of the Marianas Trench Marine National Monument, established in January 2009 by Presidential Proclamation under the authority of the Antiquities Act (16 U.S. Code §§431–433), lie within the MIRC. The prohibitions required by the Proclamation do not apply to activities and exercises of the Armed Forces (including those carried out by the U.S. Coast Guard).

The MIRC Airspace EA/OEA proposed and analyzed a Danger Zone around FDM. The Army Corps of Engineers has rule-making authority for Danger Zone establishment. The pending Danger Zone rule for FDM extends out 12 nm from a center point on FDM and over a range hazard area of approximately 452 nm^2 (Figure 2 and Figure 4).

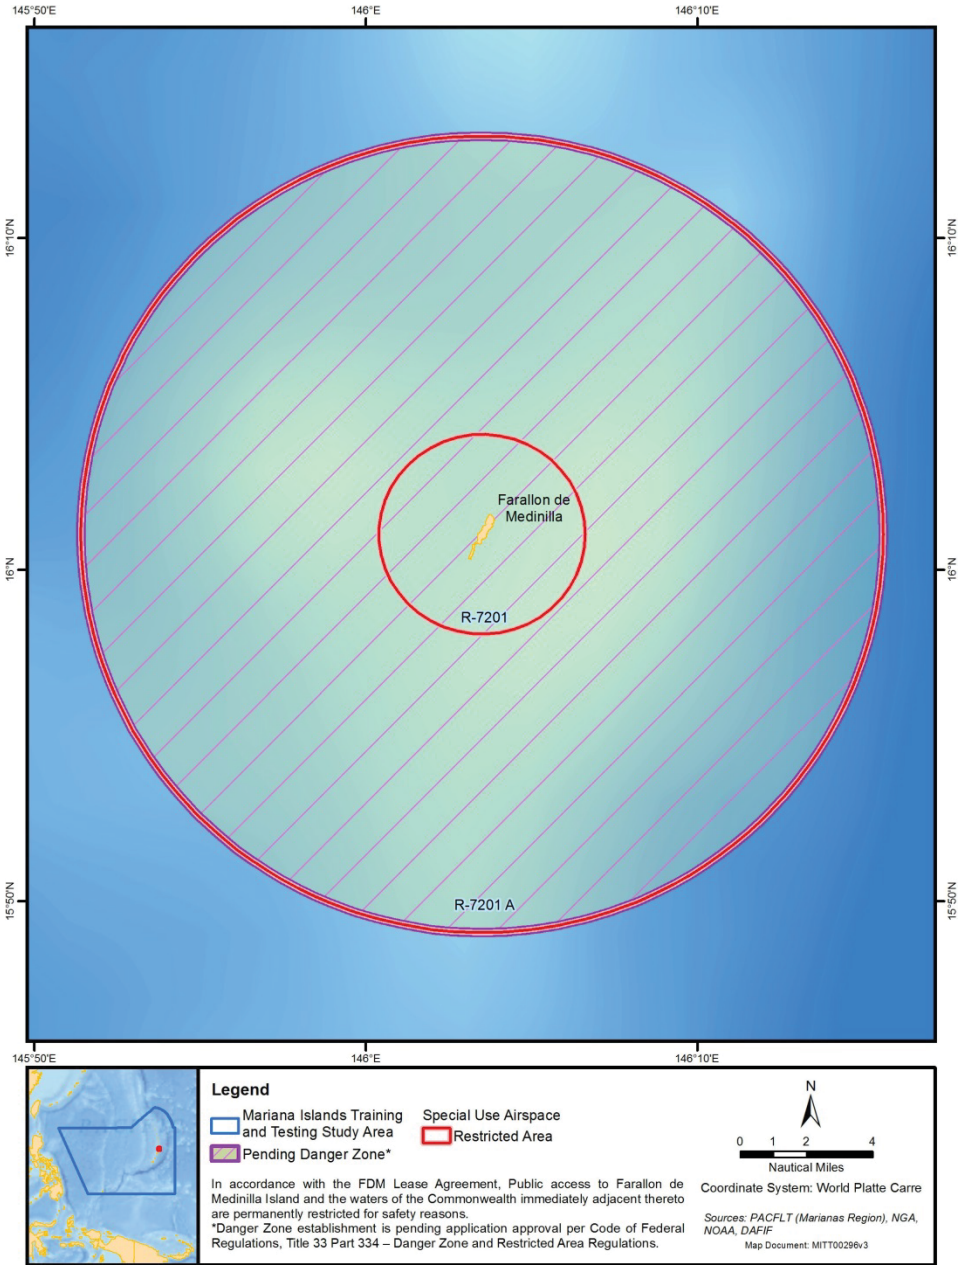

Figure 4. Farallon de Medinilla Restricted Area 7201, 7201A, and Danger Zone

2.12.2.3 Land

Commander Joint Region Marianas provides executive level installation management support to all DoD components and tenants through assigned regional installations on Guam and the Commonwealth of the Northern Mariana Islands in support of training and testing in the Marianas, including coordination with Northern Mariana Islands Commonwealth Port Authority for logistic and operational support of DoD aircraft and vessels; acts as the interface between the Navy and the civilian community; ensures compliance with all environmental laws and regulations, safety procedures, and equal opportunity policy; and performs other functions and tasks as assigned. While land based activities are not part of this consultation, a description of installations on Guam and the CNMI are provided for informational purposes only.

2.12.2.4 Guam

The Navy has control of approximately 28 square miles (mi.^{2}) (72.5 square kilometers [km^2]) of land in noncontiguous properties on Guam. There are five Navy annexes: Main Base (which includes Apra Harbor Naval Complex and Main Base/Polaris Point) (Figure 5), Naval Base Guam Munitions Site (Figure 6); Hospital Annex/Nimitz Hill, Naval Base Guam Telecommunications Site (Figure 7), and Naval Base Guam Barrigada (Figure 8).

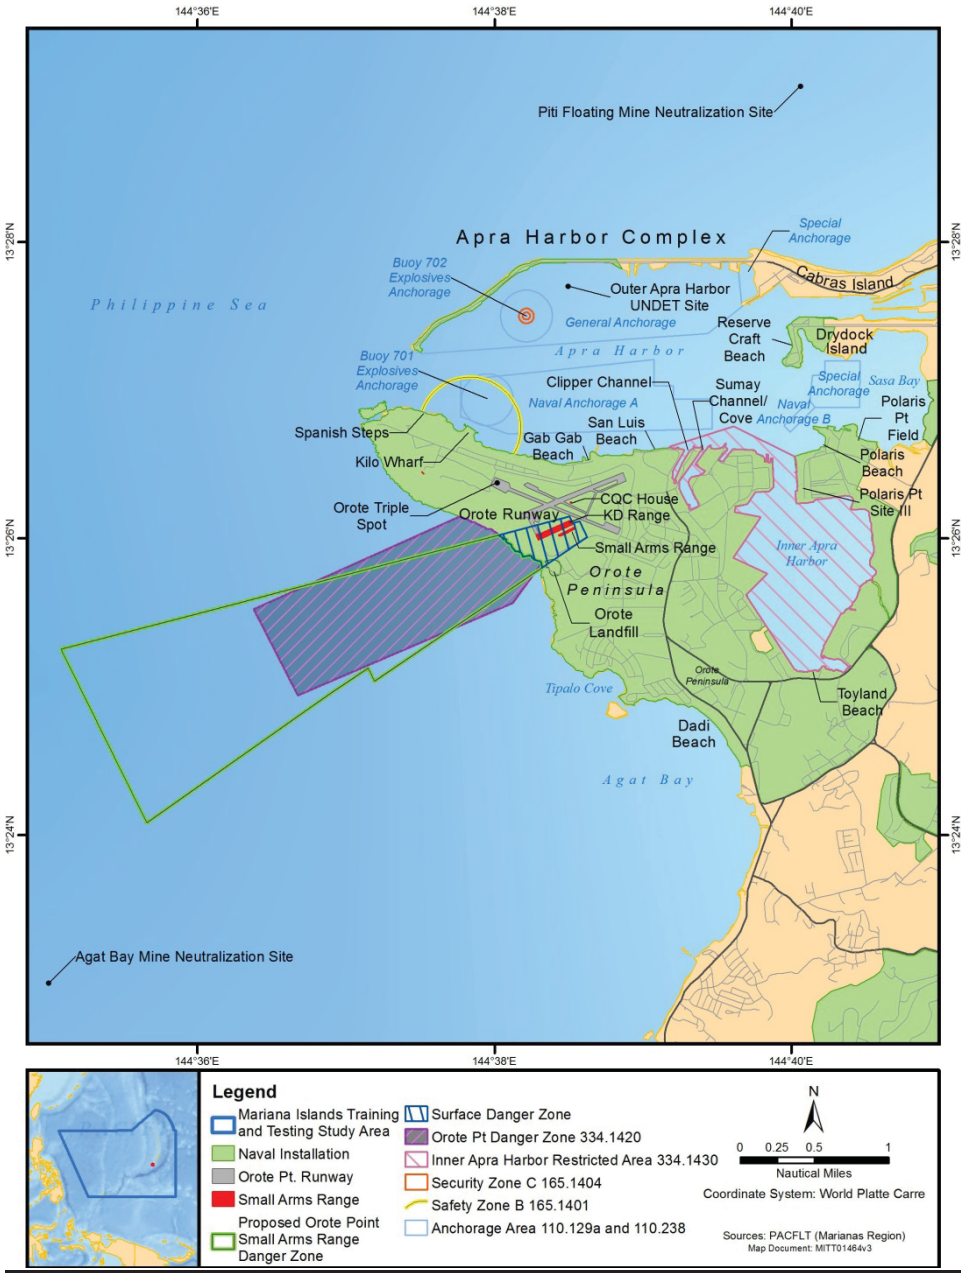

Figure 5. Apra Harbor Naval Complex (Main Base) and Main Base/Polaris Point

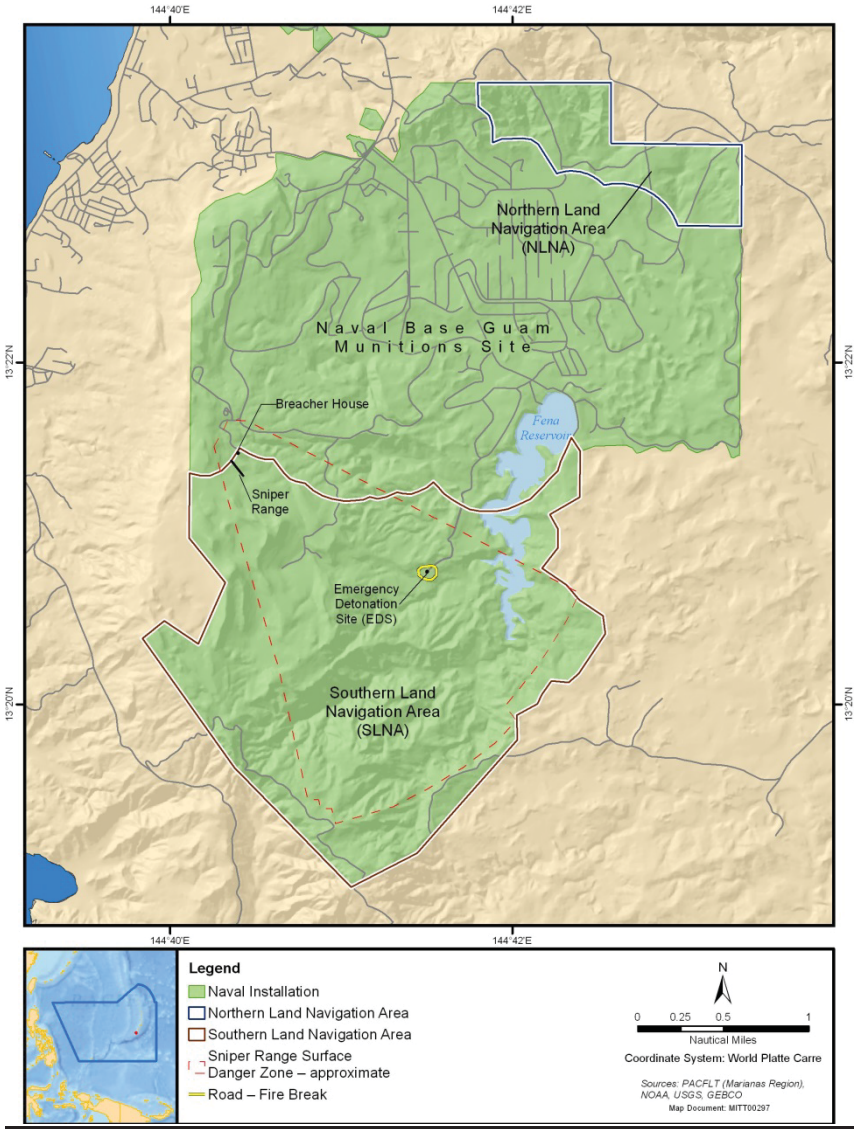

Figure 6. Naval Base Guam Munitions Site

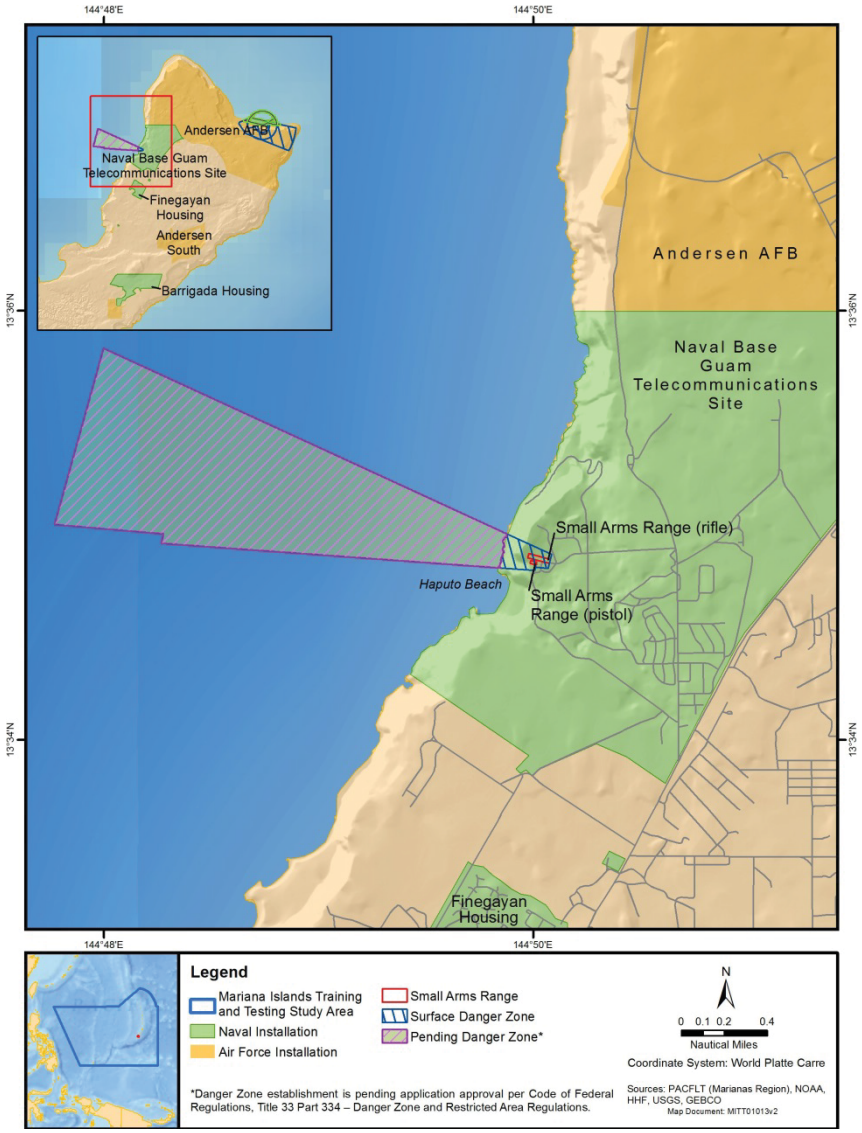

Figure 7. Naval Base Guam Telecommunications Site

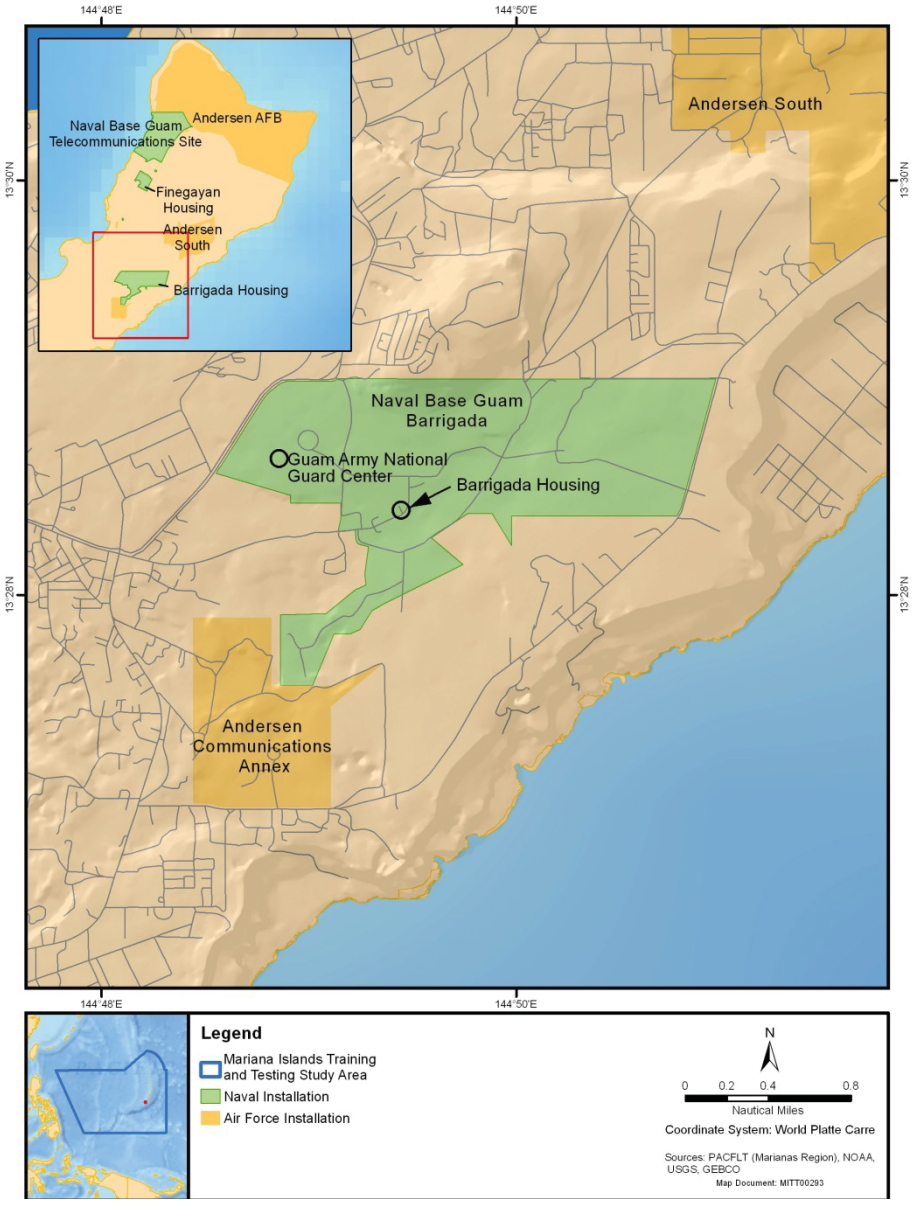

Figure 8. Naval Base Guam Barrigada

Andersen Air Force Base, one of the largest U.S. Air Force airfields, is located in the northern portion of the island of Guam. Andersen Air Force Base includes the main base and Northwest Field which covers 24.5 mi.^{2} (63.5 km^2), Andersen South 3.2 mi.^{2} (8.3 km^2), and Andersen Barrigada Annex 0.7 mi.^{2} (1.8 km^2) (Figure 9).

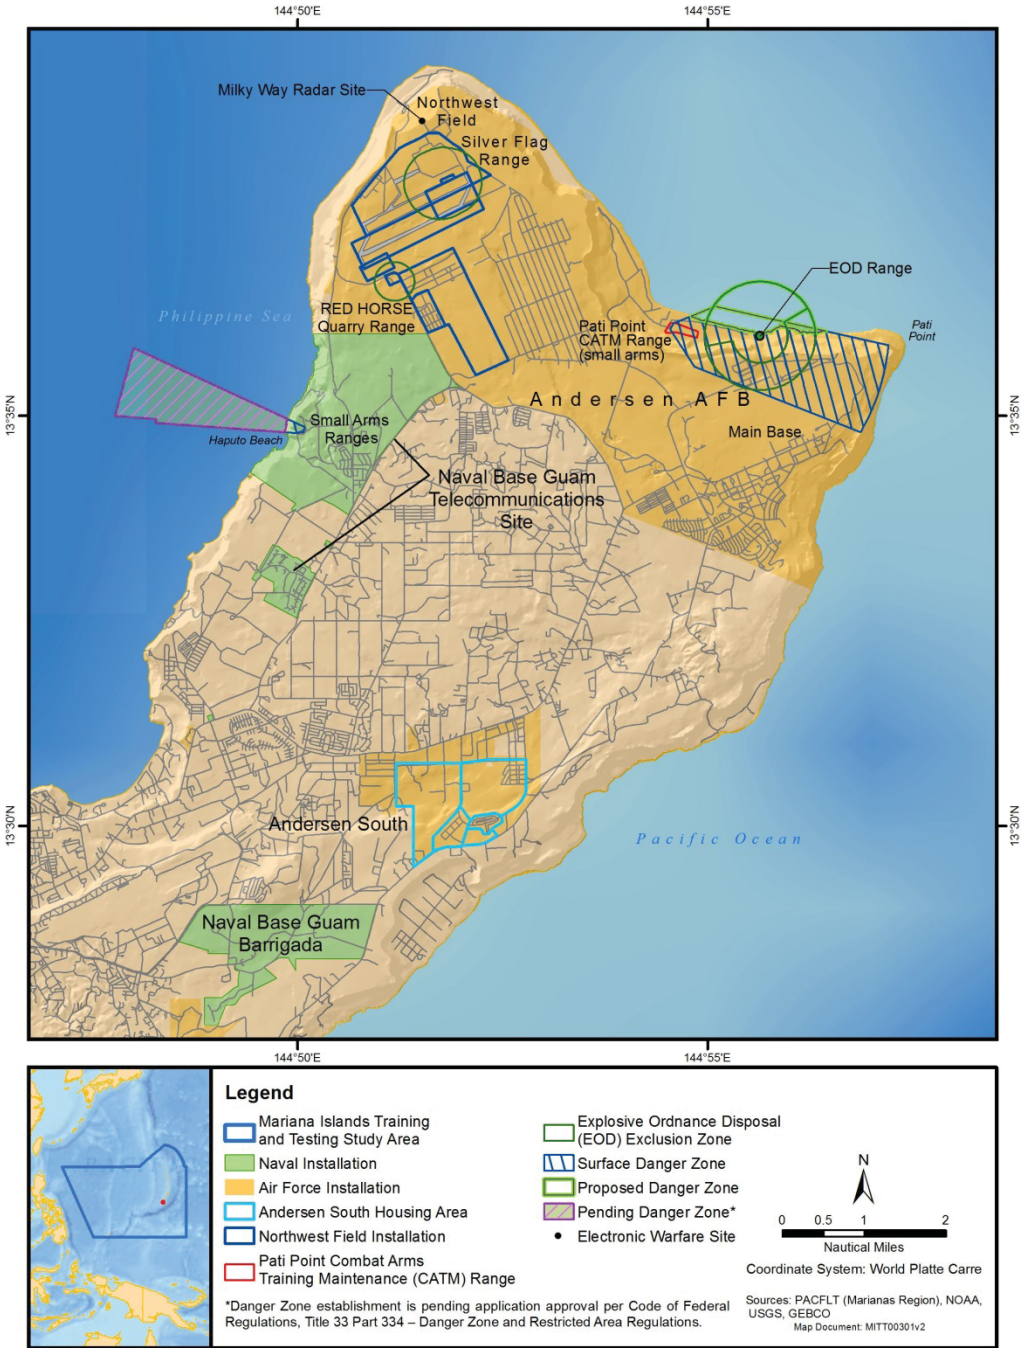

Figure 9. Andersen Air Force Base

2.12.2.5 Commonwealth of the Northern Mariana Islands

No DoD personnel are permanently stationed in the CNMI, with the exception of a U.S. Army Reserve unit located on Saipan.

Farallon de Medinilla (FDM). FDM is a rocky and uninhabited island, approximately 1.7 miles (mi.) (2.7 kilometer [km]) long and 0.3 mi. (0.5 km) wide (Figure 10). The DoD leases FDM for use as a live and inert gunnery, missile, and bombing range.

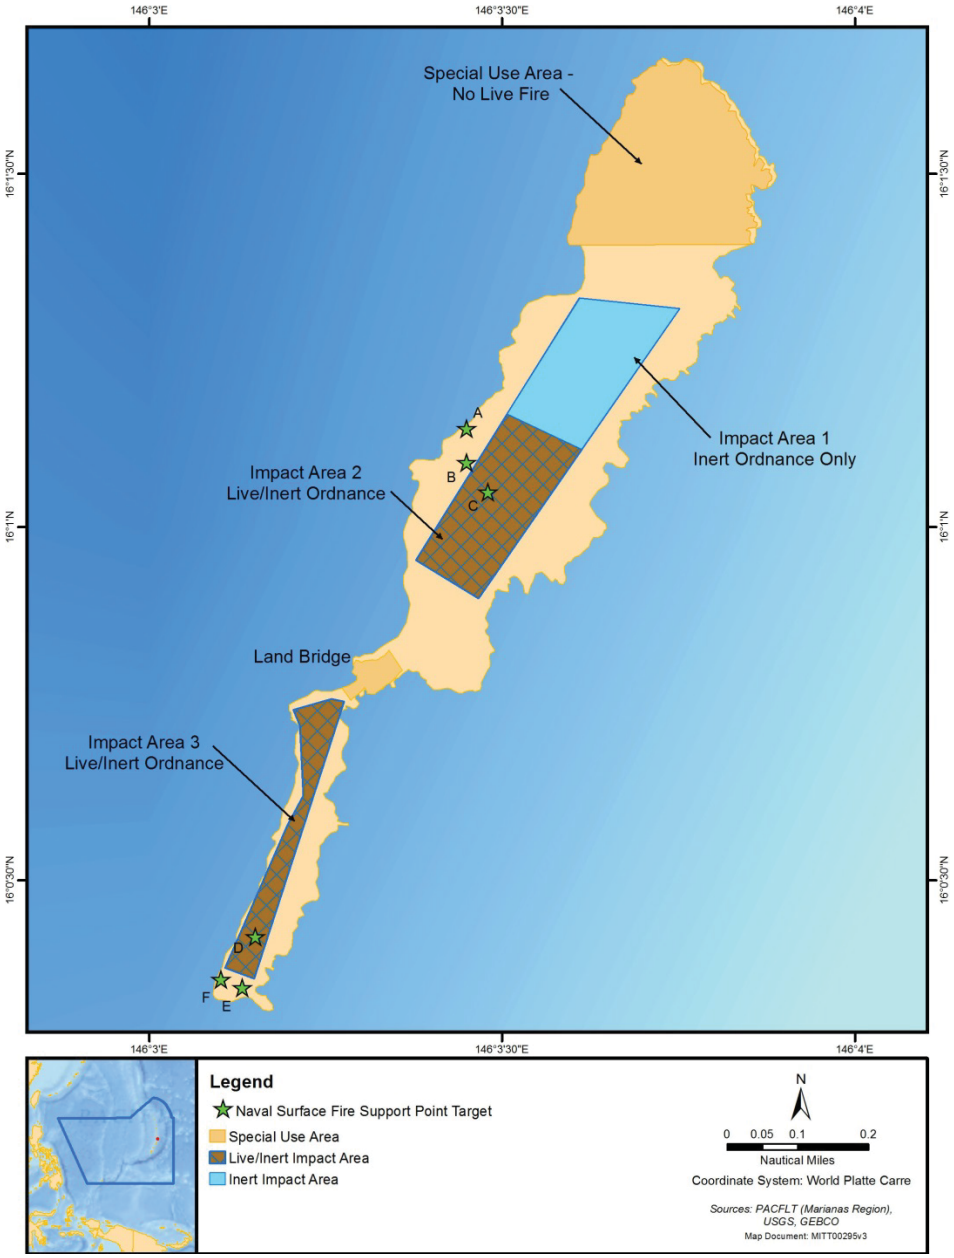

Figure 10. Farallon de Medinilla

Tinian. Tinian has a land area of approximately 39 mi.^{2} (101 km^2). The DoD leases approximately 15,347 contiguous acres (6,210.7 hectares) of northern Tinian (the Military Lease Area) for field training (Figure 11). The Military Lease Area is further divided into the Exclusive Military Use Area and the Leaseback Area.

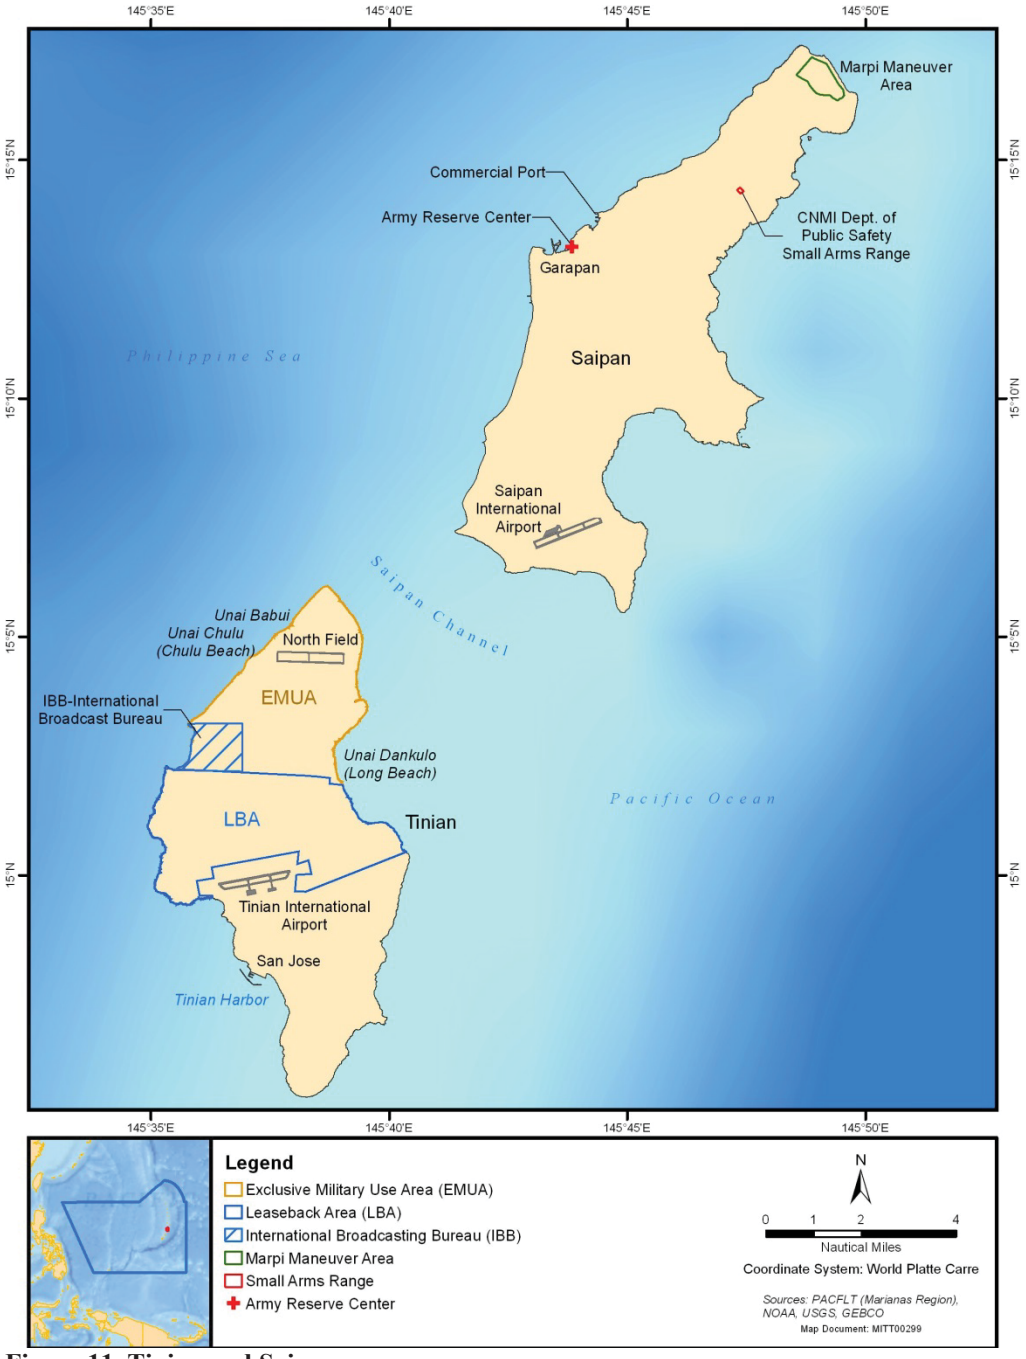

Figure 11. Tinian and Saipan

Saipan. Approximately 0.28 mi.^{2} (0.73 km^2) on Tanapag Harbor (commercial port) is leased by the DoD**.** The Army Reserve center is located in Garapan (Figure 11).

Rota. Rota is approximately 11 mi. (17.7 km) long and 3 mi. (4.8 km) wide (Figure 12). Training on Rota is scheduled with Joint Region Marianas and coordinated with Rota officials for proposed training areas and activities. Training activities conducted on Rota typically include special warfare training and combat search and rescue training.

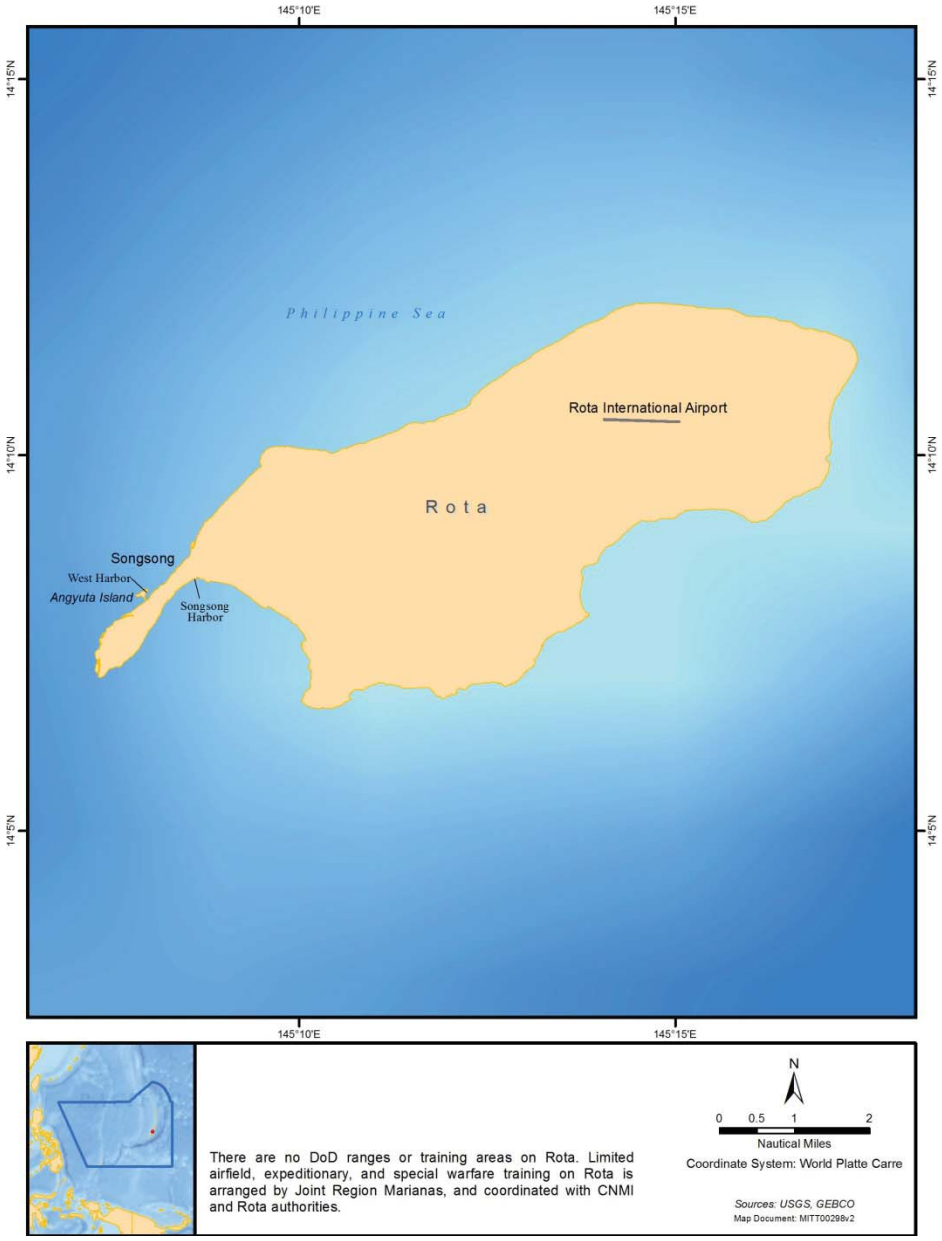

Figure 12. Rota

2.12.3 Ocean Operating Areas Outside the Bounds of the Mariana Islands Range Complex

In addition to the MIRC, the MITT Action Area is expanded and includes the area to the north of the MIRC that is within the Exclusive Economic Zone of the Commonwealth of the Northern Mariana Islands and the areas to the west of the MIRC (Figure 1). The MITT Action Area also includes a transit corridor, which is a direct route between the MIRC and the Hawaii Range Complex.

Although not part of any defined range complex, the transit corridor is important to the Navy in that it provides adequate air, sea, and undersea space in which vessels and aircraft conduct training and some sonar maintenance and testing while in transit.

The transit corridor is defined by a great circle route (e.g., shortest distance) between the MIRC and the HRC. While in transit and along the corridor, vessels and aircraft would, at times, conduct basic and routine unit level training such as gunnery and sonar training as long as the training does not interfere with the primary objective of reaching their intended destination. Ships also conduct sonar maintenance, which includes active sonar transmissions.

Effects of Navy training and testing activities with the portion of the transit corridor that lies within the Hawaii-Southern California Training and Testing (HSTT) Action Area were analyzed separately in the HSTT biological opinion. This biological opinion addresses training and testing activities along the transit corridor outside of the Action Area defined for HSTT (in and around the Hawaiian Islands).

2.12.4 Pierside Locations and Apra Harbor

The Action Area includes pierside locations in the Apra Harbor Naval Complex where surface ship and submarine sonar maintenance testing occur. For purposes of this BO, pierside locations include channels and routes to and from the Navy port in the Apra Harbor Naval Complex, and associated wharves and facilities within the Navy port and shipyard (Figure 5).

2.12.5 Nearshore Training and Testing Areas

The following table and figure describe the nearshore training and testing activities in MITT.

Table 21. Summary of Nearshore Training and Testing Activities

Nearshore Training and Testing Areas	Description
Pacific Ocean off Orote Point, Apra Harbor, Island of Guam, Mariana Islands; Small Arms Firing Range	Used for Small Arms Training. Down range Surface Danger Zone extends out over the nearshore waters of Guam off Orote Point.
Finegayan Small Arms Range	Used for small arms training. Down range Surface Danger Zone extends out over the nearshore waters of Guam off Haputo Point and overlays part of the "Small Arms Safety Drop Zone" shown on NOAA Chart 81048, Guam.
Pati Point Combat Arms Training Maintenance Small Arms Range	Used for small arms training. Down range Surface Danger Zone extends out over the nearshore waters of Guam off Pati Point.
Small Arms Firing Area	An area used by surface vessel crews to conduct small arms training. This firing area is over water west of Guam, beyond 3 nm of Guam and within territorial waters, and within a Navy "Firing Danger Area" charted on NOAA Chart 81048, Guam.
Agat Bay Mine Neutralization Site	Used by divers training to conduct underwater detonations (UNDETs). The Exclusion Zone has a minimum 640-meter (m) radius and is located beyond 3 nm of Guam and within territorial waters.
Piti Point Mine Neutralization Site	Used by divers training to conduct UNDETs. The Exclusion Zone has a minimum 640 m radius and is located within 3 nm of Guam.
Apra Harbor UNDET Site	Used by divers training to conduct UNDETs. The Exclusion Zone has a minimum 640 m radius over water, and is located within Apra Harbor. The Glass Breakwater forms the northern edge of Exclusion Zone.
Pati Point Explosive Ordnance Disposal Range	Land site used by the Air Force to dispose of ordnance. The Exclusion Zone extends partially out of Guam off Pati Point.

