Key Resources Needed for Breeding

Adult: Unknown (USFWS, 2003)

Reproduction Narrative

Adult: It is a short-lived perennial (fewer than 10 years). *Schiedea apokremnos* is a gynodioecious species, having hermaphrodite or female flowers (Sakai 1997) (USFWS, 2010). Some individuals of *Schiedea apokremnos* are functionally female and must be cross-pollinated to set seed. Flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors are unknown (Service 1995) (USFWS, 2003).

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Dry shrublands (NatureServe, 2015); coastal cliffs (USFWS, 2010)

Geographic or Habitat Restraints or Barriers

Adult: 200 - 1,100 ft. elevation (USFWS, 2010)

Habitat Narrative

Adult: Inhabits dry shrublands on steep slopes and cliff faces (NatureServe, 2015). *Schiedea apokremnos* grows in the crevices on nearly vertical coastal cliffs, from 60 to 330 meters (200 to 1,100 feet) elevation. These cliffs have sparse, dry coastal shrub vegetation (USFWS, 2010).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Not available

Species Trends:

Extirpated at 3 locations, increase in known number of individuals (USFWS, 2010)

Resiliency:

Low (inferred from USFWS, 2010; see current range/distribution)

Redundancy:

Low (inferred from USFWS, 2010)

Number of Populations:

15 subpopulations (USFWS, 2017)

Population Size:

<2500 (USFWS, 2017)

Population Narrative:

At the time of the last 5-year review in 2010 there were nine populations totaling between 750 and 850 individuals on Kauai. Recent surveys confirm individuals at Haeleele, Nualolo Kai, and Awaawapuhi, totaling at least 200 individuals (NTBG 2010a-f, 2011ad, 2012, 2014). There have not been recent surveys at Kaaweiki, Makaha, Polihale, Milolii, Honopu, Kalalau, Nakeikionaiwi, Pohakuao, Alealau, or Hanakoa, but it is likely many individuals still survive on steep, isolated cliffs in these areas. In 2016, Clark (2016) reported that *Schiedea apokremnos* is limited to a small area along coastal cliff faces in the same areas, and numbers totaled fewer than 2,500 individuals in 15 'subpopulations' (considered 'populations' by USFWS) with the largest population consisting of 300 individuals. While this represents a net increase in the number of known individuals, it should be noted that *S. apokremnos* appears to be extirpated from several of the previously known locations, and this total reflects estimates for all known sites, regardless of how recently they have been surveyed (USFWS, 2017).

Threats and Stressors

Stressor: Invasive plants (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: Invasive introduced plant species, specifically *Leucaena leucocephala* (haole koa), *Hyptis pectinata* (comb hyptis), *Opuntia* sp. (NCN), and *Pluchea carolinensis* (sourbush), are threats to *Schiedea apokremnos*. Other invasive introduced plant species include *Ageratum conyzoides* (billy goat weed), *Bryophyllum pinnatum*, *Clidemia hirta* (Koster's curse), *Conyza bonariensis* (hairy horseweed), *Elephantopus mollis* (elephant's foot), *Erigeron karvinskianus*, *Furcraea foetida* (Mauritius hemp), *Lantana camara*, *Pluchea carolinensis*, *Psidium guajava* (common guava), *Salvia occidentalis*, *Setaria parviflora*, *Syzygium cumini* (Java plum), and *Xanthium strumarium* var. *canadense* (cocklebur). Introduced invasive grasses include *Andropogon virginicus* (broomsedge), *Bromus rigidus* (riggut grass), *Ehrharta stipoides* (meadow ricegrass), *Oplismenus hirtellus* (basketgrass), and *Vulpia bromoides* (brome fescue). Introduced ferns include *Adiantum hispidulum*, *Adiantum raddianum*, *Blechnum appendiculatum*, *Christella dentata*, and *Nephrolepis multiflora* (USFWS 1995; Wood 2009) (USFWS, 2010).

Stressor: Fire (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: Because Hawaiian plants were subjected to fire during their evolution only in areas of volcanic activity and from occasional lightning strikes, they are not adapted to recurring fire regimes and are unable to recover well following a fire. The most prominent threat is fires caused by people pursuing recreational activities, and prevailing winds spreading fires to inland areas. Fire could destroy seeds as well as plants, even on steep cliffs (Clarke and Cuddihy 1980, Corn et al. 1979, Cuddihy and Stone 1990) (USFWS, 1995).

Stressor: Drought (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: Not available

Stressor: Goats (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: Goats not only disturb the cliff habitats and open areas for the incursions of introduced invasive plants, but they eat the native vegetation including *Schiedea* species (USFWS, 2010).

Stressor: Invasive insects (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: In the Hawaiian Islands, the black twig borer has many hosts, disperses easily, and is probably present at most elevations up to 670 meters (2,500 feet). *Sophonia rufofascia* (two-spotted leafhopper) is a potential threat to the Kauai cluster taxa and the surrounding

ecosystems. Recent observations indicate that this insect is killing plants on the Na Pali Coast and in the Haupū Range (Ken Wood, NTBG, personal communication 1994) (USFWS, 1995).

Stressor: Small population size (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: The small size of most populations and a restricted distribution pose potential threats to this species. A limited gene pool may depress reproductive vigor, or a single environmental disturbance could destroy a significant percentage of the extant individuals. Landslides also pose additional potential threats. Some *S. apokremnos* individuals are functionally female and must be cross-pollinated to set seed. This reproductive strategy may threaten populations with few individuals dispersed over wide areas (USFWS 1995) (USFWS, 2010).

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Schiedea apokremnos* is extremely vulnerable to the impacts of climate change, with a vulnerability score of 0.948 (on a scale of 0 being not vulnerable to 1 being most vulnerable to climate change). In addition, Fortini et al. show that Caryophyllaceae is one of the top four most vulnerable native plant families, and, at the genus level, *Schiedea* had one of the highest vulnerability scores. Therefore, additional management actions are needed to conserve this taxon into the future (USFWS, 2017).

Stressor: Hurricanes—Loss and degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Hurricanes were not specified in the last five year review. In November 1982, Hurricane Iwa struck the Hawaiian Islands, with wind gusts exceeding 100 miles per hour (mph) (161 kilometers per hour (kph)), causing extensive damage, especially on the islands of Niihau, Kauai, and Oahu (Businger 1998). In September 1992, Hurricane Iniki, a category 4 hurricane with maximum sustained wind speeds recorded at 140 mph (225 kph), passed directly over the island of Kauai. Many forest trees were destroyed (Perlman 1992), which opened the canopy and facilitated the invasion of nonnative plants (Kitayama and Mueller-Dombois 1995). A destructive hurricane holds the potential of driving a localized endemic species to extinction in a single event, and 70 percent of all listed plant species on Kauai are only found on Kauai. Hurricanes pose an ongoing and ever-present threat because they can happen at any time, although their occurrence is not predictable. Tropical cyclone frequency and intensity are projected to change as a result of climate change over the next 100 to 200 years (Vecchi and Soden 2007; Emanuel et al. 2008; Yu et al. 2010). In the central Pacific, modeling projects an increase of up to two additional tropical cyclones per year in the main Hawaiian Islands by 2100 (Murakami et al. 2013) (USFWS, 2017).

Recovery**Reclassification Criteria:**

1. A total of five to seven populations should be documented on Kauai and at least one other island where they now occur or occurred historically (USFWS, 1995).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population for short-lived perennials (USFWS, 1995).
3. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered (USFWS, 1995).

Delisting Criteria:

1. A total of eight to ten populations should be documented on Kauai and at least one other island where they now occur or occurred historically (USFWS, 1995).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population for short-lived perennials (USFWS, 1995).
3. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered (USFWS, 1995).

Recovery Actions:

- Protect current populations, control threats and monitor (USFWS, 1995).
- Expand current populations (USFWS, 1995).
- Conduct research essential to conservation of the species (USFWS, 1995).
- Establish new populations as needed to reach recovery objectives (USFWS, 1995).
- Validate and revise recovery objectives (USFWS, 1995).
- Devise and implement a public education program (USFWS, 1995).

Conservation Measures and Best Management Practices:

- Determine methods to protect populations from goats in the steep areas where the species occurs (USFWS, 2010).
- Collect seeds for adequate genetic storage (USFWS, 2010).
- Propagate for reintroduction within protected suitable habitat (USFWS, 2010).
- Establish additional populations within protected suitable habitat (USFWS, 2010).
- Survey suitable habitat in historical range to determine current status of species (USFWS, 2010).
- Work with Hawaii Division of Forestry and Wildlife and Hawaii State Parks to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2010).
- New Management Actions: • Between 2008 and 2012, the NTBG seed bank received twelve collections from Haena (one collection of 25 seeds) and Nualolo Kai (thousands of seeds from eleven different founders) (NTBG 2017). • The University of California at Irvine has 16 plants representing four founders from the population between Kalalau and Hanakoa Valley, and 64 plants representing

three founders from the Nualolo Kai population maintained in the greenhouse (UCI 2016) (USFWS, 2017).

- Recommendations for Future Actions: No new threats and no other significant new information regarding the species' biological status have been reported since the last 5-year review in 2010. Therefore, the following recommendations for future actions are reiterated for the 5-year review for 2017. • Surveys and inventories—Survey suitable habitat in historic range to determine current status of the species. • Ungulate monitoring and control—Construct fenced exclosures to exclude feral ungulates from wild populations. Protect all occurrences against browsing and disturbances from feral ungulates. • Invasive plant monitoring and control— o Control established ecosystem-altering nonnative invasive plant species around all populations. o Control invasive nonnative species that compete with the species around all populations. • Fire monitoring and control—Develop and implement fire management plans for all wild and reintroduced populations. • Predator and herbivore control research—Study *Schiedea apokremnos* populations to determine level of threat from invertebrate herbivory and any additional needed recovery actions. • Captive propagation for genetic storage and reintroduction—Continue collecting seeds from all populations for adequate genetic storage. • Reintroduction and translocation—Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. • Population biology research—Study *Schiedea apokremnos* populations to determine viable population size and structure, geographical distribution, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. • Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from landslides, drought, and tsunamis (USFWS, 2017).

SPECIES ACCOUNT: *Schiedea attenuata* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 05/13/2010; Pacific Region (R1) (USFWS, 2016)

Physical Description

An erect, sparingly branched shrub up to 75 cm tall. Leaves are opposite, and somewhat succulent. Cymes are terminal and open (NatureServe, 2015).

Taxonomy

A member of the pink family (Caryophyllaceae) (USFWS, 2010b). This species is most closely related to *S. globosa* (NatureServe, 2015).

Historical Range

Schiedea attenuata was discovered in 1991 by K. Wood during a rappel on the cliffs in an area of precipitous slopes above the Kalalau Valley on Kauai (USFWS, 2010b).

Current Range

Known from a single site in Kalalau Valley, island of Kauai, state of Hawaii (NatureServe, 2015). Individuals were last observed at the site of discovery in 1994 (M. Bruegmann 1994b; Wagner et al. 1994, p. 187; Wagner et al. 2005, pp. 45–47) (USFWS, 2010b).

Critical Habitat Designated

Yes; 4/13/2010.

Legal Description

On April 13, 2010, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea attenuata* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes two critical habitat units (CHUs), in Hawaii (75 FR 18960-19165).

Critical Habitat Designation

The critical habitat designation for *Schiedea attenuata* includes two CHUs in Kauai County, Hawaii (75 FR 18960-19165).

Kauai—Dry Cliff—Section 1: Dry Cliff—Section 1 consists of 404 ac (163 ha) in the dry cliff ecosystem, along cliffs from Kalanu to Pihea peak, within the Na Pali Coast State Park (Figure 5). The entire section is within previously designated critical habitat and is State-owned; it falls within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 67a. This section is occupied by the plants *Chamaesyce eleanoriae*, *Lysimachia scopulensis*, *Schiedea attenuata*, and *Stenogyne kealiae*. This section includes the dry cliffs, the moisture regime, and subcanopy and understory plant species identified as PCEs in the dry cliff ecosystem (Table 3).

Kauai—Dry Cliff—Section 2: Dry Cliff—Section 2 consists of 309 ac (125 ha) in the dry cliff ecosystem, including cliffs and ridges extending from Kanakou to Keanapuka and along Manono Ridge, surrounding the hanging valley Pohakuao, in the Na Pali Coast State Park (Figure 5, above). The entire section is State-owned and within previously designated critical habitat; it falls within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 67a. This section is occupied by the plant

Chamaesyce eleanoriae and includes the dry cliffs, the moisture regime, and subcanopy and understory plant species identified as PCEs in the dry cliff ecosystem (Table 3). Although Dry Cliff - Section 3 is not known to be occupied by the plants *Lysimachia scopulensis*, *Schiedea attenuata*, and *Stenogyne kealiae*, we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range of the species. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea attenuata* critical habitat consists of one component (Dry cliff) (75 FR 18960-19165):

Ecosystem: Dry Cliff. Elevation: unrestricted. Annual precipitation: < 75 in (<190 cm). Substrate: >65 degree slope, rocky talus. Canopy: None. Subcanopy: *Antidesma*, *Chamaesyce*, *Diospyros*, *Dodonaea*. Understory: *Bidens*, *Eragrostis*, *Melanthera*, *Schiedea*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contains the physical or biological features essential to the conservation of the species that may require special management considerations or protection. It is recognized that activities in and adjacent to areas designated as critical habitat may affect one or more of the PCEs found in these areas. Special management is needed throughout each of the designated critical habitat units. The following discussion of special management needs is applicable to each of the 47 Kauai species for which we are designating critical habitat. These 47 Kauai species include 41 species that are currently found in the wild, and 6 species that are not currently extant in the wild. For each of the 41 Kauai species found in the wild, we have determined that the features essential to their conservation are primarily dependent on maintaining the successful functioning of the ecosystem(s) in which they occur (Tables 3 and 4). In some cases, additional species-specific primary constituent elements have also been identified (Table 4). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical and biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, predation by nonnative species, competition with nonnative species, hurricanes, landslides, flooding, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by feral ungulates (pigs, goats, and black-tailed deer). Feral ungulates also impact the habitat through predation and trampling. The State of Hawaii provides game mammal (feral pigs and goats, and black-tailed deer) hunting opportunities on one or more State-designated public hunting areas on the islands of Kauai, Oahu, Maui, Molokai, Lanai, and Hawaii (Hawaii Administrative Rules 13-123; DLNR 2009a). Management of game animals by the State ranges from providing maximal sustained public hunting opportunities and benefits (e.g., "sustained yield") in some areas to game animal removal by State staff, or their designees, in other areas (DLNR 2009b). Public hunting areas are not fenced, and game mammals have unrestricted access

to most areas across the landscape, regardless of the underlying land use designation. While fences are sometimes built to provide protection from game mammals to the natural resources within the fenced area, the current number and locations of fences are not sufficient to prevent habitat destruction and degradation. Without special management, the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new alien plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species will help to address the threat presented by fire to three critical habitat areas in particular (Kauai—Lowland Mesic— Section 1, Kauai—Montane Mesic— Section 2, and Kauai—Dry Cliff— Section 1; see Table 5 for corresponding CFR unit numbers). This threat is primarily due to the presence of nonnative species, such as the grasses *Andropogon* sp. and *Setaria* sp., which increase the fuel load and quickly regenerate after a fire. These species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D’Antonio and Vitousek 1992, pp. 64– 66; Brooks et al. 2004, p. 680). In addition, five sections (Kauai—Dry Cliff—Section 1, Kauai—Dry Cliff— Section 2, Kauai—Wet Cliff—Section 1, Kauai—Wet Cliff—Section 2, and Kauai—Wet Cliff—Section 3; see Table 5 for corresponding CFR unit numbers) may require special management to reduce the threat of landslides and flooding, which threaten to further degrade the habitat conditions and have the potential to eliminate some species in their entirety (e.g., *Schiedea attenuata*). In summary, we find that each of the areas we are designating as critical habitat contains features essential to the conservation of the species that may require special management considerations or protection to ensure the conservation of the 47 Kauai species. These special management considerations and protections are required to preserve and maintain the essential features provided to these species by the ecosystems upon which they depend. A more detailed discussion of each of these threats is presented above, under the Summary of Factors Affecting the Species section.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Not available

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Mesic forest (NatureServe, 2015); dry cliff (USFWS, 2010b)

Geographic or Habitat Restraints or Barriers

Adult: 2,297 - 2,625 ft. elevation (USFWS, 2010b)

Environmental Specificity

Adult: Unknown (NatureServe, 2015)

Habitat Narrative

Adult: Inhabits diverse mesic forest pockets and vertical cliffs. The environmental specificity is unknown (NatureServe, 2015). It occurs on cliffs at elevations between 2,297 and 2,625 ft. (700 and 900 m) in the dry cliff ecosystem (Wagner et al. 1994, pp. 187– 190; TNCH 2007) (USFWS, 2010b).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Unknown (NatureServe, 2015)

Species Trends:

Declining (NatureServe, 2015)

Resiliency:

Very low (inferred from NatureServe, 2015; see current range/distribution)

Redundancy:

Very low (inferred from USFWS, 2010a)

Number of Populations:

1 - 5 (NatureServe, 2015)

Population Size:

1 - 50 individuals (NatureServe, 2015)

Population Narrative:

The long term population trend is unknown. It is reasonable to assume the populations have continued to decline, since all of the threats are not managed (Russell 2004) (NatureServe, 2015). There is one population totaling ten individuals (USFWS, 2010a). The last observation of this species was in 1994, when there were 20 individuals of *Schiedea attenuata* in one population in the Kalalau region of Kauai. There has only been one visit to this population and a collection was made at that time (USFWS, 2017).

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from non-native plants, goats, fire, hurricanes, landslides, and climate change. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Landslides destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. Fire can destroy dormant seeds and plants, even in steep in inaccessible areas. Successive fires can remove habitat for native species by altering microclimate conditions favorable to alien plants.

Stressor: Predation and herbivory (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species present an immediate and significant threat to *Schiedea attenuata* throughout its range due to documented browsing and trampling by pigs, goats, and deer (USFWS, 2010).

Stressor: Small populations (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: *Schiedea attenuata* is known only from a single population with fewer than 50 individuals. Research on *Pittosporum* species suggests that small populations are susceptible to loss of genetic variation through inbreeding and drift (USFWS, 2010).

Stressor:

Exposure:

Response:

Consequence:

Narrative:

Recovery

Reclassification Criteria:

In addition to achieving 5 to 10 populations with 500 mature individuals per population and all of the goals of the interim stage, all target populations must be stable, secure, and naturally reproducing for a minimum of 10 years. Species-specific management actions are not ruled out. Downlisting should not be considered until an adequate population viability analysis (PVA) has been conducted to assess needed numbers more accurately based on current management and monitoring data collected at regular intervals determined by demographic parameters of the species, although they should only be one of the factors used in making a decision to downlist. Information necessary for the PVA that should be available through monitoring (ideally annually)

includes: major limiting factors, breeding system, population structure and density, and proven management methods for major threats (USFWS, 2017).

Delisting Criteria:

In addition to achieving 5 to 10 populations with 500 mature individuals per populations and all of the goals of the interim and downlisting stages, all target populations must be stable, secure, naturally reproducing, and within secure and viable habitats for a minimum of 20 years. Species-specific management actions must no longer be necessary, but ecosystem-wide management actions are not ruled out if there are long-term agreements in place to continue management. These numbers are initial targets, but may be revised upward as additional information is available, including adequate PVAs for individual species based on current management and monitoring data collected at regular intervals determined by demographic parameters of the species, although they should only be one of the factors used in making a decision to delist. Genetic analyses should be conducted to ensure that adequate genetic representation is present within and among populations compared to the initial variation assessed in the interim stage. Numbers need to be considered on a species-by-species basis (USFWS, 2017).

Recovery Actions:

- Assess the distribution, current status, and potential future distribution of existing ecosystems and determine the most important sites for ecosystem management. Make use of landscape modeling, spatial analysis, remote sensing technology, and existing survey data to better understand species distributions and priority ecosystem areas for targeting future surveys (USFWS, 2010a).
- Initiate control of ecosystem-modifying threats, such as ungulates and invasive introduced plant species, as soon as possible within the highest priority management units (USFWS, 2010a).
- Stabilize and protect remaining extant populations of the 45 plants and 2 bird species. Conduct systematic, island-wide surveys for additional populations. Make use of landscape modeling, spatial analysis, remote sensing technology, and existing survey data to better understand distributions and priority areas for targeting future surveys (USFWS, 2010a).
- Restore and maintain multiple viable populations of the 45 plants and 2 bird species by protecting, restoring, and maintaining existing habitats or areas with potential for restoration that are within their historical range (USFWS, 2010a).
- Conduct research on control methods for introduced slugs and avian malaria (USFWS, 2010a).
- Develop an augmentation plan to collect and propagate seed from the 45 plant species that can later be utilized for population restoration, augmentation, and reintroduction (USFWS, 2010a).
- Identify threats and prioritize which ones to address first for the two birds (USFWS, 2010a).
- Determine if a captive propagation program for the two birds is necessary; if so, develop a captive propagation program (USFWS, 2010a).
- Prevent the influx of new pests and invasive species into recovery areas. Increase the efforts of the Kauai Invasive Species Committee and improve border security (USFWS, 2010a).
- Prioritize research studies that will provide information and tools aiding in the mitigation of known threats and limiting factors of the species and ecosystems (USFWS, 2010a).

- Increase outreach effort and coordination with State agencies and private landowners regarding ecosystem conservation. Promote opportunities to assist in the recovery of these species through Habitat Conservation Plans, Safe Harbor Agreements, and through various conservation partnerships funded by State and Federal agencies and private organizations (USFWS, 2010a).

Conservation Measures and Best Management Practices:

- This species is currently in controlled propagation for genetic storage and/or reintroduction efforts (USFWS, 2010a).
- RECOMMENDATIONS FOR FUTURE ACTIONS • Surveys and inventories—Continue to survey for populations of *Schiedea attenuata* in areas of potentially suitable habitat. • Ungulate monitoring and control—Protect all occurrences against browsing and disturbances from feral ungulates. Construct and maintain fenced exclosures around existing populations to prevent imminent extinction. • Invasive plant monitoring and control— o Control established ecosystem-altering nonnative invasive plant species around all populations. o Control invasive nonnative plant species around all populations that compete with the species. • Captive propagation for genetic storage and reintroduction—Continue propagation efforts for maintenance of genetic stock. • Reintroduction and translocation—Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. • Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from landslides and storms. • Population biology research—Study *Schiedea attenuata* populations to determine viable population size and structure, geographical distribution, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. • Based on the recovery criteria above, consider development of a recovery plan (USFWS, 2017).

SPECIES ACCOUNT: *Schiedea diffusa* ssp. *diffusa* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/31/2016; Pacific Region (R1) (USFWS, 2016)

Physical Description

Schiedea diffusa ssp. *diffusa* (NCN) is a reclining or weakly climbing vine in the pink family (Caryophyllaceae). This species is woody at the base, and glabrous or nearly so below, with purple-tinged hairs. Lanceolate to ovate leaves are 2 to 5 in (4 to 12 cm) long. Inflorescences have 20 to 90 flowers with purple or purple-tinged stalks. Capsules are very broadly ovoid, 0.2 to 0.3 in (5 to 7 mm) long (USFWS, 2015).

Taxonomy

Schiedea diffusa ssp. *diffusa* was described by Wawra (1825, in Wagner et al. 2005, pp. 103–104) as *S. diffusa* ssp. *angustifolia*, now a synonym. This subspecies is currently recognized as a distinct taxon in Wagner et al. (1999, pp. 511–512) and in the *Schiedea* monograph by Wagner et al. (2005, pp. 103–106), the most recently accepted taxonomic treatments of this subspecies. *Schiedea diffusa* ssp. (USFWS, 2011).

Historical Range

Schiedea diffusa ssp. *diffusa* was historically found on the islands of Molokai and Maui. On Molokai, this subspecies was known from Kawela to Waikolu valleys; on Maui, it was wideranging on both the east and west mountains (Wagner et al. 2005, p. 106) (USFWS, 2015).

Current Range

Currently, *S. diffusa* ssp. *diffusa* is known from east Maui in six occurrences (fewer than 50 individuals total), in a much smaller range, from Puu o Kalae to Keanae (spanning about 5 mi (8 km)). On Molokai, there were two occurrences totaling fewer than 10 individuals, one at west Kawela Gulch, and one on the rim of Pelekunu Valley, last observed in the 1990s (HBMP 2010) (USFWS, 2015).

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Habitat Type**

Adult: Wet forest (USFWS, 2015)

Spatial Arrangements of the Population

Adult: Clumped (inferred from USFW, 2015)

Environmental Specificity

Adult: Narrow/specialist (inferred from USFW, 2015)

Tolerance Ranges/Thresholds

Adult: Low (inferred from USFW, 2015)

Site Fidelity

Adult: High (inferred from USFW, 2015)

Habitat Narrative

Adult: *Schiedea diffusa* ssp. *diffusa* occurs in wet forest at 3,000 to 5,300 ft (915 to 1,600 m) on Molokai, and to 6,700 ft (2,050 m) on Maui, in the lowland wet (Maui) and montane wet (Maui and Molokai) ecosystems (Wagner et al. 1999, p. 512; HBMP 2010; TNCH 2007) (USFWS, 2015). Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations.

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Not defined

Resiliency:

Low (inferred from USFWS, 2015)

Representation:

Low (inferred from USFWS, 2015)

Redundancy:

Low (inferred from USFWS, 2015)

Population Narrative:

Currently, *S. diffusa* ssp. *diffusa* is known from east Maui in six occurrences (fewer than 50 individuals total), in a much smaller range, from Puu o Kalae to Keanae (spanning about 5 mi (8 km)). On Molokai, there were two occurrences totaling fewer than 10 individuals, one at west Kawela Gulch, and one on the rim of Pelekunu Valley, last observed in the 1990s (HBMP 2010) (USFWS, 2015). Low resiliency, representation and redundancy are inferred based on the species limited range, number of known populations and individuals as well as habitat requirements.

Threats and Stressors

Stressor: Feral pigs (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Feral pigs modify and destroy the habitat of *Schiedea diffusa* ssp. *diffusa* on Maui and Molokai, with evidence of the activities of these animals reported in the areas where this subspecies occurs (PEPP 2014, p. 159; HBMP 2010) (USFWS, 2015).

Stressor: Nonnative plants (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Nonnative plants modify and destroy the native habitat of *S. diffusa* ssp. *diffusa*, and displace this subspecies and other native Hawaiian plants by competing for water, nutrients, light, and space, or they may produce chemicals that inhibit the growth of other plants (Smith 1985, pp. 180–250; Vitousek et al. 1987 in Cuddihy and Stone 1990, p. 74; HBMP 2010; PEPP 2014, p. 159) (USFWS, 2015).

Stressor: Predation (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Herbivory by slugs and seed predation by rats are both reported to pose a threat to this subspecies (HBMP 2010; PEPP 2014, p. 159) (USFWS, 2015).

Stressor: Low genetic variability (USFWS, 2015)

Exposure:

Response:

Consequence: Extinction

Narrative: This subspecies may experience reduced reproductive vigor due to low levels of genetic variability, leading to diminished capacity to adapt to environmental changes, thereby lessening the probability of its long-term persistence (Barrett and Kohn 1991, p. 4; Newman and Pilson 1997, p. 361) (USFWS, 2015).

SPECIES ACCOUNT: *Schiedea diffusa* ssp. *macraei* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Region (R1) (USFWS, 2016)

Historical Range

Historically, known from the Kohala Mountains, the windward slopes of Mauna Loa, and the Olaa Tract of Hawaii Volcanoes National Park (Perlman et al. 2001, in litt.; Wagner et al. 2005; HBMP 2010 cited by USFWS 2012). (NatureServe, 2015)

Current Range

As of 2012, known only from the Kohala Mountains on the island of Hawai'i (USFWS 2012). (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Obligate and facultative autogamous also hermaphroditic (USFWS, 2013)

Reproduction Narrative

Adult: One peer reviewer stated that *Schiedea diffusa* ssp. *macraei* and *S. hawaiiensis* are obligate autogamous species (i.e., reproduces by self-pollination) and facultative autogamous (i.e., reproduces by self and cross-pollination), respectively. Because both of these species are hermaphroditic and autogamous, they are capable of regenerating from single individuals, and may not be severely hampered by inbreeding depression. Unfortunately, autogamous species of *Schiedea* also appear to be short-lived, emphasizing the importance of appropriate conditions for regeneration. Our Response: We agree that the obligate and facultative autogamous nature of *Schiedea diffusa* ssp. *macraei* and *S. hawaiiensis*, respectively, in addition to being hermaphroditic, afford these species the ability to regenerate from single individuals and may not be severely hampered by inbreeding depression (USFWS, 2013).

Habitat Type

Adult: Montane wet ecosystem (USFWS, 2013)

Habitat Narrative

Adult: Currently, there is one individual of *S. diffusa* ssp. *macraei* on the slopes of Eke in the Kohala Mountains, in the montane wet ecosystem (Wagner et al. 2005d, p. 106; Bio 2011, pers. comm.) (USFWS, 2013).

Dispersal/Migration

Population Information and Trends

Population Trends:

Unknown

Population Narrative:

Currently, there is one individual of *S. diffusa* ssp. *macraei* on the slopes of Eke in the Kohala Mountains, in the montane wet ecosystem (Wagner et al. 2005d, p. 106; Bio 2011, pers. comm.) (USFWS, 2013).

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence: loss of habitat/extinction

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (pigs and cattle), nonnative plants, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (pigs, cattle, and rats) is considered an ongoing threat to *Schiedea diffusa* ssp. *macraei* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

Stressor: Small populations (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: *Schiedea diffusa* ssp. *macraei* faces the threat of limited numbers (i.e., there are fewer than 50 individuals in the wild). This species is known from a single individual in the Kohala Mountain (USFWS, 2013).

Stressor:

Exposure:

Response:

Consequence:**Narrative:*****Recovery*****Recovery Actions:**

- There is no recovery plan for this species.

SPECIES ACCOUNT: *Schiedea haleakalensis* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Region (R1) (USFWS, 2016)

Physical Description

A shrub about 3-6 dm tall, with numerous ascending to erect stems. Leaves narrow. Flowers are borne in terminal clusters. (NatureServe, 2015)

Taxonomy

Genus endemic to Hawaiian Islands, species endemic to east Maui. (NatureServe, 2015)

Historical Range

See current range/distribution.

Current Range

Endemic to crater of Haleakala, East Maui. (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea haleakalensis* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Schiedea haleakalensis* includes six CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Subalpine—Unit 1 (and) *Palmeria dolei*—Unit 24—Subalpine (and) *Pseudonestor xanthophrys*—Unit 24— Subalpine This area consists of 10,785 ac (4,365 ha) of State land, 1,622 ac (656 ha) of privately owned land, and 3,568 ac (1,444 ha) of federally owned land (Haleakala National Park), from Kanaio north to Puu Nianiau on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the subalpine ecosystem (see Table 5). They are occupied by the plants *Bidens micrantha* ssp. *kalealaha* and *Geranium arboreum*, and contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Subalpine—Unit 1 is not known to be occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Asplenium peruvianum* var. *insulare*, *Geranium multiflorum*, *Phyllostegia bracteata*, *Schiedea haleakalensis*, or *Zanthoxylum hawaiiense*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these subalpine species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and

space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Subalpine—Unit 2 (and) *Palmeria dolei*—Unit 25—Subalpine (and) *Pseudonestor xanthophrys*—Unit 25— Subalpine This area consists of 50 ac (20 ha) of privately owned land, and 9,836 ac (3,981 ha) of federally owned land (Haleakala National Park), from the summit north to Koolau Gap and east to Kalapawili Ridge on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the subalpine ecosystem (see Table 5). They are occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Geranium multiflorum*, and *Schiedea haleakalensis*, and by the forest bird, the *akohekohe* (*Palmeria dolei*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui— Subalpine—Unit 2 is not known to be occupied by the plants *Asplenium peruvianum* var. *insulare*, *Bidens micrantha* ssp. *kalealaha*, *Geranium arboreum*, *Phyllostegia bracteata*, or *Zanthoxylum hawaiiense*, or by the forest bird, the *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these subalpine species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Dry Cliff—Unit 1 (and) *Palmeria dolei*—Unit 26—Dry Cliff (and) *Pseudonestor xanthophrys*—Unit 26— Dry Cliff This area consists of 755 ac (305 ha) of federally owned land (Haleakala National Park), from Pakaoao to Koolau Gap on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 5). Although Maui—Dry Cliff— Unit 1 is not known to be occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Bidens campylotheca* ssp. *pentamera*, *B. micrantha* ssp. *kalealaha*, *Diplazium molokaiense*, *Geranium multiflorum*, *Plantago princeps*, or *Schiedea haleakalensis*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Dry Cliff—Unit 2 consists of 688 ac (279 ha) of federally owned land (Haleakala National Park) from Haupaakea Peak to Kaupo Gap on east Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 5). It is occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Geranium multiflorum*, *Plantago princeps*, and *Schiedea haleakalensis*, and contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Dry Cliff—Unit 2 is not known to be occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. micrantha* ssp. *kalealaha*, or *Diplazium molokaiense*, we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations

within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Dry Cliff—Unit 3 (and) *Palmeria dolei*—Unit 27—Dry Cliff (and) *Pseudonestor xanthophrys*—Unit 27—Dry Cliff This area consists of 200 ac (81 ha) of federally owned land (Haleakala National Park) near Papaanui on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 5). It is occupied by the plant *Plantago princeps*, and contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Dry Cliff—Unit 3 is not currently occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Bidens campylotheca* ssp. *pentamera*, *B. micrantha* ssp. *kalealaha*, *Diplazium molokaiense*, *Geranium multiflorum*, or *Schiedea haleakalensis*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Dry Cliff—Unit 4 (and) *Palmeria dolei*—Unit 28—Dry Cliff (and) *Pseudonestor xanthophrys*—Unit 28—Dry Cliff This area consists of 315 ac (127 ha) federally owned land (Haleakala National Park), along Kalapawili Ridge on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 5). Although Maui—Dry Cliff—Unit 4 is not currently occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Bidens campylotheca* ssp. *pentamera*, *B. micrantha* ssp. *kalealaha*, *Diplazium molokaiense*, *Geranium multiflorum*, *Plantago princeps*, or *Schiedea haleakalensis*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea haleakalensis* critical habitat consists of two components. Sub-alpine (east Maui) and Dry cliff (east Maui) (81 FR 17790-18110):

Ecosystem: Subalpine. Elevation: 6,500–9,800 ft (2,000–3,000 m). Annual precipitation: 15–40 in (38–100 cm). Substrate: Dry ash, sandy loam, rocky, undeveloped soils, weathered lava. Canopy: *Chamaesyce*, *Chenopodium*, *Metrosideros*, *Myoporum*, *Santalum*, *Sophora*. Subcanopy: *Coprosma*, *Dodonaea*, *Dubautia*, *Geranium*, *Leptecophylla*, *Vaccinium*, *Wikstroemia*. Understory: Ferns, *Bidens*, *Carex*, *Deschampsia*, *Eragrostis*, *Gahnia*, *Luzula*, *Panicum*, *Pseudognaphalium*, *Sicyos*, *Tetramolopium*.

Ecosystem: Dry Cliff. Elevation: unrestricted. Annual precipitation: <75 in (<190 cm). Substrate: >65 degree slope, rocky talus. Canopy: None. Subcanopy: *Antidesma*, *Chamaesyce*, *Diospyros*, *Dodonaea*. Understory: *Bidens*, *Eragrostis*, *Melanthera*, *Schiedea*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special

management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylothea* ssp. *pentamera*, *B. campylothea* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Probably requires cross-pollination by small insects for seed set. Small flies and moths have been noted visiting the flowers at both known populations (Loope and Medeiros 1994c) (USFWS, 1997).

Breeding Season

Adult: Fruits and seeds have been observed in August/ September (USFWS, 1997).

Reproduction Narrative

Adult: Little is known about the life history of *Schiedea haleakalensis*. This species is known to be gynodioecious (bearing female and both-sexed flowers on separate plants) (Stephen Weller,

University of California at Irvine and A.C. Medeiros, personal communication 1994) and, hence, probably requires cross-pollination by small insects for seed set. Small flies and moths have been noted visiting the flowers at both known populations (Loope and Medeiros 1994c). These insects are generally relatively short- flighted. Fruits and seeds have been observed in August/ September. There are no obvious dispersal devices for seeds other than gravity and water-borne movement (USFWS, 1997).

Habitat Type

Adult: Dry subalpine cliffs (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Clumped (inferred from USFWS, 1997)

Environmental Specificity

Adult: Narrow/specialist (inferred from USFWS, 1997)

Tolerance Ranges/Thresholds

Adult: Low (inferred from USFWS, 1997)

Site Fidelity

Adult: High (inferred from USFWS, 1997)

Habitat Narrative

Adult: Dry subalpine cliffs with native shrubs. (NatureServe, 2015). The current habitat of *Schiedea haleakalensis* is in rock cracks on sheer cliffs at 1,800 and 2,440 meters (5,910 and 8,010 feet) elevation adjacent to barren lava and predominantly native subalpine shrublands and grasslands. The substrate is cinder, weathered volcanic ash, or bare lava with little or no soil development. Periodic freezing temperatures occur in this habitat. Associated native species include *Artemisia mauiensis*, *Bidens micrantha*, *Dubautia mensiezii*, *Styphelia tameiameia*, *Vaccinium reticulatum*, and *Viola chamissoniana* (Medeiros, Loope, and Holt 1986) (USFWS, 1997). Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations. Species only survives on precipitous cliff faces not accessible to goats (USFWS, 1997)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: There are no obvious dispersal devices for seeds other than gravity and water-borne movement (USFWS, 1997).

Population Information and Trends**Population Trends:**

Unknown

Resiliency:

Low (inferred from USFWS, 2011)

Representation:

Low (inferred from USFWS, 2011)

Redundancy:

Low (inferred from USFWS, 2011)

Number of Populations:

2 (USFWS, 2018)

Population Size:

18 individuals (USFWS, 2018))

Population Narrative:

New Status Information: • In 2011, there were 18 observed individuals at Kaupō Gap. Currently, *Schiedea haleakalaensis* is found in two occurrences, one at Leleiwi Pali (seven individuals) and one at Kaupō Gap (one individual) (Robertson 2016, in litt.) • In 2016, six critical habitat units in two ecosystems (subalpine and dry cliff) were designated on east Maui for *Schiedea haleakalaensis* (27,819 ac; 11,258 ha) (81 FR 17790, March 30, 2016) (USFWS, 2018).

Threats and Stressors

Stressor: Feral goats (USFWS, 1997)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: The primary threat historically responsible for the endangerment of this species is habitat degradation and herbivory by feral goats (USFWS, 1997).

Stressor: Small population size (USFWS, 1997)

Exposure:

Response:

Consequence: Extinction

Narrative: The very small remaining number of individuals of *Schiedea haleakalaensis* and the limited and scattered distribution of the species are threats since a single natural or human-caused environmental disturbance could be catastrophic to all or a significant part of the populations. In addition, the limited gene pool may depress reproductive vigor. Just as importantly, a very small, scattered population may not receive adequate cross-pollination (USFWS, 1997).

Stressor: Slugs (USFWS, 1997)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Feeding by slugs (*Milax gagates*): Based on recent unpublished evidence, recruitment of *Schiedea* germinants [seedlings] can be catastrophically suppressed by herbivory of alien slugs in the Waianae Mountains of Oahu (Steve Weller and Ann Sakai, University of California at Irvine, personal communication 1994). Nocturnal herbivory by the invasive garden slug *Milax gagates*

has been observed to partially defoliate larger, established plants of *Schiedea haleakalensis* in the western Kaupo population (A.C. Medeiros, personal observation 1994). This slug is now widespread on upper Haleakala Volcano in a variety of high-elevation sites, arid to wet, and has been observed feeding on such rare native plants as the green sword (Gagne 1983) (USFWS, 1997).

Stressor: Ants (USFWS, 1997)

Exposure:

Response:

Consequence: Loss of habitat/Loss of pollinators

Narrative: Invasion of habitat and elimination of pollinators by the Argentine ant (*Iridomyrmex humilis*): This ant species is capable of reducing or eliminating native pollinators wherever it invades on Haleakala Volcano (Cole et al. 1992). As of 1994, the invasion had descended from Kalahaka on the rim of Haleakala Crater to the crater floor very near the Holua population of *Schiedea haleakalensis* (USFWS, 1997).

Stressor: Feral ungulates (USFWS, 1997)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Feral ungulates: Although feral goats have been removed from Haleakala National Park by a program of active management and are no longer an immediate threat to native plant species within the park, the potential for the ingress and reestablishment of goats exists. Maintenance of a goat-free situation requires continuation of an active management program, which requires substantial sustained commitment by Haleakala National Park and funding for fence maintenance and goat removal (USFWS, 1997).

Stressor: Fire (USFWS, 1997)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: The possibility of fire is a threat to the existence of *Schiedea haleakalensis*; a single fire could affect a significant portion of the population of *Schiedea haleakalensis* (A.C. Medeiros, personal communication 1990) (USFWS, 1997).

Stressor: Nonnative invasive plants

Exposure:

Response:

Consequence:

Narrative: Two additional nonnative invasive plants, *Pinus radiata* (Monterey pine) and *Cortaderia jubata* (pampas grass) are observed to be a threat to *Schiedea haleakalaensis*, by modifying and degrading habitat, and by direct competition (Robertson 2016, in litt.) (USFWS, 2018).

Stressor: Drought degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Drought is observed to be a threat to populations of *S. haleakalensis* at Leleiwi Pali and Kaupō Gap (Robertson 2016, in litt.). Over the last 100 years, the Hawaiian Islands have experienced an annual decline in precipitation of over nine percent, increasing to as much as 15 percent within the last 20 years (US-NSTC 2008; Chu and Chen 2005; Diaz 2005). Drought affects plants directly by desiccation. The increase in drought frequency and intensity leads to a self-perpetuating cycle of increase in cover of nonnative plants, increase in the number of fires, and an increase of erosion (US-GCRP 2009; Warren 2011) (USFWS, 2018).

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: We previously reported that climate change may pose a threat to this species, anticipating an analysis by 2013. The assessment conducted by Fortini et al. (2013) concluded that *S. haleakalensis* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.605 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions may be needed to conserve this taxon into the future (USFWS, 2018).

Recovery

Reclassification Criteria:

For downlisting, a total of five to seven populations of *Schiedea haleakalensis* should be documented on islands where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered (USFWS, 2011).

Delisting Criteria:

For delisting, a total of eight to ten populations of *Schiedea haleakalensis* should be documented on islands where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with 300 mature individuals per population for long-lived perennials. Each population should persist at this level for a minimum of five consecutive years before delisting is considered (USFWS, 2011).

Conservation Measures and Best Management Practices:

- Continue to collect seeds and other propagules for genetic storage and reintroduction (USFWS, 2011).
- Maintain the fences around existing populations to provide protection from the negative impacts of feral ungulates (USFWS, 2011).
- Control invasive introduced species around known populations (USFWS, 2011).
- Survey areas where *Schiedea haleakalensis* has been reported to determine current status of the species (USFWS, 2011).
- Develop and implement methods to control slugs and ants (USFWS, 2011).
- Control rats in the vicinity of these populations (USFWS, 2011).

- Propagate to augment the existing populations (USFWS, 2011).
- Research limiting factors to reintroduction success and possible solutions (USFWS, 2011).
- Establish additional populations within protected suitable habitat (USFWS, 2011).
- Work with the National Park Service, Plant Extinction Prevention Program, and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2011).
- Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species (USFWS, 2011).
- New Management Actions:
 - Captive propagation for genetic storage and reintroduction—
 - o Haleakalā National Park (HNP) maintains a living collection of *S. haleakalensis*, and hand-pollination has produced more than 5,000 seeds for storage and propagation (Robertson 2016, in litt.). The HNP reported 900 seeds representing five individuals in storage in 2013; 58 plants representing four individuals in storage in 2015; and 119 plants representing four individuals in storage in 2016.
 - o Lyon Arboretum Micropropagation Laboratory reported 32 containers of propagules of *S. haleakalensis* in storage, representing one founder (Lyon Arboretum 2017).
 - o The University of California—Irvine reported one plant representing one individual in storage in 2014 (USFWS, 2018).
- Recommendations for Future Actions: Drought and two nonnative invasive plants are additional threats; however, we are not aware of any significant new information regarding the species' biological status since the last 5-year review in 2011. Thus, the following recommendations for future actions are added or reiterated for the 5-year review for 2018.
 - Surveys and inventories—Survey areas where *Schiedea haleakalensis* has been reported to determine current status of the species on east Maui.
 - Ungulate monitoring and control—Maintain fencing to provide protection from negative impacts of feral ungulates.
 - Invasive plant monitoring and control—Continue to control established ecosystem-altering nonnative invasive plant species around all populations of *S. haleakalensis*.
 - Captive propagation for genetic storage and reintroduction—Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range.
 - Reintroduction and translocation—
 - o Augment known populations and reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species.
 - o Research limiting factors contributing to failure of reintroduced individuals and populations.
 - Rodent predation and herbivory—Control rats in the vicinity of all populations.
 - Invertebrate predation and herbivory—Develop and implement methods to control slugs and ants.
 - Climate change adaptation strategy—Assess the modeled effects of climate change on this species and use to determine future landscape needed for the recovery of the species.
 - Alliance and partnership development—Work with the National Park Service, the Plant Extinction Prevention Program, and other land managers to initiate planning and contribute to ecosystem-level restoration and management to benefit this species (USFWS, 2018).

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Region (R1) (USFWS, 2016)

Physical Description

Perennial herbs or subshrubs, pale yellowish green throughout or stems purple-tinged in lower portion of the plant. Stems 3-7 dm long or perhaps longer, ascending to sprawling when longer. Leaves opposite. Leaf blades 4-5.8 cm long, 1.7-2.8 cm wide, ovate to elliptic-ovate. Inflorescences panicle-like, 30-40 cm long. Capsules broadly ovoid, 3.5-4 mm long. (NatureServe, 2015)

Taxonomy

Kartesz (1999) includes *Schiedea hawaiiensis* in *S. diffusa*, however, Wagner et al. (1999) resurrect it from synonymy (the 1990 edition included it). Only known from one individual discovered in 1996 (per Wagner 1999). Also accepted as distinct by Wagner et al. (2012). (NatureServe, 2015)

Historical Range

Schiedea hawaiiensis is endemic to the island of Hawaii in the Hawaiian Islands. It has been recorded from only two locations, both in the northern part of the island. It is on the Pohakuloa Training Area in the saddle between Mauna Kea and Mauna Loa (volcanoes). (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (pigs, goats, sheep, and mouflon), nonnative plants, fire, hurricanes, and drought. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Fire can destroy dormant seeds and plants, even in steep and inaccessible areas. Successive fires can remove habitat for native species by altering microclimate conditions favorable to alien plants. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Severe episodes of drought cannot only directly kill individuals of a species or entire populations, but drought frequently leads to an increase in the number and intensity of forest and brush fires. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (pigs, goats, sheep, mouflon, and rats) is considered an ongoing threat to *Schiedea hawaiiensis* throughout the species range. Non-

native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

Stressor: Small populations (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: *Schiedea hawaiiensis* faces the threat of limited numbers (i.e., there are fewer than 50 individuals in the wild). Habitat destruction or direct predation by ungulates, nonnative plants, drought, and fire are threats to the 25 to 40 individuals of *Schiedea hawaiiensis* (USFWS, 2013).

Stressor:

Exposure:

Response:

Consequence:

SPECIES ACCOUNT: *Schiedea helleri* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/10/1996; Pacific Region (R1) (USFWS, 2016)

Physical Description

Schiedea helleri, a member of the pink family, is a vine. The stems, smooth below and minutely hairy above, are probably prostrate and at least 0.15 m (0.5 ft) long with internodes at least 4 to 15 cm (1.6 to 6 in) long. The opposite leaves are somewhat thick and range from 10 to 14 cm (4 to 5.5 in) long and 4.5 to 6 cm (1.8 to 2.4 in) wide. The leaves are triangular, egg-shaped to heart-shaped, conspicuously three-veined, and nearly hairless to sparsely covered with short, fine hairs, especially along the margins. The perfect flowers occur in loose, open branched clusters, each branch being 20 to 26 cm (8 to 10.2 in) long. The flower contains 3 styles and probably 10 stamens. The fruits are capsules, about 3 to 3.4 mm (0.12 to 0.13 in) long. (USFWS, 1998)

Taxonomy

Genus nearly endemic to Hawaiian Islands, with one species in Tahiti, species endemic to Kauai. (NatureServe, 2015)

Historical Range

See current range/distribution.

Current Range

Endemic to the island of Kauai, state of Hawaii. (NatureServe, 2015)

Critical Habitat Designated

Yes; 2/27/2003.

Legal Description

On February 27, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Schiedea helleri* on the island of Kauai, Hawaii (68 FR 9116 - 9479).

Critical Habitat Designation

The critical habitat designation for *Schiedea helleri* includes three units totaling 2,001 acres in Kauai County, Hawaii. The units are Kauai 11—*Schiedea helleri*—a, b, c.

Kauai 11—*Schiedea helleri*—a: This unit is critical habitat for *Schiedea helleri* and is 483 ha (1,194 ac) on State land (Alakai Wilderness Preserve), containing portions of Halehaha and Halepaakai Streams. This unit provides habitat for three populations of 300 mature, reproducing individuals of the short-lived perennial *Schiedea helleri* and is currently unoccupied. This unit is essential to the conservation of the taxon because it supports habitat that is important to the establishment of additional populations on Kauai in order to reach recovery goals. The habitat features contained in this unit that are essential for this species include, but are not limited to, ridges and steep cliffs in closed *Metrosideros polymorpha*-*Dicranopteris linearis* montane wet forest, *M. polymorpha*-*Cheirodendron* spp. montane wet forest, or *Acacia koa*-*M. polymorpha* montane

mesic forest. This unit is geographically separated from the other two units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Although the Service does not feel that there is enough habitat that currently exists to reach the recovery goal of 8 to 10 populations for this species, this unit is at an appropriate distance from the other units to avoid their destruction by one naturally occurring catastrophic event. Kauai 11—*Schiedea helleri*—b: This unit is critical habitat for *Schiedea helleri* and is 154 ha (381 ac) on State land (Alakai Wilderness Preserve) on portions of Kohua Ridge and the Mohihi-Waialae Trail. This unit provides habitat for two populations of 300 mature, reproducing individuals of the short-lived perennial *Schiedea helleri* and is currently occupied with 50 to 60 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered non-viable. The habitat features contained in this unit that are essential for this species include, but are not limited to, ridges and steep cliffs in closed *Metrosideros polymorpha*-*Dicranopteris linearis* montane wet forest, *M. polymorpha*-*Cheirodendron* spp. montane wet forest, or *Acacia koa*-*M. polymorpha* montane mesic forest. This unit is geographically separated from the other two units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Although the Service does not feel that there is enough habitat that currently exists to reach the recovery goal of 8 to 10 populations for this species, this unit is at an appropriate distance from the other units to avoid their destruction by one naturally occurring catastrophic event. Kauai 11—*Schiedea helleri*—c: This unit is critical habitat for *Schiedea helleri* and is 172 ha (426 ac) on State land (Alakai Wilderness Preserve), containing portions of Kipalau Valley. This unit provides habitat for two populations of 300 mature, reproducing individuals of the short-lived perennial *Schiedea helleri* and is currently unoccupied. This unit is essential to the conservation of the taxon because it supports habitat that is important to the establishment of additional populations on Kauai in order to reach recovery goals. The habitat features contained in this unit that are essential for this species include, but are not limited to, ridges and steep cliffs in closed *Metrosideros polymorpha*-*Dicranopteris linearis* montane wet forest, *M. polymorpha*-*Cheirodendron* spp. montane wet forest, or *Acacia koa*-*M. polymorpha* montane mesic forest. This unit is geographically separated from the other two units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Although the Service does not feel that there is enough habitat that currently exists to reach the recovery goal of 8 to 10 populations for this species, this unit is at an appropriate distance from the other units to avoid their destruction by one naturally occurring catastrophic event.

Primary Constituent Elements/Physical or Biological Features

Within these units, the currently known primary constituent elements of critical habitat include, but are not limited to, the habitat components provided by:

- (i) Ridges and steep cliffs in closed *Metrosideros polymorpha*-*Dicranopteris linearis* montane wet forest, *M. polymorpha*-*Cheirodendron* spp. montane wet forest, or *Acacia koa*-*M. polymorpha* montane mesic forest and containing one or more of the following associated native plant species: *Broussaisia arguta*, *Cheirodendron* spp., *Cibotium* spp., *Cyanea* spp., *Dianella sandwicensis*, *Dubautia* spp., *Elaeocarpus bifidus*, *Hedyotis terminalis*, *Melicope* spp., *Myrsine* spp., *Poa sandwicensis*, *Scaevola procera*, *Syzygium sandwicensis*, or *Viola wailenalenae*; and

(ii) Elevations between 664 and 1,361 m (2,178 and 4,464 ft).

Special Management Considerations or Protections

Existing manmade features and structures within the boundaries of the mapped areas, such as buildings; roads; aqueducts and other water system features, including but not limited to pumping stations, irrigation ditches, pipelines, siphons, tunnels, water tanks, gaging stations, intakes, reservoirs, diversions, flumes, and wells; existing trails; campgrounds and their immediate surrounding landscaped area; scenic lookouts; remote helicopter landing sites; existing fences; telecommunications equipment towers and associated structures and equipment; electrical power transmission lines and distribution, and communication facilities and regularly maintained associated rights-of-way and access ways; radars, telemetry antennas; missile launch sites; arboreta and gardens; heiau (indigenous places of worship or shrines), and other archaeological sites; airports; other paved areas; and lawns and other rural residential landscaped areas do not contain one or more of the primary constituent elements described for each species in paragraph (b) of this section and therefore are not included in the critical habitat designations.

The following management actions are important: Feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas deemed essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas deemed essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Sexual (inferred from USFWS, 1998)

Breeding Season

Adult: February (USFWS, 1998)

Reproduction Narrative

Adult: Three plants were observed flowering by botanists from the National Tropical Botanical Garden in February 1995 (Steve Perlman, NTBG Provenance Report 1995). (USFWS, 1998)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland, cliffs (USFWS, 1998; NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations of approximately 1,070 meters (3,500 feet) (USFWS, 1998)

Environmental Specificity

Adult: Low to medium, with some key requirements (USFWS, 1998)

Habitat Narrative

Adult: *Schiedea helleri* is found on steep cliffs in closed ohia-uluhe montane wet forest on State-owned land, within or close to the Alakai Wilderness Preserve, at approximately 1,070 meters (3,500 feet) elevation. Other native plants growing in association with this population include hapuu, kanawao, olapa, *Cyanea hirtella* (haha), *Dianella sandwicensis* (ukiuki), and *Viola wailenalenae*. The federally endangered *Poa sandwicensis* is also found here (USFWS 1996). (USFWS, 1998)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

Very low (inferred from USFWS, 2010)

Redundancy:

Very low (inferred from USFWS, 2010)

Number of Populations:

3-4 (USFWS, 2017)

Population Size:

<50 (USFWS, 2010)

Population Narrative:

New Status Information: In addition to those populations cited in the previous 5-year review, new observations include the following: • At the time of the last 5-year review in 2010 there were two populations totaling between 85 and 101 individuals on Kauai. Recent surveys confirm individuals at Mohihi in three small subpopulations (this includes one previously unknown occurrence) and one individual at Nawaimaka (NTBG 2012, 2014, 2015; PEPP 2010, 2011, 2013, 2014, 2015). These populations total fewer than 50 individuals. Clark (2016) reports that there are 40 mature plants total in four subpopulations, with the largest subpopulation consisting of 20 individuals (USFWS, 2017).

Threats and Stressors

Stressor: Alien species and fire (NatureServe, 2015)

Exposure:**Response:****Consequence:**

Narrative: Major threats include alien species and fire. (NatureServe, 2015)

Stressor: Habitat modification by pigs (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: Although the recovery plan did not consider pigs (*Sus scrofa*) to be a major problem to this species, botanists since that time have repeatedly observed them as a threat to the habitat. (USFWS, 2010)

Stressor: Human trampling (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: Since weeding was done in the area at Mohihi-Waialae by Kokee Resource Conservation Program, a hunter's trail has been cut right through the population. Human trampling and damage is a concern for this population. (USFWS, 2010)

Stressor: Habitat modification by mule deer and goats (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: Mule deer (*Odocoileus hemionus*) and goats (*Capra hircus*) are also considered threats because they modify the sloping terrain, causing erosion when heavy rains and flooding occur (Perlman 2008). (USFWS, 2010)

Stressor: Invasive introduced species (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: Invasive introduced plant species which modify the habitat and compete with *Schiedea helleri* include *Hedychium gardnerianum* (kahili ginger), *Passiflora mollissima* (banana poka), and *Rubus argutus* (blackberry) (National Tropical Botanical Garden 2008). (USFWS, 2010)

Stressor: Small population size (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: In addition to all of the other threats, species like *Schiedea helleri* that are endemic to small portions of a single island are inherently more vulnerable to extinction than widespread species because of the higher risks posed to a few populations and individuals by random demographic fluctuations and localized catastrophes such as hurricanes, landslides, flooding and disease outbreaks. (USFWS, 2010)

Stressor: Low number of populations (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: The effects of these processes on this single-island endemic are exacerbated by anthropogenic threats, such as habitat loss for human development or predation by introduced species (USFWS 1998). (USFWS, 2010)

Stressor: Climate change loss or degradation of habitat

Exposure:**Response:****Consequence:**

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Schiedea helleri* is extremely vulnerable to the impacts of climate change, with a vulnerability score of 0.948 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). In addition, this assessment classified *S. helleri* as a “wink-out” species. “Wink-out” species are those species with no future climate envelope. No projected suitable climate areas exist for the species to persist in the future. Also, Fortini et al. show that Caryophyllaceae is one of the top four most vulnerable native plant families, and, at the genus level, *Schiedea* had one of the highest vulnerability scores. Therefore, additional management actions are needed to conserve this taxon into the future (USFWS, 2017).

Recovery**Reclassification Criteria:**

1. A total of five to seven populations of each taxon should be documented on Kauai where they now occur or occurred historically. (USFWS, 1998)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1998)
3. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered. (USFWS, 1998)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Kauai where they now occur or occurred historically. (USFWS, 1998)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1998)

3. Each population should persist at this level for a minimum of five consecutive years. (USFWS, 1998)

Recovery Actions:

- In order to prevent this taxon from going extinct, propagation efforts and the maintenance of adequate genetic stock ex situ should be continued. Additional wild seeds should be collected periodically until the cryopreservation method of long-term storage is perfected. This will insure that viable seed stock is available for outplanting. (USFWS, 1998)
- Monitoring of the existing population and attempts to find further populations should be undertaken. This work presents practical difficulties due to the location of one of the largest populations on a steep cliff off Mohihi Stream. Because of the habitat that the *Schiedea helleri* prefers, monitoring populations using rock-climbing techniques could cause damage to the fragile vegetation. Therefore, care must be taken not to damage cliff vegetation. (USFWS, 1998)
- Outplanting using collected seeds should be attempted immediately after further surveys are conducted to identify appropriate areas. These surveys should focus on the following areas where the *Schiedea helleri* are currently and historically found: steep cliff off Mohihi Stream and along the Mohihi Waialeale Trail and Nawaimaka Valley. (USFWS, 1998)
- Given the degraded nature of the Kauai plant cluster's habitat, their precariously low numbers, and the severity of the threats, the highest priority actions must be aimed at protecting all extant wild individuals and populations, managing habitat to enhance survival and ensuring maintenance of adequate genetic stock ex situ. (USFWS, 1995)
- It is hoped that by eliminating current threats through management, populations of the Kauai cluster taxa will expand naturally. However, in certain special instances, wild populations of the Kauai cluster taxa may need to be augmented. (USFWS, 1995)
- Research into various aspects of the life history, habitat, pollinators, reproductive biology, symbionts, optimum requirements for growth, requirements for population viability, and control of threats to each of the Kauai cluster taxa must be carried out to better understand the requirements necessary for perpetuation of these plants. (USFWS, 1995)
- If necessary to meet recovery objectives, populations should be reestablished in areas where they are known to have occurred historically, particularly if genetically uncontaminated, cultivated materials exist which are known to have originated from the historical site. (USFWS, 1995)
- The scientific validity of the recovery objectives should be reviewed as more information becomes available. (USFWS, 1995)
- A public education program is needed to increase awareness of and support for plant recovery efforts in Hawaii. (USFWS, 1995)

Conservation Measures and Best Management Practices:

- Continue to collect seeds for genetic storage and reintroduction. (USFWS, 2010)
- Control introduced invasive plant species around wild plants. (USFWS, 2010)
- Construct large-scale fences around all naturally occurring and reintroduced individuals to control feral ungulates. (USFWS, 2010)
- Assess genetic variability among and within extant populations. (USFWS, 2010)
- Reintroduce individuals into protected suitable habitat within historical range. (USFWS, 2010)

- Work with Hawaii Division of Forestry, The Nature Conservancy of Hawaii, and Wildlife and Hawaii State Parks to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species. (USFWS, 2010)
- Study *Schiedea helleri* populations with regard to population size and structure, geographical distribution, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. (USFWS, 2010)
- Investigate techniques to improve natural recruitment. (USFWS, 2010)
- New Management Actions:
 - NTBG seed bank has two large bulk collections from 2005 from Mohihi Stream. In June, 2008, 19 separate collections were made over two days from all three sites, possibly representing 19 different wild plants. There are at least four different wild plants (founders) that have been established in the NTBG nursery clonally (via cuttings) (NTBG 2017).
 - Lyon Arboretum has a collection from the one founder at Nawaimaka, 10 founders from one of the Nohihi Stream sites, and one founder from another Mohihi site (Lyon Arboretum 2017).
 - The Kokee Rare Plant Facility has 40 plants in their nursery from six founders at one Mohihi site, twelve founders from a second Mohihi site, and one founder from the third. It also has the one founder represented from Nawaimaka (Waialae). All founders are represented clonally (via cuttings; DOAFW 2016).
 - Eighteen plants have been outplanted in Mohihi (DOFAW 2016) (USFWS, 2017).
- Recommendations for Future Actions: No new threats and no other significant new information regarding the species' biological status have been reported since the last 5-year review in 2010. Therefore, the following recommendations for future actions are reiterated for the 5-year review for 2017.
 - Surveys and inventories—Survey for populations of *Schiedea helleri* in areas of potentially suitable habitat.
 - Ungulate monitoring and control—Protect all occurrences against disturbances from feral ungulates. Construct and maintain small-scale fenced exclosures around all populations to prevent imminent extinction.
 - Invasive plant monitoring and control—
 - o Control established ecosystem-altering nonnative invasive plant species around all populations.
 - o Control invasive nonnative species that compete with the species around all populations.
 - Captive propagation for genetic storage and reintroduction—Continue propagation efforts for maintenance of genetic stock.
 - Reintroduction and translocation—Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species.
 - Human interaction monitoring and management—Develop and implement effective measures to reduce impacts of hikers and trail maintenance.
 - Population biology research—Study *Schiedea helleri* populations to determine viable population size and structure, geographical distribution, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats (USFWS, 2017).

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Region (R1) (USFWS, 2016)

Physical Description

Schiedea hookeri is a relatively long-lived perennial of the Caryophyllaceae (pink) family. It is a sprawling or clumped sub-shrub (stems woody at the base) with stems 0.3 to 0.5 m (1 to 1.6 ft) long that curve slightly upward or lie close to the ground in matted clumps. The narrow, oppositely arranged leaves are 3 to 8 cm (1.2 to 3.2 in) long and 0.4 to 1.5-cm (0.2 to 0.6 in) wide. The small, perfect flowers (with both male and female reproductive parts) have no petals and are borne in open, branched clusters that are hairy and somewhat sticky. The fruit is a capsule about 3 mm (0.1 in) long (Wagner et al 1999) (USFWS, 2016).

Historical Range

Schiedea is a genus endemic to the Hawaiian Islands. Trends in distribution indicate range restriction in *Schiedea hookeri*, which historically occurred in the Waianae Mountains of Oahu and perhaps occurred on Maui (although the single fragmentary collection from East Maui may represent another species) (61 FR 53108) (USFWS, 2016).

Current Range

Currently, this species occurs only in the Waianae Mountains (USFWS, 2016).

Critical Habitat Designated

Yes; 6/13/2003.

Legal Description

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea hookeri* under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Schiedea hookeri* (77 FR 57648-57862). The critical habitat designation includes 27 critical habitat units, which encompass approximately 8,806 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Schiedea hookeri* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Schiedea hookeri* includes 27 critical habitat units, covering five ecosystem types, which encompass approximately 8,806 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Dry—Units 1, 2, 8, 9, 10, 11; , Oahu— Lowland Mesic—Units 1, 2, 3; , Oahu—Lowland Wet—Units 1, 2, 3, 4, 5; Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8; Oahu—Wet Cliff—Units 1, 2, 3, 4, 5.

Oahu—Lowland Dry—Unit 1 [102 ac (41 ha)]; This area consists of 49 ac (20 ha) of State land and 53 ac (22 ha) of privately owned land in the Waianae Mountains, extending from Haili Gulch to

Kawaipahai. Oahu—Lowland Dry— Unit 2 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland dry ecosystem in the Waianae Mountains, on Federal land within Kaena Point State Park. Oahu—Lowland Dry—Unit 8 [99 ac (40 ha)]. Oahu—This area consists of 96 ac (40 ha) of privately owned land and 3 ac (1 ha) of State land as part of the old railroad right-of-way in the lowland dry ecosystem, at the Kalaeloa Barber's Point Harbor area. Oahu—Lowland Dry—Unit 9 [37 ac (15 ha)]. This area consists of 17 ac (7 ha) of City and County land, 3 ac (1 ha) of privately owned land, 1 ac (0.5 ha) of State land, and 16 ac (6 ha) of Federal (Pearl Harbor NWR) land in the lowland dry ecosystem at Kalaeloa. Oahu—Lowland Dry— Unit 10 [43 ac (17 ha)]. This area consists of 43 ac (17 ha) of State land (DHHL) in the lowland dry ecosystem at Kalaeloa. Oahu—Lowland Dry—Unit 11 [166 ac (67 ha)]. This area consists of 166 ac (67 ha) of federal land (U.S. Navy) in the lowland dry ecosystem at Kalaeloa.

Oahu—Lowland Mesic—Unit 1 [4,448 ac (1,800 ha)]. This area consists of 3,565 ac (1,443 ha) of State land, 583 ac (236 ha) of City and County of Honolulu land, 22 ac (9 ha) of Federal land, and 277 ac (112 ha) of privately owned land in the lowland mesic ecosystem in the Waianae Mountains, encompassing a large area including the north slopes of Mt. Kaala, from the Pahole NAR to the Kaala NAR, and south to the Waianae Kai Forest Reserve (FR). Oahu—Lowland Mesic—Unit 2 [1,063 ac (430 ha)]. This area consists of 1,063 ac (430 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Puuhapapa south to Puukaua. Oahu—Lowland Mesic—Unit 3 [353 ac (143 ha)]. This area consists of 353 ac (143 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Pohakea Pass to Kaiakuakai Gulch.

Oahu—Lowland Wet—Unit 1 [541 ac (219 ha)]. This area consists of 428 ac (173 ha) of State land and 112 ac (46 ha) of City and County of Honolulu land in the lowland wet ecosystem on the windward side of the Waianae Mountains, and partially within the Mokuleia and Waianae Kai Forest Reserves. Oahu—Lowland Wet—Unit 2 [20 ac (8 ha)]. This area consists of 19 ac (8 ha) of State land in the lowland wet ecosystem on the windward side of the Waianae Mountains at Puuhapapa. Oahu—Lowland Wet—Unit 3 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland wet ecosystem on the windward side of the Waianae Mountains at Puukanehoa. Oahu—Lowland Wet—Unit 4 [27 ac (11 ha)]. This area consists of 27 ac (11 ha) in the lowland wet ecosystem on the windward side of the Waianae Mountains on State land at Puukaua.

Oahu—Dry Cliff—Unit 1 [49 ac (20 ha)]. This area consists of 49 ac (20 ha) in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the rim of Makua Valley. Oahu—Dry Cliff—Unit 2 [412 ac (167 ha)]. This area consists of 320 ac (130 ha) of State land and 91 ac (37 ha) of City and County of Honolulu land in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the ridge from Keaau to Ohikilolo. Oahu—Dry Cliff—Unit 3 [450 ac (182 ha)]. This area consists of 349 ac (141 ha) of City and County of Honolulu land and 101 ac (41 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the eastern rim of Makaha Valley along Kamaileunu Ridge. Oahu—Dry Cliff—Unit 4 [24 ac (10 ha)]. This area consists of 24 ac (10 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along Kauaopuu ridge, which divides Waianae Kai and Lualualei valleys. Oahu—Dry Cliff—Unit 6 [149 ac (60 ha)]. This area consists of 149 ac (60 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Lualualei Valley from Puukanehoa to Puukaua. Oahu—Dry Cliff—Unit 7a [68 ac (27 ha)]. This area consists of 68 ac (27 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley to Pohakea. Oahu—Dry Cliff—Unit 7b [38

ac (16 ha)]. This area consists of 38 ac (16 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley at Palikea. Oahu—Dry Cliff—Unit 8 [259 ac(105 ha)]. This area consists of 259 ac (105 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Nanakuli Valley from Palehua to Puumanawanua, and partially within the Nanakuli Forest Reserve.

Oahu—Wet Cliff—Unit 1 [235 ac (95 ha)]. This area consists of 167 ac (68 ha) of State land, 68 ac (28 ha) of City and County of Honolulu land, and less than 1 ac (less than 1 ha) of privately owned land in the wet cliff ecosystem in the Waianae Mountains, near the summit of Kaala, and partially within the Mokuleia and Waianae Kai FRs and the Kaala Natural Area Reserve. Oahu—Wet Cliff—Unit 2 [3 ac (1 ha)]. This area consists of 3 ac (1 ha) of State land in the wet cliff ecosystem in the Waianae Mountains at Puuhapapa, within a small area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. Oahu—Wet Cliff—Unit 3 [16 ac (6 ha)]. This area consists of 16 ac (6 ha) in the wet cliff ecosystem on State land in the Waianae Mountains at Puukanehoa, partially within an area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. Oahu—Wet Cliff—Unit 4 [23 ac (9 ha)]. This area consists of 23 ac (9 ha) in the wet cliff ecosystem on State land in the Waianae Mountains at Puukaua, partially overlapping an area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and recently acquired by the State. Oahu—Wet Cliff—Unit 5 [31 ac (13 ha)]. This area consists of 31 ac (13 ha) of State land in the wet cliff ecosystem in the Waianae Mountains, at Palikea and north of Palikea.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea hookeri* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Schiedea hookeri* occurs within the Lowland dry, Lowland mesic, Lowland wet, Dry cliff and Wet cliff ecosystems in the Waianae Mountain caldera complex:

Oahu—Lowland Dry—Units 1, 2, 8, 9, 10, 11. (A) Elevation: <3,300 ft (<1,000 m). (B) Annual Precipitation: <50 in (<130 cm). (C) Substrate: Weathered silty loams to stony clay, rocky ledges, little weathered lava. (D) Canopy: *Diospyros*, *Myoporum*, *Pleomele*, *Santalum*, *Sapindes*. (E) Subcanopy: *Chamaesyce*, *Dodonaea*, *Leptecophylla*, *Osteomeles*, *Psydrax*, *Scaevola*, *Wikstroemia*. (F) Understory: *Alyxia*, *Artemisia*, *Bidens*, *Chenopodium*, *Nephrolepis*, *Peperomia*, *Plumbago*, *Sicyos*, *Sida*, *Waltheria*.

Oahu— Lowland Mesic—Units 1, 2, 3. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. (E) Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. (F) Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Oahu—Lowland Wet—Units 1, 2, 3, 4, 5. (A) Elevation: <3,000 ft (<1,000 m). (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. (D) Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. (E) Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. (F) Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepidia*.

Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8. (A) Elevation: unrestricted. (B) Annual Precipitation: < 75 in (<190 cm). (C) Substrate: >65 degree slope, rocky talus. (D) Canopy: None. (E) Subcanopy: Antidesma, Chamaesyce, Diospyros, Dodonaea. (F) Understory: Bidens, Eragrostis, Melanthera, Schiedea.

Oahu—Wet Cliff—Units 1, 2, 3, 4, 5. (A) Elevation: unrestricted. (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: >65 degree slope, shallow soils, weathered lava. (D) Canopy: None. (E) Subcanopy: Broussaisia, Cheirodendron, Leptecophylla, Metrosideros. (F) Understory: Bryophytes, Ferns, Coprosma, Dubautia, Kadua, Peperomia.

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Schiedea hookeri* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Likely insect pollinated (USFWS, 2016)

Lifespan

Adult: <10 years (USFWS, 2016)

Reproduction Narrative

Adult: *Schiedea hookeri* is an outcrossing species probably pollinated by insects. Mature fruits have been observed in June and August, but seed dispersal mechanisms are unknown. This species varies considerably throughout its range in potential for vegetative (clonal) growth and spread. Upright plants at one site, for example, show little clonal potential, whereas decumbent plants at another site exhibit clonal growth by nodal rooting (68 FR 35950; Service 1999a). Plant longevity is probably similar to that of other small, semi-woody shrubs that live less than 10 years (i.e., short-lived perennials). Other demographic information for *S. hookeri* in the wild is unknown, including phenology, number of seeds produced, age at sexual maturity, survivorship to sexual maturity, number of years in reproductive condition, survivorship during reproductive life, timing of reproductive output, pollination and seed dispersal, vegetative reproduction and specific environmental requirements (USFWS, 2016).

Habitat Type

Adult: Mesic or dry lowland forest (USFWS, 2016)

Habitat Narrative

Adult: *Schiedea hookeri* occurs in the understory of diverse mesic or dry lowland forests typically dominated by *Metrosideros polymorpha* or *Diospyros* species, at elevations ranging between 350 and 900 m (1,148 and 2,953 ft) (61 FR 53108; 68 FR 35950; Wagner et al 1999). It usually grows on slopes, cliffs and cliff bases, rock walls, and ledges (USFWS, 2016).

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Seed dispersal mechanisms are unknown (USFWS, 2016).

Population Information and Trends

Population Trends:

Unknown

Number of Populations:

~8 (USFWS, 2018)

Population Size:

~500 individuals (USFWS, 2018)

Population Narrative:

New Status Information: • The IUCN recently estimated as many as 500 individuals in eight subpopulations on O'ahu (Brueggemann et al. 2016). These numbers, however, are mostly from old observations from the early 2000s (US Army 2017), and considering the degradation of habitat, are likely lower. • In 2012, critical habitat was designated in 28 units on O'ahu in five ecosystems (lowland dry, lowland mesic, lowland wet, dry cliff, and wet cliff) (10,447 ac; 4,229 ha) (77 FR 57648, September 18, 2012) (USFWS, 2018).

Threats and Stressors

Stressor: Invertebrates (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: *Schiedea hookeri* is particularly vulnerable to predation by non-native slugs and snails (61 FR 53108). Seedlings from other *Schiedea* species that occur in mesic or wet sites are apparently consumed by these alien invertebrates (USFWS, 2016).

Stressor: Lack of pollinators (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: *Schiedea* species that occur in dry areas, however, produce abundant seedlings following winter rains, perhaps because drier sites have fewer non-native invertebrate herbivores (Service 1999a). *Schiedea hookeri* also may suffer from a lack of pollinators (Service 1999a) (USFWS, 2016).

Stressor: Fire (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Wildfire ignited by military training activities is a threat to this species in the Makua and Schofield Barracks action areas (USFWS, 2016).

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: We previously reported that climate change may pose a threat to this species, anticipating an analysis by 2013. The assessment conducted by Fortini et al. (2013) concluded that *Schiedea hookeri* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.662 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions may be needed to conserve this taxon into the future (USFWS, 2018).

Recovery

Delisting Criteria:

Due to limited knowledge of life history requirements for short-term and long-term survival, the recovery plan for this species specifies interim objectives to downlisting and delisting that involve stabilization of all existing populations (Service 1999a). Conservation actions required for stabilization are described in the “Stabilization” section of the project description for this opinion. However, *S. hookeri* is not included as a target taxon for stabilization under the Makua Implementation Plan Addendum. The Army does not actively manage this species in the Makua or Schofield Barracks action areas (Service 2003a). Research on slug control in forest settings is needed to find ways to reduce invertebrate threats to *S. hookeri* and associated native plants (USFWS, 2016).

Conservation Measures and Best Management Practices:

- No information is available on conservation management for *Schiedea hookeri* since it was listed as endangered. However, about 128 individuals (30 percent of all remaining individuals) of this species occur action area in management units where they will benefit from population unit and/or ecosystem-level protection. The management units include Keaau and Kahanahaiki, which are not fenced; and Kaluakauila and Ohikilolo, which are fenced. The Nature Conservancy of Hawaii’s long-range management plan for Honouliuli Preserve includes management actions to control non-native plants, feral ungulates, and fire, and to recover rare species and restore native habitats; this plan will benefit any *S. hookeri* within the preserve. This species is represented in ex situ collections that include nine cuttings in a nursery (Harold L. Lyon Arboretum) and 30 plants in a botanical garden (Waimea Valley Audubon Center) (Service 2005b) (USFWS, 2016)
- New Management Actions: • Surveys and inventories—Although *Schiedea hookeri* is not covered under the Army INRMP, the Army Natural Resources team monitors known individuals within and around their management units in the Wai’anae Mountains of O’ahu. They reported populations of this species in the following management units: Kaluakauila, Kamā’ili, South Hale’au’au, and Mohiākea (total number of individuals not reported) (US Army 2010, 2016, 2017). They have monitored 11 plants, 10 in one location in Palikea gulch, and 1 in another location in Manuwai,

- within the last five years (US Army 2017). • Captive propagation for genetic storage and reintroduction—
- o The University of California-Irvine reported at least 13 individuals in their nursery representing three wild individuals from Wai‘anae Kai and one founder from Kaluaa (UC-Irvine 2014, 2017).
 - o Waimea Arboretum reported 16 plants in storage representing two wild individuals in 2013; 90 plants representing two individuals (2014); 36 plants representing two individuals (2015), and 40 plants representing two individuals (2017) (USFWS, 2018).
- Recommendations for Future Actions: We are not aware of any new threats or significant new information regarding the species’ biological status since the last 5-year review in 2011. Thus, the following recommendations for future actions are reiterated for the 5-year review for 2018. • Ungulate monitoring and control—Maintain existing fences and construct additional fences to protect populations from the negative impacts of feral ungulates. • Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations of *S. hookeri*. • Rodent predation and herbivory—Control rats in the vicinity of known populations. • Slug herbivory—Develop and implement methods to control slugs. • Captive propagation for genetic storage and reintroduction—Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. • Reintroduction and translocation—Augment known populations and reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. • Human disturbance—Fire mortality and reduced viability—Develop and implement a fire management plan for populations not within an Army management unit. • Stochastic events—Reduced viability—Research genetic variation between populations. • Climate change adaptation strategy—Assess the modeled effects of climate change on this species and use to determine future landscape needed for its recovery. • Alliance and partnership development—Work with the Division of Forestry and Management, the Army Natural Resources team, and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2018).