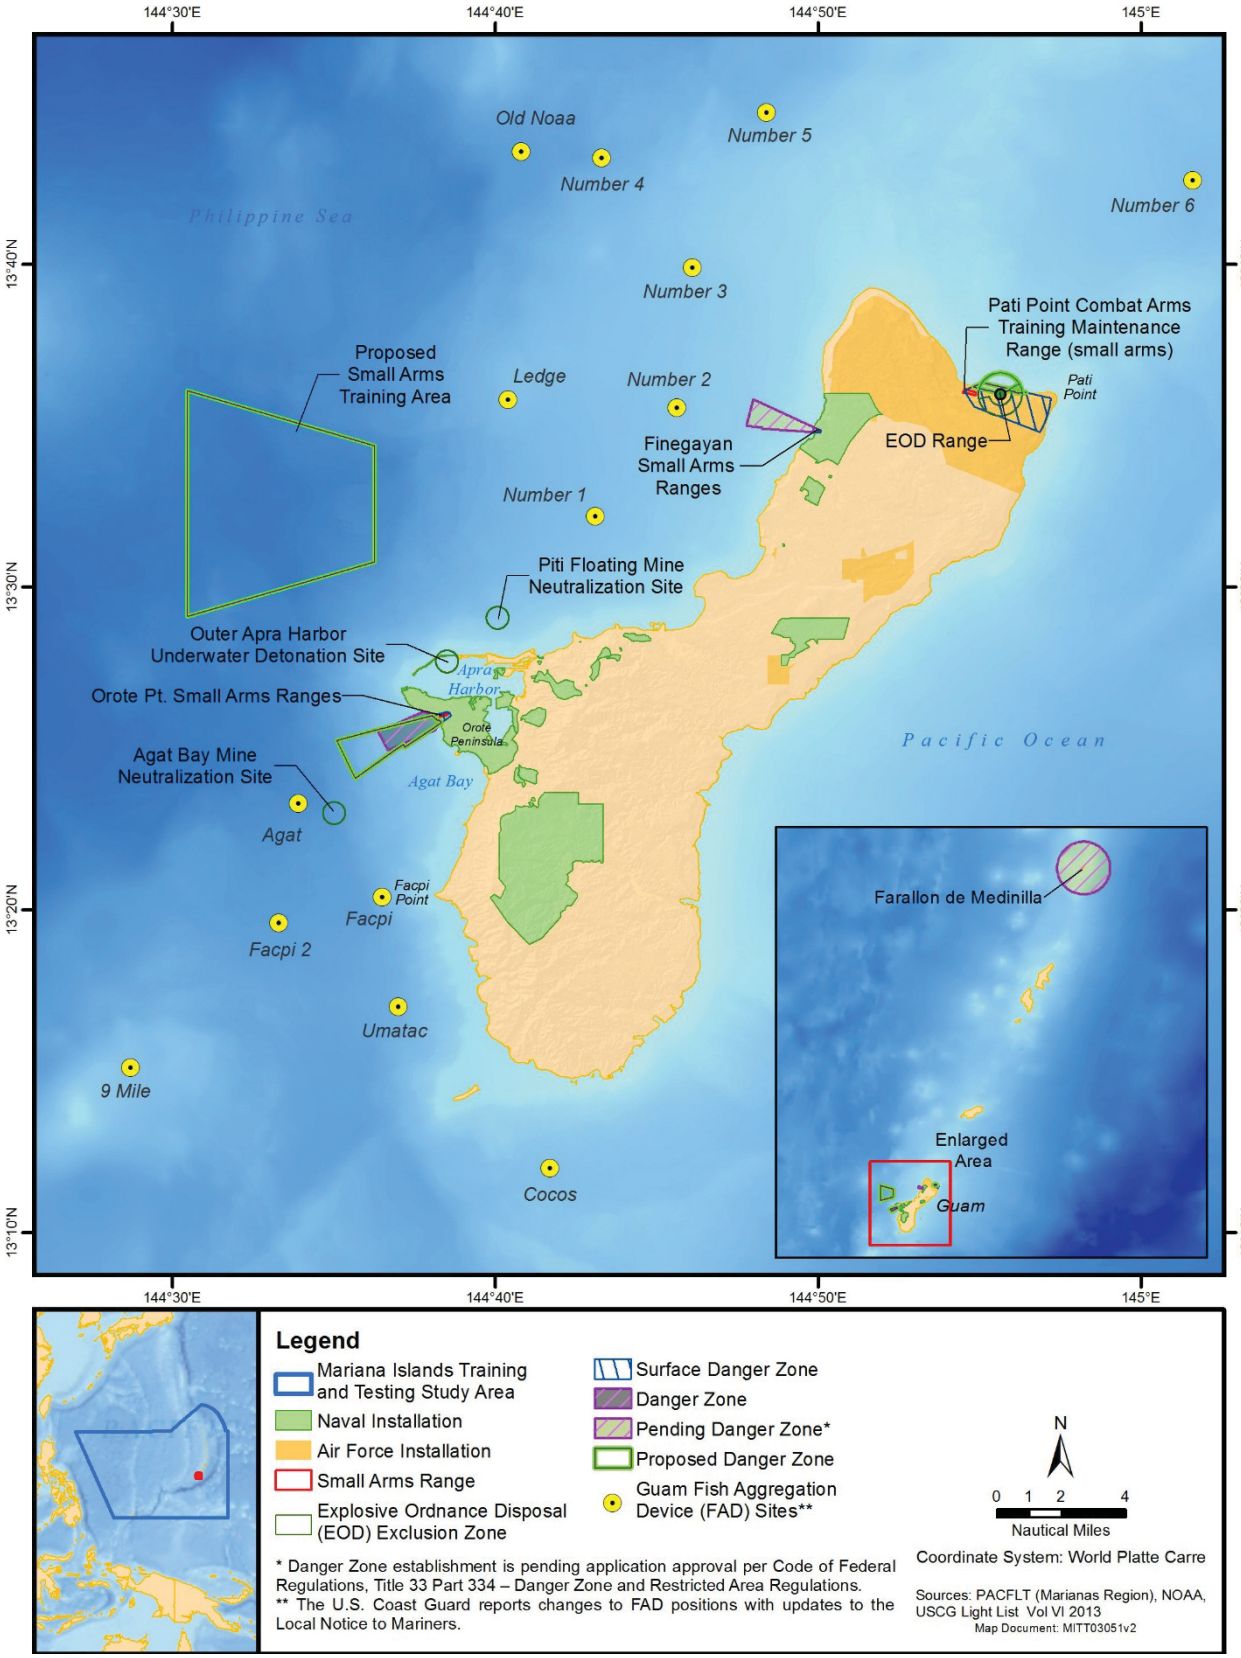

Figure 13. Nearshore Training and Testing Areas

3 APPROACH TO THE ASSESSMENT

Section 7(a)(2) of the ESA requires Federal agencies, in consultation with NMFS, to ensure that their actions are not likely to jeopardize the continued existence of endangered or threatened species, or adversely modify or destroy their designated critical habitat. The jeopardy analysis considers both survival and recovery of the species. The adverse modification analysis considers the impacts on the conservation value of designated critical habitat.

"To jeopardize the continued existence of a listed species" means to engage in an action that reasonably would be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species (50 CFR §402.02).

This biological opinion does not rely on the regulatory definition of "destruction or adverse modification" of critical habitat at 50 C.F.R. 402.02. Instead, we have relied upon the statutory provisions of the ESA to complete the following analysis.[4]

3.1 Overview of NMFS' Assessment Framework

We will use the following approach to determine whether the proposed action is likely to jeopardize listed species or destroy or adversely modify critical habitat:

- Identify the range-wide status of the species and critical habitat likely to be adversely affected by the proposed action; then
- Describe the *Environmental Baseline* in the Action Area including:
    - Past and present impacts of Federal, state, or private actions and other human activities in the Action Area;
    - Anticipated impacts of proposed Federal projects that have already undergone formal or early section 7 consultation;
    - Impacts of state or private actions that are contemporaneous with the consultation in process; then
- Analyze the effects of the proposed action on both species and their habitat; then
- Consider how the proposed action would affect the species' reproduction, numbers, and distribution; then
- Evaluate the proposed action's effects on critical habitat features; then

[4] Memorandum from William T. Hogarth to Regional Administrators, Office of Protected Resources, NMFS (Application of the "Destruction or Adverse Modification" Standard Under Section 7(a)(2) of the Endangered Species Act) (November 7, 2005).

- Describe any cumulative effects in the Action Area. Cumulative effects, as defined in our implementing regulations (50 CFR §402.02), are the effects of future state or private activities, not involving Federal activities, that are reasonably certain to occur within the Action Area. Future Federal actions that are unrelated to the proposed action are not considered because they require separate section 7 consultation;

We integrate and synthesize the above factors to assess the risk that the proposed action poses to species and critical habitat.

We assess the effects of the action with the impacts to the resources resulting from the *Environmental Baseline* and the *Cumulative Effects* to assess whether the action could reasonably be expected to:

- Reduce appreciably the likelihood of both survival and recovery of the species in the wild by reducing its numbers, reproduction, or distribution; and/or
- Reduce the conservation value of designated or proposed critical habitat. These assessments are made in full consideration of the *Status of Listed Resources* and critical habitat.

Reach jeopardy and adverse modification *Conclusion*. In this step we state our conclusions regarding jeopardy and the destruction or adverse modification of critical habitat (*Integration and Synthesis*).

If necessary, define a reasonable and prudent alternative to the proposed action. If, in completing the last step in the analysis, we determine that the action under consultation is likely to jeopardize the continued existence of listed species or destroy or adversely modify designated critical habitat, we must identify a reasonable and prudent alternative (RPA) to the action. The RPA must not be likely to jeopardize the continued existence of listed species nor adversely modify their designated critical habitat and it must meet other regulatory requirements.

3.2 "Take" and Threatened Species

ESA section 9(a) take prohibitions (16 U.S.C. 1538(a)(1)(B)) apply to all species listed as endangered. In the case of threatened species, section 4(d) of the ESA leaves it to the Secretary's discretion whether and to what extent to extend the statutory 9(a) ''take'' prohibitions, and directs the agency to issue regulations it considers necessary and advisable for the conservation of the species. At this time, NMFS has not issued section 4(d) rules for the threatened coral species or for the threatened scalloped hammerhead shark – Indo-Pacific DPS. Therefore, the take prohibitions of section 9(a) of the ESA have not been extended to these species. However, consistent with *CBD v. Salazar*, 695 F.3d 893 (9th Cir. 2012), we did assess the amount or extent of take to threatened species that is anticipated incidental to Navy training and testing activiites and included this information in the ITS. At such time a 4(d) rule is issued for these species, NMFS and the Navy may need to reinitiate consultation to amend the incidental take statement.

3.3 Defining "Significance"

In biological opinions, we focus on potential physical, chemical, or biotic stressors that are "significant" in the sense of being distinct from ambient or background. We then ask if

a. exposing individuals to those potential stressors is likely to represent a "significant" negative experience in the life history of individuals that have been exposed; and if

b. exposing individuals to those potential stressors is likely to cause the individuals to experience "significant" physical, chemical, or biotic responses; and if

c. any "significant" physical, chemical, or biotic response are likely to have "significant" consequence for the fitness of the individual animal; and if

d. exposing the physical, chemical, or biotic phenomena that we identified as constituent elements in a critical habitat designation or, in the case of critical habitat designations that do not identify constituent elements, those physical, chemical or biotic phenomena that give designated critical habitat value for the conservation of endangered or threatened species is likely to represent a "significant" change in the quantity, quality, or availability of the physical, chemical, or biotic resource; and if

e. any "significant" change in the quantity, quality, or availability of a physical, chemical, or biotic resource is likely to "significantly" reduce the conservation value of the designated critical habitat.

In all of these cases, the term "significant" means "clinically or biotically significant" rather than statistically significant because the presence or absence of statistical significance do not imply the presence or absence of clinical significance (Achinstein 2001; Royall 2004).

For populations (or sub-populations, demes, etc.), we are concerned about whether the number of individuals that are likely to experience "significant" reductions in fitness and the nature of any fitness reductions are likely to have a "significant" consequence for the viability (= probability of demographic, ecological, or genetic extinction) of the population(s) those individuals represent. Here "significant" also means "clinically or biotically significant" rather than statistically significant.

For "species" (the entity that has been listed as endangered or threatened, not the biological species concept), we are concerned about whether the number of populations that are likely to experience "significant" reductions in viability (= increases in their extinction probabilities) and the nature of any reductions in viability are likely to have "significant" consequence for the viability (= probability of demographic, ecological, or genetic extinction) of the "species" those population comprise. Here, again, "significant" also means "clinically or biotically significant" rather than statistically significant.

For designated critical habitat, we are concerned about whether the area that has been designated is likely to experience "significant" reductions in the quantity, quality, or availability of physical, chemical, or biotic resources that are likely to result in "significant" reductions in the conservation value (usually measured using the concept of "carrying capacity") of the entire are contained in the designation.

3.4 Evidence Available for the Consultation

To conduct these analyses, we considered all lines of evidence available through published and unpublished sources that represent evidence of adverse consequences or the absence of such consequences. A considerable body of scientific information on anthropogenic sounds and their

effect on marine mammals and other marine life has become available. NMFS status reviews for listed species also provide information on the status of the species including their resiliency, population trends and specific threats to recovery that contributes to our *Status of Listed Resources*, *Environmental Baseline*, and Risk Analyses.

To comply with our obligation to use the best scientific and commercial data available, we conducted electronic literature searches throughout the consultation, including within NMFS Office of Protected Resources' electronic library (using *EndNote* ® software). We examined the literature that was cited in the submittal documents and any articles we collected through our electronic searches. The U.S. Navy provided NMFS with a draft and final EIS/OEIS on training and testing that are proposed in the Action Area. We also evaluated the Navy's annual and comprehensive major training exercise and monitoring reports to assess effectiveness of mitigation and actual take incidental to actual training and testing activity levels where feasible.

Considering the information that was available, this consultation and our Opinion includes uncertainty about the basic hearing capabilities of some marine mammals, sea turtles, and fishes; how these taxa use sounds as environmental cues; how they perceive acoustic features of their environment; the importance of sound to the normal behavioral and social ecology of species; the mechanisms by which human-generated sounds affect the behavior and physiology (including the non-auditory physiology) of exposed individuals; and the circumstances that are likely to produce outcomes that have adverse consequences for individuals and populations of exposed species.

3.4.1 Consideration of new literature and pending Acoustic Guidance on the Effects of Anthropogenic Sound on Marine Mammals

NOAA is currently in the process of developing Acoustic Guidance on thresholds for onset of auditory impacts from exposure to sound, which will be used to support assessments of the effects of anthropogenic sound on marine mammals. To develop this Guidance, NOAA is compiling, interpreting, and synthesizing the best information currently available on the effects of anthropogenic sound on marine mammals, and is committed to finalizing the Guidance through a systematic, transparent process that involves internal review, external peer review, and public comment. In December 2013, NOAA released for public comment draft Acoustic Guidance that provides acoustic threshold levels for onset of permanent threshold shift (PTS) and temporary threshold shifts (TTS) in marine mammals for all sound sources. NOAA has since been working to incorporate the relevant information received during the public comment period and to make appropriate changes.

In February 2015, while NOAA was still working to finalize the Guidance, the U.S. Navy provided NOAA with a technical paper by Finneran (2015) describing Navy's proposed methodology for updating auditory weighting functions and numeric thresholds for predicting onset of auditory effects (TTS/PTS thresholds) on marine animals exposed to active sonars and other active acoustic sources utilized during Navy training and testing activities. One of the most significant differences between the criteria employed in prior Navy modeling and those proposed in Finneran (2015) is that the low-frequency cetacean and sea turtle TTS and PTS thresholds are higher at all frequencies. This change is intended to account for the relatively poor auditory sensitivities of sea turtles and the suspected elevated thresholds in low-frequency cetaceans relative to mid-frequency cetaceans.

NOAA is working to evaluate and incorporate the information in Finneran (2015) into its Acoustic Guidance before it becomes final. Before doing so, an independent peer review (i.e., second peer review of the Guidance) of the Navy's technical paper will be necessary, along with a subsequent additional public comment period (i.e., second public comment period for the Guidance). After the peer review and public comment processes are complete, NOAA will determine how best to incorporate the Navy's methodology into its final Acoustic Guidance. The Guidance likely will not be finalized until later this year. Thereafter, any new Navy modeling based on our final Acoustic Guidance would likely take a minimum of several months to complete. Consequently, the results of prior Navy modeling described in this Opinion represent the best available estimate of the number and type of take that may result from the Navy's use of acoustic sources in the MITT Action Area. NOAA's continued evaluation of all available science for the Acoustic Guidance could result in changes to the acoustic criteria used to model the Navy's activities for this consultation, and, consequently, the enumerations of "take" estimates. However, consideration of the draft Guidance and information contained in Finneran (2015) does not alter our assessment of the likely responses of affected ESA-listed species to acoustic sources employed by Navy in the MITT Action Area, or the likely fitness consequences of those responses.

Since the Navy's Phase 2 modeling (the NAEMO model considered in this Opinion), there have been ten studies on marine mammal TTS. (e.g., (Finneran et al. 2005a; Finneran et al. 2010; Finneran and Schlundt 2013; Kastelein et al. 2012a; Kastelein et al. 2012d; Kastelein et al. 2014a; Kastelein et al. 2014d; Popov et al. 2013a; Popov et al. 2011)) (Table 22).

3.4.1.1 ***Mid-frequency Cetaceans***

The results from Finneran and Schlundt (2013) demonstrate there are frequency-specific differences by species in TTS onset and growth, and suggest increased susceptibility to auditory fatigue for frequencies between approximately 10 kHz and 30 kHz. This study supports the importance of using auditory weighting functions (i.e., functional hearing groups are more susceptible to noise-induced hearing loss at certain frequencies), but is not expected to change any of the thresholds to onset TTS between those the Navy used in this consultation and the pending Acoustic Guidance (A. Scholik-Schlomer, personal communication, March 26, 2015).

Popov et al. (2013a) and Popov et al. (2014) examined the impacts of half-octave band noise on hearing in two belugas. In their 2013 study, levels beyond TTS onset were induced (i.e., threshold shifts ranged from 7.5 to 62.5 dB) with recovery occurring within 24 h. In their 2014 study, TTS onset was identical to that of a beluga from another study (i.e., NOC from Schlundt et al. (2000); i.e., these studies are not expected to result in any changes to the thresholds).

3.4.1.2 ***High-frequency Cetaceans***

All the recent TTS studies on harbor porpoises were completed by Kastelein using the same individual exposed to either octave band noise (Kastelein et al. 2012a), tones (Kastelein et al. 2013b; Kastelein et al. 2014c) , or 1 to 2 kHz sonar (Kastelein et al. 2014b). The results from Kastelein et al. (2014)are expected to necessitate a change to TTS onset thresholds for non-impulsive sounds for HF cetaceans (i.e., changed from 160 dB SEL_{cum} in Draft NOAA Guidance to 152 dB SEL_{cum}). This potential change to the TTS onset threshold could impact the enumerations of "take" estimates. However, any changes and subsequent modeling by the Navy would not alter our assessment of the likely responses of affected ESA-listed species to acoustic

sources employed by Navy in the MITT Action Area, or the likely fitness consequences of those responses. Other points of note from these Kastelein et al. studies (all of which have been demonstrated from previous marine mammal studies), include showing 1) increasing exposure duration was more effective in elevating TTS compared to increasing level of exposure, 2) low-frequency sounds are unlikely to affect ability for this species to echolocate (since echolocation occurs at much higher frequency: 125 kHz), and 3) interpulse interval plays an important role in determining TTS onset (lower level of TTS onset for continuous exposure compared to intermittent exposure; longer interpulse interval results in less incidences of TTS and faster recovery times), even with exposures with identical SEL_{cum}.

Kastelein et al. (2015) exposed a harbor porpoise to 2,760 pile driving strikes resulting in an unweighted level of 180 dB SEL_{cum}, but threshold shifts of less than 6 dB were induced (i.e., mean threshold shift of 2.3 to 3.6 dB). Thus, are not expected to result in any changes to the thresholds the Navy used in this consultation to those proposed in the pending Acoustic Guidance.

3.4.1.3 ***Phocid Pinnipeds***

Two more recent studies for phocid pinnipeds (harbor seal) were completed by Kastelein et al. (Kastelein et al. 2013a; Kastelein et al. 2012b). Neither of these studies are expected to result in changes in the TTS onset threshold from those the Navy used in this consultation to those proposed in the pending Acoustic Guidance. Of note, the results for Kastelein et al. (2012b) were excluded from consideration from NOAA's analysis because the exposure durations were greater than 1 h (i.e., durations were 120 and 240 minutes of continuous exposure) and considered unlikely to be encountered by wild individuals. The exposure in Kastelein et al. (2013a) resulted in a 44 dB threshold shift that took 4 days to recover (199 dB SEL_{cum}; note that this exposure level is higher than what is being proposed in the Guidance for PTS onset, which is 197 dB SEL_{cum}, and that the exposure in Kastelein did result in recovery).

Table 22. Available underwater marine mammal threshold shift peer reviewed studies (since 2011).

+Peer reviewed studies available and evaluated as of 1 March 2015. Note: Two papers expected to publish in the near future. However, for all these studies, a TS could not be induced. Thus, neither study affects the acoustic threshold levels and are instead included for completeness.

^Note: Some individuals have been used in multiple studies.

3.4.2 The U.S. Navy's Exposure Estimates

To estimate exposure of marine species to acoustic sounds, the Navy uses acoustic modeling and marine mammal density information developed by the Navy in cooperation with NMFS. A subsequent review on behalf of NMFS by the Center for Independent Experts analyzed the various approaches the Navy used for acoustic effects analyses, leading to the refinement of the previous methodologies for determining acoustic effects. The result was the development of a standard Navy model for acoustic effects, the Navy Acoustic Effects Model (NAEMO).

This Opinion analyzes the environmental consequences based on marine mammal density data, and acoustic modeling methodology that employs acoustic criteria, and new scientific information as summarized below.

3.4.2.1 *The U.S. Navy Acoustic Effects Model (NAEMO)*

Since 1997, the U.S. Navy has modeled the potential acoustic effects on marine mammals and sea turtles from Navy training and testing activities. Various models used "area density" approaches in which acoustic footprints were computed and then multiplied by animal densities to calculate effects. As a result of a review conducted by the Center for Independent Experts, the Navy refined its process. The current model—the Navy Acoustic Effects Model (NAEMO)—is the model used by the Navy to estimate the potential acoustic effects of proposed Navy training and testing activities on marine mammals and sea turtles. We have verified methodology and data used in NAEMO and accept the modeling conclusions on exposure of marine species. A detailed discussion of the NAEMO is contained in chapter 3.4.3.1.6 of the EIS/OEIS, which is incorporated by reference. A full description of NAEMO can be accessed in the Naval Undersea Warfare Center Newport Technical Report 12,071a, 23 August 2013 (updated from 12 March 2012).

3.4.2.1.1 Overview

NAEMO is comprised of seven modules: Scenario Builder, Environment Builder, Acoustic Builder, Marine Species Distribution Builder, Scenario Simulator, Post Processor, and Report Generator. Scenario Builder defines where an activity would occur, the duration of the activity, a description of the activity, and what platforms would be participating. Once a platform is identified, all the sound sources typically associated with that platform are displayed, thus

providing standardization and repeatability when different analysts are entering data. Individual sources can be turned on or off according to the requirements of the scenario. Platforms are either stationary or can be moved through the Action Area in either a defined track or random straight-line movement.

Environment Builder extracts all of the oceanographic and environmental data required for a scenario simulation. When an area is selected, information on bathymetry, sound speed profiles, wind speeds, and bottom properties are extracted from an array of points across the region.

Acoustic Builder generates acoustic propagation data. It reads the Scenario Builder file, allows the user to define analysis points for propagation software, and creates the propagation model inputs. Depending on the source characteristics, the propagation models utilized are Comprehensive Acoustic Simulation System/Gaussian Ray Bundle , Range-Dependent Acoustic Model , or Reflection and Refraction Multilayered Ocean/Ocean Bottoms with Shear Wave Effects (REFMS).

Marine Species Distribution Builder allows the user to distribute marine species within the modeling environment in accordance with the bathymetry and relevant descriptive data. Marine species density data, which include seasonal information when available, are obtained from the Navy Marine Species Density Database (NMSDD); the sizes of cells and density of marine species within each cell vary by species and location.

Scenario Simulator executes the simulation and records the sound received by each marine mammal and sea turtle in the area. It incorporates the scenario definition, sound propagation data, and marine species distribution data and ultimately provides raw data output for each simulation. Most scenarios are run in 4- to 12-hour segments based on representative training and testing activities. Some scenarios are evaluated by platform and single locations, while others are evaluated in multiple locations within a single range complex or testing range. Within each scenario, multiple ship track iterations are run to provide a set of raw data results.

Post Processor provides the computation of estimated effects that exceed defined threshold criteria from each of the raw data files produced by Scenario Simulator. The post-processed computations determine harassment and mortality as defined by the MMPA for military readiness activities. It also tabulates and graphs the output data for review.

Report Generator assembles a series of simulation results from multiple post-processing runs and produces a combined result. Multipliers can be applied to each scenario to compute the effects of conducting them multiple times. Results can also be exported via Microsoft Excel files for further analysis and reporting.

Modeled effects from NAEMO were used to support the U.S. Navy's analyses in the MITT EIS/OEIS, mitigation strategies, Biological Evaluations, and MMPA incidental take authorization applications. We have verified methodology and data used in NAEMO and accept the modeling conclusions on exposure of marine species. A full description of NAEMO can be accessed in the Naval Undersea Warfare Center Newport Technical Report 12,071a, August 23, 2013 (updated from 12 March 2012). The following paragraphs provide an overview of the NAEMO process and its more critical data inputs.

The NAEMO improves upon previous modeling efforts in several ways. First, unlike earlier methods that modeled acoustic sources individually, the NAEMO has the capability to run all sources within a scenario simultaneously, providing a more realistic depiction of the potential effects of an activity. Second, previous models calculated sound received levels within set volumes of water and spread animals uniformly across the volumes; in the NAEMO, animats (virtual animals) are distributed non-uniformly based on higher resolution species-specific density, depth distribution, and group size, and animats serve as dosimeters, recording energy received at their location in the water column. Third, a fully three-dimensional environment is used for calculating sound propagation and animat exposure in the NAEMO, rather than a two-dimensional environment where the worst case sound pressure level across the water column is always encountered. Additionally, NAEMO expands upon previous modelling efforts by incorporating Type II frequency weighting functions, incorporating a behavioral response function, and developing estimates from a new density function (NMSDD). Finally, current efforts incorporate site-specific bathymetry, sound speed profiles, wind speed, and bottom properties into the propagation modeling process rather than the flat-bottomed provinces used during earlier modeling (NUWC 2012).

Using data from the NMSDD, the NAEMO derives an abundance (total number of individuals (i.e., animats)) for the modeled area. The NAEMO then distributes the animats into an area bounded by the maximum distance acoustic energy propagates out to a threshold value (energy footprint). For example, for non-impulsive sources, animats that could receive sound pressure levels greater than or equal to 120 dB are distributed. Animats are distributed based on density differences across the area, the group (pod) size, and known depth distributions (dive profiles) (see Marine Species Modeling Team (2012b) for a discussion of animal dive profiles in detail). Animats change depths every 4 minutes but do not otherwise mimic actual animal behaviors, such as avoidance or attraction to a stimulus (horizontal movement), or foraging, social, or traveling behaviors.

Schecklman et al. (2011) argue static distributions underestimate acoustic exposure compared to models with three-dimensionally moving animals. Their static method is different from the NAEMO in several ways. First, they distribute the entire population at a depth -typical for that species and those animats remain static at that position throughout the entire simulation. In the NAEMO, animats are placed horizontally dependent on non-uniform density information, and then move vertically over time based on species-specific diving behavior. Second, the static method calculates acoustic received level for designated volumes of the ocean and then sumsthe animats that occur within that volume, rather than using the animats themselves as dosimeters, as in the NAEMO. Third, Schecklman et al. (2011) ran 50 iterations of the moving distribution to arrive at an average number of exposures, but because they rely on uniform horizontal density (and static depth density) only a single iteration of the static distribution is realized. In addition to moving the animats vertically, the NAEMO overpopulates the animats over a non-uniform density and then resamples the population a number of times to arrive at an average number of exposures. Tests comparing fully moving animats and horizontally static animats with vertical mobility were compared during development of the NAEMO. For vertical position updates occurring more frequently than every 5 minutes, the number of estimated exposures was similar between the NAEMO and the fully moving distribution; however, computational time was much longer for the fully moving distribution.

The NAEMO calculates the likely propagation for various levels of energy (sound or pressure) resulting from each non-impulse or impulse source used during a training or testing event. These calculations account for bathymetric relief and bottom types (e.g., reflective), estimated sound speeds, and sea surface roughness. Platforms (such as a ship using one or more sound sources) are modeled moving across an area representative of what would normally occur during a training or testing scenario. The model uses typical platform speeds and event durations. Moving source platforms either travel along a predefined track or move in straight lines from a random initial starting point, reflecting at the edges of a predefined boundary. Static sound sources are stationary in a fixed location for the duration of a scenario. Modeling locations were chosen based on historical data where activities have been ongoing and to include environmental variation within the Study.

The NAEMO records the energy received by each animat within the energy footprint of the event and calculates the number of animats having received levels of energy exposures that fall within defined impact thresholds.

Predicted effects on the animats are tallied and the most severe effect (e.g., PTS over TTS) predicted for a given animat is assumed. Each scenario, or each 24-hour period for scenarios lasting greater than 24 hours, is independent of all others.Therefore, the same individual could be impacted during each independent scenario or 24-hour period. In few instances, although the activities themselves all occur within the MITT Action Area, sound may propagate beyond the boundary of the Action Area. Any exposures occurring outside the boundary of the Action Area are counted as if they occurred within the Action Area boundary or within the Action Area for this Opinion.

3.4.2.1.2 Model Assumptions

There are limitations to the data used in the NAEMO, and the results must be interpreted within these context. While the most accurate data and input assumptions have been used, when there is a lack of definitive data to support an aspect of the modeling, assumptions assumed to overestimate exposures have been chosen:

Animats are modeled as being underwater, stationary, and facing the source and therefore always predicted to receive the maximum sound level (i.e., no porpoising or pinnipeds' heads above water). Some odontocetes have been shown to have directional hearing, with best hearing sensitivity facing a sound source and higher hearing thresholds for sounds propagating towards the rear or side of an animal (Kastelein et al. 2009; Mooney et al. 2008; Popov and Supin 2009).

- Animats do not move horizontally (but change their position vertically within the water column), which may overestimate physiological effects such as hearing loss, especially for slow moving or stationary sound sources in the model.

- Animats are stationary horizontally and therefore do not avoid the sound source, unlike in the wild where animals would most often avoid exposures at higher sound levels, especially those exposures that may result in PTS.

- Animats are assumed to receive the full impulse of the initial positive pressure wave of an explosion, although the impulse-based thresholds (onset mortality and onset slight lung injury) assume an impulse delivery time adjusted for animal size and depth. Therefore, these impacts are overestimated at farther distances and increased depths.

- Multiple exposures within any 24-hour period are considered one continuous exposure for the purposes of calculating the temporary or permanent hearing loss, because there are not sufficient data to estimate a hearing recovery function for the time between exposures.

- Mitigation measures implemented during training exercises and testing activities were not considered in the model. In reality, sound-producing activities would be reduced, stopped, or delayed if marine mammals are detected within the mitigation zones.

3.4.3 Navy Marine Species Density Database (NMSDD)

There is no single source of density data for every geographic area, marine species, and season of the year because of the costs, resources, and effort that would be required to provide sufficient survey coverage to estimate density. Therefore, to characterize the marine species density for large affected areas such as the MITT Action Area, the Navy compiled data from several sources, resulting in the Pacific Navy Marine Species Density Database (NMSDD) Technical Report dated September 2013.

For estimating densities of marine mammals and sea turtles in the MITT Action Area, the Navy selected representative areas (Figure 14) including the MITT Action Area including pelagic and nearshore environments and the transit corridor to represent the range of different habitats that could occur along the corridor, including both island (Wake Island) and open ocean habitats.

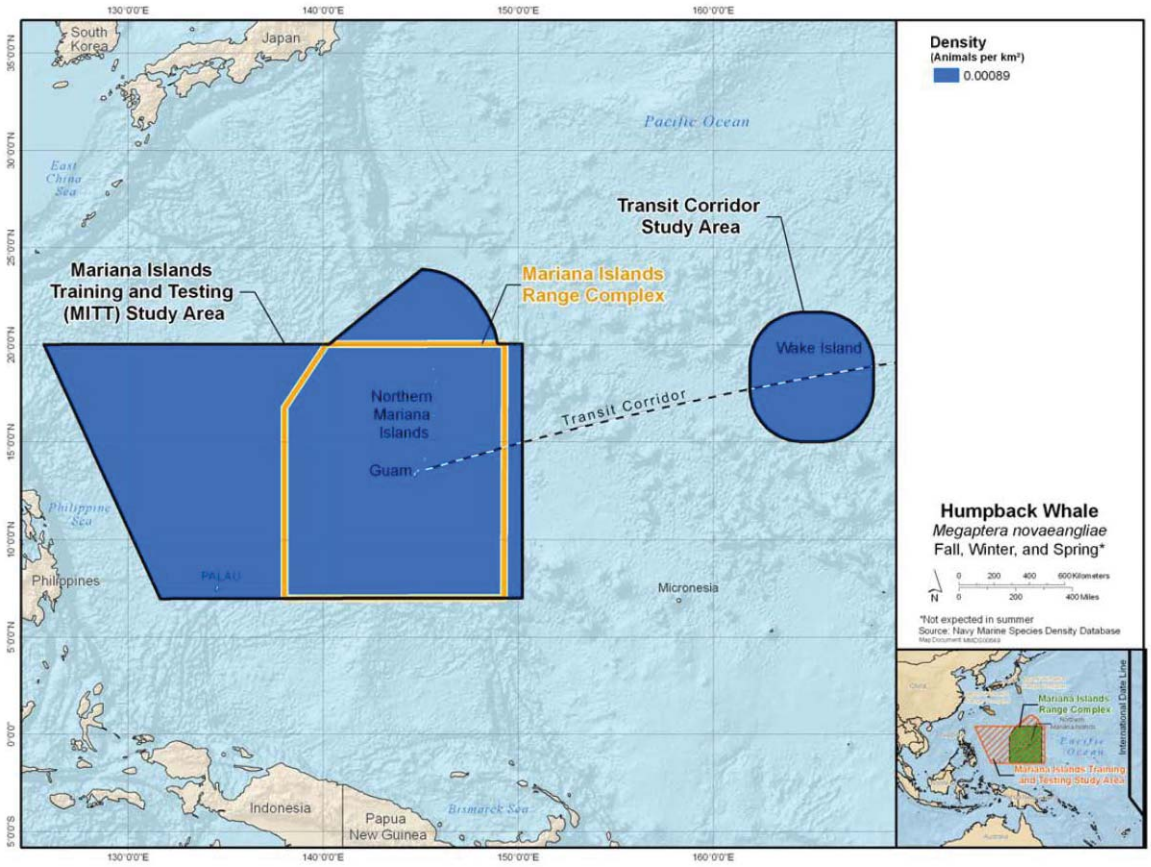

Figure 14. Example of Respresentative Areas Selected for Estimating Marine Species Densities

3.4.4 Differences Between Navy Modeling Considered in Previous Biological Opinions and this Biological Opinion

Phase I (roughly 2008 through 2012) of the Navy's at-sea environmental planning and permitting effort including MIRC addressed U.S. Navy training and testing activities in a number of separate documents. Different modeling processes were used to estimate the effects of sound on marine species incidental to military readiness activities. Phase II (roughly 2013 through 2021) methodology eliminates the varying modeling processes by utilizing a standard model, NAEMO, for all acoustic effects analyses.

The first step earlier in the Phase I modeling process involved propagation modeling. For sonars, the Comprehensive Acoustic System Simulation (CASS)/Gaussian Ray Bundle (GRAB) model was used. Explosive sources were analyzed using either Reflection and Refraction in Multilayered Ocean/Ocean Bottoms with Shear Wave Effects (REFMS) or a modified version of CASS/GRAB. Phase II modeling retains some of the Phase I features, such as use of the same propagation model (i.e., CASS/GRAB), for developing tonal source footprints. Phase II uses REFMS exclusively for explosive propagation and includes the addition of the Range-Dependent Acoustic Model (RAM) to model non-explosive impulsive sources (i.e., airguns).

For Phase I, footprints were created for each active source used in an activity, and the movements of the source were modeled over the operating area. Only one source type was modeled at a time. Unlike Phase I, NAEMO has the capability to simultaneously run multiple sources during a scenario, affording a more realistic depiction of the potential effects of an activity. For example, transmissions emitted by a surface combatant with its hull-mounted sonar, a helicopter with its dipping sonar, a torpedo's homing sonar, and the countermeasures discharged by the targeted submarine can be modeled simultaneously.

Although the acoustic propagation was modeled in three dimensions during Phase I analyses, in some cases, the three-dimensional (3-D) footprint was collapsed into a two-dimensional (2-D) acoustic footprint by utilizing the maximum received level, irrespective of the depth, at each range step. In other areas, a volumetric, 3-D footprint was developed to allow for variations in animal depth. For Phase II analyses, the 3-D acoustic propagation field was maintained throughout the analysis process.

Phase I distributed marine species uniformly in the respective density cells over the area being modeled. The animals were distributed in two dimensions, except in locations where data for species-specific dive profiles were available. In those areas, the animals were distributed in 3-D. In the 2-D distribution, all animals within the range of the maximum energy field would be affected, while in the volumetric approach, effects depended on where the animals were in the water column in relation to the propagation pattern. In Phase II, data on species-specific habitat preference, podding behavior, and dive profiles were taken into account and used to distribute individual animals in the model. An animat, or virtual representation of a marine animal, serves as a dosimeter, recording the energy received from all active sources during a scenario, resulting in the cumulative effects of all sources being accounted for when the impacts are analyzed.

Another difference between Phase I and Phase II modeling involves the environmental data used during propagation modeling. Phase II incorporates bathymetry into the propagation modeling process for non-impulsive sources and non-explosive impulsive (i.e., airgun) sources; Phase I used flat-bottomed bathymetry. Flat-bottom bathymetry will continue to be used in Phase II for all impulsive sources, as it was in Phase I. Futhermore, Phase II uses range-dependent sound speeds, wind speed, and bottom properties.

3.4.5 Discussion of Finneran and Schlundt 2010 and 2011 Dolphin Studies in the Context of Phase II Modeling

The Navy incorporated the data from two Finneran studies (2010 and 2011), in coordination with other scientific literature, to develop auditory weighting functions and "weighted" thresholds for auditory criteria. A summary of the findings from the two papers is provided below as well as an explanation of how the Navy incorporated the results of these papers into the weighting functions and thresholds used to support the MITT EIS/OEIS and this Opinion. We address the likely reasons that takes for ESA species declined when comparing the take estimates for MIRC to the MITT, despite the fact that one might have anticipated the application of the two recent Finneran papers (Finneran 2010) (Finneran 2011) would have resulted in increased estimated takes overall. The Navy and NMFS determined it was appropriate to use a new Navy model—NAEMO—that is considered the best available information and incorporates the new weighting functions and thresholds. NAEMO also incorporates a number of other significant changes and enhancements compared with the SAIC model used in MIRC. This paper surmises that the

changes in density data and distributions incorporated in NAEMO was likely the main factor that influenced an overall reduction of take estimates for ESA species between MIRC and the MITT estimates used in this Biological Opinion.