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Region (R1) (USFWS, 2016)

Physical Description

Perennial herbs or subshrubs, pale yellowish green throughout. Stems 4.0-7.6 dm long, ascending to sprawling when longer. Leaves opposite. Leaf blades 4.5-10.5 cm long, 1.4-2.6 cm wide, lanceolate to oblong-elliptic. Inflorescence panicle-like, 40-50 cm long. Capsules ovoid, 3.7-4.2 mm long. (NatureServe, 2015)

Taxonomy

New species; published in Novon 9: 284-287. 1999. (NatureServe, 2015)

Historical Range

See current range/distribution.

Current Range

Endemic to the island of Maui in the Hawaiian Islands. It was discovered at a location on the north flank of Haleakala in the Hanawi Natural Area Reserve (NatureServe, 2015).

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea jacobii* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes five detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Schiedea jacobii* includes five CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Montane Wet—Unit 1 (and) *Palmeria dolei*—Unit 10—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 10— Montane Wet This area consists of 1,313 ac (531 ha) of State land and 798 ac (323 ha) of privately owned land, at Haiku Uka on the northern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Cyanea duvalliorum*, *C. maritae*, *C. mceldowneyi*, *Huperzia mannii*, *Melicope balloui*, and *Phyllostegia pilosa*, and by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 1 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp.

haleakalaensis, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 2 (and) *Palmeria dolei*—Unit 11—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 11— Montane Wet This area consists of 4,075 ac (1,649 ha) of State land, 9,633 ac (3,898 ha) of privately owned land, and 875 ac (354 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Puukaukanu and upper Waihoi Valley, on the northern and northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Geranium hanaense*, *G. multiflorum*, and *Wikstroemia villosa*, and by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 2 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea glabra*, *C. maritae*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, and *Schiedea jacobii*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 3 (and) *Palmeria dolei*—Unit 12—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 12— Montane Wet This area consists of 2,228 ac (902 ha) of federally owned land (Haleakala National Park) in Kipahulu Valley, on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. maritae*, and *Melicope ovalis*, and by the forest bird, *kiwikiu* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 3 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea duvalliorum*, *C. glabra*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P.*

mannii, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest bird, the akohekohe (*Palmeria dolei*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 4 (and) *Palmeria dolei*—Unit 13—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 13— Montane Wet This area consists of 180 ac (73 ha) of State land and 1,653 ac (669 ha) of federally owned land (Haleakala National Park), in Kaapahu Valley on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *Cyrtandra ferripilosa*, and *Huperzia mannii*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 4 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea duvalliorum*, *C. glabra*, *C. mceldowneyi*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 5 (and) *Palmeria dolei*—Unit 14—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 14— Montane Wet This area consists of 222 ac (90 ha) of State land, and 165 ac (67 ha) of federally owned land (Haleakala National Park), near Kaumakani on the eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plant *Bidens campylotheca* ssp. *pentamera*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 5 is not currently occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the

reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea jacobii* critical habitat consists of one component. Montane wet (east Maui) (81 FR 17790-18110):

Ecosystem: Montane Wet. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: >75 in (>190 cm). Substrate: Well-developed soils, montane bogs. Canopy: *Acacia*, *Charpentiera*, *Cheirodendron*, *Metrosideros*. Subcanopy: *Broussaisia*, *Cibotium*, *Eurya*, *Ilex*, *Myrsine*. Understory: *Ferns*, *Carex*, *Coprosma*, *Leptecophylla*, *Oreobolus*, *Rhynchospora*, *Vaccinium*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire,

drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History

Food/Nutrient Resources

Adult: No information found.

Habitat Type

Adult: Wet cliffs (USFWS, 2016)

Spatial Arrangements of the Population

Adult: Clumped (inferred from USFWS, 2016)

Environmental Specificity

Adult: Narrow/specialist (inferred from USFWS, 2016)

Tolerance Ranges/Thresholds

Adult: Low (inferred from USFWS, 2016)

Site Fidelity

Adult: High (inferred from USFWS, 2016)

Habitat Narrative

Adult: Discovered in 1992, the single occurrence consisted of nine individuals along wet cliffs between Hanawi Stream and Kuhiwa drainage (in Hanawi Natural Area Reserve), in the montane wet ecosystem on east Maui (Wagner et al. 1999j, p. 286) (USFWS, 2016). Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations (one).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: No information found.

Population Information and Trends**Population Trends:**

Possible extirpated in the wild unless the 2011 outplanting was successful.

Population Narrative:

Schiedea jacobii (NCN), a short-lived perennial herb or subshrub in the pink family (Caryophyllaceae), occurs only on Maui (Wagner et al. 1999j, p. 284). Discovered in 1992, the single occurrence consisted of nine individuals along wet cliffs between Hanawi Stream and Kuhiwa drainage (in Hanawi NAR), in the montane wet ecosystem on east Maui (Wagner et al. 1999j, p. 286). By 1995, only four plants could be relocated in this location. It appeared that the other five known individuals had been destroyed by a landslide (Wagner et al. 1999j, p. 286). In 2004, one seedling was observed in the same location, and in 2010, no individuals were relocated (Perlman 2010, in litt.). The State of Hawaii plans to outplant propagated individuals in a fenced area in Hanawi Natural Area Reserve in 2011 (Oppenheimer 2010a, in litt.; Perlman 2010, in litt.) (USFWS, 2016).

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (goats, axis deer, and cattle), drought, landslides, treefalls, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Drought, landslides, and treefalls destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (goats, axis deer, cattle, and slugs) is considered an ongoing threat to *Schiedea jacobii* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

Stressor: Small populations (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: *Schiedea jacobii* faces the threat of limited numbers (i.e., there are fewer than 50 individuals in the wild). The only known wild individuals of *Schiedea jacobii* were likely destroyed by landslides because of their location along wet cliffs between Hanawi Stream and Kuhiwa drainage in the montane wet ecosystem on east Maui. The State plans to outplant propagated individuals in Hanawi Natural Area Reserve in 2011 (USFWS, 2013).

Recovery

SPECIES ACCOUNT: *Schiedea kaalae* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/29/1991; Pacific Region (R1) (USFWS, 2016)

Physical Description

Schiedea kaalae is a short-lived perennial of the Caryophyllaceae (pink) family. It has a short woody caudex (perennial stem at the ground surface) less than 20 cm (8 in) tall, with short branches that trail along the ground and end in rosettes of thick, oppositely arranged leaves. The small, perfect flowers (with both male and female reproductive parts) are borne in open, branched clusters up to 40 cm (15.6 in) long. The fruit is a small capsule filled with tiny, dark seeds (Wagner et al 1999; Makua Implementation Team 2003).

Current Range

Schiedea is a genus endemic to the Hawaiian Islands. Historic data indicate *Schiedea kaalae* was known from the north-central and south-central Waianae Mountains and the northern Koolau Mountains of Oahu. When listed in 1991, there were five occurrences in the Waianae Mountains and two occurrences in the Koolau Mountains that together totaled less than 100 individuals (56 FR 55770). In 2003, eight population units totaling 24 to 25 individuals indicated a steady decline for this species (Makua Implementation Team 2003). The latest information available indicates an increasing in detection due to more diligent survey effort and augmentation, with 10 population units totaling 235 individuals located on Federal, State, and private lands (68 FR 35950) (Table SB 34). Of these, 62 individuals are naturally occurring and 173 are augmentations from greenhouse-propagated stock. A new population unit was recently discovered at Kahana, and additional individuals were discovered at the Makua population unit (U.S. Army Garrison 2005b). None of the population units have reached the numeric targets for stabilization (defined as 50 mature individuals for short-lived perennials).

Critical Habitat Designated

Yes; 9/18/2012.

Legal Description

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea kaalae* under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Schiedea kaalae* (77 FR 57648-57862). The critical habitat designation includes 20 critical habitat units, which encompass approximately 13,765 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Schiedea kaalae* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Schiedea kaalae* includes 20 critical habitat units, covering three ecosystem types, which encompass approximately 13,765 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Mesic—

Units 1, 2, 3, 4, 5, 6, 7; Oahu—Lowland Wet—Units 1, 2, 3, 4, 5; Oahu— Wet Cliff—Units 1, 2, 3, 4, 5, 6, 7, 8.

Oahu—Lowland Mesic—Unit 1 [4,448 ac (1,800 ha)]. This area consists of 3,565 ac (1,443 ha) of State land, 583 ac (236 ha) of City and County of Honolulu land, 22 ac (9 ha) of Federal land, and 277 ac (112 ha) of privately owned land in the lowland mesic ecosystem in the Waianae Mountains, encompassing a large area including the north slopes of Mt. Kaala, from the Pahole NAR to the Kaala NAR, and south to the Waianae Kai Forest Reserve (FR). Oahu—Lowland Mesic—Unit 2 [1,063 ac (430 ha)]. This area consists of 1,063 ac (430 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Puuhapapa south to Puukaua. Oahu—Lowland Mesic—Unit 3 [353 ac (143 ha)]. This area consists of 353 ac (143 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Pohakea Pass to Kaiakuakai Gulch. Oahu—Lowland Mesic—Unit 4 [20 ac (8 ha)]. This area consists of 20 ac (8 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, between the Waipilopilo and Hanaimoa gulches, on State-owned land within the Hauula Forest Reserve. Oahu—Lowland Mesic—Unit 5 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, in Maakua Gulch and ridge; is State-owned; and within the Hauula FR. Oahu—Lowland Mesic—Unit 6 [247 ac (100 ha)]. This area consists of 12 ac (5 ha) State land and 235 ac (95 ha) of privately owned land in the lowland mesic ecosystem on the windward side of the Koolau Mountains, inland of Kaaawa Point, and is partially within Ahupuaa O Kahana State Park. Oahu—Lowland Mesic—Unit 7 [1,669 ac (676 ha)]. This area consists of 681 ac (276 ha) of State land, 129 ac (52 ha) of City and County of Honolulu land, and 852 ac (345 ha) of privately-owned land in the lowland mesic ecosystem on the leeward side of the Koolau Mountains, on Waialae Nui ridge.

Oahu—Lowland Wet—Unit 1 [541 ac (219 ha)]. This area consists of 428 ac (173 ha) of State land and 112 ac (46 ha) of City and County of Honolulu land in the lowland wet ecosystem on the windward side of the Waianae Mountains, and partially within the Mokuleia and Waianae Kai Forest Reserves. Oahu—Lowland Wet—Unit 2 [20 ac (8 ha)]. This area consists of 19 ac (8 ha) of State land in the lowland wet ecosystem on the windward side of the Waianae Mountains at Puuhapapa. Oahu—Lowland Wet—Unit 3 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland wet ecosystem on the windward side of the Waianae Mountains at Puukanehoa. Oahu—Lowland Wet—Unit 4 [27 ac (11 ha)]. This area consists of 27 ac (11 ha) in the lowland wet ecosystem on the windward side of the Waianae Mountains on State land at Puukaua. Oahu—Lowland Wet—Unit 5 [74 ac (30 ha)]. This area consists of 74 ac (30 ha) of State land in the lowland wet ecosystem, on the windward side of the Waianae Mountains at Palikea.

Oahu—Wet Cliff—Unit 1 [235 ac (95 ha)]. This area consists of 167 ac (68 ha) of State land, 68 ac (28 ha) of City and County of Honolulu land, and less than 1 ac (less than 1 ha) of privately owned land in the wet cliff ecosystem in the Waianae Mountains, near the summit of Kaala, and partially within the Mokuleia and Waianae Kai FRs and the Kaala Natural Area Reserve. Oahu—Wet Cliff—Unit 2 [3 ac (1 ha)]. This area consists of 3 ac (1 ha) of State land in the wet cliff ecosystem in the Waianae Mountains at Puuhapapa, within a small area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. Oahu—Wet Cliff—Unit 3 [16 ac (6 ha)]. This area consists of 16 ac (6 ha) in the wet cliff ecosystem on State land in the Waianae Mountains at Puukanehoa, partially within an area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. Oahu—Wet Cliff—Unit 4 [23 ac (9 ha)]. This area consists of 23 ac (9 ha) in the wet

cliff ecosystem on State land in the Waianae Mountains at Puukaua, partially overlapping an area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and recently acquired by the State. Oahu—Wet Cliff—Unit 5 [31 ac (13 ha)]. This area consists of 31 ac (13 ha) of State land in the wet cliff ecosystem in the Waianae Mountains, at Palikea and north of Palikea. Oahu—Wet Cliff—Unit 6 [151 ac (61 ha)]. This area consists of 151 ac (61 ha) in the wet cliff ecosystem on State land on the windward side of the Koolau Mountains in Kaipapau Gulch, entirely within the Kaipapau Forest Reserve. Oahu—Wet Cliff—Unit 7 [144 ac (58 ha)]. This area consists of 144 ac (58 ha) in the wet cliff ecosystem in State land on the windward side of the Koolau Mountains in Hauula Gulch, entirely within the Hauula Forest Reserve. Oahu—Wet Cliff—Unit 8 [4,649 ac (1,881 ha)]. This area consists of 1,479 ac (598 ha) of State land, 1,281 ac (519 ha) of City and County of Honolulu land, 5 ac (2 ha) of Federal land, and 1,884 ac (762 ha) of privately owned land, in the wet cliff ecosystem along the summit of the Koolau Mountains, overlapping portions of Sacred Falls State Park, the Waiahole FR (Waiahole and Iolekaa sections), the Kaneohe and Honolulu Watershed FRs, and the Nuana Pali State Wayside.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea kaalae* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Schiedea kaalae* occurs within the Lowland mesic, Lowland wet and Wet cliff ecosystems in the Waianae Mountain caldera complex and the Lowland mesic and Wet cliff ecosystems in the Koolau Mountain caldera complex:

Oahu—Lowland Mesic—Units 1, 2, 3, 4, 5, 6, 7. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. (E) Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. (F) Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Oahu—Lowland Wet—Units 1, 2, 3, 4, 5. (A) Elevation: <3,000 ft (<1,000 m). (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. (D) Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. (E) Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. (F) Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Oahu—Wet Cliff—Units 1, 2, 3, 4, 5, 6, 7, 8. (A) Elevation: unrestricted. (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: >65 degree slope, shallow soils, weathered lava. (D) Canopy: None. (E) Subcanopy: *Broussaisia*, *Cheirodendron*, *Leptecophylla*, *Metrosideros*. (F) Understory: *Bryophytes*, *Ferns*, *Coprosma*, *Dubautia*, *Kadua*, *Peperomia*.

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Schiedea kaalae* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats

will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History

Food/Nutrient Resources

Lifespan

Adult: probably <10 years

Breeding Season

Adult: flowers from March through June

Reproduction Narrative

Adult: Schiedea kaalae flowers from March through June. Cultivated plants are capable of self-pollination, but *S. kaalae* is an outcrossing species that requires pollinators, probably insects, for fruit production (Wagner et al 2005). In the field, biologists have observed a non-native syrphid fly visiting the plants (Makua Implementation Team 2003). Plant longevity probably is similar to that of other small, semi-woody shrubs that live less than 10 years (i.e., short-lived perennials) (Makua Implementation Team 2003). Other demographic information on *S. kaalae* in the wild is unknown, including number of seeds produced, age at sexual maturity, survivorship to sexual maturity, number of years in reproductive condition, survivorship during reproductive life, timing of reproductive output, pollination and seed dispersal, vegetative reproduction and specific environmental requirements.

Habitat Type

Adult: Mesic to wet forest

Habitat Narrative

Adult: Schiedea kaalae in the Waianae Mountains is consistently found on steep slopes and shaded sites in the understory of diverse mesic forest and wet forest, usually in gulch bottoms or low to mid gulch slopes, at elevations between 210 to 790 m (689-2,592 ft). It often grows on slopes with sparse groundcover and occasionally in cracks in rock embankments. In the Koolau Mountains, *S. kaalae* occurs in gulch bottoms and on lower gulch slopes within mesic to wet habitats, some of which are constantly wet from seeping water. Plants can grow on gentle to moderate slopes, steep rock embankments, and nearly vertical cliffs (56 FR 55770; Makua Implementation Team 2003). Where *S. kaalae* occurs in the same drainages as its relatives *S. hookeri*, *S. nuttallii*, *S. obovata*, and *S. pentandra*, it is usually found in the drier areas.

Dispersal/Migration

Population Information and Trends

Number of Populations:

10

Population Size:

235

Population Narrative:

In 2003, eight population units totaling 24 to 25 individuals indicated a steady decline for this species (Makua Implementation Team 2003). The latest information available indicates an increasing in detection due to more diligent survey effort and augmentation, with 10 population units totaling 235 individuals located on Federal, State, and private lands (68 FR 35950) (Table SB 34). Of these, 62 individuals are naturally occurring and 173 are augmentations from greenhouse-propagated stock. A new population unit was recently discovered at Kahana, and additional individuals were discovered at the Makua population unit (U.S. Army Garrison 2005b). None of the population units have reached the numeric targets for stabilization (defined as 50 mature individuals for short-lived perennials). Demographic information in the wild is unknown, as *Schiedea kaalae* seedlings and immature plants are seldom seen, especially in Waianae population units. The apparent lack of recruitment is probably due to seedling predation by non-native slugs and snails (Makua Implementation Team 2003; U.S. Army Garrison 2004a, 2005b). The Nature Conservancy of Hawaii has propagated and outplanted *S. kaalae* from seed and cuttings, but no seedlings have been observed at those outplanting sites (U.S. Army Garrison 2004a). No information is available on the survival rate of immature outplantings. Individuals of this species are at risk from training-related wildfire in the Makua and Schofield Barracks Military Reservation action areas. Thus, *S. kaalae* is characterized by extremely low numbers that are increasing only by augmentation and occasional discovery of new occurrences.

Threats and Stressors**Stressor:****Exposure:****Response:****Consequence:**

Narrative: *Schiedea kaalae* was listed as endangered because of major ecosystem-level threats to its survival and recovery. *Schiedea kaalae* is particularly vulnerable to predation by non-native slugs and snails. One study noted, for example, that seedling mortality for the related species *S. obovata* doubled when exposed to slug herbivory (U.S. Army Garrison 2005b). In addition to the very low risk of training-related wildfire from military activities at Makua, one individual of *S. kaalae* is exposed to the risk of training-related wildfire at Mohiakea Gulch in the Schofield Barracks Military Reservation action area (Service 2003a). Most importantly, occurrences of *Schiedea kaalae* are vulnerable to extirpation from naturally occurring events and/or reduced reproductive vigor due to small population size and limited distribution (56 FR 55770; 68 FR 35950; Service 1995a, 1998a). In addition, *S. kaalae* and the related species *S. nuttallii* and *S. pentandra* are characterized by low isozyme variability and inbreeding due to small population size (Wagner et al 2005). Reductions in population size could result in expression of inbreeding depression among progeny, for example in reduced reproductive vigor, with potentially deleterious consequences for the long-term persistence of this species. However, low levels of genetic diversity in *S. kaalae* populations may not be detrimental to the species as plants from populations that appear to have undergone repeated self-fertilization are vigorous in cultivation (Makua Implementation Team 2003). Nonetheless, the science of conservation biology has documented a general pattern of population collapse for a wide range of plant and animal species (Dennis et al 1991; Schemske et al 1994; Morris et al 1999; Menges 2000). According to this pattern, *S. kaalae* already is in a phase of “quasi-extinction,” with numbers that have

declined to the point where demographic stochasticity alone can result in extirpation. Thus, *S. kaalae* has a very high background risk of species extinction, and any additional threats could eliminate expectation of its long-term persistence.

Recovery

Conservation Measures and Best Management Practices:

- Conservation actions that should be implemented for the recovery of *Schiedea kaalae* are described in the introduction to the “Status and Environmental Baseline of the Species and Critical Habitat” section. Due to limited knowledge of life history requirements for short-term and long-term survival, the recovery plan for this species specifies interim objectives to downlisting and delisting that involve stabilization of all existing populations (Service 1995a, 1998a). The three population units identified for stabilization of *S. kaalae* are all located on State or private lands. The Army proposes to manage an additional two population units for stabilization at Maakua and Kahana, in the Koolau Mountains (U.S. Army Garrison 2005b). Research on slug control in forest settings is needed to find ways to reduce invertebrate threats to *S. kaalae* and associated native plants.
- Ongoing Conservation Actions: The Makua Implementation Team (2003) has developed stabilization protocols for *Schiedea kaalae*, which are incorporated in the Army’s Makua Implementation Plan Addendum (U.S. Army Garrison 2005a). Population units of *S. kaalae* are fenced in the Pahole, South Ekahanui, Kaluua and Waieli, Makuaa, Mohiakea, and North Palawai population units; weeds are partially controlled only in the Mohiakea, North Palawai, and Kahana population units (U.S. Army Garrison 2005b). In addition, this species occurs in three management units where it will benefit from population unit and/or ecosystem-level protection. The management units include Lower Kahana, which is not fenced; and Ekahanui and Pahole, which are fenced. The South Ekahanui population unit is augmented by The Nature Conservancy of Hawaii. The Nature Conservancy of Hawaii’s long-range management plan for Honouliuli Preserve includes management actions to control non-native plants, feral ungulates, and fire, and to recover rare species and restore native habitats, including the South Ekahanui population unit of *S. kaalae*. Seeds and cuttings have been taken from the recently discovered plants in the Kahana population unit for propagation and augmentation (U.S. Army Garrison 2005b). Obtaining sufficient seed for genetic storage of *Schiedea kaalae* is difficult because plants do not produce much seed at one time. This species can be propagated from both seed and cuttings. Germination rates of fresh seeds vary from less than 15 percent to 75 percent (U.S. Army Garrison 2005b). The Nature Conservancy of Hawaii has propagated this species successfully from seed in the greenhouse, and has reintroduced plants to three sites in Honouliuli Preserve. Survivorship of these outplants appears good, but they have not yet produced any seedlings (U.S. Army Garrison 2005b). This species is represented in several ex situ collections, including one apical vegetative bud in micropropagation (Harold L. Lyon Arboretum), 23 cuttings in a nursery (Harold L. Lyon Arboretum), 17 plants in a nursery (Harold L. Lyon Arboretum), nine plants in a botanical garden (Waimea Valley Audubon Center), 598 ungerminated seeds in a nursery (Harold L. Lyon Arboretum), 6000 seeds in seed storage (Lyon Arboretum Seed Storage Facility), and 193 seedlings in a nursery (Harold L. Lyon Arboretum) (Service 2005b).

SPECIES ACCOUNT: *Schiedea kauaiensis* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Region (R1) (USFWS, 2016)

Physical Description

A generally hairless, erect subshrub, with stems normally 0.3 to 1.5 m long. Its apetalous flowers have small, green or sometimes purple-tinged sepals, and are borne in open branched inflorescences (as cited in U.S. Fish and Wildlife Service 1996). (NatureServe, 2015)

Taxonomy

Wagner et al. (2005) recognize *Schiedea kauaiensis* with *S. wichmanii* as a synonym. Note that, although Wagner and Herbst (1999) commented that *S. nuttallii* var. *pauciflora* would be included in *S. kauaiensis*, *S. nuttallii* var. *pauciflora* was actually included in the newly published species, *S. perlmanii*, in Wagner et al. (2005). (NatureServe, 2015)

Historical Range

Historically no additional range. (NatureServe, 2015)

Current Range

Currently known from northwestern Kauai. (NatureServe, 2015)

Critical Habitat Designated

Yes; 2/27/2003.

Legal Description

On February 27, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Schiedea kauaiensis* on the island of Kauai, Hawaii (68 FR 9116 - 9479).

Critical Habitat Designation

The critical habitat designation for *Schiedea kauaiensis* includes four units totaling 2,291 acres in Kauai County, Hawaii. The units are Kauai 11—*Schiedea kauaiensis*—a, b, c, d.

Kauai 11—*Schiedea kauaiensis*—a: This unit is critical habitat for *Schiedea kauaiensis* and is 12 ha (29 ac) on private land, containing Pohakukane Cliffs. This unit provides habitat for one population of 300 mature, reproducing individuals of the short-lived perennial *Schiedea kauaiensis* and is currently unoccupied. This unit is essential to the conservation of the taxon because it supports habitat that is important to the establishment of additional populations on Kauai in order to reach recovery goals. The habitat features contained in this unit that are essential for this species include, but are not limited to, steep slopes in diverse mesic to wet *Acacia koa*-*Metrosideros polymorpha* forest. This unit is geographically separated from the other three units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Kauai 11—*Schiedea kauaiensis*—b: This unit is critical habitat for *Schiedea kauaiensis* and is 395 ha (975 ac) on State land (Kokee and Na Pali Coast State Parks). This unit contains Kahuamaa Flat, and Kalahu, Pihea, and Puu o Kila Summits, and Kalalau Lookout. This unit provides habitat for two

populations of 300 mature, reproducing individuals of the shortlived perennial *Schiedea kauaiensis* and is currently occupied with five plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable. The habitat features contained in this unit that are essential for this species include, but are not limited to, steep slopes in diverse mesic to wet *Acacia koa*-*Metrosideros polymorpha* forest. This unit is geographically separated from the other three units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Kauai 11—*Schiedea kauaiensis*—c: This unit is critical habitat for *Schiedea kauaiensis* and is 510 ha (1,260 ac) on State land (Kuia NAR). This unit contains portions of Kuia and Mahanaloa Valleys and Milolii Ridge. This unit provides habitat for three populations of 300 mature, reproducing individuals of the short-lived perennial *Schiedea kauaiensis* and is currently occupied with 17 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable. The habitat features contained in this unit that are essential for this species include, but are not limited to, steep slopes in diverse mesic to wet *Acacia koa*-*Metrosideros polymorpha* forest. This unit is geographically separated from the other three units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Kauai 11—*Schiedea kauaiensis*—d: This unit is critical habitat for *Schiedea kauaiensis* and is 11 ha (28 ac) on State land (Hono o Na Pali NAR), containing portions of Kalalau Trail. This unit provides habitat for one population of 300 mature, reproducing individuals of the short-lived perennial *Schiedea kauaiensis* and is currently unoccupied. This unit is essential to the conservation of the taxon because it supports habitat that is important to the establishment of additional populations on Kauai in order to reach recovery goals. The habitat features contained in this unit that are essential for this species include, but are not limited to, steep slopes in diverse mesic to wet *Acacia koa*-*Metrosideros polymorpha* forest. This unit is geographically separated from the other three units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe.

Primary Constituent Elements/Physical or Biological Features

Within these units, the currently known primary constituent elements of critical habitat include, but are not limited to, the habitat components provided by:

(i) Steep slopes in diverse mesic to wet *Acacia koa*-*Metrosideros polymorpha* forest and containing one or more of the following associated plant species: *Alphitonia ponderosa*, *Cryptocarya mannii*, *Diospyros* spp., *Dodonaea viscosa*, *Euphorbia haeleeleana*, *Exocarpos luteolus*, *Leptocophylla tameiameia*, *Microlepia strigosa*, *Nestegis sandwicensis*, *Peucedanum sandwicense*, *Pisonia* spp., *Psychotria* spp., or *Psydrax odorata*; and

(ii) Elevations between 117 and 1,290 m (385 and 4,232 ft).

Special Management Considerations or Protections

Existing manmade features and structures within the boundaries of the mapped areas, such as buildings; roads; aqueducts and other water system features, including but not limited to pumping stations, irrigation ditches, pipelines, siphons, tunnels, water tanks, gaging stations, intakes, reservoirs, diversions, flumes, and wells; existing trails; campgrounds and their

immediate surrounding landscaped area; scenic lookouts; remote helicopter landing sites; existing fences; telecommunications equipment towers and associated structures and equipment; electrical power transmission lines and distribution, and communication facilities and regularly maintained associated rights-of-way and access ways; radars, telemetry antennas; missile launch sites; arboreta and gardens; heiau (indigenous places of worship or shrines), and other archaeological sites; airports; other paved areas; and lawns and other rural residential landscaped areas do not contain one or more of the primary constituent elements described for each species in paragraph (b) of this section and therefore are not included in the critical habitat designations.

The following management actions are important: Feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas deemed essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas deemed essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History

Food/Nutrient Resources

Breeding Season

Adult: Fruit and flowers have been observed in July and August, and flowering material has been collected in September (S. Weller in litt. 1994) (USFWS, 1998).

Reproduction Narrative

Adult: Little is known about the life history of this taxon. Fruit and flowers have been observed in July and August, and flowering material has been collected in September (S. Weller in litt. 1994). There is no evidence of regeneration from seed under field conditions. Seedlings of species of *Schiedea* occurring in mesic or wet sites are apparently consumed by introduced slugs and snails. These have been observed feeding on *Schiedea membranacea*, another mesic forest species that occurs on Kauai. In contrast to mesic-forest species, *Schiedea* occurring in dry areas produce abundant seedlings following winter rains, presumably because there are fewer alien consumers in the drier sites (S. Weller, personal communication 1997). Reproductive cycles, longevity, specific environmental requirements and limiting factors are unknown (USFWS, 1998).

Habitat Type

Adult: Mesic to wet forest (USFWS, 1998)

Spatial Arrangements of the Population

Adult: Clumped (inferred from USFWS, 2008)

Environmental Specificity

Adult: Narrow/specialist (inferred from USFWS, 2008)

Tolerance Ranges/Thresholds

Adult: Low (inferred from USFWS, 2008)

Site Fidelity

Adult: High (inferred from USFWS, 2008)

Habitat Narrative

Adult: Schiedea kauaiensis typically grows in diverse mesic forest on steep slopes (as cited in U.S. Fish and Wildlife Service 1996). (NatureServe, 2015). Schiedea kauaiensis typically grows in diverse mesic to wet forest on steep slopes. Associated plant taxa include Psychotria hexandra (kopiko), Exocarpus luteolus (heau), lama, the federally threatened Peucedanum sandwicense (makou), and the federally endangered Euphorbia haeleeleana (akoko) (USFWS 1996a; S. Weller, in litt. 1994) (USFWS, 1998). Two known population (USFWS, 2008). Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations.

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Reproductive cycles, longevity, specific environmental requirements and limiting factors are unknown (USFWS, 1998).

Population Information and Trends**Resiliency:**

Low (inferred from NatureServe, 2015))

Representation:

Low (inferred from NatureServe, 2015))

Redundancy:

Low (inferred from NatureServe, 2015))

Number of Populations:

5-6 (USFWS, 2017)

Population Size:

~12 individuals (USFWS, 2017)

Population Narrative:

New Status Information: In addition to those populations cited in the previous 5-year review, new observations include the following: • At the time of the last 5-year review in 2008 there were 2 populations totaling 12 individuals at Mahanaloa and Limahuli on Kauai. An individual at Limahuli was last observed in 2011 (PEPP 2011). Recent surveys have confirmed individuals at Makaha (1 to 5) and Mahanaloa (1) (NTBG 2013b, 2016a-b; PEPP 2015), and discovered new populations at Nualolo (3), Awaawapuhi (1) and Manoa (2) (NTBG 2011, 2012, 2013a, c, 2014a;

PEPP 2014, 2015). These five to six small populations had totaled 12 or fewer individuals at the time. The IUCN Red List of Threatened Species reports only nine individuals at five locations, with the largest population consisting of three plants (Clark 2016). The Plant Extinction Prevention Program's 2016 estimates document further decline, observing the one individual at Mahanaloa, only one individual at Nualolo, and two individuals each at Mahanaloa and Manoa (PEPP 2017) (USFWS, 2017).

Threats and Stressors

Stressor: Feral animals (USFWS, 2008)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Threats to *Schiedea kauaiensis* include habitat destruction by feral goats (*Capra hircus*), pigs (*Sus serofa*), and cattle (*Ros taurus*) (Factors A and D); landslides and erosion resulting from the ungulate destruction of habitat (Factor E) (USFWS, 2008).

Stressor: Invasive plants (USFWS, 2008)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Competition from invasive introduced plant species is listed as a threat to this species (USFWS, 2008).

Stressor: Fire (USFWS, 2008)

Exposure:

Response:

Consequence: Extinction/Loss of habitat

Narrative: *Schiedea kauaiensis* is also potentially threatened by fire, particularly in years of low rainfall (USFWS 2003) (USFWS, 2008)..

Stressor: Small population size/geography (USFWS, 2008)

Exposure:

Response:

Consequence: Extinction

Narrative: In addition to all of the other threats, species like *Schiedea kauaiensis* that are endemic to small portions of a single island are inherently more vulnerable to extinction than widespread species because of the higher risks posed to a few populations and individuals by random demographic fluctuations and localized catastrophes such as hurricanes and disease outbreaks (Factor E). When considered on their own, the natural processes associated with being a single island endemic do not affect *S. kauaiensis* to such a degree that it is threatened or endangered with extinction in the foreseeable future, but these natural processes can exacerbate the threat from anthropogenic factors, such as habitat loss for human development or predation by alien species (Factor E) (USFWS 1998) (USFWS, 2008).

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Schiedea kauaiensis* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.742 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). In addition, Fortini et al. show that Caryophyllaceae is one of the top four most vulnerable native plant families, and, at the genus level, *Schiedea* had one of the highest vulnerability scores. Therefore, additional management actions are needed to conserve this taxon into the future (USFWS, 2017).

Recovery**Reclassification Criteria:**

For downlisting, a total of five to seven populations of each taxon should be documented on Kauai and at least one other island where they now occur or occurred historically. In certain cases, however, a particular taxon may be eligible for downlisting even if all five to seven of the populations are on only one island, provided all of the other recovery criteria have been met and the populations in question are widely distributed and secure enough that one might reasonably conclude that the taxon is not in danger of extinction throughout all or a significant part of its range. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 1995).

Delisting Criteria:

For delisting, a total of 8 to 10 populations of each taxon should be documented on Kauai and at least one other island where they now occur or occurred historically. As with downlisting, there may be cases in which a particular taxon may be eligible for delisting even if all 8 to 10 of the populations are on only one island, provided all of the other recovery criteria have been met and the populations in question are widely distributed and secure enough that one might reasonably conclude that the taxon is not likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of 5 consecutive years (USFWS, 1995).

Conservation Measures and Best Management Practices:

- Collect material from every remaining individual for genetic storage and reintroduction (USFWS, 2008).
- Control ungulates and weeds in the vicinity of the remaining wild individuals (USFWS, 2008).
- Continue reintroducing individuals into protected suitable habitat within historical range (USFWS, 2008).
- Study *Schiedea kauaiensis* populations with regard to population size and structure, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements,

and limiting factors. There is a need to monitor current occurrences and search for more individuals, as well as to continue genetic storage, propagation and outplanting (USFWS, 2008).

- New Management Actions: • PEPP has been collecting seeds and cuttings for collections at DOFAW, NTBG, and UCI (PEPP 2010, 2012, 2014, 2015). The Kokee Rare Plant Facility has one founder represented by six plants in their nursery from the Nualolo wild plant (DOFAW 2016). • NTBG has plants in their nurseries from seed and cutting collections at Makaha, Mahanaloa, Limahuli. In their seed bank they have collections from Awaawapuhi, Mahanaloa, Makaha (plant #1), and serves as a backup for the University of California, Irvine (UCI) collection (NTBG 2017). • UCI has seeds and plants from one to two founders in Mahanaloa, as well as plants from two founders in Makaha and one founder from Nualolo (UCI 2017). • PEPP is monitoring populations at Mahanaloa, Nualolo, Manoa, Awaawapuhi, and Makaha (PEPP 2010, 2011, 2012, 2014, 2015) (USFWS, 2017).
- Recommendations for Future Actions: No new threats and no other significant new information regarding the species' biological status have been reported since the last 5-year review in 2008. Therefore, the following recommendations for future actions are reiterated for the 5-year review for 2017. • Surveys and inventories—Survey for populations of *Schiedea kauaiensis* in areas of potentially suitable habitat and monitor known occurrences. • Ungulate monitoring and control—Protect all occurrences against browsing and disturbances from feral ungulates. Construct and maintain small-scale fenced exclosures around all populations to prevent imminent extinction. • Invasive plant monitoring and control— o Control established ecosystem-altering nonnative invasive plant species around all populations. o Control invasive nonnative species that compete with the species around all populations. • Fire monitoring and control—Develop and implement fire prevention management plans. • Predator and herbivore monitoring and control—Determine and implement effective control methods for slugs. • Captive propagation for genetic storage and reintroduction—Continue to collect seeds for adequate genetic storage. • Reintroduction and translocation—Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. • Population biology research—Study *Schiedea kauaiensis* populations to determine viable population size and structure, geographical distribution, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. • Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered throughout historic range to reduce impacts from landslides (USFWS, 2017).

SPECIES ACCOUNT: *Schiedea kealiae* (Ma`oli`oli)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/10/1996; Pacific Region (R1) (USFWS, 2016)

Physical Description

A subshrub with weakly ascending to sprawling stems 2 - 5 dm long that form loose clumps. Small flowers are borne in terminal clusters (NatureServe, 2015).

Taxonomy

A member of the pink family (Caryophyllaceae) (USFWS, 2003).

Historical Range

The species is endemic to Oahu, Hawaii (NatureServe, 2015). Historically, *Schiedea kealiae* was known from the northern Waianae Mountains and one collection from the Palikea area, near the southern end of the same mountain range (USFWS 1996b; 1998).

Current Range

Currently, populations are located on the cliffs above Dillingham Airfield and Camp Erdman and at Kaena Point at the northern end of the Waianae Mountains (USFWS, 2003).

Critical Habitat Designated

Yes; 6/17/2003.

Legal Description

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea kealiae* (Ma`oli`oli) under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Schiedea kealiae* (77 FR 57648-57862). The critical habitat designation includes 10 critical habitat units, which encompass approximately 1,493 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Ctenitis squamigera* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Schiedea kealiae* includes 10 critical habitat units, covering two ecosystem types, which encompass approximately 1,493 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Coastal—Units 1, 13, 14, 15, Oahu—Lowland Dry—Units 1, 2, 8, 9, 10, 11.

Oahu—Coastal—Unit 1 [958 ac (388 ha)]. This area consists of 946 ac (383 ha) of State land, 11 ac (4 ha) of Federal land, and 2 ac (1 ha) of privately owned land in the coastal ecosystem along the northwestern coast of Oahu from Kaena Point east to Kauhao Pali and southeast to Keawaula. This unit is partially within Kaena Point State Park. Oahu—Coastal—Unit 13 [23 ac (10 ha)]. This area consists of 19 ac (8 ha) of City and County land, 1 ac (0.5 ha) of State land, and 3 ac (1 ha) of

privately owned land in the coastal ecosystem at Kalaeloa. Oahu—Coastal—Unit 14 [4 ac (2 ha)]. This area consists of 2 ac (1 ha) of City and County of Honolulu land, and 2 ac (1 ha) of Federal land (U.S. Coast Guard) in the coastal ecosystem at Kalaeloa. Oahu—Coastal—Unit 15 [33 ac (13 ha)]. This area consists of 9 ac (4 ha) of State land, 2 ac (1 ha) of privately owned land, and 21 ac (9 ha) of Federal (Pearl Harbor NWR) land at Kalaeloa.

Oahu—Lowland Dry—Unit 1 [102 ac (41 ha)]; This area consists of 49 ac (20 ha) of State land and 53 ac (22 ha) of privately owned land in the Waianae Mountains, extending from Haili Gulch to Kawaipahai. Oahu—Lowland Dry— Unit 2 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland dry ecosystem in the Waianae Mountains, on Federal land within Kaena Point State Park. Oahu—Lowland Dry—Unit 8 [99 ac (40 ha)]. Oahu—This area consists of 96 ac (40 ha) of privately owned land and 3 ac (1 ha) of State land as part of the old railroad right-of-way in the lowland dry ecosystem, at the Kalaeloa Barber's Point Harbor area. Oahu—Lowland Dry—Unit 9 [37 ac (15 ha)]. This area consists of 17 ac (7 ha) of City and County land, 3 ac (1 ha) of privately owned land, 1 ac (0.5 ha) of State land, and 16 ac (6 ha) of Federal (Pearl Harbor NWR) land in the lowland dry ecosystem at Kalaeloa. Oahu—Lowland Dry— Unit 10 [43 ac (17 ha)]. This area consists of 43 ac (17 ha) of State land (DHHL) in the lowland dry ecosystem at Kalaeloa. Oahu—Lowland Dry—Unit 11 [166 ac (67 ha)]. This area consists of 166 ac (67 ha) of federal land (U.S. Navy) in the lowland dry ecosystem at Kalaeloa.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea kealiae* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Schiedea kealiae* occurs within the Coastal and Lowland dry ecosystems in the Waianae Mountain caldera complex:

Oahu—Coastal—Units 1, 13, 14, 15. (A) Elevation: <980 ft (<300 m). (B) Annual Precipitation: <20 in (<50 cm). (C) Substrate: Well-drained, calcareous, talus slopes; dunes; weathered clay soils; ephemeral pools; mudflats. (D) Canopy: Hibiscus, Myoporum, Santalum, Scaevola. (E) Subcanopy: Gossypium, Sida, Vitex. (F) Understory: Eragrostis, Jacquemontia, Lyceum, Nama, Sesuvium, Sporobolus, Vigna.

Oahu— Lowland Dry—Units 1, 2, 8, 9, 10, 11. (A) Elevation: <3,300 ft (<1,000 m). (B) Annual Precipitation: <50 in (<130 cm). (C) Substrate: Weathered silty loams to stony clay, rocky ledges, little weathered lava. (D) Canopy: Diospyros, Myoporum, Pleomele, Santalum, Sapindes. (E) Subcanopy: Chamaesyce, Dodonaea, Leptecophylla, Osteomeles, Psydrax, Scaevola, Wikstroemia. (F) Understory: Alyxia, Artemisia, Bidens, Chenopodium, Nephrolepis, Peperomia, Plumbago, Sicyos, Sida, Waltheria.

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Schiedea kealiae* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats

will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Sexual: cross-pollination, self-pollination (USFWS, 1998)

Lifespan

Adult: < 10 years (USFWS, 2013)

Breeding Season

Adult: December (USFWS, 1998)

Key Resources Needed for Breeding

Adult: Wind (USFWS, 2013)

Reproduction Narrative

Adult: The species is considered to be wind pollinated (S. Weller, University of California, Irvine, pers. comm. 2012). This species is a short-lived perennial (fewer than 10 years) (USFWS, 2013). It has been observed in flower in December. A series of self pollinations, within-population crosses, and crosses among occurrences has demonstrated that many related *Schiedea* species experience moderately strong inbreeding depression (USFWS, 1998).

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Dry shrublands and forests (NatureServe, 2015); *Erythrina sandwicensis* or *Pisonia sandwicensis* forest (USFWS, 2010)

Geographic or Habitat Restraints or Barriers

Adult: 200 - 1,000 ft. elevation (USFWS, 2010)

Habitat Narrative

Adult: Inhabits dry shrublands and forests on headlands, cliffs and cliff ledges not far from the coast (NatureServe, 2015). *Schiedea kealiae* is usually found on steep slopes and cliff faces at elevations from 60 to 305 meters (200 to 1,000 feet), in dry remnant *Erythrina sandwicensis* (wiliwili) or *Pisonia sandwicensis* (aalu, papala kepau, alaa) forest (USFWS, 2010).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends

Population Trends:

Not available

Resiliency:

Very low (inferred from USFWS, 2003; see current range/distribution)

Redundancy:

Low (inferred from USFWS, 2003)

Number of Populations:

4 (USFWS, 2003)

Population Size:

265 - 315 (USFWS, 2003)

Population Narrative:

Currently, there are 4 occurrences totaling between 265 and 315 plants (USFWS, 2003).

Threats and Stressors

Stressor: Nonnative plants (USFWS, 2003)

Exposure:

Response:

Consequence:

Narrative: It is threatened by competition with the nonnative plant species *Leucaena leucocephala*, *Panicum maximum*, and *Schinus terebinthifolius* (USFWS, 2003).

Stressor: Climate change (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. However, current climate change analyses in the Pacific Islands lack sufficient spatial resolution to make predictions on impacts to this species (USFWS, 2013).

Stressor: Predation (USFWS, 2003)

Exposure:

Response:

Consequence:

Narrative: Seedlings of *Schiedea* species occurring in mesic or wet sites are apparently consumed by introduced unidentified slugs and snails, which have been observed feeding on *Schiedea membranacea*, a mesic forest species from Kauai (USFWS, 2010).

Stressor: Lack of pollinators (USFWS, 2003)

Exposure:

Response:

Consequence:

Narrative: Not available

Stressor: Small population size (USFWS, 2003)

Exposure:

Response:

Consequence:

Narrative: This species is at risk of extinction from naturally occurring events and/or reduced reproductive vigor due to the small number of existing occurrences. The Kaena Point occurrence is additionally threatened by naturally occurring rock slides and fire (HINHP Database 2001; Service 1998b; 61 FR 53089) (USFWS, 2003).

Stressor: Habitat destruction and modification (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Feral ungulates, especially goats (*Capra hircus*) and pigs (*Sus scrofa*), as well as fires and landslides (Perlman 2008) (USFWS, 2010).

Recovery

Reclassification Criteria:

1. A total of five to seven populations of the species should be documented on Oahu and at least one other island where it now occurs or occurred historically (USFWS, 1998).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure, with a minimum of 300 mature individuals per population (for short-lived perennials) (USFWS, 1998).
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 1998).

Delisting Criteria:

1. A total of 8 to 10 populations of the species should be documented on Oahu and at least one other island where it now occurs or occurred historically (USFWS, 1998).
2. Oahu and at least one other island where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population (for short-lived perennials) (USFWS, 1998).
3. Each population should persist at this level for a minimum of 5 consecutive years (USFWS, 1998).

Recovery Actions:

- Protect habitat and control threats (USFWS, 1998).
- Expand existing wild populations (USFWS, 1998).
- Conduct essential research (USFWS, 1998).
- Develop and maintain monitoring plans (USFWS, 1998).

- Reestablish wild populations within historic range (USFWS, 1998).
- Validate and revise recovery criteria (USFWS, 1998).
- Control competing alien plant species (USFWS, 1998).
- Control of introduced snails and slugs (USFWS, 1998).
- Research on pollinators (USFWS, 1998).
- Reduce substrate loss (USFWS, 1998).
- Provide protection from fire (USFWS, 1998).

Conservation Measures and Best Management Practices:

- Captive propagation for genetic storage and reintroduction - Continue collecting material for genetic storage and propagation for reintroduction. Investigate new propagation methods (USFWS, 2013).
- Invertebrate control research - Investigate slug herbivory and appropriate insect control methods (USFWS, 2013).
- Ungulate exclosures - Fence remaining populations to protect them from the impacts of feral ungulates (USFWS, 2013).
- Ecosystem-altering invasive plant species control - Remove competing invasive introduced plant species within fenced areas and maintain those areas free of invasive introduced plants (USFWS, 2013).
- Fire protection – Develop and implement fire prevention plans to protect the most vulnerable populations (USFWS, 2013).
- Population biology research - Implement genetic studies to assess the viability of remaining populations. Investigate the causes of reproductive failure and techniques to improve natural recruitment (USFWS, 2013).
- Surveys / inventories – Survey geographical and historical range for a thorough current assessment of the species status (USFWS, 2013).
- Alliance and partnership development - Initiate planning and contribute to implementation of ecosystem level restoration and management to benefit this taxon (USFWS, 2013).
- Threats research – Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species (USFWS, 2013).

SPECIES ACCOUNT: *Schiedea laui* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 06/27/2013; Pacific Region (R1) (USFWS, 2017)

Physical Description

A short-lived perennial herb or subshrub (USFWS, 2016).

Taxonomy

A member of the pink family (Caryophyllaceae) (USFWS, 2016).

Historical Range

Discovered in Kamakou Preserve in 1998 (USFWS, 2016).

Current Range

Known only from Molokai (USFWS 2012). (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea laui* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes three detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Schiedea laui* includes three CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Molokai—Montane Wet—Unit 1 (and) *Palmeria dolei*—Unit 40—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 40— Montane Wet This area consists of 1,545 ac (625 ha) of State land, and 1,851 ac (749 ha) of privately owned land, from the headwaters of Waialeale Stream and above Pelekunu Valley, eastward along the summit area to Mapulehu, in northcentral Molokai. These units are occupied by the plants *Bidens wiebkei*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea mannii*, *C. profuga*, *Phyllostegia hispida*, and *Pteris lidgatei*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Montane Wet—Unit 1 is not known to be occupied by *Adenophorus periens*, *Cyanea procera*, *C. solanacea*, *Hesperomannia arborescens*, *Lysimachia maxima*, *Melicope reflexa*, *Phyllostegia mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea laui*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their

small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Montane Wet—Unit 2 (and) *Palmeria dolei*—Unit 41—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 41—Montane Wet This area consists of 871 ac (353 ha) of State land, and 39 ac (16 ha) of privately owned land, from Honukaupu to Olokui (between Pelekunu and Wailau valleys), in north-central Molokai. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). Although Molokai—Montane Wet—Unit 2 is not known to be occupied by *Adenophorus periens*, *Bidens wiebkei*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea mannii*, *C. procera*, *C. profuga*, *C. solanacea*, *Hesperomannia arborescens*, *Lysimachia maxima*, *Melicope reflexa*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Pteris lidgatei*, *Schiedea laui*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Montane Wet—Unit 3 consists of 77 ac (31 ha) of State land, and 726 ac (294 ha) of privately owned land, above the east rim of Wailau Valley on eastern Molokai. This unit is occupied by the plant *Melicope reflexa*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Montane Wet—Unit 3 is not known to be occupied by *Adenophorus periens*, *Bidens wiebkei*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea mannii*, *C. procera*, *C. profuga*, *C. solanacea*, *Hesperomannia arborescens*, *Lysimachia maxima*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Pteris lidgatei*, *Schiedea laui*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea laui* critical habitat consists of one component. Montane wet (Molokai) (81 FR 17790-18110):

Ecosystem: Montane Wet. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: >75 in (>190 cm). Substrate: Well-developed soils, montane bogs. Canopy: *Acacia*, *Charpentiera*, *Cheirodendron*, *Metrosideros*. Subcanopy: *Broussaisia*, *Cibotium*, *Eurya*, *Ilex*, *Myrsine*. Understory: Ferns, *Carex*, *Coprosma*, *Leptecophylla*, *Oreobolus*, *Rhynchospora*, *Vaccinium*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cooki*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant

species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D’Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: No information found.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Cave/montane wet ecosystem (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Clumped (inferred from NatureServe, 2015)

Environmental Specificity

Adult: Narrow/specialist (inferred from NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: Low (inferred from NatureServe, 2015)

Site Fidelity

Adult: High (inferred from NatureServe, 2015)

Habitat Narrative

Adult: Species inhabits a cave along a narrow stream corridor at the base of a waterfall in the montane wet ecosystem on Molokai (USFWS 2012). Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the fact that there is only one known population (NatureServe, 2015).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: No information found.

Population Information and Trends**Population Trends:**

Not available

Resiliency:

Very low (inferred from NatureServe, 2015)

Redundancy:

Very low (inferred from NatureServe, 2015)

Number of Populations:

1 (NatureServe, 2015)

Population Size:

24 - 34 (NatureServe, 2015)

Population Narrative:

There are 24 to 34 individuals known as of 2010 (Bakutis 2010 cited by USFWS 2012.). One location, a cave in Kamakou Preserve (Bakutis 2010 cited by USFWS 2012). (NatureServe, 2015) In 1998, when this species was first observed, there were 19 individuals located in a cave along a narrow stream corridor at the base of a waterfall in the Kamakou Preserve, in the montane wet ecosystem (Wagner et al. 2005b, pp. 90– 92). By 2000, only 9 individuals with a few immature plants and seedlings were relocated, and in 2006, 13 plants were seen (Wagner et al. 2005b, pp. 90–92; PEPP 2007, p. 57) (USFWS, 2016).

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative plants, flooding, landslides, and hurricanes. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Flooding and landslides destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (rats, and slugs) is considered an ongoing threat to *Schiedea laui* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

Stressor: Small populations (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: *Schiedea laui* faces the threat of limited numbers (i.e., there are fewer than 50 individuals in the wild). The 24 to 34 individuals of *Schiedea laui* are facing imminent threats from flooding and landslides because of their location in a grotto (USFWS, 2013).

Stressor:

Exposure:

Response:

Consequence:

Narrative:

Recovery**Recovery Actions:**

- There is no recovery plan for this species.

SPECIES ACCOUNT: *Schiedea lydgatei* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/08/1992; Pacific Region (R1) (USFWS, 2017)

Physical Description

A subshrub with stems 1-4 dm long. Flowers are borne in terminal clusters. (NatureServe, 2015)

Taxonomy

Genus endemic to Hawaiian Islands, species endemic to eastern Molokai. (NatureServe, 2015) A member of the pink family (Caryophyllaceae) (USFWS, 2016).

Historical Range

Historically no additional range. (NatureServe, 2015)

Current Range

Current range includes Eastern Molokai. (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea lydgatei* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one detailed critical habitat unit (CHU), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Schiedea lydgatei* includes one CHU in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Molokai—Lowland Mesic—Unit 1 (and) Palmeria dolei—Unit 37—Lowland Mesic (and) Pseudonestor xanthophrys—Unit 37— Lowland Mesic This area consists of 3,489 ac (1,412 ha) of State land, and 5,281 ac (2,137 ha) of privately owned land, from Waianui Gulch to Mapulehu, in central Molokai. These units are occupied by the plants *Alectryon macrococcus*, *Ctenitis squamigera*, *Cyanea dunbariae*, *C. mannii*, *C. profuga*, *Cyperus fauriei*, *Cyrtandra filipes*, *Gouania hillebrandii*, *Labordia triflora*, *Neraudia sericea*, *Santalum haleakalae* var. *lanaiense*, *Schiedea lydgatei*, *S. sarmentosa*, *Silene alexandri*, *S. lanceolata*, *Spermolepis hawaiiensis*, and *Zanthoxylum hawaiiense*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Lowland Mesic—Unit 1 is not known to be occupied by *Asplenium dielirectum*, *Bonamia menziesii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea procera*, *C. solanacea*, *Diplazium molokaiense*, *Festuca molokaiensis*, *Flueggea neowawraea*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Melicope mucronulata*, *M. munroi*, *M. reflexa*, *Phyllostegia haliakalae*, *P. mannii*, *P. pilosa*, *Sesbania*

tomentosa, *Stenogyne bifida*, or *Vigna o-wahuensis*, or the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea lydgatei* critical habitat consists of one component. Lowland mesic (Molokai) (81 FR 17790-18110):

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further

degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkii*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History

Food/Nutrient Resources**Reproductive Strategy**

Adult: Wind and moth pollinated; sexual: cross-pollination, self-pollination (USFWS, 2011)

Breeding Season

Adult: This species was observed with flowers and fruit in June 1990 (HHP 1990g) (USFWS, 1995).

Reproduction Narrative

Adult: *Schiedea lydgatei* has a hermaphroditic breeding system, which is rare among dry habitat adapted *Schiedea* species (Weller and Sakai 2010). A study of outcrossing and pollination biology on the maintenance of hermaphroditism in *S. lydgatei* found that both wind and native moths in the family Pyralidae are responsible for its pollination. Outcrossing rates were generally high, especially in years when many plants flowered during the same time period. High outcrossing rates and substantial inbreeding depression indicated that at present females would not be favored in the population. Pollination by both wind and insects is consistent with the hypothesis that hermaphroditism is the result of a relatively recent reversal, as the ancestor of *S. lydgatei* was probably wind pollinated and gynodioecious, with few females. A shift from wind to predominately insect pollination on Molokai may have resulted in increased outcrossing rates and prevented the expression of high inbreeding depression among progeny of hermaphrodites, a condition that would select against females and favor a reversal to hermaphroditism. Because few females were likely to have been present in ancestral populations that colonized Molokai, the founder effect is another potential explanation for loss of females. In either case, current high levels of outcrossing prevent re-establishment of females in populations of *S. lydgatei* (Norman et al. 1997) (USFWS, 2011). This species was observed with flowers and fruit in June 1990 (HHP 1990g). Currently, no additional life history information is available (USFWS, 1996).

Habitat Type

Adult: Dry to mesic grasslands, shrublands, and forests (USFWS, 1996)

Spatial Arrangements of the Population

Adult: Clumped (inferred from USFWS, 1996)

Environmental Specificity

Adult: Narrow/specialist (inferred from USFWS, 1996)

Tolerance Ranges/Thresholds

Adult: Low (inferred from USFWS, 1996)

Site Fidelity

Adult: High (inferred from USFWS, 1996)

Habitat Narrative

Adult: Species inhabits dry to moist shrublands and forests. Ridgetops and gulch slopes. (NatureServe, 2015). This species is found along ridges and on cattle trails in dry to mesic grasslands, shrublands, and forests with scattered native and alien trees. It ranges in elevation

from about 600 to 650 meters (2,000 to 2,100 feet). Associated plant species include aalii, ohia, pukiawe, and uluhe (USEWS 1992) (USFWS, 1996). As of 2010, there are at least 200 individuals in 5 populations located between Kawela and Malolelau Gulch on Molokai (Oppenheimer 2010a) (USFWS, 2011). Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations.

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Decreasing (USFWS, 2011)

Resiliency:

Low (inferred from USFWS, 2011)

Representation:

Low (inferred from USFWS, 2011)

Redundancy:

Low (inferred from USFWS, 2016)

Number of Populations:

2 (USFWS, 2018)

Population Size:

> 1000 (USFWS, 2018)

Population Narrative:

New Status Information: • There are two populations (Kawela and Kūpā'ia) on Moloka'i estimated to total more than 1,000 individuals combined (Bakutis 2018, in litt.). • Visits to the Kawela population in 2018 documented suspected hybrids between *Schiedea lydgatei* and *S. sarmentosa* (Weisenberger 2018, in litt.). • In 2016, one critical habitat unit in the lowland mesic ecosystem was designated on Moloka'i for *Schiedea lydgatei* (8,770 ac; 3,549 ha) (81 FR 17790, March 30, 2016) (USFWS, 2018).

Threats and Stressors

Stressor: Fire (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Fire is listed as a threat to this species (USFWS, 2011)

Stressor: Feral goats, rats and slugs

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Feral goats are a threat based both in terms of habitat modification and herbivory. Slugs and rats are a threat due to herbivory (USFWS, 2011).

Stressor: Invasive plants (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Introduced invasive plant species are also a threat to *Schiedea lydgatei* because they compete with the species for water, light, and nutrients (USFWS, 2011).

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: We previously reported that climate change may pose a threat to this species, anticipating an analysis by 2013. The assessment conducted by Fortini et al. (2013) concluded that *S. lydgatei* is extremely vulnerable to the impacts of climate change, with a vulnerability score of 0.983 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). In addition, *S. lydgatei* is one of the most vulnerable native Hawaiian plant species that has a projected future climate envelope. Therefore, additional management actions are needed to conserve this taxon into the future, such as locating key microsites that overlap with current and future climate envelopes for outplanting efforts (USFWS, 2018).

Recovery

Reclassification Criteria:

For downlisting, a total of five to seven populations of each taxon should be documented on Molokai and at least one other island where they now occur or occurred historically. In certain cases, however, a particular taxon may be eligible for downlisting even if all five to seven of the populations are on only one island, provided all of the other recovery criteria have been met and the populations in question are widely distributed and secure enough that one might reasonably conclude that the taxon is not in danger of extinction throughout all or a significant part of its range. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 1996).

Delisting Criteria:

For taxa other than *Tetramolopium rockii*, the following delisting criteria are recommended. A total of 8 to 10 populations of each taxon should be documented on Molokai and at least 1 other island where they now occur or occurred historically. As with downlisting, there may be cases in which a particular taxon may be eligible for delisting even if all 8 to 10 of the populations are on

only 1 island, provided all of the other recovery criteria have been met and the populations in question are widely distributed and secure enough that one might reasonably conclude that the taxon is not likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of 5 consecutive years (USFWS, 1996).

Recovery Actions:

- U.S. Fish and Wildlife Service. 1996. Recovery Plan for the Molokai Plant Cluster. U.S. Fish and Wildlife Service, Portland, OR. 143 pp (USFWS, 1996).

Conservation Measures and Best Management Practices:

- Survey areas where *Schiedea lydgatei* have been reported to establish current status of the species (USFWS, 2011).
- Monitor known populations and continue collection of seeds or cuttings for genetic storage and reintroduction (USFWS, 2011).
- Research methods to increase and maintain numbers of female individuals within populations (USFWS, 2011).
- Completely fence existing populations to provide protection from the negative impacts of feral ungulates (USFWS, 2011).
- Control invasive introduced plant species around known populations (USFWS, 2011).
- Control rats in the vicinity of these populations (USFWS, 2011).
- Develop and implement methods to control introduced slugs (USFWS, 2011).
- Propagate to augment the existing populations (USFWS, 2011).
- Establish additional populations within protected suitable habitat (USFWS, 2011).
- Develop and implement a wildfire management plan (USFWS, 2011).
- Work with East Molokai Watershed Partnership Program, Hawaii Division of Forestry and Wildlife, and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2011).
- Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species (USFWS, 2011).
- New Management Actions:
 - Captive propagation for genetic storage and reintroduction—In 2014, the University of California—Irvine reported 10 plants from Mākolēlau in storage, representing 10 different individuals (USFWS, 2018).
- Recommendations for Future Actions: Hybridization may be a new threat to this species; however, we are not aware of any significant new information regarding the species' biological status since the last 5-year review in 2011. Thus, the following recommendations for future actions are added or reiterated for the 5-year review for 2018.
 - Surveys and inventories—Survey areas where *Schiedea lydgatei* has been reported to determine current status of the species on Molokaʻi.
 - Ungulate monitoring and control—Fence existing populations to provide protection from negative impacts of feral ungulates.
 - Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations of *S. lydgatei*.
 - Fire destruction or degradation of habitat—Develop and implement a wildfire management plan.
 - Captive propagation for genetic storage and reintroduction—Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range.

Reintroduction and translocation— o Augment known populations and reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. o Research methods to increase and maintain numbers of female individuals within populations. o Study the possible effects of hybridization on this species. • Rodent predation and herbivory— Control rats in the vicinity of all populations. • Invertebrate predation and herbivory—Develop and implement methods to control slugs. • Climate change adaptation strategy—Assess the modeled effects of climate change on this species and use to determine future landscape needed for the recovery of the species. • Alliance and partnership development—Work with the East Molokaʻi Watershed Partnership program, the Hawaiʻi Division of Forestry and Wildlife, and other land managers to initiate planning and contribute to ecosystem-level restoration and management to benefit this species (USFWS, 2018).

SPECIES ACCOUNT: *Schiedea membranacea* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/10/1996; Pacific Region (R1) (USFWS, 2016)

Physical Description

A perennial herb that dies back to a woody caudex in the dry season. Stems are 5-10 dm long, and apparently unbranched. The small flowers are borne in terminal clusters. (NatureServe, 2015)

Taxonomy

Endemic genus of 22 species, species endemic to NW Kauai. (NatureServe, 2015)

Historical Range

See current range/distribution.

Current Range

Endemic to northwest Kauai. (NatureServe, 2015)

Critical Habitat Designated

Yes; 2/27/2003.

Legal Description

On February 27, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Schiedea membranacea* on the island of Kauai, Hawaii (68 FR 9116 - 9479).

Critical Habitat Designation

The critical habitat designation for *Schiedea membranacea* includes four units totaling 3,311 acres in Kauai County, Hawaii. The units are Kauai 11—*Schiedea membranacea*—a, b, c, d.

Kauai 11—*Schiedea membranacea*—a: This unit is critical habitat for *Schiedea membranacea* and is 251 ha (620 ac) on State land (Alakai Wilderness Preserve) within the Koaie Canyon. This unit provides habitat for two populations of 300 mature, reproducing individuals of the shortlived perennial *Schiedea membranacea* and is currently occupied with 6 to 10 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered non-viable. The habitat features contained in this unit that are essential for this species include, but are not limited to, cliffs or cliff bases of mesic or wet habitats, in lowland or montane shrubland, or forest communities dominated by *Acacia koa*, *Pipturus* spp. and *Metrosideros polymorpha* or *Urticaceae* shrubland on talus slopes. This unit is geographically separated from the other three units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Kauai 11—*Schiedea membranacea*—b: This unit is critical habitat for *Schiedea membranacea* and is 234 ha (580 ac) on State land (Kokee and Na Pali Coast State Parks). This unit contains Kalahu and Puu o Kila Summits and Kalalu Lookout. This unit provides habitat for one population of 300 mature, reproducing individuals of the short-lived perennial

Schiedea membranacea and is currently occupied with 24 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered non-viable. The habitat features contained in this unit that are essential for this species include, but are not limited to, cliffs or cliff bases of mesic or wet habitats, in lowland or montane shrubland, or forest communities dominated by *Acacia koa*, *Pipturus* spp. and *Metrosideros polymorpha* or *Urticaceae* shrubland on talus slopes. This unit is geographically separated from the other three units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Kauai 11—*Schiedea membranacea*—c: This unit is critical habitat for *Schiedea membranacea* and is 528 ha (1,303 ac) on State land (Kuia NAR and Puu Ka Pele Forest Reserve). This unit contains portions of Kuia and Mahanaloa Valleys and Milolii Ridge. This unit provides habitat for three populations of 300 mature, reproducing individuals of the short-lived perennial *Schiedea membranacea* and is currently occupied with 266 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable. The habitat features contained in this unit that are essential for this species include, but are not limited to, cliffs or cliff bases of mesic or wet habitats, in lowland or montane shrubland, or forest communities dominated by *Acacia koa*, *Pipturus* spp. and *Metrosideros polymorpha* or *Urticaceae* shrubland on talus slopes. This unit is geographically separated from the other three units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Kauai 11—*Schiedea membranacea*—d: This unit is critical habitat for *Schiedea membranacea* and is 327 ha (810 ac) on State land (Kuia NAR and Kokee State Park). This unit contains portions of Awaawapuhi and Honopu Trails and Kainamau Summit. This unit provides habitat for one population of 300 mature, reproducing individuals of the short-lived perennial *Schiedea membranacea* and is currently occupied with eight plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered non-viable. The habitat features contained in this unit that are essential for this species include, but are not limited to, cliffs or cliff bases of mesic or wet habitats, in lowland or montane shrubland, or forest communities dominated by *Acacia koa*, *Pipturus* spp. and *Metrosideros polymorpha* or *Urticaceae* shrubland on talus slopes. This unit is geographically separated from the other three units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe.

Primary Constituent Elements/Physical or Biological Features

Within these units, the currently known primary constituent elements of critical habitat include, but are not limited to, the habitat components provided by:

- (i) Cliffs or cliff bases in mesic or wet habitats in lowland or montane shrubland or forest communities dominated by *Acacia koa*, *Pipturus* spp. and *Metrosideros polymorpha* or *Urticaceae* shrubland on talus slopes and containing one or more of the following associated native plant species: *Alphitonia ponderosa*, *Alyxia oliviformis*, *Asplenium* spp., *Athyrium sandwicensis*, *Bobea brevipes*, *Boehmeria grandis*, *Cyrtandra* spp., *Diplazium sandwichianum*, *Dodonaea viscosa*, *Eragrostis variabilis*, *Hedyotis terminalis*, *Hibiscus waimeae*, *Joinvillea ascendens* ssp. *ascendens*, *Labordia helleri*, *Lepidium serra*, *Lysimachia kalalauensis*, *Machaerina*

angustifolia, Mariscus pennatifolius, Melicope spp., Myrsine spp., Perrottetia sandwicensis, Pisonia spp., Pleomele aurea, Poa mannii, Poa sandwicensis, Pouteria sandwicensis, Psychotria spp., Psydrax odorata, Remya kauaiensis, Sadleria cyatheoides, Scaevola procera, Thelypteris cyatheoides, Thelypteris sandwicensis, or Touchardia latifolia; and

(ii) Elevations between 423 and 1,259 m (1,386 and 4,131 ft).

Special Management Considerations or Protections

Existing manmade features and structures within the boundaries of the mapped areas, such as buildings; roads; aqueducts and other water system features, including but not limited to pumping stations, irrigation ditches, pipelines, siphons, tunnels, water tanks, gaging stations, intakes, reservoirs, diversions, flumes, and wells; existing trails; campgrounds and their immediate surrounding landscaped area; scenic lookouts; remote helicopter landing sites; existing fences; telecommunications equipment towers and associated structures and equipment; electrical power transmission lines and distribution, and communication facilities and regularly maintained associated rights-of-way and access ways; radars, telemetry antennas; missile launch sites; arboreta and gardens; heiau (indigenous places of worship or shrines), and other archaeological sites; airports; other paved areas; and lawns and other rural residential landscaped areas do not contain one or more of the primary constituent elements described for each species in paragraph (b) of this section and therefore are not included in the critical habitat designations.

The following management actions are important: Feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas deemed essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas deemed essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Outcrossing (USFWS, 2010)

Reproduction Narrative

Adult: Schiedea membranacea has been determined to be strongly outcrossing, with a high level of inbreeding depression (Culley et al. 1999). For this reason, the lack of observed pollinators is a serious concern (USFWS, 2010). Schiedea membranacea appears to be a long-lived perennial. Plants marked in Mahanaloa Gulch in 1987 were alive in 1997, despite Hurricane Iniki. There was no evidence of recruitment in the population, despite the production of abundant seed during all years of observation (1987, 1994-1997). Schiedea membranacea is extremely diverse at allozyme loci, based on observations of plants from Mahanaloa Gulch (mean number of alleles per locus+3.00; percentage of polymorphic loci=66.7; mean heterozygosity=0.366). As

expected for a genetically diverse species, inbreeding depression is very high. In an artificial crossing program, the relative inbreeding depression averaged over 11 maternal parents was 0.73, suggesting that very few selfed progeny would survive to adulthood if germination were successful. Under current conditions of pollination, *Schiedea membranacea* is largely outcrossed, based on outcrossing rates of 0.925 in 1993 and 0.749 in 1994. Pollinators for *Schiedea membranacea* are unknown. No visitors have been seen during the daytime, and none were observed during one set of night observations (Steve Weller, University of California at Irvine, personal communication 1997) (USFWS, 1998).

Habitat Type

Adult: Moist and wet forest (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Clumped (inferred from USFWS, 1998)

Environmental Specificity

Adult: Narrow/specialist (inferred from USFWS, 1998)

Tolerance Ranges/Thresholds

Adult: Low (inferred from USFWS, 1998)

Site Fidelity

Adult: High (inferred from USFWS, 1998)

Habitat Narrative

Adult: Moist and wet forests in gulch bottoms. (NatureServe, 2015). This species is typically found on cliffs and cliff bases in a wide variety of mesic to wet habitats between 520 and 1,160 meters (1,700 and 3,800 feet) elevation. The vegetation ranges from open to closed lowland to montane shrubland to forest communities with either a variety of canopy and understory species or dominated by kukui, mamaki, or ohia (USFWS 1996) (USFWS, 1998). Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations.

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Decreasing (USFWS, 2010)

Number of Populations:

5 (USFWS, 2017)

Population Size:

84 individuals (USFWS, 2017)

Population Narrative:

New Status Information: In addition to those populations cited in the previous 5-year review, new observations include the following: • At the time of the last 5-year review in 2010 there were 5 populations totaling fewer than 90 individuals at Awaawapuhi, Kalalau, Koaie canyon, Kuia, Mahanaloa, Nualolo, Paaiki, Waialae, and Wainiha on Kauai. The status of populations at Waialae, Paaiki, Nualolo, and Koaie canyon has not been reported since 2010. Recent surveys have confirmed individuals at Kalalau (1), Kuia (5), Wainiha (55), Awaawapuhi (3), and Mahanaloa (20) (NTBG 2009, 2014, 2015a-g, 2016; PEPP 2010, 2011, 2013, 2014, 2015). Individuals were rediscovered at Wainiha, where *Schiedea membranacea* was last observed 20 years ago (PEPP 2015). There are 2 occurrences, one of about 35 individuals and another of about 20 individuals at this location (PEPP 2015). • These populations total 5 small occurrences with 84 individuals. In 2016, the IUCN Red List of Threatened Species reported 4 subpopulations totaling 45 individuals, most of which are at Mahanaloa (Clark 2016). It is uncertain why there is a discrepancy in estimates, as it appears the Wainiha population, which had been considered the largest population in the past, may have not been included in the assessment, or may have recently suffered a drastic population decline (USFWS, 2017).

Threats and Stressors

Stressor: Feral goats and pigs (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Threats to this species throughout its range include habitat degradation and herbivory by feral goats (*Capra hircus*) and pigs (*Sus scrofa*) (USFWS, 2010).

Stressor: Invasive plants (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Competition with invasive introduced plants is listed as a threat to this species (USFWS, 2010).

Stressor: Snails (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Various species of introduced snails have been observed feeding on flowers and developing seed capsules, and introduced garlic snails (*Oxychilus alliarius*) are common near the individuals (USFWS, 2010).

Stressor: Climate change (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Climate change may also pose a threat to *Schiedea membranacea* (Factors A and E). However, current climate change models do not allow us to predict specifically what those effects, and their extent, would be for this species (USFWS, 2010).

Stressor: Ungulate degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Mule (black-tailed) deer (*Odocoileus hemionus*) modify and degrade habitat by disturbing and destroying vegetative cover, trampling plants and seedlings, reducing or eliminating plant regeneration by damaging seeds and seedlings, and increasing erosion by creating large areas of bare soil (Loope 1998; van Riper and van Riper 1982). Mule deer and evidence of their activities have been observed at Kuia and Awaawapuhi where *Schiedea membranacea* occurs (NTBG 2014, 2015g) (USFWS, 2017).

Stressor: Landslides and flooding destruction or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: *Schiedea membranacea* occurs on steep cliffs that are subject to landslides that can destroy individual plants and populations (NTBG 2015b-d). Landslides destabilize substrates, damage and destroy individual plants, and alter hydrological patterns (Stearns 1985). Habitat disturbance by feral goats can lead to landslides (USFWS, 2017).

Stressor: Erosion degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Erosion due to natural weathering and also resulting from activities of feral goats and deer destabilizes the habitat of *Schiedea membranacea* and can destroy individual plants and populations (PEPP 2010, 2011, 2013, 2014). • Drought degradation of habitat—Drought affects plants directly by desiccation and leads to an increase in the number of forest and brush fires (Giambelluca et al. 1991), causing a reduction of native plant cover and habitat (D’Antonio and Vitousek 1992). Drought is reported to be a threat to populations of *Schiedea membranacea* at Mahanaloa and Kuia (PEPP 2013, 2014) (USFWS, 2017)

Stressor: Hurricanes—Loss and degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Hurricanes were omitted in the last five year review. In November 1982, Hurricane Iwa struck the Hawaiian Islands, with wind gusts exceeding 100 miles per hour (mph) (161 kilometers per hour (kph)), causing extensive damage, especially on the islands of Niihau, Kauai, and Oahu (Businger 1998). In September 1992, Hurricane Iniki, a category 4 hurricane with maximum sustained wind speeds recorded at 140 mph (225 kph), passed directly over the island of Kauai. Many forest trees were destroyed (Perlman 1992), which opened the canopy and facilitated the invasion of nonnative plants (Kitayama and Mueller-Dombois 1995). A destructive hurricane holds the potential of driving a localized endemic species to extinction in a single event, and 70 percent of all listed plant species on Kauai are only found on Kauai. Hurricanes pose an ongoing and ever-present threat because they can happen at any time, although their occurrence is not predictable. Tropical cyclone frequency and intensity are projected to change as a result of climate change over the next 100 to 200 years (Vecchi and Soden 2007; Emanuel et

al. 2008; Yu et al. 2010). In the central Pacific, modeling projects an increase of up to two additional tropical cyclones per year in the main Hawaiian Islands by 2100 (Murakami et al. 2013) (USFWS, 2017).

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Schiedea membranacea* is vulnerable to the impacts of climate change, with a vulnerability score of 0.458 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). In addition, Fortini et al. show that Caryophyllaceae is one of the top four most vulnerable native plant families, and, at the genus level, *Schiedea* had one of the highest vulnerability scores. Therefore, additional management actions are needed to conserve this taxon into the future. • Ungulate predation or herbivory—Herbivory by deer is an additional threat to *Schiedea membranacea* (NTBG 2014, 2015g) (USFWS, 2017).

Stressor: Rodent predation or herbivory

Exposure:

Response:

Consequence:

Narrative: Herbivory by rats is noted to be a threat to *Schiedea membranacea* at the Wainiha, Awaawapuhi, and Kuia population (HBMP 2010; NTBG 2015). Rats eat virtually every part of plants and at every stage: fleshy fruits, seeds, flowers, stems, leaves, shoot, seedlings, and roots (Russell 1980; Cuddihy and Stone 1990). The effects on plants range from reduced vigor and decreased reproduction to mortality of individuals and complete lack of recruitment (NTBG 2009, 2014, 2015b-d, g, 2016; PEPP 2015) (USFWS, 2017).

Stressor: Herbivory by slugs

Exposure:

Response:

Consequence:

Narrative: Herbivory by slugs has been reported as a threat to this species (NTBG 2009, 2015a, e-f) (USFWS, 2017).

Stressor: Human disturbance

Exposure:

Response:

Consequence:

Narrative: Hiking and trail maintenance impacts—Trampling of plants has been reported as a threat to this species (2015e) (USFWS, 2017).

Stressor: Stochastic events

Exposure:

Response:**Consequence:**

Narrative: Reduced viability due to low numbers—*Schiedea membranacea* has been determined to be strongly outcrossing, with a high level of inbreeding depression (Culley et al. 1999).

Pollinators of *S. membranacea* may be native moths in the Pyralid family, similar to those observed on *S. lydgatei* (Norman et al. 1997), but this has not been confirmed by observations (USFWS, 2017).

Recovery**Reclassification Criteria:**

For downlisting, a total of five to seven populations of each taxon should be documented on Kauai and at least one other island where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered (USFWS, 1995).

Delisting Criteria:

For delisting, a total of 8 to 10 populations of each taxon should be documented on Kauai and at least one other island where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of five consecutive years (USFWS, 1995).

Conservation Measures and Best Management Practices:

- Continue collecting seeds from all individuals for genetic storage and reintroduction (USFWS, 1995).
- Construct exclosures around existing populations to protect from negative impacts from feral ungulates (USFWS, 2010).
- Propagate material for augmentation of existing populations and reintroductions, as suitable protected sites become available (USFWS, 2010).
- Conduct surveys, particularly in areas where *Schiedea membranacea* has not been observed since the 1990s, which include Paaiki, Nualolo, Koaie, Makaha, Waialae Ridge, and Awaawapuhi (USFWS, 2010).
- Research the presence of a seed bank (USFWS, 2010).
- Research the cause of low recruitment in the natural populations (USFWS, 2010).
- Determine the species and abundance of pollinators (USFWS, 2010).
- Work with Hawaii Division of Forestry and Wildlife, especially in Kuia and Mahanaloa, and Hawaii State Parks to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2010).
- New Management Actions: • NTBG has collected hundreds of seeds of *Schiedea membranacea* from populations for storage and propagation. Five founders from Wainiha are represented in the seed bank. There are also three separate collections from the Mahanaloa population. There are plants from several different founders from Mahanaloa (NTBG 2017). • The University of California, Irvine has seven founders from Mahanaloa represented in their greenhouse, and 24 plants from five

founders at Wainiha (UCI 2017). • PEPP has been collecting seeds for collections at NTBG and DOFAW nurseries (PEPP 2011, 2014). • PEPP is monitoring populations at Mahanaloa, Kuia, and Wainiha (PEPP 2010, 2011, 2013, 2014, 2015) (USFWS, 2017).

- Recommendations for Future Actions: Mule (black-tailed) deer have been reported as a threat to the habitat and to individuals of *Schiedea membranacea*, as well as herbivory by rats and slugs. In addition, drought, landslides, erosion, and human trampling have been reported as threats to this species. With fewer than 90 individuals, and no single populations of more than 55 individuals of this facultative outcrosser, inbreeding depression is a potential threat. No other significant new information regarding the species' biological status has been reported since the last 5-year review in 2010. Therefore, the following recommendations for future actions are added or reiterated for the 5-year review for 2017. • Surveys and inventories—Conduct surveys, particularly in areas where *Schiedea membranacea* has not been observed since the 1990s, which include Paaiki, Nualolo, Koaie, Makaha, and Waialae Ridge. • Ungulate monitoring and control—Construct small-scale exclosures around existing populations to protect from negative impacts from feral ungulates to prevent imminent extinction. Protect all occurrences against disturbances from feral ungulates. • Invasive plant monitoring and control— o Control established ecosystem-altering nonnative invasive plant species around all populations. o Control invasive nonnative species that compete with the species around all populations. • Predator and herbivore monitoring and control— o Determine and implement effective control methods for slugs. o Implement effective control methods for nonnative snails. o Implement effective control methods for rodents. • Captive propagation for genetic storage and reintroduction—Continue propagation efforts for maintenance of genetic stock. • Reintroduction and translocation—Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. • Human interaction monitoring and management—Develop and implement effective measures to reduce the impact of collecting, hiking, and trail maintenance. • Population biology research—Study *Schiedea membranacea* populations to determine viable population size and structure, geographical distribution, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. • Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered throughout historic range to reduce impacts from low numbers of individuals.

SPECIES ACCOUNT: *Schiedea nuttallii* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Region (R1) (USFWS, 2016)

Physical Description

Schiedea nuttallii is a short-lived perennial of the Caryophyllaceae (pink family). It is an erect subshrub (stems woody at the base) up to 1.5 m (4.9 ft) tall with purple-tinged, oppositely-arranged leaves 5 to 13 cm (2.0 to 5.1 in) long. The small, perfect flowers (with both male and female reproductive parts) are borne in terminal clusters 20 to 25 cm (7.8 to 9.8 in) long. The tiny hard, black seeds are contained within small papery capsules 2.5 to 3.5 mm (0.1 to 0.14 in) long (Wagner et al 1999; Makua Implementation Team 2003) (USFWS, 2016).

Historical Range

Historic data indicate considerable range restriction in *Schiedea nuttallii*, which was one of the most widely distributed species in the genus with documented occurrences on Oahu, Molokai (recently extirpated), and West Maui (historical) (Wagner et al 2005). On Oahu, *S. nuttallii* was recorded from scattered occurrences throughout the Waianae Mountains and the southeastern Koolau Mountains (USFWS, 2016).

Current Range

The species is now restricted to the northern Waianae Mountains; plants in the southern Waianae Mountains have not been seen since the late 1970s (Makua Implementation Team 2003). Plants are located on Federal and State lands (68 FR 35950). The Ekahanui Gulch occurrence at the privately owned Honouliuli Preserve, which was noted when the species was listed, has not been seen since 1978 (Service 1999a) (USFWS, 2016).

Critical Habitat Designated

Yes; 6/17/2003.

Legal Description

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea nuttallii* under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Schiedea nuttallii* (77 FR 57648-57862). The critical habitat designation includes 7 critical habitat units, which encompass approximately 7,823 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Schiedea nuttallii* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

On February 27, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Schiedea nuttallii* on the island of Kauai, Hawaii (68 FR 9116 - 9479).

Critical Habitat Designation

The critical habitat designation for *Schiedea nuttallii* includes 7 critical habitat units, covering one ecosystem type, which encompasses approximately 7,823 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Mesic—Units 1, 2, 3, 4, 5, 6, 7.

Oahu—Lowland Mesic—Unit 1 [4,448 ac (1,800 ha)]. This area consists of 3,565 ac (1,443 ha) of State land, 583 ac (236 ha) of City and County of Honolulu land, 22 ac (9 ha) of Federal land, and 277 ac (112 ha) of privately owned land in the lowland mesic ecosystem in the Waianae Mountains, encompassing a large area including the north slopes of Mt. Kaala, from the Pahole NAR to the Kaala NAR, and south to the Waianae Kai Forest Reserve (FR). Oahu—Lowland Mesic—Unit 2 [1,063 ac (430 ha)]. This area consists of 1,063 ac (430 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Puuhapapa south to Puukaua. Oahu—Lowland Mesic—Unit 3 [353 ac (143 ha)]. This area consists of 353 ac (143 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Pohakea Pass to Kaiakuakai Gulch. Oahu—Lowland Mesic—Unit 4 [20 ac (8 ha)]. This area consists of 20 ac (8 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, between the Waipilopilo and Hanaimoa gulches, on State-owned land within the Hauula Forest Reserve. Oahu—Lowland Mesic—Unit 5 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, in Maakua Gulch and ridge; is State-owned; and within the Hauula FR. Oahu—Lowland Mesic—Unit 6 [247 ac (100 ha)]. This area consists of 12 ac (5 ha) State land and 235 ac (95 ha) of privately owned land in the lowland mesic ecosystem on the windward side of the Koolau Mountains, inland of Kaaawa Point, and is partially within Ahupuaa O Kahana State Park. Oahu—Lowland Mesic—Unit 7 [1,669 ac (676 ha)]. This area consists of 681 ac (276 ha) of State land, 129 ac (52 ha) of City and County of Honolulu land, and 852 ac (345 ha) of privately-owned land in the lowland mesic ecosystem on the leeward side of the Koolau Mountains, on Waialae Nui ridge.

The critical habitat designation for *Schiedea nuttallii* includes one unit totaling 697 acres in Kauai County, Hawaii. The unit is Kauai 7—*Schiedea nuttallii*—a.

Kauai 7—*Schiedea nuttallii*—a: This unit is critical habitat for *Schiedea nuttallii* and is 282 ha (698 ac) on private land. This unit contains Hauapu and Naluakeina Summits and Queen Victoria's Profile. This unit provides habitat for two populations of 100 mature, reproducing individuals of the long-lived perennial *Schiedea nuttallii* and is currently occupied with ten to 50 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered non-viable. It provides habitat for the westernmost range of the species that is unique to Kauai. The habitat features contained in this unit that are essential for this species include, but are not limited to, cliffs in lowland diverse mesic forest dominated by *Metrosideros polymorpha*. This unit provides for two populations within this multi-island species' historical range on Kauai that are some distance away from the other critical habitat for this species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophic event.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea nuttallii* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Schiedea nuttallii*

occurs within the indicated ecosystem in the Waianae Mountain caldera complex and was known historically (last observed > 20 yrs ago) from indicated ecosystem in the Koolau Mountain caldera complex:

Oahu—Lowland Mesic—Units 1, 2, 3, 4, 5, 6, 7. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: Acacia, Diospyros, Metrosideros, Myrsine, Pouteria, Santalum. (E) Subcanopy: Dodonaea, Freycinetia, Leptecophylla, Melanthera, Osteomeles, Pleomele, Psydrax. (F) Understory: Carex, Dicranopteris, Diplazium, Elaphoglossum, Peperomia.

Within this unit, the currently known primary constituent elements of critical habitat include, but are not limited to, the habitat components provided by:

- (i) Cliffs in lowland diverse mesic forest dominated by *Metrosideros polymorpha* and containing one or more of the following associated native plant species: *Antidesma platyphyllum* var. *hillebrandii*, *Bidens valida*, *Chamaesyce celastroides*, *Eragrostis variabilis*, *Hedyotis acuminata*, *Hedyotis fluvialis*, *Heteropogon contortus*, *Lepidium* spp., *Lobelia niihauensis*, *Psychotria* spp., *Perrottetia sandwicensis*, or *Pisonia* spp.; and
- (ii) Elevations between 127 and 702 m (418 and 2,303 ft).

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Schiedea nuttallii* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

The following management actions are important: Feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas deemed essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas deemed essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Insect pollinated (USFWS, 2016)

Lifespan

Adult: <10 years (USFWS, 2016)

Breeding Season

Adult: Flowers and fruits are abundant in the wet season and less so throughout the year (USFWS, 2016).

Reproduction Narrative

Adult: Flowers and fruits are abundant in the wet season and less so throughout the year. *Schiedea nuttallii* is an outcrossing species that requires pollinators, probably insects, for fruit production (Wagner et al 2005). Plant longevity probably is similar to that of other small, semi-woody shrubs that live less than 10 years (i.e., short-lived perennials) (Makua Implementation Team 2003). Other demographic information for *S. nuttallii* in the wild is unknown, including longevity, number of seeds produced, age at sexual maturity, survivorship to sexual maturity, number of years in reproductive condition, survivorship during reproductive life, timing of reproductive output, pollination and seed dispersal in the wild, vegetative reproduction in the wild, and specific environmental requirements (USFWS, 2016).

Habitat Type

Adult: Rock walls/forest slopes (USFWS, 2016)

Habitat Narrative

Adult: *Schiedea nuttallii* occurs in the understory of diverse mesic forest at elevations between 400 and 730 m (1,312 and 2,395 ft). It typically grows on steep rock walls and forested slopes of north-facing gulches in *Acacia koa*-*Metrosideros polymorpha* lowland mesic forest and *Metrosideros polymorpha*-*Dodonaea viscosa* forest (68 FR 35950) (USFWS, 2016).

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Increasing (USFWS, 2016)

Number of Populations:

2 (USFWS, 2016)

Population Size:

91 (USFWS, 2016)

Population Narrative:

Currently, this species consists of only two known population units totaling 94 individuals (Table SB 35). The Kahanahaiki portion of the Kahanahaiki to Pahole population unit is located on Makua. The Pahole portion of the Kahanahaiki to Pahole population unit and the Kapuna-Keawapilau Ridge population unit are located in Pahole Natural Area Reserve. The Kahanahaiki to Pahole population unit currently contains 80 mature individuals, and may meet the numerical criterion for stability (defined as 50 mature, reproducing individuals for short-lived perennials). This population unit increased from about 48 total individuals in 2003 to 91 total individuals in

2006, primarily owing to Army augmentation efforts (Makua Implementation Team 2003, U.S. Army Garrison 2006d). About 50 percent of all currently existing individuals are augmentations from greenhouse-propagated stock, including about 52 percent of all mature individuals and 36 percent of all immature individuals. The Kahanahaiki to Pahole population unit is located within low to very low zones at risk from training-related wildfire (USFWS, 2016).

Threats and Stressors

Stressor: Non-native slugs and snails (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: *Schiedea nuttallii* is particularly vulnerable to predation by non-native slugs and snails. Seedlings have been observed in wild populations, but recruitment is reduced because of these alien invertebrates. Augmented *S. nuttallii* individuals seem to survive the initial outplanting transition but are subsequently weakened by invertebrate injury (Makua Implementation Team 2003). One study noted, for example, that seedling mortality for the related species *S. obovata* doubled when exposed to slug herbivory (U.S. Army Garrison 2005b) (USFWS, 2016).

Stressor: Black twig borer (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: This species also may be threatened by the black twig borer *Xylosandrus compactus*, which causes slight to severe defoliation and reduced plant vigor that may kill branches or the entire plant (68 FR 35950; U.S. Army Garrison 2004a). Black twig borer predation would be of particular concern for *S. nuttallii* because no control methods are available that do not also harm native scolytid beetles (USFWS, 2016).

Stressor: Fire (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Regarding fire vulnerability, *S. nuttalli* is a small, understory herbaceous plant less than 1.5 m (4.9 ft) tall with stems that are woody only at the base. Whether *S. nuttallii* resprouts or regenerates from buried seeds after fire is unknown, but it is probably similar to most native Hawaiian plants in lack of resistance or tolerance to fire (USFWS, 2016).

Stressor: Stochastic events/reduced vegetative vigor (USFWS, 2016)

Exposure:

Response:

Consequence: Extinction

Narrative: Most importantly, occurrences of *Schiedea nuttallii* are vulnerable to extirpation from naturally occurring events such as landslides and/or reduced reproductive vigor due to small population size and limited distribution (61 FR 53108; 68 FR 35950; Service 1999a) (USFWS, 2016).

Stressor: Low isozyme variability (USFWS, 2016)

Exposure:**Response:****Consequence:** Extinction

Narrative: *S. nuttallii* and the related species *S. kaalae* and *S. pentandra* are characterized by low isozyme variability and inbreeding due to small population size (Wagner et al 2005). Reductions in population size could result in expression of inbreeding depression among progeny, for example in reduced reproductive vigor, with potentially deleterious consequences for the long-term persistence of this species. The science of conservation biology has documented a general pattern of population collapse for a wide range of plant and animal species (Dennis et al 1991; Schemske et al 1994; Morris et al 1999; Menges 2000). According to this pattern, *S. nuttallii* already is in a phase of “quasi-extinction” with numbers that have declined to the point where demographic stochasticity alone can result in extirpation. Thus, *S. nuttallii* has a very high background risk of species extinction and any additional threats could eliminate expectation of its long-term persistence (USFWS, 2016).

Recovery**Delisting Criteria:**

Conservation actions that should be implemented for the recovery of *Schiedea nuttallii* are described in the introduction to the “Status and Environmental Baseline of the Species and Critical Habitat” section. Due to limited knowledge of life history requirements for short-term and long-term survival, the recovery plan for this species specifies interim objectives to downlisting and delisting that involve stabilization of all existing populations (Service 1999a). Research on slug control in forest settings is needed to find ways to reduce invertebrate threats to *S. nuttallii* and associated native plants.

Conservation Measures and Best Management Practices:

- The Makua Implementation Team (2003) has developed stabilization protocols for *Schiedea nuttallii*, which are incorporated in the Army’s Makua Implementation Plan Addendum (U.S. Army Garrison 2005a). The Army has been augmenting occurrences in the Kahanahaiki and Pahole population unit since 2003. In addition, this species is located in occurrences over three management units where it will benefit from population unit and/or ecosystem-level protection. The management units include Upper Kapuna, which is not fenced; and Kahanahaiki and Pahole, which are fenced. *Schiedea nuttallii* has been successfully propagated by tissue culture from seed, and from cuttings. The germination rate of fresh seed is about 50 percent, and the success rate of cuttings is 10 to 50 percent. Seed can be stored with little or no decrease in viability, but germination trials have not yet been conducted because so few plants are available to provide material (U.S. Army Garrison 2005b). Both remaining population units, Kahanahaiki to Pahole and Kapuna-Keawapilau Ridge, are represented in ex situ collections (U.S. Army Garrison 2005b). In 2005, these ex situ collections included 108 cuttings in nurseries (Army Environmental Division, Oahu, and Harold L. Lyon Arboretum), 54 ungerminated seeds in a nursery (Harold L. Lyon Arboretum), 1,300 seeds in seed storage (Lyon Arboretum Seed Storage Facility), and 20 seedlings in a nursery (Harold L. Lyon Arboretum) (Service 2005b).

SPECIES ACCOUNT: *Schiedea obovata* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Region (R1) (USFWS, 2016)

Physical Description

A subshrub 3-10 dm tall, with somewhat fleshy leaves, and congested clusters of 7-12 white and green flowers. (NatureServe, 2015)

Historical Range

Historically, this species was known from the northern and southern parts of the Waianae Mountains (USFWS, 2016)

Current Range

Endemic to Waianae Mountains of Oahu (NatureServe, 2015).

Critical Habitat Designated

Yes; 6/17/2003.

Legal Description

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea obovata* under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Schiedea obovata* (77 FR 57648-57862). The critical habitat designation includes 11 critical habitat units, which encompass approximately 7,332 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Schiedea obovata* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Schiedea obovata* includes 11 critical habitat units, covering two ecosystem types, which encompass approximately 7,332 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Mesic—Units 1, 2, 3; Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8.

Oahu—Lowland Mesic—Unit 1 [4,448 ac (1,800 ha)]. This area consists of 3,565 ac (1,443 ha) of State land, 583 ac (236 ha) of City and County of Honolulu land, 22 ac (9 ha) of Federal land, and 277 ac (112 ha) of privately owned land in the lowland mesic ecosystem in the Waianae Mountains, encompassing a large area including the north slopes of Mt. Kaala, from the Pahole NAR to the Kaala NAR, and south to the Waianae Kai Forest Reserve (FR). Oahu—Lowland Mesic—Unit 2 [1,063 ac (430 ha)]. This area consists of 1,063 ac (430 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Puuhapapa south to Puukaua. Oahu—Lowland Mesic—Unit 3 [353 ac (143 ha)]. This area consists of 353 ac (143 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Pohakea Pass to Kaiakuakai Gulch.

Oahu—Dry Cliff—Unit 1 [49 ac (20 ha)]. This area consists of 49 ac (20 ha) in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the rim of Makua Valley. Oahu—Dry Cliff—Unit 2 [412 ac (167 ha)]. This area consists of 320 ac (130 ha) of State land and 91 ac (37 ha) of City and County of Honolulu land in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the ridge from Keaau to Ohikilolo. Oahu—Dry Cliff—Unit 3 [450 ac (182 ha)]. This area consists of 349 ac (141 ha) of City and County of Honolulu land and 101 ac (41 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the eastern rim of Makaha Valley along Kamaileunu Ridge. Oahu—Dry Cliff—Unit 4 [24 ac (10 ha)]. This area consists of 24 ac (10 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along Kauaopuu ridge, which divides Waianae Kai and Lualualei valleys. Oahu—Dry Cliff—Unit 6 [149 ac (60 ha)]. This area consists of 149 ac (60 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Lualualei Valley from Puukanehoa to Puukaua. Oahu—Dry Cliff—Unit 7a [68 ac (27 ha)]. This area consists of 68 ac (27 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley to Pohakea. Oahu—Dry Cliff—Unit 7b [38 ac (16 ha)]. This area consists of 38 ac (16 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley at Palikea. Oahu—Dry Cliff—Unit 8 [259 ac(105 ha)]. This area consists of 259 ac (105 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Nanakuli Valley from Palehua to Puumanawanua, and partially within the Nanakuli Forest Reserve.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea obovata* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Schiedea obovata* occurs within the Lowland mesic and Dry cliff ecosystems in the Waianae Mountain caldera complex:

Oahu—Lowland Mesic—Units 1, 2, 3. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: Acacia, Diospyros, Metrosideros, Myrsine, Pouteria, Santalum. (E) Subcanopy: Dodonaea, Freycinetia, Leptecophylla, Melanthera, Osteomeles, Pleomele, Psydrax. (F) Understory: Carex, Dicranopteris, Diplazium, Elaphoglossum, Peperomia.

Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8. (A) Elevation: unrestricted. (B) Annual Precipitation: < 75 in (<190 cm). (C) Substrate: >65 degree slope, rocky talus. (D) Canopy: None. (E) Subcanopy: Antidesma, Chamaesyce, Diospyros, Dodonaea. (F) Understory: Bidens, Eragrostis, Melanthera, *Schiedea*.

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Schiedea obovata* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats

will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Self-fertilizing (USFWS, 2016)

Lifespan

Adult: 3-6 years (USFWS, 2016)

Breeding Season

Adult: Flowers and fruit are produced year-round, especially in response to rainfall during winter and spring (USFWS, 2016).

Reproduction Narrative

Adult: Plants generally flower after two years of growth, and are normally self-fertilizing (Makua Implementation Team 2003). Flowers and fruit are produced year-round, especially in response to rainfall during winter and spring. Seed dispersal mechanism is unknown, although the plant's "false berry" possibly may attract fruit-eating birds that may disperse the seeds (Makua Implementation Team 2003). Plants survive 3 to 6 years, or less under drought conditions (Service 1995a, Service 1998a). Population units in the wild have been known to disappear for a number of years and then reappear after large rainfall events, apparently owing to persistence of seeds in the soil seed bank (U.S. Army Garrison 2004a). Other demographic information for *S. obovata* in the wild is unknown, including number of seeds produced, survivorship to sexual maturity, number of years in reproductive condition, survivorship during reproductive life, seed dispersal, vegetative reproduction and specific environmental requirements (USFWS, 2016).

Habitat Type

Adult: Forested ridges and slopes (USFWS, 2016)

Habitat Narrative

Adult: *Schiedea obovata* occurs on ridges and slopes in lowland diverse mesic forests dominated by *Acacia koa* and *Metrosideros polymorpha*, at elevations of 560 to 760 m (1,837 to 2,494 ft) (USFWS, 2016).

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Unknown

Number of Populations:

2 (USFWS, 2016)

Population Size:

389 individuals (USFWS, 2016))

Population Narrative:

Currently, two population units, Kahanahaiki to Pahole and Keawapilau to West Makaleha, total 389 individuals located on Federal and State lands (68 FR 35950) (Table SB 36). The Kahanahaiki to Pahole population unit has met numerical criteria for stabilization (defined for this species as 100 mature individuals per population unit) (Makua Implementation Team 2003). The existing population units also are located within low and very low fire risk zones for training-related wildfire. Demographic data indicate *Schiedea obovata* is increasing in numbers only due to augmentation efforts and the discovery of a new population unit in North West Makaleha. About 82 percent of all of individuals are augmentations from greenhouse-propagated stock. Recruitment of seedlings and immature plants into the mature population is limited by predation by non-native slugs and snails that feed on and damage leaves and stems (Makua Implementation Team 2003; U.S. Army Garrison 2004a; U.S. Army Garrison 2005b). One study noted, for example, that seedling mortality doubled when exposed to slug herbivory (U.S. Army Garrison 2005b). Furthermore, slugs have the potential to completely halt seedling regeneration in several sites (U.S. Army Garrison 2004a, 2005b). Thus, *S. obovata* is characterized by declining in the current range and two existing population units with low numbers, of which one is exceeding minimum numerical criteria for stabilization and increasing through augmentation and discovery of new individuals (USFWS, 2016).

Threats and Stressors

Stressor: Slugs and snails (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: *Schiedea obovata* is particularly vulnerable to predation by non-native slugs and snails (Makua Implementation Team 2003; U.S. Army Garrison 2005b) (USFWS, 2016).

Stressor: Residential development (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Residential development is listed as a threat to this species (USFWS, 2016).

Stressor: Reforestation (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Reforestation with non-native trees is listed as a threat to this species (USFWS, 2016).

Stressor: Military installations (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Establishment of military installations is listed as a threat to this species (USFWS, 2016).

Stressor: Trampling/collection

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Trampling and illegal collecting by people is listed as a threat to this species (USFWS, 2016).

Stressor: Stochastic events (USFWS, 2016)

Exposure:

Response:

Consequence: Extinction

Narrative: Population units of *S. obovata* are vulnerable to extirpation from naturally occurring events such as rockslides and/or reduced reproductive vigor due to small population size and limited distribution (56 FR 55770; 68 FR 35950; Service 1995a, 1998a) (USFWS, 2016).

Stressor: Drought (USFWS, 2016)

Exposure:

Response:

Consequence: Population fluctuation

Narrative: This species experiences large population fluctuations related to drought and its natural recruitment is severely reduced by slug predation (U.S. Army Garrison 2005c) (USFWS, 2016).

Recovery

Delisting Criteria:

Conservation actions that should be implemented for the recovery of *Schiedea obovata* are described in the introduction to the "Status and Environmental Baseline of the Species and Critical Habitat" section. Due to limited knowledge of life history requirements for short-term and long-term survival, the recovery plan for this species specifies interim objectives to downlisting and delisting that involve stabilization of all existing populations (Service 1995a, 1998a). At least 50 mature, reproducing individuals are needed per population unit to attain stabilization criteria for short-lived perennials. However, because of the common, large declines or fluctuations in numbers of *S. obovata*, the Makua Implementation Team (2003) identified a stabilization target of at least 100 mature individuals for each population unit of this species. An increased stabilization criterion is needed because any adverse disturbance during a major low point in a population unit's fluctuation could extirpate that unit. In addition to stabilizing the two existing population units, a third population unit must be established by reintroduction and managed for stabilization outside the action area. Research on slug control in forest settings is needed to find ways to reduce this threat to *S. obovata* and associated native plants (USFWS, 2016).

The Makua Implementation Team (2003) has developed stabilization protocols for *Schiedea obovata*, which are incorporated in the Army's Makua Implementation Plan Addendum (U.S. Army Garrison 2005a). This species occurs in the Kahanahaiki, Pahole, and West Makaleha

Management Units where it will benefit from population unit and/or ecosystem-level protection. The Army and the Hawaii Division of Forestry and Wildlife have been outplanting this species within fenced exclosures since 1999. The Kahanahaiki to Pahole population unit is located within the fenced Kahanahaiki and Pahole Management Units, and the North West Makaleha site within the Keawapilau to West Makaleha population unit is fenced. Fence construction is planned for the entire West Makaleha Management Unit in 2007. Invasive weeds are controlled at extant *S. obovata* sites, but not at historical sites. *Schiedea obovata* seed can be successfully stored and remain viable for several years, and outplantings have been successful (U.S. Army Garrison 2005b). In 2005, this species was represented in the following ex situ collections: one cutting in a nursery (Army Environmental Division, Oahu), 14 plants in a botanical garden (Waimea Valley Audubon Center), 161 seeds in micropropagation (Harold L. Lyon Arboretum), 236,814 seeds in seed storage (Lyon Arboretum Seed Storage Facility), and 13 seedlings in micropropagation (Harold L. Lyon Arboretum) (Service 2005b) (USFWS, 2016).

SPECIES ACCOUNT: *Schiedea pubescens* (ma'oli'oli)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/31/2016; Pacific Region (R1) (USFWS, 2016)

Physical Description

Schiedea pubescens is a reclining or weakly climbing vine with a woody base. The plant is glabrous except for the inflorescence, which has dense purple-tinged hairs. The stems are 3.3 to 20 feet (ft) (1 to 6 meters (m)) long with internodes that are usually 2.4 to 4.7 inches (in) (6 to 12 centimeters (cm)) long. Opposite, green leaves are sometimes purple tinged especially along the midrib. In addition they are thick, leathery and narrowly lanceolate. The tiny flowers are perfect and are arranged in open cymes. The inflorescence is 12 to 20 in (30 to 50 cm) long with green bracts, which are sometimes tinged with purple (Wagner et al. 1999a, p. 519).

Taxonomy

Kingdom: Plantae; Phylum: Anthophyta; Class: Dicotyledoneae; Order: Caryophyllales; Family: Caryophyllaceae (Pinks). *Schiedea pubescens* was described by Hillebrand (1888). This species is recognized as a distinct taxon in the Manual of Flowering Plants of Hawaii (Wagner et al. 1999a, p. 519), and Wagner et al. (2005).

Historical Range

Schiedea pubescens was historically found scattered on the islands of Molokai, Lanai, and Maui. On Molokai, it was found from Kalae to Pukoo ridge; on Maui, it was known from the western mountains at Olowalu, Kaanapali, and Waihee, and from the eastern mountains at Makawao; and on Lanai, it was known from the Lanaihale area (HBMP 2008). On Lanai, it was known from the Lanaihale summit area but has not been observed since 1922 (USFWS, 2016).

Current Range

This species, which is declining and extremely threatened, is known from 13 populations on Maui, Molokai, and Hawaii (Wood, in litt. 2001; Oppenheimer, in litt. 2006; HBMP 2008; Bakutis, in litt. 2010; Oppenheimer, in litt. 2010; Perlman, in litt. 2010).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual: cross-pollination (USFWS, 2016)

Reproduction Narrative

Adult: This species is outcrossing (USFWS, 2016).

Habitat Type

Adult: Diverse mesic to wet forest

Habitat Vegetation or Surface Water Classification

Adult: Forest - Hardwood

Habitat Narrative

Adult: This species occurs in diverse mesic to wet *Metrosideros* (ohia) forest at elevations between 2,000 and 3,000ft (600 and 900 m) (Hawaii Biodiversity and Mapping Program (HBMP) 2008; Wagner et al. 1999a, 519).

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Not available

Redundancy:

Schiedea pubescens (ma'oli'oli)

Number of Populations:

Molokai: 1; Maui: 7 (USFWS, 2016)

Population Size:

Molokai: < 30 (USFWS, 2016)

Population Narrative:

Currently, this species is known from one occurrence on Molokai totaling fewer than 30 individuals. The occurrence on east Maui has not been re-observed, but this species is found at seven locations on west Maui (Wood 2001, in litt.; Oppenheimer 2006, in litt.; Bakutis 2010, in litt.; HBMP 2010; MNTF 2010, in litt.; Oppenheimer 2010, in litt.; PEPP 2014, pp. 162–163; Oppenheimer 2015, in litt.) (USFWS, 2016).

Threats and Stressors

Stressor: Feral pigs, goats, and nonnative plants

Exposure:

Response: Habitat degradation and destruction

Consequence:

Narrative: *Schiedea pubescens* is highly and imminently threatened by feral pigs (*Sus scrofa*) and feral goats (*Capra hircus*) that degrade and destroy habitat (HBMP 2008). Evidence of the activities of feral pigs has been reported at the Hawaii, Maui, and Molokai populations, and of feral goats at the Hawaii population (HBMP 2008). Hawaiian ecosystems, having evolved without hoofed mammals, are susceptible to large-scale disturbance by pigs, goats, and other introduced ungulates (Loope et al. 1991). Because of demonstrated habitat modifications by feral pigs and goats, such as destruction of native plants, disruption of topsoil leading to erosion, and establishment and spread of nonnative plants, the U.S. Fish and Wildlife Service (FWS) believes they are a threat to *S. pubescens*.

Stressor: Predation (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: Feral pigs have been observed browsing on young shoots, leaves and fronds of a wide variety plants, of which over 85 percent were endemic species (Diong 1982). A stomach content analyses also showed that the pigs food sources consisted of native plants, 60 percent of which were *Cibotium* spp.(tree ferns), alternating with *Psidium cattleianum* when it was available. Pigs have also been observed felling and removing the bark of *Clermontia*, *Cibotium*, *Coprosma*, *Psychotria*, and *Hedyotis* species (herbaceous and woody plants), and causing enough damage to kill larger trees over a few months of repeated feedings (Diong 1982). Goats browse on introduced grasses and native plants and are able to reach more remote and inaccessible areas than other ungulates. They thrive on a variety of food plants and are instrumental in the decline of native vegetation in many areas (Cuddihy and Stone 1990). Because Hawaii's native plants evolved without any browsing or grazing mammals present, many lost natural defenses to such impacts (Carlquist 1980). Browsing by ungulates has been observed on many other native species, including common and rare or endangered species (Cuddihy and Stone 1990; Loope et al. 1991). Therefore, though we have no direct evidence of browsing for this species, it is likely that pigs and goats impact *S. pubescens* directly as well as the surrounding habitat. Herbivory by slugs and seed predation by rats are both reported to be threats to *S. pubescens* on Maui (HBMP 2010; PEPP 2014, p. 162; Duvall 2015, in litt.) (USFWS, 2016).

Stressor: Fire

Exposure:

Response:

Consequence:

Narrative: Fire is a likely threat to the population in the Army's Pohakuloa Training Area on the island of Hawaii (HBMP 2008). This area is dry, windy, and at risk of fire due to military training activities. The fire-adapted nonnative grass, *Pennisetum setaceum*, is a serious pest in dry areas as it can alter the fire characteristics of its habitat (Smith 1989). Because Hawaiian plants were subjected to fire during their evolution only in areas of volcanic activity and from occasional lightning strikes, they are not adapted to recurring fire regimes and do not quickly recover following a fire. Alien plants are often better adapted to fire than native plant species, and some fire-adapted grasses have become widespread in Hawaii. Native shrubland and dry forest can thus be converted to land dominated by alien grasses. The presence of such species in Hawaiian ecosystems greatly increases the intensity, extent, and frequency of fire, especially during drier months or drought. Fire-adapted alien plant taxa can reestablish in a burned area, resulting in a reduction in the amount of native vegetation after each fire. Fire can destroy dormant seeds as well as plants, even in steep or inaccessible areas. Fires may result from natural causes, or may be accidentally or purposely started by humans (Cuddihy and Stone 1990).

Stressor: Low genetic variation (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: This species is outcrossing; however, very low population sizes may have reduced its genetic variation (Weller 2015, in litt.) (USFWS, 2016).

Stressor: Climate change (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: Fortini et al. (2013, p. 88) found that, as environmental conditions are altered by climate change, *S. pubescens* is unlikely to tolerate or adapt to projected changes in temperature and moisture, and is unlikely to be able to move to areas with more suitable climatic conditions (USFWS, 2016).

Recovery

Recovery Actions:

- Survey for populations of *Schiedea pubescens* in areas of potentially suitable habitat.
- Remove feral pigs and goats from areas where *S. pubescens* populations exist and prevent reinvasion through the use of exclosures.
- Control alien plants using physical, mechanical, and biological control methods, as well as herbicides when necessary.
- Conduct research into potential biocontrol species.
- Begin propagation efforts for maintenance of genetic stock.
- Reintroduce individuals of *S. pubescens* into suitable habitat within historic range that is being managed for known threats to this species.

Conservation Measures and Best Management Practices:

- Remove feral pigs and goats from areas where *S. pubescens* populations exist and prevent reinvasion through the use of exclosures.
- Control alien plants using physical, mechanical, and biological control methods, as well as herbicides when necessary.
- Begin propagation efforts for maintenance of genetic stock.
- Reintroduce individuals of *S. pubescens* into suitable habitat within historic range that is being managed for known threats to this species.

SPECIES ACCOUNT: *Schiedea salicaria* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Region (R1) (USFWS, 2016)

Physical Description

An erect subshrub or shrub, 3-18 dm tall. Inflorescences terminal, 8-11 cm long. (NatureServe, 2015)

Taxonomy

Hawaiian endemic genus of 22 species, species endemic to west Maui. No varieties recognized by Wagner et al. (NatureServe, 2015)

Historical Range

See current range/distribution.

Current Range

Endemic to the southern and eastern side of West Maui, state of Hawaii. (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea salicaria* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes two detailed critical habitat units (CHUs), in Maui County in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Schiedea salicaria* includes two CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Lowland Dry—Unit 5 consists of 3,615 ac (1,463 ha) of State land, and 43 ac (17 ha) of privately owned land, from Panaewa to Manawainui on the western and southern slopes of west Maui. This unit is occupied by the plants *Asplenium dielerectum*, *Bidens campylotheca* ssp. *pentamera*, *Cenchrus agrimonioides*, *Gouania hillebrandii*, *Kadua coriacea*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and *Tetramolopium capillare*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 5 is not known to be occupied by *Ctenitis squamigera*, *Cyanea obtusa*, *Hesperomannia arbuscula*, *Hibiscus brackenridgei*, *Lysimachia lydgatei*, *Neraudia sericea*, *Schiedea salicaria*, *Sesbania tomentosa*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes,

suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 6 consists of 3 ac (1 ha) of State land, and 237 ac (96 ha) of privately owned land, from Paleaahu Gulch to Puu Hona on the southern slopes of west Maui. This unit is occupied by the plants *Hibiscus brackenridgei* and *Schiedea salicaria*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 6 is not known to be occupied by *Asplenium dielerectum*, *Bidens campylotheca* ssp. *pentamera*, *Cenchrus agrimonoides*, *Ctenitis squamigera*, *Cyanea obtusa*, *Gouania hillebrandii*, *Hesperomannia arbuscula*, *Kadua coriacea*, *Lysimachia lydgatei*, *Neraudia sericea*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Spermolepis hawaiiensis*, *Tetramolopium capillare*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea salicaria* critical habitat consists of one component. Lowland dry (west Maui) (81 FR 17790-18110):

Ecosystem: Lowland Dry. Elevation: <3,300 ft (<1,000 m). Annual precipitation: <50 in (<130 cm). Substrate: Weathered silty loams to stony clay, rocky ledges, littleweathered lava. Canopy: *Diospyros*, *Myoporum*, *Pleomele*, *Santalum*. Subcanopy: *Chamaesyce*, *Dodonaea*, *Leptecophylla*, *Osteomeles*, *Psydrax*, *Scaevola*, *Wikstroemia*. Understory: *Alyxia*, *Artemisia*, *Bidens*, *Chenopodium*, *Nephrolepis*, *Peperomia*, *Sicyos*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species

that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*,

Bidens campylotheca ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: No information found.

Habitat Type

Adult: Dry shrublands (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Clumped (inferred from USFWS, 2016)

Environmental Specificity

Adult: Narrow/specialist (inferred from USFWS, 2016)

Tolerance Ranges/Thresholds

Adult: Low (inferred from USFWS, 2016)

Site Fidelity

Adult: High (inferred from USFWS, 2016)

Habitat Narrative

Adult: Species inhabits dry shrublands on steep slopes and ridgetops. (NatureServe, 2015). Currently, this species is found in three occurrences: Kaunoahua gulch (500 to 1,000 individuals), Puu Hona (about 50 individuals), and Waikapu Stream (3 to 5 individuals), in the lowland dry ecosystem on west Maui (TNC 2007; Oppenheimer 2010k, in litt.; Oppenheimer 2010l, in litt.) (USFWS, 2016). Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations.

Dispersal/Migration

Dispersal/Migration Narrative

Adult: No information found.

Population Information and Trends**Population Trends:**

Decreasing (NatureServe, 2015)

Number of Populations:

1 - 5 (NatureServe, 2015)

Population Size:

250 - 2500 individuals (NatureServe, 2015)

Population Narrative:

While there are no historic records of numbers of populations or individuals, qualitative accounts indicate this species was not uncommon on West Maui (Russell 2004). Decline of 30-70% Original estimated total for this species ranges from about 1,000 to about 2,000. Although, U.S Fish and Wildlife Service currently have an 2005 estimate as 100 to 300 (USFWS 2006). Total number of occurrences are 5, of those 4 are known extant occurrences found on the island of Maui. (NatureServe, 2015)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (goats, axis deer, and cattle), nonnative plants, fire, drought, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Fire can destroy dormant seeds and plants, even in steep and inaccessible areas. Successive fires can remove habitat for native species by altering microclimate conditions favorable to alien plants. Drought destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities.. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (axis deer, cattle, and goats) is considered an ongoing threat to *Schiedea salicaria* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

SPECIES ACCOUNT: *Schiedea sarmentosa* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/10/1996; Pacific Region (R1) (USFWS, 2017)

Physical Description

A many-branched subshrub 30-45 cm tall. The flowers are borne in terminal clusters.
(NatureServe, 2015)

Taxonomy

Schiedea sarmentosa is being resurrected by W.L. Wagner (W.L. Wagner, pers. comm. to Christa Russell, 1994); Kartesz's 1994 Checklist included *S. sarmentosa* in synonymy of *S. menziesii*, but the 1999 Synthesis recognizes the taxon as a distinct species. *Schiedea menziesii* had Candidate, Category 2 status in the 1990 and 1993 USFWS notices of review, but in Oct., 1995, only *S. sarmentosa* was proposed for listing and the Oct. 10, 1996 determination to list *S. sarmentosa*, explains that the switch is due to the fact that, "*S. sarmentosa* was included in *S. menziesii* by Wagner et al. (1990). Warren Wagner and Stephen Weller, who are preparing a monograph of the genus, now consider *S. sarmentosa* to be a separate species." *S. menziesii* is not mentioned in the Oct. 31, 1996 reprint of the List of Endangered and Threatened Wildlife and Plants or in the Sept. 1997 notice of review. (NatureServe, 2015) A member of the pink family (Caryophyllaceae) (USFWS, 2016).

Historical Range

Historically no additional range. (NatureServe, 2015)

Current Range

Current range includes Molokai. (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Schiedea sarmentosa* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one detailed critical habitat unit (CHU), in Maui County in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Schiedea sarmentosa* includes one CHU in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Molokai—Lowland Mesic—Unit 1 (and) *Palmeria dolei*—Unit 37—Lowland Mesic (and) *Pseudonestor xanthophrys*—Unit 37— Lowland Mesic This area consists of 3,489 ac (1,412 ha) of State land, and 5,281 ac (2,137 ha) of privately owned land, from Waianui Gulch to Mapulehu, in central Molokai. These units are occupied by the plants *Alectryon macrococcus*, *Ctenitis squamigera*, *Cyanea dunbariae*, *C. mannii*, *C. profuga*, *Cyperus fauriei*, *Cyrtandra filipes*, *Gouania hillebrandii*, *Labordia triflora*, *Neraudia sericea*, *Santalum haleakalae* var. *lanaiense*, *Schiedea*

lydgatei, *S. sarmentosa*, *Silene alexandri*, *S. lanceolata*, *Spermolepis hawaiiensis*, and *Zanthoxylum hawaiiense*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Lowland Mesic—Unit 1 is not known to be occupied by *Asplenium dielirectum*, *Bonamia menziesii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea procera*, *C. solanacea*, *Diplazium molokaiense*, *Festuca molokaiensis*, *Flueggea neowawraea*, *Isodendron pyriformis*, *Kadua laxiflora*, *Melicope mucronulata*, *M. munroi*, *M. reflexa*, *Phyllostegia haliakalae*, *P. mannii*, *P. pilosa*, *Sesbania tomentosa*, *Stenogyne bifida*, or *Vigna o-wahuensis*, or the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Schiedea sarmentosa* critical habitat consists of one component. Lowland mesic (Molokai) (81 FR 17790-18110):

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*,

Cyperus trachysanthos, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookii*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus perianthus*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkii*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C.*

duvalliorum, C. hamatiflora ssp. hamatiflora, C. horrida, C. kunthiana, C. magnicalyx, C. mannii, C. maritae, C. mceldowneyi, C. profuga, C. solanacea, Cyrtandra filipes, C. munroi, Diplazium molokaiense, Dubautia plantaginea ssp. humilis, Geranium hanaense, G. multiflorum, Hesperomannia arborescens, Huperzia mannii, Kadua laxiflora, Lysimachia lydgatei, L. maxima, Melicope balloui, M. ovalis, Phyllostegia hispida, P. mannii, P. pilosa, Plantago princeps, Platanthera holochila, Pteris lidgatei, Remya mauiensis, Santalum haleakalae var. lanaiense, Schiedea laui, Stenogyne bifida, S. kauaulaensis, Wikstroemia villosa, and Zanthoxylum hawaiiense) found on steep slopes and cliffs, or in narrow gulches.

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Possibly wind pollinated, sexual (USFWS, 1998)

Reproduction Narrative

Adult: The flowers are female on some plants and bisexual on others. The population in Makolelau Gulch has a frequency of females of 31 percent. Based on analyses of pollen-ovule ratios, pollen size, inflorescence structure, and comparison to other Schiedea species tested in a wind tunnel, Schiedea sarmentosa could be wind-pollinated (Steven Weller, University of California, Irvine, personal communication 1997). No other life history information for this species is available (USFWS, 1998).

Habitat Type

Adult: Steeply sloped shrubland (USFWS, 1998)

Habitat Vegetation or Surface Water Classification

Adult: Lwoland dry or mesic shrubland (USFWS, 1998)

Dependencies on Specific Environmental Elements

Adult: Lwoland mesic ecosystem (see population narrative)

Geographic or Habitat Restraints or Barriers

Adult: 2,000 - 2,600 ft. elevation (USFWS, 1998)

Spatial Arrangements of the Population

Adult: Clumped (Inferred from NatureServe, 2015 and USFWS, 1998)

Environmental Specificity

Adult: Narrow/specialist (Inferred from NatureServe, 2015 and USFWS, 1998)

Tolerance Ranges/Thresholds

Adult: Low (Inferred from NatureServe, 2015 and USFWS, 1998)

Site Fidelity

Adult: High (Inferred from NatureServe, 2015 and USFWS, 1998)

Habitat Narrative

Adult: Dry and moist forests and shrublands. Often on rocky gulch slopes and cliffs. (NatureServe, 2015). *Schiedea sarmentosa* is typically found on steep slopes in ohia-Dodonaea viscosa (aalii) lowland dry or mesic shrubland between 610 and 790 meters (2,000 and 2,600 feet) elevation (I-THP 1991b, 1993b; HPCC 1991b, 1992). Associated species include *Syphelia tameiameia* (pukiawe), *Chenopodium oahuensis* (aheahea), *Alyxia oliviformis* (maile), *Pleomele* sp. (hala pepe), and *Chamaesyce* sp. (akoko) (HHP 1993b; HPCC 1991b, 1992) (USFWS, 1998). lumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations.

> 1000 (USFWS, 2018)

Population Narrative:

New Status Information: • There is one population estimated to total more than 1,000 individuals on Moloka'i (Bakutis 2018, in litt.) • Visits to the Kawela population in 2018 documented suspected hybrids between *Schiedea lydgatei* and *S. sarmentosa* (Weisenberger 2018, in litt.). • In 2016, one critical habitat unit in the lowland mesic ecosystem was designated on Moloka'i for *Schiedea sarmentosa* (8,770 ac; 3,549 ha) (81 FR 17790, March 30, 2016) (USFWS, 2018).

Threats and Stressors

Stressor: Feral goats, rats and slugs (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Goats, rats (*Rattus* spp.), and slugs (unidentified species) may eat parts of this plant (Perlman 2010; Wood 2010). Spittle bugs (the juvenile stage of certain leafhoppers) were observed on this species in April 2009 (Oppenheimer 2010). In addition, goats degrade the habitat through trampling the species (USFWS, 2011).

Stressor: Invasive plants (USFWS, 2011)

Exposure:**Response:**

Consequence: Loss of habitat

Narrative: Invasive plants are listed as a threat to this species (USFWS, 2011).

Stressor: Climate change loss or degradation of habitat

Exposure:**Response:**

Consequence: Loss of habitat

Narrative: We previously reported that climate change may pose a threat to this species, anticipating an analysis by 2013. The assessment conducted by Fortini et al. (2013) concluded that *S. sarmentosa* is extremely vulnerable to the impacts of climate change, with a vulnerability score of 0.977 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions are needed to conserve this taxon into the future, such as locating key microsites that overlap with current and future climate envelopes for outplanting efforts (USFWS, 2018).

Recovery**Reclassification Criteria:**

A total of five to seven populations of each taxon should be documented on Molokai. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 2011).

Delisting Criteria:

A total of 8 to 10 populations of each taxon should be documented on Molokai. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population. Each population should persist at this level for a minimum of 5 consecutive years (USFWS, 2011).

Conservation Measures and Best Management Practices:

- Conduct surveys where *Schiedea sarmentosa* has been reported to determine current status of the species (USFWS, 2011).
- Continue collection of seeds or cuttings for genetic storage and reintroduction (USFWS, 2011).
- Monitor known populations (USFWS, 2011).
- Fence all populations to provide protection from the negative impacts of feral ungulates (USFWS, 2011).
- Control invasive introduced plant species around all populations (USFWS, 2011).

- Control rats in the vicinity of these populations (USFWS, 2011).
- Develop and implement methods to control slugs and spittle bugs (USFWS, 2011).
- Establish additional populations within protected suitable habitat (USFWS, 2011).
- Develop and implement a wildfire management plan (USFWS, 2011).
- Work with the East Molokai Watershed Partnership and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2011).
- Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species (USFWS, 2011).
- New Management Actions: • Captive propagation for genetic storage and reintroduction—In 2014, the University of California—Irvine reported 12 plants from Mākolēlau in storage, representing 12 different individuals (USFWS, 2018).
- Recommendations for Future Actions: Hybridization may be a new threat to this species; however, we are not aware of any significant new information regarding the species' biological status since the last 5-year review in 2011. Thus, the following recommendations for future actions are added or reiterated for the 5-year review for 2018. • Surveys and inventories—Survey areas where *Schiedea sarmentosa* has been reported to determine current status of the species on Moloka'i. • Ungulate monitoring and control—Fence existing populations to provide protection from negative impacts of feral ungulates. • Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations of *S. sarmentosa*. • Fire destruction or degradation of habitat—Develop and implement a wildfire management plan. • Captive propagation for genetic storage and reintroduction—Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. • Reintroduction and translocation—
 - o Augment known populations and reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species.
 - o Research methods to increase and maintain numbers of female individuals within populations.
 - o Study the possible effects of hybridization on this species.• Rodent predation and herbivory—Control rats in the vicinity of all populations. • Invertebrate predation and herbivory—Develop and implement methods to control slugs and spittle bugs. • Climate change adaptation strategy—Assess the modeled effects of climate change on this species and use to determine future landscape needed for the recovery of the species. • Alliance and partnership development—Work with the East Molokai Watershed Partnership program, the Hawai'i Division of Forestry and Wildlife, and other land managers to initiate planning and contribute to ecosystem-level restoration and management to benefit this species.

SPECIES ACCOUNT: *Schiedea spergulina* var. *leiopoda* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Region (R1) (USFWS, 2016)

Physical Description

An erect or weakly erect subshrub 3-6 dm tall. The small flowers are borne in terminal clusters. (NatureServe, 2015)

Taxonomy

Gray (1854) described *Schiedea spergulina* based upon a specimen collected in 1840 on Kauai during the United States Exploring Expedition. The specific epithet means “resembling *Spergula*,” another genus in the same plant family. Two varieties of *Schiedea spergulina* are recognized in the current treatment of the genus (Wagner et al. 1990): the typical variety, which includes var. *degeneriana*, named by Sherff (1956); and var. *leiopoda* (Sherff 1944), which includes var. *major*, also named by Sherff (1944) (USFWS, 1995).

Historical Range

Historically no additional range. (NatureServe, 2015)

Current Range

Current range includes southern Kauai. (NatureServe, 2015)

Critical Habitat Designated

Yes; 2/27/2003.

Legal Description

On February 27, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Schiedea spergulina* var. *leiopoda* on the island of Kauai, Hawaii (68 FR 9116 - 9479).

Critical Habitat Designation

The critical habitat designation for *Schiedea spergulina* var. *leiopoda* includes one unit totaling 11 acres in Kauai County, Hawaii. The unit is Kauai 9—*Schiedea spergulina* var. *leiopoda*—a.

Kauai 9—*Schiedea spergulina* var. *leiopoda*—a: This unit is critical habitat for *Schiedea spergulina* var. *leiopoda* and is 5 ha (11 ac) on private land within Lawai Valley. This unit provides habitat for one population of 300 mature, reproducing individuals of the shortlived perennial *Schiedea spergulina* var. *leiopoda* and is currently occupied with 135 to 150 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered non-viable. The habitat features contained in this unit that are essential for this species include, but are not limited to, bare rock outcrops or sparsely vegetated portions of rocky cliff faces or cliff bases in diverse lowland dry to mesic forests. Although the Service does not feel that there is enough habitat designated to reach the recovery goal of 8 to 10 populations, this

species is a very narrow endemic and probably never naturally occurred in more than a single or a few populations.

Primary Constituent Elements/Physical or Biological Features

Within this unit, the currently known primary constituent elements of critical habitat include, but are not limited to, the habitat components provided by:

(i) Bare rock outcrops or sparsely vegetated portions of rocky cliff faces or cliff bases in diverse lowland dry to mesic forests and containing one or more of the following native plant species: *Acacia koa*, *Artemisia australis*, *Bidens sandwicensis*, *Carex meyenii*, *Chamaesyce celastroides*, *Dianella sandwicensis*, *Doryopteris* spp., *Eragrostis variabilis*, *Erythrina sandwicensis*, *Gahnia* spp., *Heliotropium* spp., *Lepidium serra*, *Lipochaeta connata*, *Microlepis strigosa*, *Nestegis sandwicensis*, *Nototrichium sandwicense*, *Panicum lineale*, *Peucedanum sandwicense*, or *Wilkesia gymnoxiphium*; and

(ii) Elevations between 21 and 90 m (69 and 294 ft).

Special Management Considerations or Protections

Existing manmade features and structures within the boundaries of the mapped areas, such as buildings; roads; aqueducts and other water system features, including but not limited to pumping stations, irrigation ditches, pipelines, siphons, tunnels, water tanks, gaging stations, intakes, reservoirs, diversions, flumes, and wells; existing trails; campgrounds and their immediate surrounding landscaped area; scenic lookouts; remote helicopter landing sites; existing fences; telecommunications equipment towers and associated structures and equipment; electrical power transmission lines and distribution, and communication facilities and regularly maintained associated rights-of-way and access ways; radars, telemetry antennas; missile launch sites; arboreta and gardens; heiau (indigenous places of worship or shrines), and other archaeological sites; airports; other paved areas; and lawns and other rural residential landscaped areas do not contain one or more of the primary constituent elements described for each species in paragraph (b) of this section and therefore are not included in the critical habitat designations.

The following management actions are important: Feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas deemed essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas deemed essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Little is known about the life history of *Schiedea spergulina* var. *leipoda*. Flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors are unknown (USFWS, 1995).

Habitat Type

Adult: Rock outcrops (USFWS, 1995)

Spatial Arrangements of the Population

Adult: Clumped (inferred from USFWS, 1995 and USFWS, 2010)

Environmental Specificity

Adult: Narrow/specialist (inferred from USFWS, 1995 and USFWS, 2010)

Tolerance Ranges/Thresholds

Adult: Low (inferred from USFWS, 1995 and USFWS, 2010)

Site Fidelity

Adult: High (inferred from USFWS, 1995 and USFWS, 2010)

Habitat Narrative

Adult: This taxon is usually found on bare rock outcrops or sparsely vegetated portions of rocky cliff faces or cliff bases in diverse lowland mesic forests at elevations between 180 and 800 meters (590 and 3,000 feet). Plant taxa associated with *Schiedea spergulina* var. *spergulina* include ahinahina, Chinaberry, lantana, Sacramento bur, and *Nototrichium sandwicense* (kului) (USFWS 1994a) (USFWS, 1995). Historically, *Schiedea spergulina* var. *leipoda* was found on a ridge on the east side of Hanapepe on Kauai and one population of approximately 50 to 100 individuals was known on the west side of Lawai Valley on Kauai, on a plateau and adjacent cliffs above the McBryde Garden of the National Tropical Botanical Garden (National Tropical Botanical Garden 2008; USFWS 1995). Currently the Hanapepe population has not been seen for many years, and the Lawai Valley population has between 120 to 325 individuals, including mature, immature, and seedlings. Seeds have been collected from 160 different individuals in the last four years (National Tropical Botanical Garden 2008; Perlman 2009; N, Tangalin, National Tropical Botanical Garden, pers. comm. 2009) (USFWS, 2010). Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations.

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Little is known about the life history of *Schiedea spergulina* var. *leipoda*. Flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors are unknown (USFWS, 1995).

Population Information and Trends**Population Trends:**

Unknown (NatureServe, 2015)

Number of Populations:

1 (USFWS, 2017)

Population Size:

85 individuals (USFWS, 2017)

Population Narrative:

At the time of the last 5-year review in 2010 there was 1 population totaling between 120 to 325 individuals at Lawai Valley on Kauai. Currently, this population is declining, and there are at least 85 individuals in the same area (NTBG 2012, 2016a-b). In 2016, IUCN reported 5 subpopulations of *S. spergulina* (with no varieties) totaling approximately 600 individuals (Clark 2016) (USFWS, 2017).

Threats and Stressors

Stressor: Invasive plants

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Invasive plants are listed as a threat to this species (USFWS, 2010)

Stressor: Climate change (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Climate change may also pose a threat to *Schiedea spergulina* var. *leiopoda* (Factors A and E). However, current climate change models do not allow us to predict specifically what those effects, and their extent, would be for this species (USFWS, 2010).

Stressor: Feral goat (USFWS< 1995)

Exposure:

Response:

Consequence: Loss of individuals/Loss of habitat

Narrative: Habitat degradation and erosion caused by feral goats (*Capra hircus*) is listed as a threat to this species (USFWS, 1995).

Stressor: Stochastic events (USFWS, 1995)

Exposure:

Response:

Consequence: Extinction

Narrative: Stochastic natural events such as fire, landslides, etc. are a threat to this species due to its limited range and single extant population (USFWS, 1995).

Stressor: Pesticides (USFWS, 1995)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: The use of pesticides on nearby sugarcane fields is listed as a threat to this species (USFWS, 1995).

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Schiedea spergulina* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.702 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). In addition, Fortini et al. show that Caryophyllaceae is one of the top four most vulnerable native plant families, and, at the genus level, *Schiedea* had one of the highest vulnerability scores. Therefore, additional management actions are needed to conserve this taxon into the future (USFWS, 2017).

Stressor: Hurricanes—Loss and degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Hurricanes were omitted in the last five year review. In November 1982, Hurricane Iwa struck the Hawaiian Islands, with wind gusts exceeding 100 miles per hour (mph) (161 kilometers per hour (kph)), causing extensive damage, especially on the islands of Niihau, Kauai, and Oahu (Businger 1998). In September 1992, Hurricane Iniki, a category 4 hurricane with maximum sustained wind speeds recorded at 140 mph (225 kph), passed directly over the island of Kauai. Many forest trees were destroyed (Perlman 1992), which opened the canopy and facilitated the invasion of nonnative plants (Kitayama and Mueller-Dombois 1995). A destructive hurricane holds the potential of driving a localized endemic species to extinction in a single event, and 70 percent of all listed plant species on Kauai are only found on Kauai. Hurricanes pose an ongoing and ever-present threat because they can happen at any time, although their occurrence is not predictable. Tropical cyclone frequency and intensity are projected to change as a result of climate change over the next 100 to 200 years (Vecchi and Soden 2007; Emanuel et al. 2008; Yu et al. 2010). In the central Pacific, modeling projects an increase of up to two additional tropical cyclones per year in the main Hawaiian Islands by 2100 (Murakami et al. 2013) (USFWS, 2017).

Recovery

Reclassification Criteria:

For downlisting, a total of five to seven populations of *Schiedea spergulina* var. *leiopoda* should be documented on islands where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered (USFWS, 2010).

Delisting Criteria:

For delisting, a total of eight to ten populations of *Schiedea spergulina* var. *leiopoda* should be documented on islands where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of five consecutive years before delisting is considered (USFWS, 2010).

Conservation Measures and Best Management Practices:

- Continue control of invasive introduced plant species at the one known population (USFWS, 2010).
- Continue to collect for adequate genetic storage and reintroduction (USFWS, 2010).
- Establish additional populations (USFWS, 2010).
- Conduct surveys throughout historical range to determine the current status of the species as a whole, which is necessary before the species can be reclassified (USFWS, 2010).
- Work with Hawaii Division of Forestry and Wildlife to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit future reintroduced populations of this species (USFWS, 2010).
- Update the listed entity on 50 CFR 17 to match the currently recognized taxonomy after a thorough status survey has been completed (USFWS, 2010).
- New Management Actions: • NTBG has been collecting thousands of seeds of *Schiedea spergulina* from Lawai for storage and propagation. They have at least 30 founders represented in their seed bank (NTBG 2017). • The University of California, Irvine has nine founders from Lawai represented by 120 plants in their greenhouse (UCI 2017). • PEPP was monitoring the Lawai population; however, the *S. spergulina* var. *leiopoda* was recently downgraded from PEP (fewer than 50 in the wild) to POP (potential PEP) as a result of the reported combination of the two varieties (PEPP 2012, 2013) (USFWS, 2017).
- Recommendations for Future Actions: No new threats and no other significant new information regarding the species' biological status have been reported since the last 5-year review in 2010. Therefore, the following recommendations for future actions are reiterated for the 5-year review for 2017. • Surveys and inventories—Conduct surveys throughout historical range to determine the current status of the species as a whole, which is necessary before the species can be reclassified. • Captive propagation for genetic storage and reintroduction—Continue propagation efforts for maintenance of genetic stock. • Reintroduction and translocation—Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. • Update the listed entity on 50 CFR 17.12 to combine *S. spergulina* var. *leiopoda* with *S. spergulina* and remove *S. spergulina* var. *leiopoda* if further genetic studies verify this taxonomic change (USFWS, 2017).

Species Taxonomic and Listing Information

Listing Status: Threatened; 02/25/1994; Pacific Region (R1) (USFWS, 2016)

Physical Description

An erect or weakly erect subshrub 3-6 dm tall. The flowers are borne in terminal clusters. (NatureServe, 2015)

Taxonomy

Gray (1854) described *Schiedea spergulina* based upon a specimen collected in 1840 on Kauai during the United States Exploring Expedition. The specific epithet means “resembling *Spergula*,” another genus in the same plant family. Two varieties of *Schiedea spergulina* are recognized in the current treatment of the genus (Wagner et al. 1990): the typical variety, which includes var. *degeneriana*, named by Sherff (1956); and var. *leiopoda* (Sherff 1944), which includes var. *major*, also named by Sherff (1944) (USFWS, 1995).

Historical Range

Historically no additional range. (NatureServe, 2015)

Current Range

Current range includes Waimea Canyon area of Kauai. (NatureServe, 2015)

Critical Habitat Designated

Yes; 2/27/2003.

Legal Description

On February 27, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Schiedea spergulina* var. *spergulina* on the island of Kauai, Hawaii (68 FR 9116 - 9479).

Critical Habitat Designation

The critical habitat designation for *Schiedea spergulina* var. *spergulina* includes three units totaling 1,059 acres in Kauai County, Hawaii. The units are Kauai 11—*Schiedea spergulina* var. *spergulina*—a, b and Kauai 13—*Schiedea spergulina* var. *spergulina*—c.

Kauai 11—*Schiedea spergulina* var. *spergulina*—a: This unit is critical habitat for *Schiedea spergulina* var. *spergulina* and is 131 ha (324 ac) on State land (Na Pali Coast State Park) within Kalalau Valley. This unit provides habitat for two populations of 300 mature, reproducing individuals of the short-lived perennial *Schiedea spergulina* var. *spergulina* and is currently occupied with one plant. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable. The habitat features contained in this unit that are essential for this species include, but are not limited to, bare rock outcrops or sparsely vegetated portions of rocky cliff faces or cliff bases in diverse lowland dry to

mesic forests. This unit is geographically separated from the other two units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Although the Service does not feel that there is enough habitat that currently exists to reach the recovery goal of 8 to 10 populations for this species, this unit is at an appropriate distance from the other units to avoid their destruction by one naturally occurring catastrophic event. Kauai 11—*Schiedea spergulina* var. *spergulina*—b: This unit is critical habitat for *Schiedea spergulina* var. *spergulina* and is 77 ha (191 ac) on State land within Kawaiiki Valley. This unit provides habitat for two populations of 300 mature, reproducing individuals of the short-lived perennial *Schiedea spergulina* var. *spergulina* and is currently occupied with five plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable. The habitat features contained in this unit that are essential for this species include, but are not limited to, bare rock outcrops or sparsely vegetated portions of rocky cliff faces or cliff bases in diverse lowland dry to mesic forests. This unit is geographically separated from the other two units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Although the Service does not feel that there is enough habitat that currently exists to reach the recovery goal of 8 to 10 populations for this species, this unit is at an appropriate distance from the other units to avoid their destruction by one naturally occurring catastrophic event.

Kauai 13—*Schiedea spergulina* var. *spergulina*—c: This unit is critical habitat for *Schiedea spergulina* var. *spergulina* and is 221 ha (545 ac) on State land within Waimea Canyon. This unit provides habitat for two populations of 300 mature, reproducing individuals of the short-lived perennial *Schiedea spergulina* var. *spergulina* and is currently unoccupied. This unit is essential to the conservation of the taxon because it supports habitat that is important to the establishment of additional populations on Kauai in order to reach recovery goals. The habitat features contained in this unit that are essential for this species include, but are not limited to, bare rock outcrops or sparsely vegetated portions of rocky cliff faces or cliff bases in diverse lowland dry to mesic forests. This unit is geographically separated from the other two units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Although the Service does not feel that there is enough habitat that currently exists to reach the recovery goal of 8 to 10 populations for this species, this unit is at an appropriate distance from the other unit to avoid their destruction by one naturally occurring catastrophic event.

Primary Constituent Elements/Physical or Biological Features

Within these units, the currently known primary constituent elements of critical habitat include, but are not limited to, the habitat components provided by:

(i) Bare rock outcrops or sparsely vegetated portions of rocky cliff faces or cliff bases in diverse lowland dry to mesic forests and containing one or more of the following associated plant species: *Acacia koa*, *Artemisia australis*, *Bidens sandwicensis*, *Carex meyenii*, *Chamaesyce celastroides*, *Dianella sandwicensis*, *Doryopteris* spp., *Eragrostis variabilis*, *Erythrina sandwicensis*, *Gahnia* spp., *Heliotropium* spp., *Lepidium serra*, *Lipochaeta connata*, *Microlepia strigosa*, *Nestegis sandwicensis*, *Nototrichium sandwicense*, *Panicum lineale*, *Peucedanum sandwicense*, or *Wilkesia gymnoxiphium*; and

(ii) Elevations between 145 and 829 m (474 and 2,718 ft).

Special Management Considerations or Protections

Existing manmade features and structures within the boundaries of the mapped areas, such as buildings; roads; aqueducts and other water system features, including but not limited to pumping stations, irrigation ditches, pipelines, siphons, tunnels, water tanks, gaging stations, intakes, reservoirs, diversions, flumes, and wells; existing trails; campgrounds and their immediate surrounding landscaped area; scenic lookouts; remote helicopter landing sites; existing fences; telecommunications equipment towers and associated structures and equipment; electrical power transmission lines and distribution, and communication facilities and regularly maintained associated rights-of-way and access ways; radars, telemetry antennas; missile launch sites; arboreta and gardens; heiau (indigenous places of worship or shrines), and other archaeological sites; airports; other paved areas; and lawns and other rural residential landscaped areas do not contain one or more of the primary constituent elements described for each species in paragraph (b) of this section and therefore are not included in the critical habitat designations.

The following management actions are important: Feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas deemed essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas deemed essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Little is known about the life history of *Schiedea spergulina* var. *spergulina*. Flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors are unknown (USFWS, 1995).

Habitat Type

Adult: Rock outcrops (USFWS, 1995)

Spatial Arrangements of the Population

Adult: Clumped (inferred from USFWS, 1995 and USFWS, 2010)

Environmental Specificity

Adult: Narrow/specialist (inferred from USFWS, 1995 and USFWS, 2010)

Tolerance Ranges/Thresholds

Adult: Low (inferred from USFWS, 1995 and USFWS, 2010)

Site Fidelity

Adult: High (inferred from USFWS, 1995 and USFWS, 2010)

Habitat Narrative

Adult: This taxon is usually found on bare rock outcrops or sparsely vegetated portions of rocky cliff faces or cliff bases in diverse lowland mesic forests at elevations between 180 and 800 meters (590 and 3,000 feet). Plant taxa associated with *Schiedea spergulina* var. *spergulina* include ahinahina, Chinaberry, lantana, Sacramento bur, and *Nototrichium sandwicense* (kului) (USFWS 1994a) (USFWS, 1995). There are 6 known populations totaling 440 to 585 individuals (USFWS, 2010). Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations.

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Little is known about the life history of *Schiedea spergulina* var. *spergulina*. Flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors are unknown (USFWS, 1995).

Population Information and Trends**Population Trends:**

Unknown (NatureServe, 2015)

Number of Populations:

4 (USFWS, 2017)

Population Size:

500-1000 individuals (USFWS, 2017)

Population Narrative:

At the time of the last 5-year review in 2010 there were six populations totaling between 440 to 585 individuals at Kaeha, Waimea, Koaie, Hipalau, Kalalau, and Kahuamaa Flat on Kauai. Currently, there are 1,000 or more individuals along Waimea Canyon road and at least four individuals at Makaha (NTBG 2011a-d, 2012a-i, 2014a-b). The status of populations at Kalalau rim, Koaie, and Kaeha has not been reported since 2008. In 2016, Clark reported five subpopulations of *S. spergulina* (with no varieties) totaling approximately 600 individuals (Clark 2016). Considering population estimates for *Schiedea spergulina* var. *leiopoda* are approximately 100 individuals, this puts the range of known plants for *Schiedea spergulina* var. *spergulina* at between 500 to 1,000 individuals total at four populations (USFWS, 2017).

Threats and Stressors

Stressor: Feral goats (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Habitat degradation and erosion caused by feral goats (*Capra hircus*) is listed as a threat to this species (USFWS, 2010).

Stressor: Invasive plants (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Competition with invasive introduced plant species is listed as a threat to this species (USFWS, 2010).

Stressor: Fire (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Fire is listed as a threat to this species (USFWS, 2010)

Stressor: Climate change (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Climate change may also pose a threat to *Schiedea spergulina* var. *spergulina* (Factors A and E). However, current climate change models do not allow us to predict specifically what those effects, and their extent, would be for this species (USFWS, 2010).

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Schiedea spergulina* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.702 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). In addition, Fortini et al. show that Caryophyllaceae is one of the top four most vulnerable native plant families, and, at the genus level, *Schiedea* had one of the highest vulnerability scores. Therefore, additional management actions are needed to conserve this taxon into the future (USFWS, 2017).

Stressor: Hurricanes—Loss and degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Hurricanes were omitted in the last five year review. In November 1982, Hurricane Iwa struck the Hawaiian Islands, with wind gusts exceeding 100 miles per hour (mph) (161 kilometers per hour (kph)), causing extensive damage, especially on the islands of Niihau, Kauai, and Oahu (Businger 1998). In September 1992, Hurricane Iniki, a category 4 hurricane with

maximum sustained wind speeds recorded at 140 mph (225 kph), passed directly over the island of Kauai. Many forest trees were destroyed (Perlman 1992), which opened the canopy and facilitated the invasion of nonnative plants (Kitayama and Mueller-Dombois 1995). A destructive hurricane holds the potential of driving a localized endemic species to extinction in a single event, and 70 percent of all listed plant species on Kauai are only found on Kauai. Hurricanes pose an ongoing and ever-present threat because they can happen at any time, although their occurrence is not predictable. Tropical cyclone frequency and intensity are projected to change as a result of climate change over the next 100 to 200 years (Vecchi and Soden 2007; Emanuel et al. 2008; Yu et al. 2010). In the central Pacific, modeling projects an increase of up to two additional tropical cyclones per year in the main Hawaiian Islands by 2100 (Murakami et al. 2013) (USFWS, 2017).

Recovery

Reclassification Criteria:

For downlisting, a total of five to seven populations of *Schiedea spergulina* var. *spergulina* should be documented on islands where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered (USFWS, 2010).

Delisting Criteria:

For delisting, a total of eight to ten populations of *Schiedea spergulina* var. *spergulina* should be documented on islands where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of five consecutive years before delisting is considered (USFWS, 2010).

Conservation Measures and Best Management Practices:

- Control goats around existing populations (USFWS, 2010).
- Continue to collect for adequate genetic storage and propagation (USFWS, 2010).
- Establish reintroductions within protected suitable habitat (USFWS, 2010).
- Conduct surveys throughout historical range to determine the current status of the species, which is necessary before the species can be reclassified (USFWS, 2010).
- Work with Hawaii Division of Forestry and Wildlife and other landowners to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2010).
- Update the listed entity on 50 CFR 17 to match the currently recognized taxonomy after thorough surveys of the species have been conducted (USFWS, 2010).
- New Management Actions: • NTBG has one collection of this former variety of *Schiedea spergulina* from Makaha in their seed bank. They have plants from Waimea Canyon in the nursery (NTBG 2017).
 - The University of California, Irvine, has one founder represented by nine plants in their greenhouse from the Waimea Canyon population (USFWS, 2017).
- Recommendations for Future Actions: No new threats and no other significant new information regarding the species' biological status have been reported since the last 5-year review in 2010.

Therefore, the following recommendations for future actions are reiterated for the 5-year review for 2017. • Surveys and inventories—Conduct surveys throughout historic range to determine the current status of the species as a whole, which is necessary before the species can be reclassified. • Ungulate monitoring and control—Construct fenced exclosures to provide protection against feral ungulates. Protect all populations against browsing and disturbances from feral ungulates. • Invasive plant monitoring and control— o Control invasive nonnative plant species at all known populations. o Control invasive plant species that compete with the species around all known populations. • Fire monitoring and control—Develop and implement fire management plans for all wild and reintroduced populations. • Captive propagation for genetic storage and reintroduction—Continue to collect for adequate genetic storage and reintroduction. • Reintroduction and translocation—Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. • Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from landslides. • Population biology research—Study *Schiedea spergulina* var. *spergulina* populations to determine viable population size and structure, geographical distribution, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. • Update the listed entity on 50 CFR 17.12 to combine *S. spergulina* var. *leiopoda* with *S. spergulina* and remove *S. spergulina* var. *leiopoda* if further genetic studies verify this taxonomic change (USFWS, 2017).

SPECIES ACCOUNT: *Schiedea stellarioides* (Laulihilihi)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/10/1996; Pacific Region (R1) (USFWS, 2016)

Physical Description

A weakly erect to sprawling subshrub 3-6 dm tall. Leaves are narrow. The small flowers are borne in open clusters. (NatureServe, 2015)

Taxonomy

Mann and Brigham first collected a specimen of *Schiedea stellarioides* in the mountains of Kauai between 1864 and 1865. Benedict Pierre George Hochreutiner and E.E. Sherff published several varieties of this species, characterized only by slight differences in leaf-shape and size, which are not recognized in the current treatment of the family (USFWS 1996) (USFWS, 1998).

Historical Range

See current range/distribution

Current Range

Current range Kauai, recently rediscovered (1991-1992); known historically from Kauai.

Critical Habitat Designated

Yes; 2/27/2003.

Legal Description

On February 27, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Schiedea stellarioides* on the island of Kauai, Hawaii (68 FR 9116 - 9479).

Critical Habitat Designation

The critical habitat designation for *Schiedea stellarioides* includes two units totaling 3,432 acres in Kauai county, Hawaii. The units are Kauai 11—*Schiedea stellarioides*—a, b.

Kauai 11—*Schiedea stellarioides*—a: This unit is critical habitat for *Schiedea stellarioides* and is 1,259 ha (3,113 ac) on State land (Alakai Wilderness Preserve and Puu Ka Pele Forest Reserve). This unit contains portions of Kaluahaulu and Kawaiiki Ridges, and Kawaiiki and Kipalau Valleys. This unit provides habitat for five populations of 300 mature, reproducing individuals of the shortlived perennial *Schiedea stellarioides* and is currently occupied with 200 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered non-viable. The habitat features contained in this unit that are essential for this species include, but are not limited to, steep slopes in closed *Acacia koa*-*Metrosideros polymorpha* lowland or montane mesic forest or shrubland. This unit is geographically separated from the other unit designated as critical habitat for this islandendemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Although the Service does not feel that there is enough habitat that currently exists to reach the recovery goal of 8 to 10 populations for this species, this unit is at an appropriate size and distance from

the other unit to avoid their destruction by one naturally occurring catastrophic event. Kauai 11—*Schiedea stellarioides*—b: This unit is critical habitat for *Schiedea stellarioides* and is 129 ha (320 ac) on State land (Alakai Wilderness Preserve) within upper Waialae Valley. This unit provides habitat for one population of 300 mature, reproducing individuals of the short-lived perennial *Schiedea stellarioides* and is currently unoccupied. This unit is essential to the conservation of the taxon because it supports habitat that is important to the establishment of additional populations on Kauai in order to reach recovery goals. The habitat features contained in this unit that are essential for this species include, but are not limited to, steep slopes in closed *Acacia koa*/*Metrosideros polymorpha* lowland or montane mesic forest or shrubland. This unit is geographically separated from the other unit designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Although the Service does not feel that there is enough habitat that currently exists to reach the recovery goal of 8 to 10 populations for this species, this unit is at an appropriate distance from the other unit to avoid their destruction by one naturally occurring catastrophic event.

Primary Constituent Elements/Physical or Biological Features

Within these units, the currently known primary constituent elements of critical habitat include, but are not limited to, the habitat components provided by:

- (i) Steep slopes in closed *Acacia koa*/*Metrosideros polymorpha* lowland or montane mesic forest or shrubland and containing one or more of the following native plant species: *Alsinidendron viscosum*, *Artemisia australis*, *Bidens cosmoides*, *Chenopodium* spp., *Dianella sandwicensis*, *Dodonaea viscosa*, *Mariscus* spp., *Melicope* spp., *Nototrichium sandwicense*, *Pipturus* spp., *Leptecophylla tameiameia*, *Syzygium sandwicensis*, or *Zanthoxylum dipetalum*; and
- (ii) Elevations between 376 and 1,251 m (1,135 and 4,102 ft).

Special Management Considerations or Protections

Existing manmade features and structures within the boundaries of the mapped areas, such as buildings; roads; aqueducts and other water system features, including but not limited to pumping stations, irrigation ditches, pipelines, siphons, tunnels, water tanks, gaging stations, intakes, reservoirs, diversions, flumes, and wells; existing trails; campgrounds and their immediate surrounding landscaped area; scenic lookouts; remote helicopter landing sites; existing fences; telecommunications equipment towers and associated structures and equipment; electrical power transmission lines and distribution, and communication facilities and regularly maintained associated rights-of-way and access ways; radars, telemetry antennas; missile launch sites; arboreta and gardens; heiau (indigenous places of worship or shrines), and other archaeological sites; airports; other paved areas; and lawns and other rural residential landscaped areas do not contain one or more of the primary constituent elements described for each species in paragraph (b) of this section and therefore are not included in the critical habitat designations.

The following management actions are important: Feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas deemed essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations;

maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas deemed essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History

Food/Nutrient Resources

Breeding Season

Adult: Plants were observed flowering by botanists from the National Tropical Botanical Garden in February 1995 (USFWS, 1998).

Reproduction Narrative

Adult: Plants were observed flowering by botanists from the National Tropical Botanical Garden in February 1995 (Steve Perlman, NTBG Provenance Report 1995). No additional life history information for this species is currently available (USFWS, 1998).

Habitat Type

Adult: Mesic forest (USFWS, 1998)

Spatial Arrangements of the Population

Adult: Clumped (USFWS, 2010; USFWS, 1998)

Environmental Specificity

Adult: Narrow/specialist (USFWS, 2010; USFWS, 1998)

Tolerance Ranges/Thresholds

Adult: Low (USFWS, 2010; USFWS, 1998)

Site Fidelity

Adult: High (USFWS, 2010; USFWS, 1998)

Habitat Narrative

Adult: *Schiedea stellarioides* is found on steep slopes in a closed koa-ohia lowland to montane mesic forest between 610 and 1,120 meters (2,000 and 3,680 feet) elevation (USFWS 1996). Associated plant species include aalii, alani, ukiuki, *Bidens cosmoides* (poola nui), *Mariscus* sp., and *Styphelia tameiameia* (pukiawe) (USFWS 1996) (USFWS, 1998). USFWS (2010) notes that there are 3 known populations with likely less than 200 total plants. Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations.

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Plants were observed flowering by botanists from the National Tropical Botanical Garden in February 1995 (Steve Perlman, NTBG Provenance Report 1995). No additional life history information for this species is currently available (USFWS, 1998).