Finneran and Schlundt (2010)

Finneran and Schlundt (Finneran and Schlundt 2010) measured temporary threshold shift (TTS) in a single female bottlenose dolphin (*Tursiops truncatus*) after exposure to tones at 3 and 20 kHz in order to examine the effects of exposure frequency on the onset and growth of TTS. The preliminary data provide evidence of frequency specific differences in TTS onset and growth between the 3 kHz and 20 kHz exposures. At 20 kHz, where bottlenose dolphin hearing sensitivity is better, TTS not only began at a lower exposure level compared to the 3 kHz exposures, but also grew at a faster rate. This demonstrated that damage risk criteria for dolphins exposed to underwater sound should account for the exposure frequency and that criteria developed for lower frequencies (e.g. 3 kHz) may underestimate the amount of TTS if applied to higher frequencies (e.g. 20 kHz), where hearing sensitivity is better. This research suggests the need for analogous data across the entire audible range so that potential effects of various frequency tones can be properly assessed.

Finneran and Schlundt (2011)

For humans, acoustic damage-risk criteria rely on numeric thresholds based on "weighted" noise levels. Weighted noise levels are calculated by applying a frequency-dependent filter, or "weighting function" to the measured sound pressure before calculation of the overall sound pressure level (SPL). The weighting functions are designed to emphasize frequencies where sensitivity to sound is high and to de-emphasize frequencies where sensitivity is low. This technique allows for a single, weighted damage-risk criterion, regardless of the sound frequency. Weighting functions for humans are derived from equal loudness contours—graphs representing the SPLs that led to a sensation of equal loudness magnitude in the listener as a function of sound frequency (Suzuki and Takeshima 2004). Equal loudness contours are derived from loudness experiments where the listener is asked to judge the relative loudness of two tones with different frequencies. Prior to Finneran and Schlundt (2011a) there were no direct measurements of subjective loudness in non-human animals from which to develop equal loudness contours. Finneran and Schlundt (2011a)trained a bottlenose dolphin to perform a loudness comparison test, where the listener indicated which of two sequential tones was louder. This study demonstrated that a non-human animal could be conditioned for subjective loudness testing and therefore, it was possible to directly measure loudness levels in some species. Additional data is required to more accurately predict the relationship below 2.5 kHz. The weighting function derived here is substantially different than the "M-weighting function" proposed for mid-frequency cetaceans in Southall et al. (Southall et al. 2007b), which is nearly flat over the range of ~1–30 kHz and thus does not mirror the change in equal loudness contours observed over that frequency range. Nor does the M-weighting function capture the difference in TTS onset and growth reported for a single bottlenose dolphin tested at 3 and 20 kHz in Finneran and Schlundt (2010).

3.4.6 Post Processing. Avoidance Behavior and Mitigation Measures as Applied to Sonar and Active Acoustic Sources

As described in the modeling technical report, DEIS/OEIS, the model accounts for an animat's position vertically in the water column by taking into account species-specific dive profiles; however, it does not account for an animat's horizontal movement, so the model assumes that an animal would remain stationary and tolerate repeated intense sound exposures at very close distances. This assumption is invalid because animals are likely to leave the area to avoid intense sound exposure that could cause injury. Similarly, the modeling assumes that certain species known to avoid areas of high anthropogenic activity would remain in the very close vicinity of all Navy training and testing activities, regardless of how many vessels or low-flying aircraft (i.e., helicopters) are involved. The outputs of the model, therefore, present an unrealistically high estimate of acoustic impacts in close proximity to certain Navy training and testing activities.

Additionally, the modeling currently does not account for implementation of mitigation designed to avoid or reduce marine mammal and sea turtle exposures to explosives and high intensity sound, nor does it account for standard operating procedures (procedures designed for the safety of personnel and equipment) implemented to ensure safety and mission success, but which may have incidental environmental benefits. That is, the modeling assumes that any mitigations measures, such as sonar power-down or delay of a detonation, would not be implemented even if an animal could be sighted within the mitigation zone. The Navy's proposed mitigations were developed in cooperation with NMFS and are designed to reduce environmental impacts while being operationally feasible. It is difficult to assess the effectiveness of mitigation measures; however, NMFS assesses annual exercise reports and comprehensive summary reports to assess general trends in implementation andany observed responses to mitigation. The outputs of the model (without mitigation), therefore, present an unrealistically high estimate of acoustic impacts within the mitigation zones of certain Navy training and testing activities.

In order to provide a holistic quantitative assessment of acoustic impacts, the post-model analysis quantitatively assessed the effect of animal avoidance behavior and implementation of mitigation, considering the following:

- Best available science on species' behavior
- Number of platforms (i.e., aircraft, vessels) used during specific activities
- Ability to detect specific species
- Ability to observe the mitigation zone around different platforms during different activities

The steps of the post-model analysis are briefly summarized in Table 23 and presented in the order they are expected to occur during an actual training or testing activity, which is also the order in which they were mathematically considered in the post-model analysis. When feasible for a given activity, mitigation begins prior to the actual production of underwater sound (e.g., 10–30 minutes, dependent upon platform, prior to most sonar and explosive activities); therefore,

mitigation effectiveness is applied in the post-model analysis before animal avoidance is quantified.

Table 23. Post Model Acoustic Impact Analysis Process

Is the Sound Source Sonar/Other Active Acoustic Source or Explosives?	
Sonar and Other Active Acoustic Sources	Explosives
S-1. Is the activity preceded by multiple vessel activity or hovering helicopter?	E-1. Is the activity preceded by multiple vessel activity or hovering helicopter?
Species sensitive to human activity (i.e., beaked whales) are assumed to avoid the activity area, putting them out of the range to Level A harassment. Model-estimated PTS to these species during these activities are unlikely to actually occur and, therefore, are considered to be TTS (animal is assumed to move into the range of potential TTS). The activities preceded by multiple vessel movements or hovering helicopters are listed in Tables 3.4-14 and 3.4-15 in Section 3.4.4.1.2 (Avoidance Behavior and Mitigation Measures as Applied to Sonar and Other Active Acoustic Sources) in the FEIS.	Species sensitive to human activity (i.e., beaked whales) are assumed to avoid the activity area, putting them out of the range to mortality. Model-estimated mortalities to these species during these activities are unlikely to actually occur and, therefore, are considered to be injuries (animal is assumed to move into the range of potential injury). The activities preceded by multiple vessel movements or hovering helicopters are listed in Section 3.4.4.2.2 (Avoidance Behavior and Mitigation as Applied to Explosives) in the FEIS.
S-2. Can Lookouts observe the activity-specific mitigation zone (see Chapter 5) up to and during the sound-producing activity?	E-2. Can Lookouts observe the activity-specific mitigation zone (see Chapter 5) up to and during the sound-producing activity?
If Lookouts are able to observe the mitigation zone up to and during a sound-producing activity, the sound-producing activity would be halted or delayed if a marine mammal is observed and would not resume until the animal is thought to be out of the mitigation zone (per the mitigation measures in Chapter 5). Therefore, model-estimated PTS exposures are reduced by the portion of animals that are likely to be seen [Mitigation Effectiveness (1, 0.5, or 0) x Sightability, g(0)]. Any animals removed from the model-estimated PTS are instead assumed to be TTS (animal is assumed to move into the range of TTS). The g(0) value is associated with the platform (vessel or aircraft) with the dedicated Lookout(s). For activities with lookouts on both platforms, the higher g(0) is used for analysis. The Mitigation Effectiveness values are provided in Section 3.4.4.1.2 (Avoidance Behavior and Mitigation Measures as Applied to Sonar and Other Active Acoustic Sources) in the FEIS.	If Lookouts are able to observe the mitigation zone up to and during an explosion, the explosive activity would be halted or delayed if a marine mammal is observed and would not resume until the animal is thought to be out of the mitigation zone (per the mitigation measures in Chapter 5). Therefore, model-estimated mortalities and injuries are reduced by the portion of animals that are likely to be seen [Mitigation Effectiveness (1, 0.5, or 0) x Sightability, g(0)]. Any animals removed from the model-estimated mortalities or injuries are instead assumed to be injuries or behavioral disturbances, respectively (animals are assumed to move into the range of a lower effect). The g(0) value is associated with the platform (vessel or aircraft) with the dedicated Lookout(s). For activities with lookouts on both platforms, the higher g(0) is used for analysis. The g(0) values are provided in Table 3.4-8. The Mitigation Effectiveness values are provided in Table 3.4-21 in Section 3.4.2.2 (Avoidance Behavior and Mitigation as Applied to Explosives) in the FEIS.

3.4.6.1 Mitigation

The Navy Acoustic Effects Model estimates acoustic effects without taking into account any shutdown or delay of the activity when marine mammals are present and detectable within the mitigation zone; therefore, the model overestimates impacts to marine mammals within mitigation zones. The post-model analysis considers and quantifies the potential for mitigation to reduce the likelihood or risk of PTS (due to sonar and other active acoustic sources) and injuries and mortalities (due to explosives).

Two factors are considered when quantifying the effectiveness of mitigation: (1) the extent to which the type of mitigation proposed for a sound-producing activity (e.g., active sonar) allows for observation of the mitigation zone prior to and during the activity and (2) the sightability of each species that may be present in the mitigation zone, which is affected by species-specific characteristics.

3.4.6.2 Avoidance

At close ranges and high sound levels approaching those that could cause PTS, avoidance of the area immediately around the sound source is the assumed behavioral response for most cases. Because the Navy Acoustic Effects Model does not consider horizontal movement of animats, including avoidance of high-intensity sound exposures, it over-estimates the number of marine mammals and sea turtles that would be exposed to sound sources that could cause injury. In other words, the model estimates PTS impacts as though an animal would tolerate an injurious sound exposure without moving away from the sound source. Therefore, the potential for avoidance is considered in the Navy's post-model analysis.

3.5 Treatment of "Cumulative Impacts" (in the sense of NEPA)

The U.S. Council on Environmental Quality defined "cumulative effects" (which we refer to as "cumulative impacts" to distinguish between NEPA and ESA uses of the same term) as "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions" (40 CFR §1508.7). The effects analyses of biological opinions considered the "impacts" on listed species and designated critical habitat that result from the incremental impact of an action by identifying natural and anthropogenic stressors that affect endangered and threatened species throughout their range (the *Status of Listed Resources*) and within an Action Area (the *Environmental Baseline*, which articulate the pre-existing impacts of activities that occur in an Action Area, including the past, contemporaneous, and future impacts of those activities). We assess the effects of a proposed action by adding their direct and indirect effects to the impacts of the activities we identify in an *Environmental Baseline* (50 CFR §402.02), in light of the impacts of the status of the listed species and designated critical habitat throughout their range; as a result, the results of our effects analyses are equivalent to those contained in the "cumulative impact" sections of NEPA documents.

We considered cumulative impacts as part of our consultation. Specifically, we considered (1) stressors that accumulate in the environment, and (2) effects that represent either the response of individuals, populations, or species to that accumulation of stressors. Further, we considered the likely impacts of these accumulative phenomema on an annual basis, over the duration of the five-year MMPA regulations, and under the assumption that these activities would continue into

the reasonably foreseeable future. Given the ongoing nature of the proposed activities, we assume that the type, amount, and extent of training and testing do not exceed maximum levels assessed in the action.

In the sense of Item 1, which captures the normal usage of "cumulative impacts," we concluded that phenomena like sound and ship strike do not accumulate in the environment (sound energy rapidly transforms into other forms of energy and ship strikes are independent events), although phenomena like the acreage of habitat destroyed and concentrations of toxic chemicals, sediment, and other pollutants accumulate.

In the sense of Item 2, we considered phenomena that accumulate in individuals and individually contribute or collectively determine the probable fitness of the individuals that comprise a population. These include, the passage of time and its corollary, the passage or loss of time (specifically, the loss of time to reproduce, to forage, and to migrate, etc.); reproductive success; longevity; energy debt, including allostatic loading; body burdens of toxic chemicals; the fitness costs of behavioral decisions (canonical costs); injuries and tissue damage; and overstimulation of sensory organs (which would include noise-induced losses of hearing sensitivity).

At the level of populations, phenomena that "accumulate" include population abundance; the number or percent of individuals in a population with lifetime reproductive success greater than 2.0; the number or percent of individuals in a population with lifetime reproductive success equal to 2.0; the number or percent of individuals in a population with lifetime reproductive success less than 2.0; the number or percent of individuals that emigrate from a population per unit time; the number or percent of individuals that immigrate into a population per unit time; mortality within a particular age or stage over generation time; and the reservoir of juveniles in a population that have a high probability of surviving to the age of reproduction (population momentum or its absence).

At the species level, when feasible, we accumulate those phenomena that allow us to estimate the extinction risks facing a species. These include increases or decreases in the number of occurrences or populations; the extinction probability of particular occurrences; variance in the rates of population growth or decline; and demographic stochasticity.

Cummulative effects also include effects of future State, tribal, local, or private actions that are reasonably certain to occur in the Action Area considered in this biological opinion. Future Federal actions that are unrelated to the action are not considered in this section because they require separate consultation pursuant to Section 7 of the ESA.

4 STATUS OF LISTED RESOURCES

This section identifies the ESA-listed species that potentially occur within the Action Area that may be affected by Mariana Islands training and testing. It then summarizes the biology and ecology of those species and what is known about their life histories in the Action Area. The species potentially occurring within the Action Area are listed in Table 24, along with their regulatory status.

Table 24. ESA-listed Species That May be Affected by MITT Activities

Species	ESA Status	Critical Habitat	Recovery Plan	Recent Trend†
Marine Mammals – Cetaceans				
Blue Whale (*Balaenoptera musculus*)	E – 35 FR 18319	-- --	07/1998	-
Fin Whale (*Balaenoptera physalus*)	E – 35 FR 18319	-- --	75 FR 47538	?
Humpback Whale (*Megaptera novaeangliae*)*	E – 35 FR 18319	-- --	55 FR 29646	↑
Sei Whale (*Balaenoptera borealis*)	E – 35 FR 18319	-- --	76 FR 43985	?
Sperm Whale (*Physeter macrocephalus*)	E – 35 FR 18319	-- --	75 FR 81584	?
Sea Turtles				
Green Turtle (*Chelonia mydas*)*	T – 43 FR 32800	63 FR 46693	63 FR 28359	↕
Hawksbill Turtle (*Eretmochelys imbricata*)	E – 35 FR 8491	63 FR 46693	63 FR 28359	↓

Acropora retusa	T – 79 FR 53851	-- --	-- --	?
Seriatopora aculeata	T – 79 FR 53851	-- --	-- --	?

***Green sea turtles in the Action Area were proposed as an endangered Central-West Pacific DPS on March 23, 2015 (80 FR 15271). Humpback whales in the Action Area were proposed as a threatened Western North Pacific DPS on April 21, 2015. Although these DPS designation are not final, this Opinion will analyze the effects of green sea turtle and humpback whale take separately on both the currently listed entities (range-wide) and the proposed DPSs.**
† Species status trends from the FY 2013 to 2014 Report to Congress (NMFS 2015): ↑ increasing, ↓ decreasing, ↕ mixed, ? unknown, - stable,
‡NMFS determined neither *Acropora tenella nor Pavona diffluens* occur in the Action Area.

Table 25 summarizes the stressor categories and potential for effects as assessed by the Navy. Our rationale for concurrence with Navy determinations of may affect, not likely to adversely affect, are summaried in Section 4.1 below. Species that are not likely to be adversely affected by any of the stressors in Table 25 were not carried forward in our effects analysis. Species that were likely to be adversely affected by any of the stressor categories are carried forward in our effects analysis.

Table 25. Summary of Navy ESA Effect Determinations and NMFS Final Determinations

Stressor	Navy Determinations		NMFS Final Determinations
	Likely to adversely affect	Not likely to adversely affect	Concurrence with Navy Determination (Yes or No)
Acoustic Stressors			
Non-implusive Acoustic Stressors - Sonar and Other Active Acoustic Sources	Humpback Whale, Blue Whale, Fin Whale, Sei Whale, Sperm Whale, Green Turtle, Hawksbill Turtle, Loggerhead Turtle, Leatherback Turtle	Olive Ridley Turtle, Corals	Yes
Impulsive Acoustic Stressors - Explosives	Green Turtle, Hawksbill Turtle, Scalloped Hammerhead Shark	Humpback Whale, Blue Whale, Fin Whale, Sei Whale, Sperm Whale, Loggerhead Turtle, Olive Ridley Turtle, Leatherback Turtle, **Corals***	**Yes for all determinations except corals. *We determined that impulsive acoustic stressors would be likely to adversely affect *Acropora globiceps*.**
Weapons Firing, Launch, and Impact Noise	--	Humpback Whale, Blue Whale, Fin Whale, Sei Whale, Sperm Whale, Green Turtle, Hawksbill Turtle, Loggerhead Turtle, Olive Ridley Turtle, Leatherback Turtle, Scalloped Hammerhead Shark	Yes
Aircraft Noise	--	Humpback Whale, Blue Whale, Fin Whale, Sei Whale, Sperm Whale, Green Turtle, Hawksbill Turtle, Loggerhead Turtle, Olive Ridley Turtle, Leatherback Turtle. Scalloped Hammerhead Shark	Yes
Vessel Noise	--	Humpback Whale, Blue Whale, Fin Whale, Sei Whale, Sperm Whale, Green Turtle, Hawksbill Turtle, Loggerhead Turtle, Olive Ridley Turtle, Leatherback Turtle, Scalloped Hammerhead Shark	Yes
Energy Stressors			

Stressor	Navy Determinations		NMFS Final Determinations
	Likely to adversely affect	Not likely to adversely affect	Concurrence with Navy Determination (Yes or No)
Electromagnetic Devices	--	Humpback Whale, Blue Whale, Fin Whale, Sei Whale, Sperm Whale, Green Turtle, Hawksbill Turtle, Loggerhead Turtle, Olive Ridley Turtle, Leatherback Turtle, Scalloped Hammerhead Shark	Yes
Physical Disturbance and Strike			
Vessel Strike	--	Humpback Whale, Blue Whale, Fin Whale, Sei Whale, Sperm Whale, Green Turtle, Hawksbill Turtle, Loggerhead Turtle, Olive Ridley Turtle, Leatherback Turtle, Corals, Scalloped Hammerhead Shark,	Yes
In-Water Devices	--	Humpback Whale, Blue Whale, Fin Whale, Sei Whale, Sperm Whale, Green Turtle, Hawksbill Turtle, Loggerhead Turtle, Olive Ridley Turtle, Leatherback Turtle, Corals, Scalloped Hammerhead Shark	Yes
Military Expended Materials	--	Humpback Whale, Blue Whale, Fin Whale, Sei Whale, Sperm Whale, Green Turtle, Hawksbill Turtle, Loggerhead Turtle, Olive Ridley Turtle, Leatherback Turtle, **Corals***, Scalloped Hammerhead Shark	**Yes for all determinations except corals. *We determined that military expended materials would be likely to adversely affect corals.**
Entanglement			
Fiber Optic Cables and Guidance Wires	--	Humpback Whale, Blue Whale, Fin Whale, Sei Whale, Sperm Whale, Green Turtle, Hawksbill Turtle, Loggerhead Turtle, Olive Ridley Turtle, Leatherback Turtle, Scalloped Hammerhead Shark	Yes

Stressor	Navy Determinations		NMFS Final Determinations
	Likely to adversely affect	Not likely to adversely affect	Concurrence with Navy Determination (Yes or No)
Decelerators/ Parachutes	--	Humpback Whale, Blue Whale, Fin Whale, Sei Whale, Sperm Whale, Green Turtle, Hawksbill Turtle, Loggerhead Turtle, Olive Ridley Turtle, Leatherback Turtle, Scalloped Hammerhead Shark	Yes
Ingestion			
Munitions	--	Humpback Whale, Blue Whale, Fin Whale, Sei Whale, Sperm Whale, Green Turtle, Hawksbill Turtle, Loggerhead Turtle, Olive Ridley Turtle, Scalloped Hammerhead Shark	Yes
Military Expended Materials Other Than Munitions	--	Humpback Whale, Blue Whale, Fin Whale, Sei Whale, Sperm Whale, Green Turtle, Hawksbill Turtle, Loggerhead Turtle, Olive Ridley Turtle, Leatherback Turtle, Scalloped Hammerhead Shark	Yes
Secondary Stressors			
Explosives, Metals, Chemicals, Disease, Parasites, Sedimentation	--	Humpback Whale, Blue Whale, Fin Whale, Sei Whale, Sperm Whale, Green Turtle, Hawksbill Turtle, Loggerhead Turtle, Olive Ridley Turtle, Leatherback Turtle, Corals, Scalloped Hammerhead Shark	Yes

-- indicates no species with that determination.

4.1 Species and Designated Critical Habitat Not Considered Further in this Opinion

As described in the *Approach to the Assessment* section of this Opinion, NMFS uses two criteria to identify those endangered or threatened species or critical habitat that are not likely to be adversely affected by proposed Mariana Islands training and testing. The first criterion is *exposure* or some reasonable expectation of a co-occurrence between one or more potential stressor associated with training and testing activities and a particular listed species or designated critical habitat. If we conclude that a listed species or designated critical habitat is not likely to be exposed to training and testing activities, we must also conclude that the listed species or critical habitat is not likely to be adversely affected by those activities. The second criterion is the probability of a *response* given exposure, which considers *susceptibility.* For example, a species

may be exposed to noise from explosions of ordnance, but may be unlikely to be affected by the sound (at sound pressure levels they are likely to be exposed to). We applied these criteria to the species listed in Table 24.

4.1.1 Olive Ridley Sea Turtle

Only one record of an olive ridleys sea turtle has been documented for Guam or the CNMI, allegedly captured near Saipan (Pritchard 1977). Olive ridley sea turtles are rare in the MITT Action Area. For the purposes of modeling effects to species within the Action Area the Navy has estimated the olive ridley sea turtle abundance at 0.000001 animals per km^2. The U.S. Navy determined that stressors resulting from sonar and other active acoustic sources, explosives, weapons firing/launch/impact noise, aircraft noise, vessel noise, electromagnetic devices, vessels and in-water devices, fiber optic cables/wires/parachutes, and military expended materials may affect, but are not likely to adversely affect olive ridley sea turtles as the activities would not impose fitness consequences on an individual that could result in "take" due to very low potential for co-ocurrence of individuals and specific stressors.

The exposure of olive ridley sea turtles to acoustic stressors, including non-impulsive (e.g. sonar) and impulsive sources (e.g. explosives), are anticipated to be rare. Navy models predict 12 exposures at greater than 120 dB from non-impulsive acoustic stressors related to training activities and 15 exposures from testing activities. None of these exposures are anticipated to be greater than 150 dB or rise to the level of take (≥ 175 dB re 1 μPa root mean square). Navy modeling also predicts zero exposures of olive ridley sea turtles to impulsive acoustic stressors greater than 120 dB or 150 dB. Noise from infrequent and short duration munition firing and low density of moving vessels and aircraft are not reasonably expected to co-occur with the rare olive ridley sea turtle. Olive ridley sea turtles would be need to be within 198 m of electromagnetic devices to detect it and potentially respond to it behaviorally. Given the rarity of this species in the Action Area it is not reasonable to expect olive ridley sea turtles to be exposed to electromagnetic (energy) stressors. The Navy's mitigation measures to avoid collisions (lookouts and "safe speed" procedures) and the rarity of olives ridley sea turtles in the Action Area indicate it is not reasonable to expect this species to collide with vessels in the Action Area. Similarly, the rarity of this species and the low speed of non-vessel in-water devices and small footprint of military expended materials indicate it is not reasonable to expect collisions with either of these stressor sources. Fiber optic cables, guidance wires, and decelerators/parachutes used by the Navy are designed to sink quickly. Fiber optic cables do not form loops and break easily reducing the likelihood of entanglement. Guide wires, which are very thin and of a relatively low breaking strength, are used only in deep waters. After sinking to the ocean bottom these wires, would break down within 2 years and no longer pose any risk. Decelerators and parachutes are also used over deep water where sea turtles are not expected to be foraging. Given the limited time entanglement stressors will be present in the water column, the low break-strength and looping ability of fiber optic cables, and the use of these materials over deep water indicates it is not reasonable to expect entranglement of olive ridley sea turtles to occur. The ingestion of small and medium caliber projectiles and other military expended materials is not likely to occur because olive ridley sea turtles are rare in the Action Area and most expendable materials are used over deeper waters where this species is not expected to forage, therefore the ingestion of expended materials is not reasonably expected to occur. Given the rarity of this species it is not reasonable to expect they would be exposed to secondary stressors such as explosion byproducts, metals, chemicals, or exposure to disease.

We conclude that annual training and testing activities in the MITT Action Area are not likely to adversely affect the olive ridley sea turtle in a given year or cumulatively into the reasonably foreseeable future due to a lack of potential for exposure to stressors. Since we anticipate olive ridley sea turtle occurrence to be rare and the potential for exposure to stressors from training and testing activities would be discountable, we do not consider this species further in this Opinion.

4.1.2 Acropora retusa

Colonies of *Acropora retusa* are flat plates with short, thick finger-like branches. Branches look rough and spiky because radial corallites are variable in length. Colonies are typically brown or green in color. *Acropora retusa* is easily confused with other digitate *Acropora* species. It can be distinguished from *Acropora globiceps*, *Acropora gemmifera*, *Acropora monticulosa*, *Acropora macrostomata*, and most other digitate *Acropora* by the rough, spiky branch surfaces due to variable length radial corallites. It can be distinguished from *Acropora humilis* and *Acropora cophodactyla* by the small, tubular, axial corallite. It can be distinguished from *Acropora branchi* by thicker branches when *Acropora branchi* has branches at all (79 FR 53852).

4.1.2.1 Distribution and Abundance

Acropora retusa is distributed from the Red Sea and the Indian Ocean to the central Pacific. Veron (2014) reported that this species is confirmed in 23 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional 21. Wallace (1999b) reports its occurrence in five of her 29 Indo-Pacific areas, many of which are larger than Veron's ecoregions. Richards (2009) estimated its range at 68 million km^2. Within U.S. waters, this species is confirmed in American Samoa, Guam, and the PRIA. (http://www.fpir.noaa.gov/PRD/prd_coral.html).

Veron (2014) reports that *Acropora retusa* occupied 0.5 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.21 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as ''rare.'' Overall abundance was described as ''common in South Africa, rare elsewhere.'' Veron did not infer trends in abundance from these data. According to the Final Rule (79 FR 53852), *Acropora retusa's* absolute abundance is at least millions of colonies at the time of listing.

Within the Mariana Islands, *Acropora retusa* is confirmed in Guam, but not in CNMI (NMFS 2015 "Listed Corals in the Indo-Pacific: *Acropora retusa*, 4 p."). On Guam, a recent review of available coral survey data from numerous sites around the island showed *Acropora retusa* at only one location. Several surveys were conducted within Apra Harbor, but the species was not found there (NMFS/PIRO/HCD Guam coral database, 2015).

4.1.2.2 Habitat

Acropora retusa inhabits shallow water upper reef slopes and tidal pools. It has been reported from depths of 1 to 5 m (79 FR 53852) and down to 11 m (D. Fenner, personal communication, 2015).

4.1.2.3 Reproduction and Growth

Little is known of reproduction and growth in *Acropora retusa*. The available genus-level information for *Acropora* is the best available information, as provided in the *Acropora*

globiceps status (Section 4.2.11.3) . *Acropora retusa* is a hermaphroditic spawner with lecithotrophic (yolk-sac) larvae (79 FR 53852).

4.1.2.4 Status and trends

Acropora retusa was listed as threatened on September 10, 2014 (79 FR 53851). The abundance of *A. retusa* has likely declined over the past 50 to 100 years although a precise quantification is not possible based on the limited species specific information. The species is highly susceptible to ocean warming, and is susceptible to coral disease, ocean acidification, trophic effects of fishing, nutrients over-enrichment, and predation, all of which have increased in the past 50 to 100 years, and continue to increase throughout much of its range. *Acropora retusa*'s geographic distribution extends from the Red Sea and Indian Ocean to the central Pacific. Its depth range is at least zero to 5 meters in upper reef slopes, reef flats, and adjacent habitats. Its absolute abundance is at least millions of colonies across its range. While spatial variability of threats such as ocean warming and acidification across the species' range moderates vulnerability because many colonies are either not exposed to threats or do not negatively respond to a threat at any given point in time, the threats are increasing and will continue to increase in the foreseeable future, thus the species is expected to continue to decline. However, there is inadequate data to quantify current and future population status and trends on any spatial scale, let alone across the range of the species (79 FR 53852).

4.1.2.5 Natural threats

Of the nine primary threats to reef-building corals (ocean warming, coral disease, ocean acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade), only predation is considered a natural threat. Due to the lack of species-specific information on the susceptibility of *Acropora retusa*to predation, we summarize the available information on this threat to *Acropora* species in general: The studies cited in the Status Review Report (Brainard et al. 2011b) and Final Rule (79 FR 53852) on predation in *Acropora* report that predators such as crown-of-thorns starfish and *Drupella* snails prefer to eat *Acropora* over other genera. Thus, the available information suggests that *Acropora globiceps* is likely to have some susceptibility to predation (79 FR 53852).

4.1.2.6 Anthropogenic threats

Of the nine primary threats to reef-building corals (ocean warming, coral disease, ocean acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade), all but predation are considered anthropogenic threats. Due to the lack of species-specific information on the susceptibilities of *Acropora retusa*to these threats, we summarize the available information for *Acropora* species in general.

Based on the information from the Status Review Report (Brainard et al. 2011b) and Final Rule (79 FR 53852), we make the following inferences regarding the susceptibilities of an unstudied *Acropora* species to these eight anthropogenic threats. For ocean warming, nearly all the studies cited on thermal stress in *Acropora* report high levels of bleaching in response to warming events. Thus, it is possible to predict that an unstudied *Acropora* species is likely to be highly susceptible to warming-induced bleaching, as long as some considerations are kept in mind: (1) Despite high overall susceptibility within the genus to warming-induced bleaching, there can be high variability between species and habitats (Done et al. 2003); (2) colonies that bleach do not necessarily die (in general, *Acropora* species have higher post-bleaching mortality than corals as

a whole, but there is high variability in response throughout the genus); (3) recovery from bleaching provides the mechanism for acclimatization; and (4) while most *Acropora* species readily bleach in response to warming events, most also have the capacity to reestablish local populations relatively quickly through their rapid growth and asexual reproduction capacity.

Diseases are generally more common in *Acropora* than other coral genera, although there are numerous documented exceptions, depending on location. These studies also demonstrate high variability in disease susceptibility across *Acropora* species, depending on growth form, with wide divergence of disease susceptibilities among colony morphological groups under the same conditions. Thus, it is possible to predict that an unstudied *Acropora* species is likely to have some susceptibility to disease. The studies cited above on ocean acidification in *Acropora* report impacts on skeletal growth rates. Thus, it is possible to predict that an unstudied *Acropora* species is likely to have some susceptibility to ocean acidification in terms of impacts on skeletal growth. Most studies on the effects of land-based sources of pollution suggest that an unstudied *Acropora* species is likely to have some susceptibility to sedimentation and nutrient enrichment. The trophic effects of fishing alters trophic interactions by reducing herbivory on algae by removal of herbivorous fish from coral reef systems by fishing, thereby providing a competitive advantage for space to algae over coral. An unstudied *Acropora* species is likely to have some susceptibility to the trophic effects of fishing. Because *Acropora* are not generally sediment-tolerant and are faster growing species, an unstudied *Acropora* species is likely to have some susceptibility to sea-level rise. Because *Acropora* species are some of the most popular coral species to collect and trade, an unstudied *Acropora* species is likely to have some susceptibility to collection and trade.

According to the Status Review Report (Brainard et al. 2011b) and Final Rule (79 FR 53852), there is little if any species-specific information on the susceptibilities of *Acropora globiceps* to threats. However, based on genus-level information, we infer that *Acropora retusa* is likely to be highly susceptible to ocean warming and to have some susceptibility to disease, acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, and collection and trade (79 FR 53852).

4.1.2.7 Critical habitat

The NMFS has not designated critical habitat for *Acropora retusa*.

4.1.2.8 Conclusion

Acropora retusa is only known to occur at a single location within the MITT Action Area. This location is in Fouha Bay in southwestern Guam, away from MITT activities. As such, it is unlikely MITT activities will occur within close proximity of adult *Acropora retusa* colonies or that the planktonic eggs, sperm, embryos, or larvae of this species would coincide with MITT activities. Therefore, adverse effects to *Acropora retusa* resulting from MITT activities are not reasonbably expected to occur and are discountable.

4.1.3 *Seriatopora aculeata*

Colonies of *Seriatopora aculeata* have pencil-thick, short, branches which taper sharply at the end, usually in fused clumps. Colonies are pink or cream in color. *S. aculeata* can easily be confused with *Seriatopora stellata*, which also has branches which taper sharply at the end,

however, in *S. stellata* corallites on branch sides are in rows and raised, while on *S. aculeata* they are not (79 FR 53852).

4.1.3.1 Distribution and Abundance

Seriatopora aculeata is distributed from Australia, Fiji, Indonesia, Japan, Papua New Guinea, and Madagascar to the Marshall Islands. Veron reports that *S. aculeata* is confirmed in 19 of his 133 Indo-Pacific ecoregions, and strongly predicted to be found in an additional seven. Within U.S. waters, this species is confirmed in Guam and CNMI (http://www.fpir.noaa.gov/PRD/prd_coral.html). According to the Final Rule (79 FR 53852) *S. aculeata*'s absolute abundance is at least millions of colonies at the time of listing.

Veron (2014) reports that *S. aculeata* occupied 10.3 percent of 2,984 dive sites sampled in 30 ecoregions of the Indo-Pacific, and had a mean abundance rating of 1.70 on a 1 to 5 rating scale at those sites in which it was found. Based on this semi-quantitative system, the species' abundance was characterized as ''common,'' and overall abundance was described as ''uncommon.'' Veron did not infer trends in abundance from these data.

Within the Mariana Islands, *S. aculeata* is confirmed in both Guam and CNMI (NMFS 2015 "Listed Corals in the Indo-Pacific: *Seriatopora aculeata*, 4 p."). On Guam, a recent review of available coral survey data from numerous sites around the island showed *S. aculeata* at two locations around the island. Several surveys were conducted within Apra Harbor, but the species was not found there (NMFS/PIRO/HCD Guam coral database, 2015). In CNMI, coral survey data shows *S. aculeata* on reef slopes at numerous sites around Saipan (Douglas Fenner, personal communication, 2015).

4.1.3.2 Habitat

S. aculeata generally inhabits the reef slope and back-reef, including but not limited to upper reef slopes, mid-slope terraces, lower reef slopes, reef flats, and lagoons. Around Guam it is known to occur along exposed seaward reef slopes with good water circulation and low sedimentation, although it is also found in areas with high sedimentation rates. It is reported from depths of 3 to 40 m (79 FR 53852).

4.1.3.3 Reproduction and Growth

The reproductive characteristics of *Seriatopora aculeata* have not been determined, but its congeners are hermaphroditic brooders. The larvae of the other *Seriatopora* species studied contain zooxanthellae, leading to the development of autotrophic larvae that can supplement maternal provisioning with energy sources provided by their photosynthetic symbionts. The minimum size and estimated age at first reproduction have not been determined for *Seriatopora aculeata*. However, for the congener *Seriatopora hystrix*, the minimum diameter is 8 cm and the estimated age at first reproduction is 1 to 2 years. Larval longevity has not been determined in this genus. *Seriatopora hystrix* can undergo polyp bailout during environmentally stressful conditions and successfully reattach (though at low rates) to the substrate; however, this potential mode of asexual reproduction has not been documented for *Seriatopora aculeata* (Brainard et al, 2011). Little is known of *S. aculeata*'s life history. The much more common species, *S. hystrix*, is a simultaneous hermaphrodite that reproduces sexually via brooded larvae (79 FR 53852).

4.1.3.4 Status and trends

S. aculeata was listed as threatened on September 10, 2014 (79 FR 53851). The abundance of *S. aculeata* has likely declined over the past 50 to 100 years although a precise quantification is not possible based on the limited species specific information (79 FR 53852). The species is highly susceptible to ocean warming, and is susceptible to disease, ocean acidification, trophic effects of fishing, sedimentation, nutrients, sea-level rise, predation, and collection and trade, all of which have increased in the past 50 to 100 years, and continue to increase throughout much of its range. *S. aculeata* is distributed from Madagascar to the Marshall Islands. Its depth range is 3 to 40 meters, and it occurs in a broad range of habitats on the reef slope and back-reef. Its absolute abundance is at least millions of colonies across its range. While spatial variability of threats such as ocean warming and acidification across the species' range moderates vulnerability because many colonies are either not exposed to threats or do not negatively respond to a threat at any given point in time, the threats are increasing and will continue to increase in the foreseeable future, thus the species is expected to continue to decline. However, there is inadequate data to quantify current and future population status and trends on any spatial scale, let alone across the range of the species (79 FR 53852).

4.1.3.5 Natural threats

Of the nine primary threats to reef-building corals (ocean warming, coral disease, ocean acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade), only predation is considered a natural threat. Due to the lack of species-specific information on the susceptibility of *S. aculeata* to predation, we summarize the available information on this threat to *Seriatopora* species in general: The studies cited in the Status Review Report (Brainard et al. 2011b) and Final Rule (79 FR 53852) on predation in *Seriatopora* report that the genus *Seriatopora* is susceptible to predation by *Drupella* snails and crown-of-thorns starfish. Thus, the available information suggests that *S. aculeata* is likely to have some susceptibility to predation (79 FR 53852).

4.1.3.6 Anthropogenic threats

Of the nine primary threats to reef-building corals (ocean warming, coral disease, ocean acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, predation, and collection and trade), all but predation are considered anthropogenic threats. Due to the lack of species-specific information on the susceptibilities of *S. aculeata* to these threats, we summarize the available information for *Seriatopora* species in general.

Based on the information from the Status Review Report (Brainard et al. 2011b) and Final Rule (79 FR 53852), we make the following inferences regarding the susceptibilities of an unstudied *Seriatopora* species to these eight anthropogenic threats. For ocean warming, nearly all the studies cited on thermal stress in *Seriatopora* report high levels of bleaching in response to warming events. Thus, it is possible to predict that an unstudied *Seriatopora* species is likely to be highly susceptible to warming-induced bleaching, as long as some considerations are kept in mind: (1) Despite high overall susceptibility within the genus to warming-induced bleaching, there can be high variability between species and habitats (Done et al. 2003); (2) colonies that bleach do not necessarily die (in general, *Seriatopora* species have higher post-bleaching mortality than corals as a whole, but there is high variability in response throughout the genus); (3) recovery from bleaching provides the mechanism for acclimatization; and (4) while most *Seriatopora* species readily bleach in response to warming events, most also have the capacity to

reestablish local populations relatively quickly through their rapid growth and asexual reproduction capacity.

Seriatopora species have been reported to be susceptible to one disease but not to another, and to have disease in one area and not in another. Diseases are generally more common in *Acropora* than other coral genera, although there are numerous documented exceptions, depending on location. Thus, it is possible to predict that an unstudied *Seriatopora* species is likely to have some susceptibility to disease. There is no information available on the effects of any other threat for *Seriatopora* species. The Status Review Report (Brainard et al. 2011b) concluded that ocean acidification, sedimentation, nutrients, trophic effects of fishing, and sea-level rise all have significant effects on corals, and so we conclude that *Seriatopora* has some susceptibility to them. *Seriatopora* is heavily traded, thus we conclude that *Seriatopora* has some susceptibility to collection and trade.

According to the Status Review Report (Brainard et al. 2011b) and Final Rule (79 FR 53852), there is little if any species-specific information on the susceptibilities of *S. aculeata* to threats. However, based on genus-level information, we infer that *S. aculeata* is likely to be highly susceptible to ocean warming and to have some susceptibility to disease, acidification, sedimentation, nutrients, trophic effects of fishing, sea-level rise, and collection and trade (79 FR 53852).

4.1.3.7 Critical habitat

The NMFS has not designated critical habitat for *S. aculeata*.

4.1.3.8 Conclusion

Seriatopora aculeata is only known to occur at a single location within the MITT Action Area. This location is in southwestern Guam, away from MITT activities. As such, it is unlikely MITT activities will occur within close proximity of adult *S. aculeata* colonies or that the planktonic eggs, sperm, embryos, or larvae of this species would coincide with MITT activities. Therefore, adverse effects to *S. aculeata* resulting from MITT activities are not reasonbably expected to occur and are discountable.