Population Information and Trends

Population Trends:

Decreasing (USFWS, 2010)

Number of Populations:

3 (USFWS, 2010))

Population Size:

~200 (USFWS, 2010))

Population Narrative:

Historically, *Schiedea stellarioides* was found at the sea cliffs of Hanakapiai Beach, Kaholuamanu-Opaewela region, the ridge between Waialae and Nawaimaka Valleys, and Haupu Range on the island of Kauai. At the time of listing this species was found only at the ridge between Waialae and Nawaimaka Valleys on State land, just 0.8 kilometer (0.5 mile) northwest of the Kaholuamanu-Opaewela region. This population of approximately 500 to 1,000 individuals was found on steep slopes in a closed *Acacia koa* (*koa*) – *Metrosideros polymorpha* (*ohia*) lowland to montane mesic forest between 610 and 1,120 meters (2,000 and 3,680 feet) elevation. The plants were scattered in approximately a 2-kilometer (1.25-mile) by 0.3-kilometer (0.2-mile) area (USFWS 1996). This situation remains substantially the same, although an additional population in Kawaiiki has been observed, and no plants have been noted from Nawaimaka Stream for some time. The total number of plants may now be less than 200 in the previously known populations (Perlman 2008; National Tropical Botanical Garden 2008). One hundred or more individuals were observed on the south rim of the Waialae Valley by botanists of the National Tropical Botanical Garden at 1,005 to 1,066 meters (3,300 to 3,500 feet) elevation in the years from 1991 through 2004 (Perlman 2008). At a visit in May 2008 Ken Wood of the National Tropical Botanical Garden estimated about 200 plants in the area (Wood 2008). A smaller population occurs in upper Kawaiiki Valley, along the slope below Kaluahaula Ridge. Fifty to sixty scattered individuals were noted through 2001 by Ken Wood of National Tropical Botanical Garden in the Kawaiiki area (Wood 2008) and by Perlman in 2005 (Perlman 2008). The top of a drainage below Kawaiiki Ridge was visited in June 2004 by botanist Natalia Tangalin from the National Tropical Botanical Garden (Tangalin 2005) who saw 20 plants and collected seed from three of them, and in July 2005 by Perlman and Tangalin, who observed about 50 individuals (Perlman 2008; Tangalin 2005; National Tropical Botanical Garden 2008). In May 2008, Wood observed about 20 individuals in this area of Kawaiiki, off Kaluahaula ridge, in the upper forest and drainage to the south of Koaie and north of Waialae (Wood 2008). The third location at the Nawaimaka stream near Waialae was last visited in February 1995 by Steve Perlman (Perlman 2008) and in July 1996 by Ken Wood (Wood 2008). Although the number of plants at that time was not noted, they were observed to be flowering in February (Perlman 2008) (USFWS, 2010). New Status Information: In addition to those populations cited in the previous 5-year review, new observations include the following: • At the time of the last 5-year review in 2010 there were four populations totaling fewer than 200 individuals at Kaholuamanu-Opaewela, Kawaiiki, Waialae, and Nawaimaka. The status of the population at

Kaholuamanu-Opaewela has not been reported since 2010, and *S. stellarioides* has not been reported at Hanakapiai and Haupu since the early 1900s. Currently, there are two populations, one at Kawaiiki to Kaluahaulu ridge and one along the ridge between Waialae and Nawaimaka valleys including above the water fall at Waialae. These occurrences total at least 100 individuals (NTBG 2009, 2010, 2013, 2014, 20151-d; PEPP 2011, 2012, 2013, 2014, 2015). In 2016, IUCN Red List of Threatened Species reported two 'subpopulations' (considered populations by USFWS) of 50 individuals each at the same locations (Clark 2016) (USFWS, 2017).

Threats and Stressors

Stressor: Feral/invasive animals (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Major threats to this species are feral goats, deer, pigs and rats both in terms of trampling and predation (USFWS< 2010).

Stressor: Fire (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Fire is listed as a major threat to this species (USFWS, 2010).

Stressor: Invasive plants (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Invasive plants are listed as a major threat to this species (USFWS, 2010).

Stressor: Climate change (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Climate change may also pose a threat to *Schiedea stellarioides* (Factors A and E). However, current climate change models do not allow us to predict specifically what those effects, and their extent, would be for this species (USFWS, 2010)..

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Schiedea stellarioides* is extremely vulnerable to the impacts of climate change, with a vulnerability score of 0.878 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). In addition,

Fortini et al. show that Caryophyllaceae is one of the top four most vulnerable native plant families, and, at the genus level, *Schiedea* had one of the highest vulnerability scores. Therefore, additional management actions are needed to conserve this taxon into the future (USFWS, 2017).

Stressor: Hurricanes—Loss and degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Hurricanes were omitted in the last five year review. In November 1982, Hurricane Iwa struck the Hawaiian Islands, with wind gusts exceeding 100 miles per hour (mph) (161 kilometers per hour (kph)), causing extensive damage, especially on the islands of Niihau, Kauai, and Oahu (Businger 1998). In September 1992, Hurricane Iniki, a category 4 hurricane with maximum sustained wind speeds recorded at 140 mph (225 kph), passed directly over the island of Kauai. Many forest trees were destroyed (Perlman 1992), which opened the canopy and facilitated the invasion of nonnative plants (Kitayama and Mueller-Dombois 1995). A destructive hurricane holds the potential of driving a localized endemic species to extinction in a single event, and 70 percent of all listed plant species on Kauai are only found on Kauai. Hurricanes pose an ongoing and ever-present threat because they can happen at any time, although their occurrence is not predictable. Tropical cyclone frequency and intensity are projected to change as a result of climate change over the next 100 to 200 years (Vecchi and Soden 2007; Emanuel et al. 2008; Yu et al. 2010). In the central Pacific, modeling projects an increase of up to two additional tropical cyclones per year in the main Hawaiian Islands by 2100 (Murakami et al. 2013) (USFWS, 2017).

Recovery

Reclassification Criteria:

For downlisting, a total of five to seven populations of each taxon should be documented on Kauai where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 1998).

Delisting Criteria:

For delisting, a total of 8 to 10 populations of each taxon should be documented on Kauai where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of 5 consecutive years (Species is a short-lived perennial) (USFWS, 1998).

Conservation Measures and Best Management Practices:

- Fence areas where this species grows to protect against pig damage (USFWS, 2010).
- Determine and implement methods to control rat and slug control around known plants (USFWS, 2010).
- Continue to collect seeds for genetic storage and reintroduction (USFWS, 2010).
- Propagate plants for outplanting (USFWS, 2010).

- Work with Hawaii Division of Forestry and Wildlife and Hawaii State Parks to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2010).
- New Management Actions: • NTBG has several collections from Kawaiiki represented by plants in their nursery. The NTBG seed bank has six founders represented from the Waialae population from a collection in 2008, and one collection from Kawaiiki in 2015 (NTBG 2017). • The University of California, Irvine has 11 founders represented by 12 plants total in their nursery from the Waialae Valley population. • The Lyon Arboretum seed bank has 17 founders represented from a 2010 collection at Nawaimaka, and four founders represented from a 2016 collection at Kawaiiki (Lyon Arboretum 2017). • PEPP is monitoring individuals at Kawaiiki, and outplanted at least 10 individuals, of which 6 survive, with some natural reproduction (PEPP 2011, 2012, 2013, 2014, 2015) (USFWS, 2017).
- Recommendations for Future Actions: No new threats and no other significant new information regarding the species' biological status have been reported since the last 5-year review in 2010. Therefore, the following recommendations for future actions are reiterated for the 5-year review for 2017. • Surveys and inventories—Survey for populations of *Schiedea stellarioides* in areas of potentially suitable habitat. • Ungulate monitoring and control—Protect all occurrences against disturbances from feral ungulates. Construct and maintain fenced exclosures around all populations. • Invasive plant monitoring and control— o Control established ecosystem-altering nonnative invasive plant species around all populations. o Control invasive nonnative species that compete with the species around all populations. • Fire monitoring and control—Develop and implement fire management plans for all wild and reintroduced populations. • Predator and herbivore monitoring and control—Implement effective control methods for rodents. Captive propagation for genetic storage and reintroduction—Continue propagation efforts for maintenance of genetic stock. • Reintroduction and translocation—Continue to reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. • Population biology research—Study *Schiedea stellarioides* populations to determine viable population size and structure, geographical distribution, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats (USFWS, 2017).

SPECIES ACCOUNT: *Schiedea trinervis* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/29/1991; Pacific Region (R1) (USFWS, 2016)

Physical Description

An erect, branched subshrub 3-8 dm tall. The white and green flowers are borne in clusters of 7-20. (NatureServe, 2015)

Taxonomy

No new taxonomic information has been received since the last 5-year review (USFWS 2009). However, the 2012 supplement to the Manual of the Flowering Plants of Hawaii (Wagner et al. 2012) reiterates the change from the genus *Alsinidendron* to the currently accepted *Schiedea*. In 2012, USFWS revised the taxonomic status for this species when it revised critical habitat on Oahu, with no change in range or distribution (USFWS 2012). This species is now listed as *Schiedea trinervis* (USFWS, 2013).

Historical Range

See current range/distribution

Current Range

Current range: Waianae Mountains of Oahu. Historically no additional range.

Critical Habitat Designated

Yes; 6/17/2003.

Legal Description

September 18, 2012, the U.S. Fish and Wildlife Service (Service), revised critical habitat for *Schiedea trinervis* on Oahu.

Critical Habitat Designation

Oahu—Montane Wet—Unit 1, Oahu—Dry Cliff—Unit 1, Oahu—Dry Cliff—Unit 2, Oahu—Dry Cliff—Unit 3, Oahu—Dry Cliff—Unit 4, Oahu—Dry Cliff—Unit 6, Oahu—Dry Cliff—Unit 7a, Oahu—Dry Cliff—Unit 7b, Oahu—Dry Cliff—Unit 8, Oahu—Wet Cliff—Unit 1, Oahu—Wet Cliff—Unit 2, Oahu—Wet Cliff—Unit 3, Oahu—Wet Cliff—Unit 4, and Oahu—Wet Cliff—Unit 5 constitute critical habitat for *Schiedea trinervis* on Oahu.

Oahu—Montane Wet—Unit 1 consists of 18 ac (7 ha) of City and County of Honolulu land, 352 ac (142 ha) of State land, and less than 1 ac (less than one ha) of privately-owned land in the montane wet ecosystem at the summit of the Waianae Mountains at Kaala, and partially within the Mokuleia Forest Reserve and the Kaala Natural Area Reserve. This unit is occupied by the plants *Cyanea acuminata*, *C. calycina*, *Labordia cyrtandrae*, *Melicope christophersenii*, and *Schiedea trinervis*, and includes the wet forest and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 4). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations.

Oahu—Dry Cliff—Unit 1 consists of 49 ac (20 ha) in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the rim of Makua Valley. This unit is on State land within the Pahole Natural Area Reserve, and includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). This unit is occupied by the plants *Alectryon macrococcus*, *Cenchrus agrimonioides*, *Chamaesyce herbstii*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Kadua degeneri*, *Plantago princeps* var. *princeps*, and *Schiedea obovata*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 1 is not currently occupied by *Abutilon sandwicense*, *Achyranthes splendens* var. *rotundata*, *Bonamia menziesii*, *Chamaesyce kuwaleana*, *Diellia falcata*, *D. unisora*, *Dubautia herbtsobatae*, *Eragrostis fosbergii*, *Flueggea neowawraea*, *Gouania meyenii*, *G. vitifolia*, *Isodendron laurifolium*, *I. pyrifolium*, *Kadua parvula*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *M. saint-johnii*, *Neraudia angulata*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Platydesma cornuta* var. *decurrans*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Sanicula mariversa*, *Schiedea hookeri*, *S. trinervis*, *Silene lanceolata*, *S. perlmannii*, *Spermolepis hawaiiensis*, *Tetramolopium filiforme*, *T. lepidotum* ssp. *lepidotum*, or *Viola chamissoniana* ssp. *chamissoniana*, the Service has determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 2 consists of 320 ac (130 ha) of State land and 91 ac (37 ha) of City and County of Honolulu land in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the ridge from Keaau to Ohikilolo. This unit is almost entirely within the Makua Keaau Forest Reserve, and includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). Dry Cliff—Unit 2 is occupied by the plants *Abutilon sandwicense*, *Alectryon macrococcus*, *Dubautia herbtsobatae*, *Gouania vitifolia*, *Kadua parvula*, *Lepidium arbuscula*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *Nototrichium humile*, *Peucedanum sandwicense*, *Platydesma cornuta* var. *decurrans*, *Pleomele forbesii*, *Sanicula mariversa*, *Schiedea hookeri*, *Tetramolopium filiforme*, and *Viola chamissoniana* ssp. *chamissoniana*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 2 is not currently occupied by *Achyranthes splendens* var. *rotundata*, *Bonamia menziesii*, *Cenchrus agrimonioides*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *D. unisora*, *Eragrostis fosbergii*, *Flueggea neowawraea*, *Gouania meyenii*, *Isodendron laurifolium*, *I. pyrifolium*, *Kadua degeneri*, *Korthalsella degeneri*, *Lipochaeta lobata* var. *leptophylla*, *Melicope saint-johnii*, *Neraudia angulata*, *Phyllostegia kaalaensis*, *Plantago princeps*, *Pteralyxia macrocarpa*, *Schiedea obovata*, *S. trinervis*, *Silene lanceolata*, *S. perlmannii*, *Spermolepis hawaiiensis*, or *Tetramolopium lepidotum* ssp. *lepidotum*, the Service has determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of

individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 3 consists of 349 ac (141 ha) of City and County of Honolulu land and 101 ac (41 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the eastern rim of Makaha Valley along Kamaileunu Ridge. This unit is partially within the Waianae Kai Forest Reserve, and includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). This unit is occupied by the plants *Abutilon sandwicense*, *Alectryon macrococcus*, *Bonamia menziesii*, *Diellia falcata*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Flueggea neowawraea*, *Gouania meyenii*, *Isodendron laurifolium*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *Neraudia angulata*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Schiedea hookeri*, *Silene lanceolata*, *Tetramolopium filiforme*, and *Viola chamissoniana* ssp. *chamissoniana*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 3 is not currently occupied by *Achyranthes splendens* var. *rotundata*, *Cenchrus agrimonioides*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia unisora*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua degeneri*, *K. parvula*, *Melicope saint-johnii*, *Plantago princeps*, *Platydesma cornuta* var. *decurrens*, *Sanicula mariversa*, *Schiedea obovata*, *S. trinervis*, *Silene perlmanii*, *Spermolepis hawaiiensis*, or *Tetramolopium lepidotum* ssp. *lepidotum*, the Service has determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 4 consists of 24 ac (10 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along Kauaopuu ridge, which divides Waianae Kai and Lualualei valleys. This unit is partially within the Waianae Kai Forest Reserve, and includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). This unit is occupied by the plants *Alectryon macrococcus*, *Chamaesyce kuwaleana*, and *Spermolepis hawaiiensis*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 4 is not currently occupied by *Abutilon sandwicense*, *Achyranthes splendens* var. *rotundata*, *Bonamia menziesii*, *Cenchrus agrimonioides*, *Chamaesyce herbstii*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *D. unisora*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Flueggea neowawraea*, *Gouania meyenii*, *G. vitifolia*, *Isodendron laurifolium*, *I. pyriformis*, *Kadua degeneri*, *K. parvula*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *M. saintjohnii*, *Neraudia angulata*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Plantago princeps*, *Platydesma cornuta* var. *decurrens*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Sanicula mariversa*, *Schiedea hookeri*, *S. obovata*, *S. trinervis*, *Silene lanceolata*, *S. perlmanii*, *Tetramolopium filiforme*, *T. lepidotum* ssp. *lepidotum*, or *Viola chamissoniana* ssp. *chamissoniana*, the Service has determined this area to be essential for the conservation and

recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 6 consists of 149 ac (60 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Lualualei Valley from Puukanehoa to Puukaua. This area was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). The unit is occupied by the plants *Cenchrus agrimonioides*, *Diellia unisora*, *Flueggea neowawraea*, *Lepidium arbuscula*, *Lobelia niihauensis*, *Melicope saintjohnii*, *Neraudia angulata*, *Plantago princeps*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, and *Tetramolopium lepidotum* ssp. *lepidotum*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 6 is not currently occupied by *Abutilon sandwicense*, *Achyranthes splendens* var. *rotundata*, *Alectryon macrococcus*, *Bonamia menziesii*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Gouania meyenii*, *G. vitifolia*, *Isodendron laurifolium*, *I. pyrifolium*, *Kadua degeneri*, *K. parvula*, *Korthalsella degeneri*, *Lipochaeta lobata* var. *leptophylla*, *Melanthera tenuifolia*, *Melicope makahae*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Platydesma cornuta* var. *decurrens*, *Sanicula mariversa*, *Schiedea hookeri*, *S. obovata*, *S. trinervis*, *Silene lanceolata*, *S. perlmanii*, *Spermolepis hawaiiensis*, *Tetramolopium filiforme*, or *Viola chamissoniana* ssp. *chamissoniana*, the Service has determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 7a consists of 68 ac (27 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley to Pohakea. This area was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4), and is occupied by the plants *Flueggea neowawraea*, *Kadua parvula*, *Melicope saint-johnii*, *Plantago princeps*, *Platydesma cornuta* var. *decurrens*,

Pleomele forbesii, *Silene perlmanii*, and *Viola chamissoniana* ssp. *chamissoniana*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 7a is not currently occupied by *Abutilon sandwicense*, *Achyranthes splendens* var. *rotundata*, *Alectryon macrococcus*, *Bonamia menziesii*, *Cenchrus agrimonioides*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *D. unisora*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Gouania meyenii*, *G. vitifolia*, *Isodendron laurifolium*, *I. pyrifolium*, *Kadua degeneri*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *Neraudia angulata*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Pteralyxia*

macrocarpa, *Sanicula mariversa*, *Schiedea hookeri*, *S. obovata*, *S. trinervis*, *Silene lanceolata*, *Spermolepis hawaiiensis*, *Tetramolopium filiforme*, or *T. lepidotum* ssp. *lepidotum*, the Service has determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 7b consists of 38 ac (16 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley at Palikea. This area was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). Although Oahu—Dry Cliff—Unit 7b is not currently occupied by *Abutilon sandwicense*, *Achyranthes splendens* var. *rotundata*, *Alectryon macrococcus*, *Bonamia menziesii*, *Cenchrus agrimonioides*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *D. unisora*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Flueggea neowawraea*, *Gouania meyenii*, *G. vitifolia*, *Isodendron laurifolium*, *I. pyriforme*, *Kadua degeneri*, *K. parvula*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *M. saintjohnii*, *Neraudia angulata*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Plantago princeps*, *Platydesma cornuta* var. *decurrens*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Sanicula mariversa*, *Schiedea hookeri*, *S. obovata*, *S. trinervis*, *Silene lanceolata*, *S. perlmannii*, *Spermolepis hawaiiensis*, *Tetramolopium filiforme*, *T. lepidotum* ssp. *lepidotum*, or *Viola chamissoniana* ssp. *chamissoniana*, the Service has determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Wet Cliff—Unit 1 consists of 167 ac (68 ha) of State land, 68 ac (28 ha) of City and County of Honolulu land, and less than 1 ac (less than 1 ha) of privately owned land in the wet cliff ecosystem in the Waianae Mountains, near the summit of Kaala, and partially within the Mokuleia and Waianae Kai FRs and the Kaala Natural Area Reserve. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 4). Wet Cliff—Unit 1 is occupied by the plants *Cyanea calycina*, *Melicope christophersenii*, and *Schiedea trinervis*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations.

Oahu—Wet Cliff—Unit 2 consists of 3 ac (1 ha) of State land in the wet cliff ecosystem in the Waianae Mountains at Puuhapapa, within a small area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 4). Wet Cliff—Unit 2 is occupied by the plants *Cyanea calycina* and *Melicope christophersenii*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing

the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Wet Cliff—Unit 2 is not currently occupied by *Cyanea acuminata*, *Labordia cyrtandrae*, *Lobelia oahuensis*, *Phyllostegia hirsuta*, *Pteralyxia macrocarpa*, *Schiedea hookeri*, *S. kaalae*, or *S. trinervis*, the Service has determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Wet Cliff—Unit 3 consists of 16 ac (6 ha) in the wet cliff ecosystem on State land in the Waianae Mountains at Puukanehoa, partially within an area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 4). Although Oahu—Wet Cliff—Unit 3 is not currently occupied by *Cyanea acuminata*, *C. calycina*, *Labordia cyrtandrae*, *Lobelia oahuensis*, *Melicope christophersenii*, *Phyllostegia hirsuta*, *Pteralyxia macrocarpa*, *Schiedea hookeri*, *S. kaalae*, or *S. trinervis*, the Service has determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Wet Cliff—Unit 4 consists of 23 ac (9 ha) in the wet cliff ecosystem on State land in the Waianae Mountains at Puukaua, partially overlapping an area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 4). This unit is occupied by the plants *Phyllostegia hirsuta* and *Schiedea hookeri*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Wet Cliff—Unit 4 is not currently occupied by *Cyanea acuminata*, *C. calycina*, *Labordia cyrtandrae*, *Lobelia oahuensis*, *Melicope christophersenii*, *Pteralyxia macrocarpa*, *Schiedea kaalae*, or *S. trinervis*, the Service has determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Wet Cliff—Unit 5 consists of 31 ac (13 ha) of State land in the wet cliff ecosystem in the Waianae Mountains, at Palikea and north of Palikea. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 4). Although Oahu—Wet Cliff—Unit 5 is not currently occupied by *Cyanea acuminata*, *C. calycina*, *Labordia cyrtandrae*, *Lobelia oahuensis*, *Melicope christophersenii*, *Phyllostegia hirsuta*, *Pteralyxia macrocarpa*, *Schiedea hookeri*, *S. kaalae*, or *S. trinervis*, the Service has determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small

numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Primary Constituent Elements/Physical or Biological Features

(i) In unit Oahu—Montane Wet—Unit 1, the physical and biological features of critical habitat are: (A) Elevation: 3,300 to 6,600 ft (1,000 to 2,000 m). (B) Annual precipitation: Greater than 75 in (190 cm). (C) Substrate: Well-developed soils, montane bogs. (D) Canopy: Acacia, Charpentiera, Cheirodendron, Metrosideros. (E) Subcanopy: Broussaisia, Cibotium, Eurya, Ilex, Myrsine. (F) Understory: Ferns, Carex, Coprosma, Leptecophylla, Oreobolus, Rhynchospora, Vaccinium.

(ii) In units Oahu—Dry Cliff—Unit 1, Oahu—Dry Cliff—Unit 2, Oahu—Dry Cliff—Unit 3, Oahu—Dry Cliff—Unit 4, Oahu—Dry Cliff—Unit 6, Oahu—Dry Cliff—Unit 7a, Oahu—Dry Cliff—Unit 7b, and Oahu—Dry Cliff—Unit 8, the physical and biological features of critical habitat are: (A) Elevation: Unrestricted. (B) Annual precipitation: Less than 75 in (190 cm). (C) Substrate: Greater than 65 degree slope, rocky talus. (D) Canopy: None. (E) Subcanopy: Antidesma, Chamaesyce, Diospyros, Dodonaea. (F) Understory: Bidens, Eragrostis, Melanthera, Schiedea.

(iii) In units Oahu—Wet Cliff—Unit 1, Oahu—Wet Cliff—Unit 2, Oahu—Wet Cliff—Unit 3, Oahu—Wet Cliff—Unit 4, and Oahu—Wet Cliff—Unit 5, the physical and biological features of critical habitat are: (A) Elevation: Unrestricted. (B) Annual precipitation: Greater than 75 in (190 cm). (C) Substrate: Greater than 65 degree slope, shallow soils, weathered lava. (D) Canopy: None. (E) Subcanopy: Broussaisia, Cheirodendron, Leptecophylla, Metrosideros. (F) Understory: Bryophytes, Ferns, Coprosma, Dubautia, Kadua, Peperomia.

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Little information found although NatureServe (2015) notes the species reproduces sexually.

Reproduction Narrative

Adult: SEXUAL; (NatureServe, 2015). Alsiniidendron trinerve flowers and fruits throughout the year with the possible exception of fall (USFWS 1995) (USFWS, 1998).

Habitat Type

Adult: Wet/mesic forest (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Clumped (USFWS, 2013)

Environmental Specificity

Adult: Narrow/specialist (USFWS, 1998; USFWS, 2013)

Tolerance Ranges/Thresholds

Adult: Low (USFWS, 1998; USFWS, 2013)

Site Fidelity

Adult: High (USFWS, 1998; USFWS, 2013)

Habitat Narrative

Adult: Species inhabits slopes or ridges in wet forest or wetter portions of diverse mesic forest. Also found in drier forests. (NatureServe, 2015). *Alsinidendron trinerve* typically grows on slopes in wet forest or the wetter portions of diverse mesic forest dominated by ohia and flex anomala (kawau) at an elevation of 900 to 1,200 meters (3,000 to 4,000 feet) (USFWS 1995). Associated plants include *Coprosma* sp. (pilo), *Gunnera* (apeape), *Melicope* sp. (alani), *Cibotium* sp. (hapuu), *Antidesma platyphylla* (hame), and mamaki (USFWS 1995) (USFWS, 1998). USFWS (2013) notes that there is only one known population. Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations (One).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: No information found.

Population Information and Trends**Population Trends:**

Increasing (USFWS, 2013)

Resiliency:

Low (USFWS, 2013)

Representation:

Low (USFWS, 2013)

Redundancy:

Low (USFWS, 2013)

Number of Populations:

1 - 5 (NatureServe, 2015)

Population Size:

1 - 1000 individuals (NatureServe, 2015)

Population Narrative:

Fragility unknown. Less than forty plants. Two current (between 1982 and 1997) and four historical occurrences. (NatureServe, 2015). In 2010, a few individuals of *Schiedea trinervis* were rediscovered in East Makalela, an area to be fenced after the signing of an U. S. Army Garrison and State of Hawaii real estate agreement (U.S. Army Garrison 2010). In 2011, there were a total of 666 individuals in all populations of which 200 were mature and 185 were immature individuals, and 281 were seedlings (U.S. Army Garrison 2011) (USFWS, 2013). Low

resiliency, redundancy and representation are based on the species only having one known population with a limited number of individuals.

Threats and Stressors

Stressor: Ungulates (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Trampling from feral animals (especially pigs) is listed as a threat to this species (USFWS, 2013)

Stressor: Military training activities (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: This species sole population is found on an army installation. Military training activities are a threat to this species (USFWS, 2013).

Stressor: Alien plant species (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Alien plant species are known to alter the ecosystem and are listed as a threat to this species (USFWS, 2013).

Stressor: Human trampling (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Trampling by humans is listed as a threat to this species (USFWS, 2013).

Stressor: Over-collection (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Collection by humans is listed as a threat to this species (USFWS, 2013).

Stressor: Slugs (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Predation by slugs is listed as a threat to this species (USFWS, 2013).

Stressor: Climate change (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Climate change may pose a threat to this species. However, current climate change analyses in the Pacific Islands lack sufficient spatial resolution to make predictions on impacts to this species. The Pacific Islands Climate Change Cooperative (PICCC) funded climate modeling that will help resolve these spatial limitations. High spatial resolution climate outputs are expected in 2013 (USFWS, 2013).

Recovery

Reclassification Criteria:

For downlisting, a total of five to seven populations of each taxon should be documented on Oahu and at least one other island where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 1998).

Delisting Criteria:

A total of 8 to 10 populations of each taxon should be documented on Oahu and at least one other island where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of 5 consecutive years (USFWS, 1998).

Conservation Measures and Best Management Practices:

- Surveys/inventories o Search for additional individuals of *Schiedea trinervis* in its historical range. o Continue mapping the entire range of populations (USFWS, 2013).
- Population biology research o Study *Schiedea trinervis* populations with regard to population size and structure, geographical distribution, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. o Determine if additional populations should be reintroduced or if this species can be recovered with one large population (USFWS, 2013).
- Genetic research - Assess genetic variability within the one extant population (USFWS, 2013).
- Existing population management and restoration o Protect, manage within current wild populations o Manage all individuals of *Schiedea trinervis* (USFWS, 2013).
- Alliance and partnership development - Alliance and partnership development - Continue planning and contribute to implementation of ecosystem-level management and restoration to benefit this species with the U.S. Army Garrison, Hawaii Division of Forestry and Wildlife, and other landowners (USFWS, 2013).
- Captive propagation for genetic storage and reintroduction: Complete collection of fruit from wild individuals; augment these collections with seed from reintroduced individuals to add genetic diversity of ex situ seed storage (USFWS, 2013).
- Ecosystem-altering invasive plant species control: Control introduced invasive plant species around wild and reintroduced plants (USFWS, 2013).
- Ungulate exclosures - Construct large-scale fences to control feral ungulates around entire population and reintroduced individuals (USFWS, 2013).

- Reintroduction / translocation - Continue reintroducing individuals into protected suitable habitat within historical range (USFWS, 2013).
- Threats research - Investigate techniques to improve natural recruitment, including the development of an effective slug control method (USFWS, 2013).

SPECIES ACCOUNT: *Schiedea verticillata* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 08/21/1996; Pacific Region (R1) (USFWS, 2016)

Physical Description

A fleshy, perennial herb with an enlarged root. Stems are ascending, sometimes pendent, 4-6 dm long. The plant dies back to its root during the dry season. (NatureServe, 2015)

Taxonomy

The first specimens of *Schiedea verticillata* were collected near Derby's Landing in 1923. Brown (in Christophersen and Caum 1931) chose the specific epithet to refer to the verticillate (whorled) arrangement of the leaves. Although Sherff (1944) transferred the species to the genus *Alsinidendron*, current workers (Wagner et al. 1990) consider it to be a species of *Schiedea* (USFWS, 1998).

Historical Range

See current range/distribution

Current Range

Known only on Nihoa Island in Hawaii (USFWS, 2003).

Critical Habitat Designated

Yes; 5/22/2003.

Legal Description

On May 22, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat for *Schiedea verticillata*.

Critical Habitat Designation

Nihoa 3 constitutes critical habitat for *Schiedea verticillata*. This unit is critical habitat for *Schiedea verticillata* and is 69 ha (171 ac) on federally owned land. It includes the entire island, which is part of the HINWR. The unit provides habitat that is essential to the conservation of 300 mature, reproducing individuals of this short-lived perennial and, based on surveys conducted in 1996, contained at least 11 colonies and a total of at least 372 individuals. The habitat features contained in this unit that are essential for this species include, but are not limited to, rocky scree, soil pockets, and cracks on coastal cliff faces and in *Pritchardia remota* coastal mesic forest that contain one or more of the following associated native species and lichens: *Eragrostis variabilis*, *Rumex albescens*, and *Tribulus cistoides*. This critical habitat unit is essential to the conservation of the species because it supports extant colonies of *S. verticillata* and includes habitat that is important to the expansion of the present population on Nihoa.

Primary Constituent Elements/Physical or Biological Features

On Nihoa, the currently known primary constituent elements of critical habitat for *Schiedea verticillata* include, but are not limited to, the habitat components provided by:

(1) Rocky scree, soil pockets, and cracks on coastal cliff faces and in *Pritchardia remota* coastal mesic forest and containing one or more of the following associated native plant species: *Eragrostis variabilis*, *Rumex albescens*, *Tribulus cistoides*, or lichens; and

(2) Elevations between 30 and 242 m (100 and 800 ft).

Special Management Considerations or Protections

In general, taking all of the recommended management actions into account, the following management actions are ranked in order of importance. It should be noted, however, that, on a case-by-case basis, some of these actions may rise to a higher level of importance for a particular species or area, depending on the biological and physical requirements of the species and the location(s) of the individual plants: (1) Nonnative plant control; (2) Rodent control; (3) Invertebrate pest control; (4) Fire control; (5) Maintenance of genetic material of the endangered plant species; (6) Propagation, reintroduction, and/or augmentation of existing populations into areas deemed essential for the recovery of the species; (7) Ongoing management of the wild, outplanted, and augmented populations; (8) Maintenance of natural pollinators and pollinating systems, when known; (9) Habitat management and restoration in areas deemed essential for the recovery of the species; (10) Monitoring of the wild, outplanted, and augmented populations; (11) Rare plant surveys; and (12) Control of human activities/ access

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Unknown (USFWS, 1998)

Dependency on Other Individuals or Species

Adult: Moth pollinated (USFWS, 2017).

Reproduction Narrative

Adult: *Schiedea verticillata* is a short-lived perennial. Conant's data (1985) indicated that the reproductive cycle may not be seasonal, since many life stages were found simultaneously throughout the year. Her observations also indicated that the plants flower, set, and disperse seed in a relatively short period of time (USFWS, 1998). A 2015 study provided evidence in support of moth pollination of *S. verticillata*. In addition, genetic analysis shows that *S. verticillata* maintains a high level of genetic diversity despite being a single-island endemic (*S. Weller pers. comm. in Plentovich et al. 2015*)(USFWS, 2017).

Habitat Type

Adult: Cliff faces (USFWS, 1998)

Spatial Arrangements of the Population

Adult: Clumped (inferred from USFWS, 1998)

Environmental Specificity

Adult: Narrow/specialist (inferred from USFWS, 1998)

Tolerance Ranges/Thresholds

Adult: Low (inferred from USFWS, 1998)

Site Fidelity

Adult: High (inferred from USFWS, 1998)

Habitat Narrative

Adult: *Schiedea verticillata* typically grows in soil pockets and cracks on coastal cliff faces at elevations between 30 and 242 meters (100 and 800 feet). Associated taxa include *Tribulus cistoides*, *Eragrostis variabilis*, *Rumex albescens*, and lichens on surrounding rock (USFWS, 1998). Clumped spatial arrangement of the population, narrow environmental specificity, low tolerance ranges and high site fidelity and ecological integrity of the community are inferred based on the species unique habitat requirements and the low number of known populations.

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: *Schiedea verticillata* is a short-lived perennial. Conant's data (1985) indicated that the reproductive cycle may not be seasonal, since many life stages were found simultaneously throughout the year. Her observations also indicated that the plants flower, set, and disperse seed in a relatively short period of time. The means of pollination are unknown (USFWS, 1998).

Population Information and Trends**Population Trends:**

Stable to increasing (USFWS, 2009)

Number of Populations:

8 (USFWS, 2017)

Population Size:

1 - 1000 individuals (NatureServe, 2015)

Population Narrative:

Schiedea verticillata was discovered on Nihoa in 1923 and described in 1931 by Forrest Brown, and has never been found elsewhere. All but one of the historically known colonies were still known to be extant at the time of the critical habitat designation (USFWS 2003), and colony locations and plant numbers were observed to shift with each visit. However, total numbers island-wide remained relatively stable until the large increase during the last census in 2006. Populations are apparently able to recover from recent periodic vagrant grasshopper (*Schistocerca nitens*) infestations (USFWS, 2009). Currently there are eight estimated to be 1,000 individuals from Dog's Head to Derby's Beach, at Devil's Slide, Needle Rock, Miller's Peak, Albatross Plateau, Middle Valley, Tanager Peak, and Tunnel Cave on the island of Nihoa (USFWS, 2017).

Threats and Stressors

Stressor: Alien plants and insects (USFWS, 1998)

Exposure:**Response:**

Consequence: Loss of habitat

Narrative: Alien plant and insect species on the island may be posing threats to this species (USFWS, 1998).

Stressor: Rodent predation (USFWS, 1998)

Exposure:**Response:**

Consequence: Loss of individuals

Narrative: Rodent predation could prove disastrous for *Schiedea verticillata*, since rodents may be attracted to feed on its fleshy root. Rodents have yet to be found on Nihoa but the threat of their unintentional transport there is ongoing (USFWS, 1998).

Stressor: Stochastic extinction/Reduced vegetative vigor (USFWS, 1998)

Exposure:**Response:**

Consequence: Extinction

Narrative: It is threatened by stochastic extinction and/or reduced reproductive vigor due to its very restricted range, small numbers, and the vulnerability of plants to disturbance events in their steep, rocky habitat (Conant 1985) (USFWS, 1985).

Stressor: Fire/human disturbance (USFWS, 1998)

Exposure:**Response:**

Consequence: Loss of habitat/loss of individuals

Narrative: Fire and other human disturbances also pose potential threats to this species (USFWS, 1998).

Stressor: Climate change loss or degradation of habitat (USFWS, 2017)

Exposure:**Response:****Consequence:**

Narrative: Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. This assessment was not conducted specifically for *Schiedea verticillata*. However, it was concluded that the genus *Schiedea* (with a vulnerability score of 0.512; on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change) is the genus most vulnerable to climate change. Therefore, additional management actions are needed to conserve this taxon into the future (USFWS, 2017).

Recovery**Reclassification Criteria:**

For downlisting, interim objectives must be attained. In addition, a total of at least five colonies should exist on Nihoa and successful propagation and outplanting ex situ must be underway. Each of these must be stable, secure, and naturally reproducing. Colony sizes on Nihoa should

be increased with caution, and only if there is good evidence that Nihoa can support additional colony growth without negative ecological impacts. This is a concern because of Nihoa's small size and its relatively intact, native ecosystem. Colony sizes will ultimately be determined by the carrying capacity of the site where they are grown. However, a preliminary target level for *Schiedea verticillata* is a minimum of 300 mature individuals per colony. Each colony should be stable or increasing minimum of five consecutive years before downlisting is considered. The need for continued species-specific management actions should not preclude downlisting. As a component of threat control, a remote monitoring system should be installed on Nihoa to detect and record illegal landings and shipwrecks on the island and relay the information to National Wildlife Refuge (NWR) staff in Honolulu (USFWS, 2009).

Delisting Criteria:

To achieve delisting objectives, downlisting objectives must be attained. In addition, delisting may be considered with the establishment of one to three additional colonies on an island other than Nihoa. Necker Island, Kilauea Point, and Midway Atoll NWRs should be assessed for suitability since they are protected areas, have plant nursery facilities, and have full-time staffs. Midway has a similar climate to Nihoa and Kilauea Point, with has north-facing cliffs similar to those on Nihoa. Should establishment of one to three colonies of this taxon on an island other than Nihoa occur, delisting may be considered when they have reached the same targets as those described for downlisting, including a minimum of 300 mature individuals per colony. Each colony should be stable or increasing for a minimum of five consecutive years. If the establishment of this taxon on a second island proves unfeasible, delisting may be considered if the downlisting objectives have been met and the colonies persist at target levels for a minimum of ten years. In order to initiate delisting in any of the above situations, there should no longer be a need for continued species-specific management actions, but delisting may proceed if there is a continuing need for ecosystem-wide management actions (USFWS, 2009).

Recovery Actions:

- 1. Invasive plant monitoring and control— Continue to prevent invasion of any introduced species to Nihoa and control invasive introduced plant species in all existing populations and periodically monitor to ensure invasive species are not establishing nearby (USFWS, 2017).
- 2. Predator and herbivore monitoring and control—Determine if control of the vagrant grasshopper is needed, and if so, develop an efficient and effective control method (USFWS, 2017).
- 3. Captive propagation for genetic storage and reintroduction—Continue seed and cuttings collection for ex situ genetic storage (USFWS, 2017).
- 4. Reintroduction and translocation— Begin reintroduction efforts to increase underrepresented individuals into suitable habitat being managed for known threats to this species and Assess feasibility of outplanting *Schiedea verticillata* on Lehua Island State Bird Sanctuary, Necker Island National Wildlife Refuge (NWR), Kilauea Point NWR, and Midway Atoll NWR, which are the closest islands to Nihoa and are managed for conservation (USFWS, 2017).
- 5. Human disturbance—Continue to restrict access to Nihoa Island (USFWS, 2017).
- 6. Population biology research—Study *Schiedea verticillata* populations to determine viable population size and structure, geographical distribution, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats (USFWS, 2017).

Conservation Measures and Best Management Practices:

- Continue seed and cuttings collection for ex situ genetic storage and reintroduction from underrepresented individuals (USFWS, 2009).
- Continue to restrict human access (USFWS, 2009).
- Control invasive introduced plant species in all existing populations and periodically monitor to ensure invasive species are not establishing nearby (USFWS, 2009).
- Continue to prevent invasion of any introduced species on Nihoa (USFWS, 2009).
- Determine if control of the vagrant grasshopper is needed, and if so, develop an efficient and effective control method (USFWS, 2009).
- Assess feasibility of outplanting *Schiedea verticillata* on Lehua Island State Bird Sanctuary, Necker Island National Wildlife Refuge (NWR), Kilauea Point NWR, and Midway Atoll NWR, which are the closest islands to Nihoa and are managed for conservation (USFWS, 2009).
- Work with Hawaii Division of Forestry and Wildlife and NWRs to provide ecosystem level restoration and management of reintroduction sites to benefit this species (USFWS, 2009).
- Study *Schiedea verticillata* populations with regard to population size and structure, geographical distribution, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats (USFWS, 2009).

SPECIES ACCOUNT: *Schiedea viscosa* (= *Alsinidendron viscosum*) (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/10/1996; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Alsinidendron viscosum, a member of the pink family, is a weakly climbing or sprawling subshrub. The stems are 0.6 to 3 m (2.0 to 9.8 ft) long, and densely covered with fine glandular hairs throughout. The thin and membranous leaves are narrowly elliptic and are 2.5 to 5 cm (1.0 to 2.0 in) long and 0.8 to 1.8 cm (0.3 to 0.7 in) wide. Usually three to nine flowers are arranged in loose clusters with stalks ranging from 2 to 3.5 cm (0.8 to 1.4 in) long. The four sepals are white, thin, and membranous, and remain so at maturity. The outer two sepals greatly overlap the inner ones. The sepals are oblong in shape and 8 to 9 millimeters (0.3 inch) long, but enlarge to approximately 12 mm (0.5 in) long in fruit, completely enclosing the fruit at maturity. The stamens are scarcely fused at the base and the basal outgrowths are about 3 mm (0.1 in) long, nearly as wide, and two-toothed. The fruits are egg-shaped capsules, 8 to 12 mm (0.3 to 0.5 in) long, and opening by five to seven valves. The seeds are dark reddish brown, and approximately 0.8 mm (0.03 in) long with a minutely hairy surface. (USFWS, 1998)

Taxonomy

Described by H. Mann in 1866 as *Schiedea viscosa* from collections he made between 1864 and 1865 with W. Brigham, E.E. Sherff later transferred the species to *Alsinidendron*, which was considered distinct from *Schiedea* based on a suite of characters (Wagner et al. 1999). More recently, based on molecular and morphological data, Wagner et al. (2005) concluded that *Alsinidendron* formed a monophyletic group within *Schiedea*, and should therefore be subsumed into the latter genus. As such, the synonym *Schiedea viscosa* H. Mann was reestablished as the recognized species name. Therefore, the Service will refer to the taxon as *S. viscosa* throughout the remainder of this review. *Alsinidendron viscosum* is closely related to *Alsinidendron lychnoides*, which differs primarily in having wider leaves and more capsule valves and flowers per cluster (USFWS 1996). (USFWS, 2009; USFWS, 1998)

Historical Range

Historically, *Alsinidendron viscosum* was found at the Kaholuamano, Kokee, Halemanu, Nawaimaka, and Waialae areas of northwestern Kauai (USFWS 1996). (USFWS, 1998)

Current Range

This species is currently found only in Kauai. (NatureServe, 2015)

Critical Habitat Designated

Yes; 2/27/2003.

Legal Description

On February 27, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Schiedea viscosa* (= *Alsinidendron viscosum*) on the island of Kauai, Hawaii (68 FR 9116 - 9479).

Critical Habitat Designation

The critical habitat designation for *Schiedea viscosa* (= *Alsinidendron viscosum*) includes four units totaling 2,066 acres in Kauai County, Hawaii. The units are Kauai 11—*Alsinidendron viscosum*—a, b, c, d.

Kauai 11—*Alsinidendron viscosum*—a: This unit is critical habitat for *Alsinidendron viscosum* and is 736 ha (1,820 ac) on State land (Alakai Wilderness Preserve). This unit contains portions of Kaluahaulu and Kawaiiki Ridge. This unit provides habitat for seven populations of 300 mature, reproducing individuals of the shortlived perennial *Alsinidendron viscosum* and is currently occupied with 26 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered non-viable. The habitat features contained in this unit that are essential for this species include, but are not limited to, steep slopes in *Acacia koa*-*Metrosideros polymorpha* lowland or montane mesic forest. This unit is geographically separated from other units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Kauai 11—*Alsinidendron viscosum*—b: This unit is critical habitat for *Alsinidendron viscosum* and is 17 ha (42 ac) on State land (Kokee State Park) and contains a portion of Kumuela Ridge. This unit, in combination with *Alsinidendron viscosum*—c, provides habitat for one population of 300 mature, reproducing individuals of the short-lived perennial *Alsinidendron viscosum* and is currently unoccupied. This unit is essential to the conservation of the taxon because it supports habitat that is essential to the establishment of additional populations on Kauai in order to reach recovery goals. The habitat features contained in this unit that are essential for this species include, but are not limited to, steep slopes in *Acacia koa*-*Metrosideros polymorpha* lowland or montane mesic forest. This unit is geographically separated from other units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Kauai 11—*Alsinidendron viscosum*—c: This unit is critical habitat for *Alsinidendron viscosum* and is 22 ha (55 ac) on State land (Kokee State Park) and contains a portion of Kauaikinana Stream and Kumuela Trail and Ridge. This unit, in combination with *Alsinidendron viscosum*—b, provides habitat for one population of 300 mature, reproducing individuals of the short-lived perennial *Alsinidendron viscosum* and is currently unoccupied. This unit is essential to the conservation of the taxon because it supports habitat that is essential to the establishment of additional populations on Kauai in order to reach recovery goals. The habitat features contained in this unit that are essential for this species include, but are not limited to, steep slopes in *Acacia koa*-*Metrosideros polymorpha* lowland or montane mesic forest. This unit is geographically separated from other units designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. Kauai 11—*Alsinidendron viscosum*—d: This unit is critical habitat for *Alsinidendron viscosum* and is 61 ha (150 ac) on State land (Alakai Wilderness Preserve) and contains a portion of Mohihi Waiālae Trail and Kohua Ridge. This unit provides habitat for one population of 300 mature, reproducing individuals of the shortlived perennial *Alsinidendron viscosum* and is currently occupied with 26 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered non-viable. The habitat features contained in this unit that are essential for this species include, but are not limited to, steep slopes in *Acacia koa*-*Metrosideros polymorpha* lowland or montane mesic forest. This unit is geographically separated from the

other three units designated as critical habitat for this island-endemic species to avoid all recovery populations from being destroyed by one naturally occurring catastrophe. The 267 other plants on Kauai are not included in critical habitat because the habitat they occupy is not considered essential to the conservation of this species. The more appropriate habitat on Kauai, within its historical range, are being designated as critical habitat.

Primary Constituent Elements/Physical or Biological Features

Within these units, the currently known primary constituent elements of critical habitat include, but are not limited to, the habitat components provided by:

(i) Steep slopes in *Acacia koa*/*Metrosideros polymorpha* lowland and montane mesic forest and containing one or more of the following native plant species: *Alyxia oliviformis*, *Asplenium polyodon*, *Bidens cosmoides*, *Bobea* spp., *Carex meyenii*, *Carex wahuensis*, *Coprosma* spp., *Dianella sandwicensis*, *Dodonaea viscosa*, *Doodia kunthiana*, *Dryopteris glabra*, *Dryopteris unidentata*, *Dryopteris wallichiana*, *Dubautia laevigata*, *Gahnia* spp., *Ilex anomala*, *Melicope* spp., *Panicum nephelophilum*, *Pleomele aurea*, *Psychotria* spp., *Pteridium aquilinum* var. *decompositum*, *Schiedea stellarioides*, or *Vaccinium dentatum*; and

(ii) Elevations between 754 and 1,224 m (2,474 and 4,016 ft).

Special Management Considerations or Protections

The following management actions are important: Feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas deemed essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas deemed essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: *Alsinidendron viscosum* was observed in flower during January, February, and April 1995 (5. Perlman, NTBG, Provenance Report 1995). Herbarium vouchers at Bernice P. Bishop Museum (C. Imada, Bernice P. Bishop Museum, pers. comm. 2008) and National Tropical Botanical Garden (2008a) were flowering in January, February, March, April, May, June, and December; fruiting specimens were found from January, February, March, April, July or August, and December. Seeds are self-fertilized in cultivation (Wagner et al. 2005). (USFWS, 1998)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 820 and 1,070 meters on steep slopes (USFWS, 1998)

Environmental Specificity

Adult: Low, with few key requirements (USFWS, 1998)

Habitat Narrative

Adult: *Alsinidendron viscosum* is typically found at elevations between 820 and 1,070 meters (2,700 and 3,510 feet), on steep slopes in *Acacia koa* (*koa*)-*ohia* lowland mesic or wet forest. Associated plant species include *Alyxia oliviformis* (*maile*), *Bobea* sp. (*ahakea*), *Carex* sp., *Dodonaea viscosa* (*aalii*), *ilex anomala* (*aiea*), *Melicope* sp. (*alani*), *Pleomele* sp. (*halapepe*), and *Psychotrias* (*kopiko*) (USFWS 1996). (USFWS, 1998)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

Very low (inferred from USFWS, 2009)

Redundancy:

Very low (inferred from USFWS, 2009)

Number of Populations:

4-7 (USFWS, 2009)

Population Size:

30 - 300 individuals (USFWS, 2009)

Population Narrative:

The critical habitat designation for Kauai and Niihau (USFWS 2003) reports seven populations with about 319 individuals, all on State-owned land at the Halemanu-Kokee Trail, Mohihi-Waialae Trail, Kawaiiki Valley, Waialae Falls, and Nawaimaka Valley in the Alakai Wilderness Preserve, Kokee State Park, and the Na Pali-Kona Forest Reserve. Perlman (2006) listed four populations with 30 individuals as of mid-2005, and Katie Cassell of the Kokee Resource Conservation Program reported a few more individuals in Kokee in 2007, although exact numbers are unknown (USFWS 2008). (USFWS, 2009). At the time of the last 5-year review in 2009 there were four populations totaling 30 or more individuals from Nawaimaka Valley and Mohihi-Waialae Trail on the island of Kauai. Since then, there are between nine and 16 occurrences totaling fewer than 300 individuals (NTBG 2008, 2010, 2011, 2012a-b, 2013a-e, 2014a-b, 2015, 2016; PEPP 2011, 2012, 2013, 2014, 2015). In 2016, Clark reported 100

individuals in nine 'subpopulations' (considered as populations by USFWS), with the largest population consisting of only 20 individuals (Clark 2016). These populations occur in Kokee, Kawaiiki, Koaie, Mohihi, and Poomau (USFWS, 2017).

Threats and Stressors

Stressor: Invasive plant species (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Introduced invasive plant species threatening *S. viscosa* include *Lantana camara* (lantana), *Psidium guajava* (guava), *P. cattleianum* (strawberry guava), *Gravillea robusta* (silk-oak), *Erigeron karvinskianus* (daisy fleabane), *Hedychium gardnerianum* (kahili ginger), *Rubus argutus* (prickly Florida blackberry), and *Melinis minutiflora* (molasses grass) (USFWS 1996, 1998, 2003; K. Wood, Research Biologist, National Tropical Botanical Garden, pers. comm. 2008). (USFWS, 2009)

Stressor: Habitat degradation and predation (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Habitat degradation and predation by feral pigs (*Sus scrofa*), goats (*Capra hircus*), and mule deer (*Odocoileus hemionus*) continue to be threats to the remaining individuals of *Schiedea viscosa*. (USFWS, 2009)

Stressor: Small population size (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: In addition to all of the other threats, species like *Schiedea viscosa* that are endemic to small portions of a single island are inherently more vulnerable to extinction than widespread species because of the higher risks posed to a few populations and individuals by random demographic fluctuations and localized catastrophes such as hurricanes, landslides, flooding and disease outbreaks. When considered on their own, the natural processes associated with being a single island endemic do not affect *S. viscosa* to such a degree that it is threatened or endangered with extinction in the foreseeable future, but these natural processes can exacerbate the threat from anthropogenic factors, such as habitat loss from or predation by introduced species (USFWS 1998). (USFWS, 2009)

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Schiedea viscosa* is extremely

vulnerable to the impacts of climate change, with a vulnerability score of 0.839 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). In addition, Fortini et al. show that Caryophyllaceae is one of the top four most vulnerable native plant families, and, at the genus level, *Schiedea* had one of the highest vulnerability scores. Therefore, additional management actions are needed to conserve this taxon into the future (USFWS, 2017).

Recovery

Reclassification Criteria:

1. A total of five to seven populations of each taxon should be documented on Kauai where they now occur or occurred historically. (USFWS, 1998)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1998)
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered. (USFWS, 1998)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Kauai where they now occur or occurred historically. (USFWS, 1998)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1998)
3. Each population should persist at this level for a minimum of 5 consecutive years. (USFWS, 1998)

Recovery Actions:

- Remove alien plants inside completed enclosures. The U.S. Fish and Wildlife Service intends to fence the Nawaikama population in 1998 to protect it from imminent destruction by goats. Once enclosed, this area should be surveyed and managed to reduce threats from the following plant species: prickly Florida blackberry, lantana, and molasses grass. (USFWS, 1998)
- Additional enclosures should be constructed around the Waialae Ridge population, the Ditch Trail population and the Mohihi-Waialae Trail population. Once enclosed, those areas should undergo management to remove alien plants. (USFWS, 1998)
- In order to prevent this taxon from going extinct, propagation efforts and the maintenance of adequate genetic stock ex situ should be continued. Additional wild seeds should be collected periodically until the cryopreservation method of long-term storage is perfected. This will insure that viable seed stock is available for outplanting. (USFWS, 1998)
- Ongoing monitoring in those areas that are fenced should be used to determine the most appropriate outplanting sites in the future. Outplanting in these areas can boost population numbers to reduce risk of extinction from naturally occurring events or from reduced

reproductive vigor, due to the small numbers of extant populations and individuals. (USFWS, 1998)

Conservation Measures and Best Management Practices:

- Continue seed collection for ex situ genetic storage and future reintroductions. (USFWS, 2009)
- Manage feral ungulates and invasive introduced plant species around remaining individuals. (USFWS, 2009)
- Augment populations as plants become available in nurseries and habitat is protected. (USFWS, 2009)
- Reintroduce individuals into suitable habitat within historical range that is being managed for known threats to this species. (USFWS, 2009)
- Assess of genetic variability within extant and ex situ populations. (USFWS, 2009)
- Continue surveys for additional populations and individuals in known historical sites and other areas of suitable habitat. (USFWS, 2009)
- Study *Schiedea viscosa* populations with regard to population size and structure, geographical distribution, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. (USFWS, 2009)
- Update the name of the listed entity in 50 CFR 17 to match the currently recognized taxonomy. (USFWS, 2009)
- New Management Actions: • NTBG seed bank has 33 collections from seven populations totaling thousands of seeds. Dozens of plants are also in the NTBG nursery (NTBG 2017). The University of California at Irvine has 22 plants in their nursery from Mohihi-Waialae Trail (UCI 2014). PEPP botanists collected seeds for propagation at Lyon Arboretum and NTBG (PEPP 2011, 2013, 2015). Lyon Arboretum's Seed Conservation Laboratory has over 150,000 seeds in storage. There are nine founders represented from Halemanu, one from Waineke, 16 founders from one site and one founder from another site in Kawaiiki, two founders from Mohihi, six founders from Kehua Ridge, and 22 founders from Poomau. This totals 57 founders, over half of the known plants. Lyon Arboretum's Micropropagation lab maintains explants from three founders from Kokee (Lyon Arboretum 2017). The Kokee Rare Plant Facility has 50 plants from four founders (three from Poomau and one from Mohihi) at its nursery (DOFAW 2016). • PEPP outplanted *Schiedea viscosa* into monitored exclosures at Kawaiiki (12 individuals), Koaie (13 individuals), and Kumuwela (23 individuals) (PEPP 2012, 2013, 2014). • PEPP monitors wild populations of *Schiedea viscosa* at Kawaiiki, Mohihi, Koaie, Kokee Ditch Trail, Halemanu, and Kohua ridge (PEPP 2011, 2012, 2013, 2014, 2015) (USFWS, 2017).
- Recommendations for Future Actions: No new threats and no other significant new information regarding the species' biological status have been reported since the last 5-year review in 2009. Therefore, the following recommendations for future actions are reiterated for the 5-year review for 2017. • Surveys and inventories—Survey for additional populations and individuals in known historical sites and other areas of suitable habitat. • Ungulate monitoring and control—Protect all occurrences against browsing and disturbances from feral ungulates. Continue to construct and maintain fenced exclosures around all populations. • Invasive plant monitoring and control— o Control established ecosystem-altering nonnative invasive plant species around all populations. o Control nonnative plant species in the immediate vicinity of *Schiedea viscosa* populations that compete with this species. • Captive propagation for genetic storage and reintroduction—Continue collection of seeds and propagation for reintroduction, using hand pollination of flowers to increase seed set, where possible. • Reintroduction and translocation—Continue to reintroduce individuals into suitable habitat within historical range that is being managed for known threats to this species.

- Population biology research—Study *Schiedea viscosa* populations to determine viable population size and structure, geographical distribution, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats (USFWS, 2017).

SPECIES ACCOUNT: *Schoenocrambe argillacea* (Clay reed-mustard)

Species Taxonomic and Listing Information

Listing Status: Threatened; 01/14/1992; Mountain-Prairie Region (Region 6) (USFWS, 2016)

Physical Description

A perennial herbaceous plant in the mustard family, with sparsely leafed stems 15 to 30 cm (6 to 12 in) tall arising from a woody root crown. The leaves are very narrow with a smooth margin, 10 to 35 mm (0.4 to 1.4 in) long and, usually, less than 2 mm (0.1 inch) wide. The leaf blades are alternately arranged on the stem and, for the most part, are attached directly to the stem without a petiole. The narrow, fleshy leaves are covered with a white, waxy surface. The flowers of clay reed-mustard have petals that are pale lavender to whitish with prominent purple veins and measure 8 to 11 mm (0.3 to 0.4 inch) long and 3.5 to 4.5 mm (0.14 to 0.18 inch) wide. The entire flowers are about 1 cm (0.4 inch) across in full anthesis and are displayed in a raceme of 3 to 20 flowers at the end of the plant's leafy stems. Flowers are pale lavender to whitish with conspicuous purple veins. Blooms in late April and early May. (USFWS, 2016; NatureServe, 2015)

Taxonomy

The species was first discovered and recorded by Dr. Duane Atwood in 1976. It was described as *Thelypodium argillacea* in 1977, moved to the genus *Schoenocrambe* in 1982, and most recently renamed *Hesperidanthus argillaceus* (Al-Shehbaz 2010). The latter is the name now accepted for this species by the Flora of North America and the integrated taxonomic information system (Al-Shehbaz 2010; ITIS 2017). (USFWS, 2019)

Current Range

Endemic to the Uinta Basin (Book Cliffs area) in Uintah County, northeast Utah. Known range is only about 24 km x 12 km, from the west side of the Green River to the east side of Willow Creek (USFWS 1994). Franklin (2005) describes the three population areas as follows: "along the east slopes of Big Pack Mountain and in Broome Canyon to the east; along the west slopes of Wild Horse Bench, from the vicinity of Kings Canyon and south nearly to The Wrinkles; and along the slopes of the canyons above Ray's Bottom, on the west side of the Green River." (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (USFWS, 1994)

Breeding Season

Adult: April to May (USFWS, 1994)

Reproduction Narrative

Adult: Flowering occurs from April to May and fruiting occurs May to June in all three species. Reproduction in each of the three species is sexual. (USFWS, 1994)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Bare rock/talus/scree, barrens, desert (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Occurs at elevations between 1440 to 1765 meters (NatureServe, 2015)

Habitat Narrative

Adult: Occurs within shadscale, Indian ricegrass, pygmy sagebrush, and other mixed desert shrub communities on precipitous, typically north-facing slopes. On these slopes (elevations from 1440 to 1765 m), plants grow in both exposed and protected sites, with protected sites usually having the more robust plants. Substrates consist of at-the-surface bedrock, scree, and fine-textured soils, often clay soils rich in gypsum (shale barrens) overlain with sandstone talus. Occurs about the zone of contact between the Tertiary lower Uinta Formation and the Evacuon Creek Member of the upper Green River shale Formation. Commonly associated species include *Eriogonum corymbosum*, *Ephedra torreyana*, *Atriplex confertifolia*, *Atriplex gardneri* var. *cuneata*, *Elymus salinus*, *Tetradymia nuttallii*, and *Amelanchier utahensis*; other associates include *Agropyron smithii*, *Arabis pendulina*, *Arabis pulchra*, *Artemisia nova*, *Astragalus chamaeleuce*, *Astragalus convallarius*, *Brickellia oblongifolia*, *Castilleja chromosa*, *Chrysothamnus viscidiflorus*, *Cryptantha rollinsii*, *Cymopterus fendleri*, *Eriogonum ovalifolium*, *Euphorbia fendleri*, *Leptodactylon pungens*, *Penstemon carnosus*, *Petradora pumila*, *Cymopterus terebinthinus*, *Stipa hymenoides*, *Tetradymia spinosa*, and *Thelesperma subnudum*. (NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Unknown (NatureServe, 2015)

Number of Populations:

3 (USFWS, 2011)

Population Size:

~6,000 (USFWS, 2011)

Population Narrative:

Schoenocrambe argillacea occurs in six populations in Uintah County. In 1992, the Utah Natural Heritage Program completed an extensive survey of potential habitat for Schoenocrambe argillacea and estimated the total number of S. argillacea was 6,000 plants (Franklin 1992; Service 1994). (USFWS, 2011)

Threats and Stressors

Stressor: Oil and gas development (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Oil and gas development remains a significant threat to Schoenocrambe argillacea populations and habitat (Service 1990; 1994). All Federal lands on which known populations of S. argillacea occur are leased for oil and gas development (Utah Division of Oil, Gas, and Mining (UDOGM) 2011). To date, oil and gas development within known S. argillacea areas has been moderate. The Service does not know the actual ground disturbance at this point from oil and gas development, but the Service estimates approximately 5 acres (2 hectares) of total disturbance per well, including roads and infrastructure. After excluding directional wells (which are usually drilled from existing well pads), the Service calculated that at least 130 acres are disturbed within S. argillacea populations as mapped, and an additional 85 acres could be disturbed as currently approved oil and gas wells are drilled within the next 2 years (UDOGM 2011). Oil and gas development remains a significant threat to Schoenocrambe argillacea populations and habitat (Service 1990; 1994). All Federal lands on which known populations of S. argillacea occur are leased for oil and gas development (Utah Division of Oil, Gas, and Mining (UDOGM) 2011). To date, oil and gas development within known S. argillacea areas has been moderate. The Service does not know the actual ground disturbance at this point from oil and gas development, but the Service estimates approximately 5 acres (2 hectares) of total disturbance per well, including roads and infrastructure. After excluding directional wells (which are usually drilled from existing well pads), the Service calculated that at least 130 acres are disturbed within S. argillacea populations as mapped, and an additional 85 acres could be disturbed as currently approved oil and gas wells are drilled within the next 2 years (UDOGM 2011). (USFWS, 2011)

Stressor: Habitat fragmentation (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Schoenocrambe argillacea exists in small, low-density populations that are likely prone to negative effects from habitat fragmentation. For example, small plant populations fluctuate more widely over time and the smaller the remnant, the more susceptible the population is to extinction (Soulé et al. 1992; Forman and Alexander 1998; Menges 2002; Lienert 2004). Small plant populations can lose genetic variation and their population viability decreases (Ellstrand and Elam 1993; Lienert 2004; Kolb 2008). Fruit set, germination rate, offspring survival, and total numbers of flowers per plant are higher in large populations than in small populations (Paschke et al. 2002). Similarly, the number of capsules per plant and the number of seedlings per plant are positively correlated with population size (Schmidt and Jensen 2000). Roads associated with energy exploration and development cause a high level of habitat fragmentation. Increased oil and gas developments result in more roads developed near and potentially in Schoenocrambe

argillacea habitat. Ecological effects of roads to plants can extend more than 328 feet (100 meters) from the road (Angold 1997; Forman 2000; Forman and Deblinger 2000). Disturbance can occur directly from construction or indirectly from road dust, discussed further below (Eller 1977; Spatt and Miller 1981; Thompson et al. 1984; Farmer 1993; Angold 1997; Sharifi et al. 1997; Trombulak and Frissell 2000; Hobbs 2001; Myers-Smith et al. 2006). There is a strong correlation between vegetation composition and health with distance from a road, although it may take decades for the full effects of road development to be realized (Auerbach et al. 1997; Myers-Smith et al. 2006). (USFWS, 2011)

Stressor: Road dust (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Schoenocrambe argillacea may be impacted by the indirect effects of road dust associated with oil and gas development. Road traffic mobilizes and spreads dust (Farmer 1993; Trombulak and Frissell 2000), and for every vehicle traveling 1 mile (1.6 kilometers) of unpaved roadway once a day, every day for a year, approximately 2.5 tons of dust are deposited along a 1,000-foot (~300-meter) corridor centered on the road (Sanders pers. comm. 2008). Dust deposition tends to be highest near the road and decreases with increasing distance from the road (Everett 1980; Spatt and Miller 1981; Walker and Everett 1987; Santelmann and Gorham 1988; Myers-Smith et al. 2006). For example, in one study, 97 percent of dust was deposited within 410 feet (125 meters) of the road (Walker and Everett 1987). The distance from a road at which dust can affect vegetation varies (see McCrea 1984; Myers-Smith et al. 2006), but negative impacts can occur up to 984 feet (300 meters) away from the road (Everett 1980). Using information from these studies, the BLM now implements a buffer of 300 feet (91 meters) for surface disturbance activities near *S. argillacea* occupied habitat and a requirement for monitoring plants where surface disturbance occurs within the 300-foot (91-meter) buffer. Dust negatively affects photosynthesis, respiration, transpiration, water use efficiency, leaf conductance, growth rate, plant vigor, gas exchange, and allows the penetration of phytotoxic gaseous pollutants (Eller 1977; Spatt and Miller 1981; Thompson et al. 1984; Farmer 1993; Sharifi et al. 1997; Trombulak and Frissell 2000; Hobbs 2001). Dust comprised of finer particulates caused more improper functioning of the stomata than larger particles (Ricks and Williams 1974; Eller and Brunner 1975; Eveling and Bataille 1984; Rawson and Clarke 1988; Hirano et al. 1995). Improperly functioning stomata result in increased water loss in two ways: due to an increased transpiration rate because of increased leaf temperatures and due to clogged stomata that are unable to close at night (Hirano et al. 1995). Dust also can inhibit sunlight from reaching plant surfaces (Sharifi et al. 1997). Additionally, dusted leaves were 4 to 5°F (2 to 3°C) warmer (Sharifi et al. 1997) than undusted, control leaves (Hirano et al. 1995). Dust from roads also impacts soil quality and vegetation type. Soils near roads can have significantly lower nutrient levels, altered organic horizon depth, higher bulk density, and lower moisture (Auerbach et al. 1997). Furthermore, soil characteristics and plant community composition can remain significantly different up to 28 years after road development (Myers-Smith et al. 2006). (USFWS, 2011)

Stressor: Plant-pollinator interactions (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Many of the negative effects of habitat fragmentation to plants are due to effects on plant-pollinator interactions (Debinski and Holt 2000; Moody-Weis and Heywood 2001; Aizen et al. 2002; Gathmann and Tscharntke 2002; Lennartsson 2002; Kolb 2008). Fragmented plant populations appear to be less attractive to insect pollinators, which spend more time in larger, unfragmented plant habitats (Aizen et al. 2002; Goverde et al. 2002; Lennartsson 2002; Kolb 2008). Furthermore, insect pollinator diversity increases in larger populations (Mustajarvi et al. 2001) and decreases in isolated habitats with smaller plant population size (Steffan-Dewenter and Tscharntke 1999). Lower pollinator visitation rates were associated with lower seed sets and reproductive success in fragmented sites compared to intact sites (Jennersten 1988). Bumblebees visit more flowers on fewer flower stalks in sparser plant populations (Mustajarvi et al. 2001; Goverde et al. 2002). This leads to increased self-pollination or near-neighbor pollination and contributes to inbreeding (Goverde et al. 2002; Lennartsson 2002). Inbred plants produce fewer flowers and seeds, have smaller plant height and smaller leaf-size, and reduced reproductive success (Steffan-Dewenter and Tscharntke 1999; Lienert 2004; Kolb 2008). (USFWS, 2011)

Stressor: Erosion and sedimentation (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Although oil and gas development may not occur directly on the steep habitat *Schoenocrambe argillacea* occupies, erosion or sedimentation could still impact this species, particularly if the plants are downslope of development activities. In fact, development-related erosion and sedimentation may be a particular concern to this species because it grows on precipitous hillsides. Because of this unique vulnerability, the BLM Vernal Field Office requires energy companies to get site-specific approval from both the BLM and the Service when disturbance will occur upslope of habitat (BLM 2008a). This conservation measure is in effect because the species is listed as threatened by the ESA. (USFWS, 2011)

Stressor: Predation (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: When we listed *Schoenocrambe argillacea*, the Service believed sheep and cattle grazing may have had an historical impact on this species. However, by 1994 grazing was no longer expected to impact *S. argillacea* due to changes in grazing management, namely reduced numbers of sheep and cattle on the land (Service 1994). Grazing levels have not increased appreciably since then, and thus the Service still concludes that grazing is not impacting *S. argillacea*. Elk were reported in *S. argillacea* habitat, but the Service has not determined whether they browse on this species (Glisson 2005). Insect and small mammal herbivory occurs on *S. argillacea* fruits (Glisson 2005), but the Service does not have any information that this is occurring at a level that negatively impacts the species. (USFWS, 2011)

Stressor: Small populations (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: When *Schoenocrambe argillacea* was listed, it was known to occur in 2 general areas—around the Green River and Willow Creek—in 6 populations with fewer than 6,000 individuals, and most sites contained fewer than 200 individuals. Estimates for the Recovery Plan did not indicate significant changes, and the Service does not have more recent comprehensive data indicating changes in population size. Small populations and species with limited distributions are vulnerable to relatively minor environmental disturbances (Given 1994). Small populations also are at an increased risk of extinction due to the potential for inbreeding depression, loss of genetic diversity, and lower sexual reproduction rates (Ellstrand and Elam 1993; Wilcock and Neiland 2002). Lower genetic diversity may, in turn, lead to even smaller populations by decreasing the species' ability to adapt, thereby increasing the probability of population extinction (Barrett and Kohn 1991; Newman and Pilson 1997). On the other hand, many naturally rare species have persisted for long periods within small geographic areas, and many naturally rare species exhibit traits that allow them to persist, despite their small population sizes. Species with limited climatic ranges and restricted habitat requirements are typically the most vulnerable to extinction (Intergovernmental Panel on Climate Change (IPCC) 2002; Machinski et al. 2006). The risk of extinction is expected to increase for species with low population numbers (IPCC 2002; Jump and Penuelas 2005). (USFWS, 2011)

Stressor: Invasive species (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Invasive, exotic plant species can contribute to the extinction of native plants (Soulé et al. 1992). Exotic invasive species are common along highways because seeds are carried and deposited along roads by vehicles, and spread via vehicle-caused air turbulence (Forman and Alexander 1998). Roads often promote the spread of invasive species by altering soil characteristics, stressing native plant species, and providing easier movement by wild or human vectors (Trombulak and Frissell 2000). Spread of invasive species via roads coupled with increased road dust can exacerbate the impact on native species; an increase in fine dust particles can increase nonnative, exotic plant species (Reynolds et al. 2001). Cheatgrass (*Bromus tectorum*) occurs in *S. argillacea* habitat (Glisson 2005). Cheatgrass can out-compete native species for soil nutrients and water (Melgoza et al. 1990; Aguirre and Johnson 1991; Pyke and Novak 1994). If it establishes in sufficient density in native plant communities, cheatgrass increases flammability, leading to shortened fire return intervals that make it difficult for native plants to re-establish (D'antonio and Vitousek 1992). Halogeton (*Halogeton glomeratus*) is another invasive species that is found in the vicinity of *S. argillacea* habitat, but is not documented within occupied habitat (Brunson 2009; Buys & Associates 2009). Halogeton quickly infests areas that are either left barren from fire or are exposed to some type of soil disturbance (Pavek 1992). Halogeton tends to be a poor competitor, but it can accumulate sodium in the soil and alter soil microbiota to the disadvantage of native plants (Kitchen and Jorgensen 2001; Kitchen and Carlson 2008). Although invasive species are present in *Schoenocrambe argillacea* habitat, they have not been identified in high numbers or densities. Atmospheric levels of carbon dioxide are expected to double before the end of the 21st century (IPCC 2002), which is likely to increase biomass and seed production of invasive annuals (Mayeux et al. 1994; Smith et al. 2000; Ziska et al. 2005). This effect, if manifested, could facilitate the expansion of cheatgrass and other invasive plants that could compete with and further threaten *S. argillacea*. Regardless, the Service does not currently consider invasive species a threat to *S. argillacea*. (USFWS, 2011)

Stressor: Climate change (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Climate change is likely to affect long-term survival or distribution of native species. In the southwestern United States, including Utah and *Schoenocrambe argillacea* habitat, average temperatures have increased ~1.5°F (0.8°C) compared to a 1960-1979 baseline (Karl et al. 2009). By the end of this century, temperatures are expected to warm a total of 4 to 10°F (2 to 5°C) in the Southwest (Karl et al. 2009). Hot extremes, heat waves, and heavy precipitation will increase in frequency, with the Southwest experiencing the greatest temperature increase in the continental United States (IPCC 2007). The Service does not know how changes in precipitation will affect *Schoenocrambe argillacea*. However, we do know that increased drought can be detrimental to many drought-tolerant species. Drought conditions led to a noticeable decline in survival, vigor, and reproductive output of rare plants in the Southwest during the drought years of 2001-2004 (Anderton 2002; Van Buren and Harper 2002, 2003; Hughes 2005; Clark and Clark 2007; Roth 2008a, 2008b). Effects related to climate change, such as persistent or prolonged drought conditions, may affect the long-term persistence of *S. argillacea*, but without further research or information, it is difficult to predict how. (USFWS, 2011)

Recovery

Reclassification Criteria:

1. Discover or establish a minimum of five separate populations with 2,000 or more individuals per population for each species. These populations must be demonstrated to be at or above minimum viable population levels. (USFWS, 1994)
2. Document the presence of or, if necessary, establish formal land management designations which would provide for long—term protection on undisturbed habitat for the above five populations of each species. (USFWS, 1994)

Delisting Criteria:

1. Discovery or establishment of a minimum of 10 separate populations with 2,000 or more individuals per population for each species. These populations must be demonstrated to be at or above minimum viable population levels. (USFWS, 1994)
2. Document the presence of or, if necessary, establish formal land management designations which would provide for long—term protection on undisturbed habitat for the above 10 populations of each species. (USFWS, 1994)

Recovery Actions:

- Inventory suitable habitat for *S. argillacea*, *S. barnebyi*, and *S. suffrutescens* and determine with a reasonable degree of accuracy the population and distribution of each species. (USFWS, 1994)
- Establish and conduct at least three minimum viable population studies on each of at least three different populations of each species. (USFWS, 1994)
- Document the presence of or, if necessary, establish formal land management designations which would provide for long-term protection on undisturbed habitat for each species. (USFWS, 1994)

- Control activities which affect the habitat of *S. argillacea*, *S. barnebyi*, and *S. suffrutescens* through sections 7 and 9 of the Endangered Species Act and other relevant laws and regulations. (USFWS, 1994)

Conservation Measures and Best Management Practices:

- The Service recommends creating a better distribution map for *Schoenocrambe argillacea*. Because of the difficult terrain it inhabits and previous inaccuracies in habitat mapping, we also recommend developing alternative mapping techniques, such as using satellite imagery to map and ground-truth suitable habitat. (USFWS, 2011)
- The Service recommends developing a reliable comprehensive population estimate every 5 years. Populations that are accessible by foot should be resurveyed routinely. General estimates may be used for inaccessible areas. Should additional populations and higher numbers be identified, this may address the small population size and limited distributional concerns cited in section 2.3.2.5 and 2.4 above. Improved habitat mapping and better population counts should also be considered in land use decisions to minimize impacts to the species. Finally, improved habitat maps and population estimates should be used to help revise the Recovery Plan (as recommended below). (USFWS, 2011)
- The Service will work with the BLM to establish long-term demographic monitoring plots for *Schoenocrambe argillacea*. The Service will review available information (Glisson 2005) and coordinate with experts to identify appropriate monitoring plots. Data the Service collects on survival, reproduction, and habitat condition for the species will help us identify trends, threats, and whether conservation measures incorporated thus far are effective. (USFWS, 2011)
- We will work with the BIA and the Ute Tribe to map potential habitat and survey for new populations of *Schoenocrambe argillacea*, if discovered on Uintah and Ouray Indian Reservation lands. (USFWS, 2011)
- Approximately 11 percent of mapped *Schoenocrambe argillacea* populations occur on State and private lands. The Service should work with SITLA and private landowners to survey and conserve *S. argillacea* habitat and increase outreach efforts. (USFWS, 2011)
- Basic biological and ecological information should be obtained for this species, including determining pollination mechanisms and pollinators. The habitat also needs to be better defined by accurately characterizing parent material, soil, and landscape characteristics of occupied habitat. (USFWS, 2011)
- The Service should collect seeds to include this species in the Center for Plant Conservation collection. Seeds also should be tested for viability and longevity. (USFWS, 2011)
- Once habitat requirements are better understood and reliable suitable habitat maps are developed (see above actions), the Service recommends studying the feasibility of introducing *Schoenocrambe argillacea* into new areas of unoccupied suitable habitat near existing populations. (USFWS, 2011)
- On Federal lands, the Service should continue to avoid development in *Schoenocrambe argillacea* populations and suitable, unoccupied habitat to the extent possible, until we can complete research showing what level of development in *S. argillacea* habitat is tolerable. The Service should ensure that developers follow established conservation measures when disturbance occurs and that habitat fragmentation is reduced to the extent possible. (USFWS, 2011)
- Using better distribution maps and updated survey information, we should identify and establish core conservation areas in minimally-disturbed habitat (both occupied and unoccupied) for long-term protection of *Schoenocrambe argillacea*. The Service should work with the BLM to adopt these conservation areas under a long-term conservation agreement. (USFWS, 2011)

- Use conservation area information to identify and establish an Area of Critical Environmental Concern (ACEC) on BLM land to protect *Schoenocrambe argillacea* and its habitat. The ACEC should include no surface occupancy stipulations for those areas where mineral rights are not yet leased. The ACEC can be formally recommended to the BLM and incorporated during their resource management planning process. (USFWS, 2011)
- Develop a habitat management plan, which the BLM incorporates into the RMP and implements. Ensure that all *Schoenocrambe argillacea* occurrences on public lands are within management areas where maintenance of the species is a primary management goal. (USFWS, 2011)
- Develop conservation agreements with those federal mineral leaseholders whose leases are not subject to the terms of BLM management plans protecting the plants (leases that predate the RMP/habitat management plan). Through implementation of these conservation agreements, companies would implement conservation measures necessary to protect the species from mineral extraction activities. (USFWS, 2011)
- Once the Service has new survey data and research data available, we recommend revising the Recovery Plan to explicitly address the relevant listing factors. Time and cost required to meet the criteria and recover the species should be included in the Recovery Plan. (USFWS, 2011)
- The Service will publish in the Federal Register a formal name change from *Schoenocrambe argillacea* to *Hesperidanthus argillacea* to reflect the best available science. (USFWS, 2011)
- The Service will formally request the name be changed from *Schoenocrambe argillacea* to *Hesperidanthus argillacea* in the ITIS and USDA plants databases. (USFWS, 2011)

Species Taxonomic and Listing Information

Listing Status: Endangered; 01/14/1992; Mountain-Prairie Region (Region 6) (USFWS, 2016)

Physical Description

Schoenocrambe barnebyi is a perennial herbaceous plant with sparsely leafed stems 22 to 35 cm (9 to 15 inches) tall arising from a woody root crown. The leaves are entire with a smooth margin, 1.5 to 5 cm (0.6 to 3 inches) long and 0.5 to 2.5 cm (0.2 to 1 inch) wide. The leaf blades are alternately arranged on the stem and are attached to the stem by a petiole. The flowers of *S. barnebyi* have petals that are light purple with prominent darker purple veins and measure about 12 mm (0.4 inch) long and 2.5 mm (0.1 inch) wide. The entire flowers are about 1 cm (0.4 inch) across in full anthesis and are displayed in a raceme of, commonly, two to eight flowers at the end of the plant's leafy stems (Welsh and Atwood 1980, Rollins 1982, Welsh et al. 1987). Flowers (May-June) have pale purple petals, prominently veined with darker purple. (USFWS, 1994; NatureServe, 2015)

Taxonomy

Rollins (1982), in reevaluating the cruciferous genera of *Schoenocrambe* and *Thelypodopsis*, moved *T. argillacea* and *T. barnebyi* from *Thelypodopsis* to *Schoenocrambe* as *S. argillacea* and *S. barnebyi*. Welsh and Chatterley (1985) moved *Glaucocarpuni suffrutescens* to the genus *Schoenocrambe* to complete what morphologically appears to be a discrete phylogenetic unit among the Brassicaceae. The genus *Schoenocrambe* currently includes five known species, two (*S. linearifolia* and *S. linifolia*) are abundant wide—ranging species from the dry lower elevations of the interior western Cordilleras. *S. linearifolia* occurs from southern Colorado and northern Arizona southward to western Texas and Durango and Sonora, Mexico. *S. linifolia* occurs from southeastern British Columbia, Canada, and western Montana southward to eastern Nevada and northern New Mexico. The remaining three, *S. argillacea*, *S. barnebyi*, and *S. suffrutescens*, are rare endemic species from low elevations of the northern and western portions of the Colorado Plateau in the State of Utah (Rollins 1982, Welsh et al. 1987). (USFWS, 1994)

Current Range

Endemic to the Canyonlands of south-central Utah, where known from two distinct clusters of occurrences: one in the southern portion of the San Rafael Swell near Muddy Creek in southern Emery County and the other in Capitol Reef National Park in the Fremont River drainage west of Fruita in central Wayne County. (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (USFWS, 1994)

Breeding Season

Adult: April to May (USFWS, 1994)

Reproduction Narrative

Adult: We have little information on the biology and life history of Barneby reed-mustard. Plants reproduce sexually and flower from late April to mid or late May (Welsh and Neese 1984). (USFWS, 1994)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Bare rock/talus/scree, desert (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Occurs at elevations between 1460 and 1985 meters on sparsely vegetated sites (NatureServe, 2015)

Habitat Narrative

Adult: Mixed desert shrub communities (shadscale, Eriogonum, Ephedra), in sparsely vegetated sites on steep, eroding north to northeast facing slopes (elevations between 1460 and 1985 meters). Grows in xeric, fine-textured red clay soils rich in selenium and gypsum of the Moenkopi Formation, and, rarely, on soils eroded from it that now overlie the Chinle Formation and on the Carmel Formation. Associated species include Abronia fragrans, Amelanchier utahensis, Artemisia dracunculus, Astragalus brandegeei, Atriplex confertifolia, Chrysothamnus nauseosus, Ephedra torreyana, Ephedra viridis, Eriogonum corymbosum, Erioneuron pulchellum, Erioneuron pilosum, Hilaria jamesii, Monolepis nuttalliana, Opuntia polyacantha, Phacelia rafaensis, Sporobolus sp., Stanleya pinnata, and Townsendia incana. (NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Gravity, wind and rain are thought to be the primary dispersal agent of seeds (Welsh and Neese 1984). (USFWS, 1994)

Population Information and Trends**Population Trends:**

Unknown (NatureServe, 2015)

Resiliency:

Low (inferred from USFWS, 2011)

Representation:

Low (inferred from USFWS, 2011)

Redundancy:

Low (inferred from USFWS, 2011)

Number of Populations:

2 (NatureServe, 2015)

Population Size:

2,251 (USFWS, 2011)

Population Narrative:

The Service estimates the total population to be approximately 2,251 individuals within 4 *Schoenocrambe barnebyi* populations containing a total of 15 sites (Clark 2005a). (USFWS, 2011)

Threats and Stressors

Stressor: Mining (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: The primary threat to *Schoenocrambe barnebyi* identified at the time of listing and in the Recovery Plan was habitat loss and degradation associated with future uranium mining on BLM lands (57 FR 1398, January 14, 1992; USFWS 1994). Mining related activities may result in increased surface disturbances, increased foot and vehicle traffic, reduced air quality, vegetation disturbance, and removal of top soil and overburden. Surface disturbances may impact the species by crushing or trampling plants, causing soil erosion and compaction, degrading suitable habitat, losing pollinator populations and habitat, reducing plant vigor and reproductive potential, reducing seed bank quantity and quality, and increasing invasive plant occurrences thereby increasing fire risk (Brock and Green 2003; BLM 2008a). All of the known individuals on BLM land occur in areas that are open to mineral exploration or development (BLM 2008a). Six mining claims occur near the Sy's Butte/Hidden Splendor Mine and mining activities may have extirpated a portion of this population during the 1950s and 1960s (Anderson 1985; USFWS 1994). Mining shafts from this time period are currently being closed (Conrad pers. comm. 2009; Ivory pers. comm. 2009). With the exception of the Lucky Strike Mine, there has been no mining since the 1960s (Conrad pers. comm. 2009; Ivory pers. comm. 2009). Because BLM lands remain open to mineral exploration and development and there are existing mining claims near the Sy's Butte/Hidden Splendor Mine population that may recommence at any time (Conrad pers. comm. 2009), future uranium mining continues to be a threat on BLM lands. The Service considers this threat to be currently low because it has been over 40 years since active mining occurred, and we are not aware of any current mining proposals in this area. (USFWS, 2011)

Stressor: Grazing (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Livestock grazing may result in the direct loss or damage to plants and their habitat through trampling, soil compaction, increased soil erosion, invasion of noxious weeds, and disturbance to pollinators (Kauffman et al. 1983; Fleischner 1994; Kearns et al. 1998; DiTomaso 2000). Sheep and cattle grazing were identified as possible historic threats to populations of *Schoenocrambe barnebyi* (57 FR 1398, January 14, 1992; USFWS 1994). At the time of listing, the

intensity of grazing at known *S. barnebyi* populations was not expected to significantly impact the species. Grazing intensity has not increased since we finalized the Recovery Plan (BLM 2009). However, the Service does not have any monitoring data that evaluates the effects of grazing on *S. barnebyi* populations. (USFWS, 2011)

Stressor: Off-highway vehicle use (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: The Services did not identify off-highway vehicle (OHV) activities as threats to *Schoenocrambe barnebyi* when we listed the species in 1992, nor in the Recovery Plan (57 FR 1398, January 14, 1992; USFWS 1994). The OHV use may result in the direct loss or damage to plants and their habitat through soil compaction, increased soil erosion, reduced air quality, invasion of noxious weeds, and disturbance to pollinators and their habitat (Eckert et al. 1979; Lovich and Bainbridge 1999; Ouren et al. 2007; Wilson et al. 2009). The use of OHVs in Utah has exploded in popularity over the past several decades (Burr et al. 2008). From 1998-2006, the number of registered OHVs in Utah has increased by 233% (Burr et al. 2008). The known *Schoenocrambe barnebyi* population on BLM lands (Sy's Butte/Hidden Splendor Mine) occurs in an area that is open to OHV traffic along designated routes only (BLM 2008a). Although illegal OHV use occurs within the vicinity (BLM 2011), to date, no direct or indirect impacts to the population or individual plants have been documented (Ivory 2009). Due to the remoteness of the population and the steepness of the terrain, the Service expects the overall scope of the threat to be low. (USFWS, 2011)

Stressor: Erosion (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Erosion was not considered a threat at the time of listing or in the recovery plan (57 FR 1398, January 14, 1992; USFWS 1994). However, natural erosion of *Schoenocrambe barnebyi* habitat was listed as a potential threat in a 1992 survey report for the BLM (Ecosphere 1992). *Schoenocrambe barnebyi* grows in very steep habitats with sparse vegetation. Plants may be uprooted, damaged or destroyed by gullying, slumping or rockslides. Under natural circumstances, the Service presumes the species has adapted to living on a highly erodible substrate. However, erosion may increase as climate changes. Climate change will likely increase heavy precipitation events which can increase soil erosion (Nearing et al. 2004; IPCC 2007; see section 2.3.2.5 below). In addition, erosion may be accelerated through surface disturbing activities. As previously described, OHV use and grazing occur in the habitat of *Schoenocrambe barnebyi* on BLM lands. Although the Service believes the overall threat level of these activities to be currently low, the Service does not have monitoring data to adequately evaluate the effects, including erosion, of these uses to the plants. (USFWS, 2011)

Stressor: Trampling (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: At the time of listing and in our Recovery Plan, we identified trampling by Capitol Reef visitors as the primary impact on the *Schoenocrambe barnebyi* population at Sulphur Creek (57

FR 1398, January 14, 1992; USFWS 1994). However, trampling from hiking activities was later evaluated and determined to be unlikely (Clark 1997). Visitors tend to remain along the trail in the creek bottom, away from the plants and the habitat due to the steepness of the terrain. An historic livestock trail through the population is no longer in use but is occasionally used by deer (Clark pers. comm. 2009a). All other sites within Capitol Reef were evaluated for potential impacts caused by hiking trails but none were documented (Clark 2005b). For these reasons, we no longer consider trampling a threat. (USFWS, 2011)

Stressor: Invasive species and fire (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Invasive species and fire were not considered threats at the time of listing or in the species' Recovery Plan (57 FR 1398, January 14, 1992; USFWS 1994). However, the spread of nonnative invasive species is considered the second largest threat to imperiled plants in the United States (Wilcove et al. 1998). Invasive plants—specifically exotic annuals—negatively affect native vegetation, including rare plants. One of the most substantial effects is the change in vegetation fuel properties that, in turn, alter fire frequency, intensity, extent, type, and seasonality (Menakis et al. 2003; Brooks et al. 2004; McKenzie et al. 2004). Shortened fire return intervals make it difficult for native plants to reestablish or compete with invasive plants (D'Antonio and Vitousek 1992). Mining, grazing, and unauthorized OHV use are activities that disturb soil surfaces within *Schoenocrambe barnebyi* habitat on BLM lands. In general, *B. tectorum* is known to invade areas in response to these types of surface disturbing activities (Hobbs 1989; Rejmanek 1989; Hobbs and Huenneke 1992; Evans et al. 2001). These types of surface disturbing activities do not occur on the populations in Capitol Reef. Currently wildland fires are considered unlikely to occur in *S. barnebyi*'s habitat due to the sparseness of vegetation associated with the species (Borthwick pers. comm. 2009c; Ivory pers. comm. 2009). (USFWS, 2011)

Stressor: Herbivory (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: *Schoenocrambe barnebyi* appears to be highly palatable to deer (Clark 2005b). The Service expects browsing to be localized and only affect a small portion of the populations. However, we do not have any information that browsing is occurring at a level that negatively impacts the species as a whole (Clark 2005b; Ivory 2009). For these reasons, this factor has the potential to affect the species. (USFWS, 2011)

Stressor: Small populations (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: The original listing decision cited the limited distribution and low population numbers as a factor affecting the species (57 FR 1398, January 14, 1992). The species' rarity and limited distribution make it highly vulnerable to localized stochastic extinction events. While more sites have been found since the species was listed, it remains narrowly distributed in few populations and may be in decline (Clark 1997; Anderton 2002). Half of the sites have fewer than 100 plants

(Clark 2005b; see Table 2). Although small population size is an intrinsic vulnerability of the species, some sites may hold so few plants that they are not demographically stable in the medium to long term and some may be lost as a result of natural variation in population numbers in the short term. Population genetics studies have not been undertaken for *Schoenocrambe barnebyi*, but despite the overall lack of information on the population ecology of the species, the Service does know that small populations are at an increased risk of extinction due to the potential for inbreeding depression, loss of genetic diversity, and lower sexual reproduction rates (Ellstrand and Elam 1993; Wilcock and Neiland 2002). Only the larger sites of *S. barnebyi* may have sufficient genetic variability to provide for long-term adaptation to natural or manmade changes in their environment. Small population size in and of itself is not considered a threat; however, it may increase the species' vulnerability if other threats discussed in this analysis are impacting the species. Even a small localized disturbance such as mining, OHV-related activities, or fire could result in the extirpation of a site. The Service determined the threat of climate change (see discussion below) has an overall threat level of moderate. Therefore, the Service considers the overall threat level for small population size to be moderate. (USFWS, 2011)

Stressor: Climate change (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Species with limited ranges and restricted habitat requirements also are more vulnerable to the effects of global climate change (IPCC 2002; Jump and Penuelas 2005; Machinski et al. 2006; Krause 2010). Climate change was not discussed in the original rule to list the species or in the Recovery Plan. Over the past 50 years, the frequency of cold days, cold nights, and frosts have become less frequent over most land areas, and hot days and hot nights have become more frequent (IPCC 2007). Changes in the global climate system during the 21st century are hypothesized to be larger than those observed during the 20th century (IPCC 2007). For the next two decades, a warming of about 0.2°C (0.4°F) per decade is projected (IPCC 2007). Afterward, temperature projections increasingly depend on specific emission scenarios (IPCC 2007). Various emissions scenarios suggest that by the end of the 21st century, average global temperatures are expected to increase of 0.6 to 4.0°C (1.1 to 7.2°F) with the greatest warming expected over land (IPCC 2007). Localized projections suggest the southwest may experience the greatest temperature increase of any area in the lower 48 States (IPCC 2007). Effects related to climate change, such as persistent or prolonged drought conditions, increased invasions of exotic species and pests, and increased heavy rainfall events, may affect the long-term persistence of *S. barnebyi*. Climate change could potentially reduce the overall abundance of *Schoenocrambe barnebyi*. However, a large degree of uncertainty exists regarding the extent of such effects. For these reasons, this factor has the potential to affect the species. Further studies should be conducted to monitor and minimize the effects of this potential threat. (USFWS, 2011)

Stressor: Lack of scientific knowledge/monitoring (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: The lack of scientific knowledge of *Schoenocrambe barnebyi* may cause the species to be managed below optimal levels. While not a threat in and of itself, this factor affects our ability to manage and recover the species. We lack scientific knowledge and monitoring data throughout the range of the species. We know little about *S. barnebyi*--its pollinators, range,

habitat, and population trends. For example, we do not know why the original population estimate for BLM population was 2,000 individuals but surveys since have counted less than 200 plants. We do not know whether this represents a reduction in plant numbers or is an artifact of survey effort, making it difficult to analyze overall threat levels for the species. Because of this lack of scientific knowledge, opportunities for better management of the species could potentially be missed. Based on our current limited understanding of the species, we consider the overall threat levels for threats discussed in sections 2.3.2.1, 2.3.2.4, and 2.3.2.5 are all low. We could potentially move the species toward downlisting, recovery, and eventual delisting if we could better quantify the degree of threat the species faces and work toward alleviating those threats. However, the only site that has longer, albeit irregular, monitoring data shows the plant may be in decline, potentially negatively impacted by drought (Clark 1997; Anderton 2002), and potentially able to recover (Clark pers. comm. 2009b). The lack of trend data following the drought makes it difficult to determine to what degree drought may be a threat to the species. (USFWS, 2011)

Recovery

Reclassification Criteria:

1. Discover or establish a minimum of five separate populations with 2,000 or more individuals per population for each species. These populations must be demonstrated to be at or above minimum viable population levels. (USFWS, 2011)
2. Document the presence of or, if necessary, establish formal land management designations which would provide for long—term protection on undisturbed habitat for the above five populations of each species. (USFWS, 2011)

Delisting Criteria:

1. Discovery or establishment of a minimum of 10 separate populations with 2,000 or more individuals per population for each species. These populations must be demonstrated to be at or above minimum viable population levels. (USFWS, 2011)
2. Document the presence of or, if necessary, establish formal land management designations which would provide for long—term protection on undisturbed habitat for the above 10 populations of each species. (USFWS, 2011)

Recovery Actions:

- Inventory suitable habitat for *S. argillacea*, *S. barnebyi*, and *S. suffrutescens* and determine with a reasonable degree of accuracy the population and distribution of each species. (USFWS, 2011)
- Establish and conduct at least three minimum viable population studies on each of at least three different populations of each species. (USFWS, 2011)
- Document the presence of or, if necessary, establish formal land management designations which would provide for long—term protection on undisturbed habitat for each species. (USFWS, 2011)
- Control activities which affect the habitat of *S. argillacea*, *S. barnebyi*, and *S. suffrutescens* through sections 7 and 9 of the Endangered Species Act and other relevant laws and regulations. (USFWS, 2011)

Conservation Measures and Best Management Practices:

- The BLM and Capitol Reef should establish long-term trend monitoring to provide base line demographic data for the species. In addition to collecting baseline demographic data, BLM and Capitol Reef should collect data on the species' response to habitat conditions including how the factors considered in this 5-year review are affecting the species. (USFWS, 2011)
- Determine pollinators or pollination mechanisms including the identification of pollinators, pollinator availability, and their habitat requirements. (USFWS, 2011)
- Assess seedbank viability, including seed viability and dispersal mechanisms and determining germination requirements. (USFWS, 2011)
- Analyze population genetics to assess potential impacts from inbreeding depression. (USFWS, 2011)
- Determine the species' vulnerability to prolonged drought and the potential impacts of climate change. (USFWS, 2011)
- Determine the species response to invading nonnative species and its response to increased fire frequencies. (USFWS, 2011)
- Determine habitat requirements, including soils, aspects, and climatic variables. (USFWS, 2011)
- Determine the effects livestock grazing has on the species and its habitat. (USFWS, 2011)
- Determine the effects OHV use has on the species and its habitat. (USFWS, 2011)
- Determine the effects mining has on the species and its habitat. (USFWS, 2011)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/06/1987; Mountain-Prairie Region (Region 6) (USFWS, 2016)

Physical Description

Shrubby reed-mustard is a perennial herb in the mustard family, with clumped stems 10 to 25 cm (4 to 12 inches) tall arising from a branching woody root crown. The leaves are entire with a smooth margin, 1.0 to 2.5 cm (0.4 to 1 inch) long and 0.3 to 1.0 cm (0.12 to 0.4 inch) wide. The leaf blades are alternately arranged on the stem and are sessile or attached to the stem by a short petiole. The flowers of Shrubby reed-mustard have petals that are light yellow or greenish yellow and spatulately shaped measuring about 10 mm (0.4 inch) long and 3 mm (0.12 inch) wide. The entire flowers are about 1 cm (0.4 inch) across in full anthesis and are displayed in a raceme of, commonly, 5 to 20 flowers at the end of the plant's leafy stems. This herb produces yellow flowers May through June. (USFWS, 1994; NatureServe, 2015)

Taxonomy

The species was first discovered in 1935 by Edward Graham, described by Reed Rollins as *Thelypodium suffrutescens* (Graham 1937), and, in 1938, renamed *Glaucocarpum suffrutescens* (Rollins 1938; 52 FR 37416; October 6, 1987). The species was listed under the latter name (52 FR 37416; October 6, 1987). Since then, its genus was changed to *Schoenocrambe* (57 FR 1398; January 14, 1992), *Glaucocarpum* (Al-Shehbaz 2005), and most recently *Hesperidanthus* (Al-Shehbaz 2010). This last taxonomic change is currently accepted in the Flora of North America and the integrated taxonomic information system (ITIS) (Al-Shehbaz 2010; ITIS 2017). However, The Service will still use *Schoenocrambe suffrutescens* until a formal change in the Federal Register is completed. (USFWS, 2019)

Current Range

The species is endemic to the Uinta Basin region in northeastern Utah, and found exclusively within the Lower Green-Desolation Canyon and Willow Creek watersheds. (USFWS, 2019)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (USFWS, 1994)

Dependency on Other Individuals or Species

Adult: The following native bee species may be *Schoenocrambe suffrutescens* pollinators: *Dialictus perdificilis*, *D. sedi*, *Evylaeus pulveris*, *Andrena walleye*, *A. prunorum* and *Halictus rubicundus* (USFWS 1994; Tepedino 2000; Lewis 2010). (USFWS, 2010)

Breeding Season

Adult: April to May (USFWS, 2010)

Other Reproductive Information

Adult: Shrubby reed-mustard could be pollinator limited if adequate and appropriate insect pollinators are not available (Lewis and Schupp 2014). Seed set is significantly lower in individuals that self-pollinate compared to individuals that are fertilized by cross-pollination (pollen from another plant; Lewis and Schupp 2014). These results also indicate that cross-pollination is critical for maximizing reproduction of the species. A related study of road dust impacts to shrubby reed-mustard found that increases in dust deposition reduced reproduction in the species by significantly decreasing the numbers of mature seeds produced, and showed trends of decreased seed numbers and weight (Lewis 2017). Mean stomatal conductance also significantly decreased with increasing dust presence on leaves, which may impact the overall health and reproductive capacity of the species (Lewis 2017). (USFWS 2019)

Reproduction Narrative

Adult: Reproduction is sexual (USFWS 1994), and the species is capable of self-pollination (Tepedino 2000). Flowering for this species occurs in April to May and fruiting occurs May to June. The following native bee species may be *Schoenocrambe suffrutescens* pollinators: *Dialictus perdificilis*, *D. sedi*, *Evylaeus pulveris*, *Andrena walleye*, *A. prunorum* and *Halictus rubicundus* (USFWS 1994; Tepedino 2000; Lewis 2010). (USFWS, 2010)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Desert, forest/woodland, woodland - conifer (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Occurs at elevations between 1555 and 1981 meters. (NatureServe, 2015)

Dependency on Other Individuals or Species for Habitat

Adult: Commonly on level to moderately sloping ground surfaces. Soils are dry, shallow, and fine-textured, and are usually overlain by shale fragments. (NatureServe, 2015)

Habitat Narrative

Adult: Mixed desert shrub communities and, at some locations, in pinyon -juniper and desert shrub, on semi-barren, white-shale layers of the Evacuation Creek Member of the Green River Formation. Commonly on level to moderately sloping ground surfaces. Soils are dry, shallow, and fine-textured, and are usually overlain by shale fragments. 1555-1981 m elevation. (NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Decline (NatureServe, 2015)

Species Trends:

Decline (NatureServe, 2015)

Number of Populations:

7 (USFWS, 2019)

Population Size:

3,161 (USFWS, 2019)

Additional Population-level Information:

Range-wide population trend monitoring plots were established by the BLM in 2017. Preliminary findings suggest that open interspaces are important habitat components for the species (BLM 2017). Species monitoring provided a baseline density of 1.9 shrubby reedmustard plants per one-meter squared for monitoring plots; however, subsequent consecutive surveys are needed to refine our understanding of species density (BLM 2017). It is too early to determine demographic and population trends from this monitoring effort. (USFWS, 2019)

Population Narrative:

In 2019, the Service estimated shrubby reed-mustard was limited to 3,161 individuals within three geographic areas and seven populations. The range of the Bad Land Cliffs population has been extended from the 2010 estimate after the discovery of 232 new individuals in an area that was previously unsurveyed (BLM 2017). (USFWS, 2019)

Threats and Stressors

Stressor: Oil and gas development (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Oil and gas resource development operations pose a significant threat to *Schoenocrambe suffrutescens* populations and habitat (USFWS 1990; 1994). All known populations of *S. suffrutescens* that occur on Federal lands are leased for oil and gas development (USFWS 1994). In addition, an ongoing natural gas project (currently in the first phase of development) overlaps the entire range of three of the known seven *S. suffrutescens* populations. These populations account for over 40 percent of the species' known suitable habitat and over 80 percent of all known individuals (USFWS 2008a). Development continues in unoccupied suitable habitat, thereby limiting potential expansion and recovery of the species. Furthermore, development continues to occur in habitats immediately adjacent to occupied habitats. While steps have been taken to minimize these indirect effects, it is unknown if this adjacent development is adversely impacting the viability of *S. suffrutescens* populations. These indirect effects, and the protections currently provided, are discussed below. (USFWS, 2010)

Stressor: Habitat fragmentation (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: *Schoenocrambe suffrutescens* exists in small, low-density populations that might be prone to negative effects from habitat fragmentation. For example, small plant populations fluctuate more widely over time and the smaller the remnant, the more susceptible the population is to extinction (Soulé et al. 1992; Forman and Alexander 1998; Menges 2002; Lienert 2004). Small plant populations can lose genetic variation and their population viability decreases (Ellstrand and Elam 1993; Lienert 2004; Kolb 2008). Fruit set, germination rate, offspring survival, and total numbers of flowers per plant are higher in larger populations than in small populations (Paschke et al. 2002). Similarly, the number of capsules per plant and the number of seedlings per plant are positively correlated with population size (Schmidt and Jensen 2000). Roads associated with energy exploration and development cause a high level of habitat fragmentation. Increased oil and gas developments result in more roads developed in and near *S. suffrutescens* habitat. Ecological effects of roads to plants can extend more than 328 feet (100 meters) from the road (Angold 1997; Forman 2000; Forman and Deblinger 2000). Disturbance can occur directly from construction or indirectly from road dust, discussed further below (Farmer 1993; Angold 1997; Trombulak and Frissel 2000). There is a strong correlation between vegetation composition and health with distance from a road, although it may take decades for the full effects of road development to be realized (Auerbach et al. 1997; Myers-Smith et al. 2006). (USFWS, 2010)

Stressor: Road dust (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: *Schoenocrambe suffrutescens* may be impacted by the indirect effects of road dust associated with oil and gas development. Road traffic mobilizes and spreads dust (Farmer 1993; Trombulak and Frissell 2000), and for every vehicle traveling 1 mile (1.6 kilometers) of unpaved roadway once a day, every day for a year, approximately 2.5 tons of dust are deposited along a 1,000-foot (~300-meter) corridor centered on the road (Sanders pers. comm. 2008). Dust deposition tends to be highest near the road and decreases with increasing distance from the road (Spatt and Miller 1981; Everett 1980; Walker and Everett 1987; Santelmann and Gorham 1988; Myers-Smith et al. 2006). For example, in one study 97 percent of dust was deposited within 410 feet (125 meters) of the road (Walker and Everett 1987). The distance from a road at which dust can affect vegetation varies (see McCrea 1984; Myers-Smith et al. 2006), but negative impacts can occur up to 984 feet (300 meters) away from the road (Everett 1980). Dust negatively affects photosynthesis, respiration, transpiration, water use efficiency, leaf conductance, growth rate, plant vigor, gas exchange, and allows the penetration of phytotoxic gaseous pollutants (Eller 1977; Spatt and Miller 1981; Thompson et al. 1984; Farmer 1993; Sharifi 1997; Trombulak and Frissell 2000; Hobbs 2001). Dust comprised of finer particulates was shown to cause more improper functioning of the stomata than larger particles (Ricks and Williams 1974; Eller and Brunner 1975; Eveling and Bataille 1984; Rawson and Clarke 1988; Hirano et al. 1995). Clogged stomata result in increased water loss in two ways: due to an increased transpiration rate because of increased temperatures and due to clogged stomata that are unable to close at night (Hirano et al. 1995). Other dust effects include inhibiting sunlight from reaching the surfaces of dusted plants (Sharifi et al. 1997). Additionally, a decrease in infra-red light reflectance can result in dusted leaves with a 4 to 5°F (2 to 3°C) higher temperature (Sharifi

et al. 1997) compared to undusted leaves (Hirano et al. 1995). Soils near roads can have significantly lower nutrient levels, altered organic horizon depth, higher bulk density, and lower moisture (Auerbach et al. 1997). Furthermore, soil characteristics and plant community composition can remain significantly different up to 28 years after road development (Myers-Smith et al. 2006). We do not know if dust negatively affects plant pollinators. (USFWS, 2010)

Stressor: Plant-pollinator interactions (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Many of the negative effects of habitat fragmentation to plants are due to effects on plant-pollinator interactions (Debinski and Holt 2000; Moody-Weis and Heywood 2001; Aizen et al. 2002; Gathmann and Tscharntke 2002; Lennartsson 2002; Kolb 2008). Fragmented plant populations appear to be less attractive to insect pollinators, which spend more time in larger, unfragmented plant habitats (Aizen et al. 2002; Lennartsson 2002; Kolb 2008; Goverde et al. 2002). Furthermore, insect pollinator diversity increases in larger populations (Mustajarvi et al. 2001) and decreases in isolated habitats with smaller plant population sizes (Steffan-Dewenter and Tscharntke 1999). Lower pollinator visitation rates are associated with lower seed sets and reproductive success in fragmented sites compared to intact sites (Jennersten 1988). Bumblebees were observed visiting more flowers on fewer flower stalks in sparser plant populations (Mustajarvi et al. 2001; Goverde et al. 2002). This led to increased self-pollination or near-neighbor pollination contributing to inbreeding (Goverde et al. 2002; Lennartsson 2002). Inbred plants produce fewer flowers and seeds, have smaller plant height and smaller leaf-size, and reduced reproductive success (Steffan-Dewenter and Tscharntke 1999; Lienert 2004; Kolb 2008). Overall, we believe energy related development can cause serious impacts to *Schoenocrambe suffrutescens* through habitat fragmentation, increased road dust, and disruption of plant-pollinator interactions. Current 300 feet (91 meters) buffers are likely adequate to minimize impacts to the species. Nevertheless, in 2009, the Service initiated studies to quantify the effects of continued energy development related to these factors. (USFWS, 2010)

Stressor: Building stone mining (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: *Schoenocrambe suffrutescens* habitat is associated with commercially valuable building stone. Building stone mining can directly disturb individual plants and their habitat, with other effects similar to oil and gas development, including habitat fragmentation, increased dust, and pollinator disturbance. Building stone mining was a significant historical threat to the species. Previous commercial stone excavation caused the extirpation of a portion of the species' population in the vicinity of Big and Little Pack Mountains (USFWS 1994). Today, this factor is only a substantive issue on private land. Although approximately 57 percent of mapped *Schoenocrambe suffrutescens* populations on BLM lands are open to leasing (BLM GIS data, September 2009), building stone mining does not currently occur in occupied habitat on BLM land (Hansen pers. comm. 2009). On private lands, building stone is currently mined in *Schoenocrambe suffrutescens* occupied habitat. At one site, seven individual plants and occupied habitat were destroyed (Brunson 2010). We do not know how widespread this impact is across *S. suffrutescens* habitat on private lands. With so few individuals of this species, we believe that the loss of any individuals could significantly impact the species. Therefore, based

on recently documented disturbance on private lands, the Service believes that building stone mining remains a threat to this species. (USFWS, 2010)

Stressor: Small populations (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: When *Schoenocrambe suffrutescens* was listed, it was known to occur in only nine populations with fewer than 3,000 individuals total, including three populations of fewer than 30 plants each. Recent estimates do not indicate significant changes. Small populations and species with limited distributions are vulnerable to relatively minor environmental disturbances (Given 1994). Small populations are also at an increased risk of extinction due to the potential for inbreeding depression, loss of genetic diversity, and lower sexual reproduction rates (Ellstrand and Elam 1993; Wilcock and Neiland 2002). Lower genetic diversity may, in turn, lead to even smaller populations by decreasing the species' ability to adapt, thereby increasing the probability of population extinction (Barrett and Kohn 1991; Newman and Pilson 1997). Species with limited climatic ranges and restricted habitat requirements are typically the most vulnerable to extinction (Intergovernmental Panel on Climate Change [IPCC] 2002; Machinski et al. 2006). The risk of extinction is expected to increase for species with low population numbers (IPCC 2002; Jump and Penuelas 2005). The Service lacks information on the population genetics of *Schoenocrambe suffrutescens*. Recent observations indicate this species produces more seed when it is outcrossed (Lewis 2010). Therefore, the fewer plants are located at a site, the less chance for cross-fertilization. Because population numbers are very low for this species, we consider small population size a threat to *S. suffrutescens*, but without further research or information, the Service cannot predict the magnitude of this threat. (USFWS, 2010)

Stressor: Invasive species (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Exotic species are common along highways because seeds are carried and deposited along roads by vehicles, and spread via vehicle-caused air turbulence (Forman and Alexander 1998). Roads promote the spread of invasive species by altering soil characteristics, stressing native vegetation, and providing easier movement by wild or human vectors (Trombulak and Frissell 2000). Spread of invasive species via roads coupled with increased road dust can exacerbate the impact on native species: an increase in fine dust particles can increase nonnative, exotic plant species (Reynolds et al. 2001). Invasive, exotic plant species can contribute to the extinction of native plants (Soulé et al. 1992). Cheatgrass (*Bromus tectorum*) was documented in *Schoenocrambe argillacea* habitat (Glisson 2005), in the vicinity of the Big Pack Mountain *S. suffrutescens* population. Cheatgrass can out-compete native species for soil nutrients and water (Melgoza et al. 1990; Aguirre and Johnson 1991; Pyke and Novak 1994). If it establishes in sufficient density in native plant communities, cheatgrass increases flammability, leading to shortened fire return intervals that make it difficult for native plants to re-establish (D'antonio and Vitousek 1992). Halogeton (*Halogeton glomeratus*) has been documented growing in *S. suffrutescens* occupied habitat (Brunson 2009; Buys and Associates 2009, Lewis 2010). Halogeton quickly infests areas that are either left barren from fire or disturbed from mechanical or land management means (Pavek 1992). Halogeton tends to be a poor competitor, but it can accumulate sodium in the soil and alter soil microbiota to the disadvantage of native

plants (Kitchen and Jorgensen 2001; Kitchen and Carlson 2008). Although invasive species are present in *Schoenocrambe suffrutescens* habitat, they have not been noted at high levels. Their distribution is likely to increase over time as invasive annuals increase biomass and seed production at elevated levels of carbon dioxide (Mayeux et al. 1994; Smith et al. 2000; Ziska et al. 2005). Regardless, we do not consider invasive species a threat to *S. suffrutescens* now or for the foreseeable future. (USFWS, 2010)

Stressor: Climate change (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Climate change is likely to affect long-term survival or distribution of native species. In the southwestern United States, including Utah and *Schoenocrambe suffrutescens* habitat, average temperatures have increased ~1.5°F (0.8°C) compared to a 1960-1979 baseline (Karl et al. 2009). By the end of this century, temperatures are expected to warm a total of 4 to 10°F (2 to 5°C) in the Southwest (Karl et al. 2009). Hot extremes, heat waves, and heavy precipitation will increase in frequency, with the Southwest experiencing the greatest temperature increase in the continental United States (IPCC 2007). We do not know how changes in precipitation will affect *Schoenocrambe suffrutescens*. However, we do know that increased drought can be detrimental to many drought-tolerant species. Drought conditions led to a noticeable decline in survival, vigor and reproductive output of rare plants in the southwest during the drought years of 2001-2004 (Roth 2008a, 2008b; Clark and Clark 2007; Hughes 2005; Anderton 2002; Van Buren and Harper 2002, 2003). On the other hand, there is some indication that high-stress areas may contain plants that are adapted to that stressor, and drought-adapted species may experience lower mortality during severe droughts (Gitlin et al. 2006). Effects related to climate change, such as persistent or prolonged drought conditions, may affect the long-term persistence of *Schoenocrambe suffrutescens*, but without further research or information, it is difficult to predict how. (USFWS, 2010)

Recovery

Reclassification Criteria:

1. Discover or establish a minimum of five separate populations with 2,000 or more individuals per population for each species. These populations must be demonstrated to be at or above minimum viable population levels. (USFWS, 1994)
2. Document the presence of or, if necessary, establish formal land management designations which would provide for long—term protection on undisturbed habitat for the above five populations of each species. (USFWS, 1994)

Delisting Criteria:

1. Discovery or establishment of a minimum of 10 separate populations with 2,000 or more individuals per population for each species. These populations must be demonstrated to be at or above minimum viable population levels. (USFWS, 1994)
2. Document the presence of or, if necessary, establish formal land management designations which would provide for long—term protection on undisturbed habitat for the above 10 populations of each species. (USFWS, 1994)

Recovery Actions:

- Inventory suitable habitat for *S. argillacea*, *S. barnebyi*, and *S. suffrutescens* and determine with a reasonable degree of accuracy the population and distribution of each species. (USFWS, 2011)
- Establish and conduct at least three minimum viable population studies on each of at least three different populations of each species. (USFWS, 2011)
- Document the presence of or, if necessary, establish formal land management designations which would provide for long-term protection on undisturbed habitat for each species. (USFWS, 2011)
- Control activities which affect the habitat of *S. argillacea*, *S. barnebyi*, and *S. suffrutescens* through sections 7 and 9 of the Endangered Species Act and other relevant laws and regulations. (USFWS, 2011)

Conservation Measures and Best Management Practices:

- We recommend conducting range-wide, comprehensive surveys for *Schoenocrambe suffrutescens* within the next year, especially in the Gray Knolls area on tribal land. These data should be used to define and delineate populations, and to help revise the Recovery Plan. (USFWS, 2010)
- Monitoring plots were established for testing plant response to disturbance, and basic demographic data are being collected. We recommend continuing to collect data from at least a portion of these plots indefinitely, even past the need for the disturbance study, to be able to answer basic demographic questions and to monitor reproduction. (USFWS, 2010)
- The previous geological nomenclature that was commonly used to identify potential *Schoenocrambe suffrutescens* habitat was discarded (Weiss 1990), thus complicating an already difficult search for this species. The Service needs to accurately characterize parent material, soil, and landscape characteristics for *S. suffrutescens*. This research would allow us to more accurately identify unoccupied but potentially important habitat, areas for focused surveys and reintroduction, and areas where oil and gas development are unlikely to harm the species. (USFWS, 2010)
- *Schoenocrambe suffrutescens* should be reintroduced to new areas of suitable but unoccupied habitat near existing populations. (USFWS, 2010)
- Basic biological and ecological information should be obtained for this species, including pollination mechanisms and pollinators. This research began in 2010. (USFWS, 2010)
- Studies to quantify the effects of dust, invasive species, and disturbance from continued energy development were initiated in 2009. These studies should be continued until the Service has enough data to draw conclusions. (USFWS, 2010)
- The Service should consider collecting seeds to include this species in the Center for Plant Conservation collection. Seeds should also be tested for viability and longevity. (USFWS, 2010)
- Nearly 40 percent of the mapped *Schoenocrambe suffrutescens* populations occur on non-Federal lands. We should continue to work with the Uintah and Ouray Indian Reservation, SITLA, and private landowners to survey and conserve *S. suffrutescens* habitat and increase outreach efforts. (USFWS, 2010)
- On Federal lands, the Service should continue to avoid development in *Schoenocrambe suffrutescens* populations and suitable, unoccupied habitat as much as possible, unless research becomes available to indicate that *S. suffrutescens* is unaffected by development. The Service should ensure that developers follow established conservation measures when disturbance occurs and that habitat fragmentation is reduced as much as possible. (USFWS, 2010)

- Using research collected on soil characteristics and response to disturbance, the Service should identify and establish core conservation areas in minimally-disturbed habitat (both occupied and unoccupied) for long-term protection of *S. suffrutescens*. (USFWS, 2010)
- Once the Service has new survey data and research data available, the Service recommends revising the Recovery Plan to explicitly address the relevant listing factors. Time and cost required to meet the criteria and recover the species should be included in the Recovery Plan. (USFWS, 2010)
- The Service will continue to monitor the acceptance of *Hesperidanthus* as the correct genus for this species and will officially change this species' name through an FR notice as needed. (USFWS, 2010)

SPECIES ACCOUNT: *Schoepfia arenaria* (No common name)

Species Taxonomic and Listing Information

Listing Status: Threatened; Southeast Region (Region 4) (USFWS, 2015) 4/19/1991

Physical Description

An evergreen shrub or small tree up to 20 feet or 6 meters (in) tall and with several trunks from the base reaching 4 inches or 10 centimeters (cm) in diameter. The leaves are simple, alternate, without stipules, with petioles one—eighth of an inch or 4 millimeters (mm) long; the upper surface is green and slightly shiny, and the lower surface is light green. *Schoepfia arenaria* has been observed with flowers mainly in spring and fall, and with fruits in summer and winter. Usually two or three light yellow tubular—shaped flowers are borne on the end of the stalk at the leaf bases. The fruit is elliptic, one-seeded, shiny red, and one—half inch or 12 millimeters (mm) in diameter. The wood is light brown and hard (USFWS, 1991).

Historical Range

At the time the recovery plan was signed (1992), less than 200 individuals of *S. arenaria* were known within five areas: (A) Municipality of Isabela - approximately 100 individuals of all size classes; (B) Río Abajo Commonwealth Forest (RACF) - one individual; (C) Tortuguero Lagoon Natural Reserve (TLNR) - no population estimate; (D) Municipality of Loíza in the area of Punta Maldonado, Piñones - 30 mature plants and numerous saplings and seedlings; and (E) Municipality of Fajardo at El Convento - approximately 50 individuals. (USFWS, 2016).

Current Range

known from four sites in Puerto Rico: Isabela, Pinones, Fajardo, and the Río Abajo Commonwealth Forest. (USFWS, 1991). 2016 location refinements: Less than 200 individuals of *S. arenaria* were known back then from four sites: Isabela, Loíza (Punta Maldonado, Piñones), Fajardo (El Convento), and the Río Abajo Commonwealth Forest. A fifth location is also mentioned in the recovery plan from the Tortuguero Lagoon Natural Reserve. (USFWS, 2016).

Critical Habitat Designated

Yes;

Life History

Food/Nutrient Resources

Breeding Season

Adult: This species has been observed with flowers mainly in spring and fall, and with fruits in summer and winter (USFWS, 1991).

Other Reproductive Information

Adult: Santiago-Valentín and Rojas-Vázquez (2001) recorded leaf, flower and fruit phenology for a period of one year. Their results demonstrate that although flowers and fruits can be found throughout the year, flowering and fruiting is seasonal, with production peaks during the first months of the year (February to May, dry season of Puerto Rico). Production of new leaves occurred continuously during the year. Santiago (2011) collected seeds of *S. arenaria* during the

dry season (March) and he designed an experiment to determine if mechanical scarification of the seed has a difference in the germination time. He reported that the average germination time of scarified seeds is shorter (about 20 days earlier) than non-scarified (control) seeds. Furthermore, he reported that the germination success was significantly higher in scarified seeds than control, 95% and 68%, respectively. Unfortunately, longterm seed storage does not seem to be a viable option for this species, as the seeds that were air-dried and stored over a year showed less than 10 percent germination success (Santiago 2011). Additionally, he found that growth rate of seedlings of this species is very low and suggested that *S. arenaria* is hemiparasitic (seedlings need to establish connections with a host plant to absorb the nutrients and water for survival). The author mentioned that seedlings started to become yellow and their development decreased after a year and a half, and eventually all died. (USFWS, 2016).

Reproduction Narrative

Adult: Little information is currently available concerning the life history and reproductive biology of *Schoepfia arenaria*. This species has been observed with flowers mainly in spring and fall, and with fruits in summer and winter. Usually two or three light yellow tubular-shaped flowers are borne on the end of the stalk in the leaf bases. Many seedlings have been observed under mature trees, and plants of all size classes have been observed. Pollinization mechanisms, seed production and dispersal, seed viability and germination requirements, and seedling establishment and growth should be studied. Other species in this genus are considered as hemiparasitic, due to their root interconnections with other woody species (hosts) nearby, from which they obtain soil minerals (Quevedo, pers. comm.). Future research should document interspecific relations with other native taxa in order to determine whether or not *Schoepfia arenaria* is also a hemiparasite (USFWS, 1991).

Habitat Type

Adult: Evergreen and semi-evergreen forest (USFWS, 1991)

Spatial Arrangements of the Population

Adult: Clumped (inferred from USFWS, 1991)

Tolerance Ranges/Thresholds

Adult: Low (inferred from USFWS, 1991)

Site Fidelity

Adult: High (inferred from USFWS, 1991)

Habitat Narrative

Adult: *Schoepfia arenaria*, an evergreen shrub or small tree, occurs in low elevation evergreen and semi—evergreen forests of the limestone hills of northern Puerto Rico. Deforestation and limestone hill destruction for industrial, urban, and tourist expansion have restricted this species to its present locations. It is threatened by development projects in Isabela, and by illegal land acquisition in Pinones (USFWS, 1991). Low tolerance range, high site fidelity and ecological integrity of the community are inferred based on specific habitat needs and relatively low number of populations and individuals. Clumped spatial arrangement is also inferred based on habitat needs and distribution of known populations.

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Dispersal and migration has not yet been assessed (USFWS, 1992).

Population Information and Trends**Resiliency:**

Low (inferred from USFWS, 1991)

Representation:

Low (inferred from USFWS, 1991)

Redundancy:

Low (inferred from USFWS, 1991)

Number of Populations:

Four (USFWS, 1991)

Population Size:

~190 total individuals (USFWS, 1991)

Population Narrative:

As of 1991 there were four known populations totaling approximately 190 individuals.

Threats and Stressors

Stressor: Deforestation (USFWS, 1991)

Exposure:

Response:

Consequence:

Narrative: The species has become threatened as a result of deforestation in the coastal forests and limestone hills for urban, industrial, and tourist expansion in northern Puerto Rico (USFWS, 1991).

Stressor: Agriculture (USFWS, 1991)

Exposure:

Response:

Consequence:

Narrative: Among the factors which have historically limited the distribution of *Schoepfia arenaria* include deforestation and limestone hills destruction for agriculture, grazing, and more recently for urban, industrial and tourist developments, and associated roads and service facilities (USFWS, 1991).

Stressor: Grazing (USFWS, 1991)

Exposure:

Response:

Consequence:

Narrative: Among the factors which have historically limited the distribution of *Schoepfia arenaria* include deforestation and limestone hills destruction for agriculture, grazing, and more recently for urban, industrial and tourist developments, and associated roads and service facilities (USFWS, 1991).

Stressor: Urban, industrial and tourist development (USFWS, 1991)

Exposure:

Response:

Consequence:

Narrative: Among the factors which have historically limited the distribution of *Schoepfia arenaria* include deforestation and limestone hills destruction for agriculture, grazing, and more recently for urban, industrial and tourist developments, and associated roads and service facilities (USFWS, 1991).

Recovery

Delisting Criteria:

Delisting of *Schoepfia arenaria* will be considered when the privately-owned population sites are given protected status, and at least two self-sustaining populations in Commonwealth Forest units or other protected lands have been established (USFWS, 1991).

Recovery Actions:

- Monitor and protect existing populations to prevent further habitat loss and population decline. The known populations and habitat should be monitored and protected by both public agencies and private conservation organizations in order that the decline of individuals does not continue and that the complete extinction of the species does not occur. It is essential as well to maintain a source of material for propagation (USFWS, 1991).
- Continue to gather information on the distribution and abundance of *Schoepfia arenaria*. Additional information concerning the distribution and abundance of the species will affect future management decisions and the establishment of recovery priorities (USFWS, 1991).
- Research. Basic biological information is currently needed on *Schoepfia arenaria*. Studies should focus on aspects of life history, methods of propagation, and evaluation of possible introduction sites. These studies may be critical in the recovery of the species (USFWS, 1991).
- Refine recovery goals. As additional information on the biology, ecology, propagation, and management of *Schoepfia arenaria* is gathered, it will be necessary to better define, and possibly modify, recovery goals (USFWS, 1991).
- 2016 recommended actions - 1: Conduct comprehensive surveys to determine status of the species. (USFWS, 2016).
- 2016 - 2: Develop appropriate propagation techniques to enhance existing populations and to establish new ones. (USFWS, 2016).
- 2016 - 3: Conduct studies on the pollination and seed dispersal strategies in order to assess if any of these are limiting population growth and expansion. (USFWS, 2016).
- 2016 - 4: Efforts should continue to protect populations in privately-owned lands by reducing habitat deterioration and promoting sustainable land use practices. (USFWS, 2016).

- 2016 - 5: Continue working and foster partnership with regulatory agencies to address and minimize potential adverse effects of development projects on the species and its habitat. (USFWS, 2016).
- 2016 - 6: Monitor known populations to determine its long-term status. (USFWS, 2016).
- 2016 - 7: Model potential suitable habitat using GIS tools to search for possible reintroduction sites and other potential populations that may exist. (USFWS, 2016).
- 2016 - 8: Conduct studies to determine intra and inter-population genetic diversity. (USFWS, 2016).

SPECIES ACCOUNT: *Schwalbea americana* (American chaffseed)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/29/1992; Southeast Region (Region 4)

Physical Description

Schwalbea is an erect herb with unbranched stems or stems branched only at the base, growing to a height of 3.0 to 6.0 dm (12 to 24 in). The plant is densely albeit minutely hairy throughout, including the flowers. The leaves are alternate, lance-shaped to elliptic, stalkless, 2.5 to 5.0 cm (0.8 to 2 in) long, and entire; the upper leaves are reduced to narrow bracts. The large, purplish-yellow, tubular flowers, 3.0 to 3.5 cm long (1.2 to 1.4 in) are borne singly on short stalks in the axils of the uppermost, reduced leaves (bracts) and form a many flowered, spike-like raceme. The showy flowers have a high degree of bilateral symmetry elaborated for pollination by bees (Pennell 1935). The fruit is a narrow capsule approximately 10 to 12 mm (0.4 to 0.5 in) long, with a septical dehiscence. The numerous seeds are pale greenish brown or yellowish-tan, narrowly linear, somewhat flattened or compressed, slightly curved, and enclosed in a loose-fitting, sac-like structure that provides the basis for the common name, chaffseed (Musselman and Mann 1978). Flowering occurs from April to June in the southern part of the species' range, and from June to mid-July in the northern part of its range. Fruits mature from early summer in the South to October in the North (Johnson 1988). (USFWS, 1995)

Taxonomy

Pennell (1935) recognized a northern and southern species of Schwalbea, *Schwalbea americana* L. and *Schwalbea australis* Pennell, respectively. He distinguished *Schwalbea americana* by mostly recurved hairs and leaves up to 1.0 cm (0.4 in) wide or less, and *Schwalbea australis* by a pubescence of mostly upcurved hairs and leaves up to 1.5 cm (0.6 in) wide. *Schwalbea americana* was known from Massachusetts southward to Virginia, and *Schwalbea australis* was known from North Carolina to Kentucky and southward to Florida and Louisiana. Fernald (1937) found characters of the leaves and calyx lobes to vary over the total range so that recognition of two species was unwarranted. Following an examination of herbarium material, Musselman and Mann (1977) concurred that there was little taxonomic merit in recognizing more than a single species. Therefore, the U.S. Fish and Wildlife Service accepts the more recent treatments of Fernald (1937) and Musselman and Mann (1977), which recognize *Schwalbea americana* and *Schwalbea australis* as one species, *Schwalbea americana*. In this plan, *Schwalbea americana* will be henceforth referred to as the monotypic genus *Schwalbea*. (USFWS, 1995)

Historical Range

Historically known from Massachusetts and New York south along the East Coast to Florida and west along the Gulf Coast states to Texas. (NatureServe, 2015)

Current Range

Currently found in the following states: Massachusetts, New Jersey, North Carolina, South Carolina, Georgia, Alabama, Florida, and Louisiana. (USFWS, 2019a)

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Asexual and sexual (outcrossing) (NatureServe, 2015)

Dependency on Other Individuals or Species

Adult: Schwalbea produces showy, insect-pollinated flowers with a high degree of zygomorphy elaborated for pollination by bees (Pennell 1935). (USFWS, 1995)

Breeding Season

Adult: April to June (USFWS, 1995)

Other Reproductive Information

Adult: The germination rates of collected Schwulbea seeds are high. Kirkman (1993) reported that the germination rate of seeds placed in petri dishes, with and without cold stratification, was approximately 90 percent. (USFWS, 1995)

Reproduction Narrative

Adult: This species produces showy, insect-pollinated flowers; the high degree of zygomorphy elaborated for pollination by bees (Pennell 1935). Reproduction primarily occurs via outcrossing (sexual) but can also reproduce asexually. Flowers bloom between April and June. (USFWS, 1995; NatureServe, 2015)

Habitat Type

Adult: Palustrine and terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Bog/fen, forest/woodland, savanna, woodland - mixed (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Sunny open areas (NatureServe, 2015)

Environmental Specificity

Adult: Sunny areas (NatureServe, 2015)

Dependency on Other Individuals or Species for Habitat

Adult: The root parasitic behavior of Schwalbea has been known since 1856 (Musselman and Mann 1977). Schwalbea is considered the rarest root parasitic plant in the South, and, like most parasitic Scrophulariaceae, it is not host-specific. (USFWS, 1995)

Habitat Narrative

Adult: Characteristically, Schwalbea occurs in sandy (sandy peat, sandy loam), acidic, seasonally moist to dry soils. The species is generally found in habitats described as pine flatwoods, fire-maintained savannas, ecotonal areas between peaty wetlands and xeric sandy soils, and other open grass-sedge systems (Kral 1983). Schwalbea appears to be shade intolerant and, therefore, occurs in areas maintained in an open to partially open condition. In Georgia, Schwalbea occurs in

ecotonal areas between freshwater wetlands and upland pine forests. In North Carolina, the species occurs in moist to dryish pine flatwoods, longleaf pine/wiregrass savannas, and on longleaf pine/oak sandhills composed of Upper Cretaceous deep, white sands, at the western edge of the coastal plain. In South Carolina, the predominant habitat is described as fire-maintained (or mowed, as under power lines), dry, well-drained, longleaf pine flatwoods. The soil is generally a sandy loam. In New Jersey, *Schwalbea* occurs in open areas that have been maintained by mowing within a pitch pine community. The site is next to a roadcut through a cedar swamp. (USFWS, 1995)

Dispersal/Migration

Dispersal/Migration Narrative

Adult: The structure of the *Schwalbea* seed, somewhat flattened or compressed, slightly curved, and enclosed in a loose-fitting sac-like structure, suggests wind dispersal; however, no information is available to support this hypothesis. Information is lacking on both the mechanism and distance of seed dispersal. (USFWS, 1995)

Population Information and Trends

Population Trends:

Long-term trends indicate population declines from 50 to 90%, whereas short-term trends suggest declines of 10 to 30% (NatureServe, 2015)

Species Trends:

Declining (NatureServe, 2015)

Number of Populations:

43 (USFWS, 2019a)

Population Size:

2500 - 10,000 individuals (NatureServe, 2015)

Adaptability:

Moderate (NatureServe, 2015)

Population Narrative:

When *Schwalbea* was listed as an endangered species in 1992, 19 extant occurrences were known from the following States: New Jersey (1), North Carolina (1), South Carolina (11), Georgia (4), Florida (1), and Mississippi (1). At the completion of the recovery plan in 1995, extensive searches for this species that occurred in the Southeast, namely North and South Carolina, increased the number of extant occurrences to 72: New Jersey Pleasantville, New Jersey (1), North Carolina (18), South Carolina (42), Georgia (10), and Florida (1). The last comprehensive review of this species status occurred in 2008. At that time, 53 occurrences were extant (30% of sites extant) in 2008: New Jersey (2), North Carolina (11), South Carolina (33), Georgia (4), Alabama (1), Florida (1), and Louisiana (1). It is important to note that in the 1995 recovery plan and 2008 5-year review, the terms population and occurrence were used interchangeably. Since some *Schwalbea* populations have multiple element occurrences or sites per population, the number of populations across the species range was over-reported in some

cases. In order to standardize population numbers across state boundaries, NatureServe's (2018) population delimitation guidelines were used for all extant populations across Schwalbeas' range in this five-year review. Historic and unknown occurrences were not delimited. Currently, there are 43 extant populations across the species range: Massachusetts (1), New Jersey (2), North Carolina (6), South Carolina (18), Georgia (9), Alabama (2), Florida (3), and Louisiana (2). (USFWS, 2019a)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2019a)

Exposure:

Response:

Consequence:

Narrative: Habitat destruction and adverse modification of suitable habitat for Schwalbea continue to be major threats for this species. Development along the coast continues to threaten Schwalbea by (1) direct loss of habitat and (2) indirect threats due to urbanization resulting in fire suppression from either local air pollution regulations or safety concerns. Fire suppression continues to threaten this species on both private and public lands. Conversion of longleaf flatwoods and savannas to commercial pine plantations and agriculture fields continue to threaten this species. Although new Schwalbea populations are being discovered, the number of extant populations declined by approximately 25% since the last 2008-five year review. (USFWS, 2019a)

Stressor: Herbivory (USFWS, 2019a)

Exposure:

Response:

Consequence:

Narrative: Herbivory continues to serve as a minor threat to the species, herbivores include the striped leaf beetle (*Kuschelina* sp.), Chrysomelid leaf beetle sp., and Buckeye caterpillar (*Junonia coenia*) larvae (M. Jenkins, Florida Department of Agriculture and Consumer Resources, pers. comm. 2017; Bob Dellinger, U.S. Forest Service, pers. comm. 2017). The Lethcoe, FMNF population suffered from herbivory when fresh new growth sprouted following a prescribed fire. (USFWS, 2019a)

Stressor: Small population size (USFWS, 2019a)

Exposure:

Response:

Consequence:

Narrative: Small population size was noted as a threat in the last 2008 five-year review and remains a threat today. Populations that appear stable throughout time contain at least 100 individuals. Currently, 20 populations contain 100 or more individuals. Small populations are highly vulnerable to extirpation, especially in the absence of prescribed fire. Small populations may be less resilient to environmental changes related to climate change. (USFWS, 2019a)

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2019a)

Exposure:

Response:

Consequence:

Narrative: Because the Act only grants protection to plants when a Federal nexus is involved (e.g., federal permit required, federally funded projects), existing regulatory mechanisms are inadequate to protect Schwalbea. Schwalbea receives protection from state rare plant protection laws in Massachusetts, New Jersey, North Carolina, South Carolina, Georgia, and Florida. (USFWS, 2019a)

Stressor: Drought (USFWS, 2019a)

Exposure:

Response:

Consequence:

Narrative: Since Schwalbea is mostly (can occur outside of ecotone areas in longleaf flatwoods) an ecotone species occurring in transitional areas between uplands and freshwater wetlands, an increase in drought frequency and decrease in precipitation events could threaten smaller, less resilient populations. (USFWS, 2019a)

Recovery

Reclassification Criteria:

1. Long-term protection is achieved for 50 geographically distinct, self-sustaining populations. The population sites must be protected from development and other anthropogenic threats that may interfere with the species' survival. Protection of populations on private lands will be evidenced through landowner agreements or conservation easements. Protection of Schwalbea on public lands will be secured through agreements that ensure the long-range protection, management, and monitoring of Schwalbea. Protected sites will be distributed to include, at a minimum, all of the States currently supporting Schwalbea, with at least four populations in the northern portion of the species' range. Site protection agreements will cover the immediate occurrence site and, where possible, enough contiguous unoccupied habitat to allow for dispersal and natural colonization and expansion of the species. (USFWS, 1995)
2. Management agreements or plans are developed for the 50 protected occurrence sites with the primary objective of ensuring that an ecosystem capable of supporting viable populations of Schwalbea will be permanently maintained. In the case of private ownership, these management agreements could be part of the conservation easement or landowner agreement. (USFWS, 1995)
3. Viable populations of Schwalbea are established at four sites in the northern portion of the species' range (Massachusetts to Virginia), preferably with genetic material from the only remaining northern population in New Jersey. (USFWS, 1995)
4. Biennial monitoring shows that the 50 protected populations are viable as well as stable or increasing over a 10-year period. Demographic population data will be required to meet this condition. (USFWS, 1995)
5. Life history and ecological requirements are understood sufficiently to reliably predict the effectiveness of protection, management, and monitoring. (USFWS, 1995)

Delisting Criteria:

1. Protection via a conservation mechanism is achieved for 50 geographically distinct, self-sustaining populations (Addresses listing factors A, D, and E). (USFWS, 2019b)
2. Protected populations will be distributed to include all of the states currently supporting Schwalbea, and at least four populations in the northern portion of the species range (Massachusetts to Virginia) (Addresses listing factors A, D, and E). (USFWS, 2019b)
3. The land management plans or agreements for the 50 protected Schwalbea populations must include management objectives that abate threats to Schwalbea such as fire suppression, hog damage, and/or silviculture practices (Addresses listing factors A, D, and E). (USFWS, 2019b)

Recovery Actions:

- Protect extant populations and manage habitat. Identify ownership of all known populations. Establish contact with landowners and negotiate landowner agreements or conservation easements. Ensure that activities and management on public lands are consistent with the protection and management of Schwalbea. Use existing regulatory mechanisms to protect Schwalbea. Conduct additional surveys. (USFWS, 1995)
- Expand the extent of Schwalbea in the northern portion of the current range. The New Jersey occurrence of Schwalbea, which is critical to maintaining the northern range of the species, will receive continued protection. In addition, populations should be established in New Jersey, Delaware, Maryland, New York, Connecticut, and Massachusetts to guard against the extirpation of the species from the northern portion of its range. Data are not currently available that indicate the genetic significance of the remaining northern population; however, Pennell (1935) considered the northern and southern populations of Schwalbea to be distinct species, with the southern species occurring as far north as Virginia (Reveal and Broome 1981). Genetic analyses (Recovery Task 6 below) may further support the significance of maintaining viable populations from the northern gene pool. (USFWS, 1995)
- Investigate best management techniques. Continue experiments to determine the effects of fire. Conduct experiments to determine the effects of other disturbances. (USFWS, 1995)
- Investigate the species' biology. Conduct research to obtain more comprehensive information on life history and population demography. Determine minimum viable population size. (USFWS, 1995)
- Investigate genetic variability. Genetic analyses should be conducted to determine inter and intra-genetic variability of populations. Differences in the genetic composition of populations may influence site protection and reintroduction priorities. Ongoing genetic analyses may be sufficient to determine if significant variability exists. (USFWS, 1995)
- Monitor populations. Meeting the recovery objectives is contingent upon the stabilization of viable populations over time. Consistent monitoring will provide population data necessary to determine if the recovery objectives are being met. (USFWS, 1995)
- Review recovery progress and revise recovery plan as necessary. The overall success of the recovery program should be periodically assessed, and recommendations regarding appropriate changes in recovery objectives or tasks as suggested by research, studies, or monitoring should be implemented. (USFWS, 1995)

Conservation Measures and Best Management Practices:

- Research and determine if in situ recruitment and reintroduction can occur under different levels of soil disturbance and watering regimes. (USFWS, 2019a)
- Continually search for new populations in areas managed for quail and/or red-cockaded woodpeckers or any areas with a 1-2 year fire return interval within the species' historic range. (USFWS, 2019a)
- Survey unknown and historic populations and if present negotiate landowner agreements or conservation easements. (USFWS, 2019a)
- Develop an easy and repeatable Schwalbea survey form and methodology for range-wide use in order to track/monitor recovery populations annually. (USFWS, 2019a)
- Research the germination ecology of Schwalbea in regards to moisture and light requirements and seedling recruitment / host attachment to understand Schwalbea's regeneration strategy. (USFWS, 2019a)
- Research fire seasonality effects, especially early April and late July/August fires, in conjunction with rainfall patterns/climatic fluctuations. (USFWS, 2019a)
- Continue population reintroductions within the historic range and introductions into protected areas with 1-3 year fire return intervals. (USFWS, 2019a)
- Expand the extent of Schwalbea in the northern portion of the current range. (USFWS, 2019a)

SPECIES ACCOUNT: *Sclerocactus brevihamatus* ssp. *tobuschii* (Tobusch fishhook cactus)

Species Taxonomic and Listing Information

Commonly-used Acronym: SCLTOB

Listing Status: Endangered; 12/08/1979; Southwest Region (Region 2)

Physical Description

A cactus armed with fishhook-shaped spines. The hemispheric or short-columnar stems of mature plants are 3 to 10 centimeters (cm) (1.2 to 3.9 inches (in)) tall and 1 to 10 cm (0.4 to 3.9 in) in diameter; however, although the largest recorded individuals are as much as 10 cm (3.9 in) in diameter, few wild plants are greater than 5 cm (2.0 in) in diameter (Poole and Janssen 2002, p. 7). The stems are supported on short, conical taproots from which emerge numerous fibrous roots that typically grow horizontally along the surfaces and fissures of rock strata. The stems bear tubercles (podaria) up to 12 millimeters (mm) (0.5 in) long that have a groove (sulca) along their upper surfaces. The tubercles are arranged in 5 to 8 ribs (Marshall 1952, p. 79), or from 8 to 12 ribs (Poole et al. 2007, p.442). However, we note that the tubercles within each rib are nearly distinct from each other; the ribs, which may spiral, are difficult to discern, especially in smaller individuals, and the tubercles appear to alternate. Spines arise from areoles at the apex of each tubercle. The spines are of two types: Radial spines are fine, straight, from 1 to 2 cm (0.4 to 0.8 in) long, spreading at right angles to the tubercle from the edges of the areoles. From 3 to 5 thicker, flattened central spines, 2 to 4 cm (0.8 to 1.6 in) in length, arise from nearer the center of the areoles and project more or less outward from the stem; one of the central spines is abruptly recurved, and may reach 180° of curvature in older individuals. Spines are yellowish at first, and may have reddish tips, turning gray with age. Flowers emerge from the bases of young tubercles near the stem apex, and have numerous yellow tepals. Fruits are spineless, elongate, from 2.5 to 3 cm (1 to 1.2 in) long, turning reddish-green and usually splitting open along 1 or more lines when mature. (USFWS, 2017)

Taxonomy

The genus *Ancistrocactus*, which means "fishhook", contains four species, three occurring in the region of the Rio Grande River in southern Texas and adjacent Mexico, and one occurring farther south (Benson, 1982). According to Benson (1982) this genus is mostly closely related to *Coryphantha* and *Neolloydia*, all three genera being in the vast complex group of plants intermediate between *Mammillaria* and *Echinocactus*. Systematics of the Cactaceae has always been controversial. No single treatment is universally accepted, and the steady accumulation of phylogenetic analyses has forced continual revisions. In particular, there is no consensus among cactus authorities regarding the taxa pertaining to the related genera of *Ancistrocactus*, *Sclerocactus*, and *Ferocactus*. The following sources provide a brief review of the prevailing classifications. A number of synonyms have been applied to this taxon, including *Ancistrocactus tobuschii* (W.T. Marshall) W.T. Marshall ex Backeb, *Echinocactus tobuschii* (W.T. Marshall) Weniger and *Ferocactus tobuschii* (W.T. Marshall) N.P. Taylor. (USFWS, 1987; USFWS, 2010). An extensive discussion of the taxonomy is provided in the Species Status Assessment of 2017 (USFWS, 2017).

Historical Range

Endemic to the Edwards Plateau of Texas. (USFWS, 2017)

Current Range

In the following central counties in Texas: Bandera, Edwards, Kerr, Kimble, Kinney, Real, Uvalde, and Val Verde. (USFWS, 2017)

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Sexual (USFWS, 2017)

Lifespan

Adult: >10 years (USFWS, 2017)

Dependency on Other Individuals or Species

Adult: Pollinators; most common were several species of halictid bees (USFWS, 2017)

Breeding Season

Adult: Late January to mid-March (USFWS, 2017)

Other Reproductive Information

Adult: Tobusch fishhook cactus plants begin reproducing when they have grown to a diameter of about 2 cm (occasionally less); this is estimated to require 9 years of growth in the wild. Flowering occurs between late January and mid-March, depending on locality, and lasts a few weeks in each population. Honey bees and halictid bees are effective pollinators, although the latter group may be more active later in the flowering season. The breeding system is primarily by outcrossing, although self-fertilization occurs rarely. Fruits ripen around mid-May. (USFWS, 2017)

Reproduction Narrative

Adult: Tobusch fishhook cactus grows slowly, reaching a reproductive size of about 2 centimeters (0.8 inches) in diameter after 9 years. It flowers between late January and mid-March, and its major pollinators are honey bees and halictid bees. The breeding system is primarily out-crossing, but the species is capable of self-fertilization. Reproductive individuals produce an average of 112 seeds per year. Ants may be seed predators, dispersers, or both. Mammals or birds may also accomplish longer-distance seed dispersal. We have little evidence of a persistent soil seed bank. (USFWS, 2017)

Habitat Type

Adult: Terrestrial (USFWS, 2017)

Habitat Vegetation or Surface Water Classification

Adult: Shortgrass grasslands, oak-juniper woodlands, semi-desert shrublands (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Full sunlight (USFWS, 2017)

Spatial Arrangements of the Population

Adult: Discontinuous patches (USFWS, 2018)

Environmental Specificity

Adult: Moderate, with some key requirements (USFWS, 2017)

Habitat Narrative

Adult: The riparian habitats described in the original status report are atypical. The great majority of documented populations occur in upland sites dominated by Ashe juniper-live oak woodlands and savannas on outcrops of early Cretaceous limestone. Soils are classified in the Tarrant, Ector, Eckrant, and similar series. Within a matrix of woodland and savanna, the species occurs in discontinuous patches of very shallow, gravelly soils where bare limestone rock and rock fragments comprise a large proportion of the surface cover. Associated vegetation includes small bunch grasses and forbs. The species' distribution within habitat patches is clumped and tends to be further from woody plant cover. The presence of spikemosses (*Selaginella* spp.), and perhaps other cryptogams, may be useful indicators of fine-scale habitat suitability. Wildfire (including prescribed burning) causes negligible damage to Tobusch fishhook cactus populations. The species probably does not require fire for germination, establishment, or reproduction, but periodic burning may be necessary to prevent the encroachment of woody plants into its habitats. (USFWS, 2017)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Ants remove a large proportion of seeds, pulp, and funiculi, but whether the ants consume the seeds, or effectively disperse them, is not known. Mammals or birds also consume fruits and may accomplish longer-distance seed dispersal. Moderate numbers of viable seeds have been found in the soil near live plants, but the extent and longevity of soil seed banks is unknown. (USFWS, 2017)

Population Information and Trends**Population Trends:**

Increasing (USFWS, 2017)

Resiliency:

It is likely that Tobusch fishhook cactus has multiple, resilient populations (USFWS, 2017)

Representation:

Tobusch fishhook cactus currently possesses sufficient genetic diversity to conserve long-term adaptive capability. However, habitat fragmentation and disruption of gene flow among populations may have occurred too recently to be detected through genetic analyses.

Considering the naturally low densities of Tobusch fishhook cactus populations, gene flow among them may be easily disrupted. (USFWS, 2017)

Redundancy:

It is likely that Tobusch fishhook cactus has multiple, resilient populations (USFWS, 2017)

Number of Populations:

511 sites (USFWS, 2017)

Population Size:

Globally about 480,000 individuals (USFWS, 2017)

Population Narrative:

The TXNDD (2016) lists 97 EOs, totaling 3,336 individuals in 8 counties of the Edwards Plateau of Texas. • From 2009 to 2016 we received additional sources of population data, primarily from surveys conducted for development projects. • A total of 118 permanent plots at 12 protected natural areas have been monitored from 1991 through 2013. Plot data reveals that mortality is often very high, and consistently exceeds recruitment; however, the known population sizes have steadily increased, due to the discovery of previously undetected individuals and colonies. • The probability of detecting live Tobusch fishhook cactus individuals during a single survey is highly variable; Reemts (2014) calculated an overall detection rate of 50 percent. The inability to detect all living members of a population confounds determinations of population size and demographic trends. • Demographic population viability analyses of monitored populations, using integral projection models, predicted stable or increasing trends for 2 or 3 populations, moderate declines for 2 populations, and large to precipitous declines in 5 populations over the next 50 years. When expected climate changes were included in the analyses, 4 populations responded negatively to climate changes and 6 populations responded positively (compared to PVA without climate changes). We estimate that the global population size for Tobusch fishhook cactus is about 473,000 individuals distributed over an area of over 2 million ha (5 million ac). (USFWS, 2017)

Threats and Stressors

Stressor: Land Use Changes (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Relatively little urban and industrial development is occurring within the semi-arid, sparsely populated eight-county known range of Tobusch fishhook cactus. However, a significant ongoing trend throughout the species' range is the subdivision of large ranches into many small "ranchettes," leading to a proliferation of roads, fences, power lines, and residential development, all of which contribute incrementally to habitat loss and fragmentation. Land subdivision also engenders changes in land use and management which may be both beneficial and detrimental to Tobusch fishhook cactus. For example, the predominant, historic land use throughout the Edwards Plateau has been grazing of livestock, including goats, cattle, sheep, and horses. In many cases, poor rangeland management during the last century has caused the depletion of herbaceous vegetation, cessation of the natural wildfire cycle, proliferation of dense juniper stands, soil erosion, and reduced infiltration and storage of rainwater in the soil profile;

all of these changes are likely to have harmed Tobusch fishhook cactus populations. The change to a primarily recreational land use often entails continued grazing, in order to obtain agricultural tax exemptions, but at a sustainable stocking density (landowners may subsequently convert an agricultural exemption to a wildlife exemption). Currently, both large and small landowners are more aware of and concerned with conservation issues than during the last century. Prescribed burning may be one of the most important vegetation management tools for sustaining Tobusch fishhook cactus populations; the proliferation of residential development within the species' habitat makes this tool more challenging for natural resource managers to use. The subdivision of privately-owned land and associated threats are likely to continue. (USFWS, 2017)

Stressor: Changes in vegetation and wildfire frequency. (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Bray (1904, pp. 14–15, 23–24) documented the rapid transition of grasslands to woodlands in the Edwards Plateau occurring more than a century ago; he attributed this change to over-grazing, the depletion of grasses, and the cessation of wildfires. Fonteyn et al. (1988, p. 79) state that savannas covered portions of the pre-settlement Edwards Plateau, and since 1850 were transformed to shrubland or woodland “primarily by suppression of recurring natural and anthropogenic fires and the introduction of livestock.” They list the fire-sensitive Ashe Juniper as the most successful of many woody plants that have invaded grasslands. Reemts (2014 p. 1). lists the encroachment of woody plants into the rocky, open habitat as one of several habitat-related threats to Tobusch fishhook cactus. However, the historic extent of grasslands in the Edwards Plateau is an area of active scientific debate. It is likely that woodlands were most abundant on slopes in the Balcones Escarpment (which includes the southern and eastern portion of the Tobusch fishhook cactus range) and that grasslands were more abundant on flatter, deeper soils in the western Edwards Plateau (Diamond et al. 1995, pp. 191-193; Diamond and True 2008, pp. 53-54; Murray et al. 2013, pp. 298, 302). (USFWS, 2017)

Stressor: Livestock grazing. (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: The recovery plan stated “Ancistrocactus tobuschii plants have been observed that were either uprooted or had apical meristem injuries from livestock trampling.” Nevertheless, livestock trampling and herbivory have not subsequently been identified as significant causes of mortality or damage to Tobusch fishhook cactus plants. The recurved spines and small size probably discourage herbivory of Tobusch fishhook cactus plants. Livestock are not attracted to the sparsely vegetated outcrops where Tobusch fishhook cactus plants typically occur, and the plants are protected to some degree by surrounding rocks. While livestock trampling probably occurs in grazed habitats, particular where animals are concentrated, we have no evidence that it represents a significant threat to the species. A number of healthy Tobusch fishhook cactus populations occur on well-managed rangeland. We conclude that livestock grazing, especially where juniper thinning and prescribed burning are used to manage rangeland, is generally compatible with conservation of this cactus. (USFWS, 2017)

Stressor: Illicit collection. (USFWS, 2017)

Exposure:

Response:**Consequence:**

Narrative: Many rare cactus populations have been depleted by overzealous collectors. The recovery plan lists collection by unscrupulous cactus and succulent fanciers as a threat to the species. Westlund (1991, pp. 2, 35, 39) found six specimens of Tobusch fishhook cactus, grown legally from seed, for sale in commercial nurseries. Poole and Janssen (2002, p.9) noted that one population of Tobusch fishhook cactus was heavily depleted by collection, but concluded that “collection is not currently perceived to be a grave threat.” Although illicit collection has not significantly impacted the species, the wild populations openly accessed by the public remain vulnerable. The potential threat of illicit collection might be diminished if seeds and plants of legally-propagated Tobusch fishhook cactus are easier and less expensive to obtain than wild dug specimens. (USFWS, 2017)

Stressor: Parasites. (USFWS, 2017)

Exposure:**Response:****Consequence:**

Narrative: The Tobusch fishhook cactus weevil (*Gerstaeckeria* sp. nov.) and cactus longhorn beetle (*Moneilema* spp.) parasitize and kill Tobusch fishhook cactus plants and have contributed significantly to drastic declines in many of the known populations (Calvert 2003, all). Considering that the weevil (*Gerstaeckeria* sp. nov.) is a new species, and that it may be an obligate parasite of Tobusch fishhook cactus (Calvert 2003, p. 12), the weevil itself may be no less endangered than its host. Periodic outbreaks of insect parasitism appear to be an unavoidable natural cycle. For this reason, the recovery criterion of 3,000 individuals per population may be unattainable or unsustainable, as such large cactus populations would eventually host very large parasite populations, leading to their collapse. The most appropriate conservation strategy may be to protect larger numbers of small, widely-spaced populations, rather than fewer large populations that are more vulnerable to parasites; however, we do not currently know what the optimal parameters of size and spacing should be. (USFWS, 2017)

Stressor: Other herbivory. (USFWS, 2017)

Exposure:**Response:****Consequence:**

Narrative: Poole and Birnbaum (2003, pp. 11-12) report that jackrabbits browse the cactus, but in most sites cause less than 2 percent mortality. If the root systems are not too badly damaged, they may regenerate one or more new stems. Feral hogs have uprooted plants in many sites (also observed by Reemts (2015, p. 1)). An unidentified ant species has also caused 1 percent mortality at some sites by creating mounds on top of the stems. Federally-listed plants occurring on private lands have limited protection under the ESA, unless also protected by State laws; the State of Texas also provides very little protection to listed plant species on private lands. Approximately 95 percent of Texas land area is privately-owned. It is reasonable to assume that the vast majority of existing Tobusch fishhook cactus habitat, including sites that have not been documented, occurs on private land. Therefore, most of the species' populations and habitats are not subject to Federal or State protection unless there is a Federal nexus, such as provisions of the Clean Water Act or a federally-funded project. The ESA does provide some protection for listed plants on land under Federal jurisdiction. However, Tobusch fishhook cactus populations have not been documented on Federal land. International trade of Tobusch fishhook cactus (as

Sclerocactus brevihamatus ssp. *tobuschii*) is regulated under CITES Appendix I (Convention on International Trade in Endangered Species of Wild Fauna and Flora 2009). (USFWS, 2017)

Stressor: Demographic consequences of small population size and density. (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Poole and Birnbaum (2003, p. 1) estimated an MVP of 1,200 individuals (Section II.7.5). Small populations are less able to recover from losses caused by random environmental changes (Shaffer and Stein 2000, pp. 308-310), such as fluctuations in recruitment (demographic stochasticity), variations in rainfall (environmental stochasticity), or changes in the frequency of wildfires. Tobusch fishhook cactus has a predominantly out-crossing breeding system. The probability of successful fertilization between unrelated individuals is reduced in small, isolated populations. The remaining plants would produce fewer viable seeds, further reducing population recruitment and engendering a downward spiral toward extirpation. The demographic consequences of small population size are compounded by genetic consequences (discussed below), since reduced out-crossing corresponds to increased inbreeding. In addition to population size, it is likely that population density also influences population viability; density must be high enough for gene flow within metapopulations, but low enough to minimize parasite infestations. (USFWS, 2017)

Stressor: Genetic consequences of small population sizes. (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Small, reproductively isolated populations are susceptible to the loss of genetic diversity, to genetic drift, and to inbreeding. The loss of genetic diversity may reduce the ability of a species or population to resist pathogens and parasites, to adapt to changing environmental conditions, or to colonize new habitats. Conversely, populations that pass through a “genetic bottleneck” may subsequently benefit through the elimination of harmful alleles. Nevertheless, the net result of loss of the genetic diversity is likely to be a loss of fitness and lower chance of survival of populations and of the subspecies. Genetic drift is a change in the frequencies of alleles in a population over time. Genetic drift can arise from random differences in founder populations and the random loss of rare alleles in small isolated populations. Genetic drift may have a neutral effect on fitness, but is also a cause of the loss of genetic diversity in small populations. Genetic drift may also result in the adaptation of an isolated population to the climates and soils of specific sites, leading to the development of distinct ecotypes and to speciation. For example, the genetic divergence of *Sclerocactus brevihamatus* subspecies *brevihamatus* and *tobuschii* (Section II.2; Rayamajhi 2015, pp. 67, 98) may have resulted when populations of the species *brevihamatus* migrated into separate geographic regions, and once separated, each population adapted to different soils, climate, and pollinator species. Inbreeding depression is the loss of fitness among offspring of closely related individuals. While most animal species are susceptible to inbreeding depression, plant species vary greatly in response to inbreeding. Rayamajhi (2015, pp. 63-64) found relatively high inbreeding coefficients in 3 of 8 populations, which he attributed to mating of close relatives within small, isolated populations. Nevertheless, we do not know to what extent inbreeding has reduced fitness of these populations. (USFWS, 2017)

Stressor: Private land ownership. (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: A large portion of the known individuals and populations of Tobusch fishhook cactus occurs on privately owned land. This does not constitute a threat to the subspecies, and in fact many landowners have demonstrated interest and enthusiasm for its conservation. However, private ownership makes conservation more challenging for several reasons. Access to populations and habitats is subject to the interests of hundreds of individual landowners. Consequently, our knowledge of the subspecies' actual status is far from complete. Establishing and maintaining cooperative relationships with large numbers of private landowners is time-consuming, and these important relationships may lapse when personnel of conservation organizations retire or pursue other career choices. The ownership of private lands changes hands over time, and future owners may choose not to continue conservation efforts that were supported by previous owners. Hence, it is difficult to assure permanent conservation on private lands. These challenges underscore the importance of effective landowner outreach in the conservation of Tobusch fishhook cactus. (USFWS, 2017)

Stressor: Climate change. (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: The Fifth Assessment Report of the Intergovernmental Panel on Climate Change (IPCC) (IPCC 2013, p. 23) projects the following changes by the end of the 21st century, relative to the 1986 to 2005 averages: It is virtually certain that most land areas will experience warmer and/or fewer cold days and nights; it is virtually certain that most land areas will experience warmer and/or more frequent hot days and nights; it is very likely that the frequency and/or duration of warm spells and heat waves will increase in most land areas; it is very likely that the frequency, intensity, and/or amount of heavy precipitation will increase in mid-latitude land masses; it is likely that the intensity and/or duration of droughts will increase on a regional to global scale. We do not know how Tobusch fishhook cactus responded to prior climate changes, nor can we determine how these projected climate changes, forecast by the range of models and emissions scenarios, will affect the synecology of Tobusch fishhook cactus and its habitat. Warmer winters could extend the growing season and improve reproduction and survival of Tobusch fishhook cactus, but might also increase survival of parasite larvae. Heavier, less frequent rainfall could reduce establishment of Tobusch fishhook cactus seedlings, but perhaps less so than the bunch grasses that it competes with. Zaya et al. (2014, pp. 37-38) projected that expected climate changes will be detrimental to 4 populations and beneficial to 6 others. Thus, although it is likely that the projected climate changes will affect the survival of Tobusch fishhook cactus in infinitely complex ways, we do not currently know what the net result of beneficial and detrimental effects will be. (USFWS, 2017)

Recovery

Reclassification Criteria:

No longer applicable due to revision to Threatened status. (USFWS, 2018)

Delisting Criteria:

1. Populations or portions of metapopulations occur within 10 or more protected natural areas. Protected natural areas include lands owned by federal, state, or local government agencies, or by private landowners, that are legally protected for the purpose of conserving native plants and animals and their habitats. Examples include, but are not limited to, state parks, state natural areas, and state wildlife management areas, conservation easements on private lands, lands owned and managed for conservation by non-profit organizations, and legally-binding long-term management agreements with other public agencies or private landowners. To be considered under this criterion, the potential habitats of Tobusch fishhook cactus must be managed in a manner that promotes the continued survival of the subspecies. (USFWS, 2019)
2. The 10 or more protected natural areas described in the previous criterion must conserve the full geographic and ecological range of the subspecies. To meet this criterion, one or more protected natural areas must occur within each of four equal-area quadrants (northeast, northwest, southeast, and southwest) of the subspecies' natural range. (USFWS, 2019)
3. Populations or portions of metapopulations within each protected natural area have 1,200 or more mature individuals. This criterion may be met by combining multiple protected areas that occur within the same metapopulation, as defined above. (USFWS, 2019)
4. Periodic monitoring indicates that the minimum viable population level of 1,200 mature individuals within each protected natural area has remained stable or has increased over a period of 45 years. Monitoring (censuses) of each protected natural area must be conducted at least once every 5 years. The size of large populations may be estimated through statistically valid sampling methods. (USFWS, 2019)

Recovery Actions:

- 1. Remove immediate human threats to *Ancistrocactus tobuschii* by protecting known populations from collecting and habitat destruction. (USFWS, 1987)
- 2. Establish a permanent living collection at a botanical garden or university. Even though plants in a living collection can not substitute for healthy populations in natural habitats, a living collection would still contribute significantly to the overall recovery effort. Much information on ecological requirements and reproductive potential could be obtained most easily from a living collection. In addition, a permanent well documented and accessible living collection, together with appropriate seed banking, could provide an important source of material for non-destructive research, maintenance of wild populations, and public awareness. An adequate living collection would remove the necessity of repeatedly returning to wild populations to collect plants for various recovery projects. (USFWS, 1987)
- 3. Minimize long-range threats to *Ancistrocactus tobuschii* by development of biological information relevant to recovery. A better understanding of the demography of populations and the life history and ecological requirements of the species would provide information useful to management. (USFWS, 1987)
- 4. Establish a long-term (five year) survey program to more precisely determine the true distribution of the species. Surveys for this cactus will be difficult because it is easily overlooked, particularly in the summer and fall when it is hidden by perennial grasses. (USFWS, 1987)
- 5. Develop a comprehensive trade management plan for all cacti. Studies are needed to determine what species are in trade, the overall trend of trade in listed cacti, and the feasibility of reducing collecting pressure on wild populations by promoting a commercial

artificial propagation program. These studies should be national in scope and address all cacti. The results will be used to develop policy and a comprehensive trade management plan for all cacti. Strategies for effective implementation of law enforcement responsibilities under ESA, CITES, Lacey Act, and State laws need to be developed. (USFWS, 1987)

- 6. Develop a program to provide propagated plants and seeds to the commercial market. If information from task 5 indicates that artificial propagation will reduce collecting from the wild, an effort should be made to see that adequate sources of propagated plants are commercially available. This may be particularly helpful for *Ancistrocactus tobuschii* because several of the historic sites are easily accessible and already well known from the literature. (USFWS, 1987)
- 7. Develop public awareness, appreciation, and support for preservation of the species. Public education is extremely important to this species' successful recovery. Landowners usually do not realize that this species exists and most will support protection and conservation efforts if they learn that a unique plant grows on their land. (USFWS, 1987)
- Recommended Future Actions from 2010 5-Year Review: 1. Continue monitoring and surveying the established protected reserves. 2. Conduct surveys of high-potential habitat within the known range of the species, focusing on sites that have not previously been surveyed. 3. Establish new reserves, using the LBJWC conservation fund and other resources. 4. Conduct public outreach efforts to encourage conservation of the species and its habitat on private lands; establish a private landowner support group, similar to the group now actively working to conserve Texas snowbells (*Styrax platanifolius* ssp. *texasus*). 5. Continue to investigate ecology and management, with special emphasis on woody plant control and prescribed burning; compare effects of prescribed burning conducted at different times of the year. 6. Investigate the factors influencing reproduction and dispersal in the wild, with emphasis on the fate of seeds collected by ants. 7. Apply sound management, as needed, to protected sites. 8. Investigate the phylogenetic and taxonomic relationship between *Sclerocactus brevihamatus* ssp. *brevihamatus*, *S. brevihamatus* ssp. *tobuschii*, *S. scheeri*, and other closely related taxa of *Sclerocactus* and/or *Ancistrocactus*. 9. Collect seeds of representative populations for propagation and seed banking, establish germ-plasm (live plant) refugia, and develop techniques for successful propagation and reintroduction. 10. Revise the 1987 recovery plan. (USFWS, 2010)

SPECIES ACCOUNT: *Sclerocactus brevispinus* (Pariette cactus)

Species Taxonomic and Listing Information

Listing Status: Threatened; 09/15/2009; Mountain-Prairie Region (R6) (USFWS, 2016)

Physical Description

Small cactus with very short (2 mm) central hooked or straight spines. (NatureServe, 2015)

Taxonomy

The original listing rule for *S. glaucus* (44 FR 58868, October 11, 1979) included all hookless (straight central spines) *Sclerocactus* populations in western Colorado and northeastern Utah, and referred to them as *S. glaucus* per Benson (1966, pp. 50-57; 1982, pp. 728-729). This taxonomic classification is not supported by the results of more recent research. Genetic studies (Porter et al. 2000), common garden experiments (Hochstätter 1993; Welsh et al. 2003), and a reevaluation of the morphological characteristics of *S. glaucus*, led to separating this species into three distinct species: *S. brevispinus*, *S. glaucus*, and *S. wetlandicus* (Hochstätter 1993; Heil and Porter 2004). We recognized these three distinct species as threatened on September 15, 2009 (74 FR 47112). The Flora of North America recognizes 15 species in the genus *Sclerocactus*, including these 3 species (Heil and Porter 2004). Comparative DNA sequences (Porter et al. 2000) infer common ancestry between *S. brevispinus* and *S. wetlandicus*, but infer *S. glaucus* is more closely related to *S. parviflorus* (Devil's claw cactus) and *S. whipplei* (Whipple's fishhook cactus). The common name for *S. glaucus* was changed to Colorado hookless cactus as the species is endemic to western Colorado. *S. wetlandicus* is now known as the Uinta Basin hookless cactus as this species occurs across Utah's Uinta Basin. *S. brevispinus* is now known as the Pariette cactus as it is limited to the Pariette Draw of the central Uinta Basin. The Uinta Basin hookless cactus complex will be used to refer to the combination of all three species previously listed as a single entity (USFWS, 2010)

Current Range

Known only from a single area a few miles across in the Pariette Draw region of Duchesne County, Utah, U.S.A.