4.2 Listed Species Considered Further in this Opinion

Based on the anticipated exposure and response of species to stressors, we identified endangered and threatened species or critical habitat that are likely to be adversely affected by proposed MITT activities.

This section of our Opinion consists of narratives for each of the threatened and endangered species that occur in the Action Area and that may be adversely affected by Navy activities in the MITT Action Area. In each narrative, we present a summary of information on each species to provide a foundation for the exposure analyses that appear later in this opinion. We present information on the diving and social behavior of the different species because that behavior helps determine whether aerial and ship board surveys are likely to detect each species. We also summarize information on the vocalizations and hearing of the different species because that background information lays the foundation for our assessment of the how the different species are likely to respond to sounds produced by the Navy's training exercises and testing activities. Then we summarize information on the threats to the species and the species' status given those

threats to provide points of reference for the jeopardy determinations we make later in this opinion. That is, we rely on a species' status and trend to determine whether or not an action's direct or indirect effects are likely to increase the species' probability of becoming extinct.

4.2.1 Blue Whale

The blue whale, *Balaenoptera musculus* (Linnæus 1758), is a cosmopolitan species of baleen whale. It is the largest animal ever known to have lived on Earth: adults in the Antarctic have reached a maximum body length of about 33 m (108 ft) and can weigh more than 150,000 kg (330,700 lbs). The largest blue whales reported from the North Pacific are a female that measured 26.8 m (88 ft) taken at Port Hobron in 1932 (Reeves et al. 1985) and a 27.1 m (89 ft) female taken by Japanese pelagic whaling operations in 1959 (NMFS 1998c).

As is true of other baleen whale species, female blue whales are somewhat larger than males. Blue whales are identified by the following characteristics: a long-body and comparatively slender shape; a broad, flat "rostrum" when viewed from above; a proportionately smaller dorsal fin than other baleen whales; and a mottled gray color pattern that appears light blue when seen through the water. Blue whales may reach 70 to 80 years of age (COSEWIC 2002b; Yochem and Leatherwood 1985b).

4.2.1.1 Distribution

Blue whales inhabit all oceans and typically occur near the coast, over the continental shelf, although they are also found in oceanic waters. Blue whales are highly mobile, and their migratory patterns are not well known (Perry et al. 1999; Reeves et al. 2004). Blue whales migrate toward the warmer waters of the subtropics in the fall to reduce energy costs, avoid ice entrapment, and reproduce (NMFS 1998a).

4.2.1.2 Population Structure

For this and all subsequent species, the term "population" refers to groups of individuals whose patterns of increase or decrease in abundance over time are determined by internal dynamics (births resulting from sexual interactions between individuals in the group and deaths of those individuals) rather than external dynamics (immigration or emigration). This definition is a reformulation of definitions articulated by Futuymda (1986) and Wells and Richmond (1995) and is more restrictive than those uses of 'population' that refer to groups of individuals that co-occur in space and time but do not have internal dynamics that determine whether the size of the group increases or decreases over time (see review by Wells and Richmond 1995). The definition we apply is important to section 7 consultations because such concepts as 'population decline,' 'population collapse,' 'population extinction,' and 'population recovery' apply to the restrictive definition of 'population' but do not explicitly apply to alternative definitions. As a result, we do not treat the different whale "stocks" recognized by the International Whaling Commission or other authorities as populations unless those distinctions were clearly based on demographic criteria. We do, however, acknowledge those "stock" distinctions in these narratives.

At least three subspecies of blue whales have been identified based on body size and geographic distribution (*B. musculus intermedia*, which occurs in the higher latitudes of the Southern Oceans, *B. m. musculus*, which occurs in the Northern Hemisphere, and *B. m. brevicauda* which occurs in the mid-latitude waters of the southern Indian Ocean and north of the Antarctic

convergence), but this consultation will treat them as a single entity. Readers who are interested in these subspecies will find more information in Gilpatrick et al. (1997), Kato et al. (1995), Omura et al. (1970), and Ichihara (1966).

Until recently, blue whale population structure had not been tested using molecular or nuclear genetic analyses (Reeves et al. 1998). A recent study by Conway (2005) suggested that the global population could be divided into four major subdivisions, which roughly correspond to major ocean basins: eastern North and tropical Pacific Ocean, Southern Indian Ocean, Southern Ocean, and western North Atlantic Ocean. The eastern North/tropical Pacific Ocean subpopulation includes California, western Mexico, western Costa Rica, and Ecuador, and the western North Pacific Ocean subpopulation (including blue whales in the MITT Action Area) (Conway 2005). Genetic studies of blue whales occupying a foraging area south of Australia (most likely pygmy blue whales) have been found to belong to a single population (Attard et al. 2010). For this Opinion, blue whales are treated as four distinct populations as outlined by Conway (2005).

Blue whales occur widely throughout the North Pacific. Acoustic monitoring has recorded blue whales off Oahu and the Midway Islands, although sightings or strandings in Hawaiian waters have not been reported (Barlow et al. 1997a; Northrop et al. 1971; Thompson and Friedl 1982a). Nishiwaki (1966) notes blue whale occurrence among the Aleutian Islands and in the Gulf of Alaska, but until recently, no one has sighted a blue whale in Alaska for some time, despite several surveys (Carretta et al. 2005; Forney and Brownell Jr. 1996a; Leatherwood et al. 1982c; Stewart et al. 1987), possibly supporting a return to historical migration patterns (Anonmyous. 2009).

Blue whales are thought to summer in high latitudes and move into the subtropics and tropics during the winter (Yochem and Leatherwood 1985b). Minimal data suggest whales in the western region of the North Pacific may summer southwest of Kamchatka, south of the Aleutians, and in the Gulf of Alaska, and winter in the lower latitudes of the western Pacific (Sea of Japan, the East China, Yellow, and Philippine seas) and less frequently in the central Pacific, including Hawaii (Carretta et al. 2005; Stafford 2003a; Stafford et al. 2001a; Watkins et al. 2000), although this population is severely depleted or has been extirpated (Gilpatrick and Perryman. 2009). However, acoustic recordings made off Oahu showed bimodal peaks of blue whales, suggesting migration into the area during summer and winter (McDonald and Fox 1999; Thompson and Friedl 1982a).

Blue whales from both the eastern and western North Pacific have been heard, tracked, or harvested in waters off Kodiak Island; acoustic detections are made in the Gulf of Alaska from mid-July to mid-December and a peak from August through November (COSEWIC 2002a; Ivashin and Rovnin. 1967; Moore et al. 2006; Stafford 2003b; Stafford et al. 2007; Yochem and Leatherwood 1985a). Although acoustic detections in the Gulf of Alaska were absent since the late 1960s, recordings have increased during 1999 to 2002 and a few sightings have been made in the northern Gulf of Alaska (Calambokidis et al. 2009; Moore et al. 2006; NOAA 2004; Stafford 2003b; Stafford et al. 2007; Stafford and Moore 2005a). However, surveys in the western Gulf of Alaska and east of Kodiak Island have not found blue whales (Rone et al. 2010; Zerbini et al. 2006). Blue whales are rarely observed in nearshore Alaskan waters, but seem to prefer continental shelf edge waters; such areas in the Gulf of Alaska were formerly feeding

grounds for blue whales prior to severe depletion (Rice and Wolman. 1982). Call detections of blue whales from the western North Pacific indicate a greater likelihood of these individual occurring southwest of Kodiak Island (Stafford 2003b).

4.2.1.3 Reproduction

Gestation takes 10 to 12 months, followed by a 6 to 7 month nursing period. Sexual maturity occurs at 5 to 15 years of age and calves are born at 2 to 3 year intervals (COSEWIC 2002b; NMFS 1998b; Yochem and Leatherwood 1985b). Recent data from illegal Russian whaling for Antarctic and pygmy blue whales support sexual maturity at 23 m and 19 to 20 m, respectively (Branch and Mikhalev 2008). The mean intercalving interval in the Gulf of California is roughly two and a half years (Sears et al. 2014). Once mature, females return to the same areas where they were born to give birth themselves (Sears et al. 2014).

4.2.1.4 Movement

Blue whales are highly mobile, and their migratory patterns are not well known (Perry et al. 1999; Reeves et al. 2004). Blue whales migrate toward the warmer waters of the subtropics in fall to reduce energy costs, avoid ice entrapment, and reproduce (NMFS 1998a). Satellite tagging indicates that, for blue whales tagged off Southern California, movement is more linear and faster (3.7 km/h) while traveling versus while foraging (1.7 km/h)(Bailey et al. 2009). Residency times in what are likely prey patches averages 21 days and constituted 29 percent of an individual's time overall, although foraging could apparently occur at any time of year for tagged individuals (Bailey et al. 2009). Broad scale movements also varied greatly, likely in response to oceanographic conditions influencing prey abundance and distribution (Bailey et al. 2009). Blue whales along Southern California were found to be traveling 85 percent of the time and milling 11 percent (Bacon et al. 2011).

4.2.1.5 Feeding

Data indicate that some summer feeding takes place at low latitudes in upwelling-modified waters, and that some whales remain year-round at either low or high latitudes (Clarke and Charif 1998a; Hucke-Gaete et al. 2004; Reilly and Thayer 1990; Yochem and Leatherwood 1985b). One population feeds in California waters from June to November and migrates south in winter/spring (Calambokidis et al. 1990; Mate et al. 1999). Prey availability likely dictates blue whale distribution for most of the year (Burtenshaw et al. 2004b; Clapham et al. 1999; Sears 2002 as cited in NMFS 2006a). The large size of blue whales requires higher energy requirements than smaller whales and potentially prohibits fasting Mate et al. (1999). Krill are the primary prey of blue whales in the North Pacific (Kawamura 1980; Yochem and Leatherwood 1985b). Blue whales typically occur alone or in groups of up to five animals, although larger foraging aggregations of up to 50 have been reported including aggregations mixed with other rorquals such as fin whales (Corkeron et al. 1999; Shirihai 2002). While feeding, blue whales show slowed and less obvious avoidance behavior then when not feeding (Sears et al. 1983 as cited in NMFS 2005c). Barlow (2003) reported mean group sizes of 1.0 to 1.9 during surveys off California, Oregon, and Washington.

4.2.1.6 Diving and Social Behavior

Blue whales spend more than 94 percent of their time underwater (Lagerquist et al. 2000). Generally, blue whales dive 5 to 20 times at 12 to 20 sec intervals before a deep dive of 3 to 30 min (Croll et al. 1999a; Leatherwood et al. 1976; Maser et al. 1981; Yochem and Leatherwood

1985a). Average foraging dives are 140 m deep and last for 7.8 min (Croll et al. 2001a). Non-foraging dives are shallower and shorter, averaging 68 m and 4.9 min (Croll et al. 2001a). However, dives of up to 300 m are known (Calambokidis et al. 2003). Nighttime dives are generally shallower (50 m).

Blue whales occur singly or in groups of two or three (Aguayo 1974; Mackintosh 1965; Nemoto 1964; Pike and Macaskie 1969; Ruud 1956; Slijper 1962). However, larger foraging aggregations, even with other species such as fin whales, are regularly reported (Corkeron et al. 1999; Fiedler et al. 1998; Schoenherr 1991; Shirihai 2002). Little is known of the mating behavior of blue whales. The primary and preferred diet of blue whales is krill (euphausiids).

Satellite tagging indicates that, for blue whales tagged off Southern California, movement is more linear and faster (3.7 km/h) while traveling versus while foraging (1.7 km/h)(Bailey et al. 2009). Residency times in what are likely prey patches averages 21 days and constituted 29 percent of an individual's time overall, although foraging could apparently occur at any time of year for tagged individuals (Bailey et al. 2009). Broad scale movements also varied greatly, likely in response to oceanographic conditions influencing prey abundance and distribution (Bailey et al. 2009). Blue whales along Southern California were found to be traveling 85 percent of the time and milling 11 percent (Bacon et al. 2011). While feeding, blue whales show slowed and less obvious avoidance behavior then when not feeding (Sears et al. 1983 as cited in NMFS 2005c). In review of a 24-year blue whale sighting history, Sears et al. (Sears et al. 2013) documented a link between female blue whales sighted in the Gulf of California and the U.S. West Coast, although the authors suggest that only some of the U.S. West Coast blue whales migrate to the Gulf of California.

4.2.1.7 Vocalization and Hearing

Blue whales produce prolonged low-frequency vocalizations that include moans in the range from 12.5 to 400 Hz, with dominant frequencies from 16 to 25 Hz, and songs that span frequencies from 16 to 60 Hz that last up to 36 seconds repeated every 1 to 2 minutes (see McDonald et al. 1995). Berchok et al. (2006b) examined vocalizations of St. Lawrence blue whales and found mean peak frequencies ranging from 17.0 to 78.7 Hz. Reported source levels are 180 to 188 dB re 1µPa, but may reach 195 dB re 1µPa (Aburto et al. 1997b; Clark and Gagnon 2004; Ketten 1998; McDonald et al. 2001a). Samaran et al. (2010) estimated Antarctic blue whale calls in the Indian Ocean at 179 ± 5 dB re 1 μPa_{rms} -1 m in the 17 to 30 Hz range and pygmy blue whale calls at 175± 1 dB re 1 μPa_{rms} -1 m in the 17 to 50 Hz range.

As with other baleen whale vocalizations, blue whale vocalization function is unknown, although numerous hypotheses exist (maintaining spacing between individuals, recognition, socialization, navigation, contextual information transmission, and location of prey resources) (Edds-Walton 1997; Payne and Webb. 1971; Thompson et al. 1992). Intense bouts of long, patterned sounds are common from fall through spring in low latitudes, but these also occur less frequently while in summer high-latitude feeding areas. Short, rapid sequences of 30 to 90 Hz calls are associated with socialization and may be displays by males based upon call seasonality and structure. The low-frequency sounds produced by blue whales can, in theory, travel long distances, and it is possible that such long-distance communication occurs (Edds-Walton 1997; Payne and Webb. 1971). The long-range sounds may also be used for echolocation in orientation or navigation (Tyack 1999).

Cetaceans have an auditory anatomy that follows the basic mammalian pattern, with some modifications to adapt to the demands of hearing in the sea. The typical mammalian ear is divided into the outer ear, middle ear, and inner ear. The outer ear is separated from the inner ear by the tympanic membrane, or eardrum. In terrestrial mammals, the outer ear, eardrum, and middle ear function to transmit airborne sound to the inner ear, where the sound is detected in a fluid. Since cetaceans already live in a fluid medium, they do not require this matching, and thus do not have an air-filled external ear canal. The inner ear is where sound energy is converted into neural signals that are transmitted to the central nervous system via the auditory nerve. Acoustic energy causes the basilar membrane in the cochlea to vibrate. Sensory cells at different positions along the basilar membrane are excited by different frequencies of sound (Tyack 1999). Baleen whales have inner ears that appear to be specialized for low-frequency hearing. In a study of the morphology of the mysticete auditory apparatus, Ketten (1997b) hypothesized that large mysticetes have acute infrasonic hearing.

Blue whale vocalizations tend to be long (>20 s), low-frequency (<100 Hz) signals (Thomson and Richardson 1995), with a range of 12 to 400 Hz and dominant energy in the infrasonic range of 12 to 25 Hz (Ketten 1998; McDonald et al. 2001b; Mellinger and Clark 2003). Vocalizations are predominantly songs and calls. Blue whale calls have high acoustic energy, with reports of 186 to 188 dB re 1 µPa-m (Cummings and Thompson 1971; McDonald et al. 2001b) and 195 dB re 1 µPa-m (Aburto et al. 1997a) source levels. Calls are short-duration sounds (2 to 5 s) that are transient and frequency-modulated, having a higher frequency range and shorter duration than song units and often sweeping down in frequency (80 to 30Hz), with seasonally variable occurrence.

Blue whale songs consist of repetitively patterned sounds produced over time spans of minutes to hours, or even days (Cummings and Thompson 1971; McDonald et al. 2001b). The songs are divided into pulsed/tonal units, which are continuous segments of sound, and phrases, which are repeated combinations of 1 to 5 units (Mellinger and Clark 2003; Payne and McVay 1971). A song is composed of many repeated phrases. Songs can be detected for hundreds, and even thousands of kilometers (Stafford et al. 1998), and have only been attributed to males (McDonald et al. 2001b; Oleson et al. 2007a). Worldwide, songs are showing a downward shift in frequency (Mcdonald et al. 2009). For example, a comparison of recordings from November 2003 and November 1964 and 1965 reveals a long-term shift in the frequency of blue whale calling near San Nicolas Island. In 2003, the spectral energy peak was 16 Hz compared to ~22.5 Hz in 1964 and 1965, illustrating a more than 30 percent shift in call frequency over four decades (McDonald et al. 2006b). McDonald et al. (2009) observed a 31 percent downward frequency shift in blue whale calls off the coast of California, and also noted lower frequencies in 7 of the world's 10 known blue whale songs originating in the Atlantic, Pacific, Southern, and Indian Oceans. Many possible explanations for the shifts exist, but none have emerged as the probable cause.

Although general characteristics of blue whale calls are shared in distinct regions (McDonald et al. 2001b; Mellinger and Clark 2003; Rankin et al. 2005; Thompson et al. 1996), some variability appears to exist among different geographic areas (Rivers 1997). Sounds in the North Atlantic have been confirmed to have different characteristics (i.e., frequency, duration, and repetition) than those recorded in other parts of the world (Berchok et al. 2006a; Mellinger and Clark 2003). Clear differences in call structure suggestive of separate populations for the western

and eastern regions of the North Pacific have also been reported (Stafford et al. 2001b); however, some overlap in calls from these geographically distinct regions have been observed, indicating that the whales may have the ability to mimic calls (Stafford and Moore 2005b).

In Southern Califronia, blues whales produce two predominant call types: Type B and D. B-calls are stereotypic of the blue whale population found in the eastern North Pacific (McDonald et al. 2006b) and are produced exclusively by males and associated with mating behavior (Oleson et al. 2007a). These calls have long durations (20 sec) and low frequencies (10 to 100 Hz); they are produced either as repetitive sequences (song) or as singular calls. The B call has a set of harmonic tonals, and may be paired with a pulsed type A call. Blue whale D calls are down-swept in frequency (100 to 40 Hz) with duration of several seconds. These calls are similar worldwide and are associated with feeding animals; they may be produced as call- counter call between multiple animals (Oleson et al. 2007c). In the SOCAL Range Complex region, D calls are produced in highest numbers during the late spring and early summer, and in diminished numbers during the fall, when A-B song dominates blue whale calling (Hildebrand et al. 2011; Hildebrand et al. 2012; Oleson et al. 2007d).

Calling rates of blue whales tend to vary based on feeding behavior. Stafford et al. (2005b) recorded the highest calling rates when blue whale prey was closest to the surface during its vertical migration. Wiggins et al. (2005) reported the same trend of reduced vocalization during daytime foraging followed by an increase at dusk as prey moved up into the water column and dispersed. Blue whales make seasonal migrations to areas of high productivity to feed, and vocalize less at the feeding grounds than during migration (Burtenshaw et al. 2004a). Oleson et al. (2007d) reported higher calling rates in shallow diving (<100 ft) whales, while deeper diving whales (>165 ft) were likely feeding and calling less.

Direct studies of blue whale hearing have not been conducted, but it is assumed that blue whales can hear the same frequencies that they produce (low-frequency) and are likely most sensitive to this frequency range (Ketten 1997a; Richardson et al. 1995c). Based on vocalizations and anatomy, blue whales are assumed to predominantly hear low-frequency sounds below 400 Hz (Croll et al. 2001b) (Croll et al. 2001c; Oleson et al. 2007d; Stafford and Moore 2005b). In terms of functional hearing capability, blue whales belong to the low-frequency group, which have a hearing range of 7 Hz to 22 kHz (Southall et al. 2007b).

Nevertheless, recent studies indicate that blue whales can hear and respond to sounds in the mid-frequency range. Nineteen controlled exposure experiments were conducted on blue whales during the Southern California-10 behavorial response study (Southall et al. 2011a) and 13 in the Southern California-11 behavorial response study (Southall et al. 2012). Both controlled exposure experiments simulated exposure to Navy MFA sonar. Behavioral response was observed in some blue whales and consisted primarily of small changes in dive behavior and general avoidance of the sound source. Preliminary assessments showed behavior appearing to return to baseline shortly after the transmissions ended, however, it is possible that the changes observed were a direct response to the transmission or some other unknown or un-analyzed factors (Southall et al. 2012). During other controlled exposure experiments, blue whales responded to a mid-frequency sound source, with a source level between 160 to 210 dB re 1 µPa at 1 m and a received sound level up to 160 dB re 1 µPa, by exhibiting generalized avoidance responses and changes to dive behavior (Goldbogen et al. 2013). However, reactions were

temporary and were not consistent across individuals based on received sound levels alone. Results were likely the result of a complex interaction between sound exposure factors such as proximity to sound source and sound type (mid-frequency sonar simulation vs. pseudo-random noise), environmental conditions, and behavioral state. Surface feeding whales did not show a change in behavior during controlled exposure experiments, but deep feeding and non-feeding whales showed temporary reactions that often quickly abated after sound exposure. Distances of the sound source from the whales during controlled exposure experiments were sometimes less than a mile. Melcón et al. (2012) tested whether MFA sonar and other anthropogenic noises in the mid-frequency band affected the "D-calls" produced by blue whales in the Southern California Bight. The likelihood of an animal calling decreased with the increased received level of mid-frequency sonar, beginning at a sound pressure level of approximately 110 to 120 dB re 1 µPa. It is not known whether the lower rates of calling actually indicated a reduction in feeding behavior or social contact since the study used data from remotely deployed, passive acoustic monitoring buoys.

4.2.1.8 Status and Trends

Blue whales (including all subspecies) were originally listed as endangered in 1970 (35 FR 18319), and this status has continued since the inception of the ESA in 1973. Blue whales are also listed as endangered on the IUCN Red List of Threatened Animals (IUCN 2010) and are protected by the Convention on International Trade in Endangered Species of wild flora and fauna and the MMPA. Critical habitat has not been designated for blue whales.

It is difficult to assess the current status of blue whales globally because (1) there is no general agreement on the size of the blue whale population prior to whaling and (2) estimates of the current size of the different blue whale populations vary widely. We may never know the size of the blue whale population in the North Pacific prior to whaling, although some authors have concluded that their population numbered about 200,000 animals before whaling. Similarly, estimates of the global abundance of blue whales are uncertain. Since the cessation of whaling, the global population of blue whales has been estimated to range from 11,200 to 13,000 animals (Maser et al. 1981). These estimates, however, are more than 20 years old.

Estimates of blue whale abundance in the North Pacific are uncertain. Prior to whaling, Gambell (1976) reported there may have been as many as 4,900 blue whales. Blue whales were hunted in the Pacific Ocean, where 5,761 were killed from 1889 to 1965 (Perry et al. 1999). This estimate does not account for under-reporting by Soviet whalers, who took approximately 800 more individuals than were reported (Ivashchenko et al. 2013). The IWC banned commercial whaling in the North Pacific in 1966, although Soviet whaling continued after the ban. Although blue whale abundance has likely increased since its protection in 1966, the possibility of unauthorized harvest by Soviet whaling vessel, incidental ship strikes, and gillnet mortalities make this uncertain. Punt (2010) estimated the rate of increase for blue whales in the eastern North Pacific to be 3.2 percent annually (1.4 SE) between 1991 and 2005, while Calambokidis et al. (2010) estimated a growth rate of 3 percent annually.

To our knowledge, there have been no recent sightings of blue whales in the Action Area. The closest documented sighting occurred in 1995 near Cocos (Brent Tibbatts, pers. comm., June 25, 2013, as cited in Uyeyama (2014)). The Pacific Islands Fisheries Science Center has deployed high-frequency acoustic recording packages (HARPS) to monitor marine mammals in the U.S.

Exclusive Economic Zone (EEZ) around the CNMI. These monitors have acoustically detected blue whales (Oleson et al. 2013), though given the long distance blue whale calls can travel it is not known if the animals were actually within the Action Area. With the exception of sightings by observers on fishing vessels (Carretta et al. 2011), there have been no sightings of blue whales during systematic surveys off Hawaii (Barlow 2006; Mobley Jr. et al. 2000), and no blue whales were detected during a 2007 winter survey of the Action Area nor during Navy-funded monitoring for the MIRC in 2009 through 2015 (Fulling et al. 2011; HDR 2011; HDR 2012a; Hill et al. 2013; Hill et al. 2011; Ligon et al. 2011; Oleson and Hill 2010) . The Navy's NMSDD estimates 0.00001 blue whales per km^2 in the MITT Action Area (DoN 2014).

4.2.1.9 Natural Threats

As the world's largest animals, blue whales are only occasionally known to be killed by killer whales (Sears et al. 1990; Tarpy 1979). Blue whales engage in a flight response to evade killer whales, which involves high energetic output, but show little resistance if overtaken (Ford and Reeves 2008). Blue whales are known to become infected with the nematode *Carricauda boopis*, which are believed to have caused mortality in fin whale due to renal failure (Lambertsen 1986).

4.2.1.10 Anthropogenic Threats

Blue whales have faced threats from several historical and current sources. Blue whale populations are severely depleted originally due to historical whaling activity.

Increasing oceanic noise may impair blue whale behavior. Although available data do not presently support traumatic injury from sonar, the general trend in increasing ambient low-frequency noise in the deep oceans of the world, primarily from ship engines, could impair the ability of blue whales to communicate or navigate through these vast expanses (Aburto et al. 1997c; Clark 2006). Blue whales off California altered call levels and rates in association with changes in local vessel traffic (Mckenna 2011).

To date, there has not been a ship strike as a result of Navy training and testing activities in the Study Area; however, ship strike is a concern for balaenopterids in the North Pacific. In the California/Mexico stock of blue whales, annual incidental mortality due to ship strikes averaged one whale every 5 years, but we cannot determine if this reflects the actual number of blue whales struck and killed by ships (i.e., individuals not observed when struck and those who do not strand; Barlow et al. (1997a)). Ship strikes have recently averaged roughly one every other year (eight ship strike incidents are known (Jensen and Silber 2004)), but in September 2007, ships struck five blue whales within a few-day period off southern California (Calambokidis personal communication 2008)(Berman-Kowalewski et al. 2010). Dive data support a surface-oriented behavior during nighttime that would make blue whales particularly vulnerable to ship strikes during this time. Ship strikes were implicated in the deaths of five blue whales, from 2004 to 2008 (Carretta et al. 2012). Four of these deaths occurred in 2007, the highest number recorded for any year. During 2004 to 2008, there were an additional eight injuries of unidentified large whales attributed to ship strikes. Several blue whales have been photographed in California with large gashes in their dorsal surface that appear to be from ship strikes (J. Calambokidis, personal communication). Blue whale mortality and injuries attributed to ship strikes in California waters averaged 1.0 per year for 2004 to 2008. Ship strike is an issue for blue whales of Sri Lanka engaged in foraging in shipping lanes, with several individuals stranding or being found with evidence of being struck (De Vos et al. 2013; Ilangakoon 2012).

There is a paucity of contaminant data regarding blue whales. Available information indicates that organochlorines, including dichloro-diphenyl-trichloroethane (DDT), polychlorinated biphenyls (PCB), benzene hexachloride (HCH), hexachlorobenzene (HCB), chlordane, dieldrin, methoxychlor, and mirex have been isolated from blue whale blubber and liver samples (Gauthier et al. 1997b; Metcalfe et al. 2004). Contaminant transfer between mother and calf occurs, meaning that young often start life with concentrations of contaminants equal to their mothers, before accumulating additional contaminant loads during life and passing higher loads to the next generation (Gauthier et al. 1997a; Metcalfe et al. 2004). This is supported by ear plug data showing maternal transfer of pesticides and flame retardants in the first year of life (Trumble et al. 2013). These data also support pulses of mercury in body tissues of the male studied (Trumble et al. 2013).

4.2.1.11 Critical Habitat

The NMFS has not designated critical habitat for blue whales.

4.2.2 Fin Whale

The fin whale, *Balaenoptera physalus* (Linnæus 1758), is a cosmopolitan species of baleen whale (Gambell 1985b). Fin whales are the second-largest whale species by length. Fin whales are long-bodied and slender, with a prominent dorsal fin set about two-thirds of the way back on the body. The streamlined appearance can change during feeding when the pleated throat and chest area becomes distended by the influx of prey and seawater, giving the animal a tadpole-like appearance. The basic body color of the fin whale is dark gray dorsally and white ventrally, but the pigmentation pattern is complex. The lower jaw is gray or black on the left side and creamy white on the right side. This asymmetrical coloration extends to the baleen plates as well, and is reversed on the tongue. Individually distinctive features of pigmentation, along with dorsal fin shapes and body scars, have been used in photo-identification studies (Agler et al. 1990). Fin whales can be found in social groups of 2 to 7 whales. Aguilar and Lockyer (1987) suggested annual natural mortality rates in northeast Atlantic fin whales may range from 0.04 to 0.06. This is supported by an estimated annual survival rate of 0.955 for Gulf of St. Lawrence fin whales (Ramp et al. 2014). Fin whales live 70 to 80 years (Kjeld et al. 2006b).

4.2.2.1 Distribution

Fin whales are distributed widely in every ocean except the Arctic Ocean. In the North Atlantic Ocean, fin whales occur in summer foraging areas from the coast of North America to the Arctic, around Greenland, Iceland, northern Norway, Jan Meyen, Spitzbergen, and the Barents Sea. In the western Atlantic, they winter from the edge of sea ice south to the Gulf of Mexico and the West Indies. In the eastern Atlantic, they winter from southern Norway, the Bay of Biscay, and Spain with some whales migrating into the Mediterranean Sea (Gambell 1985b).

In the Southern Hemisphere, fin whales are distributed broadly south of 50°S in the summer and migrate into the Atlantic, Indian, and Pacific Oceans in the winter, along the coast of South America (as far north as Peru and Brazil), Africa, and the islands in Oceania north of Australia and New Zealand (Gambell 1985b).

Fin whales undertake migrations from low-latitude winter grounds to high-latitude summer grounds and extensive longitudinal movements both within and between years (Mizroch et al. 1999a). Fin whales are sparsely distributed during November through April, from 60° N, south to

the northern edge of the tropics, where mating and calving may take place (Mizroch et al. 1999a). However, fin whales have been sighted as far as 60° N throughout winter (Mizroch et al. 1999b). A resident fin whale population may exist in the Gulf of California (Tershy et al. 1993).

Fin whales are observed year-round off central and southern California with peak numbers in the summer and fall (Barlow 1997; Campbell et al. 2015; Dohl et al. 1983; Forney et al. 1995a). Peak numbers are seen during the summer off Oregon, and in summer and fall in the Gulf of Alaska and southeastern Bering Sea (Moore et al. 2000; Perry et al. 1999). Fin whales are observed feeding in Hawaiian waters during mid-May, and their sounds have been recorded there during the autumn and winter (Balcomb 1987; Northrop et al. 1968; Shallenberger 1981; Thompson and Friedl 1982a). They have been recorded at Nihoa and other areas of the NWHI in the winter and spring months (Meigs et al. 2013). Fin whales in the western Pacific winter in the Sea of Japan, the East China, Yellow, and Philippine seas (Gambell 1985a).

The distribution of fin whales in the Pacific during the summer includes the northern area of the Hawaii portion of the Action Area to 32° N off the coast of California (Barlow 1995b; Forney et al. 1995b). Fin whales are relatively abundant in north Pacific offshore waters, including the Hawaii portion of the Action Area (Berzin and Vladimirov 1981; Mizroch et al. 2009). Fin whales have been recorded in the eastern tropical Pacific (Ferguson 2005) and are frequently sighted there during offshore ship surveys.

Locations of breeding and calving grounds for the fin whale are unknown, but it is known that the whales typically migrate seasonally to higher latitudes every year to feed and migrate to lower latitudes to breed (Kjeld et al. 2006a; Macleod et al. 2006). The fin whale's ability to adapt to areas of high productivity controls migratory patterns (Canese et al. 2006; Reeves et al. 2002). Fin whales are one of the fastest cetaceans, capable of attaining speeds of 25 mi. (40.2 km) per hour (Jefferson et al. 2008; Marini et al. 1996).

In the North Pacific Ocean, fin whales occur in summer foraging areas in the Chukchi Sea, the Sea of Okhotsk, around the Aleutian Islands, and the Gulf of Alaska; in the eastern Pacific, they occur south to California; in the western Pacific, they occur south to Japan. Fin whales in the eastern Pacific winter from California south; in the western Pacific, they winter from the Sea of Japan, the East China and Yellow Seas, and the Philippine Sea (Gambell 1985b). The overall distribution may be based on prey availability. Fin whales are larger and faster than humpback and right whales and are less concentrated in nearshore environments.

4.2.2.2 Population Structure

Fin whales have two recognized subspecies: *Balaoptera physalus physalus* occurs in the North Atlantic Ocean while *B. p. quoyi* (Fischer 1829) occurs in the Southern Ocean. A third possible subspecies occurs off South America (Archer et al. 2013; Gray 1865; Van Waerebeek and Engblom 2007). Globally, fin whales are sub-divided into three major groups: Atlantic, Pacific, and Antarctic. Within these major areas, different organizations use different population structure.

In the North Pacific Ocean, the International Whaling Commission recognizes two "stocks": (1) East China Sea and (2) rest of the North Pacific (Donovan 1991). However, Mizroch et al. (1984a) concluded that there were five possible "stocks" of fin whales within the North Pacific

based on histological analyses and tagging experiments: (1) East and West Pacific that intermingle around the Aleutian Islands; (2) East China Sea; (3) British Columbia; (4) Southern-Central California to Gulf of Alaska; and (5) Gulf of California. Based on genetic analyses, Berube et al. (1998) concluded that fin whales in the Sea of Cortez represent an isolated population that has very little genetic exchange with other populations in the North Pacific Ocean (although the geographic distribution of this population and other populations can overlap seasonally). They also concluded that fin whales in the Gulf of St. Lawrence and Gulf of Maine are distinct from fin whales found off Spain and in the Mediterranean Sea.

Regardless of how different authors structure the fin whale population, mark-recapture studies have demonstrated that individual fin whales migrate between management units (Mitchell 1974a; Sigurjonsson et al. 1989), which suggests that these management units are not geographically isolated populations.

Mizroch et al. (1984a) identified five fin whale "feeding aggregations" in the Pacific Ocean: (1) an eastern group that move along the Aleutians, (2) a western group that move along the Aleutians (Berzin and Rovnin 1966; Nasu 1974b); (3) an East China Sea group; (4) a group that moves north and south along the west coast of North America between California and the Gulf of Alaska (Rice 1974a); and (5) a group centered in the Sea of Cortez (Gulf of California).

4.2.2.3 Reproduction

Fin whales reach sexual maturity between 5–15 years of age (COSEWIC 2005; Gambell 1985a; Lockyer 1972). Mating and calving occurs primarily from October-January, gestation lasts approximately 11 months, and nursing occurs for 6 to 11 months (Boyd et al. 1999; Hain et al. 1992). The average calving interval in the North Atlantic is estimated at about 2 to 3 years (Agler et al. 1993; Christensen et al. 1992). The location of winter breeding grounds is uncertain but mating is assumed to occur in pelagic mid-latitude waters (Perry et al. 1999). This was recently contradicted by acoustic surveys in the Davis Strait and off Greenland, where singing by fin whales peaked in November through December; the authors suggested that mating may occur prior to southbound migration (Simon et al. 2010). Although seasonal migration occurs between presumed foraging and breeding locations, fin whales have been acoustically detected throughout the North Atlantic Ocean and Mediterranean Sea year-round, implying that not all individuals follow a set migratory pattern (Notarbartolo-Di-Sciara et al. 1999; Simon et al. 2010). (Notarbartolo-Di-Sciara et al. 1999; Simon et al. 2010)(Notarbartolo-Di-Sciara et al. 1999; Simon et al. 2010)Reductions in pregnancy rates appear correlated with reduced blubber thickness and prey availability (Williams et al. 2013). Recent IWC scientific whaling data suggest that, compared to commercial whaling periods, preganancy rates have decreased, age at sexual maturity has increased, size growth is slowing, and males now compose a slightly higher proportion of the population than female (Gunnlaugsson et al. 2013).

4.2.2.4 Feeding

Most fin whales in the Southern Hemisphere migrate seasonally from Antarctic feeding areas in the summer to low-latitude breeding and calving grounds in winter. Fin whales in the North Atlantic eat pelagic crustaceans (mainly krill and schooling fish such as capelin, herring, and sand lance (Borobia and Béland 1995; Christensen et al. 1992; Hjort and Ruud 1929; Ingebrigtsen 1929; Jonsgård 1966; Mitchell 1974b; Overholtz and Nicolas 1979; Sergeant 1977; Shirihai 2002; Watkins et al. 1984). In the North Pacific, fin whales also prefer euphausiids and

large copepods, followed by schooling fish such as herring, walleye pollock, and capelin (Kawamura 1982a; Kawamura 1982b; Ladrón De Guevara et al. 2008; Nemoto 1970; Paloma et al. 2008). Fin whales frequently forage along cold eastern current boundaries (Perry et al. 1999). Antarctic fin whales feed on krill, *Euphausia superba*, which occurs in dense near-surface schools (Nemoto 1959). However, off the coast of Chile, fin whales are known to feed on the euphausiid *E. mucronata* (Antezana 1970; Perez et al. 2006). Feeding may occur in waters as shallow as 10 m when prey are at the surface, but most foraging is observed in high-productivity, upwelling, or thermal front marine waters (Gaskin 1972; Nature Conservancy Council 1979 as cited in ONR 2001; Panigada et al. 2008; Sergeant 1977). While foraging, fin whales in the Mediterranean Sea have been found to move through restricted territories in a convoluted manner (Lafortuna et al. 1999). Fin whales in the central Tyrrhenian Sea appear to ephemerally exploit the area for foraging during summer, particularly areas of high primary productivity (Arcangeli et al. 2013).

4.2.2.5 Diving and Social Behavior

The amount of time fin whales spend at the surface varies. Some authors have reported that fin whales make 5 to 20 shallow dives, each of 13 to 20 s duration, followed by a deep dive of 1.5 to 15 min (Gambell 1985a; Lafortuna et al. 2003; Stone et al. 1992). Other authors have reported that the fin whale's most common dives last 2 to 6 min (Hain et al. 1992; Watkins 1981b). The most recent data support average dives of 98 m and 6.3 min for foraging fin whales, while non-foraging dives are 59 m and 4.2 min (Croll et al. 2001a). However, Lafortuna et al. (1999) found that foraging fin whales have a higher blow rate than when traveling. Foraging dives in excess of 150 m are known (Panigada et al. 1999).

Fin whales along Southern California were found to be traveling 87 percent of the time and milling 5 percent in groups that averaged 1.7 individuals (Bacon et al. 2011). Most fin whales in the Southern Hemisphere migrate seasonally from Antarctic feeding areas in the summer to low-latitude breeding and calving grounds in winter. Fin whales tend to avoid tropical and pack-ice waters, with the high-latitude limit of their range set by ice and the lower-latitude limit by warm water of approximately 15° C (Sergeant 1977). Fin whale concentrations generally form along frontal boundary, or mixing zones between coastal and oceanic waters, which corresponds roughly to the 200 m isobath (the continental shelf edge) (Cotte et al. 2009; Nasu 1974a).

4.2.2.6 Vocalization and Hearing

Fin whales produce a variety of low-frequency sounds in the 10 Hz to 200 Hz range (Edds 1988; Thompson et al. 1992; Watkins 1981c; Watkins et al. 1987). Typical vocalizations are long, patterned pulses of short duration (0.5 to 2 s) in the 18 Hz to 35 Hz range, but only males are known to produce these (Clark et al. 2002; Patterson and Hamilton 1964). Richardson et al. (1995c) reported the most common sound as a 1 second vocalization of about 20 Hz, occurring in short series during spring, summer, and fall, and in repeated stereotyped patterns in winter. Au (Au and Green 2000) reported moans of 14 Hz to 118 Hz, with a dominant frequency of 20 Hz, tonal vocalizations of 34 Hz 150 Hz, and songs of 17 Hz to 25 Hz (Cummings and Thompson 1994; Edds 1988; Watkins 1981c). Source levels for fin whale vocalizations are 140 to 200 dB re 1µPa-m (see also Clark and Gagnon 2004; as compiled by Erbe 2002b). The source depth of calling fin whales has been reported to be about 50 m (Watkins et al. 1987).

Although their function is still in doubt, low-frequency fin whale vocalizations travel over long distances and may aid in long-distance communication (Edds-Walton 1997; Payne and Webb. 1971). During the breeding season, fin whales produce pulses in a regular repeating pattern, which have been proposed to be mating displays similar to those of humpbacks (Croll et al. 2002). These vocal bouts last for a day or longer (Tyack 1999).

The inner ear is where sound energy is converted into neural signals that are transmitted to the central nervous system via the auditory nerve. Acoustic energy causes the basilar membrane in the cochlea to vibrate. Sensory cells at different positions along the basilar membrane are excited by different frequencies of sound (Tyack 1999). Baleen whales have inner ears that appear to be specialized for low-frequency hearing. In a study of the morphology of the mysticete auditory apparatus, Ketten (1997b) hypothesized that large mysticetes have acute infrasonic hearing. In a study using computer tomography scans of a calf fin whale skull, Cranford and Krysl (2015) found sensitivy to a broad range of frequencies between 10 Hz and 12 kHz and a maximum sensitivity to sounds in the 1 kHz to 2 kHz range.

Direct studies of fin whale hearing have not been conducted, but it is assumed that fin whales can hear the same frequencies that they produce (low) and are likely most sensitive to this frequency range (Ketten 1997a; Richardson et al. 1995c).

Fin whales produce a variety of low frequency (< 1 kHz) sounds, but the most typically recorded is a 20 Hz pulse lasting about 1 second, and reaching source levels of 189 ± 4 dB re 1 µPam (Charif et al. 2002; Clark et al. 2002; Edds 1988; Richardson et al. 1995c; Sirovic et al. 2007; Watkins 1981c; Watkins et al. 1987). These pulses frequently occur in long sequenced patterns, are down swept (e.g., 23 to 18 Hz), and can be repeated over the course of many hours (Watkins et al. 1987). In temperate waters, intense bouts of these patterned sounds are very common from fall through spring, but also occur to a lesser extent during the summer in high latitude feeding areas (Clarke and Charif 1998b). The seasonality and stereotypic nature of these vocal sequences suggest that they are male reproductive displays (Watkins 1981c; Watkins et al. 1987); a notion further supported by recent data linking these vocalizations to male fin whales only (Croll et al. 2002). In Southern California, the 20 Hz pulses are the dominant fin whale call type associated both with call-counter-call between multiple animals and with singing (Navy 2010; Navy 2012). An additional fin whale sound, the 40 Hz call described by Watkins (1981c), was also frequently recorded, although these calls are not as common as the 20 Hz fin whale pulses. Seasonality of the 40 Hz calls differed from the 20 Hz calls, since 40 Hz calls were more prominent in the spring, as observed at other sites across the northeast Pacific (Sirovic et al. 2012). Source levels of Eastern Pacific fin whale 20-Hz calls has been reported as 189 +/- 5.8 dB re 1uPa at 1m (Weirathmueller et al. 2013). Although acoustic recordings of fin whales from many diverse regions show close adherence to the typical 20 Hz bandwidth and sequencing when performing these vocalizations, there have been slight differences in the pulse patterns, indicative of some geographic variation (Thompson et al. 1992; Watkins et al. 1987).

Responses to conspecific sounds have been demonstrated in a number of mysticetes, and there is no reason to believe that fin whales do not communicate similarly (Edds-Walton 1997). The low-frequency sounds produced by fin whales have the potential to travel over long distances, and it is possible that long-distance communication occurs in fin whales (Edds-Walton 1997; Payne and Webb. 1971). Also, there is speculation that the sounds may function for long range

echolocation of large-scale geographic targets such as seamounts, which might be used for orientation and navigation (Tyack 1999).

Although no studies have directly measured the sound sensitivity of fin whales, experts assume that fin whales are able to receive sound signals in roughly the same frequencies as the signals they produce. This suggests fin whales, like other baleen whales, are more likely to have their best hearing capacities at low frequencies, including frequencies lower than those of normal human hearing, rather than at mid- to high-frequencies (Ketten 1997a). Several fin whales were tagged during the Southern California-10 BRS and no obvious responses to a mid-frequency sound source were detected by the visual observers or in the initial tag analysis (Southall et al. 2011a). Results of studies on blue whales (Goldbogen et al. 2013) (Southall et al. 2011a), which have similar auditory physiology compared to fin whales, indicate that some individuals hear some sounds in the mid-frequency range and exhibit behavioral responses to sounds in this range depending on received level and context. In terms of functional hearing capability fin whales belong to the low-frequency group, which have a hearing range of 7 Hz to 22 kHz (Southall et al. 2007b).

4.2.2.7 Status and Trends

Fin whales were originally listed as endangered in 1970 (35 FR 18319), and this status has continued since the inception of the ESA in 1973. Although fin whale population structure remains unclear, various abundance estimates are available. Pre-exploitation fin whale abundance is estimated at 464,000 individuals worldwide; the estimate for 1991 was roughly 25 percent of this (Braham 1991). Historically, worldwide populations were severely depleted by commercial whaling, with more than 700,000 whales harvested in the twentieth century (Cherfas 1989). The most recent abundance estimates for fin whales that we are aware of are 16,625 individuals in the North Pacific Ocean and 119,000 individuals worldwide (Braham 1991). Fin whales of the north Pacific appear to be increasing in abundance although the trend is unclear or declining thoughout the rest of their range (NMFS 2011a).

Based on ecological theory and demographic patterns derived from several hundred imperiled species and populations, fin whales appear to exist at population sizes that are large enough to avoid demographic phenomena that are known to increase the extinction probability of species that exist as “small” populations (that is, “small” populations experience phenomena such as demographic stochasticity, inbreeding depression, and Allee effects, among others, that cause their population size to become a threat in and of itself). As a result, we assume that fin whales are likely to be threatened more by exogenous threats such as anthropogenic activities (primarily whaling, entanglement, and ship strikes) or natural phenomena (such as disease, predation, or changes in the distribution and abundance of their prey in response to changing climate) than endogenous threats caused by the small size of their population.

Fin whales are typically not expected south of 20°N during summer and are less likely to occur near Guam (Miyashita et al. 1996). Miyashita et al. (1996) presented a compilation of at-sea sighting results by species, from commercial fisheries vessels in the Pacific Ocean from 1964 to 1990. For fin whales in August, Miyashita et al. (1996) reported no sightings south of 20°N, and significantly more sightings north of 40°N. However, they also showed limited search effort south of 20°N. There were no fin whale sightings during the winter 2007 survey of the Action Area (Fulling et al. 2011)nor during Navy-funded monitoring for the MIRC in 2009 through

2013 (HDR 2011; HDR 2012a; Hill et al. 2013; Hill et al. 2011; Ligon et al. 2011; Oleson and Hill 2010). The Pacific Islands Fisheries Science Center has deployed several passive acoustic monitoring devices to monitor marine mammals and ambient noise levels in U.S. EEZ waters off the Mariana Islands. Recordings from these instruments are currently being analyzed, but it has been confirmed that fin whales have been acoustically detected (Oleson et al. 2013). The Navy's NMSDD estimates 0.00001 fin whales per km^2 in the MITT Action Area (DoN 2014).

4.2.2.8 Natural Threats

Natural sources and rates of mortality are largely unknown, but Aguilar and Lockyer (1987) suggested annual natural mortality rates might range from 0.04 to 0.06 for northeast Atlantic fin whales. The occurrence of the nematode *Crassicauda boopis* appears to increase the potential for kidney failure and may be preventing some fin whale populations from recovering (Lambertsen 1992). Adult fin whales engage in a flight responses (up to 40 km/h) to evade killer whales, which involves high energetic output, but show little resistance if overtaken (Ford and Reeves 2008). Shark attacks may also result in serious injury or death in very young and sick individuals (Perry et al. 1999).

4.2.2.9 Anthropogenic Threats

Fin whales have undergone significant exploitation, but are currently protected under the IWC. Fin whales are still hunted in subsistence fisheries off West Greenland. In 2003, two males and four females were landed and two others were struck and lost (IWC 2005). In 2004, five males and six females were killed, and two other fin whales were struck and lost. Between 2003 and 2007, the IWC set a catch limit of up to 19 fin whales in this subsistence fishery. However, the scientific recommendation was to limit the number killed to four individuals until accurate populations could be produced (IWC 2005). In the Antarctic Ocean, fin whales are hunted by Japanese whalers who have been allowed to kill up to 10 fin whales each year for the 2005 to 2006 and 2006 to 2007 seasons under an Antarctic Special Permit NMFS (2006c). Japanese whalers plan to kill 50 whales per year starting in the 2007 to 2008 season and continuing for the next 12 years (IWC 2006; Nishiwaki et al. 2006).

Fin whales experience significant injury and mortality from fishing gear and ship strikes (Carretta et al. 2007; Douglas et al. 2008; Lien 1994; Perkins and Beamish 1979; Waring et al. 2007a). Between 1969 and 1990, 14 fin whales were captured in coastal fisheries off Newfoundland and Labrador; of these seven are known to have died because of capture (Lien 1994; Perkins and Beamish 1979). According to Waring et al. (2007a), four fin whales in the western North Atlantic died or were seriously injured in fishing gear, while another five were killed or injured as a result of ship strikes between January 2000 and December 2004. Between 1999 and 2005, there were 15 reports of fin whales strikes by vessels along the U.S. and Canadian Atlantic coasts (Cole et al. 2005a; Nelson et al. 2007a). Of these, 13 were confirmed, resulting in the deaths of 11 individuals. Similarly, 2.4 percent of living fin whales from the Mediterranean show ship strike injury and 16 percent of stranded individuals were killed by vessel collision (Panigada et al. 2006). There are also numerous reports of ship strikes off the Atlantic coasts of France and England (Jensen and Silber 2004).

Management measures aimed at reducing the risk of ships hitting right whales should also reduce the risk of collisions with fin whales. In the Bay of Fundy, recommendations for slower vessel speeds to avoid right whale ship strike appear to be largely ignored (Vanderlaan et al. 2008).

However, new rules for seasonal (June through December) slowing of vessel traffic to 10 knots and changing shipping lanes by less than one nautical mile to avoid the greatest concentrations of right whales are predicted to be capable of reducing fin whale ship strike mortality by 27 percent in the Bay of Fundy region. Jensen and Silber's (2004) review of the NMFS' ship strike database revealed fin whales as the most frequently confirmed victims of ship strikes (26 percent of the recorded ship strikes [n = 75/292 records]), with most collisions occurring off the east coast, followed by the west coast of the U.S. and Alaska/Hawaii. Five of seven fin whales stranded along Washington State and Oregon showed evidence of ship strike with incidence increasing since 2002 (Douglas et al. 2008). From 1994 to 1998, two fin whales were presumed killed by ship strikes. More recently, in 2002, three fin whales were struck and killed by vessels in the eastern North Pacific (Jensen and Silber 2003c).

The vast majority of ship strike mortalities are never identified, and actual mortality is higher than currently documented; however, it is Navy policy to report all ship strikes.

Increased noise in the ocean stemming from shipping seems to alter the acoustic patterns of singing fin whales, possibly hampering reproductive parameters across wide regions (Castellote et al. 2012b).

The organochlorines DDE, DDT, and PCBs have been identified from fin whale blubber, but levels are lower than in toothed whales due to the lower level in the food chain that fin whales feed at (Aguilar and Borrell 1988; Borrell 1993; Borrell and Aguilar 1987; Henry and Best 1983; Marsili and Focardi 1996). Females contained lower burdens than males, likely due to mobilization of contaminants during pregnancy and lactation (Aguilar and Borrell 1988; Gauthier et al. 1997a; Gauthier et al. 1997b). Contaminant levels increase steadily with age until sexual maturity, at which time levels begin to drop in females and continue to increase in males (Aguilar and Borrell 1988).

Climate change also presents a potential threat to fin whales, particularly in the Mediterranean Sea, where fin whales appear to rely exclusively upon northern krill as a prey source. These krill occupy the southern extent of their range and increases in water temperature could result in their decline and that of fin whales in the Mediterranean Sea (Gambaiani et al. 2009).

4.2.2.10 Critical Habitat

The NMFS has not designated critical habitat for fin whales.

4.2.3 Humpback Whale

Humpback whales (*Megaptera novaeangliae*) are distinguished from other whales in the same Family (Balaenopteridae) by extraordinarily long flippers (up to 5 m or about 1/3 total body length), a more robust body, fewer throat grooves (14 to 35), more variable dorsal fin, and utilization of very long (up to 30 min.), complex, repetitive vocalizations (songs) (Payne and McVay 1971) during courtship. Their grayish-black baleen plates, approximately 270 to 440 on each side of the jaw, are intermediate in length (6570 cm) to those of other baleen whales. Humpbacks in different geographical areas vary somewhat in body length, but maximum recorded size is 18m (Winn and Reichley 1985a).

The whales are generally dark on the back, but the flippers, sides and ventral surface of the body and flukes may have substantial areas of natural white pigmentation plus acquired scars (white or

black). Researchers distinguish individual humpbacks by the apparently unique black and white patterns on the underside of the flukes as well as other individually variable features (Glockner and Venus 1983; Katona and Whitehead 1981; Kaufman and Osmond 1987).

4.2.3.1 Distribution

Humpback whales are a cosmopolitan species that occur in the Atlantic, Indian, Pacific, and Southern oceans. Humpback whales migrate seasonally between warmer, tropical or sub-tropical waters in winter months (where they breed and give birth to calves, although feeding occasionally occurs) and cooler, temperate or sub-Arctic waters in summer months (where they feed). In both regions, humpback whales tend to occupy coastal waters. However, migrations are undertaken through deep, pelagic waters (Winn and Reichley 1985a).

In the eastern and central North Pacific Ocean, the summer range of humpback whales includes coastal and inland waters from Point Conception, California, north to the Gulf of Alaska and the Bering Sea, and west along the Aleutian Islands to the Kamchatka Peninsula and into the Sea of Okhotsk (Tomlin 1967, Nemoto 1957, Johnson and Wolman 1984 as cited in NMFS 1991). These whales migrate to calving grounds near Hawaii, southern Japan, the Mariana Islands, and Mexico during the winter months.

4.2.3.2 Population Structure

Though the ESA-listed entity is the worldwide population of humpback whales, some evidence suggests there may be multiple distinct populations within the North Pacific Ocean. Descriptions of the population structure of humpback whales differ depending on whether an author focuses on where humpback whales winter or where they feed. During winter months in northern or southern hemispheres, adult humpback whales migrate to specific areas in warmer, tropical waters to reproduce and give birth to calves. During summer months, humpback whales migrate to specific areas in northern temperate or sub-arctic waters to forage. In summer months, humpback whales from different "reproductive areas" will congregate to feed; in the winter months, whales will migrate from different foraging areas to a single wintering area. In either case, humpback whales appear to form "open" populations; that is, populations that are connected through the movement of individual animals.

Based on genetic and photo-identification studies, Hill and DeMaster (1998a) recognized four stocks, likely corresponding to populations of humpback whales in the North Pacific Ocean: two in the eastern North Pacific, one in the central North Pacific, and one in the western Pacific (Hill and DeMaster 1998a). However, gene flow between them may exist. Humpback whales summer in coastal and inland waters from Point Conception, California, north to the Gulf of Alaska and the Bering Sea, and west along the Aleutian Islands to the Kamchatka Peninsula and into the Sea of Okhotsk (Johnson and Wolman 1984; Nemoto 1957; Tomilin 1967). These whales migrate to Hawaii, southern Japan, the Mariana Islands, and Mexico during winter. However, more northerly penetrations in Arctic waters occur on occasion (Hashagen et al. 2009). The central North Pacific population winters in the waters around Hawaii while the eastern North Pacific population (also called the California-Oregon-Washington stock) winters along Central America and Mexico. However, Calambokidis et al. (1997) identified individuals from several populations wintering (and potentially breeding) in the areas of other populations, highlighting the potential fluidity of population structure. Herman (1979) presented extensive evidence that humpback whales associated with the main Hawaiian Islands immigrated there only in the past

200 years. Winn and Reichley (1985a) identified genetic exchange between the humpback whales that winter off Hawaii and Mexico (with further mixing on feeding areas in Alaska) and suggested that humpback whales that winter in Hawaii may have emigrated from Mexican wintering areas. A "population" of humpback whales winters in the South China Sea east through the Philippines, Ryukyu Retto, Ogasawara Gunto, Mariana Islands, and Marshall Islands, with occurrence in the Mariana Islands, at Guam, Rota, and Saipan from January through March (Darling and Cerchio 1993; Eldredge 1991; Eldredge 2003; Fulling et al. 2011; Rice 1998). During summer, whales from this population migrate to the Kuril Islands, Bering Sea, Aleutian Islands, Kodiak, Southeast Alaska, and British Columbia to feed (Angliss and Outlaw 2008; Calambokidis 1997; Calambokidis et al. 2001).

Separate feeding groups of humpback whales are thought to inhabit western U.S. and Canadian waters, with the boundary between them located roughly at the U.S./Canadian border. The southern feeding ground ranges between 32° and 48° N, with limited interchange with areas north of Washington State (Calambokidis et al. 2004; Calambokidis et al. 1996). On April 21, 2015, NMFS proposed to divide the globally listed endangered humpback whale population into 14 DPSs (80 FR 22304). Ten of these DPS are not proposed for listing under the ESA while two are proposed as endangered and two are proposed as threatened. The humpback whales in the Action Area belong to the proposed threatened Western North Pacific DPS.

4.2.3.3 Reproduction and Growth

Humpback whale calving and breeding generally occurs during winter at lower latitudes. Gestation takes about 11 months, followed by a nursing period of up to 1 year (Baraff and Weinrich 1993). Sexual maturity is reached at between 5 to 7 years of age in the western North Atlantic, but may take as long as 11 years in the North Pacific, and perhaps over 11 years (e.g., southeast Alaska, Gabriele et al. 2007). Females usually breed every 2 to 3 years, although consecutive calving is not unheard of (Clapham and Mayo 1987; 1990; Glockner-Ferrari and Ferrari 1985 as cited in NMFS 2005b; Weinrich et al. 1993). Males appear to return to breeding grounds more frequently than do females (Herman et al. 2011). Larger females tend to produce larger calves that may have a greater chance of survival (Pack et al. 2009). Females appear to preferentially select larger-sized males (Pack et al. 2012). In some Atlantic areas, females tend to prefer shallow nearshore waters for calving and rearing, even when these areas are extensively trafficked by humans (Picanco et al. 2009). Offspring appear to return to the same breeding areas at which they were born one they are independent (Baker et al. 2013).

In calving areas, males sing long complex songs directed towards females, other males, or both. The breeding season can best be described as a floating lek or male dominance polygamy (Clapham 1996). Calving occurs in the shallow coastal waters of continental shelves and oceanic islands worldwide (Perry et al. 1999). Males court females in escort groups and compete for proximity and presumably access to reproduce females (particularly larger females)(Pack et al. 2009). Although long-term relationships do not appear to exist between males and females, mature females do pair with other females; those individuals with the longest standing relationships also have the highest reproductive output, possibly as a result of improved feeding cooperation (Ramp et al. 2010). Site fidelity off Brazilian breeding grounds was extremely low, both within and between years (Baracho-Neto et al. 2012).

Generation time for humpback whales is estimated at 21.5 years, with individuals surviving from 80-100 years (COSEWIC 2011).

4.2.3.4 Feeding

During the feeding season, humpback whales form small groups that occasionally aggregate on concentrations of food that may be stable for long-periods of times. Humpbacks use a wide variety of behaviors to feed on various small, schooling prey including krill and fish (Hain et al. 1982; Hain et al. 1995; Jurasz and Jurasz 1979; Weinrich et al. 1992; Witteveen et al. 2011). The principal fish prey in the western North Atlantic are sand lance, herring, and capelin (Kenney et al. 1985). There is good evidence of some territoriality on feeding and calving areas (Clapham 1994; Clapham 1996; Tyack 1981). Humpback whales are generally believed to fast while migrating and on breeding grounds, but some individuals apparently feed while in low-latitude waters normally believed to be used exclusively for reproduction and calf-rearing (Danilewicz et al. 2009; Pinto De Sa Alves et al. 2009). Some individuals, such as juveniles, may not undertake migrations at all (Findlay and Best. 1995). Additional evidence, such as songs sung in northern latitudes during winter, provide additional support to plastic seasonal distribution (Smith and G.Pike 2009). Relatively high rates of resighting in foraging sites in suggest whales return to the same areas year after year (Ashe et al. 2013; Kragh Boye et al. 2010). This trend appears to be maternally linked, with offspring returning to the same areas their mother brought them once calves are independent (Baker et al. 2013; Barendse et al. 2013). Humpback whales in foraging areas may forage largely or exclusively at night when prey are closer to the surface while in foraging areas (Friedlaender et al. 2013). Humpback whales primarily feed along the shelf break and continental slope (Green et al. 1992; Tynan et al. 2005b).

4.2.3.5 Diving and Social Behavior

In Hawaiian waters, humpback whales remain almost exclusively within the 1,800 m isobath and usually within water depths of less than 182 m. Maximum diving depths are approximately 170 m (but usually <60 m), with a very deep dive (240 m) recorded off Bermuda (Hamilton et al. 1997). Dives can last for up to 21 min, although feeding dives ranged from 2.1 to 5.1 min in the North Atlantic (Dolphin 1987). In southeast Alaska, average dive times were 2.8 min for feeding whales, 3.0 min for non-feeding whales, and 4.3 min for resting whales (Dolphin 1987). In the Gulf of California, humpback whale dive durations averaged 3.5 min (Strong 1990). Because most humpback prey is likely found within 300 m of the surface, most humpback dives are probably relatively shallow. In Alaska, capelin are the primary prey of humpback and are found primarily between 92 and 120 m; depths to which humpbacks apparently dive for foraging (Witteveen et al. 2008).

Humpback whales migrate seasonally between warmer, tropical or sub-tropical waters in winter months (where they breed and give birth to calves, although feeding occasionally occurs) and cooler, temperate or sub-Arctic waters in summer months (where they feed; (Gendron and Urban 1993). In both regions, humpback whales tend to occupy shallow, coastal waters. However, migrations are undertaken through deep, pelagic waters (Winn and Reichley 1985b). Humpback whales wintering in the West Indies migrate relatively directly to the Gulf of Maine and areas around Iceland and Norway (Kennedy et al. 2013). Some individuals may not migrate, or species occurrence in foraging areas may extend beyond summer months (Van Opzeeland et al. 2013). Average group size near Kodiak Island is 2 to 4 individuals, although larger groups are seen near

Shuyak and Sitkalidak islands and groups of 20 or more have been documented (Wynne et al. 2005).

4.2.3.6 Vocalization and Hearing

Humpback whale vocalization is much better understood than is hearing. Different sounds are produced that correspond to different functions: feeding, breeding, and other social calls (Dunlop et al. 2008). Males sing complex sounds while in low-latitude breeding areas in a frequency range of 20 Hz to 4 kHz with estimated source levels from 144 to 174 dB (Au et al. 2006b; Au et al. 2000b; Frazer and Mercado III 2000; Richardson et al. 1995c; Winn et al. 1970). Males also produce sounds associated with aggression, which are generally characterized as frequencies between 50 Hz to 10 kHz and having most energy below 3 kHz (Silber 1986; Tyack 1983). Such sounds can be heard up to 9 km away (Tyack 1983). Other social sounds from 50 Hz to 10 kHz (most energy below 3 kHz) are also produced in breeding areas (Richardson et al. 1995c; Tyack 1983). While in northern feeding areas, both sexes vocalize in grunts (25 Hz to 1.9 kHz), pulses (25 to 89 Hz), and songs (ranging from 30 Hz to 8 kHz but dominant frequencies of 120 Hz to 4 kHz) which can be very loud (175 to 192 dB re 1 μPa at 1 m) (Au et al. 2000b; Erbe 2002a; Payne 1985; Richardson et al. 1995c; Thompson et al. 1986). However, humpbacks tend to be less vocal in northern feeding areas than in southern breeding areas (Richardson et al. 1995c).

Humpback whales are known to produce three classes of vocalizations: (1) "songs" in the late fall, winter, and spring by solitary males; (2) social sounds made by calves (Zoidis et al. 2008) or within groups on the wintering (calving) grounds; and (3) social sounds made on the feeding grounds (Thomson and Richardson 1995). The best-known types of sounds produced by humpback whales are songs, which are thought to be reproductive displays used on breeding grounds only by adult males (Clark and Clapham 2004; Gabriele and Frankel. 2002; Helweg et al. 1992; Schevill et al. 1964; Smith et al. 2008). Singing is most common on breeding grounds during the winter and spring months, but is occasionally heard in other regions and seasons (Clark and Clapham 2004; Gabriele and Frankel. 2002; McSweeney et al. 1989). Au et al. (2000a) noted that humpbacks off Hawaii tended to sing louder at night compared to the day. There is geographical variation in humpback whale song, with different populations singing a basic form of a song that is unique to their own group. However, the song evolves over the course of a breeding season, but remains nearly unchanged from the end of one season to the start of the next (Payne et al. 1983). The song is an elaborate series of patterned vocalizations that are hierarchical in nature, with a series of songs ('song sessions') sometimes lasting for hours (Payne and McVay 1971). Components of the song range from below 20 Hz up to 4 kHz, with source levels measured between 151 and 189 dB re 1 μPa-m and high-frequency harmonics extending beyond 24 kHz (Au et al. 2006b; Winn et al. 1970).

Social calls range from 20 Hz to 10 kHz, with dominant frequencies below 3 kHz (D'Vincent et al. 1985; Dunlop et al. 2008; Silber 1986; Simao and Moreira 2005). Female vocalizations appear to be simple; Simao and Moreira (2005) noted little complexity.

"Feeding" calls, unlike song and social sounds are a highly stereotyped series of narrow-band trumpeting calls. These calls are 20 Hz to 2 kHz, less than 1 second in duration, and have source levels of 162 to 192 dB re 1 μPa-m (D'Vincent et al. 1985; Thompson et al. 1986). The fundamental frequency of feeding calls is approximately 500 Hz (D'Vincent et al. 1985) (D'Vincent et al. 1985; Thompson et al. 1986). The acoustics and dive profiles associated with

humpback whale feeding behavior in the northwest Atlantic has been documented with Digital Acoustic Recording Tags (DTAGs[5]) (Stimpert et al. 2007). Underwater lunge behavior was associated with nocturnal feeding at depth and with multiple bouts of broadband click trains that were acoustically different from toothed whale echolocation: Stimpert et al. (Stimpert et al. 2007) termed these sounds "mega-clicks" which showed relatively low received levels at the DTAGs (143 to 154 dB re 1 µPa), with the majority of acoustic energy below 2 kHz.

Humpback whale audiograms using a mathematical model based on the internal structure of the ear estimate sensitivity is from 700 Hz to 10 kHz, with maximum relative sensitivity between 2 kHz and 6 kHz (Ketten and Mountain 2014). Previously mentioned research by Au et al. (2001) and Au et al. (2006a) off Hawaii indicated the presence of high-frequency harmonics in vocalizations up to and beyond 24 kHz. While recognizing this was the upper limit of the recording equipment, it does not demonstrate that humpbacks can actually hear those harmonics, which may simply be correlated harmonics of the frequency fundamental in the humpback whale song. The ability of humpbacks to hear frequencies around 3 kHz may have been demonstrated in a playback study. Maybaum (1990) reported that humpback whales showed a mild response to a handheld sonar marine mammal detection and location device with frequency of 3.3 kHz at 219 dB re 1µPa-m or frequency sweep of 3.1 kHz to 3.6 kHz (although it should be noted that this system is significantly different from the Navy's hull mounted sonar). In addition, the system had some low frequency components (below 1 kHz) which may have been an artifact of the acoustic equipment. This possible artifact may have affected the response of the whales to both the control and sonar playback conditions.

Results of studies on blue whales (Goldbogen et al. 2013) (Southall et al. 2011a), which have similar auditory physiology compared to humpback whales, indicate that some individuals hear some sounds in the mid-frequency range and exhibit behavioral responses to sounds in this range depending on received level and context. In terms of functional hearing capability humpback whales belong to low-frequency cetaceans which have a hearing range of 7 Hz to 22 kHz (Southall et al. 2007b).

Humpback whales are the most abundant ESA-listed species observed during Navy visual surveys in the winter months. To date, humpback whales have been documented as the species which has received the highest sound pressure levels from US Navy mid-frequency active sonar (MFAS) training (i.e. at least 183 dB re 1microPa) based upon an analysis which utilized shipboard Marine Mammal Observer sightings on February 18, 2011 (Farak et al. 2011), combined with PMRF range hydrophone data (Martin and Manzano-Roth 2012). Analysis of PMRF range hydrophone data for purpose of estimating received levels on marine mammals has

[5] *DTAG is a novel archival tag, developed to monitor the behavior of marine mammals, and their response to sound, continuously throughout the dive cycle. The tag contains a large array of solid-state memory and records continuously from a built-in hydrophone and suite of sensors. The sensors sample the orientation of the animal in three dimensions with sufficient speed and resolution to capture individual fluke strokes. Audio and sensor recording is synchronous so the relative timing of sounds and motion can be determined precisely Johnson, M. P., and P. L. Tyack. 2003. A digital acoustic recording tag for measuring the response of wild marine mammals to sound. IEEE Journal of Oceanic Engineering 28(1):3-12..*

also been done in conjunction with satellite tagged animals (Baird et al. 2014) and aerial focal follows (Mobley Jr. and Pacini 2013). Passive acoustic monitoring (PAM) of PMRF hydrophones during Navy training for the month of Feb from 2011 to 2013 has shown that acoustically localized minke whales are reduced during periods involving MFAS training activity when compared to other periods of time (Martin et al. 2014) . PAM monitoring for beaked whale foraging dives at PMRF has also shown reduced foraging dive rates during periods of MFAS training with estimated receive levels on the group dive members (mean levels of 109 dB re 1 microPa) in February of 2012 (Manzano-Roth et al. 2013a). Acoustic analysis has also shown that marine mammals near the sea surface can be exposed to higher estimated receive levels due to ducted propagation, that typically exists at PMRF. Analysis of behaviors observed during one focal follow taken during aerial surveys, in conjunction with estimated received levels using PMRF passive acoustic data products, are reported as a case study of a single focal follow on a humpback whale in the vicinity of MFAS (Mobley Jr. and Pacini 2013).

4.2.3.7 Status and Trends

Humpback whales were originally listed as endangered in 1970 (35 FR 18319), and this status remains under the ESA. On April 21, 2015, NMFS proposed to divide the globally listed endangered humpback whale population into 14 DPSs (80 FR 22304). The humpback whales in the Action Area belong to the proposed threatened Western North Pacific DPS.

It is estimated that 15,000 humpback whales resided in the North Pacific in 1905 (Rice 1978a). However, from 1905 to 1965, nearly 28,000 humpback whales were harvested in whaling operations, reducing the number of all North Pacific humpback whale to roughly 1,000 (Perry et al. 1999). The overall abundance of humpback whales in the north Pacific was recently estimated at 21,808 individuals (coefficient of variation = 0.04), confirming that this population of humpback whales has continued to increase and is now greater than some pre-whaling abundance estimates (Barlow et al. 2011). Data indicates the north Pacific population has been increasing at a rate of between 5.5 percent and 6.0 percent per year, therefore approximately doubling every 10 years (Calambokidis et al. 2008a).

Modeled abundance increase in southeastern Alaska was 5.1 percent annually from 1986 to 2008 (Hendrix et al. 2012); a more specific estimate from Glacier Bay, the site of a long-term monitoring study over roughly the same time frame found a rate of increase of 4.4 percent (Saracco et al. 2013). For Asia, an annual rate of growth of 6.7 percent has been estimated (Calambokidis et al. 2008b).

In the Pacific, the stock structure of humpback whales is defined based on feeding areas because of the species' fidelity to feeding grounds (Carretta et al. 2010). The NMFS has designated four stocks for management purposes under the MMPA: (1) the Central North Pacific stock, with feeding areas from Southeast Alaska to the Alaska Peninsula; (2) the Western North Pacific stock, with feeding areas from the Aleutian Islands, Bering Sea, and Russia; (3) the California, Oregon, Washington, and Mexico stock, with feeding areas off the U.S. west coast; and (4) the American Samoa stock, with feeding areas as far south as the Antarctic Peninsula (Allen and Angliss 2010c). Humpback whales in the Action Area are most likely part of the Western North Pacific stock, since this population is known to winter in the Ogasawara Islands, Ryukyu (Okinawa) Islands, Taiwan, the Philippines, and the Mariana Islands (Calambokidis et al. 2008a). The current population estimate for this stock is 938 to 1,107 animals (Allen and Angliss

2011). The Navy's NMSDD estimates 0.00089 humpback whales per km^2 in the MITT Action Area (DoN 2014).

The April 21, 2015 proposed rule to designate 14 DPSs for humpback whales indicates the humpack whales in the MITT Action Area are part of the proposed Western North Pacific DPS. This DPS has an abundance estimate of approximately 1,000 individuals as described above for the Western North Pacific MMPA stock.

Humpback whales have only been infrequently sighted during the Navy's routine aerial surveys of Farallon de Medinilla (FDM); two sightings in 2006 (January and March), both close to the island, and another sighting in February 2007, 18 miles (mi.) (29 kilometers [km]) north of Saipan (Vogt 2008). During a ship survey in the Action Area (January through April 2007), humpback whales were observed and/or detected acoustically in both deep (2,625 to 3,940 feet [ft.] [800 to 1,200 m]) and shallow (1,234 ft. [374 m]) waters northeast of Saipan (Fulling et al. 2011). Acoustic detections of humpback song were also made during these sightings as well as on other occasions (Fulling et al. 2011). These observations suggest that there could be a small wintering population of humpback whales transiting during migration through the Action Area (Fulling et al. 2011; Ligon et al. 2011). During Navy-funded monitoring for the MIRC in 2009 through 2014, no humpback whales were sighted (Fulling et al. 2011; HDR 2011; HDR 2012a; Hill et al. 2013; Hill et al. 2011; Ligon et al. 2011; Oleson and Hill 2010). However, preliminary HARP data analysis shows detection of humpback whales off Saipan from February to May (Oleson et al. 2014).

4.2.3.8 Natural Threats

Natural sources and rates of mortality of humpback whales are not well known. Based upon prevalence of tooth marks, attacks by killer whales appear to be highest among humpback whales migrating between Mexico and California, although populations throughout the Pacific Ocean appear to be targeted to some degree (Steiger et al. 2008). Juveniles appear to be the primary age group targeted. Humpback whales engage in grouping behavior, flailing tails, and rolling extensively to fight off attacks. Calves remain protected near mothers or within a group and lone calves have been known to be protected by presumably unrelated adults when confronted with attack (Ford and Reeves 2008).

Parasites and biotoxins from red-tide blooms are other potential causes of mortality (Perry et al. 1999). The occurrence of the nematode *Crassicauda boopis* appears to increase the potential for kidney failure in humpback whales and may be preventing some populations from recovering (Lambertsen 1992). Studies of 14 humpback whales that stranded along Cape Cod between November 1987 and January 1988 indicate they apparently died from a toxin produced by dinoflagellates during this period. One-quarter of humpback whales of the Arabian Sea population show signs of tattoo skin disease, which may reduce the fitness of afflicted individuals (Baldwin et al. 2010). Emaciated calf and juvenile humpbacks were found in numbers an order of magnitude higher than normal along Western Australia in 2009 due to unknown causes (Coughran et al. 2013).

4.2.3.9 Anthropogenic Threats

Three human activities are known to threaten humpback whales: whaling, commercial fishing, and shipping. Historically, whaling represented the greatest threat to every population of whales and was ultimately responsible for listing several species as endangered.

Humpback whales are also killed or injured during interactions with commercial fishing gear. Like fin whales, humpback whales have been entangled by fishing gear off Newfoundland and Labrador, Canada. A total of 595 humpback whales were reported captured in coastal fisheries in those two provinces between 1969 and 1990, of which 94 died (Lien 1994; Perkins and Beamish 1979). From 1979 through 2008, 1,209 whales were recorded entangled, 80 percent of which were humpback whales (Benjamins et al. 2012). Along the Atlantic coast of the U.S. and the Maritime Provinces of Canada, there were 160 reports of humpback whales being entangled in fishing gear between 1999 and 2005 (Cole et al. 2005b; Nelson et al. 2007b). Of these, 95 entangled humpback whales were confirmed, with 11 whales sustaining injuries and nine dying of their wounds. Along the Pacific coast of Canada, 40 humpback whales have been reported as entangled since 1980, four of which are known to have died (COSEWIC 2011; Ford et al. 2009). Between 30 and 40 percent of humpback whales in the Arabian Sea show scarring from entanglements, with fishing effort on the rise (Baldwin et al. 2010). Alava et al. (2012) reported that 0.53 percent of humpback whale populations breeding along Ecuador are bycaught annually in commercial fishing gear (mortality of 15 to 33 individuals per year). From 2004 to 2008, 18 humpback whales were observed to be entangled along the U.S. west coast, of which 14 were considered seriously injured and two are known to have died (Carretta et al. 2013b). From 2006 to 2010, 29 entangled whales were identified with serious injury or mortality resulting from the entanglement (Waring et al. 2013). From 1996 to 2000, 22 humpback whales of the Central North Pacific population were found entangled in fishing gear (Angliss and Lodge. 2004). In 1996, a vessel from the Pacific Missile Range Facility in Hawaii rescued an entangled humpback, removing two crabpot floats from the whale. A photography study of humpback whales in southeastern Alaska in 2003 and 2004 found at least 53 percent of individuals showed some kind of scarring from fishing gear entanglement (Neilson et al. 2005). There are also reports of entangled humpback whales from the Hawaiian Islands. In 1991, a humpback whale was observed entangled in longline gear and released alive (Hill et al. 1997). In 1995, a humpback whale in Maui waters was found trailing numerous lines (not fishery-related) and entangled in mooring lines. The whale was successfully released, but subsequently stranded and was attacked and killed by tiger sharks in the surf zone. From 2001 through 2006, there were 23 reports of entangled humpback whales in Hawaiian waters; 16 of these reports were from 2005 and 2006. A photography study of humpback whales in southeastern Alaska in 2003 and 2004 found at least 53 percent of individuals showed some kind of scarring from fishing gear entanglement (Neilson et al. 2005). Between 30 and 40 percent of humpback whales in the Arabian Sea show scarring from entanglements, with fishing effort on the rise (Baldwin et al. 2010). Alava et al. (2012) reported that 0.53 percent of humpback whale populations breeding along Ecuador are bycaught annually in commercial fishing gear (mortality of 15 to 33 individuals per year). Ten humpback whales were found entangled in gill nets or long lines between 1995 and 2002 off Peru (Garcia-Godos et al. 2013).

Many of the entangled humpback whales observed in Hawaiian waters brought the gear with them from higher latitude feeding grounds; for example, the whale the U.S. Navy rescued in 1996 had been entangled in gear that was traced to a recreational fisherman in southeast Alaska.

Thus far, 6 of the entangled humpback whales observed in the Hawaiian Islands have been confirmed to have been entangled in gear from Alaska. Nevertheless, humpback whales are also entangled in fishing gear in the Hawaiian Islands. Since 2001, there have been 5 observed interactions between humpback whales and gear associated with the Hawaii-based longline fisheries (NMFS 2008a). In each instance, however, all of the whales were disentangled and released or they were able to break free from the gear without reports of impairment of the animal's ability to swim or feed.