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Predominately insect pollinated (surrogate *S. glaucus* information) (USFWS, 2007)

Breeding Season

Adult: Flowering occurs in April-May, and fruits mature in May-June (surrogate *S. glaucus* information) (NatureServe, 2015).

Reproduction Narrative

Adult: Reproduction is predominantly sexual, although individuals may sprout multiple stems. Flowering occurs in April-May, and fruits mature in May-June. The species appears to be predominantly outcrossing but is marginally self-compatible. Ants and gravity appear to be the primary dispersal mechanisms (Peggy Lyon pers comm. 1998). Seed dispersal may be a limiting factor in the distribution of *Sclerocactus glaucus* (NatureServe, 2015). Information from *S. glaucus* is being used as a surrogate information for *S. wetlandicus* due to the species similarities and based on the following quote 'Because we lack life history data specific to *S. wetlandicus*, we have included life history data for *S. glaucus*, which should correlate to characteristics for *S. wetlandicus*' USFWS, 2010. Believed to be dispersed by heavy down-pours (Tepedino et al. 2010).; ABIOTIC; Water; (NatureServe, 2015). The species' life history is poorly known, but it is thought to be a longlived perennial usually flowering after 3 or 4 years. A broad assemblage of native bees, and possibly other insects including ants and beetles, pollinates *S. brevispinus* (USFWS 1990, p. 7) (USFWS, 2007).

Habitat Type

Adult: Clay badlands (NatureServe, 2015)

Environmental Specificity

Adult: Narrow/specialist (NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: Low (inferred from NatureServe, 2015)

Site Fidelity

Adult: High (inferred from NatureServe, 2015)

Habitat Narrative

Adult: Species is endemic to highly saline and alkaline soils, restricted to clay badlands within a single geologic formation in Utah. Occurs on exposed clay hills and in saltbush and sagebrush flats, 1400-1500 m. (NatureServe, 2015). High ecological integrity of the population and site fidelity as well as low tolerance ranges are inferred based on the species habitat requirements of the species and the relatively small geographic area this species inhabits.

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Unknown

Number of Populations:

1 - 5 (NatureServe, 2015)

Threats and Stressors

Stressor: Oil and Gas Development and Associated Impacts (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: The BLM is monitoring *S. brevispinus* populations and neighboring *Sclerocactus* species, including impacts associated with oil and gas development. Initial results show potential effects of oil and gas development (i.e., roads and well pads) on the survival and reproductive success of *S. brevispinus* (72 FR 53215, September 18, 2007) (USFWS, 2010).

Stressor: Collection (USFWS, 2010)**Exposure:****Response:****Consequence:** Loss of individuals

Narrative: Illegal collection is a significant threat to *S. brevispinus*. The original listing of *S. glaucus* concluded that the cactus is prized among collectors and threatened by unregulated commercial trade (44 FR 58869, October 11, 1979). Collectors prefer larger, reproductive age individuals, leaving behind a younger, less reproductive population. As of 2006, approximately 96 percent of the known range of *S. brevispinus* (at the time, 5,733 ha or 14,166 ac) was within 400 m (1,312 ft) of a well (Service 2006). Such development facilitates human access and discovery by illegal collectors (72 FR 53216, September 18, 2007) (USFWS, 2010).

Stressor: Livestock Grazing and Trampling (USFWS, 2010)**Exposure:****Response:****Consequence:** Loss of individuals

Narrative: Nearly all *S. brevispinus* potential habitat on BLM land is leased for grazing. The species range overlaps four BLM grazing allotments. Most of the area is grazed by sheep, either continuously or on a deferred rotation, with some cattle grazing on the western and eastern edges of *S. brevispinus* potential habitat. Livestock grazing results in *S. brevispinus* mortality when livestock trample individual cacti (Service 1990; Utah Natural Heritage Program 2006; BLM 2008; 72 FR 53215, September 18, 2007). Overgrazing—the continued heavy grazing beyond the recovery capacity of forage plants (Vallentine 1990)—by domestic livestock degrades western ecosystem functions and structures (Fleischner 1994). Overgrazing can facilitate the establishment of invasive species like cheatgrass (Masters and Sheley 2001), which are difficult to eradicate and tend to outcompete native vegetation, including cacti. Invasive weeds (including *Bromus tectorum* and *Halogeton glomeratus*) are prevalent on BLM lands in the range of *S. brevispinus* cactus and less so on tribal lands where grazing has been concentrated in areas outside of suitable cactus habitat (72 FR 53214, September 18, 2007) (USFWS, 2010).

Stressor: Predation (USFWS, 2010)**Exposure:****Response:****Consequence:** Loss of individuals

Narrative: Parasitism by the cactus-borer beetle (*Moneilema semipunctatum*) is a significant but localized source of mortality to all *Sclerocactus* species on the Colorado Plateau, especially in larger, mature, reproducing individuals (Service 1990; 72 FR 53216, September 18, 2007). Parasitism is identified as a threat to *Sclerocactus* plants, however additional studies are needed to determine the long-term, population-level effects of the cactus-borer beetle to *S. brevispinus*. Another source of mortality is lagomorph and rodent browsing. While there have been numerous observations of *Sclerocactus* being removed by desert cottontail rabbits (*Sylvilagus audubonii*) and unknown rodents (CNHP 2010b; BioLogic 2008; Clayton 2006), in subsequent years some of

these plants have re-sprouted (Clayton 2010). Browsing likely goes unnoticed unless a marked individual is revisited within a 1- to 2-year period. We know very little about the magnitude of this threat (USFWS, 2010)

Stressor: Climate Change, Drought, and Impacts to the Vegetative Community (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Climate change is likely to affect long-term survival of native species, including *S. brevispinus*, especially if longer or more frequent droughts occur. For the southwestern region of the United States, warming is occurring more rapidly than elsewhere in the country with an increase of 1.5°F (0.8°C) since 1979 (Karl et al. 2009). Under lower emission scenarios temperature is expected to increase 5°F (2.8°C) and under higher emission scenarios temperature is expected to increase 10°F (5.6°C) by the end of the century, from the 1979 baseline (Karl et al. 2009). Other future projections for the southwest include more intense and longer-lasting heat waves, an increased probability of droughts that are worsened by higher temperatures, heavier downpours, increased flooding, and increased erosion (Karl et al. 2009, pp. 129-134). The levels of aridity of recent drought conditions and perhaps those of the 1950s drought years may become the new climatology for the southwestern United States (Seager et al. 2007). Effects related to climate change (e.g., such as persistent or prolonged drought conditions, changes in community assemblages and the ability of nonnative species to succeed) may affect long-term persistence of *S. brevispinus*. While the potential impacts of climate change could be serious, improved projections are needed to better understand this potential threat. *S. brevispinus* mortality due to drought is well documented (Service 1990; 72 FR 53217, September 18, 2007). Many dead *S. brevispinus* individuals were observed in the Uinta Basin after the severe drought of 1976 to 1977 (Service 1990). In addition, noxious weeds are often able to out-compete native species under drought conditions (Everard et al. 2010). Drought conditions could further hinder BLM's efforts to control noxious weeds and restore native vegetation, which is already difficult due to the extreme environment of the Uinta Basin (Service 1990; BLM 2005, 2008) (USFWS, 2010).

Stressor: Pesticides (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: *S. brevispinus* lives in or near areas that receive herbicide and pesticide treatments to remove undesirable species, such as noxious weeds and insect pests (Service 1990). Individual cacti are likely to be directly affected by these chemicals, and indirectly by effects on pollinators or by movement of contaminated soils (Service 1990). However, specifics of the species' pollination biology are currently unquantified (USFWS, 2010)

Stressor: Vulnerability Related to Population Size and Distribution (USFWS, 2010)

Exposure:

Response:

Consequence: Extinction

Narrative: *S. brevispinus*' small population size and restricted distribution means the species is vulnerable to extinction by natural processes or human disturbance (Ellestrand and Elam 1993; Levin et al. 1996). For example, random events causing population fluctuations or population

extirpations become a serious concern when the number of individuals or the geographic distribution of the species is very limited. Similarly, a single human-caused or natural environmental disturbance could destroy the entire population. The species' slow reproductive rate also increases the risk of effects of stochastic events as it is unlikely that the species will be able to rebound quickly (e.g., exhibit a high rate of population growth), even if environmental conditions improved after such an event. Other issues related to this factor include loss of genetic variability, which may reduce a species ability to respond to changing environmental conditions, (Godt et al. 1996) and inbreeding depression, which can decrease fertility and survival rates (Levin et al. 1996). No information exists to indicate that the species' range and population numbers have been significantly larger than they are currently, except for recent documented losses due to oil and gas development and illegal collection (USFWS, 2010).

Stressor: Inadequacy of Existing Regulatory Mechanisms (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: We are not aware of any city, county or state laws, ordinances or zoning that provide for protection or conservation of the *S. brevispinus* or its habitat. Removal, damage, or destruction of plants on private lands is can be allowed through consultation with the Service. Conservation needs of *S. brevispinus* are addressed through interagency consultation (section 7 requirements) typically between the Service, BLM, and Bureau of Indian Affairs (BIA). Through this process, conservation measures are implemented on a project-by-project basis to minimize the loss of individual cacti from oil and gas activities. These measures include preconstruction cactus surveys and a required buffer around individual cacti. For example, the Castle Peak/Eightmile Flat Oil and Gas Expansion Project Final Environmental Impact Statement included conservation measures to specifically protect *S. brevispinus* and its habitat (BLM 2005). The BLM also has attempted to establish protected areas for *S. brevispinus*. The Pariette Wetlands Area of Critical Environmental Concern (ACEC) was established in 1994. The ACEC, intended to provide protection for this species, contains approximately 1,250 ha (3,086 ac) or 8 percent of the potential habitat of *S. brevispinus*. Management prescriptions for the ACEC state that the BLM will authorize no action in suitable habitat for threatened and endangered species if it would jeopardize the continued existence of the species or result in severe modification of the habitat (BLM 2008). Although the BLM Vernal Field Office Resource Management Plan designated the Pariette Wetlands ACEC as "no surface occupancy" for oil and gas development (BLM 2008), pre-existing lease rights still allow surface disturbance from oil and gas development within the ACEC (BLM 2005). As of November 2009, the ACEC contains one well for approximately every 30 ha (74 ac), with more development planned. The BLM is currently deferring approval of new wells and ancillary facilities located within the Pariette Wetlands ACEC until a master development plan is completed. In addition to the ACEC and project-specific protections such as cactus surveys, we need to establish consistent guidance and Resource Management Plan designations that provide adequate regulatory mechanisms over the longer term to protect large portions of the range of the *S. brevispinus* (USFWS, 2010).

Recovery

Recovery Actions:

- A Recovery Plan has not been published for this species.

SPECIES ACCOUNT: *Sclerocactus glaucus* (Colorado hookless Cactus)

Species Taxonomic and Listing Information

Listing Status: Threatened; 10/11/1979; Mountain-Prairie Region (Region 6) (USFWS, 2016)

Physical Description

A squat, globular, spiny succulent. Each mature stem is 3-12 cm tall, 4-9 cm wide, although during the driest part of the year the stem may shrink to below ground-level. Central spines are straight (hookless). The plants are inconspicuous except when in flower (April-May), when showy, fragrant, pink to magenta flowers appear at the top of the stem. (NatureServe, 2015)

Taxonomy

The original listing rule for *S. glaucus* (44 FR 58868, October 11, 1979) included all hookless (straight central spines) *Sclerocactus* populations in western Colorado and northeastern Utah, and referred to them as *S. glaucus* per Benson (1966, pp. 50-57; 1982, pp. 728-729). Genetic studies (Porter et al. 2000), common garden experiments (Hochstätter 1993; Welsh et al. 2003), and a reevaluation of the morphological characteristics of *S. glaucus* have led to separating this species into three distinct species: *S. brevispinus*, *S. glaucus*, and *S. wetlandicus* (Hochstätter 1993; Heil and Porter 2004). The Flora of North America recognizes 15 species in the genus *Sclerocactus*, including these 3 species (Heil and Porter 2004). Comparative DNA sequences (Porter et al. 2000) infer common ancestry between *S. brevispinus* and *S. wetlandicus*, but infer *S. glaucus* is more closely related to *S. parviflorus* (Devil's claw cactus) and *S. whipplei* (Whipple's fishhook cactus). The common name for *S. glaucus* was changed to Colorado hookless cactus as the species is endemic to western Colorado. *S. wetlandicus* is now known as the Uinta Basin hookless cactus as this species occurs across Utah's Uinta Basin. *S. brevispinus* is now known as the Pariette cactus as it is limited to the Pariette Draw of the Central Uinta Basin. (USFWS, 2010)

Current Range

Colorado hookless cactus is an endemic plant found in Delta, Montrose, Mesa, and Garfield Counties, Colorado. There are two population centers of Colorado hookless cactus: (1) on alluvial river terraces of the Gunnison River from near Delta, Colorado, to southern Mesa County, Colorado; and (2) on alluvial river terraces of the Colorado River and in the Plateau and Roan Creek drainages in the vicinity of DeBeque, Colorado (Service 1990). (USFWS, 2010)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Predominately sexual (outcrossing) but can reproduce asexually (NatureServe, 2015)

Lifespan

Adult: 10-20 years (NatureServe, 2010)

Breeding Season

Adult: April to May (NatureServe, 2015)

Reproduction Narrative

Adult: Reproduction is predominately sexual, although individuals may sprout multiple stems. Flowering occurs in April-May, and fruits mature in May-June. The species appears to be predominantly outcrossing but is marginally self-compatible. Although no long-term demographic data is available, field observations suggest that plants may live for 10-20 years in good conditions (Ellen Mayo, Peggy Lyon pers. comm.) Population size may vary widely between years (Jim Ferguson, pers. comm.). Plants are typically sparsely distributed even in larger populations. Stems may fluctuate in size according to seasonal moisture availability, shrinking below the soil surface in dry times. Predation by a cactus borer beetle has been observed in Colorado populations, and may be very heavy in a localized area. Some herbivory by rodents has also been observed. (NatureServe, 2015)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Desert, forest/woodland, shrubland/chaparral, woodland - conifer (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Occurs at elevations between 1200 and 2000 m (NatureServe, 2015)

Environmental Specificity

Adult: Moderate (inferred from NatureServe, 2015)

Habitat Narrative

Adult: The Colorado hookless cactus is found on exposed, gravel-covered, clay hills, saltbush or sagebrush flats, or pinyon-juniper woodlands at elevations from 1400 to 2000 m (Flora of North America Editorial Committee 2003). Populations occur primarily on alluvial benches along the Colorado and Gunnison Rivers and their tributaries. *Sclerocactus glaucus* generally occurs on gravelly, or rocky surfaces on river terrace deposits and lower mesa slopes. Exposures vary, but *S. glaucus* is more abundant on south-facing slopes. Soils are usually coarse, gravelly river alluvium above the river flood plains usually consisting of Mancos shale with volcanic cobbles and pebbles on the surface. Elevations range from 1200-2000 m. Associated vegetation is typically desert scrub dominated by shadscale (*Atriplex confertifolia*), galleta (*Hilaria jamesii*), black-sage (*Artemisia nova*), and Indian rice grass (*Stipa hymenoides*). Other important species include two similar spherical or cylindrical cactus species, strawberry hedgehog cactus (*Echinocereus triglochidiatus* var. *melanacanthus*) and Simpson's pincushion cactus (*Pediocactus simpsonii*). Other important species in the plant community include the prickly pear cactus (*Opuntia polyacantha*), winterfat (*Krascheninnikovia lanata*), yucca (*Yucca harrimaniae*), snakeweed (*Gutierrezia sarothrae*), low rabbitbrush (*Chrysothamnus viscidiflorus*), sand dropseed (*Sporobolus cryptandrus*), and Salina wildrye (*Elymus salinus*) (USFWS 1990, Scheck 1994). Fire is not typically characteristic of *S. glaucus* habitat, but areas with large infestations of cheatgrass (*Bromus tectorum*) may build up sufficient fuel to carry fire into *S. glaucus* populations. (NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Ants and gravity appear to be the primary dispersal mechanisms (Peggy Lyon pers comm. 1998). Seed dispersal may be a limiting factor in the distribution of *Sclerocactus glaucus*. (NatureServe, 2015)

Population Information and Trends**Population Trends:**

Unknown (NatureServe, 2015)

Resiliency:

Medium (inferred from USFWS, 2010)

Population Growth Rate:

Unknown (NatureServe, 2015)

Number of Populations:

98 (USFWS, 2010)

Population Size:

~19,000 (USFWS, 2010)

Population Narrative:

The species has been documented at 98 element occurrences (EOs) totaling approximately 13,300 individuals (CNHP 2010b). Forty-two of the EOs have not been observed in over 20 years. Over 6,000 additional individuals were located recently in field surveys for a proposed electric transmission line and a proposed oil and gas wastewater evaporation facility north of Delta, Colorado (Bio-Logic 2008; 2009). These newly discovered individuals have not yet been incorporated into the CNHP database. Therefore, by combining the new survey data and the CNHP data, we estimate the total known population of Colorado hookless cactus at over 19,000 plants. (USFWS, 2010)

Threats and Stressors

Stressor: Mineral and energy development (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: The 1990 Recovery Plan identified threats associated with mineral and energy development including: oil and gas, oil shale and tar sands, sand and gravel quarrying, gold dredging, and building stone collecting and quarrying. A gravel mining project proposed near Whitewater, Colorado, poses a threat to several Colorado hookless cactus individuals (BLM 2010). The BLM recently closed an area where recreational gold panners were causing disturbance in close proximity to a Colorado hookless cactus occurrence (BLM 2009b). Oil and gas development remains a meaningful factor in the long-term conservation of the Colorado

hookless cactus. Thirty-six percent of the federally-owned potential habitat approximately 164,000 ac (66,000 ha) is leased for oil and gas development (Service 2010b). Increased surface disturbance from wells, roads and pipelines for oil and gas projects can result in the following impacts to S. and habitat. Oil and gas development fragments and destroys S. habitat (BLM 2005, 2008a). Each well disturbs approximately 1.5 ac (0.6 ha) of surface area (74 FR 47112, September 15, 2009). Increased erosion, soil compaction, and sedimentation can kill cacti (BLM 2005). Cactus seeds can be buried and lost due to erosion runoff from well-field facilities (BLM 2005). Increased surface disturbance increases airborne dust. Dust accumulation on cacti increases tissue temperature and reduces photosynthesis, thus decreasing plant growth, vigor, and water use efficiency (Farmer 1993; Sharifi et al. 1997). Dust effects can extend up to 300 m from roads (Everett 1980). Energy development requires the addition of access roads in previously undeveloped areas. In most cases, these access roads are open to the public. The ORV trail use increases erosion, fugitive dust, soil compaction, sedimentation, and can crush cactus (Service 1990; BLM 2008a). Human access can result in illegal collection and the direct loss of individual plants (Service 1990; BLM 2005). Oil and gas development increases weed invasions because of the associated surface disturbance. Increased invasive weeds alter the ecological characteristics of cactus habitat, making it less suitable for the species (Service 1990; BLM 2008a).

Stressor: Utility corridors (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: A BLM and Department of Energy designated Westwide Energy Corridor covers 70,142 ac (28,385 ha) of BLM land that is potential habitat for Colorado hookless cactus (Service 2010b; BLM 2008b). The BLM identified preferred corridors to limit the proliferation of additional rights-of-way across the landscape, but utilities are not limited to these corridors (BLM 2008b).

Twenty-nine of the species' 98 occurrences are at least partially located within this energy corridor (Service 2010b; BLM 2008b). Specific pipeline and transmission line routes within the energy corridor are not yet identified. The TransColorado (TransCO) gas pipeline resides in this corridor. Many of the 29 aforementioned occurrences were discovered during surveys for this project. The TransCO project resulted in transplantation of approximately 1,200 Colorado hookless cactus individuals. Monitoring documented a 19-percent mortality rate for the 129 monitored individuals between 1999 and 2003 (Bio-Logic 2008). Surveys for a new powerline north of Delta, Colorado (not in the designated energy corridor), located approximately 5,200 Colorado hookless cactus individuals (Bio-Logic 2008). Up to 100 individuals may be transplanted or destroyed during construction of this powerline in 2010 (Bio-Logic 2008). (USFWS, 2010)

Stressor: Invasive species (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Invasive weeds, including *Bromus tectorum* (cheatgrass) and *Halogeton glomeratus* (halogeton), are prevalent on BLM and private lands within the range of Colorado hookless cactus (CNHP 2010b). Invasive weeds alter the ecological characteristics of cactus habitat, making it less suitable for the species (Service 1990; BLM 2008a). In addition, invasive weeds are often able to out-compete native species under drought conditions (Everard et al. 2010). Several

EO records include cheatgrass invasion as a threat, and BLM attributes downward trend at several locations to cheatgrass invasion (CNHP 2010b; BLM 2009a). (USFWS, 2010)

Stressor: Off road vehicle use (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Despite ORV use being common within Colorado hookless cactus habitat, there have been few documented impacts to the plants. Observers documented ORV use as a threat to 3 of the 98 EOs (CNHP 2010b). Additionally, illegal off road driving damaged Colorado hookless cactus individuals during construction of the Collbran pipeline (WestWater Engineering 2009). The ORV use is expected to increase along with expected human population increases in the region in which Colorado hookless cactus is native and with increasing popularity and availability of improved ORVs. This is expected to result in an increase in damage to Colorado hookless cactus individuals and habitat (Service 1990). (USFWS, 2010)

Stressor: Water development (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: The 1990 Recovery Plan identified water development as a threat to the species. It is likely that reservoir and irrigation canal development have impacted Colorado hookless cactus occurrences in the past; however, we have no documentation of those impacts. Two water reservoir projects known as Roan Creek and Sulphur Gulch have been proposed within potential and occupied habitat of Colorado hookless cactus. These potential reservoirs could permanently destroy plants and their habitat through project construction and inundation. After evaluation of numerous alternatives, the Roan Creek and Sulphur Gulch projects are no longer being considered (Bray and Drager pers. comm. 2008; Grand River Consulting Corporation 2009). Since the proposals have been withdrawn, these threats are not imminent. (USFWS, 2010)

Stressor: Collection (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: The original listing of the Uinta Basin hookless cactus complex concluded that the cactus is prized among collectors and threatened by unregulated commercial trade (44 FR 58869, October 11, 1979). Collectors prefer larger, reproductive age individuals, leaving behind a younger, less reproductively fit population. We are not aware of illegal removal of *Sclerocactus* in Colorado prior to 2009. Three Colorado hookless cactus individuals were removed illegally in 2009 from sites proposed for a natural gas pipeline and a sewer pipeline in Mesa County, Colorado (Service 2010a; Glenne 2009). It did not appear that these plants were removed by collectors, but rather these were acts of vandalism. Additional damage to cacti occurred during project construction on the same natural gas pipeline (WestWater Engineering 2009). These incidents show that additional development increases risk to cacti of vandalism and removal by increasing human presence in areas previously rarely visited by humans. (USFWS, 2010)

Stressor: Livestock grazing and trampling (USFWS, 2010)

Exposure:

Response:**Consequence:**

Narrative: Of the 450,000 ac (182,000 ha) of Colorado hookless cactus potential habitat on Federal lands, approximately 94 percent, 424,000 ac (172,000 ha) falls within grazing allotments. Moderate to heavy domestic livestock grazing has been observed to cause physical damage to Sclerocactus plants through trampling, but we have no evidence to suggest that cattle browse on individual Sclerocactus plants (Service 1990). A study on another federally listed cactus, *S. wrightiae*, found that cacti density increased more rapidly in a fenced plot excluded from cattle grazing than in an unfenced plot with a reduced cattle stocking rate (Clark and Clark 2007). Overgrazing (the continued heavy grazing beyond the recovery capacity of forage plants) by domestic livestock can have a negative impact on North American xeric ecosystems (Jones 2000; Vallentine 1990). For example, overgrazing can facilitate the establishment of invasive species like *Bromus tectorum* (Masters and Sheley 2001), which are difficult to eradicate and tend to outcompete native vegetation, including cacti. (USFWS, 2010)

Stressor: Predation (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: Another source of mortality is lagomorph and rodent browsing on Colorado hookless cactus. While there have been numerous observations of *S. glaucus* individuals being removed by desert cottontail rabbits (*Sylvilagus audubonii*) and unknown rodents (CNHP 2010b; BioLogic 2008; Clayton 2006), some of these plants have re-sprouted in subsequent years (Clayton 2010). Browsing likely goes unnoticed unless a marked individual is revisited within a 1- to 2-year period. We know very little about the magnitude of this threat. Parasitism by the cactus-borer beetle (*Moneilema semipunctatum*) is a significant but localized source of mortality to all Sclerocactus species on the Colorado Plateau, especially in larger, mature, reproducing individuals (Service 1990; 74 FR 47112, September 15, 2009). Additional studies are needed to determine the long-term, population-level effects of the cactus-borer beetle to Colorado hookless cactus. (USFWS, 2010)

Stressor: Herbicides and pesticides (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: Colorado hookless cactus lives in or near areas that receive herbicide and pesticide treatments to remove undesirable species, such as cheatgrass and crop harming insects (Service 1990). Individual cacti are likely to be directly affected by herbicide use, and indirectly by effects of pesticides on pollinators (Service 1990). However, we cannot fully assess the magnitude of this threat, since the specific species that pollinate Colorado hookless cactus are currently unknown. (USFWS, 2010)

Stressor: Hybridizations (USFWS, 2010)

Exposure:**Response:****Consequence:**

Narrative: Extinction due to hybridization, both natural and human influenced, can be a major concern for rare and endangered species (Denver Botanic Gardens 2009b). Colorado hookless

cactus may hybridize with *S. parviflorus* (Heil & Porter 1987; Woodruff 2009; CNHP 2010b). The extent to which hybridization is occurring is unknown. Genetic research investigating this issue is essential for planning management and recovery efforts. The Denver Botanic Gardens has begun collecting floral tissue to examine the population genetic structure within and among the two population centers of Colorado hookless cactus and investigate the potential threat of introgression with *S. parviflorus* (Denver Botanic Gardens 2009b). (USFWS, 2010)

Stressor: Climate change, drought, and impacts to the vegetative community (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Climate change is likely to affect long-term survival of native species, including *Sclerocactus*, especially if longer or more frequent droughts occur. For the southwestern region of the United States, warming is occurring more rapidly than elsewhere in the country with an increase of 1.5°F (0.8°C) since 1979 (Karl et al. 2009). Under lower emission scenarios temperature is expected to increase 5°F (2.8°C) and under higher emission scenarios temperature is expected to increase 10°F (5.6°C) by the end of the century, from the 1979 baseline (Karl et al. 2009). Other future projections for the southwest include more intense and longer-lasting heat waves, an increased probability of droughts that are worsened by higher temperatures, heavier downpours, increased flooding, and increased erosion (Karl et al. 2009, pp. 129-134). The levels of aridity of recent drought conditions and perhaps those of the 1950s drought years may become the new climatology for the southwestern United States (Seager et al. 2007). Effects related to climate change (e.g., persistent or prolonged drought conditions, changes in community assemblages and the ability of nonnative species to succeed) may affect long-term persistence of Colorado hookless cactus. While the potential impacts of climate change could be significant, improved localized projections are needed to better understand this potential threat. In addition, invasive weeds are often able to out-compete native species under drought conditions (Everard et al. 2010). Drought conditions could further hinder BLM's efforts to control invasive weeds and restore native vegetation, which is already difficult due to the extreme environment of the Colorado and Gunnison River basins (Service 1990; BLM 2005, 2008a). (USFWS, 2010)

Recovery

Reclassification Criteria:

Reclassification criteria are not available.

Delisting Criteria:

Delisting criteria are not available.

Recovery Actions:

- Completion of a comprehensive survey throughout the species' range. (USFWS, 2010)
- Surveys also should more accurately delineate the Colorado hookless cactus range relative to other *Sclerocactus* species. (USFWS, 2010)
- Locate possible population connectivity corridors. (USFWS, 2010)
- Continue ongoing monitoring efforts and expand monitoring to include a larger and more representative sample of occupied sites. (USFWS, 2010)

- Identify sites in urgent need of habitat protection, set protection priorities, and implement protective measures. In the long run, land management agencies should establish formal land management designations to provide for long-term protection of important populations and habitat. (USFWS, 2010)
- Oil and gas leasing and other mineral extraction activities should avoid occupied sites and other important habitat. (USFWS, 2010)
- Develop and implement standard conservation measures to minimize future project and use impacts. (USFWS, 2010)
- Coordinate with land management agencies, project proponents, and other partners early in the planning process to limit direct and indirect impacts of planned activities. (USFWS, 2010)
- Prevent the collection of Colorado hookless cactus plants from natural populations. (USFWS, 2010)
- Resolve the taxonomic status of Colorado hookless cactus regarding the species relationship with *S. parviflorus*. Secondly, this study would assess genetic differences between Colorado hookless cactus populations. (USFWS, 2010)
- Continue research into Colorado hookless cactus life history and ecology, including pollinators. (USFWS, 2010)
- Study population dynamics and conduct a population viability analysis. (USFWS, 2010)
- Encourage investigations that project *Sclerocactus* species' vulnerability and response to climate change. (USFWS, 2010)
- Improve our understanding of livestock and native (e.g., rodent) grazing impacts. (USFWS, 2010)
- Monitor cactus-borer beetle (*Moneilema semipunctatum*) infestations, and study the relationship of episodic infestations with drought and other environmental factors. (USFWS, 2010)
- Monitor changes in invasive species prevalence and impacts on Colorado hookless cactus. Additionally, continue to explore approaches to minimize the risk posed by invasives and associated remediation actions. (USFWS, 2010)

Conservation Measures and Best Management Practices:

- Make a final determination on the proposed the taxonomic revision splitting *Sclerocactus glaucus* into *S. brevispinus*, *S. glaucus*, and *S. wetlandicus*. We expect to make a final determination on this proposal in 2008. (USFWS, 2008)
- Issue a proposed and final rulemaking to reclassify *S. brevispinus* from threatened to endangered as described in our recent 12-month finding (72 FR 53211, September 18, 2007). (USFWS, 2008)
- Develop a recovery plan for each of the three species. As required by Section 4(f)(1)(B), each recovery plan should incorporate: (i) a description of such site-specific management actions as may be necessary to achieve the plan's goal for the conservation and survival of the species; (ii) objective, measurable criteria which, when met, would result in a determination, in accordance with the provisions of this section, that the species be removed from the list; and (iii) estimates of the time required and the cost to carry out those measures needed to achieve the plan's goal and to achieve intermediate steps toward that goal. (USFWS, 2008)
- Conduct range-wide inventories for each species. Once completed, continue and improve population monitoring for each species. (USFWS, 2008)

SPECIES ACCOUNT: *Sclerocactus mesae-verdae* (Mesa Verde cactus)

Species Taxonomic and Listing Information

Listing Status: Threatened; 11/29/1979; Southwest Region (Region 2) (USFWS, 2016)

Physical Description

The Mesa Verde cactus stems are usually singular, globose, 3.2-6.5 cm tall (1.5 - 3 in) and of equal diameter; central spine 0 (possibly 1-4); radial spines 8-11, 6-13 mm long (1/4-1/2 in), white, tan, straw or gray; flowers 2 cm in diameter (3/4 in), cream to yellow; fruit green, becoming brown with age and splitting open horizontally; seeds black. In late April a yellow or cream-colored flower blooms on top of the stem. (USFWS, 1984)

Taxonomy

Sclerocactus mesae-verdae and *S. wrightiae* have several morphological features in common: stem size, shape and color; flower shape and color; fruit dehiscence (not bearing scale leaves); and the ability to retract into the soil during periods of drought. *S. mesae-verdae* has 0-1 central spines, 8-11 radial spines, cream to yellow flowers with no fragrance, brownish-black seeds, while *S. wrightiae* has 4-6 central spines, 5-10 radial spines, cream to pink flowers with fragrance, and black seeds. (USFWS, 1984)

Current Range

Occurs only in parts of Montezuma County, Colorado and San Juan County, New Mexico. Mostly on Navajo Indian Reservation lands (Roth, pers. comm., 1998). (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual and asexual (USFWS, 2010)

Lifespan

Adult: ~20 years (USFWS, 2010)

Dependency on Other Individuals or Species

Adult: Pollen grain collected from the field averaged 91 percent viability (Cully et al. 1993) and the most frequent visitors and potential pollinators were small, solitary bees of the family Halictidae (Cully et al. 1993; Heil and Porter 1994; Colorado Natural Areas Program 2005; Navajo Nation Heritage Program 2004). Other common visitors included pleasing fungus beetles (*Tritoma* sp.) and blister beetles (*Epicauta* sp.), but it is still not known which insects are the effective pollinators for this cactus (Cully et al. 1993). (USFWS, 2010)

Breeding Season

Adult: Late April to early May (USFWS, 2010)

Key Resources Needed for Breeding

Adult: Repeated freezing and thawing (vernalization), seed coat scarification, and the proper temperature and moisture are required for successful germination (Service 1984). (USFWS, 2010)

Reproduction Narrative

Adult: *Sclerocactus mesae-verdae* is a perennial desert plant that grows slowly and has a lifespan of approximately 20 years (Colorado Natural Areas Program 2005). Stems begin producing flowers when they are about 2 cm (0.8 in) in diameter or about 8 years old and begin to flower each year after reaching 4 cm (1.6 in) in diameter (New Mexico State Forestry Division 2007). Flowers are diurnal, bloom from late April into early May, and open daily for up to five days (Heil and Porter 1994). Flowers possess both male and female organs (hermaphroditic) indicating self-compatibility, yet Heil and Porter (1994) suggest that self-fertilization rarely is found in the genus *Sclerocactus*. Tepedino (1998) found that a single plant can self-fertilize (selfing) using pollen from another flower on the same plant (geitonogamy) and produce viable seed, but not pollen from the same flower (autogamy). However, 50 percent less seed is produced from self-compatible fertilization when compared to the pollen donor coming from a flower on a nearby plant (xenogamy or outcrossing) (Tepedino 1998). Pollen grain collected from the field averaged 91 percent viability (Cully et al. 1993) and the most frequent visitors and potential pollinators were small, solitary bees of the family Halictidae (Cully et al. 1993; Heil and Porter 1994; Colorado Natural Areas Program 2005; Navajo Nation Heritage Program 2004). Other common visitors included pleasing fungus beetles (*Tritoma* sp.) and blister beetles (*Epicauta* sp.), but it is still not known which insects are the effective pollinators for this cactus (Cully et al. 1993). Repeated freezing and thawing (vernalization), seed coat scarification, and the proper temperature and moisture are required for successful germination (Service 1984). Seed dispersal distance and seed bank sampling found a total seed load around mature plants averaging 200 seeds within a 1 meter (m) (3.3 feet [ft]) radius with 80 percent of the seeds 0 - 3 cm (0 - 1 in) deep in the soil (Cully et al. 1993).

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Desert (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Open sunny areas (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Restricted to dry exposed hills and mesas at elevations about 1,400 to 2,000 m; sparsely vegetated areas (USFWS, 2010; NatureServe, 2015)

Environmental Specificity

Adult: Medium (USFWS, 2010)

Tolerance Ranges/Thresholds

Adult: Moderate (USFWS, 2010)

Habitat Narrative

Adult: *Sclerocactus mesae-verdae* are restricted to sparsely vegetated badlands of clay loam soils derived from upper Cretaceous Mancos shale in Colorado, and Mancos and Fruitland shale in New Mexico (Service 1984). Populations are located in a narrow strip of land between Cortez, Colorado, and Sheep Springs, New Mexico, at elevations ranging from 1,400 to 2,000 m (4,600 - 6,560 ft) (Heil and Porter 1994; Coles and Naumann 2003). These formations erode easily, forming low, rolling hills where plants are found on hilltops and benches, but less so in basins or swales (Cully et al. 1993; Coles and Naumann 2003). The soils are sodic (high alkalinity; pH 7.5 to 8), gypsiferous (poor permeability), and have shrink-swell tendencies which make harsh sites for plant growth (Potter et al. 1985). However, during severe hot or cold dry periods, individual plants shrink and retract back into soils which can minimize desiccation or dehydration (Heil and Porter 1994). Colorado State University soil lab results on Colorado Natural Areas Program plots (2001) revealed clay and silty clay loams in texture, with low water permeability. Sodium, calcium, selenium and iron levels are elevated, while organic matter, phosphate and nitrate levels are low. Cracks in the clay soil, where the seeds fall and may germinate, are apparently an important part of the plant's microhabitat. Soils are typically high in selenite. Vegetative associates, though low in total percent ground cover (5 to 18 percent), include *Atriplex cuneata* (valley saltbush) and *A. corrugata* (mat saltbush) in New Mexico, and *A. corrugata*, *A. confertifolia* (shadscale saltbush), *A. gardneri* (Gardner's saltbush), and *Artemisia spinescens* (bud sagebrush) in Colorado (Cully et al. 1993; Coles and Naumann 2003). In both states, *A. corrugata* was consistently found to be the dominant shrub. (USFWS, 2010; NatureServe, 2015)

Dispersal/Migration**Dispersal**

Adult: Moderate (USFWS, 2010)

Dispersal/Migration Narrative

Adult: Harvester ants (*Pogonomyrmex* sp.) and erosional processes (rain) are the most effective short-range seed dispersers; whereas, wind may be more important to long-range dispersal (Cully et al. 1993; Rojas-Arechiga and Vasquez-Yanes 2000). Seed predation is well known in desert areas with frugivores (fruit eaters) being another type of important dispersal agent. Mainly rodents, but also birds, lizards, and some mammals prey on fruits and seeds (Rojas-Arechiga and Vasquez-Yanes 2000). No long-range dispersal was observed by rodents or birds for this species (Cully et al. 1993; Colorado Natural Areas Program 2005; Navajo Natural Heritage Program 2005). (USFWS, 2010)

Population Information and Trends**Population Trends:**

Long-term trends are unknown but short-term trends indicate a decline of 10-30% (NatureServe, 2015)

Resiliency:

Low (inferred from NatureServe, 2015)

Representation:

Low (inferred from USFWS, 2010)

Population Growth Rate:

Slow growth and reproduce success rate (NatureServe, 2015)

Number of Populations:

78 (NatureServe, 2015)

Population Size:

10,000 individuals (NatureServe, 2015)

Population Narrative:

Slow growth and low reproductive success rate; the taking of a few plants can deplete/extirpate a population. There is insufficient data to characterize long-term population trends but short-term trends indicate a decline of 10-30%. Approximately 2000 individuals have been documented in element occurrence records (CNHP 2012, NHPM 2003), although the species is estimated to be represented by as many as 10,000 individuals (Coles 2003). A total of 78 occurrences have been documented, 22 in Colorado and 56 in New Mexico (CNHP 2012, NHPM 2003). Twenty of the occurrences report less than 10 individuals each. (NatureServe, 2015)

Threats and Stressors

Stressor: Highway construction and right-of-ways for transmission lines (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: The Navajo Nation and BLM have consulted with the Service for various projects that have taken place or are planned to occur in areas with occupied or suitable habitat for *S. mesae-verdae*. We provide a list of consultations in order to convey the number and diversity of projects and to acknowledge the continuing compliance of the Navajo Nation and BLM with accounting for rare species. In each case, however, after the Service provided non-jeopardy opinions, we did not receive any further information regarding implementation of conservation measures, including post-construction surveys or progress reports. To ensure that the conservation measures are implemented and effective, and to apply adaptive management, if needed, to modify measures to assist the cactus, providing documentation of the outcome of these projects and other monitoring data would be very beneficial to the Service. By sharing information about the effects of projects, all parties managing *S. mesae-verdae* can be informed of what conditions are most favorable for this cactus and what conservation measures are the most worthwhile for promoting this species' recovery and moving toward delisting. There is a need for a *S. mesae-verdae* multi-agency working group to share and disseminate information regarding this listed species to promote education, protection, and recovery. (USFWS, 2010)

Stressor: Off-highway vehicles (OHVs) (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: The 1984 recovery plan correctly anticipated that OHV use would be one of the greatest human-caused threats to *S. mesae-verdae*. The use of OHVs appears to have increased

within the Navajo Nation (Roth 2009, pers. comm.) and on BLM lands ((Jamison 2009, pers. comm.). This increase is most likely due to the recent energy boom and the resultant population boom within San Juan County; a 55 percent increase in population from 1980 to 2006 (<http://wrdc.usu.edu/htm/publications/>). National all-terrain and off-highway vehicles retail sales from 1993-2003 show a dramatic increase from 2,920 total vehicles sold in 1993 to a total of 8,010 vehicles sold by 2003 (Cordell et al. 2005). However, the perception of increased OHV traffic may be more of an issue of unmanaged/unregulated use where one vehicle could cause extensive and severe habitat damage with one trip through closed areas. When a vehicle runs over a cactus, the growing tip is often damaged resulting in a failure to flower and set seed as well as an increased vulnerability to desiccation, herbivory, and pathogens. Cacti can also be directly uprooted or irreversibly damaged from OHVs or any other form of forceful contact. In addition to these direct impacts to the cactus, indirect effects from OHV riding also occur such as damage or destruction of annual and perennial plants, destruction of fragile soil crusts, soil erosion and compaction, alteration of drainage patterns, formation of dust, and proliferation of weeds (Brooks 2009; Lei 2009). Erosion and denuding of plants on dry soils from unauthorized OHV use changes soil properties and alters the hydrological dynamics of an area, with impacts spanning from the microhabitat to the landscape scale. These factors increase run-off and decrease the infiltration of precipitation into soils, further diminishing water storage and accessibility to plant roots. Off-highway vehicle activity can also disturb fragile cyanobacterial-lichen soil crusts, a dominant source of nitrogen in desert ecosystems (Belnap 1996). Belnap (1996) showed that anthropogenic surface disturbances may have serious implications for nitrogen budgets in cold-desert ecosystems similar to those occupied by *S. mesae-verdae*. Soil crusts also appear to be an important source of water for plants, as crusts were shown to have 53 percent greater volumetric water content than bare soils during the late fall when winter annuals are becoming established (DeFalco et al. 2001). Once the soil crusts are disturbed, non-native plants may colonize, become established, and outcompete native perennial and annual plant species (DeFalco et al. 2001). Surface disturbance from OHV activity can cause erosion and large amounts of dust to be discharged into the air. Recent studies addressing surface dust impacts on gas exchanges of desert shrubs showed that plants encrusted by dust have reduced photosynthesis and decreased water-use efficiency, which may decrease primary production during seasons when photosynthesis occurs (Wijayratne et al. 2005; Sharifi et al. 1997). Sharifi et al. (1997) also showed reduction in maximum leaf conductance, transpiration, and water-use efficiency due to dust. These effects may impact desert plants including *S. mesae-verdae*. Impacts from constant OHV use, causing soil, vegetation, and hydrological disturbances, have the capacity to compound over time, particularly if the source of OHV impacts is located high in a drainage (Brooks and Lair 2005). Repeated OHV trail use leads to new routes that are not included in road databases (Brooks and Lair 2009). As a result, continual unauthorized OHV use, especially off-trail riding, can create conditions less and less supportive for a habitat specialist such as this cactus species. Furthermore, reduced moisture availability and ground cover from OHV use can interact with other variables such as climate change or grazing, exacerbating drying conditions an already arid system. (USFWS, 2010)

Stressor: Coal mining (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: About 90 percent of known *S. mesae-verdae* habitat occurs in areas that lack coal reserves (Parker et al. 1977). The 1984 recovery plan reported that no coal mining was being

actively pursued within occupied habitat, although several strip mining operations were within a few miles of the Waterflow cactus population (Service 1984). This cactus population was the only one known growing on the coal-bearing Fruitland formation (Service 1984). We are not aware of any effects resulting from coal mining on this species (Sivinski 2000). Thus, we believe that coal mining is not currently a threat and is not likely to threaten the species in the foreseeable future. (USFWS, 2010)

Stressor: Oil and gas exploration and production (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: About 70 percent of the known occupied *S. mesae-verdae* habitat is located on Navajo Nation lands. Navajo Nation lands contain significant deposits of coal, oil, and natural gas. Development of energy resources in the Four Corners Basin continues to increase (Energy, Minerals, and Natural Resources Department 2008). The Fruitland Coal formation of the San Juan Basin is the largest coal bed methane producer in the United States (Energy, Minerals, and Natural Resources Department 2008). These resources occur subsurface in ancient marine shale layers, primarily Fruitland and Mancos layers, which coincide with *S. mesae-verdae* habitat. Nearly all known cactus habitat has the potential to be affected by natural gas or oil exploration and development. Another mineral, a decomposed type of coal (humate), is also found under much of *S. mesae-verdae* habitat (Colorado Natural Areas Program 2004). Humate is used as a soil conditioner and additive to drilling mud which increases the potential for development. About 12.1 billion tons of humate occur within the San Juan Basin (McLemore et al. 2002). Ground disturbing impacts from these activities include the construction and maintenance of pipelines, power lines, and associated roads; the total clearing of all vegetation on an average of three acres for every oil or gas well pad and associated facilities; and associated commercial and residential development. These activities lead to long-term degradation, fragmentation, or loss of habitat, with impacts to *S. mesae-verdae* similar to those described above in the OHV section. Most *S. mesae-verdae* habitat occurs on the Mancos Formation, with the Rattlesnake, Shiprock-Gallup, Horseshoe-Gallup, and Hogback oil fields located within high quality habitat. Destruction of cactus habitat from these oil fields appears to be extensive (Roth 2008, pers. comm.); however, data quantifying the size of each oil field, number of cactus mortalities, and leasing of other areas for associated activities are not available. (USFWS, 2010)

Stressor: Commercial and residential development (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Commercial and residential development threatens *S. mesae-verdae* on private and Tribal lands (Service 2009). Since the species was listed, cactus habitat has been increasingly impacted from urban development on Navajo Nation lands (Navajo Natural Heritage Program 2004). Urban development is not allowed within a BLM ACEC or on New Mexico State trust lands. The status of urban development on Ute Mountain Ute lands regarding this cactus is unknown at this time. Impacts from urban development include habitat loss, fragmentation, and degradation, along with other factors relating to soil, vegetation, and hydrologic disturbances described in more detail in the off-highway vehicles section above. These impacts not only directly damage cacti, but also can make occupied and potentially usable habitat inhospitable to *S. mesae-verdae* and result in the decline of individuals and populations. Urban development,

including homes, roads, power lines, pipelines, and waterlines; increased recreational activities, including use of OHVs; and commercial facilities have expanded in the proximity of Shiprock. In an effort to off-set the Navajo fairground project interfacing with the cactus, the Northern Navajo Fairground Conservation Area was established in 2001 to use for transplanting cacti that otherwise would be destroyed by the construction of the fairground. However, it is unknown at this time if signs and fences are in place to protect this area. (USFWS, 2010)

Stressor: Livestock grazing and trampling (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: The 1984 Recovery Plan (Service) stated that livestock grazing was not believed to be a significant threat. Since that time, nearly all monitoring has documented disturbance of *S. mesae-verdae* by livestock. Livestock grazing occurs throughout the range of the cactus, and impacts from trampling, such as uprooted cacti, partially or entirely crushed cacti, and soil disturbance immediately adjacent to cactus individuals are regularly observed (Ecosphere Environmental Services 1985). Cattle have also been observed eating *S. mesae-verdae* (Service 1984; Ecosphere Environmental Services 1985). Livestock grazing continues to be permitted by the BLM within the Hogback ACEC (Bureau of Land Management 2003b). Navajo Nation staff noted heavy sheep and cattle grazing at the Sheep Springs population that historically supported *S. mesae-verdae* prior to 2004 (Navajo Natural Heritage Program 2004), but now appears to be extirpated (Roth 2008, pers. comm.). Three additional occupied areas on Tribal land were observed to have extensive livestock damage (Navajo Natural Heritage Program 2004). In Colorado, livestock trampling was also documented and believed to be the primary source of cactus mortality in 2005 (Colorado Natural Areas Program 2005). The 1984 Recovery Plan reported that when livestock are fenced in cactus habitat, trampling of the species could occur. High intensity grazing associated with fenced private or Tribal residences is likely to result in the permanent loss of cacti through trampling and soil compaction (Service 2009). On larger fenced acres, ranchers drive their trucks and OHVs off-road, tracking or herding their livestock (Jamison 2009, pers. comm.). Likewise, during capture of feral horse herds on the Navajo Nation, soils have become compacted within *S. mesae-verdae* habitat (Service 2009). Based on the increase in habitat degradation due to livestock trampling, whether it be compacted soils or vegetation displacement resulting in increased soil erosion and dust formation, we believe that livestock grazing and trampling has become a moderate threat to this species for the foreseeable future. (USFWS, 2010)

Stressor: Collectors (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Cacti are desirable plants whose wild populations in the U.S. and Mexico have been subject to illegal collection and trade (Robbins 2003). Some cactus hobbyists, known as cactophiles, are well known for their passion and interest in rare cacti. Many of these collectors have illegally obtained certain species for their private collections (Robbins 2003). In summary, illegal collection leads to the direct loss of plants and has threatened some *S. mesae-verdae* populations. Cactus collecting will probably continue at some level into the foreseeable future, but such activities are difficult to document and we have not discovered any new information to suggest that cactus theft is increasing (CITES 2000; Robbins 2003; Martin 2009). Although illegal

collection of *S. mesae-verdae* was considered a significant threat at the time of listing and during the development of the Recovery Plan, as evidenced by the second recovery criterion which directly addresses this threat, collecting appears to have decreased since the publishing of the Recovery Plan and is now considered a minor threat to the species for the foreseeable future. (USFWS, 2010)

Stressor: Predation (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: All *Sclerocactus* are susceptible to disease and predation, but only predation has been observed in this species. The longhorn cactus beetle (*Moneilema semipunctatum*) normally feeds upon *Opuntia* spp. However, during the 2002-2003 period of severe drought, the longhorn cactus beetle fed upon *S. mesaeverdae* and substantially reduced all of the monitored populations. Although the longhorn cactus beetle is a native species and *S. mesae-verdae* has likely evolved with it, this beetle has the potential to cause serious mortality in the foreseeable future with periodic atypical population eruptions. Native to the Great Plains and Intermountain West, a migratory, noctuid moth, the army cutworm (*Euxoa* spp), destroyed many *S. mesae-verdae* in the BLM Hogback ACEC study area during the drought of 2002-2003 (Bureau of Land Management 2003b). Numerous cacti also were reported killed by the army cutworm on Navajo Nation land (Roth 2008, pers. comm.). Since this insect is generally associated with agricultural crops which are found nearby BLM and Navajo Nation lands, but will also consume native plants, particularly grasses, the threat is still substantial. In 2003, a third type of cactus predator was observed in the Colorado (Navajo Natural Heritage Program 2004). Unfortunately, the identity of the predator was not determined, but the effects to the plant appear to be similar to those from the longhorn cactus beetle (Navajo Natural Heritage Program 2004). The Service believes that insect predators can be an ongoing, yet minor threat to *S. mesae-verdae*. However, during atypical drought episodes, the threat from these predators can be severe into the foreseeable future. (USFWS, 2010)

Stressor: Pesticide use (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Pesticides are considered a potential threat because they could directly harm a plant, but also could indirectly kill pollinators of *S. mesae-verdae* or their host plants (Service 1984). Herbicides are commonly used for noxious weed control, but no documentation has been provided on herbicide application occurring, and whether any *S. mesae-verdae* populations have been directly or indirectly affected. On the other hand, agricultural use of pesticides has been reported on nearby BLM lands. Pesticides, particularly insecticides, are linked to bee declines (Kearns et al 1998; Kremen et al. 2002; National Academy of Sciences 2007), with the abundance and diversity of wild bee communities negatively correlated with increasingly intensive chemical applications of pesticides (Tuell and Isaacs 2010). Although the toxicity of pesticides to pollinators is challenging to quantify in a field setting and varies depending on the chemistry, quantity applied, degree of contact, area treated, and seasonal timing (Mineau et al. 2008; Tuell and Isaacs 2010), some pesticides cause immediate mortality to bees if applied upon crops while bees are actively foraging (Johansen 1977). Both wild and honey bee (*Apis mellifera*) declines have been found in areas adjacent to sprayed fields, suggesting a wider spatial impact to the

pollinator community than just a targeted area (Kevan 1975; Kevan et al. 1990). Furthermore, depending on the seasonal timing of pesticide application, effects to pollinator communities may be chronic and cumulative, yet difficult to assess due to the different phenologies and nesting situations of pollinator species (Desneaux et al. 2007; Tuell and Isaacs 2010). Pesticide application, particularly aerial spraying, occurs in the local agricultural areas to control crop pests, including army cutworms (*Euxoa* spp). Most of the *S. mesae-verdae* populations are miles away and would not be impacted by drift (Sivinski 2000). However, a few cactus populations are situated near agricultural areas, such as the Waterflow population, which is close to an apple orchard and alfalfa field, yet it has been successfully setting fruit until the severe drought of 2002-2003. Due to the lack of information, we are uncertain whether pesticides directly or indirectly affect the survival of *S. mesae-verdae*. Thus, we do not consider pesticides to be a threat to this species in the foreseeable future. (USFWS, 2010)

Stressor: Climate change (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Based on the unequivocal evidence of warming of the earth's climate from observations of increases in average global air and ocean temperatures, widespread melting of glaciers and polar ice caps, and rising sea levels recorded in the Intergovernmental Panel on Climate Change Report (IPCC 2007), climate change is now a consideration for Federal agency analysis (GAO 2007). The earth's surface has warmed by an average of 0.74 °C (1.3 °F) during the 20th century (IPCC 2007). The IPCC (2007) projects that there will very likely be an increase in the frequency of hot extremes, heat waves, and heavy precipitation events as a result of climate change. Increases in predatory insects are also predicted with climate change (Enquist and Gori 2008). This was documented for *S. mesae-verdae* during the drought of 2002-2003 with the unusual and extensive invasion of the longhorn cactus beetle and the army cutworm. The drought combined with concurrent insect infestations significantly reduced *S. mesae-verdae* populations and recovery has been extremely slow. *Sclerocactus mesae-verdae* is likely to have experienced and rebounded from periods of drought and cycles of insect predation in the past. However, should substantial climate change materialize with increased severity and frequency of drought, it would likely reduce the long-term survivorship of this species. Since the documented decline of *S. mesae-verdae* was concurrent with the drought of the early 2000s, the Service believes that climate change is a severe threat to this species in the foreseeable future. (USFWS, 2010)

Recovery

Reclassification Criteria:

Reclassification criteria are not available.

Delisting Criteria:

1. Establish at least two restricted use areas for selected portions of *S. mesaeverdae* habitat on the Navajo Indian Reservation and on Bureau of Land Management (BLM) administered lands. (USFWS, 2010)

2. Provide *S. mesae-verdae* stock to trade outlets to help relieve the black market demand through the addition of 10,000 plants per year to commercial nurseries for 5 years. (USFWS, 2010)

Recovery Actions:

- Major actions listed in the recovery plan include species monitoring, management, and protection of the five known populations; establishment of at least two (additional) areas of restricted use; surveys of all potential species' habitat; development of a commercial artificial propagation program; and research into the distribution, population biology, and ecology of this species. (USFWS, 2010)

Conservation Measures and Best Management Practices:

- Revise the recovery plan for this species to incorporate new information on biology, ecology, threats, and management recommendations. Objective and measurable recovery criteria for down and delisting of the species should be developed which addresses all listing factors relevant to this species. (USFWS, 2010)
- Recommend more stringent off-highway vehicle use restrictions and stronger enforcement of OHV laws in known and potential cacti habitat. (USFWS, 2010)
- Develop a *S. mesae-verdae* multi-agency working group to share and disseminate information regarding this listed species to promote education, protection, and recovery. (USFWS, 2010)
- Develop standardized survey and monitoring protocols for this species to be conducted annually by well trained personnel. Continue monitoring of known sites as well as adding new sites to provide a robust dataset for long-term trend analysis. (USFWS, 2010)
- Develop a mitigation banking requirement (a system whereby project proponents pay for plants to be preserved in an area suitable for their preservation as mitigation for losses incurred during projects). (USFWS, 2010)
- Implement and monitor new transplant projects with experimental manipulations (watering, shading, planting depth, etc.) and controls to determine required establishment needs. (USFWS, 2010)
- Provide legally grown seeds and plants of *S. mesae-verdae* to the commercial succulent trade, but law enforcement must remain vigilant against the theft of cacti throughout its range. (USFWS, 2010)
- Provide viable *S. mesae-verdae* seeds to a seed bank operating under the Center for Plant Conservation guidelines. (USFWS, 2010)
- Collect data on seed dispersal and growth past the germination stage, timing of seed set, and seedling establishment to more clearly define the vulnerable life history stages of this species. (USFWS, 2010)
- Determine microhabitat needs of this species ("nurse" plants, pollinators, precipitation needs - amount and timing, slope and aspect requirements, disturbance patterns, etc.) to further quantify potential habitat for a transplant and mitigation site. (USFWS, 2010)
- Collect data on the biology, demographics, ecology, and movements of the longhorn cactus beetle and the army cutworm to determine their long-term significance as predators of this species. (USFWS, 2010)

SPECIES ACCOUNT: *Sclerocactus wetlandicus* (Uinta Basin hookless cactus)

Species Taxonomic and Listing Information

Listing Status: Threatened; 09/15/2009; Mountain-Prairie Region (R6) (USFWS, 2016)

Physical Description

S. wetlandicus is a barrel-shaped cactus that ranges from 4 to 18 centimeters (cm) (1.5 to 7 inches (in.)) tall, with exceptional plants up to 30 cm (12 in.) tall. The stems have typically 12 to 15 ribs that extend from the ground to the tip of the plant. Along the ribs are areoles (small, cushion-like areas) with hooked spines radiating out (Heil and Porter 2004). There are two types of spines, radial and central, defined by the size and position on the plant (see Figure 1) (74 FR 47112, September 15, 2009). The 6 to 14 radial spines are located around the margin of the areole, extending in a plane parallel to the body of the plant. The radial spines are white or gray to light brown, and are 6 to 20 mm (0.24 to 0.8 in.) long. The one to five central spines (usually three) are 15 to 30 mm (0.5 to 2.0 in.) long, are generally longer than radial spines, and extend from the center of the areole. The central spines include abaxial and lateral forms. Abaxial spines are typically single and are noticeably bent at an angle usually less than 90 degrees. Lateral spines are usually present in pairs on either side of the abaxial spine, but are more or less straight and diverge from the abaxial spine at an acute angle (usually 20 to 50 degrees). The funnel-shaped flowers usually have pink to violet tepals (petal-like flower parts not differentiated into petals and sepals) with yellow stamens (the male reproductive organ of the flower), and are 2 to 5 cm (0.8 to 2 in.) long and 2 to 5 cm (0.8 to 2 in.) in diameter (74 FR 47112, September 15, 2009). The fruit is short, barrel-shaped, reddish or reddish grey when ripe, 7 to 12 mm (0.3 to 0.5 in.) wide, and 9 to 25 mm (0.35 to 1.0 in.) long (USFWS, 2010).

Taxonomy

The original listing rule for *S. glaucus* (44 FR 58868, October 11, 1979) included all hookless (straight central spines) *Sclerocactus* populations in western Colorado and northeastern Utah, and referred to them as *S. glaucus* per Benson (1966, pp. 50-57; 1982, pp. 728-729). This taxonomic classification is not supported by the results of more recent genetic and morphological research. Genetic studies (Porter et al. 2000), common garden experiments (Hochstätter 1993b; Welsh et al. 2003), and a reevaluation of the morphological characteristics of *S. glaucus* have led to separating this species into three distinct species: *S. brevispinus*, *S. glaucus*, and *S. wetlandicus* (Hochstätter 1993b; Heil and Porter 2004). The Flora of North America recognizes 15 species in the genus *Sclerocactus*, including these 3 species (Heil and Porter 2004). Comparative DNA sequences (Porter et al. 2000) infer common ancestry between *S. brevispinus* and *S. wetlandicus*, but infer *S. glaucus* is more closely related to *S. parviflorus* (Devil's claw cactus) and *S. whipplei* (Whipple's fishhook cactus). The common name for *S. glaucus* was changed to Colorado hookless cactus as the species is endemic to western Colorado. *S. wetlandicus* is now known as the Uinta Basin hookless cactus as this species occurs across Utah's Uinta Basin. *S. brevispinus* is now known as the Pariette cactus as it is limited to the Pariette Draw of the central Uinta Basin. The Uinta Basin hookless cactus complex will be used to refer to the combination of all three species previously listed as a single entity (USFWS, 2010).

Current Range

Known only from Duchesne and Uintah counties, Utah (Flora of North America Editorial Committee (2003).

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Predominately insect pollinated (surrogate *S. glaucus* information) (USFWS, 2007)

Breeding Season

Adult: Flowering occurs in April-May, and fruits mature in May-June (surrogate *S. glaucus* information) (NatureServe, 2015).

Reproduction Narrative

Adult: Reproduction is predominantly sexual, although individuals may sprout multiple stems. Flowering occurs in April-May, and fruits mature in May-June. The species appears to be predominantly outcrossing but is marginally self-compatible. Ants and gravity appear to be the primary dispersal mechanisms (Peggy Lyon pers comm. 1998). Seed dispersal may be a limiting factor in the distribution of *Sclerocactus glaucus* (NatureServe, 2015). Information from *S. glaucus* is being used as surrogate information for *S. wetlandicus* due to the species similarities and based on the following quote 'Because we lack life history data specific to *S. wetlandicus*, we have included life history data for *S. glaucus*, which should correlate to characteristics for *S. wetlandicus*' USFWS, 2010. Believed to be dispersed by heavy down-pours (Tepedino et al. 2010).; ABIOTIC; Water; (NatureServe, 2015). The species' life history is poorly known, but it is thought to be a longlived perennial usually flowering after 3 or 4 years. A broad assemblage of native bees, and possibly other insects including ants and beetles, pollinates *S. brevispinus* (USFWS 1990, p. 7) (USFWS, 2007).

Habitat Type

Adult: Salt desert shrub (NatureServe, 2015)

Environmental Specificity

Adult: Narrow/specialist (NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: Low (inferred from NatureServe, 2015)

Site Fidelity

Adult: High (inferred from NatureServe, 2015)

Habitat Narrative

Adult: Species inhabits salt desert shrub communities and pinon-juniper woodlands on river benches, valley slopes, and rolling hills (Franklin 2005). Gravel-covered clay hills, desert

grasslands, saltbush, and rabbitbrush flats (Flora of North America Editorial Committee 2003). (NatureServe, 2015). High ecological integrity of the population and site fidelity as well as low tolerance ranges are inferred based on the species habitat requirements of the species and the relatively small geographic area this species inhabits.

Dispersal/Migration

Dispersal

Adult: Believed to be dispersed by heavy down-pours (NatureServe, 2015)

Dispersal/Migration Narrative

Adult: Believed to be dispersed by heavy down-pours (Tepedino et al. 2010).; ABIOTIC; Water; (NatureServe, 2015)

Population Information and Trends

Population Trends:

Unknown

Resiliency:

Low (inferred from NatureServe, 2015)

Representation:

Low (inferred from NatureServe, 2015)

Redundancy:

Low (inferred from NatureServe, 2015)

Number of Populations:

6 - 80 (NatureServe, 2015)

Population Narrative:

Approximately 8 occurrences observed since 1989 and 17 others last observed earlier (UTNHP 2009). (NatureServe, 2015). We do not have long-term status or trend population (USFWS, 2010). Low resiliency, redundancy and representation are inferred based on the relatively low number of known populations and the small geographic area this species is known to inhabit. data for *S. wetlandicus* (USFWS, 2010).

Threats and Stressors

Stressor: Oil and Gas Development and Associated Impacts (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: The BLM is monitoring *S. wetlandicus* and neighboring *Sclerocactus* species, including impacts associated with oil and gas development. Initial results show that there may be impacts from oil and gas development (i.e., roads and well pads) on the survival and reproductive success

of *S. brevispinus* (72 FR 53215, September 18, 2007), and similar effects could be expected for *S. wetlandicus* (USFWS, 2010).

Stressor: Collection (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Illegal collection is a significant threat to *S. wetlandicus*. The original listing of *S. glaucus* concluded that the cactus is prized among collectors and threatened by unregulated commercial trade (44 FR 58869, October 11, 1979). Collectors prefer larger, reproductive age individuals, leaving behind a younger, less reproductive population. Approximately 40 percent of the potential habitat of *S. wetlandicus* is within 400 meters (1,312 feet) of a well (Service 2009). Such development facilitates human access and discovery by illegal collectors (72 FR 53216, September 18, 2007) (USFWS, 2010).

Stressor: Livestock Grazing and Trampling (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: A majority of *S. wetlandicus* potential habitat on BLM land is leased for grazing. At least 28 grazing allotments overlap with *S. wetlandicus* potential habitat, with both cattle and sheep grazing continuously and on deferred rotation. Livestock grazing results in *S. wetlandicus* mortality when livestock trample individual cacti (Service 1990; Utah Natural Heritage Program 2006; BLM 2008; 72 FR 53215, September 18, 2007). Overgrazing—the continued heavy grazing beyond the recovery capacity of forage plants (Vallentine 1990) - by domestic livestock degrades western ecosystem functions and structures (Fleischner 1994). Overgrazing can facilitate the establishment of invasive species like cheatgrass (Masters and Sheley 2001), which are difficult to eradicate and tend to outcompete native vegetation, including cacti. Invasive weeds (including *Bromus tectorum* and *Halogeton glomeratus*) are prevalent on BLM lands in the range of *S. wetlandicus* cactus and less so on tribal lands where grazing has been concentrated in areas outside of suitable cactus habitat (72 FR 53214, September 18, 2007) (USFWS, 2010).

Stressor: Predation (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Parasitism by the cactus-borer beetle (*Moneilema semipunctatum*) is a significant but localized source of mortality to all *Sclerocactus* species on the Colorado Plateau, especially in larger, mature, reproducing individuals (Service 1990; 72 FR 53216, September 18, 2007). Parasitism is identified as a threat to *Sclerocactus* plants; however, additional studies are needed to determine the long-term, population-level effects of the cactus-borer beetle to *S. wetlandicus*. Another source of mortality is lagomorph and rodent browsing. While there have been numerous observations *Sclerocactus* being removed by desert cottontail rabbits (*Sylvilagus audubonii*) and unknown rodents (Colorado Natural Heritage Program 2010b; BioLogic 2008; Clayton 2006), in subsequent years some of these plants have re-sprouted (Clayton 2010). Browsing likely goes unnoticed unless a marked individual is revisited within a 1- to 2-year period. We know very little about the magnitude of this threat (USFWS, 2010).

Stressor: Climate Change, Drought, and Impacts to the Vegetative Community (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Climate change is likely to affect long-term survival of native species, including *S. wetlandicus*, especially if longer or more frequent droughts occur. For the southwestern region of the United States, warming is occurring more rapidly than elsewhere in the country with an increase of 1.5°F (0.8°C) since 1979 (Karl et al. 2009). Under lower emission scenarios temperature is expected to increase 5°F (2.8°C) and under higher emission scenarios temperature is expected to increase 10°F (5.6°C) by the end of the century, from the 1979 baseline (Karl et al. 2009). Other future projections for the southwest include more intense and longer-lasting heat waves, an increased probability of droughts that are worsened by higher temperatures, heavier downpours, increased flooding, and increased erosion (Karl et al. 2009, pp. 129-134). The levels of aridity of recent drought conditions and perhaps those of the 1950s drought years may become the new climatology for the southwestern United States (Seager et al. 2007). Effects related to climate change (e.g., persistent or prolonged drought conditions, changes in community assemblages and the ability of nonnative species to succeed) may affect long-term persistence of *S. wetlandicus*. While the potential impacts of climate change could be serious, improved projections are needed to better understand this potential threat. *S. wetlandicus* mortality due to drought is well documented (Service 1990; 72 FR 53217, September 18, 2007). Many dead *S. wetlandicus* individuals were observed in the Uinta Basin after the severe drought of 1976 to 1977 (Service 1990). In addition, noxious weeds are often able to out-compete native species under drought conditions (Everard et al. 2010). Drought conditions could further hinder BLM's efforts to control noxious weeds and restore native vegetation, which is already difficult due to the extreme environment of the Uinta Basin (Service 1990; BLM 2005, 2008) (USFWS, 2010).

Stressor: Herbicides and Pesticides (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: *S. wetlandicus* lives in or near areas that receive herbicide and pesticide treatments to remove undesirable species, such as noxious weeds and insect pests (Service 1990). Individual cacti are likely to be directly affected by these chemicals, and indirectly by effects on pollinators or by movement of contaminated soils (Service 1990). However, specifics of the species' pollination biology are currently unquantified (USFWS, 2010).

Stressor: Inadequacy of Existing Regulatory Mechanisms (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: We are not aware of any city, county, or State laws, ordinances, or zone that provide for protection or conservation of the *S. wetlandicus* or its habitat. Removal, damage, or destruction of plants on private lands is not prohibited under the Act. Removal from Federal lands is prohibited without a permit, but can be allowed through consultation with the Service. The BLM sometimes authorizes adverse effects to the *S. wetlandicus* if it will not jeopardize the continued existence of the species. Conservation needs of *S. wetlandicus* are addressed through interagency consultation (section 7 requirements) typically between the Service, BLM, and

Bureau of Indian Affairs. Through this process, conservation measures are implemented on a project-by-project basis to minimize the loss of individual cacti from oil and gas activities. These measures include preconstruction cactus surveys and a required buffer around individual cacti. For example, the Castle Peak/Eightmile Flat Oil and Gas Expansion Project Final Environmental Impact Statement included conservation measures to specifically protect *S. wetlandicus* and its habitat (BLM 2005). In addition to these project-specific protections, we need to establish consistent guidance and Resource Management Plan designations that provide adequate regulatory mechanisms over the longer term to protect large portions of the range of the *S. wetlandicus* (USFWS, 2010).