More humpback whales are killed in collisions with ships than any other whale species except fin whales (Jensen and Silber 2003a). Of 123 humpback whales that stranded along the Atlantic coast of the U.S. between 1975 and 1996, 10 (8.1 percent) showed evidence of collisions with ships (Laist et al. 2001). From 1975 through 2011, 68 collisions were actually witnessed in the main Hawaiian Islands, 63 percent involving calves and subadults, with the rate of collisions increasing over time even accounting for higher numbers of whales present (Lammers et al. 2013). Between 1999 and 2005, there were 18 reports of humpback whales being struck by vessels along the Atlantic coast of the U.S. and the Maritime Provinces of Canada (Cole et al. 2005b; Nelson et al. 2007b). Of these reports, 13 were confirmed as ship strikes and in seven cases, ship strike was determined to be the cause of death. Along Pacific Canada, 21q reports of ship strikes involving humpback whales were reported from 2001 to 2008 (COSEWIC 2011; Ford et al. 2009). From 2006 to 2010, 10 instances of mortality stemming from vessel collision were documented (Waring et al. 2013). In the Bay of Fundy, recommendations for slower vessel speeds to avoid right whale ship strike appear to be largely ignored (Vanderlaan et al. 2008). However, new rules for seasonal (June through December) slowing of vessel traffic to 10 knots and changing shipping lanes by less than one nautical mile to avoid the greatest concentrations of right whales are expected to reduce the chance of humpback whales being hit by ships by 9 percent. The first estimate of population-level effects of entanglement were recently produced, with over 12 percent of the Gulf of Maine population of humpbacks acquiring new scars from entanglement interactions annually (Mattila and Rowles 2010). Two humpbacks were recorded as ships truck and died along the west coast from 2004 to 2008; a third was known to have been struck but its outcome is unknown (Carretta et al. 2013b). On the Pacific coast, a humpback whale is killed about every other year by ship strikes (Barlow et al. 1997b). The humpback whale calf that was found stranded on Oahu with evidence of vessel collision (propeller cuts) in 1996 suggests that ship collisions might kill adults, juvenile, and calves (NMFS unpublished data). Although data for actual strikes is lacking off Pacific Panama, study of shipping data and satellite tag data on humpback whales showed that 8 of 15 whales tagged came within 200 m of 81 different ships on 98 occasions in a period of 11 days (Guzman et al. 2013).

Organochlorines, including PCB and DDT, have been identified from humpback whale blubber (Gauthier et al. 1997a). Higher PCB levels have been observed in western Atlantic waters versus Pacific waters along the United States and levels tend to increase with individual age (Elfes et al. 2010); eastern Atlantic individuals fall between these two in contaminant burden (Ryan et al. 2014). Although humpback whales in the Gulf of Maine and off Southern California tend to have the highest PCB concentrations, overall levels are on par with other baleen whales, which are generally lower than odontocete cetaceans (Elfes et al. 2010). As with blue whales, these contaminants are transferred to young through the placenta, leaving newborns with contaminant loads equal to that of mothers before bioaccumulating additional contaminants during life and passing the additional burden to the next generation (Metcalfe et al. 2004). Contaminant levels

are relatively high in humpback whales as compared to blue whales. Humpback whales feed higher on the food chain, where prey carry higher contaminant loads than the krill that blue whales feed on.

Foraging locations in the North Atlantic have shifted by significant distances over the past few decades, potentially as a result of global warming (Palsboll et al. 2013).

4.2.3.10 Critical Habitat

The NMFS has not designated critical habitat for humback whales.

4.2.4 Sei Whale

Sei whales (pronounced "say" or "sigh"; *Balaenoptera borealis*) are members of the baleen whale family and are considered one of the "great whales" or rorquals. Two subspecies of sei whales are recognized, *B. b. borealis* in the Northern Hemisphere and *B. b. schlegellii* in the Southern Hemisphere. These large animals can reach lengths of 40 to 60 ft (12 to 18 m) and weigh 100,000 lbs (45,000 kg). Females may be slightly longer than males. Sei whales have a long, sleek body that is dark bluish-gray to black in color and pale underneath. The body is often covered in oval-shaped scars (probably caused from cookie-cutter shark and lamprey bites) and sometimes has subtle "mottling".

The Sei is regarded as the fastest swimmer among the great whales, reaching bursts of speed in excess of 20 knots. When a sei whale begins a dive it usually submerges by sinking quietly below the surface, often remaining only a few meters deep, leaving a series of swirls or tracks as it move its flukes. When at the water's surface, sei whales can be sighted by a columnar or bushy blow that is about 10 to 13 feet (3 to 4 m) in height. The dorsal fin usually appears at the same time as the blowhole, when the animal surfaces to breathe. This species usually does not arch its back or raise its flukes when diving.

Sei whales become sexually mature at 6 to 12 years of age when they reach about 45 ft (13 m) in length, and generally mate and give birth during the winter in lower latitudes. Females breed every 2 to 3 years, with a gestation period of 11 to 13 months. Females give birth to a single calf that is about 15 ft (4.6 m) long and weighs about 1,500 lbs (680 kg). Calves are usually nursed for 6 to 9 months before being weaned on the preferred feeding grounds. Sei whales have an estimated lifespan of 50 to 70 years.

4.2.4.1 Distribution

The sei whale occurs in all oceans of the world except the Arctic. The migratory pattern of this species is thought to encompass long distances from high-latitude feeding areas in summer to low-latitude breeding areas in winter; however, the location of winter areas remains largely unknown (Perry et al. 1999). Sei whales are often associated with deeper waters and areas along continental shelf edges (Hain et al. 1985a). This general offshore pattern is disrupted during occasional incursions into shallower inshore waters (Waring et al. 2004b). The species appears to lack a well-defined social structure and individuals are usually found alone or in small groups of up to six whales (Perry et al. 1999). When on feeding grounds, larger groupings have been observed (Gambell 1985d).

In the North Pacific Ocean, sei whales occur from the Bering Sea south to California (on the east) and the coasts of Japan and Korea (on the west). During the winter, sei whales are found

from 20° to 23°N (Gambell 1985d; Masaki 1977a). Sasaki et al. (2013) demonstrated that sei whale in the North Pacific are strongly correlated with sea surface temperatures between 13.1 and 16.8 degrees C. Sei whales have been seen in monitoring efforts in Hawaii in 2007 and in 2010.

4.2.4.2 Population Structure

The population structure of sei whales is not well defined, but presumed to be discrete by ocean basin (north and south), except for sei whales in the Southern Ocean, which may form a ubiquitous population or several discrete ones.

Mark-recapture, catch distribution, and morphological research indicate more than one population may exist in the North Pacific – one between 155° and 175° W, and another east of 155° W (Masaki 1976a; Masaki 1977a). Sei whales have been reported primarily south of the Aleutian Islands, in Shelikof Strait and waters surrounding Kodiak Island, in the Gulf of Alaska, and inside waters of southeast Alaska and south to California to the east and Japan and Korea to the west (Leatherwood et al. 1982b; Nasu 1974b). Sightings have also occurred in Hawaiian waters. In Navy-funded surveys 2007 through 2012, there were three confirmed sighting of sei whales for a total of five individuals—all made from vessels (HDR 2012b). Two sightings were documented northeast of Oahu in 2007 (Smultea et al. 2007), while the third was encountered near Perret Seamount west of the Island of Hawaii in 2010 (HDR 2012b). Bottom depths for the sei whale sightings were from 3,100 to 4,500 m. Sightings were made during BSS 2-4. Smultea et al. (2010) noted that the lack of sightings of sei whales in the Hawaiian Islands may be due to misidentification and/or poor sighting conditions. Sei whales have been occasionally reported from the Bering Sea and in low numbers on the central Bering Sea shelf (Hill and DeMaster 1998a). Whaling data suggest that sei whales do not venture north of about 55° N (Gregr et al. 2000). Harwood (1987) evaluated Japanese sighting data and concluded that sei whales rarely occur in the Bering Sea. Harwood (1987) reported that 75 to 85 percent of the North Pacific population resides east of 180°. Considering the many British Columbia whaling catches in the early to mid 1900s, sei whales have clearly utilized this area in the past (Gregr et al. 2000; Pike and Macaskie 1969). Masaki (1977a) reported sei whales concentrating in the northern and western Bering Sea from July through September, although other researchers question these observations because no other surveys have reported sei whales in the northern and western Bering Sea.

Sei whales appear to prefer to forage in regions of steep bathymetric relief, such as continental shelf breaks, canyons, or basins situated between banks and ledges (Best and Lockyer 2002; Gregr and Trites 2001b; Kenney and Winn 1987), where local hydrographic features appear to help concentrate zooplankton, especially copepods. In their foraging areas, sei whales appear to associate with oceanic frontal systems (Horwood 1987b). In the north Pacific, sei whales are found feeding particularly along the cold eastern currents (Perry et al. 1999). Masaki (1977a) presented sightings data on sei whales in the North Pacific from the mid-1960s to the early 1970s. Over that time interval sei whales did not appear to occur in waters of Washington State and southern British Columbia in May or June, their densities increased in those waters in July and August (1.9 to 2.4 and 0.7 to 0.9 whales per 100 miles of distance for July and August, respectively), then declined again in September. More recently, sei whales have become known for an irruptive migratory habit in which they appear in an area then disappear for time periods that can extend to decades.).

4.2.4.3 Reproduction

Very little is known regarding sei whale reproduction. Reproductive activities for sei whales occur primarily in winter. Gestation is about 12.7 months, calves are weaned at 6–9 months, and the calving interval is about 2–3 years (Gambell 1985c; Rice 1977). Sei whales become sexually mature at about age 10 (Rice 1977). Of 32 adult female sei whales harvested by Japanese whalers, 28 were found to be pregnant while one was pregnant and lactating during May–July 2009 cruises in the western North Pacific (Tamura et al. 2009).

4.2.4.4 Movement

The migratory pattern of this species is thought to encompass long distances from high-latitude feeding areas in summer to low-latitude breeding areas in winter; however, the location of winter areas remains largely unknown (Perry et al. 1999). Sei whales are often associated with deeper waters and areas along continental shelf edges (Hain et al. 1985b). This general offshore pattern is disrupted during occasional incursions into shallower inshore waters (Waring et al. 2004a). The species appears to lack a well-defined social structure and individuals are usually found alone or in small groups of up to six whales (Perry et al. 1999). When on feeding grounds, larger groupings have been observed (Gambell 1985c).

4.2.4.5 Feeding

Sei whales are primarily planktivorous, feeding mainly on euphausiids and copepods, although they are also known to consume fish (Waring et al. 2006). In the Northern Hemisphere, sei whales consume small schooling fish such as anchovies, sardines, and mackerel when locally abundant (Konishi et al. 2009; Mizroch et al. 1984b; Rice 1977). Sei whales in the North Pacific feed on euphausiids and copepods, which make up about 95 percent of their diets (Calkins 1986a). The dominant food for sei whales off California during June-August is northern anchovy, while in September-October whales feed primarily on krill (Rice 1977). The balance of their diet consists of squid and schooling fish, including smelt, sand lance, Arctic cod, rockfish, pollack, capelin, and Atka mackerel (Nemoto and Kawamura 1977b). In the Southern Ocean, analysis of stomach contents indicates sei whales consume *Calanus* spp. and small-sized euphasiids with prey composition showing latitudinal trends (Kawamura 1974). Sei whales in the Southern Hemisphere may reduce direct interspecific competition with blue and fin whales by consuming a wider variety of prey and by arriving later to feeding grounds (Kirkwood 1992b). Rice (1977) suggested that the diverse diet of sei whales may allow them greater opportunity to take advantage of variable prey resources, but may also increase their potential for competition with commercial fisheries. In the North Pacific, sei whales appear to prefer feeding along the cold eastern currents (Perry et al. 1999). Sei whales have the flexibility to skim or engulf prey (Brodie and Vikingsson 2009).

4.2.4.6 Diving and Social Behavior

Generally, sei whales make 5 to 20 shallow dives of 20 to 30 second duration followed by a deep dive of up to 15 minutes (Gambell 1985d). The depths of sei whale dives have not been studied; however the composition of their diet suggests that they do not perform dives in excess of 300 meters. Sei whales are usually found in small groups of up to 6 individuals, but they commonly form larger groupings when they are on feeding grounds (Gambell 1985d).

Sei whales are primarily planktivorous, feeding mainly on euphausiids and copepods, although they are also known to consume fish (Waring et al. 2007b). In the Northern Hemisphere, sei

whales consume small schooling fish such as anchovies, sardines, and mackerel when locally abundant (Mizroch et al. 1984a; Rice 1977). Sei whales in the North Pacific feed on euphausiids and copepods, which make up about 95 percent of their diets (Calkins 1986b). The dominant food for sei whales off California during June through August is northern anchovy, while in September and October whales feed primarily on krill (Rice 1977). The balance of their diet consists of squid and schooling fish, including smelt, sand lance, Arctic cod, rockfish, pollack, capelin, and Atka mackerel (Nemoto and Kawamura 1977a). In the Southern Ocean, analysis of stomach contents indicates sei whales consume Calanus spp. and small-sized euphasiids with prey composition showing latitudinal trends (Kawamura 1974). Evidence indicates that sei whales in the Southern Hemisphere reduce direct interspecific competition with blue and fin whales by consuming a wider variety of prey and by arriving later to feeding grounds (Kirkwood 1992a). Rice (1977) suggested that the diverse diet of sei whales may allow them greater opportunity to take advantage of variable prey resources, but may also increase their potential for competition with commercial fisheries.

Little is known about the actual social system of these animals. Groups of two to five individuals are typically observed, but sometimes thousands may gather if food is abundant. However, these large aggregations may not be dependent on food supply alone, as they often occur during times of migration. Norwegian workers call the times of great sei whale abundance "invasion years." During mating season, males and females may form a social unit, but strong data on this issue are lacking.

4.2.4.7 Vocalization and Hearing

Data on sei whale vocal behavior is limited, but includes records off the Antarctic Peninsula of broadband sounds in the 100 Hz to 600 Hz range with 1.5 s duration and tonal and upsweep calls in the 200 Hz to 600 Hz range of 1 to 3 s durations (McDonald et al. 2005). Differences may exist in vocalizations between ocean basins (Rankin et al. 2009). Vocalizations from the North Atlantic consisted of paired sequences (0.5 to 0.8 sec, separated by 0.4 to 1.0 sec) of 10 to 20 short (4 msec) FM sweeps between 1.5 to 3.5 kHz (Richardson et al. 1995c).

Recordings made in the presence of sei whales have shown that they produce sounds ranging from short, mid-frequency pulse sequences (Knowlton et al. 1991; Thompson et al. 1979) to low frequency broadband calls characteristic of mysticetes (Baumgartner et al. 2008; McDonald et al. 2005; Rankin and Barlow 2007). Off the coast of Nova Scotia, Canada, Knowlton et al. (1991) recorded two-phased calls lasting about 0.5 to 0.8 s and ranging in frequency from 1.5 kHz to 3.5 kHz in the presence of sei whales—data similar to that reported by Thompson et al. (1979). These mid-frequency calls are distinctly different from low-frequency tonal and frequency swept calls recorded in later studies. For example, calls recorded in the Antarctic averaged 0.45 ± 0.3 s in duration at 433 ± 192 Hz, with a maximum source level of 156 ± 3.6 dB re 1 µPa-m (McDonald et al. 2005). During winter months off Hawaii, (Rankin and Barlow 2007)recorded down swept calls by sei whales that exhibited two distinct low frequency ranges of 100 Hz to 44 Hz and 39 Hz to 21 Hz, with the former range usually shorter in duration. Similar sei whale calls were also found near the Gulf of Maine in the northwest Atlantic, ranging from 82.3 Hz to 34.0 Hz and averaging 1.38 s in duration (Baumgartner et al. 2008). These calls were primarily single occurrences, but some double or triple calls were noted as well. It is thought that the difference in call frequency may be functional, with the mid-frequency type serving a reproductive purpose and the low frequency calls aiding in feeding/social communication (McDonald et al. 2005). Sei

whales have also been shown to reduce their calling rates near the Gulf of Maine at night, presumably when feeding, and increase them during the day, likely for social activity (Baumgartner and Fratantoni 2008). Off the Mariana Islands, 32 sei whale calls were recorded, 25 of which were backed up by sightings (Norris et al. 2012). The peak mean frequency of these calls ranged from 890.6 Hz to 1,046.9 Hz with a mean duration of 3.5 to 0.2 seconds. Norris et al. (2012)reported that simultaneous acoustic detections of called were made from the towed array during three visual sightings. The encounters occurred primarily in the central and southern region of the study area, ranging from the island of Tinian to the southeast corner of the study area. A higher concentration was found in the southeast corner and along the Mariana Trench (Norris et al. 2012).

While no data on hearing ability for this species are available, Ketten (1997b) hypothesized that mysticetes have acute infrasonic hearing. Results of studies on blue whales (Goldbogen et al. 2013) (Southall et al. 2011a), which have similar auditory physiology compared to sei whales, indicate that some individuals hear some sounds in the mid-frequency range and exhibit behavioral responses to sounds in this range depending on received level and context. In terms of functional hearing capability, sei whales belong to low-frequency cetaceans which have a hearing range of 7 Hz to 22 kHz (Southall et al. 2007b). There are no tests or modeling estimates of specific sei whale hearing ranges.

4.2.4.8 Status and Trends

The sei whale was originally listed as endangered in 1970 (35 FR 18319), and this status remained since the inception of the ESA in 1973.

Ohsumi and Fukuda (1975) estimated that sei whales in the North Pacific numbered about 49,000 whales in 1963, had been reduced to 37,000 to 38,000 whales by 1967, and reduced again to 20,600 to 23,700 whales by 1973. From 1910 to 1975, approximately 74,215 sei whales were caught in the entire North Pacific Ocean (Horwood 1987a; Perry et al. 1999). From the early 1900s, Japanese whaling operations consisted of a large proportion of sei whales: 300 to 600 sei whales were killed per year from 1911 to 1955. The sei whale catch peaked in 1959, when 1,340 sei whales were killed. In 1971, after a decade of high sei whale catch numbers, sei whales were scarce in Japanese waters. Japanese and Soviet catches of sei whales in the North Pacific and Bering Sea increased from 260 whales in 1962 to over 4,500 in 1968 to 1969, after which the sei whale population declined rapidly (Mizroch et al. 1984b). This estimate does not account for over-reporting by Soviet whalers, who took approximately 3,700 fewer individuals than were reported (Ivashchenko et al. 2013). When commercial whaling for sei whales ended in 1974, the population in the North Pacific had been reduced to 7,260 to 12,620 animals (Tillman 1977). The most current population estimate for sei whales in the entire north Pacific is 9,110 (Calambokidis et al. 2008a) and 25,000 individuals worldwide (Braham 1991).

NMFS has designated three stocks of sei whale for management purposes under the MMPA in the north Pacific: (1) the Hawaii stock, (2) the California/Oregon/Washington stock, and (3) the Alaska stock (Carretta et al. 2011). Little is known about the stock structure of sei whales in the Action Area. Various scientists have described the seasonal distribution of sei whales as occurring from 20° N to 23° N during the winter and from 35° N to 50° N during the summer (Horwood 2009; Masaki 1976b; Masaki 1977b; Smultea et al. 2010). However, sei whales were sighted during the 2007 survey of the Action Area, thus providing evidence that this species

occurs south of 20°N in the winter (Fulling et al. 2011). Observations during the Navy-funded 2007 survey of the Action Area indicated this species most often occurs in deep water (10,381 to 30,583 ft. [3,164 to 9,322 m]). Most sei whale sightings were also associated with steep bathymetric relief (e.g., steeply sloping areas), including sightings adjacent to the Chamorro Seamounts east of the CNMI (Fulling et al. 2011). All confirmed sightings of sei whales were south of Saipan (approximately 15° N) with concentrations in the southeastern corner of the Action Area (Fulling et al. 2011). Sightings also often occurred in mixed groups with Bryde's whales. Sei whales were considered to be extralimital in the Action Area but during the 2007 systematic survey, sei whales were sighted on 16 occasions with a resulting abundance estimate of 166 individuals (CV = 0.49) (Fulling et al. 2011). No data on the current population trend are available; however, the population in the North Pacific is expected to have increased since sei whales began receiving protection in 1976 (Carretta et al. 2013a). A sei whale was also detected with sonobuoys on the January to February 2010 Oscar Elton Sette Cruise from Hawaii to Guam. However, the information we have did not allow us to determine if this detection occurred in the MITT Action Area. The Navy's NMSDD seasonally estimates between zero and 0.00029 sei whales per km^2 in the MITT Action Area (DoN 2014).

4.2.4.9 Natural Threats

Andrews (1916) suggested that killer whales attacked sei whales less frequently than fin and blue whales in the same areas. Sei whales engage in a flight responses to evade killer whales, which involves high energetic output, but show little resistance if overtaken (Ford and Reeves 2008). Endoparasitic helminths (worms) are commonly found in sei whales and can result in pathogenic effects when infestations occur in the liver and kidneys (Rice 1977).

4.2.4.10 Anthropogenic Threats

Human activities known to threaten sei whales include whaling, commercial fishing, and vessel strikes. Historically, whaling represented the greatest threat to every population of sei whales and was ultimately responsible for listing sei whales as an endangered species. Sei whales are thought to not be widely hunted, although harvest for scientific whaling or illegal harvesting may occur in some areas. In 2009, 100 sei whales were killed during western North Pacific surveys (Bando et al. 2010).

Sei whales are occasionally killed in collisions with vessels; however, there are no known Navy ship strikes in the area. Of three sei whales that stranded along the U.S. Atlantic coast during 1975 to 1996, two showed evidence of collisions (Laist et al. 2001). Between 1999 and 2005, there were three reports of sei whales being struck by vessels along the U.S. Atlantic coast and Canada's Maritime Provinces (Cole et al. 2005b; Nelson et al. 2007b). Two of these ship strikes were reported as having resulted in death. New rules for seasonal (June through December) slowing of vessel traffic in the Bay of Fundy to 10 knots and changing shipping lanes by less than one nautical mile to avoid the greatest concentrations of right whales are predicted to reduce sei whale ship strike mortality by 17 percent.

Sei whales are known to accumulate DDT, DDE, and PCBs (Borrell 1993; Borrell and Aguilar 1987; Henry and Best 1983). Males carry larger burdens than females, as gestation and lactation transfer these toxins from mother to offspring.

4.2.4.11 Critical Habitat
The NMFS has not designated critical habitat for sei whales.

4.2.5 Sperm Whale
Sperm whales (*Physeter macrocephalus*) are the largest of the odontocetes (toothed whales) and the most sexually dimorphic cetaceans, with males considerably larger than females. Adult females may grow to lengths of 36 feet (11 m) and weigh 15 tons (13,607 kg). Adult males, however, reach about 52 feet (16 m) and may weigh as much as 45 tons (40,823 kg).

The sperm whale is distinguished by its extremely large head, which takes up to 25 to 35 percent of its total body length. It is the only living cetacean that has a single blowhole asymmetrically situated on the left side of the head near the tip. Sperm whales have the largest brain of any animal (on average 17 pounds (7.8 kg) in mature males). However, compared to their large body size, the brain is not exceptional in size. Sperm whales are mostly dark gray, but oftentimes the interior of the mouth is bright white, and some whales have white patches on the belly. Their flippers are paddle-shaped and small compared to the size of the body, and their flukes are very triangular in shape. They have small dorsal fins that are low, thick, and usually rounded.

4.2.5.1 Distribution
Sperm whales are distributed in all of the world's oceans, from equatorial to polar waters, and are highly migratory. Mature males range between 70º N in the North Atlantic and 70º S in the Southern Ocean (Barlow et al. 1997b; Perry et al. 1999), whereas mature females and immature individuals of both sexes are seldom found higher than 50º N or S (Barlow et al. 1997b). In winter, sperm whales migrate closer to equatorial waters (Kasuya and Miyashita 1988; Waring 1993) where adult males join them to breed.

4.2.5.2 Population Structure
There is no clear understanding of the global population structure of sperm whales (Dufault et al. 1999). Recent ocean-wide genetic studies indicate low, but statistically significant, genetic diversity and no clear geographic structure, but strong differentiation between social groups (Lyrholm and Gyllensten 1998; Lyrholm et al. 1996; Lyrholm et al. 1999). Chemical analysis also suggest significant differences in diet for animals captured in different regions of the North Atlantic. However, vocal dialects indicate parent-offspring transmission that indicates differentiation in populations (Rendell et al. 2011). Vocal differences exist not only across ocean basins, but also over much smaller spatial scales (Amano et al. 2014). Therefore, population-level differences may be more extensive than are currently understood.

The IWC currently recognizes four sperm whale stocks: North Atlantic, North Pacific, northern Indian Ocean, and Southern Hemisphere (Dufault et al. 1999; Reeves and Whitehead 1997). The NMFS recognizes six stocks under the MMPA: three in the Atlantic/Gulf of Mexico and three in the Pacific (Alaska, California-Oregon-Washington, and Hawaii; (Perry et al. 1999; Waring et al. 2004a). Genetic studies indicate that movements of both sexes through expanses of ocean basins are common, and that males, but not females, often breed in different ocean basins than the ones in which they were born (Whitehead 2003). Sperm whale populations appear to be structured socially, at the level of the clan, rather than geographically (Whitehead 2003; Whitehead et al. 2008). Matrilinear groups in the eastern Pacific share nuclear DNA within broader clans, but North Atlantic matrilinear groups do not share this genetic heritage (Whitehead et al. 2012).

Sperm whales are found throughout the North Pacific and are distributed broadly in tropical and temperate waters to the Bering Sea as far north as Cape Navarin in summer, and occur south of 40° N in winter (Gosho et al. 1984; Miyashita et al. 1995 as cited in Carretta et al. 2005; Rice 1974b). Sperm whales are found year-round in Californian and Hawaiian waters (Barlow 1995a; Dohl et al. 1983; Forney et al. 1995a; Lee 1993; Mobley Jr . et al. 2000; Rice 1960; Shallenberger 1981), but they reach peak abundance from April through mid-June and from the end of August through mid-November (Rice 1974b). They are seen in every season except winter (December-February) off Washington and Oregon (Green et al. 1992). Summer/fall surveys in the eastern tropical Pacific (Wade and Gerrodette 1993) show that although sperm whales are widely distributed in the tropics, their relative abundance tapers off markedly towards the middle of the tropical Pacific and northward towards the tip of Baja California (Carretta et al. 2006). Sperm whales occupying the California Current region are genetically distinct from those in the eastern tropical Pacific and Hawaiian waters (Mesnick et al. 2011), although occurrence seems to be continuance from California through Hawaii (Barlow and Taylor 2005). The discreteness of the latter two areas remains uncertain (Mesnick et al. 2011).

In the Gulf of Alaska, sperm whales have been sighted along the Aleutian Trench as well as over deeper waters and have been detected acoustically throughout the year (Forney and Brownell Jr. 1996b; Mellinger et al. 2004). Occurrence is higher from July through September than January through March (Mellinger et al. 2004; Moore et al. 2006). The vast majority of individuals in the region are likely male based upon whaling records and genetic studies; the area is a summer foraging area for these individuals (Allen and Angliss 2010a; Reeves et al. 1985; Straley and O'Connell 2005; Straley et al. 2005). Mean group size has been reported to be 1.2 individuals (Wade et al. 2003; Waite 2003). However, female groups may rarely occur at least up to the central Aleutian Islands (Fearnbach et al. 2012).

4.2.5.3 Movement

Mature males range between 70º N in the North Atlantic and 70º S in the Southern Ocean (Perry et al. 1999; Reeves and Whitehead 1997), whereas mature females and immature individuals of both sexes are seldom found higher than 50º N or S (Reeves and Whitehead 1997). In winter, sperm whales migrate closer to equatorial waters (Kasuya and Miyashita 1988; Waring et al. 1993a) where adult males join them to breed. Movement patterns of Pacific female and immature male groups appear to follow prey distribution and, although not random, movements are difficult to anticipate and are likely associated with feeding success, perception of the environment, and memory of optimal foraging areas (Whitehead et al. 2008). However, no sperm whale in the Pacific has been known to travel to points over 5,000 km apart and only rarely have been known to move over 4,000 km within a time frame of several years. This means that although sperm whales do not appear to cross from eastern to western sides of the Pacific (or vice-versa), significant mixing occurs that can maintain genetic exchange. Movements of several hundred kilometers are common, (i.e. between the Galapagos Islands and the Pacific coastal Americas). Movements appear to be group or clan specific, with some groups traveling straighter courses than others over the course of several days. However, general transit speed averages about 4 km/h. Sperm whales in the Caribbean region appear to be much more restricted in their movements, with individuals repeatedly sighted within less than 160 km of previous sightings.

4.2.5.4 Habitat

Sperm whales have a strong preference for waters deeper than 1,000 m (Reeves and Whitehead 1997; Watkins 1977), although Berzin (1971a) reported that they are restricted to waters deeper than 300 m. While deep water is their typical habitat, sperm whales are rarely found in waters less than 300 m in depth (Clarke 1956b; Rice 1989c). Sperm whales have been observed near Long Island, New York, in water between 40 to 55 m deep (Scott and Sadove 1997b). When they are found relatively close to shore, sperm whales are usually associated with sharp increases in topography where upwelling occurs and biological production is high, implying the presence of a good food supply (Clarke 1956b). Such areas include oceanic islands and along the outer continental shelf.

Sperm whales are frequently found in locations of high productivity due to upwelling or steep underwater topography, such as continental slopes, seamounts, or canyon features (Jaquet and Whitehead 1996a; Jaquet et al. 1996). Cold-core eddy features are also attractive to sperm whales in the Gulf of Mexico, likely because of the large numbers of squid that are drawn to the high concentrations of plankton associated with these features (Biggs et al. 2000a; Davis et al. 2000c; Davis et al. 2000d; Davis et al. 2000e; Davis et al. 2002a; Wormuth et al. 2000). Surface waters with sharp horizontal thermal gradients, such as along the Gulf Stream in the Atlantic, may also be temporary feeding areas for sperm whales (Griffin 1999; Jaquet et al. 1996; Waring et al. 1993a). Sperm whales over George's Bank were associated with surface temperatures of 23.2 to 24.9° C (Waring et al. 2003).

Local information is inconsistent regarding some aspects of sperm whale habitat utilization. Gregr and Trites (2001a) reported that female sperm whales off British Columbia were relatively unaffected by the surrounding oceanography. However, Tynan et al. (2005a) reported increased sperm whales densities with strong turbulence-associated topographic features along the continental slope near Heceta Bank.

4.2.5.5 Reproduction

Female sperm whales become sexually mature at an average of 9 years or 8.25 to 8.8 m (Kasuya 1991). Males reach a length of 10 to 12 m at sexual maturity and take 9 to 20 years to become sexually mature, but require another 10 years to become large enough to successfully breed (Kasuya 1991; Würsig et al. 2000). Mean age at physical maturity is 45 years for males and 30 years for females (Waring et al. 2004a). Adult females give birth after roughly 15 months of gestation and nurse their calves for 2 to 3 years (Waring et al. 2004a). The calving interval is estimated to be every 4 to 6 years between the ages of 12 and 40 (Kasuya 1991; Whitehead et al. 2008). In the North Pacific, female sperm whales and their calves are usually found in tropical and temperate waters year round, while it is generally understood that males move north in the summer to feed in the Gulf of Alaska, Bering Sea, and waters off of the Aleutian Islands (Kasuya and Miyashita 1988). It has been suggested that some mature males may not migrate to breeding grounds annually during winter, and instead may remain in higher latitude feeding grounds for more than 1 year at a time (Whitehead and Arnbom 1987).

Sperm whale age distribution is unknown, but sperm whales are believed to live at least 60 years (Rice 1978b). Estimated annual mortality rates of sperm whales are thought to vary by age, but previous estimates of mortality rate for juveniles and adults are now considered unreliable (IWC

1980). In addition to anthropogenic threats, there is evidence that sperm whale age classes are subject to predation by killer whales (Arnbom et al. 1987; Pitman et al. 2001).

Stable, long-term associations among females form the core of sperm whale societies (Christal et al. 1998). Up to about a dozen females usually live in such groups, accompanied by their female and young male offspring. Young individuals are subject to alloparental care by members of either sex and may be suckled by non-maternal individuals (Gero et al. 2009). Group sizes may be smaller overall in the Caribbean Sea (6 to 12 individuals) versus the Pacific (25 to 30 individuals)(Jaquet and Gendron 2009). Groups may be stable for long periods, such as for 80 days in the Gulf of California (Jaquet and Gendron 2009). Males start leaving these family groups at about 6 years of age, after which they live in "bachelor schools," but this may occur more than a decade later (Pinela et al. 2009). The cohesion among males within a bachelor school declines with age. During their breeding prime and old age, male sperm whales are essentially solitary (Christal and Whitehead 1997).

4.2.5.6 Diving and Social Behavior

Sperm whales are probably the deepest and longest diving mammalian species, with dives to 3 km down and durations in excess of 2 hours (Clarke 1976; Watkins et al. 1993; Watkins et al. 1985a). However, dives are generally shorter (25 to 45 min) and shallower (400 to 1,000 m). Dives are separated by 8 to 11 min rests at the surface (Gordon 1987; Jochens et al. 2006; Papastavrou et al. 1989; Watwood et al. 2006; Würsig et al. 2000). Sperm whales typically travel approximately 3 km horizontally and 0.5 km vertically during a foraging dive (Whitehead 2003). Differences in night and day diving patterns are not known for this species, but, like most diving air-breathers for which there are data (rorquals, fur seals, and chinstrap penguins), sperm whales probably make relatively shallow dives at night when prey are closer to the surface.

Unlike other cetaceans, there is a preponderance of dive information for this species, most likely because it is the deepest diver of all cetacean species and therefore generates a lot of interest. Sperm whales feed on large and medium-sized squid, octopus, rays and sharks, on or near the ocean floor (Clarke 1986; Whitehead 2002b). Some evidence suggests that they do not always dive to the bottom of the sea floor (likely if food is elsewhere in the water column), but that they do generally feed at the bottom of the dive. Davis et al. (2007) report that dive-depths (100 to 500 m) of sperm whales in the Gulf of California overlapped with depth distributions (200 to 400 m) of jumbo squid, based on data from satellite-linked dive recorders placed on both species, particularly during daytime hours. Their research also showed that sperm whales foraged throughout a 24-hour period, and that they rarely dove to the sea floor bottom (>1000 m). The most consistent sperm whale dive type is U-shaped, during which the whale makes a rapid descent to the bottom of the dive, forages at various velocities while at depth (likely while chasing prey) and then ascends rapidly to the surface. There is some evidence that male sperm whales, feeding at higher latitudes during summer months, may forage at several depths including <200 m, and utilize different strategies depending on position in the water column (Teloni et al. 2007).

Movement patterns of Pacific female and immature male groups appear to follow prey distribution and, although not random, movements are difficult to anticipate and are likely associated with feeding success, perception of the environment, and memory of optimal foraging areas (Whitehead 2008). However, no sperm whale in the Pacific has been known to travel to

points over 5,000 km apart and only rarely have been known to move over 4,000 km within a time frame of several years. This means that although sperm whales do not appear to cross from eastern to western sides of the Pacific (or vice-versa), significant mixing occurs that can maintain genetic exchange. Movements of several hundred miles are common, (i.e. between the Galapagos Islands and the Pacific coastal Americas). Movements appear to be group or clan specific, with some groups traveling straighter courses than others over the course of several days. However, general transit speed averages about 4 km/h. Sperm whales in the Caribbean region appear to be much more restricted in their movements, with individuals repeatedly sighted within less than 160 km of previous sightings.

Gaskin (1973) proposed a northward population shift of sperm whales off New Zealand in the austral autumn based on reduction of available food species and probable temperature tolerances of calves.

Sperm whales have a strong preference for waters deeper than 1,000 m (Barlow et al. 1997b; Watkins and Schevill 1977), although Berzin (1971b) reported that they are restricted to waters deeper than 300 m. While deep water is their typical habitat, sperm whales are rarely found in waters less than 300 m in depth (Clarke 1956a; Rice 1989b). Sperm whales have been observed near Long Island, New York, in water between 40 and 55 m deep (Scott and Sadove 1997a).

Sperm whales are frequently found in locations of high productivity due to upwelling or steep underwater topography, such as continental slopes, seamounts, or canyon features (Jaquet 1996; Jaquet and Whitehead 1996b). Cold-core eddy features are also attractive to sperm whales in the Gulf of Mexico, likely because of the large numbers of squid that are drawn to the high concentrations of plankton associated with these features (Biggs et al. 2000b; Davis et al. 2000b; Davis et al. 2002b). Surface waters with sharp horizontal thermal gradients, such as along the Gulf Stream in the Atlantic, may also be temporary feeding areas for sperm whales (Griffin 1999; Jaquet and Whitehead 1996b; Waring et al. 1993b). Sperm whales over George's Bank were associated with surface temperatures of 23.2 to 24.9 °C (Waring et al. 2004b).

Local information is inconsistent regarding sperm whale tendencies. Gregr and Trites (2001b) reported that female sperm whales off British Columbia were relatively unaffected by the surrounding oceanography. However, Tynan et al. (2005b) reported increased sperm whales densities with strong turbulence associated topographic features along the continental slope near Heceta Bank. Two noteworthy strandings in the region include an infamous incident (well publicized by the media) of attempts to dispose of a decomposed sperm whale carcass on an Oregon beach by using explosives. In addition, a mass stranding of 47 individuals in Oregon occurred during June 1979 (Norman et al. 2004a; Rice et al. 1986).

4.2.5.7 Feeding

Sperm whales appear to feed regularly throughout the year (NMFS 2006d). It is estimated they consume about 3 to 3.5 percent of their body weight daily (Lockyer 1981). They seem to forage mainly on or near the bottom, often ingesting stones, sand, sponges, and other non-food items (Rice 1989c). A large proportion of a sperm whale's diet consists of low-fat, ammoniacal, or luminescent squids (Clarke 1996; Clarke 1980b; Martin and Clarke 1986). While sperm whales feed primarily on large and medium-sized squids, the list of documented food items is fairly long and diverse. Prey items include other cephalopods, such as octopi, and medium- and large-sized

demersal fishes, such as rays, sharks, and many teleosts (Angliss and Lodge 2004; Berzin 1972; Clarke 1977; Clarke 1980a; Rice 1989c). The diet of large males in some areas, especially in high northern latitudes, is dominated by fish (Rice 1989c). In some areas of the North Atlantic, however, males prey heavily on the oil-rich squid *Gonatus fabricii*, a species also frequently eaten by northern bottlenose whales (Clarke 1997).

4.2.5.8 Vocalization and Hearing

Sound production and reception by sperm whales are better understood than in most cetaceans. Sperm whales produce broad-band clicks in the frequency range of 100 Hz to 20 kHz that can be extremely loud for a biological source (200 to 236 dB re 1μPa), although lower source level energy has been suggested at around 171 dB re 1 μPa (Goold and Jones 1995; Møhl et al. 2003; Weilgart and Whitehead 1993a; Weilgart and Whitehead 1997b). Most of the energy in sperm whale clicks is concentrated at around 2 kHz to 4 kHz and 10 kHz to 16 kHz (Goold and Jones 1995; NMFS 2006d; Weilgart and Whitehead 1993a). The highly asymmetric head anatomy of sperm whales is likely an adaptation to produce the unique clicks recorded from these animals (Cranford 1992; Norris and Harvey 1972; Norris and Harvey. 1972). Long, repeated clicks are associated with feeding and echolocation (Goold and Jones 1995; Weilgart and Whitehead 1993a; Weilgart and Whitehead 1997b). However, clicks are also used in short patterns (codas) during social behavior and intragroup interactions (Weilgart and Whitehead 1993a). They may also aid in intra-specific communication. Another class of sound, “squeals”, are produced with frequencies of 100 Hz to 20 kHz (e.g., Weir et al. 2007).

Our understanding of sperm whale hearing stems largely from the sounds they produce. The only direct measurement of hearing was from a young stranded individual from which auditory evoked potentials were recorded (Carder and Ridgway 1990). From this whale, responses support a hearing range of 2.5 kHz to 60 kHz. However, behavioral responses of adult, free-ranging individuals also provide insight into hearing range; sperm whales have been observed to frequently stop echolocating in the presence of underwater pulses made by echosounders and submarine sonar (Watkins et al. 1985a; Watkins and Schevill 1975b). They also stop vocalizing for brief periods when codas are being produced by other individuals, perhaps because they can hear better when not vocalizing themselves (Goold and Jones 1995). Because they spend large amounts of time at depth and use low-frequency sound, sperm whales are likely to be susceptible to low frequency sound in the ocean (Croll et al. 1999b).

Recordings of sperm whale vocalizations reveal that they produce a variety of sounds, such as clicks, gunshots, chirrups, creaks, short trumpets, pips, squeals and clangs (Goold 1999b). Sperm whales typically produce short-duration repetitive broadband clicks with frequencies below 100 Hz to >30 kHz (Watkins 1977)and dominant frequencies between 1 kHz to 6 kHz and 10 kHz to 16 kHz. The source levels can reach 236 dB re 1 μPa-m (Mohl et al. 2003). The clicks of neonate sperm whales are very different from typical clicks of adults in that they are of low directionality, long duration, and low-frequency (between 300 Hz and 1.7 kHz) with estimated source levels between 140 to 162 dB re 1 μPa-m (Madsen et al. 2003). Clicks are heard most frequently when sperm whales are engaged in diving and foraging behavior (Miller et al. 2004; Whitehead and Weilgart 1991). Creaks (rapid sets of clicks) are heard most frequently when sperm whales are foraging and engaged in the deepest portion of their dives, with inter-click intervals and source levels being altered during these behaviors (Laplanche et al. 2005; Miller et al. 2004).

When sperm whales are socializing, they tend to repeat series of group-distinctive clicks (codas), which follow a precise rhythm and may last for hours (Watkins and Schevill 1977). Codas are shared between individuals in a social unit and are considered to be primarily for intragroup communication (Rendell and Whitehead 2004; Weilgart and Whitehead 1997a). Recent research in the South Pacific suggests that in breeding areas the majority of codas are produced by mature females (Marcoux et al. 2006). Coda repertoires have also been found to vary geographically and are categorized as dialects, similar to those of killer whales (Pavan et al. 2000; Weilgart and Whitehead 1997a). For example, significant differences in coda repertoire have been observed between sperm whales in the Caribbean and those in the Pacific (Weilgart and Whitehead 1997a). Three coda types used by male sperm whales have recently been described from data collected over multiple years: these include codas associated with dive cycles, socializing, and alarm (Frantzis and Alexiadou 2008).

Direct measures of sperm whale hearing have been conducted on a stranded neonate using the auditory brainstem response technique: the whale showed responses to pulses ranging from 2.5 kHz to 60 kHz and highest sensitivity to frequencies between 5 kHz to 20 kHz (Ridgway and Carder 2001). Other hearing information consists of indirect data. For example, the anatomy of the sperm whale's inner and middle ear indicates an ability to best hear high-frequency to ultrasonic hearing (Ketten 1992). The sperm whale may also possess better low-frequency hearing than other odontocetes, although not as low as many baleen whales (Ketten 1992). Reactions to anthropogenic sounds can provide indirect evidence of hearing capability, and several studies have made note of changes seen in sperm whale behavior in conjunction with these sounds. For example, sperm whales have been observed to frequently stop echolocating in the presence of underwater pulses made by echo-sounders and submarine sonar (Watkins et al. 1985b; Watkins and Schevill 1975a). In the Caribbean, Watkins et al. (1985b) observed that sperm whales exposed to 3.25 kHz to 8.4 kHz pulses (presumed to be from submarine sonar) interrupted their activities and left the area. Similar reactions were observed from artificial noise generated by banging on a boat hull (Watkins et al. 1985b). André et al. (1997)reported that foraging whales exposed to a 10 kHz pulsed signal did not ultimately exhibit any general avoidance reactions: when resting at the surface in a compact group, sperm whales initially reacted strongly, and then ignored the signal completely (André et al. 1997). Thode et al. (2007) observed that the acoustic signal from the cavitation of a fishing vessel's propeller (110 dB re 1 μPa^2 between 250 Hz and 1.0 kHz) interrupted sperm whale acoustic activity and resulted in the animals converging on the vessel. The full range of functional hearing for the sperm whale is estimated to occur between approximately 150 Hz and 160 kHz, placing them among the group of cetaceans that can hear mid-frequency sounds (Southall et al. 2007).

Sperm whales have been observed by marine mammal observers aboard Navy surface ships during training events and detected on the PMRF range hydrophones; however, MFAS was not active so no behavioral response data exists during naval training events. However, a sperm whale was tagged for a controlled exposure experiment during BRS-10. The sperm whale did not appear to demonstrate obvious behavioral changes in dive pattern or production of clicks (Miller et al. 2012; Sivle et al. 2012; Southall et al. 2011b).

4.2.5.9 Status and Trends

Sperm whales were originally listed as endangered in 1970 (35 FR 18319), and this status remained with the inception of the ESA in 1973. Although population structure of sperm whales

is unknown, several studies and estimates of abundance are available. Sperm whale populations probably are undergoing the dynamics of small population sizes, which is a threat in and of itself. In particular, the loss of sperm whales to directed Soviet whaling likely inhibits recovery due to the loss of adult females and their calves, leaving sizeable gaps in demographic and age structuring (Whitehead 2003).

The most comprehensive abundance estimate for sperm whales we are aware of is from Whitehead (2002a), who estimated that there are approximately 76,803 sperm whales in the eastern tropical Pacific, eastern North Pacific, Hawaii, and western North Pacific, and a worldwide population of 360,000 individuals. The tropical Pacific is home to approximately 26,053 sperm whales and the western North Pacific has approximately 29,674 (Whitehead 2002a). There was a dramatic decline in the number of females around the Galapagos Islands during 1985 to 1999 versus 1978 to 1992 levels, likely due to migration to nearshore waters of South and Central America (Whitehead and Mesnick 2003).

Sperm whales are sighted off Oregon in every season except winter (Green et al. 1992). However, sperm whales are found off California year-round (Barlow 1995a; Dohl et al. 1983; Forney et al. 1995a), with peak abundance from April to mid-June and from August to mid-November (Rice 1974b).

Hill and DeMaster (1999) concluded that about 258,000 sperm whales were harvested in the North Pacific between 1947-1987. This estimate does not account for under-reporting by Soviet whalers, who took approximately 31,000 more individuals than were reported (Ivashchenko et al. 2013). Although the IWC protected sperm whales from commercial harvest in 1981, Japanese whalers continued to hunt sperm whales in the North Pacific until 1988 (Reeves and Whitehead 1997). In 2000, the Japanese Whaling Association announced plans to kill 10 sperm whales in the Pacific Ocean for research. Although consequences of these deaths are unclear, the paucity of population data, uncertainly regarding recovery from whaling, and re-establishment of active programs for whale harvesting pose risks for the recovery and survival of this species. Sperm whales are also hunted for subsistence purposes by whalers from Lamalera, Indonesia, where a traditional whaling industry has been reported to kill up to 56 sperm whales per year.

NMFS has designated three stocks of sperm whale for management purposes under the MMPA in the north Pacific: (1) the Hawaii stock, (2) the California/Oregon/Washington stock, and (3) the Alaska stock (Carretta et al. 2013a). Little is known about the stock structure of sperm whales in the Action Area.

Preliminary results of a coda review (Norris et al. 2012) “provide new insights into the sperm whale social units occurring within this region of the western Pacific Ocean.” The presence of the 'short' and 'regular' vocal clans identified from the acoustic encounters in this dataset can be used as putative indicators of sperm whale stock structure for this region (Marcoux et al. 2006). The vocal repertoires identified in the review may provide information on the occurrence of vocal clans in the western Pacific Ocean. The vocal repertoires identified (Norris et al. 2012) suggest a potential cultural and acoustic link to vocal clans found in the eastern tropical Pacific Ocean and greatly extends the known range for the 'regular' and 'short' vocal clans. Whaling records demonstrate sightings year-round in the Action Area (Townsend 1935). There are also at least four stranding records for this area spanning the period from 1962 to 2013 (Eldredge 1991; Eldredge 2003; Kami and Lujan 1976; Kerrigan 2013). During the Navy-funded survey in 2007,

there were multiple sightings that included young calves and large bulls (Fulling et al. 2011). These findings are consistent with an earlier sighting of a group of sperm whales that included a newborn calf off the west coast of Guam (Eldredge 2003). During the 2007 survey, sperm whales were observed in waters 2,670 to 32,584 ft. (809–9,874 m) deep (Fulling et al. 2011). During a small boat survey around Guam and Saipan in February and early March of 2010, there were two sperm whale sightings: (1) a group of nine animals off Orote Point, Guam, inshore from the 1,640 ft. (500 m) isobath; and (2) a group of six animals northwest of Saipan in waters greater than 3,281 ft. (1,000 m) deep (Ligon et al. 2011). A group of 10 sperm whales was also sighted during small boat surveys off western Guam in waters approximately 3,940 ft. deep (1,200 m) in March 2012 (HDR 2012a).

The sperm whale was the most frequently sighted cetacean (21 sightings) during the 2007 survey with acoustic detections almost three times higher (61) than visual detections in the field (Fulling et al. 2011). Post processing of the acoustic data resulted in 91 distinct localizations of individual sperm whales. Based on a preliminary analysis, the distribution of sperm whales appeared to be clustered in three main regions of MIRC, the northeast, central, and southwest portions, with a few others in the trench and offshore regions (Norris et al. 2012). Line-transect abundance estimates derived from these survey data yielded an estimate of 705 (CV = 0.60) sperm whales in the Action Area (Fulling et al. 2011). The Navy's NMSDD estimates 0.00291 sperm whales per km^2 in the MITT Action Area (DoN 2014).

The sperm whale was the most frequently sighted cetacean (21 sightings) during the 2007 survey with acoustic detections almost three times higher (61) than visual detections in the field (Fulling et al. 2011). Post processing of the acoustic data resulted in 91 distinct localizations of individual sperm whales. The Navy's NMSDD estimates 0.00291 sperm whales per km^2 in the MITT Action Area (DoN 2014).

4.2.5.10 Natural Threats

Sperm whales are known to be occasionally predated upon by killer whales (Jefferson and Baird 1991; Pitman et al. 2001) and large sharks (Best et al. 1984) and harassed by pilot whales (Arnbom et al. 1987; Palacios and Mate 1996; Rice 1989d; Weller et al. 1996; Whitehead 1995). Strandings are also relatively common events, with one to dozens of individuals generally beaching themselves and dying during any single event. Although several hypotheses, such as navigation errors, illness, and anthropogenic stressors, have been proposed (Goold et al. 2002; Wright 2005), direct widespread causes of strandings remain unclear. Calcivirus and papillomavirus are known pathogens of this species (Lambertsen et al. 1987; Smith and Latham 1978).

4.2.5.11 Anthropogenic Threats

Sperm whales historically faced severe depletion from commercial whaling operations. From 1800 to 1900, the IWC estimated that nearly 250,000 sperm whales were killed by whalers, with another 700,000 from 1910 to 1982 (IWC Statistics 1959 to 1983). However, other estimates have included 436,000 individuals killed between 1800 and 1987 (Carretta et al. 2005).

However, all of these estimates are likely underestimates due to illegal and inaccurate killings by Soviet whaling fleets between 1947–1973. In the Southern Hemisphere, these whalers killed an estimated 100,000 whales that they did not report to the IWC (Yablokov et al. 1998), with smaller harvests in the Northern Hemisphere, primarily the North Pacific, that extirpated sperm whales from large areas (Yablokov and Zemsky 2000). Additionally, Soviet whalers disproportionately killed adult females in any reproductive condition (pregnant or lactating) as well as immature sperm whales of either gender.

Following a moratorium on whaling by the IWC, significant whaling pressures on sperm whales were eliminated. However, sperm whales are known to have become entangled in commercial fishing gear and 17 individuals are known to have been struck by vessels (Jensen and Silber 2004). Japan maintains an active whaling fleet, killing up to 10 sperm whales annually (IWC 2008). In 2009, one sperm whale was killed during western North Pacific surveys (Bando et al. 2010).

Whale-watching vessels are known to influence sperm whale behavior (Richter et al. 2006).

In U.S. waters in the Pacific Ocean, sperm whales are known to have been incidentally captured only in drift gillnet operations, which killed or seriously injured an average of nine sperm whales per year from 1991 to 1995 (Barlow et al. 1997b). Interactions between longline fisheries and sperm whales in the Gulf of Alaska have been reported over the past decade (Hill and Demaster 1998b; Rice 1989a). Observers aboard Alaskan sablefish and halibut longline vessels have documented sperm whales feeding on fish caught in longline gear in the Gulf of Alaska. During 1997, the first entanglement of a sperm whale in Alaska's longline fishery was recorded, although the animal was not seriously injured (Hill and Demaster 1998b). The available evidence does not indicate sperm whales are being killed or seriously injured as a result of these interactions, although the nature and extent of interactions between sperm whales and long-line gear is not yet clear. An individual was caught and released from gillnetting, although injured, on Georges Bank during 1990. A second individual was freed, but injured, from gillnetting on George's Bank in 1995. In 1994, a sperm whale was disentangled from gillnet along the coast of Maine. In August 1993, a dead sperm whale, with longline gear wound tightly around the jaw, was found floating ~32 km off Maine. Ten sperm whale entanglements have been observed in U.S. fisheries since 1990 in the Pacific (Carretta and Enriquez 2012). Two additional whales have been found to die from ingestion of fishing gear (Jacobsen et al. 2010b). Overall, it is estimated that 3.8 sperm whales die annually along the U.S. west coast due to fisheries interaction (Carretta et al. 2013b).

Contaminants have been identified in sperm whales, but vary widely in concentration based upon life history and geographic location, with northern hemisphere individuals generally carrying higher burdens (Evans et al. 2004). Contaminants include dieldrin, chlordane, DDT, DDE, PCBs, HCB and HCHs in a variety of body tissues (Aguilar 1983; Evans et al. 2004), as well as several heavy metals (Law et al. 1996). However, unlike other marine mammals, females appear to bioaccumulate toxins at greater levels than males, which may be related to possible dietary differences between females who remain at relatively low latitudes compared to more migratory males (Aguilar 1983; Wise et al. 2009). Chromium levels from sperm whales skin samples worldwide have varied from undetectable to 122.6 μg Cr/g tissue, with the mean (8.8 μg Cr/g

tissue) resembling levels found in human lung tissue with chromium-induced cancer (Wise et al. 2009). Older or larger individuals do not appear to accumulate chromium at higher levels.

Small changes in reproductive parameters, such as the loss of adult females, can significantly alter the population trajectory of sperm whale populations (Chiquet et al. 2013).

Ingestion of marine debris can have fatal consequences even for large whales. In 1989, a stranded sperm whale along the Mediterranean was found to have died from ingesting plastic that blocked its' digestive tract (Viale et al. 1992). A sperm whale examined in Iceland had a lethal disease thought to have been caused by the complete obstruction of the gut with plastic marine debris (Lambertsen 1990). The stomach contents of two sperm whales that stranded separately in California included extensive amounts of discarded fishing netting (NMFS 2009b). A fifth individual from the Pacific was found to contain nylon netting in its stomach when it washed ashore in 2004 (NMFS 2009b). In March 2012, a sperm whale stranded dead, apparently dying as a result of plastic ingestion (de Stephanis et al. 2013).

There have not been any recent documented ship strikes involving sperm whales in the eastern North Pacific, although there are a few records of ship strikes in the 1990s. Two whales described as "possibly sperm whales" are known to have died in U.S. Pacific waters in 1990 after being struck by vessels (Barlow et al. 1997a). There is an anecdotal record from 1997 of a fishing vessel that struck a sperm whale in southern Prince William Sound in Alaska, although the whale did not appear to be injured (Laist et al. 2001). More recently in the Pacific, two sperm whales were struck by a ship in 2005, but it is not known if these ship strikes resulted in injury or mortality (NMFS 2009a). The lack of recent evidence should not lead to the assumption that no mortality or injury from collisions with vessels occurs as carcasses that do not drift ashore may go unreported, and those that do strand may show no obvious signs of having been struck by a ship (NMFS 2009a). Worldwide, sperm whales are known to have been struck 17 times out of a total record of 292 strikes of all large whales, 13 of which resulted in mortality (Jensen and Silber 2003a; Laist et al. 2001). Given the current number of reported cases of injury and mortality, it does not appear that ship strikes are a significant threat to sperm whales (Whitehead 2003).

4.2.5.12 Critical Habitat

The NMFS has not designated critical habitat for sperm whales.

4.2.6 Green Sea Turtle

Green sea turtles (*Chelonia mydas*) are the largest of all the hard-shelled sea turtles, but have a comparatively small head. While hatchlings are just 2 inches (50 mm) long, adults can grow to more than 3 feet (0.91 m) long and weigh 300 to 350 pounds (136 to 159 kg).

Adult green turtles are unique among sea turtles in that they are herbivorous, feeding primarily on sea grasses and algae. This diet is thought to give them greenish colored fat, from which they take their name. A green turtle's carapace (top shell) is smooth and can be shades of black, gray, green, brown, and yellow. Their plastron (bottom shell) is yellowish white.

Scientists estimate green turtles reach sexual maturity anywhere between 20 and 50 years, at which time females begin returning to their natal beaches (i.e., the same beaches where they were born) every two to four years to lay eggs.

4.2.6.1 Populations

The population dynamics of green turtles and all of the other sea turtles we consider in this Opinion are usually described based on the distribution and habit of nesting females, rather than their male counterparts. The spatial structure of male sea turtles and their fidelity to specific coastal areas is unknown; however, we describe sea turtle populations based on the nesting beaches that female sea turtles return to when they mature. Because the patterns of increase or decrease in the abundance of sea turtle nests over time are determined by internal dynamics rather than external dynamics, we make inferences about the growth or decline of sea turtle populations based on the status and trend of their nests.

Primary nesting aggregations of green turtles (i.e. sites with greater than 500 nesting females per year) include: Ascension Island (south Atlantic Ocean), Australia, Brazil, Comoros Islands, Costa Rica, Ecuador (Galapagos Archipelago), Equatorial Guinea (Bioko Island), Guinea-Gissau (Bijagos Archipelago), Iles Eparses Islands (Tromelin Island, Europa Island), Indonesia, Malaysia, Myanmar, Oman, Philippines, Saudi Arabia, Seychelles Islands, Suriname, and United States (Florida; NMFS and USFWS 1998d; Seminoff et al. 2002a).

Smaller nesting aggregations include: Angola, Bangladesh, Bikar Atoll, Brazil, Chagos Archipelago, China, Costa Rica, Cuba, Cyprus, Democratic Republic of Yemen, Dominican Republic, d'Entrecasteaux Reef, French Guiana, Ghana, Guyana, India, Iran, Japan, Kenya, Madagascar, Maldives Islands, Mayotte Archipelago, Mexico, Micronesia, Pakistan, Palmerston Atoll, Papua New Guinea, Primieras Islands, Sao Tome é Principe, Sierra Leone, Solomon Islands, Somalia, Sri Lanka, Taiwan, Tanzania, Thailand, Turkey, Scilly Atoll, United States (Hawaii), Venezuela, and Vietnam.

Molecular genetic techniques have helped researchers gain insight into the distribution and ecology of migrating and nesting green turtles. In the Pacific Ocean, green turtles group into two distinct regional clades: (1) western Pacific and South Pacific islands, and (2) eastern Pacific and central Pacific, including the rookery at French Frigate Shoals, Hawaii. On March 23, 2015 NMFS publishged a proposed rule to list 11 DPSs of green sea turtles (80 FR 15271). The green sea turtles in the Action Area would occur in the endangered Central West Pacific DPS if the rule is finalized as it is currently written. The Central West Pacific DPS would be part of the western Pacific and South Pacific islands regional clade.

4.2.6.2 Distribution

Green turtles are found in the Pacific Ocean, Atlantic Ocean, Indian Ocean, Carribean Sea, and Mediterranean Sea, primarily in tropical or, to a lesser extent, subtropical waters. These regions can be further divided into nesting aggregations within the eastern, central, and western Pacific Ocean; the western, northern, and eastern Indian Ocean; Mediterranean Sea; and eastern, southern, and western Atlantic Ocean, including the Carribean Sea.

Green turtles appear to prefer waters that usually remain around 20 °C in the coldest month. During warm spells (e.g., El Niño), green turtles may be found considerably north of their normal distribution. Stinson (1984a) found green turtles to appear most frequently in U.S. coastal waters with temperatures exceeding 18 °C. Further, green turtles seem to occur preferentially in drift lines or surface current convergences, probably because of the prevalence of cover and higher densities of their food items associated with these oceanic phenomena. Underwater

resting sites include coral recesses, the underside of ledges, and sand bottom areas that are relatively free of strong currents and disturbance from natural predators and humans. Available information indicates that green turtle resting areas are in proximity to their feeding areas (NMFS and USFWS 1998b).

4.2.6.3 Migration and Movement

Green sea turtles are highly mobile and undertake complex movements through geographically disparate habitats during their lifetimes (Musick and Limpus 1997b; Plotkin 2003). The periodic migration between nesting sites and foraging areas by adults is a prominent feature of their life history. After departing as hatchlings and residing in a variety of marine habitats for 40 or more years (Limpus and Chaloupka 1997), green sea turtles make their way back to the same beach from which they hatched (Carr et al. 1978; Meylan et al. 1990). At approximately 20 to 25 cm carapace length, juveniles leave pelagic habitats and enter benthic foraging areas (Bjorndal 1997a). Green sea turtles spend the majority of their lives in coastal foraging grounds (MacDonald et al. 2012). These areas include both open coastline and protected bays and lagoons. While in these areas, green sea turtles rely on marine algae and seagrass as their primary dietary constituents, although some populations also forage heavily on invertebrates. Although green sea turtles in tropical areas seem to undergo a sudden, permanent switch in habitat from oceanic to neritic habitats, individuals in more temperate areas seem to utilize a wider array of habitats dependent upon oceanographic conditions (González Carman et al. 2012). There is some evidence that individuals move from shallow seagrass beds during the day to deeper areas at night (Hazel 2009). However, avoidance of areas of greater than 10 m when moderate depths of 5 to 10 m with sea grass beds has been found, with speed and displacement from capture locations being similar at night as during the daytime (Senko et al. 2010a). East Pacific adults migrate along coastal corridors between Central American nesting and foraging locations (Blanco et al. 2012).

4.2.6.4 Habitat

Green turtles appear to prefer waters that usually remain around 20º C in the coldest month, but may occur considerably north of these regions during warm-water events, such as El Niño. Stinson (1984c) found green turtles to appear most frequently in U.S. coastal waters with temperatures exceeding 18º C. Further, green sea turtles seem to occur preferentially in drift lines or surface current convergences, probably because of the prevalence of cover and higher prey densities that associate with flotsam. For example, in the western Atlantic Ocean, drift lines commonly containing floating *Sargassum* spp. are capable of providing juveniles with shelter (NMFS and USFWS 1998c). Underwater resting sites include coral recesses, the underside of ledges, and sand bottom areas that are relatively free of strong currents and disturbance. Available information indicates that green turtle resting areas are near feeding areas (Bjorndal and Bolten 2000). Strong site fidelity appears to be a characteristic of juveniles green sea turtles along the Pacific Baja coast (Senko et al. 2010b). Recent tagging data from off the northwestern coast of Saipan and the western coast of Tinian also indicate strong site fidelity (Jones and Van Houtan 2014).

4.2.6.5 Growth and Reproduction

Most green sea turtles exhibit particularly slow growth rates, which have been attributed to their largely plant-eating diet (Bjorndal 1982). Growth rates of juveniles vary substantially among populations, ranging from <1 cm/year (Green 1993) to >5 cm/year (McDonald Dutton and

Dutton 1998), likely due to differences in diet quality, duration of foraging season (Chaloupka et al. 2004b), and density of turtles in foraging areas (Balazs and Chaloupka 2004; Bjorndal et al. 2000a; Seminoff et al. 2002b). Hart et al. (2013a) found growth rates of green sea turtles in the U.S. Virgin Islands to range from 0 to 9.5 cm annually (mean of 4.1, SD 2.4). The largest growth rates were in the 30 to 39 cm class. If individuals do not feed sufficiently, growth is stunted and apparently does not compensate even when greater-than-needed resources are available (Roark et al. 2009). In general, there is a tendency for green sea turtles to exhibit monotonic growth (declining growth rate with size) in the Atlantic and non-monotonic growth (growth spurt in mid-size classes) in the Pacific, although this is not always the case (Balazs and Chaloupka 2004; Chaloupka and Musick 1997; Seminoff et al. 2002b). It is estimated that green sea turtles reach a maximum size just under 100 cm in carapace length (Tanaka 2009). A female-bias has been identified from studies of green sea turtles (Wibbels 2003).

Consistent with slow growth, age-to-maturity for green sea turtles appears to be the longest of any sea turtle species and ranges from ~20 to 40 years or more (Balazs 1982; Chaloupka et al. 2004b; Chaloupka and Musick 1997; Frazer and Ehrhart 1985b; Hirth 1997; Limpus and Chaloupka 1997; Seminoff et al. 2002b; Zug et al. 2002; Zug and Glor 1998). Estimates of reproductive longevity range from 17 to 23 years (Carr et al. 1978; Chaloupka et al. 2004b; Fitzsimmons et al. 1995). Considering that mean duration between females returning to nest ranges from 2 to 5 years (Hirth 1997), these reproductive longevity estimates suggest that a female may nest 3 to 11 seasons over the course of her life. Each female deposits 1 to 7 clutches (usually 2 to 3) during the breeding season at 12 to 14 day intervals. Mean clutch size is highly variable among populations, but averages 110 to 115 eggs/nest. Females usually have 2 to 4 or more years between breeding seasons, whereas males may mate every year (Balazs 1983). Based on reasonable means of three nests per season and 100 eggs per nest (Hirth 1997), a female may deposit 9 to 33 clutches, or about 900 to 3,300 eggs, during her lifetime. Nesting sites appear to be related to beaches with relatively high exposure to wind or wind-generated waves (Santana Garcon et al. 2010).

Once hatched, sea turtles emerge and orient towards a light source, such as light shining off the ocean. They enter the sea in a “frenzy” of swimming activity, which decreases rapidly in the first few hours and gradually over the first several weeks (Ischer et al. 2009; Okuyama et al. 2009). Factors in the ocean environment have a major influence on reproduction (Chaloupka 2001; Limpus and Nicholls 1988; Solow et al. 2002). It is also apparent that during years of heavy nesting activity, density dependent factors (beach crowding and digging up of eggs by nesting females) may impact hatchling production (Tiwari et al. 2005; Tiwari et al. 2006). Precipitation, proximity to the high tide line, and nest depth can also significantly affect nesting success (Cheng et al. 2009). Precipitation can also be significant in sex determination, with greater nest moisture resulting in a higher proportion of males (Leblanc and Wibbels 2009). Green sea turtles often return to the same foraging areas following nesting migrations (Broderick et al. 2006; Godley et al. 2002). Once there, they move within specific areas, or home ranges, where they routinely visit specific localities to forage and rest (Godley et al. 2003; Makowski et al. 2006; Seminoff and Jones 2006; Seminoff et al. 2002a; Taquet et al. 2006). It is also apparent that some green sea turtles remain in pelagic habitats for extended periods, perhaps never recruiting to coastal foraging sites (Pelletier et al. 2003).

In general, survivorship tends to be lower for juveniles and subadults than for adults. Adult survivorship has been calculated to range from 0.82 to 0.97 versus 0.58 to 0.89 for juveniles (Chaloupka and Limpus 2005; Seminoff et al. 2003; Troëng and Chaloupka 2007), with lower values coinciding with areas of human impact on green sea turtles and their habitats (Bjorndal et al. 2003; Campbell and Lagueux 2005).

4.2.6.6 Feeding

While offshore and sometimes in coastal habitats, green sea turtles are not obligate plant-eaters as widely believed, and instead consume invertebrates such as jellyfish, sponges, sea pens, and pelagic prey (Godley et al. 1998; Hart et al. 2013b; Hatase et al. 2006b; Heithaus et al. 2002; Parker and Balazs in press; Seminoff et al. 2002a). A shift to a more herbivorous diet occurs when individuals move into neritic habitats, as vegetable mater replaces an omnivorous diet at around 59 cm in carapace length off Mauritania (Cardona et al. 2009). This transition may occur rapidly starting at 30 cm carapace length, but animal prey continue to constitute an important nutritional component until individuals reach about 62 cm (Cardona et al. 2010). Foraging within seagrass ecosystems by green sea turtles can be significant enough to alter habitat and ecological parameters, such as species composition (Lal et al. 2010). Although populations can consume a variety of prey and be considered generalists as a whole, individuals maintain a highly-selective diet over long time frames (Vander Zanden et al. 2013).

4.2.6.7 Diving

Based on the behavior of post-hatchlings and juvenile green turtles raised in captivity, we presume that those in pelagic habitats live and feed at or near the ocean surface, and that their dives do not normally exceed several meters in depth (Hazel et al. 2009; NMFS and USFWS 1998c). Recent data from Australia indicate green sea turtles rarely dive deep, staying in upper 8 m of the water column (Hazel et al. 2009). Daytime dives were shorter and shallower than were nighttime dives (Ballorain et al. 2013; Hazel et al. 2009). Green turtles migrating between the northwestern and main Hawaiian Islands reached a maximum depth greater than 445 ft. (135.6 m) at night (the deepest dives ever recorded for a green turtle) with a mean maximum night dive depth of 115 to 164 ft. (35–50 m) but only 14.1 ft. (4.3 m) during the day (Rice and Balazs 2008b). In their coastal habitat, green turtles typically make dives shallower than 100 ft. (30.5 m) (Hatase et al. 2006a; Hays et al. 2000; Hochscheid et al. 2005; Houghton et al. 2002) and often do not exceed 55 ft. (16.8 m) (Hays et al. 2000; Rice and Balazs 2008a), although they are known to feed and rest at depths of 65 to 165 ft. (19.8–50.3 m) (Balazs 1980; Brill et al. 1995b). Also, time spent resting and dive duration increased significantly with decreases in seasonal water temperatures. Subadults routinely dive to 20 m for 9 to 23 min, with a maximum recorded dive of over 1 h (Brill et al. 1995a; I-Jiunn 2009). Green sea turtles along Taiwan may rest during long, shallow dives (I-Jiunn 2009). Dives by females may be shorter in the period leading up to nesting (I-Jiunn 2009).

4.2.6.8 Vocalization and Hearing

Sea turtles are low-frequency hearing specialists, typically hearing frequencies from 30 Hz to 2,000 Hz, with a range of maximum sensitivity between 100 Hz and 800 Hz (Bartol et al. 1999c; Lenhardt 1994b; Lenhardt 2002; Moein Bartol and Ketten 2006; Ridgway et al. 1969). Piniak et al. (2012) found green sea turtle juveniles capable of hearing underwater sounds at frequencies of 50 Hz to 1,600 Hz (maximum sensitivity at 200 to 400 Hz). Hearing below 80 Hz is less sensitive but still possible (Lenhardt 1994b). Based upon auditory brainstem responses green sea

turtles have been measured to hear in the 50 Hz to 1,600 Hz range (Dow et al. 2008), with greatest response at 300 Hz (Yudhana et al. 2010); a value verified by Moein Bartol and Ketten (2006). Other studies have found greatest sensitivities are 200 to 400 Hz for the green turtle with a range of 100 Hz to 500 Hz (Moein Bartol and Ketten 2006; Ridgway et al. 1969) and around 250 Hz or below for juveniles (Bartol et al. 1999c). However, Dow et al. (2008) found best sensitivity between 50 Hz and 400 Hz.

These hearing sensitivities are similar to those reported for two terrestrial species: pond and wood turtles. Pond turtles respond best to sounds between 200 Hz and 700 Hz, with slow declines below 100 Hz and rapid declines above 700 Hz, and almost no sensitivity above 3,000 Hz (Wever and Vernon 1956). Wood turtles are sensitive up to about 500 Hz, followed by a rapid decline above 1,000 Hz and almost no responses beyond 3,000 or 4,000 Hz (Patterson 1966).

4.2.6.9 Status and Trends

Green turtles are listed as threatened under the ESA (including those within the MITT Action Area), except for breeding populations found in Florida and the Pacific coast of Mexico, which are listed as endangered.

On March 23, 2015 NMFS published a proposed rule to list 11 DPSs of green sea turtles (80 FR 15271). The green sea turtles in the Action Area would occur in the endangered Central West Pacific DPS if the rule is finalized as it is currently written. Green turtle nesting occurs at low levels throughout the geographic distribution of the DPS (approximately 51 sites), with isolated locations having higher nesting activity. Only two populations are known to have >1,000 nesting turtles, with all the rest having fewer than 400 nesting females, for a total number of known nesting females of approximately 6,500 (80 FR 15271). There is insufficient long-term and standardized monitoring information to adequately describe abundance and population trends for many areas of the Central West Pacific DPS. The available information suggests a nesting population decrease in some portions of the DPS like the Marshall Islands, or unknown trends in other areas such as Palau, Papua New Guinea, the Marianas, Solomon Islands, or the FSM (Maison et al. 2010).

Using a precautionary approach, Seminoff (2002) estimates that the global green turtle population has declined by 34 percent to 58 percent over the last three generations (approximately 150 years). Causes for this decline include harvest of eggs, subadults, and adults; incidental capture by fisheries; loss of habitat; and disease.

Based on the mean annual reproductive effort, 108,761 to 150,521 females nest each year among 46 worldwide nesting sites. Overall, of the 26 sites for which data enable an assessment of current trends, 12 nesting populations are increasing, 10 are stable, and four are decreasing. Long-term continuous datasets of 20 years are available for 11 sites, all of which are either increasing or stable. Despite the apparent global increase in numbers, the positive overall trend should be viewed cautiously because trend data are available for just over half of all sites examined and very few data sets span a full green sea turtle generation (Seminoff 2004).

Green turtles are thought to be declining throughout the Pacific Ocean, with the exception of Hawaii, from a combination of overexploitation and habitat loss (Eckert 1993a; Seminoff et al.

2002a). In the western Pacific, the only major (>2,000 nesting females) populations of green turtles occur in Australia and Malaysia, with smaller colonies throughout the area. Indonesian nesting is widely distributed, but has experienced large declines over the past 50 years. Hawaii green turtles are genetically distinct and geographically isolated, and the population appears to be increasing in size despite the prevalence of fibropapillomatosis and spirochidiasis (Aguirre et al. 1998).

The East Island nesting beach in Hawaii is showing a 5.7 percent annual growth rate over >25 years (Chaloupka et al. 2008a). In the Eastern Pacific, mitochondrial DNA analysis has indicated three key nesting populations: Michoacán, Mexico; Galapagos Islands, Ecuador; and Islas Revillagigedos, Mexico (Dutton 2003). The number of nesting females per year exceeds 1,000 females at each site (NMFS and USFWS 2007a). However, historically, >20,000 females per year are believed to have nested in Michoacán alone (Clifton et al. 1982; NMFS and USFWS 2007a). Thus, the current number of nesting females is still far below historical levels. Datasets over 25 years in Chichi-jima, Japan; Heron Island, Australia; and Raine Island, Australia, show increases in abundance (Chaloupka et al. 2008a).

Historically, the Philippines (Turtle Islands) and Turtle Islands Park of Sabah, Malaysia, are two of the most important insular nesting colonies in Southeast Asia (Seminoff et al. 2004). There is evidence to suggest that green turtle populations nesting in Sabah are stable or increasing, with trends from 1993 to 2001 showing a continued upward trend (Bastinal 2002; Seminoff et al. 2004). Nesting in the Philippines has declined over time, although there are over 3,000 nesting females per year (Seminoff et al. 2004). Additionally, there appears to be a robust green turtle nesting population in Yap State, Federated States of Micronesia, with a total of 888 individual nesting green turtles tagged on Gielop Island between 2005 and 2007 (Maison et al. 2010). It is important to note, however, that increases in population abundance at individual nesting sites do not necessarily reflect population-level increases in abundance.

Green turtles have been documented nesting on many beaches in Guam and the surrounding islands (e.g., FWS BO of military buildup; (Brindock 2013)), though long-term information regarding nesting population trends in in the area are not available. There is, however, indication that the Marianas may provide more important foraging nearshore habitat than nesting (Kolinski et al. 2001; Pultz et al. 1999). Aerial surveys conducted by the Guam Division of Aquatic and Wildlife Resources indicate the year-round presence of green sea turtles in Guam's nearshore waters (Kolinski et al. 2001; NMFS and USFWS 1998c; Pultz et al. 1999). Aggregations of foraging and resting green turtles are often seen in close proximity to Guam's well-developed seagrass beds and reef flats, which are found in Cocos Lagoon, Apra Harbor, along Tarague Beach and Hila'an; in deeper waters south of Falcona Beach; and at several other locations throughout the island's shelf (DON 2003b). Guam Division of Aquatic and Wildlife Resources aerial surveys have identified turtles within Agat Bay, and stranded sea turtles have been recovered from the bay (including one with spear gun injuries). In August 2013, PIFSC researchers conducted snorkeling and boat surveys in Guam's Cocos Lagoon and observed 9 green turtles over the two days of surveys. All individuals observed were juveniles (Jones and Houtan 2014).

On Tinian, green turtle abundance and densities are highest along the island's relatively uninhabited east coast. The most recent estimate of the number of green turtles inhabiting the

nearshore waters around Tinian was 832 turtles in 2001 (Kolinski et al. 2006) and densities of approximately 11.8 animals per km^2. Between November 2013 and March 2014 the CNMI Department of Lands and Natural Resources captured 54 unique green sea turtles (and 3 recaptures), 44 around Saipan and 10 around Tinian. Catch per unit effort for all sea turtles was 3.75 turtle catches per dive-hour (Palacios et al. 2014). In August 2013, a PIFSC researcher conducted snorkeling and boat surveys off the northwestern coast of Saipan and the western coast of Tinian. The team captured four sub-adult green turtles over a four day period (Jones and Houtan 2014).

Green turtles are not as abundant at FDM as they are at some of the larger islands of the Marianas chain. At FDM, at least 9 green turtles were observed during underwater surveys in both 1999 and 2000, at least 12 green turtles were observed during surveys in 2001, and 4 were observed at the northern end of the island in 2003 (DoN 2005a). Annual diver surveys between 2005 and 2012 observed between three (2005) and nine (2009) green sea turtles at FDM (DoN 2013a). Most green turtles at FDM were found either swimming over the reef platform or resting in holes or caves (DoN 2005a) . Due to strong current and tidal conditions, the beaches at FDM are very susceptible to inundation and are highly unsuitable for nesting (DoN 2003a). Also, seagrasses and benthic algae are relatively sparse around the island and can probably support no more than a few green turtles at a time (NMFS and USFWS 1998c). Seven sea turtles were documented in 2006 and 19 in 2007 during monthly monitoring (helicopter surveys) of FDM (DoN 2010c). Monthly observations are usually low (between one and three turtle sightings); however, 12 turtles were observed in waters off FDM on 13 November 2007 (DoN 2010c). Identifying sea turtles to the species level is not possible due to safe flying heights of the helicopter, although due to the higher abundance of green sea turtles relative to hawksbill turtles, the majority of sea turtle observations are assumed to be green sea turtles (DoN 2010c).

Based on the above information, green turtles are expected to occur year round in all shelf waters of the Action Area from FDM to Guam. Around the larger islands, green turtle occurrence is concentrated in waters less than 328 ft. (100.01 m) deep, approximately 11.8 animals per km^2 (4.6 $mi.^2$). It is at these water depths where green turtle foraging and resting habitats (e.g., fringing reefs, reef flats, and seagrass beds) are usually found. Although there may not be long-term data available for Guam or CNMI, data from other Pacific regions show that green sea turtles exhibit strong site fidelity to nearshore foraging habitats for extended periods of time (Balazs 1995; Balazs and Chaloupka 2004). The Navy's NMSDD estimates 0.2968, 11.8, and 0.000391 green sea turtles per km^2 in the nearshore Guam, nearshore Tinian and other islands, and pelagic portions of the MITT Action Area, respectively (DoN 2014). Nesting females and early juveniles are known to move through oceanic waters of the Marianas chain during their reproductive and developmental migrations (Kolinski et al. 2006), but likely do not do so in large numbers.

4.2.6.10 Natural Threats

Herons, gulls, dogfish, and sharks prey upon hatchlings. Adults face predation primarily by sharks and to a lesser extent by killer whales. All sea turtles except leatherbacks can undergo "cold stunning" if water temperatures drop below a threshold level, which can be lethal. For unknown reasons, the frequency of a disease called fibropapillomatosis is much higher in green sea turtles than in other species and threatens a large number of existing subpopulations. Extremely high incidence has been reported in Hawaii, where affliction rates peaked at 47–69

percent in some foraging areas (Murakawa et al. 2000). A to-date unidentified virus may aid in the development of fibropapillomatosis (Work et al. 2009). Predators (primarily of eggs and hatchlings) also include dogs, pigs, rats, crabs, sea birds, reef fishes, and groupers (Bell et al. 1994; Witzell 1981). Green sea turtles with an abundance of barnacles have been found to have a much greater probability of having health issues (Flint et al. 2009). The fungal pathogens *Fusarium falciforme* and *F. keratoplasticum* an kill in excess of 90 percent of sea turtle embryos they infect and may constitute a major threat to nesting productivity under some conditions (Sarmiento-Ramırez et al. 2014).