Recovery

Recovery Actions:

- Reclassification and delisting criteria are not available for this species.
- A Recovery Plan has not been published for this species.

SPECIES ACCOUNT: *Sclerocactus wrightiae* (Wright fishhook cactus)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/11/1979; Mountain-Prairie Region (R6) (USFWS, 2016)

Physical Description

Wright fishhook cactus (*Sclerocactus wrightiae*) is named for Dorde Wright Woodruff who discovered Wright fishhook cactus (L. Benson) in Emery County in 1961 (Benson 1982). The species is endemic to south-central Utah occurring in scattered clusters in Wayne, Emery, and Sevier counties. Wright fishhook cactus is a small, perennial globose shaped cactus mainly 6 – 12 cm long and 4 - 8 cm in diameter growing as a single plant with a branched taproot (Welsh et al. 2008). If damaged, the cactus may form multiple stems. Spines, both lateral and central, emerge from warty protuberances called tubercles. The large, lower central spine is hooked, a noticeable character that gives the cactus its common name of “fishhook.” The flower is 3 to 4 cm in diameter, 3 to 4 cm long, white to cream or pink and fragrant. Sepaloids are green or green tinged with red or brown. Flowering occurs from late April through May and fruits are set in June. Fruits are barrel shaped and borne on the top of the cactus. Seeds are black, 2 mm long and 3.5 mm broad (Heil and Porter 1994). A distinguishing characteristic of the Wright fishhook cactus is the presence of magenta filaments with yellow anthers. Short spine length, round spines, early flowering time, small flower size, and magenta filaments help distinguish this species from other similar cacti (Heil and Porter 1994, Benson 1982).

Current Range

The known range of Wright fishhook cactus extends across approximately 696,099 acres (ac) (281,701 hectares (ha)) of Utah’s western Emery County, southeastern Sevier County, and central Wayne County.

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Almost completely self-incompatible and pollination is accomplished mostly by native sweat bees

Reproduction Narrative

Adult: Wright fishhook cactus is almost completely self-incompatible and pollination is accomplished mostly by native sweat bees (Halictidae) (Tepedino 2000). Eight species of bees from one family (halictid bees) and two genera (*Dialictus* and *Agapostemon*) are known to visit Wright fishhook cactus (Tepedino 2000). Pollination is limited by the foraging distance of the ground nesting bees, which is strongly correlated to body size (Greenleaf 2005). The distance that ground nesting bees travel from their nests is difficult to determine but it is believed that they do not travel far; the maximum travel distance reported for the two genera that pollinate Wright fishhook cactus is approximately a quarter mile (400 m) (Tepedino 2000). Cross

pollination is essential for Wright fishhook cactus to produce viable seeds; self-pollination would result in production of non-viable seeds. Little is known about the species' seed banks, seed viability, germination, dispersal, dormancy and establishment in the wild. Seeds fall directly from the base of the dry fruit onto the ground and most are believed to remain near the parent plant (USFWS 1985). Possible dispersal vectors include gravity, wind and water erosion, as well as insects and rodents (USFWS 1985, Kass 1990).

Habitat Type

Adult: Flat areas, low ridges and slopes

Habitat Narrative

Adult: Wright fishhook cactus occurs on semi-barren sites on flat areas, low ridges and slopes in sparsely vegetated arid desert environments. They occur in a variety of vegetation types including desert scrub, desert grasslands, and open pinyon-juniper woodland communities. Wright fishhook cacti are generally found between 1,290 and 2,300 m (4,230 and 7,545 ft) and occur on a variety of geologic formations including Curtis, Mancos Shale, Morrison, Summerville, Dakota, Carmel, Entrada, and Moenkopi. Soils where the species is found include a broad range of textures, including clays, sandy silts, fine sands, loam and loamy sand. Soils generally have an overlying layer of fine and medium sized gravels or a cryptobiotic soil surface crust (USFWS 1985, Kass 1990). The overall range of the species has not changed significantly since the publication of the 1985 Recovery Plan. However, survey and inventory efforts have greatly expanded our knowledge of the distribution of the species across its range. We now know of more occupied sites and in some cases, more continuous populations than at the time of listing. The known range of Wright fishhook cactus extends across approximately 696,099 acres (ac) (281,701 hectares (ha)) of Utah's western Emery County, southeastern Sevier County, and central Wayne County. Wright fishhook cactus occurs primarily on lands managed by the BLM's Price and Richfield Field Offices and by the NPS at CRNP. More than 300 localities of Wright fishhook cactus have been documented from BLM and CRNP lands. A cactus locality consists of one or more individual cacti. There are 22 localities on lands managed by the BLM's Price Field Office, 256 localities on lands managed by the Richfield field office, and 55 localities on CRNP lands. Ninety-five percent of the Wright fishhook cactus range occurs within 22 active grazing allotments, including BLM, CRNP, SITLA, and private lands. Grazing is not permitted on the BLM North Caineville Mesa (2,200 ac (890 ha)) and a small section of the Factory Butte SRMA (approximately 1,300 acres (526 ha)). Although grazing is not permitted at Goblin Valley State Park, portions of the park are not fenced and are therefore accessible to livestock from adjacent lands. The CRNP section of the Cathedral grazing allotment was retired in 1999; however, livestock trail through the area each fall when moving between their summer and winter ranges. Our most recent range-wide population estimate is 4,500 - 21,000 individuals (USFWS 2008). Inventory efforts within CRNP during 2011 – 2013 documented 2,551 live individuals in 55 localities (CRNP 2014b). This should be considered a conservative number as counting and mapping efforts at each locality were limited to four person-hours, and therefore not all cacti at a locality were counted. Potential habitat is widely available in the vicinity of known localities of the species throughout its range, and because the species is a relative generalist, abundance of habitat is not considered a limiting factor in the conservation or survival of the species. Much of this additional potential habitat has yet to be surveyed. During the 2014 field season CRNP staff conducted 106 belt transects to gather presence/absence data on Wright fishhook cacti and Winkler cacti within suitable habitat that has not been previously inventoried (Clark 2014). These efforts located 546 previously unmapped Wright fishhook cacti. Although additional

Wright fishhook cactus localities have been found since the species was listed, we cannot determine a trend. Previous surveys are not comparable because we do not have a measure of acreage surveyed or effort spent searching. The earliest estimates of 50,000 to 100,000 (Neese 1987, Kass 1990, Kass 2001a) are most likely not accurate because subsequent surveys do not support this estimate. In recent inventories conducted from 2011 and 2012, BLM and CRNP (BLM 2012a, CRNP 2012, CRNP 2013) found 10,724 individual cacti in 157 localities with the majority on BLM land. This number is likely to increase as inventories of the remaining known localities are made.

Dispersal/Migration

Population Information and Trends

Number of Populations:

130

Population Size:

2,348

Population Narrative:

Wright fishhook cactus is a long-lived species that is slow to reach reproductive maturity. Individual cacti begin flowering when around 4 to 5 years old, producing flowers generally less than 50 percent of the time (Kass 2001a, Clark and Clark 2007). The highest reproductive rates are associated with large adult plants (>3.5 in [9.0 cm] in diameter), which flower between 75 and 100 percent of the time producing a disproportionately large amount of seeds (Kass 2001a, Clark and Clark 2007). Depending on environmental conditions, Wright fishhook cactus is estimated to grow an average of 0.2 ± 0.1 in (0.5 ± 0.25 cm) in diameter within one year (Clark and Clark 2007) with seedlings growing at a faster rate than adults (Kass 2001a). Because of slow growth rates, the highest reproductive individuals may be at least 18 years old. Size class distribution of a population indicates its structure and stability, and can help to show vulnerabilities in each life stage. Between 1999 and 2008, Clark (2008a) collected size class data on Wright fishhook cactus collected at 130 of 151 sites surveyed. During these surveys, 2,348 cacti in the four size classes (excluding multiple stemmed plants) were recorded as follows: 10 percent seedlings, 37 percent juveniles, 52 percent young adults, and 2 percent old adults. Although it is likely that some seedlings were missed during this inventory effort, the percentage of old adults is likely accurate (Clark 2008a). Similar population structure results were reported from three demographic monitoring sites on BLM lands over a seven year period with most of the population in the young adult size class (Kass 2001a). Monitoring initiated at Factory Butte in 2009 also showed low numbers of seedlings (5 percent), higher numbers of juveniles (21 percent) and young adults (68 percent), and low numbers of older adults >8 cm in diameter (6 percent) (Clark 2009a). Overall, the majority of Wright fishhook cactus plants occur in the juvenile to young adult size classes throughout the range of the species (Kass 2001a, Clark and Clark 2007, Clark 2008a, Clark 2009a) with the largest and smallest size classes poorly represented. Low frequency in the occurrence in the smallest size classes indicates low levels of recruitment into the population. Demographic monitoring over a seven year period at three BLM Wright fishhook cactus monitoring plots reported a mortality to recruitment ratio of 2.5:1 in all plots (Kass 2001a). Low levels of recruitment are also reported in the Factory Butte area, where overall mortality was 8.9 percent between 2009 and 2010, and 6 percent between 2010

and 2011 (BLM 2012a). The mortality to recruitment ratio for both years was reported at 6:1 and 5:1, respectively (BLM 2012a). Low recruitment patterns and the small number of large older reproductive individuals may constitute a species wide pattern (Kass 2001a). For populations to persist in their environment, recruitment into the population must exceed mortality. Populations with a low percentage of seedlings or a low percentage of the highly reproductive individuals are potentially declining populations (Elzinga et al. 1998).

Threats and Stressors

Stressor:

Exposure:

Response:

Consequence:

Narrative: Threats to the species include damage to the habitat during mineral and gas exploration and the mining of coal, gypsum, bentonite and bentonite clay, uranium, vanadium, building stone and gravel. Livestock activity, such as trampling and uprooting of plants, is a threat. Off-road vehicle use causes damage. Illegal collecting is still a problem. The cactus apparently suffers from predation by the beetle *Moneilema semipunctatum* and perhaps other beetles. Small mammals such as Ord's kangaroo rat (*Dipodomys ordii*) and white-tailed antelope squirrel (*Ammospermophilus leucurus*) may eat the cactus. (NatureServe, 2015)

SPECIES ACCOUNT: *Scutellaria floridana* (Florida skullcap)

Species Taxonomic and Listing Information

Listing Status: Threatened; Southeast Region (R4) (USFWS, 2015) 5/8/1992

Physical Description

A perennial herb, up to 4 dm tall. Stems are solitary or few, mostly erect or ascending. Leaves are opposite, narrowly linear, 2-4 mm long, the margins strongly rolled. Flowers are solitary in the axils of leaves and are bright lavender-blue with a whitish throat. (Based on Kral 1983.) (NatureServe, 2015)

Taxonomy

The rarest of several southeastern species in this genus. (NatureServe, 2015)

Historical Range

See current range/distribution.

Current Range

Known from the Apalachicola region of the Florida panhandle from Liberty, Franklin and Gulf counties. (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Lifespan

Adult: Perennial (USFWS, 2009)

Breeding Season

Adult: Flowering is in May and June (Kral 1983) (USFWS, 2009).

Reproduction Narrative

Adult: The Florida skullcap is a perennial herb with quadrangular stems and opposite leaves. The flowers are solitary, with a bell shaped calyx and bright lavender-blue corolla. The corolla has two lips, the lower one being white in the middle. The stigma sticks out from under the flower hood with the anthers residing inside. Bumblebees, megachilids and halictids are probably important pollinators. Plants flower from mid-April through early July and are most prolific after a fire (USFWS, 2009).

Habitat Type

Adult: Pine-palmetto flatwoods, wet prairies (NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: Low (Inferred from NatureServe, 2015)

Site Fidelity

Adult: High (Inferred from NatureServe, 2015)

Habitat Narrative

Adult: Species inhabits dark, humus rich sands of pine-palmetto flatwoods, wet prairies, and savannahs. (Based on Kral 1983) Seepage slopes. (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species.

Dispersal/Migration**Motility/Mobility**

Adult: Low (inferred from NatureServe, 2015)

Dispersal

Adult: Low (inferred from NatureServe, 2015)

Population Information and Trends**Population Trends:**

Not available

Resiliency:

Moderate (inferred from NatureServe, 2015)

Representation:

Moderate (inferred from NatureServe, 2015)

Redundancy:

Moderate (inferred from NatureServe, 2015)

Number of Populations:

21 - 80 (NatureServe, 2015)

Population Size:

1000 - 2500 individuals (NatureServe, 2015)

Population Narrative:

Reported to respond positively to fire by sprouting and blooming. They stop flowering if not burned at least once every three years. Pollinator visits were infrequent in one study that examined who and when pollinators visited *Scutellaria floridana*. In addition, native bees were the primary pollinator, and factors that effect bee density could affect *S. floridana* density. Based on recent surveys within range and habitat of the species (NatureServe, 2015). Moderate resiliency, representation and redundancy are inferred based on number of populations and individuals as well as relatively large area in which this species is known to occur.

Threats and Stressors

Stressor: Logging (USFWS, 2009)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Pulpwood production in the outer Coastal Plain in the Apalachicola Basin The timber industry in North Florida became well established in the 1850s (FNAI 2005). It started in Franklin County in the 1870s and continued to be a prominent industry until the mid-1990s (Howell and Hartsell 1995). The St. Joe Timberland Company had close to a million acres in timber in the eastern region of the panhandle and they plan to continue to harvest and replant indefinitely. The Company also owned a paper mill in Port St. Joe until it was sold and shut down in 1999. According to J. Huffman (2009, pers. comm. to Negrón-Ortiz) tree farming, i.e., privately owned forest managed (clearcutting, mechanical site preparation, and pine plantations) for timber production, is a primary threat since there still is a mill in Panama City (Bay County) and there are many thousands of acres of tree farms that are smothering out *S. floridana* (as in around the SJBSBP). Therefore, tree farming is a threat to this species (USFWS, 2009).

Stressor: Real estate development (USFWS, 2009)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Urban development continues to threaten Florida skullcap. The St. Joe Timberland Company still owns the former extensive timber land in Northwest Florida, and now focuses on commercial and residential development along roadways and near or within business districts in the region. Urbanized land in Florida, statewide, is projected to double by 2060 along with doubling of the population to 36 million (<http://www.1000friendsofflorida.org/PUBS/2060/01-Northwest-Florida>). Several *S. floridana*'s locations are found along U.S. and state roads. Construction activity may directly kill individual plants or convert habitat to unsuitable space; widening may convert native habitat to managed roadside; and culvert modification may change drainage patterns, which may change seasonal hydrology. Therefore, development, road widening and new roads continue to pose a threat to the species from direct habitat loss to severe habitat modification. As explained under C.1.e, this plant has unique habitat characteristics. Working together with partners on road maintenance activities, we can find possible alternatives that will support or maintain *S. floridana* (USFWS, 2009).

Stressor: Fire suppression (USFWS, 2009)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Suppression of fire continues to threaten the pineland and savanna's flora since fire is essential for the maintenance of flatwoods (Abrahamson and Hartnett 1990). Fire influences community structure and composition (Abrahamson and Hartnett 1990), and with insufficient frequency in longleaf pine communities, a woody midstory quickly develops (Glitzenstein et al. 1995), negatively affecting the understory diversity. Thus, fire suppression continues to be a threat to *S. floridana*. Lack of fire, and subsequent growth of shrubs (particularly encroachment of *Cyrilla racemiflora* L., commonly known as swamp titi) and saplings in the understory, in addition to shading by planted pines, inhibits this species emergence (Negrón-Ortiz, 2008, pers. observ.; FNAI 2008). Declining fire frequency reduces *S. floridana* abundance in areas where it

was previously observed in great quantities (FNAI 2008). In recently burned areas, however, plant emergence is prolific within one year of the fire event (L. Keppner, 2008, pers. comm.). Several studies have shown that frequent prescribed fire regimes are important for maintenance of flatwoods diversity (Hiers et al. 2007). Therefore, frequent prescribed burnings, i.e., 1-3 yr interval, are needed to maintain optimal *S. floridana* populations. At present, the ANF utilizes a 3-5 yr interval burn rotation, Lathrop Bayou uses a 2-7 yr interval, and SJBSBP uses a 2-5 yr interval (USFWS, 2009).

Recovery

Reclassification Criteria:

Not available

Delisting Criteria:

For delisting the species, the goal is to adequately protect and manage 15 populations distributed throughout the species' historical range for 10 years. The plan states that these goals are by necessity only preliminary, and they will be refined (USFWS, 2009).

Recovery Actions:

- Protect and manage these plants outside Apalachicola National Forest (USFWS, 1994).
- Protect populations in Apalachicola National Forest and on other public lands (USFWS, 1994).
- Perform systematic and other studies (USFWS, 1994).
- Garden propagation and reintroduction (USFWS, 1994).
- Manage rights-of-way (USFWS, 1994).

Conservation Measures and Best Management Practices:

- Complete a comprehensive census (e.g., the total number of individuals, number of flowering vs. non-flowering plants, and whether seedling recruitment is occurring) throughout the present distribution including all the historical locations to determine the population numbers and range (USFWS, 2009).
- Determine the levels and distribution of genetic diversity. Knowledge of the levels and distribution of genetic variation in species of conservation concern can be important for the development of efficient and effective conservation practices. For example, the identification of populations with rare alleles or with elevated levels of genetic diversity may lead to greater efforts for their preservation relative to less genetically unique populations (USFWS, 2009).
- Conduct surveys/inventories on potentially new sites. This action can include the use of species distribution modeling methods to initially determine potential sites, with subsequent validation or inspection of the sites for plants (USFWS, 2009).
- Conduct population studies. a. Studies on the viability of dry-stored seeds, the timing of germination, and whether a persistent seed bank is present should be addressed. b. Establish and implement monitoring to address demography. Plants should be monitored several times during the first 12-month period to assess the best monitoring schedule (e.g. annually, biannually). Data from monitoring should be evaluated through 5-year reviews. • Establish permanent plots on protected locations throughout the species' historical range. Priority for populations should include those sites that can be managed with fire. For each plot: o Estimate the density, and abundance of individuals. If possible, investigate basic ecological questions (e.g., pollinators; flowering period; annual

variability in flowering; seed production). o Monitor the effect of fire (if the areas are burned) on density, fecundity, and size structure (USFWS, 2009).

- Manage ROWs Continue fostering conservation practices for utility and highway ROWs with the Forest Service, Talquin Electric, FDOT, and USFWS; a management plan should be developed and implemented (USFWS, 2009).
- The recovery plan should be updated to define objective measurable criteria and better address the five factors (USFWS, 2009).

SPECIES ACCOUNT: *Scutellaria montana* (Large-flowered skullcap)

Species Taxonomic and Listing Information

Listing Status: Threatened (effective 2/13/2002; originally listed as Endangered (effective 7/21/1986); Southeast Region (R4)

Physical Description

A perennial herb with solitary, erect, square stems, usually from 30 to 50 centimeters (cm) tall (Figure 1). The leaves are lanceolate to ovate, on 1 to 2 cm petioles, with blades 5 to 8 cm long and 3 to 5 cm wide, crenate to serrate margins, and hairy on both surfaces. The inflorescence is a terminal, leafy-bracted raceme, with or without paired lateral racemes at the base. The calyx is two-lobed (characteristic of the genus *Scutellaria*). The corolla is relatively large, 2.6 to 3.5 cm long, blue and white, and lacking a fleshy ridge (annulus) within the corolla tube near the top of the calyx. Flowering occurs from mid-May to early June and fruits mature in June and early July. Bridges (1984b) stated, "The genus *Scutellaria* can be easily recognized by its distinctive calyx, with a protrusion, or 'cap' on the upper lobe." Within the genus there are other species with which *Scutellaria montana* could be confused. Bridges (1984b) listed some important characters that a specimen must have to be characterized as *Scutellaria montana*: (1) a terminal inflorescence; (2) a large corolla (at least 2.5 cm long); (3) tapering or truncate leaf bases, never cordate; (4) a midstem with at least some stipitate glandular hairs; (5) no sessile glands on the upper leaf surface, (6) a fairly densely pubescent lower leaf surface, often with glandular hairs; and, (7) a corolla tube lacking an annulus within. (USFWS, 1996)

Historical Range

See Current Range.

Current Range

Ridge and Valley and Cumberland Plateau physiographic provinces in Georgia and Tennessee. This includes the following counties: Georgia Counties: Bartow, Catoosa, Chattooga, Dade, Floyd, Gordon, Murray, Walker, Whitfield; Tennessee Counties: Bledsoe, Hamilton, Marion, Sequatchie. (USFWS, 1996)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Insect pollinated (NatureServe, 2015)

Lifespan

Adult: 8+ years (USFWS, 1996)

Dependency on Other Individuals or Species

Adult: Pollination is principally or exclusively by Hymenoptera of the superfamily Apoidea (bees) (NatureServe, 2015).

Breeding Season

Adult: Collins (unpublished manuscript) summarizes the general life cycle as follows. "Nutlets are released from late June through early July (mid-June to mid-July?), overwinter, and apparently germinate in late March. Mature individuals that have perennated as rootstocks begin shoot growth in late March. By early April, plants are 5-10 cm tall and are pushing through the leaf litter. Anthesis typically begins during mid-May and continues through early June (NatureServe, 2015).

Reproduction Narrative

Adult: The nutlets have a smooth exterior and do not appear to be adapted for any means of long-distance dispersal; they most likely fall a short distance (≤ 5 m) from the parent plant due to explosion of mint capsule. They could be washed downslope by water, or carried by small animals, but have only remote chances of extra-population dispersal (Collins, unpublished manuscript).; The life history of *Scutellaria montana* has not been specifically studied, and relatively little of it is known. Mature nutlets were not even seen until about 1983 by workers at Shorter College, thus indicating the early stage of work on the biology of the species. Collins (unpublished manuscript) summarizes the general life cycle as follows. "Nutlets are released from late June through early July (mid-June to mid-July?), overwinter, and apparently germinate in late March. Mature individuals that have perennated as rootstocks begin shoot growth in late March. By early April, plants are 5-10 cm tall and are pushing through the leaf litter. Anthesis typically begins during mid-May and continues through early June. Pollination is principally or exclusively by Hymenoptera of the superfamily Apoidea (bees). The corolla shrivels somewhat and falls from the calyx one or two days after pollination, presumably within 24 hours of fertilization. The calyx closes around the developing fruit immediately after corolla abscission. During the next two to four weeks, the calyx and the enclosed nutlets enlarge and mature. The calyx then dehisces by the loss of the upper lip, and the nutlets are released...A different course is followed if fertilization does not occur. The corolla shrivels markedly and may or may not remain united to the calyx. The entire calyx, still open at the mouth, falls leaving the pedicel bare." Workers at Shorter College are apparently conducting demographic and autecological studies on *S. montana*. Preliminary results indicate that less than 40 % of the flowers produce mature nutlets. Collins (1976) found that in other species of this group of *Scutellaria* studied, 76 to 93% of the flowers form nutlets. This lowered rate of fruit production, and the often few-flowered inflorescences, combine to give *S. montana* a reproductive capacity less than many of its relatives. The nutlets have a smooth exterior and do not appear to be adapted for any means of long-distance dispersal; they most likely fall a short distance (≤ 5 m) from the parent plant due to explosion of mint capsule. They could be washed downslope by water, or carried by small animals, but have only remote chances of extra-population dispersal. However, as Collins (unpublished manuscript) notes, this cannot alone explain its rarity, in that all of its more widespread relatives have virtually identical seed dispersal. Conditions necessary for germination and establishment are still unknown, although the Marshall Forest population has variously been described as from 500 to 1300 plants. This may represent actual population fluctuations. *Scutellaria* species in the group to which *S. montana* belongs generally occur at fairly low density, scattered seemingly at random over fairly large areas of forest. Large colonies are seldom found, and individual plants are usually widely spaced and easily distinguishable. *S. montana* may sometimes occur in tighter colonies than many of its relatives, as indicated by its

clumped distribution at Marshall Forest. In the largest Tennessee population (ca. 5000 individuals), the plants are spaced at approximately 6" intervals (Hawks 1985b), giving a density of 4/sq ft, or ca. 40/sq meter. In the smaller Tennessee populations, however, density is 1 plant per sq meter or less, and individuals can be separated by 50m or more from the nearest *S. montana* (Bridges 1983, 1984; Bridges and Hawks 1984) Collins (unpublished manuscript) indicates that *S. montana* was only known to occur in minimally disturbed sites with a stable habitat. This would indicate it to be a plant of late-successional or climax forests. In Tennessee, some of the sites have clearly younger trees and more recent disturbances than the above would suggest. One site has trees generally 30-40 years old; most sites average trees less than 60 years old. The largest site is in a relatively old (50-60 yrs ?) forest, but is unique in that there had been a gentle ground fire about three years before the discovery of *S. montana* at the site. While *S. montana* will not, or has not been observed, to grow in early successional pine stands, it will occupy relatively mature stands with varying degrees of disturbances. Thus it can be considered a mid-to-late successional species which probably persists in, but is not restricted to, mature or climax forests. This is the typical situation for most forest herbs of the region.; BIOTIC; Hymenoptera (NatureServe, 2015). USFWS (1996) notes that this species can live for more than eight years.

Habitat Type

Adult: Oak-pine forests (NatureServe, 2015)

Environmental Specificity

Adult: Narrow. Specialist or community with key requirements common (NatureServe, 2015).

Tolerance Ranges/Thresholds

Adult: Low (NatureServe, 2015)

Site Fidelity

Adult: Moderate (NatureServe, 2015)

Habitat Narrative

Adult: SUMMARY: *Scutellaria montana* is typically found in rocky, shallow soils, and on submesic to xeric, well-drained, slightly acidic oak-pine forests in the Ridge and Valley and Cumberland Plateau provinces of Northwestern Georgia and adjacent southeastern Tennessee. In Georgia, it has been reported from elevations of 189 to 265 m on steep, lower slopes of all aspects. In Tennessee, the elevation range of the species is much greater, with one concentration of sites at 200 to 320 m on slightly sloping to steep lower to mid-slopes on the Upper Mississippian Pennington Formation. The other concentration is at 400 to 540 m on gentle to somewhat steep slopes of small ravines near the escarpment on the Cumberland Plateau, on Lower Pennsylvanian sandstone and shale (Bridges 1984). The soil is always rocky and somewhat shallow, with plants rooted in deeper soil between boulders, or on as little as 3 cm of soil over rocks (Collins, unpublished manuscript). The species appears to have little specific habitat preference, occurring in localized areas within its known range. It is unclear what limits the northern edge of its distribution (NatureServe, 2015).

Dispersal/Migration**Motility/Mobility**

Adult: Low (NatureServe, 2015)

Dispersal

Adult: Low (NatureServe, 2015)

Dispersal/Migration Narrative

Adult: The nutlets have a smooth exterior and do not appear to be adapted for any means of long-distance dispersal; they most likely fall a short distance (= 5 m) from the parent plant due to explosion of mint capsule. They could be washed downslope by water, or carried by small animals, but have only remote chances of extra population dispersal (Collins, unpublished manuscript) (NatureServe, 2015).

Population Information and Trends**Population Trends:**

Short-term trend: Declining (NatureServe, 2015).

Number of Populations:

TN: 28 populations (164 occurrences). GA: 52 occurrences (population distribution is under evaluation) (USFWS, 2015)

Population Size:

10,000 - 100,000 total individuals (NatureServe, 2015)

Population Narrative:

Appears to be self-maintaining in mature forests. However, at some sites, it is unclear whether the species is reproducing, as seedlings are infrequently detected. More than 50,000 individuals known (Fish and Wildlife Service 2002). Plants are fairly widely scattered, even within occurrences; often, additional search effort at the same site results in the discovery of additional plants. Some occurrences contain over 500 plants, but others have only 5 or 6. Many of the Georgia occurrences are small. Suitable habitat is abundant on the escarpment of the Cumberland Plateau in forests that are no longer logged or converted to pine monoculture. Suitable habitat also exists in Northern Alabama. 205 occurrences are currently mapped and considered extant, but delineating separate occurrences for this species is challenging because it occurs as small clumps that are relatively close together. Efforts are now underway to re-delineate occurrences, resulting in many closely-spaced small occurrences being lumped into fewer large occurrences with better viability ranks. Nevertheless, additional search effort for this species continues to result in the discovery of additional occurrences. Short-term Trend Comments: Areas containing two subpopulations that were declining were closed to the public (USFWS 2009). Transplantation was done at one of these subpopulations but has not yet been evaluated (USFWS 2009). Long-term Trend Comments: Three historical populations were extirpated by extensive recreational and residential development. Moderate resiliency, redundancy and representation are based on numbers of populations and individuals as well as its relatively wide-spread geography (NatureServe, 2015).

Threats and Stressors

Stressor: Logging (USFWS, 2015)

Exposure:**Response:****Consequence:** Loss of habitat**Narrative:** A recent status survey for *S. montana* in Tennessee identified the following potential threats to the species and its habitat: 1. Removal of mature forest by logging or development on private lands (USFWS, 2015).**Stressor:** ORV traffic (USFWS, 2015)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:** 2. ORV traffic on undesignated trails (USFWS, 2015)**Stressor:** Invasive exotic plants (USFWS, 2015)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:** 3. Invasive exotic plants (USFWS, 2015).**Stressor:** Trail construction (USFWS, 2015)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:** 4. Trail construction and maintenance on public and conservation lands (USFWS, 2015).**Stressor:** Power line maintenance (USFWS, 2015)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:** 5. Power line maintenance including the use of herbicide, manual, and mechanical treatments for vegetation management (USFWS, 2015).**Stressor:** Wildfire suppression (USFWS, 2015)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:** 6. Wildfire suppression involving construction of large fire lines (USFWS, 2015).**Stressor:** Recreational impacts (USFWS, 2015)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:** 7. Recreational impacts including unauthorized hiking, camping and picnicking on public and conservation lands (USFWS, 2015).**Stressor:** Mineral mining (USFWS, 2015)**Exposure:**

Response:**Consequence:** Loss of habitat**Narrative:** 8. Mineral mining and quarrying**Recovery****Reclassification Criteria:**

Not applicable.

Delisting Criteria:

Scutellaria montana (large-flowered skullcap) will be considered for delisting when there are 15 adequately protected and managed self-sustaining populations. Populations must be distributed throughout the range and must be maintained for 10 years. A population will be considered adequately protected when it is legally protected and all needed active management is provided. A population will be considered “self-sustaining” if monitoring data support the conclusion that it is reproducing successfully and is stable or increasing in size. The minimum number of individuals necessary for a self-sustaining population should be considered to be at least 100 until otherwise determined by demographic studies (USFWS, 1996).

Recovery Actions:

- Search for additional populations of Scutellaria montana and prioritize sites for protection. Since the species was listed, several additional populations have been discovered through thorough inventories of specific areas. Without a focused effort, the potential for increasing the known number of populations is slim. The ability to prioritize and protect the highest-quality sites will depend on having complete information on extant populations of the species. (USFWS, 1996)
- Protect known populations. Of the 17 populations currently known, eight are protected through public ownership or by the Tennessee River Gorge Trust and The Nature Conservancy. Eight populations, including the second and third largest, are privately owned. One population in Hamilton County, Tennessee, occurs on public and private land. The protected sites need management plans in order to effectively protect Scutellaria montana. (USFWS, 1996)
- Conduct long-term monitoring of known populations. All populations should be monitored annually for the first 5 years to check the number of individuals and to determine threats to the populations. For the larger protected populations, this should include permanent plots. (USFWS, 1996)
- Determine the effects of potential management techniques. Observations by individuals in the field can help direct studies to document the effects of potential management techniques on populations of S. montana. This work should incorporate knowledge about site management, disturbance history, and forest composition. (USFWS, 1996)
- Examine genetic diversity within and between populations. A study of the species’ genetic diversity should be conducted, and populations that are genetically diverse should be identified. This information should then be used to help set priorities for the preservation of genetic diversity. Information on genetic variability will help determine the number of populations and population size necessary to successfully maintain the species. (USFWS, 1996)

- Maintain plants and seeds ex situ. To protect against the loss of a population, attempts at propagation, using cuttings, should be attempted. In addition, seeds should be maintained at a long-term seed storage facility. (USFWS, 1996)
- Recommendation for Future Action from 2015 5-Year Review: Continue long-term monitoring using standardized protocols across the geographic range of *S. montana* to provide a basis for establishing whether populations exhibit cyclical patterns of demographic variability and for assessing population responses to local and regional environmental conditions. (USFWS, 2015)
- Recommendation for Future Action from 2015 5-Year Review: Work with TDEC, TVA, UT-Chattanooga, TNARNG, TN River Gorge Trust, TDF, NPS, and others to develop plan for collecting current census data, where needed in Tennessee, to evaluate long-term persistence and stability of populations for which recent data are lacking. Appendix B includes a draft list of EOs where census data should be collected. Georgia DNR will be collecting census data from populations in Georgia during 2014. (USFWS, 2015)
- Recommendation for Future Action from 2015 5-Year Review: Establish cooperative management agreements with landowners for protected occurrences and populations to ensure that conservation efforts for the species would continue following delisting of the species. (USFWS, 2015)
- Recommendation for Future Action from 2015 5-Year Review: Develop a post-delisting monitoring plan. (USFWS, 2015)

SPECIES ACCOUNT: *Senecio layneae* (Layne's butterweed (=Packera))

Species Taxonomic and Listing Information

Listing Status: Threatened; 11/18/1996; Pacific Southwest (R8)

Physical Description

A perennial herb of the aster family (Asteraceae) that sprouts from a rootstock. Its mostly basal lance-shaped leaves are 8 to 24 centimeters (3 to 10 inches) long. The several flower heads are 4 to 6 centimeters (2 to 3 inches) wide. Each flower head has 5 to 8 orange-yellow ray flowers (the flowers usually located on the edge of the inflorescence of members of the aster family) and numerous yellow disk flowers (flowers in the center portion of an inflorescence of a member of the aster family). *Senecio aronicoides* (rayless groundsel), *S. flaccidus* var. *douglasii* (Douglas' groundsel), and *S. vulgaris* (common groundsel) also occur on gabbro-derived soils in the Pine Hill area (Wilson 1986). These *Senecio* species can variously be differentiated from *S. layneae* by a combination of life form, type of flower, number of flower heads, flower color, and pubescence. (USFWS, 2002)

Taxonomy

Kate Layne-Curran collected the type specimen for *Senecio layneae* in May 1883 from El Dorado County, California, on Sweetwater Creek, not far from Folsom. Edward L. Greene first described *S. layneae* in 1883 (Greene 1883). Although Asa Gray (1884) reduced *S. layneae* to a variety of *S. fastigiatus*, it currently is known as *S. layneae* (Barkley 1993). *Senecio layneae* is a member of the aureoid group of *Senecio* that is united by most of the following characters: perennial herbs arising from creeping rootstocks or a stout caudex; well developed basal leaves with cauline (arising from the upper part of the stem) leaves progressively reduced upward; leaf margins without callose denticles (hard teeth); thin branching fibrous roots; and haploid chromosome numbers 22 or 23, or derived from these numbers (Barkley 1988). The aureoid group of *Senecio* is now known by some as the genus *Packera*. The type population of *S. layneae* is now thought to be extirpated due to inundation by Folsom Lake. (USFWS, 2002) In the second edition of the Jepson Manual, the genus to which Layne's butterweed belongs was changed from *Senecio* to *Packera* (Baldwin et al. 2012). (USFWS, 2019)

Historical Range

In western El Dorado County that includes the Pine Hill formation and adjacent serpentine; a few other colonies occur in the Eldorado National Forest in El Dorado County, California. (USFWS, 2002)

Current Range

On the Pine Hill formation in western El Dorado County, California; a few known isolated occurrences in El Dorado, Nevada and/or Tuolumne Counties. (USFWS, 2019)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Insect pollinated (USFWS, 2002)

Breeding Season

Adult: Senecio layneae is a perennial herb that flowers from April to July (USFWS, 2019).

Other Reproductive Information

Adult: It is unclear whether the species has the ability to resprout from its caudex after disturbance (Marsh and Ayres 2002). Although the seed of this species seems to germinate in a wide range of soil conditions and adult plants grow in a wide range of slope, aspect, light and elevation levels (Williams 2014), it appears to have little or no persistent seedbank, a short seed dispersal distance (Williams 2014), and is also shade intolerant (Baad and Hanna 1987). It is likely the species functions as a fugitive species, depending on a short fire return interval to create a regeneration niche and a supply of the short-lived seed from a nearby reproducing population to colonize the patch (Marsh and Ayres 2002). Little else is known about reproductive biology, ecology, and demography of the species. (USFWS, 2019)

Reproduction Narrative

Adult: Senecio layneae is a perennial herb that flowers from April to July (California Native Plant Society 1994). Twenty-two plants from Cameron Park were used to determine whether the predominant breeding system was self-fertilizing or outcrossing (mating not involving inbreeding). Pollinators were excluded from the flower heads with fine mesh fabric. Open pollinated flower heads had an 8-fold increase in potentially viable seeds over flower heads where the pollinators had been excluded, indicating that the predominant breeding system for Senecio layneae is outcrossing (Marsh 2000) (USFWS, 2002).

Habitat Type

Adult: Chapparral (NatureServe, 2015)

Habitat Narrative

Adult: In addition to occurring on gabbro soils, Layne's butterweed is also known to occur on serpentine soils. All serpentine sites, with the possible exception of the one in Shingle Springs, continue to support Layne's butterweed. Persistence in at least two separate habitat/soil types benefits these species by increasing their degree of representation. (USFWS, 2019)

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Stable to increasing (USFWS, 2019)

Number of Populations:

45 populations; 6 extant; 36 presumed extant; 3 possibly extirpated (USFWS, 2019)

Population Size:

Greater than 9,100 individuals (USFWS, 2019)

Population Narrative:

In general, a direct comparison of species abundance now versus at the time of listing is not possible due mainly to lack of abundance data at the time of listing. Contributing to that challenge is that there is not consistent current abundance data for many of the populations, especially those on private lands. However, given the increase in the number of populations of Layne's butterweed since listing, it is likely that overall abundance has increased for those species (CNDDDB 2018). (USFWS, 2019)

Threats and Stressors

Stressor: Habitat loss and fragmentation (USFWS, 2002)

Exposure:

Response:

Consequence:

Narrative: Historically, gold rush activities and clearing for agriculture reduced and fragmented habitat in western El Dorado County. More recently, vegetation on the Pine Hill formation has changed significantly due to commercial and residential development, road construction, and fragmentation. Commercial or residential developments have partially or completely destroyed occurrences of the species (California Natural Diversity Data Base 1998; California Department of Fish and Game 1990a, 1990b; G. Clark in litt. 1993). Proposed residential or commercial development within the Pine Hill formation threatens most of the remaining sites within the Pine Hill formation and adjacent serpentine in western El Dorado County, and either directly or indirectly will adversely affect most of the range of this species. Additionally, habitat fragments may be too small to support viable populations of animals serving as pollinators or seed dispersal agents for the species. Edge effects, which occur at the interfaces of any two or more habitat types, typically increase with habitat fragmentation and are more pronounced for natural communities bordered by human disturbances (USFWS, 2002).

Stressor: Altered fire regime (USFWS, 2002)

Exposure:

Response:

Consequence:

Narrative: The primary overall threat is encroachment of native vegetation due to succession, even on lands in conservation ownership, in the absence of the natural fire regime. The long fire return interval due to fire suppression is preventing the formation of necessary clearings for Layne's butterweed establishment and possibly the scarification of seeds needed for germination. (USFWS, 2019a)

Stressor: Land use activities (USFWS, 2002)

Exposure:

Response:

Consequence:

Narrative: The increasing number of people and changes in land uses will continue to place an increasing strain on undeveloped areas through activities such as off-road vehicle traffic, unauthorized garbage dumping, and changes in the pattern of wildfires. Horse paddocking in rural residential areas within the central and northern portions of the Pine Hill formation threatens this species. The horses, when confined, severely graze or trample most available

vegetation. The herbaceous gabbro plants are especially likely to be grazed (J. Van Ess pers. comm. 1993). (USFWS, 2002)

Stressor: Invasive nonnative plants (USFWS, 2019)

Exposure:

Response:

Consequence:

Narrative: Invasive plants continue to present a minor threat to gabbro plant species. Populations within the Pine Hill Preserve are not significantly threatened by invasive plants and any small infestations identified are largely reduced or eliminated by mechanical means (BLM 2008). However, a population of Layne's butterweed at BLM's Red Hills Kanaka Point property in Tuolumne County is threatened by yellow starthistle (*Centaurea solstitialis*) and distaff thistle (*Carthamus lanatus*) (B. Brenneman, in litt. 2018b). (USFWS, 2019)

Recovery

Reclassification Criteria:

Not applicable.

Delisting Criteria:

1. Secure and protect specified recovery areas from incompatible uses: Populations representing the range of the species including: (a) Cameron Park preserve south of Highway 50, (b) Cameron Park preserve north of Highway 50, (c) Pine Hill preserve, (d) Penny Lane preserve, (e) Salmon Falls/Martel Creek preserve, (f) occupied habitat on BLM lands in Yuba and Tuolumne Counties, and (g) occupied habitat on the Eldorado National Forest; along with adjacent unoccupied habitat and a 150-meter (500-foot) buffer. (USFWS, 2002)
2. Management plan approved and implemented for recovery areas, including survival and recovery of the species as the objective: For all populations and any occupied or unoccupied habitat identified as necessary for survival and recovery (see previous column) (USFWS, 2002).
3. Monitoring in all recommended preserves shows: (a) Stable or increasing with evidence of natural recruitment for a period of 60 years that includes normal disturbance. (b) Habitat monitoring of recommended preserves shows a mosaic of multiage class stands and habitat fragmentation has not appreciably increased (less than 5 percent) within any preserves over current (2000) conditions. (c) Spatially and temporally, the establishment of occurrences must be at least 10 percent greater than the extirpation of occurrences. (USFWS, 2002)
4. Other actions: (a) Ameliorate or eliminate threats (see Appendix H); (aa) Study importance of fire for management; (b) seeds of disjunct populations stored in at least two Center for Plant Conservation certified facilities. (c) Maintain metapopulation dynamics of at least 1 very large, 1 large, 7 medium, and 24 small occurrences throughout the Pine Hill formation; of at least 1 large, 2 medium and 5 small in western El Dorado County; of at least 2 medium and 4 small in Tuolumne County; and of at least 2 small in Yuba County. (USFWS, 2002)

Recovery Actions:

- 1. Develop and implement a cooperative program and participation plan. A cooperative program is needed to coordinate local public and private land use planning with State and

- Federal land use and recovery planning for gabbro species. A cooperative program needs to be developed focusing on western El Dorado County. A participation plan produced from this program will increase the chances of recovery for listed species. (USFWS, 2002)
- 2. Protect and secure existing populations. Natural lands that contain this species need to be protected in perpetuity. Protection of these lands includes identification and minimization of threats in perpetuity and application of appropriate and adaptive management (see Task 3) to ensure species survival and recovery. Natural lands that need protection can be categorized into two types: (1) blocks of land that contain occupied or potential habitat for two or more this species and (2) blocks of land that contain occupied or potential habitat for one this species. All potential preserve areas should be evaluated based on current mapping information and ground-truthed prior to purchase to confirm their value for recovery. (USFWS, 2002)
 - 3. Manage Habitat Managing habitat is essential to the recovery of the listed species. Habitat management includes preparation and implementation of management plans for all areas inhabited by special status species being proposed for preservation, and periodic monitoring of populations in each of these areas. Within western El Dorado County, a multi-constituent committee should be formed to oversee the management of preserves located on the Pine Hill formation. The preserve management committee should include, at a minimum, representatives from the California Department of Fish and Game, U.S. Fish and Wildlife Service, Bureau of Land Management, El Dorado County, California Department of Forestry and Fire Protection, California Native Plant Society, American River Conservancy, and a private landowner representative. (USFWS, 2002)
 - 4. Survey historical locations and other potential habitat where this species may occur. Recovery of listed species may often require relocating historic populations or locating new populations of these species. Historical locations should be surveyed to determine whether suitable habitat remains, the species persists at the sites, and/or the sites may be suitable for repatriation. Suitability of historical locations for repatriation would depend upon: (1) whether potential habitat exists, (2) the presence and magnitude of threats, and (3) whether the sites can be secured and managed for the long-term protection of the species. Surveys should also include other potential gabbro or serpentine habitat to determine whether undiscovered populations may exist. If new populations are discovered, they need to be protected and managed as discussed above. During the surveys, potential introduction sites should also be identified. (USFWS, 2002)
 - 5. Conduct necessary biological research and use results to guide recovery/conservation efforts. - Develop propagation techniques for listed plant species for which enhancement, repatriation, or introductions would be appropriate. Geographic area research is outlined in the Recovery Plan. Species-specific research is described as follows: Habitat Survey Research: Serpentine soil areas off the Pine Hill formation in El Dorado County; Serpentine and Gabbro areas in Nevada County; Serpentine near Red Hills in Tuolumne . Reproduction and Demography Research: Including determining limiting life stages, seed production and survival in soil to determine appropriate fire return period, reproductive studies identifying pollinators, seed germination studies. . Genetics research. . Other Research Needs: Influence of disturbance and fire on seedling establishment; effects of grazing; metapopulation analysis; effects of fire; fire management techniques; determine efficacy of other types of disturbance regimes for species and habitat management; feasibility of habitat restoration/ enhancement. . Management Actions Needed: Disturbance/ burning; general surveys; baseline monitoring; monitoring for trends of populations, success of management actions and threats at all populations identified for protection; monitoring for

- habitat fragmentation, major shifts in vegetation type, and tracking of occurrence establishment, and extirpation; seed banking for disjunct populations. (USFWS, 2002)
- 6. Undertake artificial enhancement, repatriation, or introduction efforts where necessary. Where it is deemed necessary, artificial enhancement, repatriation, or introduction efforts for sensitive plants should be undertaken. Prior to repatriation or introduction of sensitive plants, genetics studies are needed (see Task 5) to ensure that new populations will not disrupt unique local gene complexes. Plant repatriation or introduction efforts should be undertaken using collected seeds or plant propagules. (USFWS, 2002)
 - 7. Determine possible prescribed burning management strategies and incorporate the strategies into the management plans (Priority 1). Possible prescribed burning management strategies need to be evaluated, peer reviewed, and incorporated into management plans. (USFWS, 2002)
 - 8. Perform metapopulation-type analyses for this species (Priority 2). The results of a metapopulation-type analysis may be useful in clarifying uncertainties, data needs, and research, management priorities, and delisting criteria. Metapopulation-type analyses should be based on the results of monitoring and research. (USFWS, 2002)

Conservation Measures and Best Management Practices:

- Dedicate more resources toward the investigation of best management approaches for the Pine Hill listed plant species, even at the cost of a temporary hiatus in land acquisition efforts. Investigation should be made into fire-related and non-fire related methods of disturbance to maintain listed plant species habitat. (USFWS, 2019)
- Once the best management strategy (in terms of technique, frequency, timing, and intensity) is determined at each site, implement these management practices to achieve and maintain a habitat mosaic that enables the attainment of recovery criteria for the species.

SPECIES ACCOUNT: *Serianthes nelsonii* (Hayun lagu (=Guam), Tronkon guafi (Rota)))

Species Taxonomic and Listing Information

Listing Status: Endangered; 02/18/1987; Pacific Region (R1) (USFWS, 2016)

Physical Description

Serianthes nelsonii is a large tree in the pea family (Fabaceae, subfamily Mimosoideae). Adult trees can reach heights over 30 m (98 ft) and diameters over 1.5 m (4 ft) (USFWS 1994, p. 11). Its bark is smooth and light brown in color. Fine rusty hairs cover the flowers, seed pods, and newer vegetation growth. Leaves are doubly pinnate with many pairs of leaflets. Flowers are brush-like with pink and white coloration, and fruits are hard, dry, brown pods (Stone 1970, p. 304). Seedlings closely resemble those of a small introduced tree, *Leucaena leucocephala* (tangantangan), but can be discerned by the fine pubescence on new leaf buds (USFWS 1994, p. 6).

Current Range

Serianthes nelsonii is endemic to the islands of Guam and Rota (USFWS 1987, p. 4907). Recorded specimens on Guam were mostly from northern limestone forests, but a few trees were recorded in southern clay soils (USFWS 1994, p. 8).

Critical Habitat Designated

Yes;

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: What little is known about pollination, seed dispersal, phenology, flowering, and fruiting for this species comes mainly from incidental reports (USFWS 1994, p. 11). Fruiting occurs throughout the year, as seed pods have been observed during all months of the year (USFWS 1994, pp. 11-13). Similarly, flowering has been recorded during all months of the year, with one report (Schreiner and Nafus 1991, as cited in USFWS 1994, p. 11) reporting the highest proportion of branches with flowers in May and June. This report also indicated leaf production throughout the year with declines during the dry season from January to June. Age of reproduction in the wild is also unknown, but flowers and pods have been observed on cultivated trees as young as 10 years old (USFWS 1994, p. 13). *Serianthes nelsonii*, being a large, canopy tree species, provides habitat for a number of smaller species. This species supports a diverse community of arthropods including predator species such as spiders and mantids that may control other potentially problematic insect populations (Wiles et al. 1996, p. 233). *S. nelsonii* also hosts a variety of epiphytes including ferns, orchids, and other plants such as *Ficus* sp., and *Freycinetia reineckeii* (Wiles et al. 1996, p. 233-234).

Habitat Type

Adult: Limestone forests

Habitat Narrative

Adult: *Serianthes nelsonii* is endemic to the islands of Guam and Rota (USFWS 1987, p. 4907). Recorded specimens on Guam were mostly from northern limestone forests, but a few trees were recorded in southern clay soils (USFWS 1994, p. 8). Currently, the last remaining wild adult tree on Guam is located at NWF, AAFB in northern Guam. A new fence was constructed to exclude ungulates in 2012 by AAFB, the *Serianthes* tree and seedlings are monitored monthly by DoD. DoD has conducted research on limiting factors for seedlings, fallen seeds collected and stored for future use. In 2014, 31 *S. nelsonii* seedlings supplied to the Service by JRM were planted at the GNWR in northern Guam (Demeulenaere et al. 2015, p. 4). The 31 seedlings are maintained with 2 previously outplanted saplings on the GNWR. On AAFB, one outplanted sapling is located in the Tarague Basin. The history of *S. nelsonii*'s abundance and distribution on Rota is poorly known (USFWS 1994, p. 7), but surveys in 1994 estimated 121 adult trees with very little regeneration (Wiles et al. 1996, p. 232). Current estimates for Rota are 40 to 50 wild adult trees with little to no regeneration (J. Manglona, CNMI DLNR, pers. comm. 2015). *Serianthes nelsonii* is recorded mainly from limestone soils, with a few historical occurrences in clay soils in Guam (USFWS 1994, p. 8). Most of the adult trees in Rota occur on or near steep limestone cliffsides, and the last wild adult tree in Guam is located in rugged limestone karst habitat at NWF.

Dispersal/Migration***Population Information and Trends*****Population Size:**

50

Population Narrative:

The total wild population of *Serianthes nelsonii* is estimated to be 50 adult trees, with almost all of the population occurring in Rota, and a single wild adult tree in Guam. In addition, there are outplanted occurrences on each island, all younger than 20 years of age. Seedling propagation and outplanting on Rota have been ongoing with limited success over the past 20 years, mainly in the Isang area in southern Rota, and between the main villages of Songsong and Sinapalo. Approximately 10 outplanted individuals in Rota have survived to a reproductive age (J. Manglona, CNMI DLNR, pers. comm. 2015). Twenty seedlings were outplanted in 1999 in the Tarague Basin, on AAFB in Guam (M. Marutani, University of Guam, pers. comm. 2015). To date, only one of these saplings has survived (AAFB 2015), but has not produced any seed pods (A. Gawel, USFWS, pers. obs. 2014). In 2009, approximately 30 seedlings were planted at the GNWR; all but 5 have survived (J. Cruce, USFWS, pers. comm. 2015). In 2014, 31 seedlings were donated to GNWR by JRM and outplanted and are being maintained by the Guam Plant Extinction Prevention Program (Demeulenaere 2015, p. 4) and GNWR staff. Recent *Serianthes nelsonii* recovery efforts on Guam and Rota have been dependent on funding, the amount of available propagated seedlings in nurseries, and the seedling to adult survival rates in the wild. In early 2015, the total number of nursery seedlings and saplings in Guam and Rota was estimated at 300 individuals, with approximately 200 in Guam nurseries. However, this estimation may change rapidly if outplanting seedling survival is low. Recent studies from AAFB indicated that although many seeds fall from the Guam adult tree and many of the seeds germinate, there is very limited survival under the mother tree (AAFB 2015). Both islands'

populations have constant regeneration of wild seedlings that are several days to several months old. However, these seedlings experience incredibly high turn-over, and in recent decades, none have been known to survive to adulthood in the wild (J. Manglona, CNMI DLNR, pers. comm. 2015; AAFB 2015, pp. 4-5). Although wild seedling survival is bleak, progress has been made on increasing the likelihood of survival of outplanted individuals with new methods of insect control and exclusion, given insect herbivory and damage are the major cause of outplanted seedling early mortality (E. Demeulenare, GPEPP, pers. comm. 2015). Continued demographic decline of wild population on Rota. The decline anticipated by Wiles (1998) continues. Recent field reviews on Rota (AnnMarie Gawel, USFWS, pers. comm. 2016a & 2016b) confirmed an apparent large dieoff among the historic adult trees, relative to the approximately 120 adult trees inventoried in 1992 (Wiles et al 1996). Also, there was no regeneration (no seedlings recorded). The following is a more specific breakdown, organized by Wiles' original subpopulation numbers, all from Ann Marie Gawel, USFWS (pers. comm. 2016a & 2016b), except for subpopulations 1, 6, and 14.

- o Subpopulation 1: Of the 15 adult trees recorded in 1992, 11 remain alive (McBride field notes and GPS points, October 2016).
- o Subpopulations 2-5 and 7-10: Of the 63 adult trees in this area in 1992, only 19 were found alive in June 2016, while another 20+ large stumps and down logs (none recent) may represent some of the prior *Serianthes* lost there.
- o Subpopulation 6: Of the 4 adult trees recorded in 1992, none were found alive in this area; a large diameter snag and larger down log may represent two of the prior trees recorded here (McBride field notes and GPS points, January 2017).
- o Subpopulations 11-13: One live tree, with a full crown, was observed from the road in January 2017; Rota Forestry indicated that the rest of the 28 live trees in this area in 1992 had previously died (McBride field notes and GPS points, January 2017).
- o Subpopulation 14: Of the 8 adult trees recorded in 1992, one remains alive as of October 2016. However, this last survivor is in very poor condition, with less than 5% live crown (McBride field notes, October 2016).
- o Subpopulations 15-16: Rota Forestry observed that the 3 live *Serianthes* recorded here in 1992 have all subsequently died.

3 Rangewide demographic decline. In aggregate, including the one surviving adult *Serianthes* on Guam, the current numbers represent a 73% decline among these wild *Serianthes* trees from the 1992 baseline— from the 122 documented then to 33 currently known (USFWS, 2017). Reduction in geographic range of wild population on Rota. Along with the demographic decline, there has also been significant reduction in the known range of the wild population. At the time of the 1992 inventory, the species range on Rota could be described as largely surrounding the Mount Sabana massif, which dominates the west half of the island— a distance of nearly 8 km. Following the loss of Wiles' 1992 subpopulations in the Palii area (#'s 15 & 16), that distance has already been reduced by half to just under 4 km. Other outlying subpopulations (#14, in Lupok area, and #'s 11-13, in the Isang area) have greatly declined, down to a single surviving individual in each location at last report — representing a 93% reduction of the 36 total individuals recorded among these subpopulations in 1992. If these outlying populations are lost, the Rota population will be restricted to a 1.6 km area on the southwestern flank of Mount Sabana. Whether or not such continuing collapse transpires, 94% of today's remaining known wild *Serianthes* population on Rota survive within an area of less than 100 hectares. With this reduced range, the remaining population is highly vulnerable to large- to mid-scale disturbance events, whether of anthropogenic, climatic, or other origin (USFWS, 2017). On Guam, the lone adult tree at Ritidian continues to survive in a deteriorated condition, with no persisting natural regeneration to sustain a wild population. The one remaining mature *Serianthes* tree survives, despite evidence of its compromised condition (reduced crown volume; conks and visibly decayed wood showing development of *Ganoderma* fungus). This tree, including its flowers, fruits, seeds, and surrounding seedlings, were monitored

on a monthly basis through 2016. The prevalence of the fungus *Phellinus noxious* in other trees in close proximity this tree is a concern. While it is not established if the *Phellinus noxious* directly affects *Serianthes*, the fungus can be a lethal pathogen for several native forest tree species (AAFB 2016). Several researchers have monitored and studied the fate of seedlings under the crown. Marler and Cascasan (2015) studied the survival of seedlings germinating beneath this tree, documenting both their high recruitment potential (an average of >1 seedling emerging per day throughout 2013) and inability to survive to the juvenile stage. Over half the seedlings died within the first month after sprouting, while essentially all had died by 200 days post-emergence. During 2014-15, Marler and Musser (2015) monitored the survival and fate of 488 seedlings under the *Ritidian* tree, evaluating four different treatments as mitigations for potential seedling stressors. While insecticide, fertilizer, and supplemental lighting treatments did not meaningfully extend the longevity of test seedlings, those treated with a fungicide (Ridomil Gold) survived more than twice as long as the untreated control seedlings. This suggests that root pathogens may be significant agents of mortality, in addition to the previously-recognized problems of insect and ungulate herbivory. The capacity for *Serianthes* to regulate the soil's 4 biogeochemistry beneath its canopy was also studied; in contrast to more distant samples, those taken from within the litterfall area beneath the tree had significantly more nitrogen, carbon, calcium, magnesium, copper, and zinc; and less iron (Naval Facilities Marianas 2015). At the Guam National Wildlife Refuge, Deregnier (USFWS, pers. comm. 2016a) observed a range of insect herbivory agents, among which mealybugs have been the most problematic; their attacks on both foliage and (particularly) roots of *Serianthes* have caused 10 of 12 seedling deaths to date. Also on the Refuge, Deregnier found that outplanted trees seemed to do best in forest-gap settings: that is, with relatively high light and humidity, but low wind exposure (Ryan Deregnier, USFWS, pers. comm. 2016a). On both Guam and Rota, the high rate of loss of the remaining wild trees — together with the failure of seedlings to persist — emphasizes the importance both of studies of the mechanisms of decline in the wild populations, as well as into propagation methods to sustain the species through the near to mid-term (USFWS, 2017). In addition to these in situ studies, off-site research on Guam has contributed knowledge toward successful propagation practices and establishment of horticultural protocols. Marler et al. (2015) evaluated seedling emergence in varying shade conditions, finding that both percentage and velocity of seedling emergence for *Serianthes* were maximized in deep shade. They also found that seeds of *Serianthes* are not very short-lived, with germination observed after nine months of storage at ambient temperature and relative humidity. The University of Guam's Guam Plant Extinction Prevention Program (GPEPP) worked on in vitro seedling propagation, including tissue culture from seedling meristematic tissues to mitigate limited seed availability (GPEPP 2015) (USFWS, 2017). Other field observations: On Rota, during the June 2016 field reviews it was observed that the root masses of mature *Serianthes* trees extend laterally from the trunks 6 m or more above ground (and perhaps further sub-surface), which may provide the trees greater stability and water-uptake (AnnMarie Gawel, USFWS, pers. comm. 2016a). Older outplanted *Serianthes* became reproductive after 18-23 years (McBride, field observations August 2016), and may be capable of doing so as young as ages 12-15 (Manglona, pers. comm. 2016a & 2016b). On Guam, two trees less than 4 years old (outplanted in Nov. 2014) have produced flowers, but fruit has not yet been confirmed; these trees were known to be substantially stressed by mealybug infestations at the time (Ryan Deregnier, USFWS, pers. comm. 2016b) (USFWS, 2017). Distribution of recovered populations (future). Considering the delisting objective for Rota of having four populations separated by at least 1 km, some of these older outplanted trees may become the locations for those eventual recovery populations. Since the distribution of the currently known wild subpopulations would

only provide for two or three of the required recovery populations, it is evident that additional reintroduced (outplanted) populations may be essential to attain the delisting objective (USFWS, 2017). Anticipated: An upcoming study by E. Demeulenaere at the University of Guam on phylogenetics of *Serianthes*, which should clarify the degree of genetic similarity between the Guam and Rota populations. One objective of this study is to develop genetically-informed strategies for conservation of the species (USFWS, 2017). Anticipated: A study by GPEPP funded by McIntire Stennis to determine the genetic make-up of the *Serianthes* taxa, which will analyze the phylogenetic relationship of *Serianthes nelsonii* to other members of the *Serianthes* genus in the region. This project aims to confirm that *Serianthes nelsonii* is a valid species differing from congeners in the region (USFWS, 2017).

Threats and Stressors

Stressor: • Loss and degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Development from construction and military training has decreased the total recovery habitat for this species. *Serianthes nelsonii* habitat continues to be degraded by ungulates (Wiles et al. 1996, p. 234; DON 2013c), i.e. feral pigs and Philippine deer (*Rusa mariannae*), and by encroachment of invasive plants. In addition, declines in pollinators, seed dispersers, and insectivores have contributed to habitat loss (Wiles et al. 1996 p. 230).

Stressor: • Introduced predators and herbivores

Exposure:

Response:

Consequence:

Narrative: Introduced deer and pigs feed on *Serianthes nelsonii* (Wiles et al. 1996, p.234; Morton et al. 2000, p. 230). A number of invertebrate predators and herbivores also have been reported on this species: mealybugs (*Dysmoccocus brevipes*, *D. neobrevipes*, *Ferrisia virgate*, and *Planococcus* sp.), caterpillars of *Eurema blanda*, termites (USFWS 2012b), and katydids (A. Moore, University of Guam, pers. comm. 2014). In addition, insect predation occurs on seed pods in Rota, but the insect is unknown (USFWS 2012b).

Stressor: • Stochastic events

Exposure:

Response:

Consequence:

Narrative: Typhoons have resulted in damage and mortality to this species as well as damage to habitat (USFWS 2012b).

Recovery

Delisting Criteria:

For *Serianthes nelsonii* to be considered for delisting, the Service proposes that at least four populations be established on each island – Guam and Rota – each with a 10-year average of 500 or more reproductive plants (USFWS 1994, p. 26). The populations should have age structures comprised of a large proportion of adult trees as well as seedlings and immature

trees (USFWS 1994, p. 26). In addition, the Service recommends that the populations on Rota be separated by at least 1 km (0.621 mi), and that at least one of the populations in Guam should be in the southern part of the island (USFWS 1994, p. 26).

Recovery Actions:

- To achieve recovery needs, the Service outlines the following recovery actions (adapted from USFWS 1994, pp. 27-37):
- • Additional surveys are needed on both islands since the last surveys for this tree were in 1994. To prevent ungulate degradation and herbivory, subpopulations should be fenced wherever possible. Methodology to control insect pests should be developed and implemented. Existing individuals need to be monitored for survivorship, new threats, and any possible evidence of regeneration. Public education and community involvement should also be encouraged and developed.
- • Conduct research important to the management of *Serianthes nelsonii*. The ecology, life history, and habitat requirements of *S. nelsonii* are poorly understood and should be studied. Although a number of insect pests have been identified, many remain unidentified, and their ecology, specific effects, abundance, and especially control methods need to be investigated. The Service also recommends genetic studies, especially on the variation between Guam and Rota populations, as well as any effects from small population size and inbreeding.
- • Augment current populations and reintroduce to historical range. Plans for augmentation and reintroduction should be developed for both Guam and Rota. Areas for outplanting should be identified and secured, and plants should be propagated and transplanted to the identified areas.
- • Prevent clearing of forest next to *S. nelsonii*. Maintenance of an intact forest canopy next to *S. nelsonii* will reduce the potential of edge effects and for high winds during typhoons to break tree limbs and trunks.
- • Implement standardized control procedures for insect pests after research on insect control determines appropriate methodology.
- Propagation and outplanting programs on Guam: the Guam Plant Extinction Prevention Program propagated seedlings (seeds from the Ritidian tree) in their Rare Plant Nursery during FY2014-15; these were outplanted at the Guam National Wildlife Refuge, in partnership with Anderson AFB, USFWS, and LMS Landscape Services (Marler 2014, GPEPP 2015). From Nov. 2014 to Dec. 2016 at the Guam NWR, 68 young *Serianthes nelsonii* were outplanted, with 48 of those two- to four-year-old trees surviving as of December 13, 2016. Also, there are five surviving older (five to nine years old) outplanted *Serianthes*, planted during 2009-2012. All 73 seedlings were propagated by the University of Guam's Guam Plant Extinction Program, from seed from the last surviving adult *Serianthes* tree on Guam. These outplantings are distributed in four clusters throughout the Refuge. GPEPP recently planted 10 *Serianthes* seedlings at the University of Guam (UOG), 10 at the UOG Yigo Agricultural Research Station, and 15 at the Cotal Conservation area (USFWS, 2017).
- Outplanting sites are fenced to exclude ungulates, with individual trees enclosed in netting to prevent defoliation or other damage by insects, including mealybugs, ants, scale insects, whiteflies, psyllids, butterfly and looper caterpillars, and katydids and cerambycid beetles. Insecticidal treatment against mealybugs was conducted both directly (insecticidal soap on mealybugs themselves), and indirectly through bait poisons for their tending ants. Concern about potential negative effects of soil-borne pathogens on seeds led to the proposed usage

- of hanging seed collectors to capture some of the seedfall above the ground (AAFB 2016; Ryan Deregnier, USFWS, pers. comm. 2016a & 2016b). Finally, recent reports including monthly monitoring detail the condition, through September 2016, of the one older juvenile *Serianthes* persisting in the Tarague Basin. This is the lone survivor of 67 outplanted in 1999-2000; three had been alive as recently as 2013 (Naval Facilities Marianas 2015; AAFB 2016) (USFWS, 2017).
- Propagation and outplanting programs on Rota: from 2015-2016, 62 young *Serianthes* have been outplanted; these plants are protected by fenced enclosures and are currently two to three years old (Manglona 2016). Also, there are 10 older outplanted *Serianthes* (18-23 years old; identified as “mature” in Table 1) planted in four different locations (James Manglona, pers. comm. 2016b), among which at least 6 of 9 observed trees are currently producing flowers and seedpods (McBride, personal observation). Susceptibility of these outplants to scale insects and other pathogens necessitates their active management until reaching at least three meters in height to ensure their survival—and even larger trees are still visibly affected, if not lethally (James Manglona, pers. comm. 2016c). Some of the older outplantings are farther northeast and in lower elevations (100-125m) than the historical range of the species on Rota (above 150m, Mount Sabana massif only). This expansion of the species range on Rota through propagation could prove beneficial in the event of large-scale disturbances (USFWS, 2017).
 - Also on Rota, in 2016 Lainie Berry of CNMI Department of Lands and Natural Resources began work on surveys and propagation of *Serianthes*, under a USFWS Section 6 grant (F16AP00687). In addition to surveys for new individuals as well as all previously-known trees, efforts to propagate the species will also be undertaken. Anticipated propagation activities include seed and cutting collection, propagation via established techniques, outplanting in conservation areas, and initial monitoring. Existing fencing will be restored as needed, new fencing and signage established, and invasive plants hand-cleared where necessary to protect individual trees. This work is scheduled to conclude in 2018. Ongoing fence maintenance will be carried out by Rota Forestry, as well as longer-term monitoring if additional federal funding is secured (USFWS 2016) (USFWS, 2017).
 - In addition to the previously-described monitoring and propagation activities being conducted by Anderson AFB, in accord with the terms of their recovery permit, they have convened a *Serianthes* Strategy Team. The purpose of this team is to develop, in cooperation with AAFB, GPEPP, USFWS, and other recovery collaborators, a long-term conservation strategy for propagation and outplanting of *Serianthes nelsonii*, to replace the initial one-year strategy outlined in the permit by July 2017 (AAFB 2016) (USFWS, 2017).
 - Anticipated: The Department of Navy’s proposed relocation of the U.S. Marine Corps from Okinawa to Guam, as well as the associated activities on Guam, has been evaluated by the Service (USFWS 2015). In that Biological Opinion, the Service concluded that this project, including the construction and operation of a Live-Fire Training Range Complex (LFTRC) in close proximity to the lone surviving wild adult *Serianthes* on Guam, would likely have a number of effects on that mature tree, nearby seedlings, outplanted saplings, and the species’ recovery habitat on Guam. These anticipated effects include, but are not limited to, clearing of 948 acres of recovery habitat—including 65 acres of primary limestone karst forest, to within 100 feet of the surviving tree; increased exposure to wind loading and its potential for damage or injury to that adult tree; other abiotic and biotic edge effects, including microclimate alterations and increased invasibility by non-native species; potentially increased fire risk; potential disruption of ecological relationships such as pollination and seed dispersal; and reduced accessibility to the wild tree/seedling area and

the outplanted saplings for both research and management purposes. In that Opinion, the Service concluded 7 that the proposed action will adversely affect the last remaining adult *Serianthes nelsonii* tree in Guam, will negatively impact that wild tree and seedlings around it, and the outplanted saplings at the Refuge, and will result in the loss of 948 acres of recovery habitat. The Service further concluded that if the Department of Navy fully implements its proposed conservation measures and best management practices—including but not limited to the outplanting of 30 *Serianthes nelsonii* trees in a protected area, and their successful maintenance into adulthood—then it is unlikely that this project will preclude the recovery and survival of *S. nelsonii*. However, the Opinion also states that if new information suggests that the Guam population is distinct from *S. nelsonii* in Rota, or if the baseline for this species experiences an unforeseen major decline, this determination will need to be revisited. (For further details, see full Biological Opinion, USFWS 2015). Since *S. nelsonii* has undergone a major decline, the Navy has been notified of this status update and the Service is anticipating re-consultation (USFWS, 2017).

- Preserve the remaining genetic and geographic diversity of the species. Maintain presence of existing reproductive individuals on both islands. This will best assure continuity of seed sourcing for propagation efforts while safeguarding what remains of the species genetic diversity, and retaining some geographic distribution to mitigate the risk of catastrophic loss from disturbance events (USFWS, 2017).
- Similarly, research and other recommended actions below need be conducted in recognition that the populations between the two islands may be distinct in various ways: genetically, ecologically, or with regard to threats, and other survival or recovery issues. Original studies on each population may be necessary to inform effective management on the two islands (USFWS, 2017).
- Site / area / habitat protection – Develop and implement effective measures to reduce the impacts of military training activities, agricultural and urban development, and hurricanes (typhoons) (USFWS, 2017).
- Fire protection – Develop and implement a fire management plan for all populations (USFWS, 2017).
- Implement fencing plans for both outplanted trees and wild subpopulations as described in the recovery plan; this fencing should be designed to exclude ungulates and allow greater chance for successful establishment of seedling regeneration. As one example, the Aplalago “grove” (subpopulation #1) of 11 live adult trees could be enclosed with as little as 120-200 m of fencing, using the nearby cliff rim as a natural barrier along one side (USFWS, 2017).
- Ecosystem-altering invasive plant species control – Control invasive introduced plant species within fenced enclosures (USFWS, 2017).
- Surveys / inventories – Resurvey the historical range of the species to determine if previously unknown or newly reestablished populations exist (USFWS, 2017).
- Continue propagation and outplanting programs on both islands to establish *Serianthes* in a range of locations, particularly within the known historic distribution around the Mount Sabana massif on Rota (USFWS, 2017).
- Captive propagation for genetic storage and reintroduction:
 - o Continue to collect seeds from all existing populations and send to at least two or three different venues for propagation.
 - o Augment the species with specimens from Rota to encourage genetic mixing of the Guam population (USFWS, 2017).
- Captive propagation protocol development – Protect seed pods with a fine mesh covering to prevent predation by arthropods before seeds mature (USFWS, 2017).

- On Rota, collect seed stock at the Aplalago subpopulation (#1), to broaden the genetic diversity of current propagation material, and thus potentially augment its characteristics for survival (USFWS, 2017).
- On Rota, conduct studies of the subpopulations (#1, #7) with better recent-term survival, to identify any characteristics potentially favoring enhanced survival (USFWS, 2017).
- Invertebrate herbivory research – continue studies to identify the effects of invertebrate predation on seeds and seedlings of *S. nelsonii*. If determined to be a limiting factor, develop and implement control measures to protect the species (USFWS, 2017).
- Root pathogen research – Develop studies to identify specific root pathogens that influence the survival of *S. nelsonii* seedlings, and the mechanisms by which this occurs. If determined to be a limiting factor, develop and implement control measures to protect the species (USFWS, 2017).
- Population biology research – Research the use of hand pollination to enhance outbreeding of the species (USFWS, 2017).
- Threats research:
 - o Research what factors are limiting the natural recruitment of individuals in each population--both on Guam, and on Rota.
 - o Assess the modeled effects of climate change on this species, and use results to determine future landscape needed for the recovery of the species (USFWS, 2017).
- Alliance and partnership development – Continue to work with Guam National Wildlife Refuge, Guam Plant Extinction and Prevention Program, the CNMI's Department of Lands and Natural Resources and both its Forestry Division and Fish and Wildlife Division, the Guam Department of Agriculture's Forestry and Soil Resources and Aquatics and Wildlife Divisions and other land managers to further their implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2017).
- Review the recovery plan (USFWS 1994) to determine if any new information suggests a need to update the plan to more effectively attain recovery goals (USFWS, 2017).

Conservation Measures and Best Management Practices:

- New management actions that have occurred in the last five years include: Since *Serianthes nelsonii* was listed in 1987, outplanting of individuals have been attempted with limited success. However, several recovery projects aimed at understanding and improving outplanting efforts and management of individuals have begun since 2012:
 - The last remaining adult tree in Guam is fenced to prevent access by ungulates. The Air Force has funded research to look at ecology, seedling survival, propagation methods, and health and life history of the adult tree (AAFB 2015).
 - The Service has funded a project with the CNMI Division of Forestry in Rota to outplant and maintain *Serianthes nelsonii* in fenced plots on private property.
 - The Service has funded a multi-year project for *Serianthes nelsonii* recovery on the GNWR to be managed by a full-time biologist. This person will work with the Guam Plant Extinction Prevention Program to maintain the *S. nelsonii* seedlings that were outplanted at the GNWR in 2014. The Service is collaborating with Guam Department of Agriculture, DoD, the University of Guam, and the Guam Plant Extinction Prevention Program.
- Recommendations for Future Actions (adapted from USFWS 2012b, pp. 17-18)
 - Captive propagation for genetic storage and reintroduction:
 - o Continue to collect seeds from all existing populations and propagate at multiple locations to increase success.
 - o Perform genetic studies to determine if Guam and Rota populations are distinct.
 - Captive propagation protocol development – Protect seed pods with a fine mesh covering to prevent predation by arthropods before seeds mature.
 - Reintroduction / translocation implementation:
 - o Propagate and maintain all outplanted individuals on the GNWR to a size where insect herbivory is less likely to cause mortality. This will

likely be when plants produce multiple branches and the main stem achieves a girth sufficient enough to withstand damage from *Eurema blanda* butterflies laying eggs in the plant's tissue. • Ungulate control – Continue to protect all populations against disturbances from feral ungulates. • Invertebrate control research – Research and identify the effects of invertebrate predation on seeds and seedlings of *S. nelsonii*. If determined to be a limiting factor, develop and implement control measures to protect the species. • Population biology research – Research the use of mechanical pollination to enhance outbreeding of the species. • Surveys / inventories – Resurvey the historical range of the species to determine if previously unknown or newly reestablished populations exist. • Threats research: o Research what factors are limiting the natural recruitment of individuals in Guam. o Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species. • Ecosystem-altering invasive plant species control – Control invasive introduced plant species within fenced exclosures. • Site / area / habitat protection – Develop and implement effective measures to reduce the impacts of agricultural and urban development and hurricanes (typhoons). • Fire protection – Develop and implement a fire management plan for all populations. • Alliance and partnership development – Continue to work with GNWR, Guam Rare Plant Restoration Group, and other land managers to continue implementation of ecosystem-level restoration and management to benefit this species.

SPECIES ACCOUNT: *Sesbania tomentosa* (Ohai)

Species Taxonomic and Listing Information

Listing Status: Endangered; 11/10/1994; Pacific Region (R1) (USFWS, 2016)

Physical Description

Usually an erect to prostrate shrub; sometimes a small, erect tree. When prostrate, the branches are up to 14 m long. Trees are 2.5 - 6 m tall. Flowers are salmon tinged with yellow, orangish red, scarlet, or (rarely) pure yellow (NatureServe, 2015).

Taxonomy

A member of the pea family (Fabaceae). In the currently accepted classification by Geesink and others (1990), *S. arborea*, *S. hawaiiensis*, *S. hobdyi*, and *S. molokaiensis* are synonymized with *S. tomentosa* (USFWS, 1999).

Historical Range

It is known from Nihoa and Necker islands, part of the Papahānaumokuākea Marine National Monument, and all of the main Hawaiian Islands (Geesink et al. 1999) (USFWS, 2015).

Current Range

Currently, *Sesbania tomentosa* is known from Kauai, Molokai, Maui, Kahoolawe, Nihoa, Necker, Oahu, and Hawaii (USFWS 2012a; USFWS, 2015).

Critical Habitat Designated

Yes; 2/27/2003.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Sesbania tomentosa* (Ohai) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes 24 detailed critical habitat units (CHUs), in Maui County in Hawaii (81 FR 17790-18110).

On September 18, 2012, the U.S. Fish and Wildlife Service (Service), designated critical habitat under the Endangered Species Act of 1973, for *Sesbania tomentosa* on the island of Oahu, Hawaii.

On July 2, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Sesbania tomentosa* on the island of Hawaii (68 FR 39623 - 39722).

On May 22, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Sesbania tomentosa*, known historically from the Northwestern Hawaiian Islands.

On February 27, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Sesbania tomentosa*, known historically from the island of Kauai, Hawaii (68 FR 9116 - 9479).

Critical Habitat Designation

The critical habitat designation for *Sesbania tomentosa* includes 24 CHUs in Maui County, Hawaii with detailed unit information. There are also an unknown number of units on Lanai that contain

this species (number of units is unknown because detailed unit descriptions for Lanai are not available) (81 FR 17790-18110).