4.2.6.11 Anthropogenic Threats

Major anthropogenic impacts to the nesting and marine environment affect green sea turtle survival and recovery (Patino-Martinez 2013). At nesting beaches, green sea turtles rely on intact dune structures, native vegetation, and normal beach temperatures for nesting (Ackerman 1997). Structural impacts to nesting habitat include the construction of buildings and pilings, beach armoring and renourishment, and sand extraction (Bouchard et al. 1998; Lutcavage et al. 1997). These factors may directly, through loss of beach habitat, or indirectly, through changing thermal profiles and increasing erosion, serve to decrease the amount of nesting area available to nesting females, and may evoke a change in the natural behaviors of adults and hatchlings (Ackerman 1997; Witherington et al. 2003; Witherington et al. 2007). On the Pacific coast of Mexico in the mid-1970s, >70,000 green turtle eggs were harvested every night. Hundreds of mostly immature green sea turtles were killed between 2006 and 2008 due to bycatch and direct harvest along Baja California Sur (Senko et al. 2014). The presence of lights on or adjacent to nesting beaches alters the behavior of nesting adults (Witherington 1992) and is often fatal to emerging hatchlings as they are attracted to light sources and drawn away from the water (Witherington and Bjorndal 1991b). In addition to impacting the terrestrial zone, anthropogenic disturbances also threaten coastal marine habitats, particularly areas rich in seagrass and marine algae. These impacts include contamination from herbicides, pesticides, oil spills, and other chemicals, as well as structural degradation from excessive boat anchoring and dredging (Francour et al. 1999; Lee Long et al. 2000; Waycott et al. 2005). Ingestion of plastic and other marine debris is another source of morbidity and mortality (Stamper et al. 2009). Green sea turtles stranded in Brazil were all found to have ingested plastics or fishing debris (n = 34), although mortality appears to have resulted in three cases (Tourinho et al. 2009). Low-level bycatch has also been documented in longline fisheries (Petersen et al. 2009). Further, the introduction of alien algae species threatens the stability of some coastal ecosystems and may lead to the elimination of preferred dietary species of green sea turtles (De Weede 1996). Very few green sea turtles are bycaught in U.S. fisheries (Finkbeiner et al. 2011). However, a legal fishery operates in Madagascar that harvested about 10,000 green turtles annually in the mid-1990s. Green sea turtles are killed because they are seen as competitors for fishery resources in parts of India (Arthur et al. 2013). Between 1991 and 2011, an average of 8,169 green sea turtles were harvested annually along the Caribbean coast of Nicaragua (over 171,000 over this period); a rate that has been in decline potentially due to population depletion (Lagueux et al. 2014).

Sea level rise may have significant impacts upon green turtle nesting on Pacific atolls. These low-lying, isolated locations could be inundated by rising water levels associated with global warming, eliminating nesting habitat (Baker et al. 2006; Fuentes et al. 2010). Fuentes et al. (2010) predicted that rising temperatures would be a much greater threat in the long term to the hatching success of sea turtle turtles in general and green sea turtles along northeastern Australia

particularly. Green sea turtles emerging from nests at cooler temperatures likely absorb more yolk that is converted to body tissue than do hatchlings from warmer nests (Ischer et al. 2009). Predicted temperature rises may approach or exceed the upper thermal tolerance limit of sea turtle incubation, causing widespread failure of nests (Fuentes et al. 2010). Although the timing of loggerhead nesting depends upon sea-surface temperature, green sea turtles do not appear to be affected (Pike 2009).

Green sea turtles have been found to contain the organochlorines chlordane, lindane, endrin, endosulfan, dieldrin, DDT and PCB (Gardner et al. 2003; Miao et al. 2001). Levels of PCBs found in eggs are considered far higher than what is fit for human consumption (Van de Merwe et al. 2009). The heavy metals copper, lead, manganese, cadmium, and nickel have also been found in various tissues and life stages (Barbieri 2009). Arsenic also occurs in very high levels in green sea turtle eggs (Van de Merwe et al. 2009). These contaminants have the potential to cause deficiencies in endocrine, developmental, and reproductive health, and depress immune function in loggerhead sea turtles (Keller et al. 2006a; Storelli et al. 2007b). Exposure to sewage effluent may also result in green sea turtle eggs harboring antibiotic-resistant strains of bacteria (Al-Bahry et al. 2009). DDE has not been found to influence sex determination at levels below cytotoxicity (Keller and McClellan-Green 2004; Podreka et al. 1998). To date, no tie has been found between pesticide concentration and susceptibility to fibropapillomatosis, although degraded habitat and pollution have been tied to the incidence of the disease (Aguirre et al. 1994; Foley et al. 2005). Flame retardants have been measured from healthy individuals (Hermanussen et al. 2008). It has been theorized that exposure to tumor-promoting compounds produced by the cyanobacteria *Lyngbya majuscule* could promote the development of fibropapillomatosis (Arthur et al. 2008). It has also been theorized that dinoflagellates of the genus *Prorocentrum* that produce the tumorogenic compound okadoic acid may influence the development of fibropapillomatosis (Landsberg et al. 1999).

The primary, human-related threats to green turtles in Guam and the CNMI include direct harvesting of sea turtles and eggs as well as habitat loss due to rapidly expanding tourism, including increased coastal development on nesting beaches (NMFS and USFWS 1998c). The impacts of vessel strikes in the Central West Pacific are unknown, but not thought to be of great consequence, except possibly in Palau where high speed skiffs constantly travel throughout the lagoon south of the main islands (NMFS and USFWS 1998c). However, green turtles have been documented as occasionally being hit by boats in Guam and CNMI (e.g., unpublished data from Tammy Mae Summers; personal communication; April 7, 2015).

4.2.6.12 Critical Habitat

On September 2, 1998, critical habitat for green sea turtles was designated in coastal waters surrounding Culebra Island, Puerto Rico (63 FR 46693). Aspects of these areas that are important for green sea turtle survival and recovery include important natal development habitat, refuge from predation, shelter between foraging periods, and food for green sea turtle prey. No critical habitat is designated within the MITT Action Area for this species.

4.2.7 Hawksbill Sea Turtle

The hawksbill turtle (*Eretmochelys imbricata*) is a small to medium-sized sea turtle; adults typically range between 65 and 90 cm (26 to 35 in) in carapace length and weigh around 80 kg (176 lb) (Witzell 1983). Hawksbills are distinguished from other sea turtles by their hawk-like

beaks, posteriorly overlapping carapace scutes, and two pairs of claws on their flippers (NMFS and USFWS 1993). The carapace of this species is often brown or amber with irregularly radiating streaks of yellow, orange, black, and reddish-brown.

4.2.7.1 Populations

Hawksbill sea turtles, like other sea turtles, are divided into regional groupings that represent major oceans or seas: the Atlantic Ocean, Pacific Ocean, Indian Ocean, Caribbean Sea and Mediterranean Sea. In these regions, the population structure of hawksbill turtles are usually based on the distribution of their nesting aggregations.

4.2.7.2 Distribution

Hawksbill sea turtles occur in tropical and subtropical seas of the Atlantic, Pacific and Indian Oceans. Hawksbill sea turtles occupy different habitats depending on their life history stage. After entering the sea, hawksbill turtles occupy pelagic waters and occupy weed-lines that accumulate at convergence points. When they grow to about 20 to 25 cm carapace length, hawksbill turtles re-enter coastal waters where they inhabit and forage in coral reefs as juveniles, sub-adults and adults. Hawksbill sea turtles also occur around rocky outcrops and high energy shoals, where sponges grow and provide forage, and they are known to inhabit mangrove-fringed bays and estuaries, particularly along the eastern shore of continents where coral reefs are absent.

Hawksbills are considered the most coastal of the sea turtles that inhabit the Action Area, with juveniles and adults preferring coral reef habitats (NMFS 2013). Reefs provide shelter for resting hawksbills day and night, and they are known to visit the same resting spot repeatedly. Hawksbills are also found around rocky outcrops and high-energy shoals—optimum sites for sponge growth—as well as in mangrove-lined bays and estuaries (NMFS and USFWS 2013).

Hatchling and early juvenile hawksbills have also been found in the open ocean, in floating mats of seaweed (Musick and Limpus 1997a). Although information about foraging areas is largely unavailable due to research limitations, juvenile and adult hawksbills may also be present in open ocean environments (NMFS and USFWS 2007a). Hawksbills were once thought to be a nonmigratory species because of the proximity of suitable nesting beaches to coral reef feeding habitats and the high rates of marked turtles recaptured in these areas; however, tagging studies have shown otherwise. For example, a post-nesting female traveled 995 miles (1,601 km) from the Solomon Islands to Papua New Guinea (Meylan 1995), indicating that adult hawksbills can migrate distances comparable to those of green and loggerhead turtles.

4.2.7.3 Migration and Movement

Upon first entering the sea, neonatal hawksbills in the Caribbean are believed to enter an oceanic phase that may involve long distance travel and eventual recruitment to nearshore foraging habitat (Boulon Jr. 1994). In the marine environment, the oceanic phase of juveniles (i.e., the "lost years") remains one of the most poorly understood aspects of hawksbill life history, both in terms of where turtles occur and how long they remain oceanic. Nesting site selection in the southwest Pacific appears to favor sites with higher wind and wave exposure, possibly as a means to aid hatchling dispersal (Garcon et al. 2010). Adults along the Pacific coast of Central America exhibit highly restrictive, inshore ranges between foraging and nesting locations, most of which was mangrove estuaries (Gaos et al. 2012a). Subadult hawksbill sea turtles captured satellite tracked in the Dry Tortugas National Park showed high-degrees of site fidelity for

extended periods, although all three eventually moved to other areas outside the park (Hart et al. 2012). The same trend was found for adults tracked after nesting in the Dominican Republic, with some remaining for extended periods in the nesting area and other migrating to Honduras and Nicaragua (Hawkes et al. 2012). Satellite tracking for these individuals showed repeated returns to the same Dominican and Central American areas (Hawkes et al. 2012). Hawksbills dispersing from nesting areas along Brazil moved along coastal areas until they reached foraging areas (Marcovaldi et al. 2012). Here, genetically-identified hawksbill-loggerhead hybrids dispersed more broadly than pure-bred hawksbills (Marcovaldi et al. 2012). Home ranges tend to be small (a few square kilometers)(Berube et al. 2012). Recent tagging data from off the coast of Tinian, indicated that one subadult hawksbill remained in the area in which it was tagged for 51 days following capture, and then traveled 286 km, eventually taking up residency in the deeper waters outside of Cocos Lagoon, Guam (Jones and Houtan 2014).

4.2.7.4 Habitat

Hawksbill sea turtles are highly migratory and use a wide range of broadly separated localities and habitats during their lifetimes (Musick and Limpus 1997b; Plotkin 2003). Small juvenile hawksbills (5 to 21 cm straight carapace length) have been found in association with *Sargassum* spp. in both the Atlantic and Pacific oceans (Musick and Limpus 1997b) and observations of newly hatched hawksbills attracted to floating weeds have been made (Hornell 1927; Mellgren and Mann 1996; Mellgren et al. 1994). Post-oceanic hawksbills may occupy a range of habitats that include coral reefs or other hard-bottom habitats, sea grass, algal beds, mangrove bays and creeks (Bjorndal and Bolten 2010; Musick and Limpus 1997b), and mud flats (R. von Brandis, unpublished data in NMFS and USFWS 2007d). Eastern Pacific adult females have recently been tracked in saltwater mangrove forests along El Salvador and Honduras, a habitat that this species was not previously known to occupy (Gaos et al. 2011). Individuals of multiple breeding locations can occupy the same foraging habitat (Bass 1999; Bowen et al. 1996; Bowen et al. 2007; Diaz-Fernandez et al. 1999; Velez-Zuazo et al. 2008). As larger juveniles, some individuals may associate with the same feeding locality for more than a decade, while others apparently migrate from one site to another (Blumenthal et al. 2009a; Mortimer et al. 2003; Musick and Limpus 1997b). Larger individuals may prefer deeper habitats than their smaller counterparts (Blumenthal et al. 2009a). Nesting sites appear to be related to beaches with relatively high exposure to wind or wind-generated waves (Santana Garcon et al. 2010).

4.2.7.5 Growth and Reproduction

The best estimate of age at sexual maturity for hawksbill sea turtles is 20 to 40 years (Chaloupka and Limpus 1997; Crouse 1999). Reproductive females undertake periodic (usually non-annual) migrations to their natal beaches to nest. Movements of reproductive males are less well known, but are presumed to involve migrations to their nesting beach or to courtship stations along the migratory corridor (Meylan 1999). Females nest an average of 3 to 5 times per season (Meylan and Donnelly 1999; Richardson et al. 1999). Clutch size can be up to 250 eggs; larger than that of other sea turtles (Hirth 1980). Reproductive females may exhibit a high degree of fidelity to their nest sites.

The life history of hawksbills consists of a pelagic stage that lasts from hatching until they are approximately 22 to 25 cm in straight carapace length (Meylan 1988; Meylan and Donnelly 1999), followed by residency in coastal developmental habitats. Growth accelerates early on until turtles reach 65 to 70 cm in curved carapace length, after which it slows to negligible

amounts after 80 cm (Bell and Pike 2012). As with other sea turtles, growth is variable and likely depends upon nutrition available (Bell and Pike 2012). Juvenile hawksbills along the British Virgin Islands grow at a relatively rapid rate of roughly 9.3 cm per year and gain 3.9 kg annually (Hawkes et al. 2014).

4.2.7.6 Feeding

Dietary data from oceanic stage hawksbills are limited, but indicate a combination of plant and animal material (Bjorndal 1997b). Sponges and octocorals are common prey off Honduras (Berube et al. 2012; Hart et al. 2013b).

4.2.7.7 Diving

Hawksbill diving ability varies with age and body size. As individuals increase with age, diving ability in terms of duration and depth increases (Blumenthal et al. 2009b). Studies of hawksbills in the Caribbean have found diurnal diving behavior, with dive duration nearly twice as long during nighttime (35 to 47 min) compared to daytime (19-26 min Blumenthal et al. 2009b; Van Dam and Diez 1997). Daytime dives averaged 5 m, while nighttime dives averaged 43 m (Blumenthal et al. 2009b). However, nocturnal differences were not observed in the eastern Pacific (Gaos et al. 2012b).

Hawksbills have long dive durations, although dive depths are not particularly deep. Adult females along St. Croix reportedly have average dive times of 56 min, with a maximum time of 73.5 min (Starbird et al. 1999). Average day and night dive times were 34 to 65 and 42 to 74 min, respectively. Immature individuals have much shorter dives of 8.6 to 14 min to a mean depth of 4.7 m while foraging (Van Dam and Diez 1997).

4.2.7.8 Vocalization and Hearing

Sea turtles are low-frequency hearing specialists, typically hearing frequencies from 30 Hz to 2,000 Hz, with a range of maximum sensitivity between 100 Hz and 800 Hz (Bartol et al. 1999c; Lenhardt 1994b; Lenhardt 2002; Moein Bartol and Ketten 2006; Ridgway et al. 1969). Piniak et al. (2012) found hawksbill hatchlings capable of hearing underwater sounds at frequencies of between 50 and 1,600 Hz (maximum sensitivity at 200 to 400 Hz). Hearing below 80 Hz is less sensitive but still possible (Lenhardt 1994b).

4.2.7.9 Status and Trends

Hawksbill turtles were listed as endangered throughout their range under the ESA in 1970. Under the Convention on International Trade in Endangered Species of Wild Fauna and Flora, hawksbill turtles are identified as "critically endangered" (IUCN 2010).

The Hawksbill Sea Turtle (*Eretmochelys imbricata*) 5-year Review: Summary and Evaluation (NMFS and USFWS 2013) assessed nesting abundance and nesting trends in all regions that the hawksbill turtles inhabit. Where possible, historical population trends were determined, and most showed declines for the 20 to 100 year period of evaluation. Recent trends for 42 of the sites indicated that 69 percent were decreasing, seven percent were stable, and that 24 percent were increasing. Seven of the 83 sites occur in the central Pacific Ocean and one occurs in the eastern Pacific Ocean (Baja California, Mexico), all with decreasing long-term population trends; only the Hawaii site has a recent increasing trend. Although no historical records of abundance are known, hawksbill sea turtles are considered to be severely depleted due to the fragmentation and

low use of current nesting beaches (NMFS and USFWS 2007d). Worldwide, an estimated 21,212 to 28,138 hawksbills nest each year among 83 sites. Among the 58 sites with historic trends, all show a decline during the past 20 to 100 years.

American Samoa and Western Samoa host fewer than 30 females annually (Grant et al. 1997; Tuato'o-Bartley et al. 1993). In Guam, only 5 to 10 females are estimated to nest annually (G. Balazs, NMFS, in litt. to J. Mortimer 2007; G. Davis, NMFS, in litt. to J. Mortimer 2007) and the same is true for Hawaii, but there are indications that this population is increasing (G. Balazs, pers. comm. in NMFS and USFWS 2007d). Additional populations are known from the eastern Pacific (potentially extending from Mexico through Panama), northeastern Australia, and Malaysia (Hutchinson and Dutton 2007). El Salvador is now known to host the majority of hawksbill turtle nesting activity in the eastern Pacific, with 79.6 percent (n = 5430) of all nesting observation records, and Mexico hosting the majority of records of hawksbill turtles at sea, with 60.3 percent (n = 544) of all in-water observation records (Gaos et al. 2010). Total number of nesting females for the Central Pacific hawksbill population was estimated at 940 to 1,200 females annually for the last few years, with an overall downward trend (NMFS and USFWS 2007b). In August 2013, a PIFSC researcher and his crew captured two sub-adult hawksbills over a four days survey period off the northwestern coast of Saipan and the western coast of Tinian (Jones and Houtan 2014). Between November 2013 and March 2014 the CNMI Department of Lands and Natural Resources captured three hawksbill sea turtles, two around Tinian and one around Saipan (Palacios et al. 2014). The Navy's NMSDD estimates 1.0734, 0.1342, and 0.000024 hawksbill sea turtles per km^2 in the nearshore FDM, nearshore other islands, and pelagic portions of the MITT Action Area, respectively (DoN 2014).

4.2.7.10 Natural Threats

Sea turtles face predation primarily by sharks and to a lesser extent by killer whales. All sea turtles except leatherbacks can undergo "cold stunning" if water temperatures drop below a threshold level, which can be lethal. The only other significant natural threat to hawksbill sea turtles is from hybridization of hawksbills with other species of sea turtles. This is especially problematic at certain sites where hawksbill numbers are particularly low (Mortimer and Donnelly in review). Predators (primarily of eggs and hatchlings) include dogs, pigs, rats, crabs, sea birds, reef fishes, groupers, feral cats, and foxes (Bell et al. 1994; Ficetola 2008). In some areas, nesting beaches can be almost completely destroyed and all nests can sustain some level of depredation (Ficetola 2008). The fungal pathogens *Fusarium falciforme* and *F. keratoplasticum* an kill in excess of 90 percent of sea turtle embryos they infect and may constitute a major threat to nesting productivity under some conditions (Sarmiento-Ramırez et al. 2014).

4.2.7.11 Anthropogenic Threats

Threats to hawksbill sea turtles are largely anthropogenic, both historically and currently. Impacts to nesting beaches include the construction of buildings and pilings, beach armoring and renourishment, and sand extraction (Bouchard et al. 1998; Lutcavage et al. 1997). Because hawksbills prefer to nest under vegetation (Horrocks and Scott 1991; Mortimer 1982), they are particularly impacted by beachfront development and clearing of dune vegetation (Mortimer and Donnelly in review). The presence of lights on or adjacent to nesting beaches alters the behavior of nesting adults (Witherington 1992) and is often fatal to emerging hatchlings as they are attracted to light sources and drawn away from the water (Witherington and Bjorndal 1991b).

One of the most detrimental human threats to hawksbill sea turtles is the intensive harvest of eggs from nesting beaches. Between 1950 and 1992, approximately 1.3 million hawksbill shells were collected to supply tortoiseshell to the Japanese market, the world's largest. Before the U.S. certified Japan under the Pelly Amendment, Japan had been importing about 20 metric tons of hawksbill shell per year, representing approximately 19,000 turtles. Japan stopped importing tortoiseshell in 1993 in order to comply with CITES (Limpus and Miller 2008). Until recently, tens of thousands of hawksbills were captured and killed each year to meet demand for jewelry, ornamentation, and whole stuffed turtles (Eckert 1993c). In 1988, Japan's imports from Jamaica, Haiti and Cuba represented some 13,383 hawksbills: it is extremely unlikely that this volume could have originated solely from local waters (Eckert 1993c). Large numbers of nesting and foraging hawksbill sea turtles are captured and killed for trade in Micronesia, the Mexican Pacific coast, southeast Asia and Indonesia (NMFS and USFWS 1998e).

In addition to impacting the terrestrial zone, anthropogenic disturbances also threaten coastal marine habitats. These impacts include contamination from herbicides, pesticides, oil spills, and other chemicals, as well as structural degradation from excessive boat anchoring and dredging (Francour et al. 1999; Lee Long et al. 2000; Waycott et al. 2005). Hawksbills are typically associated with coral reefs, which are among the world's most endangered marine ecosystems (Wilkinson 2000). Although primarily spongivorous, bycatch of hawksbill sea turtles in the swordfish fishery off South Africa occurs (Petersen et al. 2009). Finkbeiner et al. (2011) estimated that annual bycatch interactions total at least 20 individuals annually for U.S. Atlantic fisheries (resulting in less than ten mortalities) and no or very few interactions in U.S. Pacific fisheries.

Future impacts from climate change and global warming may result in significant changes in hatchling sex ratios. The fact that hawksbill turtles exhibit temperature-dependent sex determination (Wibbels 2003) suggests that there may be a skewing of future hawksbill cohorts toward strong female bias (since warmer temperatures produce more female embryos).

4.2.7.12 Critical Habitat

On September 2, 1998, the NMFS established critical habitat for hawksbill sea turtles around Mona and Monito Islands, Puerto Rico (63 FR 46693). Aspects of these areas that are important for hawksbill sea turtle survival and recovery include important natal development habitat, refuge from predation, shelter between foraging periods, and food for hawksbill sea turtle prey. No critical habitat is designated within the MITT Action Area for this species.

4.2.8 Leatherback Sea Turtle

The leatherback turtle (*Dermochelys coriacea*) is the largest turtle and the largest living reptile in the world. Mature males and females can be as long as six and a half feet (2 m) and weigh almost 2000 lbs. (900 kg). The leatherback is the only sea turtle that lacks a hard, bony shell. A leatherback's carapace is approximately 1.5 inches (4 cm) thick and consists of leathery, oil saturated connective tissue overlaying loosely interlocking dermal bones. The carapace has seven longitudinal ridges and tapers to a blunt point. Adult leatherbacks are primarily black with a pinkish white mottled ventral surface and pale white and pink spotting on the top of the head. The front flippers lack claws and scales and are proportionally longer than in other sea turtles; back flippers are paddle-shaped. The ridged carapace and large flippers are characteristics that make the leatherback uniquely equipped for long distance foraging migrations.

Female leatherbacks lay clutches of approximately 100 eggs on sandy, tropical beaches. Females nest several times during a nesting season, typically at 8 to 12 day intervals. After 60 to 65 days, leatherback hatchlings with white striping along the ridges of their backs and on the margins of the flippers emerge from the nest. Leatherback hatchlings are approximately 50 to 77 cm (2 to 3 inches) in length, with fore flippers as long as their bodies, and weigh approximately 40 to 50 grams (1.4 to 1.8 ounces).

Leatherbacks lack the crushing chewing plates characteristic of sea turtles that feed on hard-bodied prey (Pritchard 1971a) Instead, they have pointed tooth-like cusps and sharp edged jaws that are perfectly adapted for a diet of soft-bodied pelagic (open ocean) prey, such as jellyfish and salps.

4.2.8.1 Populations

Leatherbacks break into four nesting aggregations: Pacific, Atlantic, and Indian oceans, and the Caribbean Sea. Detailed population structure is unknown, but is likely dependent upon nesting beach location.

Leatherbacks are found from tropical waters north to Alaska within the North Pacific and is the most common sea turtle in the eastern Pacific north of Mexico (Eckert 1993b; Stinson 1984b; Wing and Hodge 2002). The west coast of Central America and Mexico hosts nesting from September-March, although Costa Rican nesting peaks during April-May (Chacón-Chaverri and Eckert 2007; LGL Ltd. 2007). Leatherback sea turtles disappeared from India before 1930, have been virtually extinct in Sri Lanka since 1994, and appear to be approaching extinction in Malaysia (Spotila et al. 2000). In Fiji, Thailand, and Australia, leatherback sea turtles have only been known to nest in low densities and scattered sites. Leatherback nesting aggregations occur widely in the Pacific, including China, Malaysia, Papua New Guinea, Indonesia, Thailand, Australia, Fiji, the Solomon Islands, and Central America (Dutton et al. 2007; Limpus 2002). Significant nesting also occurs along the Central American coast (Márquez 1990). Although not generally known to nest on Japanese shores, two nests were identified in the central Ryukyu Islands in 2002 (Kamezaki et al. 2002a).

Nesting beaches also occur in Mexico and Costa Rica (nesting occurs October through March) are a separate population from the western Pacific beaches (Benson et al. 2007a; summary in NMFS and USFWS 2007d; Spotila 2004b). In Costa Rica, leatherbacks nest at Playa Naranjo in Santa Rosa National Park, the second-most important nesting beach on the Pacific coast (Yañez et al. 2010), Rio Oro on the Osa Peninsula, and at various beaches in Las Baulas National Park, which includes Playa Langosta and Playa Grande and contains the largest colony of leatherbacks in the Pacific (Spotila 2004b). Females typically lay six clutches per season (average nine days between nests), which incubate for 58–65 days (Lux et al. 2003). Limited nesting also occurs along Nicaragua, Panama, El Salvador, Vanuatu, and Guatemala.

In the Pacific Ocean, genetic studies have identified three distinct populations (referred to also as genetic stocks or Management Units; see (Wallace et al. 2010a)) of leatherback turtles: (1) Mexico and Costa Rica, which are genetically homogenous but distinct from the western populations; (2) Papua Barat in Indonesia, Papua New Guinea, Solomon Islands, and Vanuatu, which comprise a metapopulation representing a single genetic stock; and (3) Malaysia (Barragan and Dutton 2000; Dutton et al. 1999; Dutton 2005-2006; Dutton et al. 2000b; Dutton

et al. 2006; Dutton 2007). The genetically distinct Malaysia nesting population likely is extirpated (Chan and Liew 1996a; Dutton et al. 1999; Dutton 2005-2006).

4.2.8.2 Distribution

Leatherback turtles are widely distributed throughout the oceans of the world. The species is found in four main regions of the world: the Pacific, Atlantic, and Indian Oceans, and the Caribbean Sea. Leatherbacks also occur in the Mediterranean Sea, although they are not known to nest there. The four main regional areas may further be divided into nesting aggregations. Leatherback turtles are found on the western and eastern coasts of the Pacific Ocean, with nesting aggregations in Mexico and Costa Rica (eastern Pacific) and Malaysia, Indonesia, Australia, the Solomon Islands, Papua New Guinea, Thailand, and Fiji (western Pacific). In the Atlantic Ocean, leatherback nesting aggregations have been documented in Gabon, Sao Tome and Principe, French Guiana, Suriname, and Florida. In the Caribbean, leatherbacks nest in the U.S. Virgin Islands and Puerto Rico. In the Indian Ocean, leatherback nesting aggregations are reported in India and Sri Lanka and KwaZulu Natal, South Africa.

Leatherback turtles are highly migratory, exploiting convergence zones and upwelling areas in the open ocean, along continental margins, and in archipelagic waters (Eckert and Eckert 1988; Eckert 1999b; Morreale et al. 1994b). In a single year, a leatherback may swim more than 10,000 kilometers (Eckert 1998b). In the North Atlantic Ocean, leatherback turtles regularly occur in deep waters (>328 ft), and an aerial survey study in the north Atlantic sighted leatherback turtles in water depths ranging from 3 to 13,618 ft, with a median sighting depth of 131.6 ft (CETAP 1982). This same study found leatherbacks in waters ranging from 7 to 27.2 °C. In the Pacific Ocean, leatherback turtles have the most extensive range of any living reptile and have been reported in all pelagic waters of the Pacific between 71° N and 47° S latitude and in all other major pelagic ocean habitats (NMFS and USFWS 1998a). Leatherback turtles lead a completely pelagic existence, foraging widely in temperate waters except during the nesting season, when gravid females return to tropical beaches to lay eggs. Males are rarely observed near nesting areas, and it has been hypothesized that leatherback turtles probably mate outside of tropical waters, before females swim to their nesting beaches (Eckert and Eckert 1988).

Few quantitative data are available concerning the seasonality, abundance, or distribution of leatherbacks in the central northern Pacific Ocean. Satellite tracking studies and occasional incidental captures of the species in the Hawaii-based longline fishery indicate that deep ocean waters are the preferred habitats of leatherback turtles in the central Pacific Ocean (NMFS and USFWS 2007c). The primary migration corridors for leatherbacks are across the North Pacific Subtropical Gyre, with the eastward migration route possibly to the north of the westward migration.

The primary data available for leatherbacks in the North Pacific Transition Zone come from longline fishing bycatch reports, as well as several satellite telemetry data sets (Benson et al. 2007b). Leatherbacks from both eastern and western Pacific Ocean nesting populations migrate to northern Pacific Ocean foraging grounds, where longline fisheries operate (Dutton et al. 1998a). Leatherbacks from nesting beaches in the Indo-Pacific region have been tracked migrating thousands of kilometers through the North Pacific Transition Zone to summer foraging grounds off the coast of northern California (Benson et al. 2007b). Genetic sampling of 18 leatherback turtles caught in the Hawaiian longline fishery indicated that about 94 percent

originated from western Pacific Ocean nesting beaches (NMFS and USFWS 2007c). The remaining six percent of the leatherback turtles found in the open ocean waters north and south of the Hawaiian Islands represent nesting groups from the eastern tropical Pacific Ocean.

4.2.8.3 Migration and Movement

Leatherback sea turtles migrate throughout open ocean convergence zones and upwelling areas, along continental margins, and in archipelagic waters (Eckert 1998a; Eckert 1999a; Morreale et al. 1994a). In a single year, a leatherback may swim more than 9,600 km to nesting and foraging areas throughout ocean basins (Benson et al. 2007a; Benson et al. 2007c; Eckert 1998a; Eckert 2006; Eckert et al. 2006; Ferraroli et al. 2004; Hays et al. 2004; Sale et al. 2006). Much of this travel may be due to movements within current and eddy features, moving individuals along (Sale and Luschi 2009). Return to nesting beaches may be accomplished by a form of geomagnetic navigation and use of local cues (Sale and Luschi 2009). Leatherback females will either remain in nearshore waters between nesting events, or range widely, presumably to feed on available prey (Byrne et al. 2009; Fossette et al. 2009a).

Fossette et al. (2009b) identified three main migratory strategies in leatherbacks in the North Atlantic (almost all of studied individuals were female). One involved 12 individuals traveling to northern latitudes during summer/fall and returning to waters during winter and spring. Another strategy used by six individuals was similar to this, but instead of a southward movement in fall, individuals overwintered in northern latitudes (30–40º N, 25–30º W) and moved into the Irish Sea or Bay of Biscay during spring before moving south to between 5 and 10º in winter, where they remained or returned to the northwest Atlantic. A third strategy, which was followed by three females remaining in tropical waters for the first year subsequent to nesting and moving to northern latitudes during summer/fall and spending winter and spring in latitudes of 40–50º N. Individuals nesting in Caribbean Islands migrate to foraging areas off Canada (Richardson et al. 2012).

Females tracked from nesting beaches in Brazil stayed in waters off Brazil, Uruguay, and Argentina (Almeida et al. 2011). Adult and subadult leatherbacks caught in fisheries operating in southern waters off Uruguay (Fossette et al. 2010a; Lopez-Mendilaharsu et al. 2009) and Brazil (Almeida et al. 2011) remained in the southwestern Atlantic Ocean.

Genetic studies support the satellite telemetry data indicating a strong difference in migration and foraging fidelity between the breeding populations in the northern and southern hemispheres of the Atlantic Ocean (Dutton et al. 2013; Stewart et al. 2013). Genetic analysis of rookeries in Gabon and Ghana confirm that leatherbacks from West African rookeries migrate to foraging areas off South America (Dutton et al. 2013). Foraging adults off Nova Scotia, Canada, mainly originate from Trinidad and none are from Brazil, Gabon, Ghana, or South Africa (Stewart et al. 2013).

Leatherbacks occur along the southeastern U.S. year-round, with peak abundance in summer (TEWG 2007). In spring, leatherback sea turtles appear to be concentrated near the coast, while other times of the year they are spread out at least to the Gulf Stream. From August 2009 through August 2010 off Jacksonville, Florida, surveys sighted 48 leatherback sea turtles, while simultaneous vessel surveys sighted four leatherback sea turtles (U.S. Department of the Navy 2010).

Leatherback sea turtles feed, rest, and migrate regularly in the northern Gulf of Mexico, inhabiting deep offshore waters in the vicinity of DeSoto Canyon (Davis et al. 2000a; Landry and Costa 1999). Leatherback sea turtles feed in shallow waters on the continental shelf waters along the Florida Panhandle, the Mississippi River Delta, and the Texas coast on dense aggregations of (Collard 1990).

Satellite tracking data reveal that leatherback females leaving Mexican and Central American nesting beaches migrate towards the equator and into Southern Hemisphere waters, some passing the Galápagos Islands, and disperse south of 10º S (Dutton et al. 2006; Shillinger et al. 2010a). However, observations of leatherbacks in the Galápagos Islands are rare (Zárate et al. 2010).

Nesting site selection in the southwest Pacific appears to favor sites with higher wind and wave exposure, possibly as a means to aid hatchling dispersal (Garcon et al. 2010). Individuals nesting in Malaysia undergo migrations to tropical feeding areas, taking 5–7 months to arrive there from nesting locations (Benson et al. 2011b). Additional foraging occurs in temperate locations, including across the Pacific basin along the U.S. west coast; individuals take 10–12 months to migrate here (Benson et al. 2011b). Individuals nesting during the boreal summer move to feeding areas in the North China Sea, while boreal winter nesters moved across the Equator to forage in the Southern Hemisphere (Benson et al. 2011b).

4.2.8.4 Habitat

Leatherbacks occur throughout marine waters, from nearshore habitats to oceanic environments (Grant and Ferrell 1993; Schroeder and Thompson 1987; Shoop and Kenney 1992; Starbird et al. 1993). Movements are largely dependent upon reproductive and feeding cycles and the oceanographic features that concentrate prey, such as frontal systems, eddy features, current boundaries, and coastal retention areas (Benson et al. 2011b; Collard 1990; Davenport and Balazs 1991; Frazier 2001; HDLNR (Hawai'i Department of Land and Natural Resources) 2002). Cool, shallow, productive waters are areas where leatherbacks concentrate during late fall, winter, and early spring, where their dives become shallower and shorter, presumeably associated with foraging opportunities (Dodge et al. 2014). Aerial surveys off the western U.S. support continental slope waters as having greater leatherback occurrence than shelf waters (Bowlby et al. 1994; Carretta and Forney 1993; Green et al. 1992; Green et al. 1993). Nesting sites appear to be related to beaches with relatively high exposure to wind or wind-generated waves (Santana Garcon et al. 2010).

Areas above 30º N in the Atlantic appear to be popular foraging locations (Fossette et al. 2009b). Northern foraging areas were proposed for waters between 35º and 50º N along North American, Nova Scotia, the Gulf of Saint-Laurent, in the western and northern Gulf Stream, the Northeast Atlantic, the Azores front and northeast of the Azores Islands, north of the Canary Islands. Southern foraging was proposed to occur between 5º and 15º N in the Mauritania upwelling, south of the Cape Verde islands, over the Guinea Dome area, and off Venezuela, Guyana and Suriname.

For the western Pacific population, seven ecoregions (South China/Sulu and Sulawesi Seas, Indonesian Seas, East Australian Current Extension, Tasman Front, Kuroshio Extension, equatorial Eastern Pacific, and California Current Extension) were identified as important seasonal foraging areas (Benson et al. 2011a). Off the U.S. west coast, two areas were identified

as essential ("critical") habitat for leatherbacks in 2012. One includes the nearshore waters between Cape Flattery, Washington, and Cape Blanco, Oregon extending offshore to the 2000 meter isobaths. This area was identified as the principal Oregon/Washington foraging area and included important habitat associated with the Columbia River Plume, and Heceta Bank, Oregon. Here, great densities of primary prey species, brown sea nettle, occur seasonally north of Cape Blanco (Brodeur et al. 2005; Reese 2005; Shenker 1984). The second area identified as "critical habitat" includes offshore waters between the 200 and 3000 meter isobaths from Point Arena to Point Sur, California and waters between the coastline and the 3000 meter isobath from Point Sur to Point Arguello, California.

In the eastern Pacific Ocean, post-nesting females from Playa Grande, Costa Rica, commonly forage offshore in the South Pacific Gyre in upwelling areas of cooler, deeper water and high productivity (Shillinger et al. 2011). During the nesting season, they stay within the shallow, highly productive, continental shelf waters (Shillinger et al. 2010b).

4.2.8.5 Growth and Reproduction

It has been thought that leatherbacks reach sexual maturity somewhat faster than other sea turtles (except Kemp's ridley), with an estimated range of 3–6 years (Rhodin 1985) to 13–14 years (Zug and Parham 1996). However, recent research suggests otherwise, with western North Atlantic leatherbacks possibly not maturing until as late as 29 years of age (Avens and Goshe 2007; Avens and Goshe 2008; Avens et al. 2009). Female leatherbacks nest frequently (up to 13, average of 5–7 nests per year and about every 2-3 years)(Eckert et al. 2012). The average number of eggs per clutch varies by region: Atlantic Ocean (85 eggs), western Pacific Ocean (85 eggs), eastern Pacific Ocean (65 eggs) and Indian Ocean (>100 eggs (Eckert et al. 2012). However, up to ~30 percent of the eggs can be infertile. Thus, the actual proportion of eggs that can result in hatchlings is less than this seasonal estimate. The eggs incubate for 55–75 days before hatching.

4.2.8.6 Sex Ratio

A significant female bias exists in all leatherback populations thus far studied. An examination of strandings and in-water sighting data from the U.S. Atlantic and Gulf of Mexico coasts indicates that 60 percent of individuals were female. Studies of Suriname nesting beach temperatures suggest a female bias in hatchlings, with estimated percentages of females hatched over the course of each season at 75.4, 65.8, and 92.2 percent in 1985, 1986, and 1987, respectively (Plotkin 1995). Binckley et al. (1998) found a heavy female bias upon examining hatchling gonad histology on the Pacific coast of Costa Rica, and estimated male to female ratios over three seasons of 0:100, 6.5:93.5, and 25.7:74.3. James et al. (2007) also found a heavy female bias (1.86:1) as well as a primarily large sub-adult and adult size distribution. Leatherback sex determination is affected by nest temperature, with higher temperatures producing a greater proportion of females (Mrosovsky 1994; Witzell et al. 2005).

4.2.8.7 Feeding

Leatherbacks may forage in high-invertebrate prey density areas formed by favorable features (Eckert 2006; Ferraroli et al. 2004). Although leatherbacks forage in coastal waters, they appear to remain primarily pelagic through all life stages (Heppell et al. 2003). The location and abundance of prey, including medusae, siphonophores, and salpae, in temperate and boreal latitudes likely has a strong influence on leatherback distribution in these areas (Plotkin 1995).

Leatherback prey are frequently found in the deep-scattering layer in the Gulf of Alaska (Hodge and Wing 2000). North Pacific foraging grounds contain individuals from both eastern and western Pacific rookeries, although leatherbacks from the eastern Pacific generally forage in the Southern Hemisphere along Peru and Chile (Dutton 2005-2006; Dutton et al. 2000a; Dutton et al. 1998b). Mean primary productivity in all foraging areas of western Atlantic females is 150 percent greater than in eastern Pacific waters, likely resulting in twice the reproductive output of eastern Pacific females (Saba et al. 2007). Leatherbacks have been observed feeding on jellyfish in waters off Washington State and Oregon (Eisenberg and Frazier 1983; Stinson 1984b).

4.2.8.8 Diving