Kahoolawe—Coastal—Unit 1 consists of 1,516 ac (613 ha) of State land from Kaneloa to Lae o Kaule, including Aleale, along the southern and eastern coast of Kahoolawe. It is occupied by the plant *Kanaloa kahoolawensis* and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Kahoolawe—Coastal—Unit 1 is not known to be occupied by the plants *Sesbania tomentosa* or *Vigna owahuensis*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the physical or biological features necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 1 consists of 70 ac (28 ha) of privately owned land, and 54 ac (22 ha) of federally owned land (U.S. Coast Guard) at Laau Point, from Kahaiaawa to Keawakalani, along the western coast of Molokai. This unit is occupied by the plant *Marsilea villosa*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 1 is not known to be occupied by *Bidens wiebkkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Kahoolawe—Coastal—Unit 2 consists of 12 ac (5 ha) of State land on Puukoa, an islet off the southern coast of Kahoolawe. It is occupied by the plant *Sesbania tomentosa* and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Kahoolawe—Coastal—Unit 2 is not known to be occupied by *Kanaloa kahoolawensis* or *Vigna o-wahuensis*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 2 consists of 263 ac (106 ha) of State land, and 710 ac (287 ha) of privately owned land, from Ilio Point to Kaa Gulch, along the northwestern coast of Molokai. This

unit is occupied by the plant *Marsilea villosa* and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 2 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Kahoolawe—Coastal—Unit 3 consists of 189 ac (76 ha) of State land from Laepaki to Honokanaia along the western coast of Kahoolawe. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). Although Kahoolawe—Coastal—Unit 3 is not known to be occupied by *Kanaloa kahoolawensis*, *Sesbania tomentosa*, or *Vigna o-wahuensis*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 3 consists of 794 ac (321 ha) of State land, and 3 ac (1 ha) of federally owned land (Kalaupapa National Historical Park), from Kahi Point to Wainene, along the north-central coast of Molokai. This unit is occupied by the plants *Pittosporum halophilum*, *Schenkia sebaeoides*, and *Tetramolopium rockii*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 3 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Marsilea villosa*, *Peucedanum sandwicense*, or *Sesbania tomentosa*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Kahoolawe—Lowland Dry—Unit 1 consists of 1,220 ac (494 ha) of State land, north of Waihonu Gulch on west Kahoolawe. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). Although Kahoolawe—Lowland Dry—Unit 1 is not known to be occupied by *Gouania hillebrandii*, *Hibiscus brackenridgei*, *Kanaloa kahoolawensis*, *Neraudia sericea*, *Sesbania tomentosa*, or *Vigna owahuensis*, we have determined this area to be essential for the conservation and recovery of these lowland dry

species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 4 consists of 10 ac (4 ha) on Mokapu Island on the northern coast of Molokai. This area is State-owned, and is classified as a State Seabird Sanctuary. This unit is occupied by the plants *Peucedanum sandwicense* and *Pittosporum halophilum*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 4 is not known to be occupied by *Bidens wiebkii*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Marsilea villosa*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Kahoolawe—Lowland Dry—Unit 2 consists of 3,205 ac (1,297 ha) of State land from Lua o Kealialuna to Puu o Moaulaiki and Luamakika on the eastern side of Kahoolawe. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). Although Kahoolawe—Lowland Dry—Unit 2 is not known to be occupied by *Gouania hillebrandii*, *Hibiscus brackenridgei*, *Kanaloa kahoolawensis*, *Neraudia sericea*, *Sesbania tomentosa*, or *Vigna o-wahuensis*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 5 consists of 1 ac (0.5 ha) on Huelo islet on the northern coast of Molokai. This area is State-owned, and is classified as a State Seabird Sanctuary. This unit is occupied by the plants *Brighamia rockii*, *Peucedanum sandwicense*, and *Pittosporum halophilum*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 5 is not known to be occupied by *Bidens wiebkii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Marsilea villosa*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 6 consists of 190 ac (77 ha) of State land, and 1,685 ac (682 ha) of privately owned land, from Kaholaiki Bay to Halawa Bay, on the northeastern coast of Molokai. This unit is occupied by the plants *Bidens wiebkei*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, and *Ischaemum byrone*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 6 is not known to be occupied by *Brighamia rockii*, *Hibiscus brackenridgei*, *Marsilea villosa*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 7 consists of 49 ac (20 ha) of privately owned land from Alanuihipaka Ridge to Kalanikaula, on the northeastern coast of Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). Although Molokai—Coastal—Unit 7 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Marsilea villosa*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Lowland Dry—Unit 1 consists of 24 ac (10 ha) of privately owned land, in a small gulch northwest of Mahana, in west-central Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). Although Molokai—Lowland Dry—Unit 1 is not known to be occupied by *Bonamia menziesii*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Hibiscus brackenridgei*, *Kokia cookei*, or *Sesbania tomentosa*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Coastal—Unit 9 consists of 170 ac (69 ha) of State land and 0.3 ac (0.1 ha) of privately owned land, from Poelua Bay to Mokolea Point on the northwestern coast of west Maui. This unit is occupied by the plants *Schenkia sebaeoides* and *Sesbania tomentosa*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these

species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Coastal—Unit 9 is not known to be occupied by *Brighamia rockii*, we have determined this area to be essential for the conservation and recovery of this coastal species because it provides the PCEs necessary for the reestablishment of wild populations within its historical range. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could approach recovery.

Molokai—Lowland Dry—Unit 2 consists of 589 ac (238 ha) of State land at Kamiloloa on the southern slopes of Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). Although Molokai—Lowland Dry—Unit 2 is not known to be occupied by *Bonamia menziesii*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Hibiscus brackenridgei*, *Kokia cookei*, or *Sesbania tomentosa*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Coastal—Unit 10 consists of 147 ac (60 ha) of State land and 26 ac (10 ha) of privately owned land, from Kahakuloa Head to Waihee Point on the northeastern coast of west Maui. This unit is occupied by the plant *Schenkia sebaeoides*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Coastal—Unit 10 is not known to be occupied by *Brighamia rockii* or *Sesbania tomentosa*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within its historical range. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could approach recovery.

Molokai—Lowland Mesic—Unit 1 (and) *Palmeria dolei*—Unit 37—Lowland Mesic (and) *Pseudonestor xanthophrys*—Unit 37—Lowland Mesic This area consists of 3,489 ac (1,412 ha) of State land, and 5,281 ac (2,137 ha) of privately owned land, from Waianui Gulch to Mapulehu, in central Molokai. These units are occupied by the plants *Alectryon macrococcus*, *Ctenitis squamigera*, *Cyanea dunbariae*, *C. mannii*, *C. profuga*, *Cyperus fauriei*, *Cyrtandra filipes*, *Gouania hillebrandii*, *Labordia triflora*, *Neraudia sericea*, *Santalum haleakalae* var. *lanaiense*, *Schiedea lydgatei*, *S. sarmentosa*, *Silene alexandri*, *S. lanceolata*, *Spermolepis hawaiiensis*, and *Zanthoxylum hawaiiense*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Lowland Mesic—Unit 1 is not known to be occupied by *Asplenium dielirectum*, *Bonamia menziesii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea procera*, *C. solanacea*, *Diplazium molokaiense*,

Festuca molokaiensis, *Flueggea neowawraea*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Melicope mucronulata*, *M. munroi*, *M. reflexa*, *Phyllostegia haliakalae*, *P. mannii*, *P. pilosa*, *Sesbania tomentosa*, *Stenogyne bifida*, or *Vigna o-wahuensis*, or the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Coastal—Unit 11 consists of 6 ac (3 ha) of State land on Mokeehia Island on the northeastern coast of west Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). Although Maui—Coastal—Unit 11 is not currently occupied by *Brighamia rockii*, *Schenkia sebaeoides*, or *Sesbania tomentosa*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 1 consists of 11,465 ac (4,640 ha) of State land, 2,069 ac (837 ha) of federally owned land, and 3 ac (1 ha) of privately owned land, from Kanaio to Kahualau Gulch on the southern slopes of east Maui. This unit is occupied by the plants *Bonamia menziesii*, *Cenchrus agrimonoides*, *Flueggea neowawraea*, *Melicope adscendens*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 1 is not known to be occupied by *Alectryon macrococcus*, *Bidens micrantha* ssp. *kalealaha*, *Canavalia pubescens*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Hibiscus brackenridgei*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Sesbania tomentosa*, *Solanum incompletum*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 2 consists of 1,851 ac (749 ha) of State land at Keokea on the southern slopes of east Maui. This unit is occupied by the plants *Bonamia menziesii*, *Canavalia pubescens*, and *Hibiscus brackenridgei*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 2 is not known to be occupied by *Alectryon macrococcus*, *Bidens micrantha* ssp. *kalealaha*, *Cenchrus agrimonoides*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Flueggea neowawraea*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Santalum haleakalae*

var. *lanaiense*, *Sesbania tomentosa*, *Solanum incompletum*, *Spermolepis hawaiiensis*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 3 consists of 188 ac (76 ha) of privately owned land, at Keauhou on the southern slopes of east Maui. This unit is occupied by the plant *Canavalia pubescens*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 3 is not known to be occupied by *Bidens micrantha* ssp. *kalealaha*, *Bonamia menziesii*, *Cenchrus agrimonioides*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Flueggea neowawraea*, *Hibiscus brackenridgei*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Solanum incompletum*, *Spermolepis hawaiiensis*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 4 consists of 1,266 ac (512 ha) of State land (including the Department of Land and Natural Resources) at Ahihi-Kinau Natural Area Reserve on the southern slopes of east Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). Although Maui—Lowland Dry—Unit 4 is not currently occupied by *Bidens micrantha* ssp. *kalealaha*, *Bonamia menziesii*, *Canavalia pubescens*, *Cenchrus agrimonioides*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Flueggea neowawraea*, *Hibiscus brackenridgei*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Solanum incompletum*, *Spermolepis hawaiiensis*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 5 consists of 3,615 ac (1,463 ha) of State land, and 43 ac (17 ha) of privately owned land, from Panaewa to Manawainui on the western and southern slopes of west Maui. This unit is occupied by the plants *Asplenium dielerectum*, *Bidens campylotheca* ssp. *pentamera*, *Cenchrus agrimonioides*, *Gouania hillebrandii*, *Kadua coriacea*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and *Tetramolopium capillare*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the

conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 5 is not known to be occupied by *Ctenitis squamigera*, *Cyanea obtusa*, *Hesperomannia arbuscula*, *Hibiscus brackenridgei*, *Lysimachia lydgatei*, *Neraudia sericea*, *Schiedea salicaria*, *Sesbania tomentosa*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 6 consists of 3 ac (1 ha) of State land, and 237 ac (96 ha) of privately owned land, from Paleaahu Gulch to Puu Hona on the southern slopes of west Maui. This unit is occupied by the plants *Hibiscus brackenridgei* and *Schiedea salicaria*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 6 is not known to be occupied by *Asplenium dielerectum*, *Bidens campylotheca* ssp. *pentamera*, *Cenchrus agrimonoides*, *Ctenitis squamigera*, *Cyanea obtusa*, *Gouania hillebrandii*, *Hesperomannia arbuscula*, *Kadua coriacea*, *Lysimachia lydgatei*, *Neraudia sericea*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Spermolepis hawaiiensis*, *Tetramolopium capillare*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

The critical habitat designation for *Sesbania tomentosa* includes 15 units totaling 1,332 acres on Oahu. The units are Oahu—Coastal—Unit 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15.

Oahu—Coastal—Unit 1 consists of 946 ac (383 ha) of State land, 11 ac (4 ha) of Federal land, and 2 ac (1 ha) of privately owned land in the coastal ecosystem along the northwestern coast of Oahu from Kaena Point east to Kauhao Pali and southeast to Keawaula. This unit is partially within Kaena Point State Park. It is occupied by *Sesbania tomentosa* and includes the mixed herbland and shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the coastal ecosystem. This unit also contains unoccupied habitat that is essential to the conservation of the species by providing the PCEs necessary for the expansion of the existing wild populations. Oahu—Coastal—Unit 2 consists of 12 ac (5 ha) in the coastal ecosystem on Mokuauia, an islet east of Kalanai Point on the northeastern coast of Oahu. This unit is State-owned and is classified as a State Seabird Sanctuary. It includes the mixed herbland and shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the coastal ecosystem. Although this unit is not known to be occupied by *Sesbania tomentosa*, the Service has determined this area to be essential for the conservation and recovery of this species because it provides the PCEs necessary for the reestablishment of wild populations within the historical range of the species. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery. Oahu—Coastal—Unit 3 consists of 15 ac (6 ha) in

the coastal ecosystem, on the larger of two islets (Moku Manu) off the windward coast of Oahu near Mokapu Peninsula. This unit is Stateowned, classified as a State Seabird Sanctuary, and includes the mixed herbland and shrubland, the moisture regime, and subcanopy and understory native plant species identified as PCEs in the coastal ecosystem. Although this unit is not known to be occupied by *Sesbania tomentosa*, the Service has determined this area to be essential for the conservation and recovery of this species because it provides the PCEs necessary for the reestablishment of wild populations within the historical range of the species. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Coastal—Unit 4 consists of 3 ac (1 ha) in the coastal ecosystem, the smaller of two islets (Moku Manu) off the windward coast of Oahu near Mokapu Peninsula. This unit is Stateowned, classified as a State Seabird Sanctuary, and includes the mixed herbland and shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the coastal ecosystem. Although this unit is not known to be occupied by *Sesbania tomentosa*, the Service has determined this area to be essential for the conservation and recovery of this species because it provides the PCEs necessary for the reestablishment of wild populations within the historical range of the species. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Coastal—Unit 5 consists of 12 ac (5 ha) in the coastal ecosystem, the larger of two islands (Mokulua Islands) off the windward coast of Oahu near Wailea Point. This unit is State-owned, classified as a State Seabird Sanctuary, and includes the mixed herbland and shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the coastal ecosystem. Although this unit is not known to be occupied by *Sesbania tomentosa*, the Service has determined this area to be essential for the conservation and recovery of this species because it provides the PCEs necessary for the reestablishment of wild populations within the historical range of the species. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Coastal—Unit 6 consists of 9 ac (4 ha) in the coastal ecosystem, on the smaller of two islands (Mokulua Islands) off the windward coast of Oahu near Wailea Point. This unit is Stateowned, classified as a State Seabird Sanctuary, and includes the mixed herbland and shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the coastal ecosystem. Although this unit is not known to be occupied by *Sesbania tomentosa*, the Service has determined this area to be essential for the conservation and recovery of this species because it provides the PCEs necessary for the reestablishment of wild populations within the historical range of the species. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Coastal—Unit 7 consists of 67 ac (27 ha) in the coastal ecosystem, on the larger of two islands (Manana Island) off the windward coast of Oahu near Makapuu Point. This unit is Stateowned, classified as a State Seabird Sanctuary, and includes the mixed herbland and shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the coastal ecosystem. Although this unit is not known to be occupied by *Sesbania tomentosa*, the Service has determined this area to be essential for the conservation and recovery of this species because it provides the PCEs necessary for the reestablishment of wild populations within the historical range of the species. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Coastal—Unit 8 consists of 10 ac (4 ha) in the coastal ecosystem, on the smaller of two islands (Kaohikaipu Island) off the windward coast of Oahu near Makapuu Point. This unit is Stateowned, classified as a State Seabird Sanctuary, and includes the mixed herbland and shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the coastal ecosystem. This unit is occupied by *Sesbania tomentosa* and contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Oahu—Coastal—Unit 9 consists of 80 ac (33 ha) of State land in the coastal ecosystem on the leeward side of Makapuu Point (Puuokipahulu). Although this unit is not known to be occupied by *Sesbania tomentosa*, the Service has determined this area to be essential for the conservation and recovery of this species because it provides the PCEs necessary for the reestablishment of wild populations within the historical range of the species. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery. Oahu—Coastal—Unit 10 consists of 74 ac (30 ha) in the coastal ecosystem, owned by the City and County of Honolulu at Halona Point on the leeward side of Koko Crater, extending from Sandy Beach to Kahauloa. Although this unit is not known to be occupied by *Sesbania tomentosa*, the Service has determined this area to be essential for the conservation and recovery of this species because it provides the PCEs necessary for the reestablishment of wild populations within the historical range of the species. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery. Oahu—Coastal—Unit 11 consists of 20 ac (8 ha) of privately owned land in the coastal ecosystem, at Ihiihilauakea on Koko Head (Kaihuokapuaa). Although this unit is not known to be occupied by *Sesbania tomentosa*, the Service has determined this area to be essential for the conservation and recovery of this species because it provides the PCEs necessary for the reestablishment of wild populations within the historical range of the species. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery. Oahu—Coastal—Unit 13 consists of 19 ac (8 ha) of City and County land, 1 ac (0.5 ha) of State land, and 3 ac (1 ha) of privately owned land in the coastal ecosystem at Kalaeloa. Although this unit is not known to be occupied by *Sesbania tomentosa*, the Service has determined this area to be essential for the conservation and recovery of this species because it provides the PCEs necessary for the reestablishment of wild populations within the historical range of the species. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery. Oahu—Coastal—Unit 14 consists of 2 ac (1 ha) of City and County of Honolulu land, and 2 ac (1 ha) of Federal land (U.S. Coast Guard) in the coastal ecosystem at Kalaeloa. Although this unit is not known to be occupied by *Sesbania tomentosa*, the Service has determined this area to be essential for the conservation and recovery of this species because it provides the PCEs necessary for the reestablishment of wild populations within the historical range of the species. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery. Oahu—Coastal—Unit 15 consists of 9 ac (4 ha) of State land, 2 ac (1 ha) of privately owned land, and 21 ac (9 ha) of Federal (Pearl Harbor NWR) land at Kalaeloa. Although this unit is not known to be occupied by *Sesbania tomentosa*, the Service has determined this area to be essential for the conservation and recovery of this species because it provides the PCEs necessary for the reestablishment of wild populations within the historical range of the species. Due to the small numbers of individuals or low population sizes, this species requires

suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

The critical habitat designation for *Sesbania tomentosa* includes two units totaling 3,185 acres in Hawaii County, Hawaii. The units are Hawaii 20—*Sesbania tomentosa*—a and Hawaii 23—*Sesbania tomentosa*—b. Both units are occupied by this species. Each unit is essential to the conservation of *S. tomentosa* because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable. Each unit is geographically separated from other critical habitat for this multiisland species within its historical range in order to reduce the likelihood of all recovery populations being destroyed by one naturally occurring catastrophic event.

Hawaii 20—*Sesbania tomentosa*—a [486 ha (1,201 ac)]: This unit contains the area inland of Waiwelawela Point, all of Halemaoli Point and it lies entirely in the Pahala watershed. The unit also lies completely within HVNP; provides habitat for 1 population of 300 individuals; and is currently occupied by 10 to 15 individuals. This unit provides the southernmost critical habitat within the species' historical range.

Hawaii 23—*Sesbania tomentosa*—b [803 ha (1,984 ac)]: This unit contains Kipuka Nene, is entirely in the Kapapala watershed, and lies completely within HVNP. The unit provides habitat for 1 population of 300 individuals of *S. tomentosa*; and is currently occupied by 50 to 65 individuals. This unit provides the easternmost critical habitat within the species' historical range.

The critical habitat designation for *Sesbania tomentosa* includes two units totaling 217 acres on the islands of Nihoa and Necker. The units are Nihoa 4—*Sesbania tomentosa* and Necker 1—*Sesbania tomentosa*.

Nihoa 4—*Sesbania tomentosa*: This unit is critical habitat for *Sesbania tomentosa* and is 69 ha (171 ac) on federally owned land. It includes the entire island, which is part of the HINWR. The unit contains habitat essential to the conservation of 300 mature, reproducing individuals of this short-lived perennial and contains one island-wide population of at least 1,000 individuals. The habitat features contained in this unit that are essential for this species include, but are not limited to, shallow sandy soils on beaches and dunes in *Chenopodium oahuense* coastal dry shrubland that contain one or more of the following associated native plant species: *Pritchardia remota*, *Scaevola sericea*, *Sida fallax*, and *Solanum nelsonii*. This critical habitat unit is essential to the conservation of the species because it supports extant colonies of *Sesbania tomentosa* and is also geographically separated from designated critical habitat on other islands to avoid destruction by one naturally occurring catastrophic event.

Necker 1—*Sesbania tomentosa*: This unit is critical habitat for *Sesbania tomentosa* and is 19 ha (46 ac) on federally owned land. It includes the entire island, which is part of the HINWR. The unit contains Annexation and Summit Hills, is occupied by one population of undetermined size, and provides habitat that is essential for the conservation of up to one population of 300 mature, reproducing individuals of this short-lived perennial species. The habitat features contained in this unit that are essential for this species include, but are not limited to, shallow sandy soils on beaches and dunes in *Chenopodium oahuense* coastal dry shrubland that contain one or more of the following associated native plant species: *Sida fallax*, *Scaevola sericea*, *Solanum nelsonii*, and *Pritchardia remota*. This unit is essential to the conservation of *Sesbania tomentosa* because it

supports the only extant colony of the species on Necker. This unit also includes habitat that is important for the expansion of the present population, which is currently considered not viable. This unit is located at the westernmost range of this multi-island species and is geographically separated from designated critical habitat on other islands to avoid destruction by one naturally occurring catastrophic event.

The critical habitat designation for *Sesbania tomentosa* includes two units totaling 224 acres in Kauai County, Hawaii. The units are Kauai 8—*Sesbania tomentosa*—a and Kauai 14—*Sesbania tomentosa*—b.

Kauai 8—*Sesbania tomentosa*—a. This unit is critical habitat for *Sesbania tomentosa* and is 46 ha (115 ac) on private land, containing Pao Point and Naake Cape. This unit provides habitat for one population of 300 mature, reproducing individuals of the short-lived perennial *Sesbania tomentosa* and is currently unoccupied. This unit is essential to the conservation of the taxon because it supports habitat that is important to the establishment of additional populations on Kauai in order to reach recovery goals. It provides habitat for the westernmost range of the species. The habitat features contained in this unit that are essential for this species include, but are not limited to, sandy beaches, dunes, or pond margins in coastal dry shrublands or mixed coastal dry cliffs. This unit provides for one population within this multi-island species' historical range on Kauai that is some distance away from the other critical habitat for this species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophic event.

Kauai 14—*Sesbania tomentosa*—b This unit is critical habitat for *Sesbania tomentosa* and is 44 ha (109 ac) on State land (Polihale State Park). This unit provides habitat for one population of 300 mature, reproducing individuals of the short-lived perennial *Sesbania tomentosa* and is currently occupied with 11 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable. It provides habitat for the westernmost range of the species. The habitat features contained in this unit that are essential for this species include, but are not limited to, sandy beaches, dunes, or pond margins in coastal dry shrublands or mixed coastal dry cliffs. This unit provides for one population within this multi-island species' historical range on Kauai that is some distance away from the other critical habitat for this species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophic event.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Sesbania tomentosa* critical habitat consists of three components. Coastal (west Maui, Lanai, Molokai and Kahoolawe), Lowland dry (east Maui, west Maui, Lanai, Molokai and Lanai) and Lowland mesic (Molokai) (81 FR 17790-18110):

Ecosystem: Coastal. Elevation: <980 ft (<300 m). Annual precipitation: <20 in (<50 cm). Substrate: Well-drained, calcareous, talus slopes; dunes; weathered clay soils; ephemeral pools; mudflats. Canopy: Hibiscus, Myoporum, Santalum, Scaevola. Subcanopy: Gossypium, Sida, Vitex. Understory: Eragrostis, Jacquemontia, Lyceum, Nama, Sesuvium, Sporobolus, Vigna.

Ecosystem: Lowland Dry. Elevation: <3,300 ft (<1,000 m). Annual precipitation: <50 in (<130 cm). Substrate: Weathered silty loams to stony clay, rocky ledges, littleweathered lava. Canopy: Diospyros, Myoporum, Pleomele, Santalum. Subcanopy: Chamaesyce, Dodonaea, Leptecophylla, Osteomeles, Psydrax, Scaevola, Wikstroemia. Understory: Alyxia, Artemisia, Bidens, Chenopodium, Nephrolepis, Peperomia, Sicyos.

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: Acacia, Diospyros, Metrosideros, Myrsine, Pouteria, Santalum. Subcanopy: Dodonaea, Freycinetia, Leptecophylla, Melanthera, Osteomeles, Pleomele, Psydrax. Understory: Carex, Dicranopteris, Diplazium, Elaphoglossum, Peperomia.

Within these units, the physical and biological features of critical habitat are:

- (i) Elevation: Less than 980 ft (300 m).
- (ii) Annual precipitation: Less than 20 in (50 cm).
- (iii) Substrate: Well-drained, calcareous, talus slopes; weathered clay soils; ephemeral pools; mudflats.
- (iv) Canopy: Hibiscus, Myoporum, Santalum, Scaevola.
- (v) Subcanopy: Gossypium, Sida, Vitex.
- (vi) Understory: Eragrostis, Jacquemontia, Lyceum, Nama, Sesuvium, Sporobolus, Vigna.

Habitat features that are essential for this species include, but are not limited to, dry *Metrosideros polymorpha* forest with mixed native grasses, *Scaevola taccada* coastal dry shrubland on windswept slopes, and weathered basaltic slopes.

On Nihoa and Necker, the currently known primary constituent elements of critical habitat for *Sesbania tomentosa* include, but are not limited to, habitat components provided by:

- (1) Shallow soil on sandy beaches and dunes in *Chenopodium oahuense* coastal dry shrubland or mixed coastal dry cliffs and containing one or more of the following associated native plant species: *Pritchardia remota*, *Scaevola sericea*, *Sida fallax*, or *Solanum nelsonii*; and
- (2) Elevations between sea level and 84 m (0 and 276 ft).

Within these units, the currently known primary constituent elements of critical habitat include, but are not limited to, the habitat components provided by:

- (i) Sandy beaches, dunes, or pond margins in coastal dry shrublands or mixed coastal dry cliffs, and containing one or more of the following associated native plant species: *Chamaesyce celastroides*, *Cuscuta sandwichiana*, *Dodonaea viscosa*, *Heteropogon contortus*, *Myoporum sandwicense*, *Nama sandwicensis*, *Scaevola sericea*, *Sida fallax*, *Sporobolus virginicus*, *Vitex rotundifolia*, or *Waltheria indica*; and

(ii) Elevations between 0 and 130 m (0 and 427 ft).

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into

native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkii*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

All critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new alien plant species into native habitats. Particular attention is required during nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species will help to address the threat posed by fire to 25 of the designated ecosystem critical habitat units in particular: Oahu—Coastal—Unit 1, 9, 10, 11, 12, 13, 14, 15.

The Service publishes this final rule acknowledging that they have incomplete information regarding many of the primary biological and physical requirements for these species. However, both the Act and the relevant court orders require the Service to proceed with designation at this time based on the best information available. As new information accrues, the Service may consider reevaluating the boundaries of areas that warrant critical habitat designation.

The following management actions are important in providing a conservation benefit to the species: feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Although this unit is not known to be occupied by *Sesbania tomentosa*, the Service has determined this area to be essential for the conservation and recovery of this species because it provides the PCEs necessary for the reestablishment of wild populations within the historical range of the species. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

The following management actions are ranked in order of importance: (1) Nonnative plant control; (2) Rodent control; (3) Invertebrate pest control; (4) Fire control; (5) Maintenance of genetic material of the endangered plant species; (6) Propagation, reintroduction, and/or augmentation of existing populations into areas deemed essential for the recovery of the species; (7) Ongoing management of the wild, outplanted, and augmented populations; (8) Maintenance of natural pollinators and pollinating systems, when known; (9) Habitat management and restoration in areas deemed essential for the recovery of the species; (10) Monitoring of the wild, outplanted, and augmented populations; (11) Rare plant surveys; and (12) Control of human activities/ access.

The following management actions are important: Feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas deemed essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas deemed essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (inferred from USFWS, 2015)

Lifespan

Adult: < 10 years (USFWS, 2015)

Breeding Season

Adult: Winter - spring (USFWS, 1999)

Key Resources Needed for Breeding

Adult: Insect pollinators, especially *Hylaeus* spp. (USFWS, 2015 and 2010); winter-spring rains (USFWS, 1999)

Reproduction Narrative

Adult: It is a short-lived perennial (fewer than 10 years). Pollination studies for *S. tomentosa* at Kipuka Nene determined that six insect species were floral visitors, and native *Hylaeus* (yellow-faced bees) and *Apis mellifera* honeybees were found to be transporting pollen of the rare plant (Pratt et al. 2011). The remaining four species participated in less than 10 percent of all floral visits and they include the nonnative *Linepithema humile* (Argentine ant), *Plagiolepis alluaudi* (little yellow ant), nonnative *Conocephalus saltator* (longhorned grasshopper), and *Lampides boeticus* (bean butterfly) (USFWS, 2015). Flowering at Kaena Point is highest during the winter-spring rains, and gradually declines throughout the rest of the year (D. Hopper, in lift. 1996) (USFWS, 1999). Studies of *Sesbania tomentosa* individuals at Kaena Point on Oahu revealed that *Hylaeus* species are the primary pollinators (USFWS, 2010).

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Coastal dry shrublands and grasslands, ohia forest, mixed coastal dry cliff (USFWS, 1999); calcareous beach (NatureServe, 2015)

Habitat Narrative

Adult: Inhabits dry shrublands or (rarely) dry forests. Often coastal, less often inland. Found on calcareous beaches and sand dunes, rocky ridges and slopes, deep red soil, and on soil pockets on lava; basaltic and calcareous substrates (NatureServe, 2015). *Sesbania tomentosa* is found on sandy beaches, dunes, soil pockets on lava, and along pond margins (Geesink et al. 1990). It commonly occurs in coastal dry shrublands and grasslands, but is also known from open ohia forests and Mixed Coastal Dry Cliffs (HINHP 1995) (USFWS, 1999). Research suggests that *S. tomentosa* forms beneficial associations with mycorrhizal fungus when the plant is growing in soils with low phosphorus levels (Gemma et al. 2002) (USFWS, 2010).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Not available

Species Trends:

Stable (USFWS, 2015)

Resiliency:

Moderate (inferred from USFWS, 2015; see current range/distribution)

Redundancy:

Moderate (inferred from USFWS, 2010)

Number of Populations:

~20 (USFWS, 2010)

Population Size:

> 1,600 - 2,700 (USFWS, 2015)

Population Narrative:

There are > 1,600 to 2,700 wild individuals and approximately 475 outplanted individuals. The number of individuals has remained stable (USFWS, 2015). There are approximately 20 populations (USFWS, 2010).

Threats and Stressors

Stressor: Overutilization (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: *Sesbania tomentosa* that originated from natural populations, but is now grown from seed or vegetative propagules produced in nurseries, is available for sale by multiple nurseries and home improvement stores only within the State of Hawaii. Thus, a USFWS interstate permit under section 10(a)(1)(A) of the Endangered Species Act of 1973, as amended, is not required (USFWS, 2015).

Stressor: Predation (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Herbivory by slugs have been reported as a new threat to this species on Molokai (PEPP 2014). Rats and mice, twig borers, scales, aphids, gray bird grasshopper (*Schistocerca nitens*), black ants (USFWS, 2015).

Stressor: Habitat loss and degradation (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Ungulate herbivory, invasive plants, hiking and trail maintenance, off-road vehicles, agricultural and urban development (USFWS, 2015).

Stressor: Climate change (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high-resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *S. tomentosa* is moderately vulnerable to the impacts of climate change (USFWS, 2015).

Stressor: Loss of pollinators (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Lack of adequate pollination (USFWS, 2010).

Recovery

Reclassification Criteria:

1. A total of five to seven populations should be documented on islands where it now occurs or occurred historically (USFWS, 1999).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure with the following minimum numbers of mature individuals per population: 300 for short-lived perennials (USFWS, 1999).
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 1999).

Delisting Criteria:

1. A total of 8 to 10 populations should be documented on islands where it now occurs or occurred historically (USFWS, 1999).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with the following minimum numbers of mature individuals per population: 300 for short-lived perennials (USFWS, 1999).
3. Each population should persist at this level for a minimum of five consecutive years (USFWS, 1999).

Recovery Actions:

- Protect habitat and control threats (USFWS, 1999).
- Expand existing wild populations (USFWS, 1999).
- Conduct essential research (USFWS, 1999).
- Develop and maintain monitoring plans (USFWS, 1999).
- Reestablish wild populations within the historic range (USFWS, 1999).
- Validate and revise recovery criteria (USFWS, 1999).
- Find the reasons for poor reproductive success (USFWS, 1999).
- Construct exclosures to protect populations against feral and wild ungulates (cattle, goats, and axis deer) (USFWS, 1999).

- Control competing alien plant species (USFWS, 1999).
- Protect endangered plants from fire (USFWS, 1999).
- Construct devices to protect populations against off-road vehicular traffic (USFWS, 1999).
- Maintain adequate genetic stock (USFWS, 1999).
- Enhance wild populations and establish new populations (USFWS, 1999).

Conservation Measures and Best Management Practices:

- Surveys / inventories – Survey geographical and historical range for a current assessment of the species' status (USFWS, 2015).
- Captive propagation for genetic storage and reintroduction: Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. Evaluate genetic resources currently in storage to determine the need to place additional genetic resources in long-term storage due to this species' vulnerability to climate change (USFWS, 2015).
- Ungulate monitoring and control – Maintain existing exclosures and monitor for potential incursions (USFWS, 2015).
- Invasive plant monitoring and control – Eradicate invasive introduced plants within ungulate exclosures and maintain exclosures free of invasive plants (USFWS, 2015).
- Population viability monitoring and analysis – Continue monitoring wild and reintroduced individuals (USFWS, 2015).
- Fire monitoring and control – Develop and implement a fire management plan at the existing exclosure (USFWS, 2015).
- Climate change adaptation strategy – Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change (USFWS, 2015).
- Alliance and partnership development – Initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon (USFWS, 2015).

SPECIES ACCOUNT: *Sibara filifolia* (Santa Cruz Island rockcress)

Species Taxonomic and Listing Information

Listing Status: Endangered; 9/8/1997; Pacific Southwest (R8)

Physical Description

An annual herb, usually with a single, slender, branching stem, 1.5-3 dm tall. Leaves are finely divided into many linear lobes. Flowers (March-May) have pink or purple, spoon-shaped petals. Fruit is a long slender pod. (NatureServe, 2015)

Taxonomy

Sibara filifolia (E. Greene) was first collected by Greene in 1886 and described as *Cardamine filifolia* (Greene 1887a, p. 30). Greene later transferred it to *Arabis filifolia* (1887b, p. 390). In 1896, Greene proposed the new genus *Sibara* to accommodate the species (Greene 1896, pp. 10–12). *Sibara filifolia* has been maintained by all subsequent floristic and systematic treatments (Munz 1974, pp. 300–301; Rollins 1993, pp. 435–436; Al-Shehbaz 2012, p. 562). There have been no changes in the nomenclature or taxonomic classification of *Sibara filifolia* since it was listed (USFWS, 2012).

Historical Range

See current range/distribution.

Current Range

California endemic, currently known only from San Clemente Island (possibly still be extant on Santa Catalina Island, although not seen there since 1973); formerly collected on distant Santa Cruz Island, so thought to have been more widespread in the past (USFWS 1997). (NatureServe, 2015)

Critical Habitat Designated

Yes;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Self-pollination (USFWS, 2012)

Breeding Season

Adult: Flowers in April (USFWS, 2012)

Reproduction Narrative

Adult: *Sibara filifolia* (Santa Cruz Island rock-cress) is a diminutive and slender annual herb in the Brassicaceae (mustard family) that flowers in April (Munz 1974, pp. 300–301). It is 13 to 38 centimeters (cm) (5 to 15 inches (in)) tall. The flowers are bisexual and are borne in small terminal unbranched flower stalks called racemes. Based on greenhouse observations, it appears that *Sibara filifolia* is self-compatible and capable of self-pollination or is possibly

apomictic (capable of producing seeds without pollination) (Wall, pers. comm., 2006; K. Helenurm, University of South Dakota, pers. comm., 2006). Under natural conditions, plants typically produce 2 to 10 fruits (Helenurm, pers. comm., 2006). Seed dispersal appears to be by gravity, with many seeds likely tumbling or washing downhill (Helenurm 2003, p. 184). Past germination trials at Rancho Santa Ana Botanic Garden have proven successful by simply placing *S. filifolia* seeds in the soil (Wall, pers. comm., 2006). As discussed in the 2006 5-year review, previous studies investigating the tolerance of *S. filifolia* seed to smoke and fire suggested that the plant is not well-adapted to fire (C. Ames, Rancho Santa Ana Botanic Garden, pers. comm., 2006; Wall, pers. comm., 2006). (USFWS, 2012).

Habitat Type

Adult: Volcanic scree (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Clumped (NatureServe, 2015)

Environmental Specificity

Adult: Narrow/specialist (NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: Low (NatureServe, 2015)

Site Fidelity

Adult: High (NatureServe, 2015)

Habitat Narrative

Adult: Species is currently known only from south-facing, sunny, volcanic scree but historical populations were apparently found in shady places (NatureServe, 2015).

Dispersal/Migration**Dispersal**

Adult: Low (USFWS, 2012)

Dispersal/Migration Narrative

Adult: Seed dispersal appears to be by gravity, with many seeds likely tumbling or washing downhill (Helenurm 2003, p. 184). Past germination trials at Rancho Santa Ana Botanic Garden have proven successful by simply placing *S. filifolia* seeds in the soil (Wall, pers. comm., 2006). As discussed in the 2006 5-year review, previous studies investigating the tolerance of *S. filifolia* seed to smoke and fire suggested that the plant is not well-adapted to fire (C. Ames, Rancho Santa Ana Botanic Garden, pers. comm., 2006; Wall, pers. comm., 2006) (USFWS, 2012).

Population Information and Trends**Population Trends:**

Decreasing (NatureServe, 2015)

Resiliency:

Low (NatureServe, 2015)

Representation:

Low (NatureServe, 2015)

Redundancy:

Low (NatureServe, 2015)

Population Growth Rate:

The taxon was only known from the Channel Islands, but is believed to be extirpated from at least one. Proper management may increase suitable habitat for this taxon. Decline of >70% (NatureServe, 2015)

Population Narrative:

The taxon was only known from the Channel Islands, but is believed to be extirpated from at least one. Proper management may increase suitable habitat for this taxon. Decline of >70% (NatureServe, 2015)

Threats and Stressors

Stressor: Nonnative plants (USFWS, 2012)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Invasive nonnative plants represent a significant, ongoing, rangewide threat to *Sibara filifolia*. Vectors for their dispersal into habitat occupied by *S. filifolia* can include vehicles, humans, and other animals. Increased fire frequency, associated with nonnative plants, can also produce type conversion from shrub-dominated landscapes to those occupied by mainly invasive, nonnative, annual grasses. Nonnative invasive plant removal activities are being implemented on both islands where *S. filifolia* is known to be extant. The implementation and effectiveness of such programs may be limited to currently monitored occurrences (Wild Boar Gully (EO 7) on Santa Catalina Island), where site-specific monitoring and treatment actions are identified and implemented. The implementation is absent and effectiveness unknown for nonnative plant control at point localities associated with the occurrence at Pyramid Point (EO 2) on San Clemente Island; this area is closed due to the presence of UXO. The long-term threat to habitat occupied by *S. filifolia* may be significantly reduced if sources of invasive plant propagules and vectors that facilitate their spread are reduced or eliminated. Impacts of invasive nonnative plants on *S. filifolia* habitat will continue at significant levels in areas where these elements are not controlled (USFWS, 2012).

Stressor: Fire (USFWS, 2012)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: In summary, fire remains an ongoing threat to *Sibara filifolia* habitat on Santa Catalina and San Clemente Islands. The vulnerability results from small populations and potential type conversion of habitat resulting from fire, particularly the invasion of nonnative invasive annual grasses. Fires on San Clemente and Santa Catalina Islands occur frequently and fire prevention

measures and invasive plant control are necessary for the protection of *S. filifolia* habitat. Control of invasive nonnative grasses is necessary on Santa Catalina Island to prevent adverse fuel conditions that might impact *S. filifolia* habitat and seed bank. The FMP developed for San Clemente Island has identified measures to minimize the risk of fires spreading from the impact areas to adjoining habitat where *S. filifolia* may occur; however, lack of access will likely limit or preclude site specific management actions, fire response measures, and post-fire assessments (USFWS, 2012).

Stressor: Erosion (USFWS, 2012)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Erosion from training exercises on the island has resulted in the past. The likely extent of erosion has recently been evaluated for off-road Assault Vehicle Maneuver Areas, Artillery Firing Points, Artillery Maneuvering Points, and Infantry Operations Area (Navy 2008a, pp. G-1, G-2). The Navy has proposed an erosion control plan that would consider a variety of erosion control methods to promote sustainable land use in support of military operations in these areas) (Navy 2008a, p. G-22); however, there is no approved off-highway vehicle use until this plan comes into effect (Munson, pers. comm., 2011a). The erosion control projects developed in this plan will be implemented in ways that best avoid threatened and endangered species (Munson, pers. comm., 2011a). Erosion impacts to *Sibara filifolia* habitat do not appear to be significant at this time (USFWS, 2012).

Stressor: Trampling (USFWS, 2012)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Although trampling of native vegetation was not discussed directly as a threat in the listing rule, it was described relative to grazing of large mammalian herbivores, which together have facilitated the spread of nonnative plants on the Channel Islands (USFWS 1997a, p. 42693). The threat of trampling from large mammalian herbivores has been reduced since listing due to the removal of goats and pigs from Santa Catalina Island and San Clemente Island. The fencing surrounding Wild Boar Gully (EO 7) on Santa Catalina Island has also substantially reduced this threat. At present, the potential threat of trampling from large grazing animals (blackbuck antelope (*Antelope cervicapra*), mule deer (*Odocoileus hemionus*), and American bison (*Bison bison*)) only exists near Cape Canyon (EO 6) (Appendix 1). *Sibara filifolia* is at risk from human trampling due to the small size of the populations, although human access is regulated on each of the Channel Islands. Due to its cryptic appearance, this may result from biologists surveying or otherwise conducting management activities on the islands (Kellogg, pers. comm., 2006). On Santa Catalina Island, work crews removing invasive plant species likely represent the primary threat, as the area where the plant occurs is fenced with restricted public access. On San Clemente Island, the potential threat of trampling can result from biologists' activities as well as any military training activities that could involve troop movements through the area where the plant is distributed. The Navy proposed to brief military units on maneuver area boundaries prior to conducting operations to minimize the potential of incidental foot traffic in *S. filifolia* habitat; the use of markers to aid in identification of range boundaries or sensitive areas is considered incompatible with training (USFWS 2008, p. 140). The potential for human traffic is high, because the plant is distributed on ridgetops and flat areas rather than within inaccessible steep terrain,

(Kellogg, pers. comm., 2006). However, the incidence of impacts to *S. filifolia* is expected to be very low (USFWS, 2012).

Stressor: Small population size (USFWS, 2012)

Exposure:

Response:

Consequence: Loss of genetic variability/extinction

Narrative: The listing rule discussed the vulnerabilities associated with few occurrences of small population sizes for *Sibara filifolia* (USFWS 1997a, p. 42699). *Sibara filifolia* is vulnerable to extirpation from a number of factors such as environmental stochasticity, genetic stochasticity, demographic stochasticity, and natural catastrophes, because it is an insular endemic species presumed to currently exist as three small, narrowly distributed occurrences (Shaffer 1981, p. 131). Small population size may be the result of several conditions, including local extirpations or ongoing natural or artificial factors limiting establishment and survival of the taxon. Stochastic events represent a significant threat to small occurrences. Given the extremely restricted distribution of this species, any natural catastrophe such as a fire, landslide, or prolonged drought on an island could lead to the extirpation of the species from one of the two islands currently known to support the species. On San Clemente Island, the known extant occurrence (EO 2) of *Sibara filifolia* could be affected by a single fire. The Santa Catalina Island occurrences (EOs 6, and 7) are also closely spaced and likely to be similarly affected by a single catastrophic event. However, the presence of *S. filifolia* on separate islands improves the prospects for continued survival of the species in the event of a natural catastrophe. The likelihood of maintaining genetic diversity decreases in smaller populations (Barrett and Kohn 1991, pp. 9, 10, and 13) and elevates concern for small, isolated populations of *Sibara filifolia*. The low genetic diversity and low differentiation observed from San Clemente Island may indicate a bottleneck or potentially nearly complete selfing lineages, or both for this population (McGlaughlin, pers. comm., 2011). Loss of genetic variation could limit the likelihood of this species maintaining tolerances suited to a changing environment (Helenurm 2003, p. 185). In contrast, the observed genetic diversity found within the Santa Catalina Island indicates the importance of those populations for seed banking and other conservation activities. The risk of extinction of *Sibara filifolia* from elements inherent in its small insular population size is lessened by the conservation seed bank established at RSABG since the listing (Wall, pers. comm., 2006). While seed banking, by itself, does not remove the systematic or stochastic threats facing natural populations of *S. filifolia*, these seeds can provide source material to reestablish populations in the wild should they become extirpated (USFWS, 2012).

Stressor: Climate change (USFWS, 2012)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Impacts to *Sibara filifolia* under predicted future climate change remain unclear. While it appears reasonable to assume that this taxon may be affected, we lack sufficient certainty on knowing how and when climate change will affect the species, the extent of average temperature increases in California, or potential changes to the level of threat posed by fire on the Channel Islands. While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to *S. filifolia* at this time (USFWS, 2012).

Recovery**Recovery Actions:**

- No recovery plan or outline has been prepared for *Sibara filifolia* (USFWS, 2012).

Conservation Measures and Best Management Practices:

- Based on recommendations and genetic diversity of occurrences, establish an adequate seed bank for *Sibara filifolia* with sampling emphasis on genetically highly diverse sites on Santa Catalina and a lesser emphasis on the less diverse sites on San Clemente Island (USFWS, 2012).
- Maintain and improve invasive nonnative plant control programs with a focus on sites where *Sibara filifolia* occurs or where habitat conditions may support reemergence of the species from a dormant seed bank (USFWS, 2012).
- Continue to collaborate with the Navy on ongoing projects to assist with conservation of listed species on the island to help facilitate effective management and monitoring of *Sibara filifolia* (USFWS, 2012).
- Determine soil and habitat preferences for *Sibara filifolia* and conduct additional surveys on all three islands where *S. filifolia* has been collected historically using this data to look for previously undetected occurrences as well as identify and characterize potential reintroduction sites (USFWS, 2012).

SPECIES ACCOUNT: *Sicyos albus* (= *S. alba*) ('anunu)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Region (R1) (USFWS, 2016)

Physical Description

An annual(?) vine up to 20 m long, with black-spotted stems. Flowers and fruit are white. (NatureServe, 2015)

Taxonomy

Sicyos alba, a member of the gourd family (Cucurbitaceae), was first described by Harold St. John in 1978 as the segregate genus *Sarx*. The holotype specimen was collected in Kulani on Hawaii Island by Wayne Gagné in 1974 and is housed at Bishop Museum (Telford 1989). However, the first collection was made by the U.S. Exploring Expedition in 1840 and 1841. Telford (1989) transferred the species to the genus *Sicyos*, and indicated that the floral and vegetative morphology of *S. alba* was so close to that of *S. cucumerinus* that further studies were warranted regarding whether the two species were distinct. Wagner and Shannon (1999) summarized the nomenclatural situation for Hawaiian members of the genus (USFWS, 2012).

Current Range

Current range is in the Volcano region of Hawaii; also reported from Mauna Kea but needs verification. (NatureServe, 2015)

Critical Habitat Designated

Yes; 7/2/2003.

Legal Description

On July 2, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Sicyos albus* on the island of Hawaii (68 FR 39623 - 39722).

Critical Habitat Designation

The critical habitat designation for *Sicyos albus* includes one unit totaling 15,483 acres in Hawaii County, Hawaii. The unit is Hawaii 30—*Sicyos alba*—a.

Hawaii 30—*Sicyos alba*—a [6,266 ha (15,483 ac)]: This unit contains Puu Makaala and is entirely in the Kaahakini watershed. This unit lies within HVNP, Puu Makaala Natural Area Reserve, and Olaa-Kilauea Partnership lands. The unit provides habitat for 10 populations of 300 mature, reproducing individuals of the *S. alba* and is currently occupied by 4 individuals. This unit is essential to the conservation of *S. alba* because it supports an extant colony of this islandendemic species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable. This unit is of an appropriate size so that each potential recovery population within the unit is separated enough to avoid their destruction by one naturally occurring catastrophic event. Beyond the 10 populations provided for in this unit, no other critical habitat is designated for this species.

Primary Constituent Elements/Physical or Biological Features

Habitat features that are essential for this species include, but are not limited to, *Metrosideros polymorpha*-*Cibotium glaucum* dominated montane wet forests.

Special Management Considerations or Protections

The Service publishes this final rule acknowledging that they have incomplete information regarding many of the primary biological and physical requirements for this species. However, both the Act and the relevant court orders require the Service to proceed with designation at this time based on the best information available. As new information accrues, the Service may consider reevaluating the boundaries of areas that warrant critical habitat designation.

The following management actions are important in providing a conservation benefit to the species: feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History**Food/Nutrient Resources****Habitat Type**

Adult: Montane wet forest (USFWS, 1998)

Habitat Narrative

Adult: Species grows on wet forests on gentle, old volcanic slopes. (NatureServe, 2015). *Sicyos alba* typically grows in ohia- and hapuu-dominated Montane Wet Forests, at elevations between 975 and 1,130 meters (3,200 to 3,720 feet). Associated taxa include hapuu, kawau, kanawao, haiwale, *Stenogyne* sp., kopiko, *Perrottetia sandwicensis* (olomea), olapa, hoio, and *Cyanea tritomantha* (haha) (HHP 1991j1 ; HPCC 1991h, 1993c; Telford 1990; M. Brueggemann, in lift., 1994) (USFWS, 1998).

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Decreasing (USFWS, 2012)

Resiliency:

Low (inferred from NatureServe, 2015; USFWS, 2012)

Representation:

Low (inferred from NatureServe, 2015; USFWS, 2012)

Redundancy:

Low (inferred from NatureServe, 2015; USFWS, 2012)

Number of Populations:

1 - 5 (NatureServe, 2015)

Population Size:

1 - 1000 individuals (NatureServe, 2015)

Population Narrative:

Since this species is annual, location varies from year to year. There may not be more than a few dozen individuals at any given time. Two current (between 1982 and 1997) and three historical occurrences. (NatureServe, 2015). USFWS (2012) notes 'Species status review [FY 2011 Recovery Data Call (August 2011)]: Decreasing '. In 2007, a single individual was observed in fruit at Puu Makaala Natural Reserve Area (Plant Extinction Prevention Program 2008). From 2007 and 2008, a total of five individuals were observed at two sites in the Koa Unit of Hawaii Volcanoes National Park (Plant Extinction Prevention Program 2008). In 2010, the Plant Extinction Prevention Program (2009) reported a total of only five wild individuals of *Sicyos alba* on Hawaii Island (USFWS, 2012). Low resiliency, representation and redundancy are inferred based on this species limited geographic range, specific habitat requirements and low number of known populations.

Threats and Stressors

Stressor: Feral pigs (USFWS, 1998)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Habitat damage by feral pigs is listed as a threat to this species (USFWS, 1998).

Stressor: Trail clearing (USFWS, 1998)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Trail clearing is listed as a threat to this species (USFWS, 1998).

Stressor: Non-native plants (USFWS, 1998)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Non-native plants are listed as a threat to this species (USFWS, 1998).

Stressor: Volcanic activity (USFWS, 1998)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Habitat change due to volcanic activity is listed as a threat to this species (USFWS, 1998).

Stressor: Stochastic events (USFWS, 1998)

Exposure:

Response:

Consequence: Extinction

Narrative: Risk of extinction from man-made or natural events is listed as a threat to this species (USFWS, 1998).

Stressor: Reduced vegetative vigor (USFWS, 1998)

Exposure:

Response:

Consequence: Extinction

Narrative: Reduced vegetative vigor due to the small number of existing individuals is listed as a threat to this species (USFWS, 1998).

Recovery

Reclassification Criteria:

For downlisting, a total of five to seven populations of *Sicyos alba* should be documented on the island of Hawaii. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 500 mature individuals per population. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered (USFWS, 2012).

Delisting Criteria:

For delisting, a total of eight to ten populations of *Sicyos alba* should be documented on the island of Hawaii. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with 500 mature individuals per population. Each population should persist at this level for a minimum of five consecutive years before delisting is considered (USFWS, 2012).

Recovery Actions:

- Neither the reclassification or delisting criteria have been met (USFWS, 2012).

Conservation Measures and Best Management Practices:

- Captive propagation for genetic storage and reintroduction: o Continue to collect seeds from all existing populations and send to at least two or three different venues for propagation. o Propagate the species ex situ in at least two or three separate venues (USFWS, 2012).
- Reintroduction / translocation site identification – Determine areas within the native range of the species that are most suitable for reintroduction purposes (USFWS, 2012).
- Reintroduction / translocation implementation – Continue to reintroduce the species back into its known historical range (USFWS, 2012).
- Ungulate exclosure – Continue to construct fenced exclosures around all existing wild and reintroduced populations and monitor the fences for any signs of breaching (USFWS, 2012).
- Ungulate control – Protect all populations against disturbances from feral pigs (USFWS, 2012).
- Ecosystem-altering invasive plant species control – Control invasive introduced plant species within exclosures and from areas immediately adjacent to all known populations (USFWS, 2012).

- Surveys / inventories – Resurvey the historical geographical range of the species for previously unknown populations or individuals (USFWS, 2012).
- Population biology research – Carry out field studies to hand pollinate individuals in the wild to enhance reproductive success of the species (USFWS, 2012).
- Site / area / habitat protection – Develop and implement effective measures to reduce the impacts of hiking and trail maintenance and lava flow (USFWS, 2012).
- Threats monitoring and control: o Monitor populations at least twice a year for evidence of fence breaching by feral pigs or other introduced vertebrate species. o Monitor reintroductions and wild populations twice a year for evidence of pests or diseases. o Alliance and partnership development – Work with the National Park Service, Hawaii Division of Forestry and Wildlife, and other land managers to continue implementation of ecosystem-level restoration and management to benefit this species. o Threats research – Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species.

SPECIES ACCOUNT: *Sicyos lanceoloideus* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/31/2016; Pacific Region (R1) (USFWS, 2016a)

Physical Description

A perennial vine. Stems are 49 ft. (15 m) long with a woody base. Leaves are broadly ovate and palmately 3- to 5- lobed. Inflorescences are branched, 3 to 8 in (8 to 20 cm) long, with white flowers. Fruit are green, up to 1 in (25 mm) long and beaked (Telford 1999, p. 581) (USFWS, 2015).

Taxonomy

A member of the gourd family (Cucurbitaceae) (USFWS, 2015). *Sicyos lanceoloideus* was called "Sicyos sp. A" in Wagner et al. (1990, Manual); see Supplement (1999, P. 1873). The name was published in Novon 9(3): 444, 1999, as *Sicyos lanceoloideus* (St. John) W.L. Wagner & D.R. Herbst (NatureServe, 2015).

Historical Range

Sicyos lanceoloideus was historically found on the islands of Kauai (Kalalau Valley and Waimea Canyon) and Oahu (Waianae Mountains) (Telford 1999, p. 581) (USFWS, 2015).

Current Range

Currently, *S. lanceoloideus* occurs on Kauai in the Na Pali-Kona FR, and on Oahu in the Waianae Mountains (USFWS, 2015).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: Not available

Habitat Type

Adult: Terrestrial (USFWS, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Mesic forest (USFWS, 2015)

Geographic or Habitat Restraints or Barriers

Adult: 1,800 - 2,700 ft. elevation (USFWS, 2015)

Habitat Narrative

Adult: *Sicyos lanceoloideus* occurs on ridges or spurs in mesic forest at 1,800 to 2,700 ft. (550 to 800 m), in the dry cliff (Oahu), lowland mesic (Oahu and Kauai), and montane mesic (Kauai) ecosystems (Telford p. 581; HBMP 2010; TNCH 2007) (USFWS, 2015).

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Not available

Population Information and Trends

Population Trends:

Not available

Resiliency:

Low (inferred from USFWS, 2016b)

Redundancy:

Low (inferred from USFWS, 2016b)

Number of Populations:

8 (USFWS, 2016b)

Population Size:

Kauai: 4; Oahu: < 35 (USFWS, 2016b)

Population Narrative:

Currently, on Kauai, there are four individuals in three locations (Kishida 2015, in litt.). On Oahu, this species occurs in 5 locations in the Waianae Mountains totaling fewer than 35 individuals (HBMP 2010; U.S. Army 2014 database). Because this species is a vine, determining exact numbers is difficult (PEPP 2013, p. 189). In addition, occurrences and numbers vary widely as individuals have been observed to persist for fewer than 7 years (Sailer 2015, in litt.) (USFWS, 2016b).

Threats and Stressors

Stressor: Feral ungulates (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Feral pigs and goats modify and destroy the habitat of *Sicyos lanceoloideus* on Kauai and Oahu, with evidence of the activities of these animals reported in the areas where this species occurs (PEPP 2013, p. 189; PEPP 2014, p. 166; HBMP 2010) (USFWS, 2015).

Stressor: Nonnative plants (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Nonnative plants modify and destroy the native habitat of *S. lanceoloideus*, and displace this species and other native Hawaiian plants by competing for water, nutrients, light, and space, or they may produce chemicals that inhibit the growth of other plants (Smith 1985, pp. 180–250; Vitousek et al. 1987 in Cuddihy and Stone 1990, p. 74; HBMP 2010) (USFWS, 2015).

Stressor: Small population size/stochastic events (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Drought and fire are also reported to pose a threat to *S. lanceoloideus* (PEPP 2014, pp. 166; HBMP 2010). Owing to the small remaining number of individuals, this species may experience reduced reproductive vigor due to low levels of genetic variability, leading to diminished capacity to adapt to environmental changes, thereby lessening the probability of its long-term persistence (Barrett and Kohn 1991, p. 4; Newman and Pilson 1997, p. 361) (USFWS, 2015).

Stressor: Climate change (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Climate change may result in alteration of the environmental conditions and ecosystems that support this species. *Sicyos lanceoloideus* may be unable to tolerate or respond to changes in temperature and moisture, or may be unable to move to areas with more suitable climatic regimes (Fortini et al. 2013, p. 89) (USFWS, 2015).

Recovery

Reclassification Criteria:

Not available - this species does not have a recovery plan.

Delisting Criteria:

Not available - this species does not have a recovery plan.

Recovery Actions:

- Not available - this species does not have a recovery plan.

Conservation Measures and Best Management Practices:

- Survey for populations of *Sicyos lanceoloideus* in areas of potentially suitable habitat (USFWS, 2014).
- Continue propagation efforts for maintenance of genetic stock (USFWS, 2014).
- Reintroduce individuals into suitable habitat within historical range that is being managed for additional known threats (e.g., nonnative animals and plants) to this species (USFWS, 2014).

SPECIES ACCOUNT: *Sicyos macrophyllus* (ʻanunu, Largeleaf bur-cucumber)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/31/2016; Pacific Region (R1) (USFWS, 2016a)

Physical Description

Sicyos macrophyllus is a perennial vine with stems up to 49 feet (ft) (15 meters (m)) long and 1.6 inches (in) (4 centimeters (cm)) in diameter. Annual stems are sparsely pubescent with black spots. Leaves are broadly ovate with a narrow basal sinus and are deeply lobed. The upper leaf surface is glabrous while the lower surface is densely pubescent. Tendrils are twice branched. Flowers are either male or female, occur in pubescent panicles, and have a greenish yellow corolla. The fruit is round and green (Telford 1999, p. 578).

Taxonomy

Kingdom: Plantae; Phylum: Anthophyta; Class: Dicotyledoneae; Order: Violales; Family: Cucurbitaceae (Cucumbers). *Sicyos macrophyllus* was described by Asa Gray. This species is recognized as a distinct taxon in the Manual of Flowering Plants of Hawaii (Telford 1999, p. 578).

Historical Range

Historically, *Sicyos macrophyllus* was known from Puuwaawaa, Laupahoehoe, Puna, and South Kona on the island of Hawaii; and from Kipahulu Valley on the island of Maui there is only a single historic record from the eastern side of Haleakala (volcano) from 1919 (HBMP 2008; NatureServe 2007).

Current Range

Currently, this species occurs on the island of Hawaii at Puu Mali, Puuwaawaa (Puu Iki), Honaunau, Hakalau National Wildlife Refuge-Kona Unit, Kaohe, Kukuipope, Kipuka Maunaiu, Kipuka Ki, and Puu Huluhulu (HBMP 2008; L. Pratt, U.S.G.S. Biological Resources Discipline, pers. comm. 2008; K. Bio, Plant Extinction Prevention (PEP) Program, pers. comm. 2008).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Habitat Type

Adult: Moist and wet forests on old volcanic substrates; large portions of the species' range is now pastureland with native remnants where individuals of the species can still be found (NatureServe 2007).

Habitat Vegetation or Surface Water Classification

Adult: Forest-Hardwood, Forest/Woodland

Environmental Specificity

Adult: Unknown

Habitat Narrative

Adult: Typical habitat is wet *Metrosideros polymorpha* (ohia) forest and subalpine *Sophora chrysophylla*-*Myoporum sandwicense* (mamane-naio) forest on old volcanic substrates at elevations between 4,000 and 6,600 ft (1,200 and 2,000 m) (Hawaii Biodiversity and Mapping Program (HBMP) 2008; Telford 1999, p. 578). Large portions of the species' range is now pastureland with native remnants where individuals of the species can still be found (NatureServe 2007).

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Declining

Species Trends:

Unknown

Number of Populations:

10 populations

Population Size:

24-26 individuals

Population Narrative:

Sicyos macrophyllus is endemic to the islands of Hawaii and Maui, but currently known from 10 populations on Hawaii only, totaling between 24 and 26 individuals (HBMP 2008; L. Pratt, U.S.G.S. Biological Resources Discipline, pers. comm. 2008; K. Bio, Plant Extinction Prevention Program, pers. comm. 2008). It appears that a naturally occurring population at Kipuka Ki in Hawaii Volcanoes National Park is reproducing on its own by seeds, but seeds have not been successfully germinated under nursery conditions (HBMP 2008; L. Pratt, pers. comm. 2005). This species has been outplanted at several sites in Hawaii Volcanoes National Park and is persisting (Orlando 2015, in litt.). The individual on Maui has not been observed since 1987 (HBMP 2010) (USFWS, 2016b).

Threats and Stressors

Stressor: Habitat degradation and destruction: Feral pigs, mouflon sheep, and cattle

Exposure:

Response:

Consequence:

Narrative: *Sicyos macrophyllus* is threatened by feral pigs (*Sus scrofa*), mouflon sheep (*Ovis aries*), and feral cattle (*Bos taurus*) that degrade and destroy habitat (HBMP 2008; PEP Program 2008, p. 109). While rooting in the ground in search of the invertebrates and plant material they eat, feral pigs disturb and destroy vegetative cover, trample plants and seedlings, and threaten

forest regeneration by damaging seeds and seedlings. They disturb soil and cause erosion, especially on slopes. Alien plant seeds are dispersed on their hooves and coats as well as through their digestive tracts, and the disturbed soil is fertilized by their feces, helping these plants to establish. Pigs are a major vector in the spread of many introduced plant species (Smith 1985; Stone 1985; Medeiros et al. 1986; Scott et al. 1986; Tomich 1986; Cuddihy and Stone 1990; Wagner et al. 1999a). Sheep roam the upper elevation dry forests of Mauna Kea, Mauna Loa, and Hualalai (above 3,300 ft (1,000 m)), causing damage similar to that of goats (Stone 1985). Sheep have decimated vast areas of native forest and shrubland on Mauna Kea and continue to do so as a managed game species (Stone 1985; Cuddihy and Stone 1990). A survey conducted in 2004 of the Kahuku section of Hawaii Volcanoes National Park estimated that there were more than 2,500 sheep within the unit, and that without removals, the population doubling time would occur within 3 to 4 years (Hess et al. 2006). Cattle eat native vegetation, trample roots and seedlings, cause erosion, create disturbed areas into which alien plants invade, and spread seeds of alien plants in their feces and on their bodies. The forest in areas grazed by cattle becomes degraded to grassland pasture, and plant cover is reduced for many years following removal of cattle from an area. In addition, several alien grasses and legumes intentionally introduced for cattle forage have become invasive, noxious weeds that outcompete and replace native plants (Tomich 1986; Cuddihy and Stone 1990; Wagner et al. 1999a).

Stressor: Predation: Feral pigs, mouflon sheep, and cattle

Exposure:

Response:

Consequence:

Narrative: Predation by feral pigs, mouflon sheep, and cattle is a likely threat to *Sicyos macrophyllus* (HBMP 2008; Plant Extinction Prevention (PEP) Program 2008, p. 109). Evidence of browsing on and removal of *S. macrophyllus* by feral cattle has been observed at the population at Hakalau NWR-Kona Unit (PEP Program 2008, p. 109).

Stressor: Habitat degradation and competition: Nonnative plants

Exposure:

Response:

Consequence:

Narrative: *Sicyos macrophyllus* is threatened by alien plant species that degrade habitat and outcompete native plants (HBMP 2008; PEP Program 2008, p. 109). Competition may be for space, light, water, or nutrients, or there may be a chemical produced that inhibits growth of other plants (Smith 1985; Cuddihy and Stone 1990). In addition, nonnative pest plants found in habitat similar to that of this species have been shown to make the habitat less suitable for native species (Smathers and Gardner 1978; Smith 1985; Loope and Medeiros 1992; Medeiros et al. 1992; Ellshoff et al. 1995; Meyer and Florence 1996; Medeiros et al. 1997; Loope et al. 2004). In particular, alien pest plant species degrade habitat by modifying availability of light, altering soil water regimes, modifying nutrient cycling, or altering fire characteristics of native plant communities (Smith 1985; Cuddihy and Stone 1990; Vitousek et al. 1997). Because of demonstrated habitat modification and resource competition by nonnative plant species in habitat similar to the wet forest and subalpine forest habitat of *S. macrophyllus*, the Service believes nonnative plant species are a threat to this species.

Stressor: Stochastic events (USFWS, 2016b)

Exposure:

Response:**Consequence:**

Narrative: Stochastic events such as fire are also reported as a threat to *S. macrophyllus* (HBMP 2010) (USFWS, 2016b).

Stressor: Low genetic variability (USFWS, 2016b)

Exposure:**Response:****Consequence:**

Narrative: This species experiences reduced reproductive vigor due to low levels of genetic variability, leading to diminished capacity to adapt to environmental changes, thereby lessening the probability of its long-term persistence (Barrett and Kohn 1991, p. 4; Newman and Pilson 1997, p. 361) (USFWS, 2016b).

Stressor: Climate change (USFWS, 2016b)

Exposure:**Response:****Consequence:**

Narrative: Fortini et al. (2013, p. 89) found that, as environmental conditions are altered by climate change, *S. macrophyllus* is unlikely to tolerate or adapt to projected changes in temperature and moisture, and is unlikely to be able to move to areas with more suitable climatic conditions (USFWS, 2016b).

Recovery**Recovery Actions:**

- Survey for populations of *Sicyos macrophyllus* in areas of potentially suitable habitat.
- Remove feral pigs, sheep, and cattle from areas occupied by *S. macrophyllus* and maintain control through exclusion fencing.
- Remove and control nonnative plants.
- Conduct propagation efforts for maintenance of genetic stock.
- Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species.

Conservation Measures and Best Management Practices:

- Remove feral pigs, sheep, and cattle from areas occupied by *S. macrophyllus* and maintain control through exclusion fencing.
- Remove and control nonnative plants.
- Conduct propagation efforts for maintenance of genetic stock.
- Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species.

SPECIES ACCOUNT: *Sidalcea keckii* (Keck's Checker-mallow)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Southwest (R8) (USFWS, 2015)

Physical Description

A slender, bristly-hairy, annual herb, 1.5-3.5 dm tall. A few deep pink flowers bloom April-May. (NatureServe, 2015)

Taxonomy

A distinct species in a genus of about 22 species of western North America. (NatureServe, 2015)

Historical Range

At the time of listing, the Mine Hill *Sidalcea keckii* population existed within a 0.73 acre area. The population occurred on a privately owned 700-acre parcel of land that was used for livestock 5 grazing. The occurrence of *S. keckii* at Mine Hill in Tulare County may have been extirpated when orange groves were planted on the property. (USFWS, 2012)

Current Range

Tulare and Fresno counties (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/18/2003.

Legal Description

On March 18, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Sidalcea keckii* (Keck's Checker-mallow) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes three critical habitat units (CHUs), in California (68 FR 12863-12880).

Critical Habitat Designation

The critical habitat designation for *Sidalcea keckii* includes three CHUs in Fresno and Tulare counties, California. This species critical habitat encompasses approximately 1,085 acres (ac) (438 hectares (ha)) (68 FR 12863-12880).

Unit 1: Piedra: Unit 1 is on the western slopes of Tivy Mountain in the Piedra area of southern Fresno County. It contains 206 ha (510 ac), of which 203 ha (503 ac) are privately owned and 3 ha (7 ac) are managed by the BOR (R. Faubion, pers. comm., 2002). Of the privately owned land, 77 ha (189 ac) of proposed critical habitat is on the Tivy Mountain Reserve which is owned by SFC and established for the conservation of *Sidalcea keckii* and other rare plants. SFC uses managed grazing as a tool to reduce competing non-native grasses from *S. keckii* sites, and monitors the plant as well (SFC 2001). Another 6.5 ha (16 ac) of this unit occurs on a conservation easement held by SFC on privately owned land adjacent to the reserve. Recent surveys of the areas containing documented populations of *Sidalcea keckii* were conducted in 1998, 2000, and 2001. In 1998, surveys coordinated by the BOR found 500 to 1,000 plants in the area (Cypher 1998). Surveys conducted in 2000 and 2001 by the SFC found eight separate patches of *S. keckii* growing on both Fancher and Cibo soils (C. Peck, in litt., 2002). This unit is essential to the conservation of

the species because it is one of the two sites at which the species has been observed since the 1930s. When the number of populations or geographic distribution of a species are severely limited, as is the case when plants have only been observed recently at two locations, possible extinction or extirpation due to random events become a concern. Examples of random events that are a concern include fire and disease (Shaffer 1981, 1987; Primack 1993, Meffe and Carroll 1994). This unit is also essential because it includes the most northerly location known for *S. keckii*, and is the only location where above-ground plants with maroon-centered flowers have been documented (Cypher 1998).

Unit 2: Mine Hill: Unit 2 is about 3 km (2 mi) south of Success Dam and 5 km (3 mi) east of Porterville in Tulare County and contains 86 ha (213 ac), all of which are on privately owned land. Unit 2 encompasses a single known patch of *Sidalcea keckii*, which contained approximately 60 plants when last surveyed in 1992. At the request of the landowner, it has not been surveyed since that time. However, based on information from public comment, the standing population at Mine Hill may have been extirpated by conversion of the habitat to an orange grove. We currently do not know how much habitat may have been converted, although we believe that much of the habitat around the original population remains potentially viable and may contain a seed bank or standing plants. The Coarsegold rock outcrop soils of the area are best suited to rangeland (SCS 1982), which is the current use of the area where not converted to orchard. However the site is also zoned for mobile home development (R. Brady, Tulare County Planning Department, pers. comm., 1997). This unit is essential to the conservation of the species because it is presumably one of the two known locations where *Sidalcea keckii* plants have been observed since the 1930s. As is the case with Unit 1, when the number of populations or geographic distribution of a species are severely limited, possible extinction or extirpation due to random events become a concern. Examples of random events that are a concern include fire and disease (Shaffer 1981, 1987; Primack 1993, Meffe and Carroll 1994).

Unit 3: White River: Unit 3 is located near the town of White River in southern Tulare County. It contains 146 ha (362 ac), all of which is private land. Unit 3 contains the “type” location, specimens from which were used to first describe the species in 1940 (Wiggins 1940). This site is the only one not closely associated with serpentine rock, but contains the primary constituent elements that would support the species. This may be due to the presence of currently unknown and unmapped serpentine areas, or it may be due to an increased ability to compete on non-serpentine Cibo soils. As noted above, the White River site is one of the extremely few locations where *Sidalcea keckii* has ever been observed and may be occupied by a seed bank. *Sidalcea keckii* plants may still occur here, but none have been documented recently. Even if the species is not rediscovered at the White River site, we believe the site is essential to the conservation of the species. Because *S. keckii* has been observed at the site, it is the most appropriate site at which a reestablishment effort might be attempted. The combination of small range, few populations, and restricted habitat makes *S. keckii* susceptible to extinction or extirpation from a significant portion of its range due to random events, such as fire, disease, or other occurrences (Shaffer 1981, 1987; Primack 1993, Meffe and Carroll 1994). Such events are a concern when the number of populations or geographic distribution of a species are severely limited, as is the case with *S. keckii*. Establishment of a third location for *S. keckii* is likely to be an important component in reducing the risk of extinction due to such catastrophic events. This location also represents the southernmost extent of the known historical range of the species.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Sidalcea keckii* critical habitat consists of two components (68 FR 12863-12880):

- (i) Minimally shaded annual grasslands in the foothills of the Sierra Nevada Mountains containing open patches in which competing vegetation is relatively sparse; and
- (ii) Serpentine soils or other soils that tend to restrict competing vegetation.

Life History**Food/Nutrient Resources****Habitat Type**

Adult: Gressy slopes (Natureserve, 2015)

Dependencies on Specific Environmental Elements

Adult: Serpentine soils (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Clumped (inferred from NatureServe, 2015)

Environmental Specificity

Adult: High (inferred from NatureServe, 2015)

Site Fidelity

Adult: High (inferred from NatureServe, 2015)

Habitat Narrative

Adult: Found on grassy slopes from 120 to 425 m elevation. The extant population is in a sparsely vegetated annual grassland on red or white-colored clay soils with 2-40 percent slopes. The clay substrates are thought to be derived from serpentine. (NatureServe, 2015)

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Decreasing (NatureServe, 2015)

Resiliency:

Low (NatureServe, 2015)

Representation:

Low (NatureServe, 2015)

Redundancy:

Low (NatureServe, 2015)

Population Growth Rate:

Loss of populations because of development. Decline of 50-70% (NatureServe, 2015)

Number of Populations:

1 - 5 (NatureServe, 2015)

Population Size:

1 - 1000 individuals (NatureServe, 2015)

Population Narrative:

Loss of populations because of development. Decline of 50-70% Known historically from 3 populations in Tulare and Fresno counties, California, but the species has potentially been extirpated from each location. A new location discovered in 1998 had approximately. 900 individuals. Historical occurrence at White River near Glenville, Tulare County, California. (NatureServe, 2015). Low resiliency, representation and redundancy are based on the low number of known populations and restricted habitat requirements.

Threats and Stressors

Stressor: Agricultural conversion (USFWS, 2012)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Agricultural development is listed as a threat to this species (USFWS, 2012).

Stressor: Potential development (USFWS, 2012)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Critical Habitat Unit KECK-1 includes 205 acres of land protected by the Sierra Foothill Conservancy, federally managed lands, and some private land. There is a single unprotected parcel within the Piedra population that could potentially be developed (Stebbins 2004). However, there are no imminent plans for development at this time. The Service is not aware of any activities that would have caused destruction or modification habitat within Critical Habitat Unit KECK-1 since the last 5-Year Review in 2007 (USFWS, 2012).

Stressor: Grazing (USFWS, 2012)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: At the time of listing, cattle (*Bos taurus*) grazing was discussed as a potential threat to the species; there has been no known change since the final listing. Cattle grazing may limit encroachment of non-native grasses (C. Peck, in litt., 2002; Weiss 1999). However, cattle have been observed to cause damage to *S. keckii* by eating or trampling it, although the damage was barely noticeable a week later (Cypher 1998). Increased grazing during months of flowering, seed-set, or seed maturation could potentially reduce local population viability and negatively affect long-term conservation of this species. Summary of Factor C: Diseases do not appear to be

a threat at this time. Overgrazing by cattle may threaten the long-term conservation of this species (USFWS, 2012).

Stressor: Inadequacy of Existing Regulatory Mechanisms (USFWS, 2012)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Summary of Factor D: In summary, the Endangered Species Act is the primary Federal law that has provided protection for this species since the dates of its listing as endangered in 2000. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent their status under the Act. Therefore, we continue to believe other laws and regulations have limited ability to protect the species in absence of the Endangered Species Act (USFWS, 2012).

Stressor: Small population size (USFWS, 2012)

Exposure:

Response:

Consequence: Threat of extinction/lack of genetic variability

Narrative: Small population size increases the susceptibility of a population to extirpation from random demographic, environmental, and/or genetic events, affecting survival and reproduction of individuals (Shaffer 1981, 1987; Lande 1988; Groom et al. 2006). Small populations of annual species, such as *Sidalcea keckii*, may be more vulnerable to random environmental events such as extreme weather, disease, fire, or insect infestations (Shaffer 1981, 1987; Menges 1991; Groom et al 2006). For example, if a fire should occur before plants bloom or during the blooming season, the fire could destroy the individual plants as well as deplete the seed bank. The threat from random natural events has increased since *S. keckii* was listed because the plant now is found only at one location (USFWS, 2012).

Stressor: Altered fire regime (USFWS, 2012)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: The absence of *Sidalcea keckii* from dense grasslands, even those on serpentine clay soils, suggests that it is a poor competitor (Stebbins 1992; J. Stebbins, pers. comm. 2001). Thus, aggressive, nonnative grasses such as *Bromus madritensis* ssp. *rubens*, and *Bromus hordeaceus* could potentially outcompete *S. keckii* if conditions changed to favor these grasses. For example, soil disturbances, increased availability of soil nutrients (e.g., nitrogen deposition) from cattle feces and other sources, and absence of fire may provide ideal conditions that would allow these nonnative grasses to outcompete *S. keckii*. Non-native grasses may generate increased fuel sources that could increase intensity of fires above the normal range of variability in serpentine grasslands that support *S. keckii* (E. Cypher, California Department of Fish and Game, pers. comm. 2006). However, an appropriate fire regime may reduce the presence of nonnative grasses and benefit serpentine endemic species such as *S. keckii* (Harrison et al. 2003) (USFWS, 2012).

Stressor: Climate change (USFWS, 2012)

Exposure:

Response:**Consequence:** Loss of habitat

Narrative: Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain. It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects. While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to particular species at this time (USFWS, 2012).

Recovery**Recovery Actions:**

- There is no approved final or draft recovery plan for the species (USFWS, 2012).

Conservation Measures and Best Management Practices:

- Continue to protect property with suitable habitat for *Sidalcea keckii*. Acquisition of additional habitat through fee title or conservation easements is needed for the recovery of the species (USFWS, 2012).
- Survey additional serpentine and gabbro soil areas in Tulare and Fresno Counties to discover additional populations of *Sidalcea keckii* (USFWS, 2012).
- If additional populations of *Sidalcea keckii* are not discovered through systematic surveys, the species should be reintroduced into protected land within critical habitat units (USFWS, 2012).
- Continue monitoring the status and trend of *Sidalcea keckii* to determine whether this species is stable, increasing, or declining (USFWS, 2012).
- Continue genetic studies to confirm the species identity of plants preliminarily identified as *Sidalcea keckii* so that we can more accurately determine the actual number of populations, the geographic range, and types of habitats that support this species (USFWS, 2012).

SPECIES ACCOUNT: *Sidalcea nelsoniana* (Nelson's checker-mallow)

Species Taxonomic and Listing Information

Listing Status: Threatened; 03/15/1993; Pacific Region (R1)

Physical Description

It has tall, lavender to deep pink flowers that are borne in somewhat open clusters 50 to 150 cm (19.2 to 48 inches) tall at the end of short stalks (USFWS 1993). Plants are partially dioecious, in that they have either perfect flowers (male and female) or pistillate flowers (female only) (USFWS, 2016).

Taxonomy

Nelson's checkermallow is a perennial herb in the mallow family (Malvaceae) (USFWS, 2016).

Current Range

Nelson's checkermallow primarily occurs in Oregon's Willamette Valley, but is also found at several sites in Oregon's Coast Range and at two sites in the Puget Trough of southwestern Washington. The plant's range extends from southern Benton County, Oregon, north to Cowlitz County, Washington, and from central Linn County, Oregon, west to the crest of the Coast Range. In the late 1990s, the species was known to occur in 65 occurrences within five relict population centers in Oregon and Washington and occupy approximately 273 acres (USFWS 1998) (USFWS, 2016).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Insect pollinated (USFWS, 2016)

Breeding Season

Adult: Flowering typically occurs from late May to mid-July, but may extend into September in the Willamette Valley (USFWS, 2016).

Reproduction Narrative

Adult: The plant can reproduce vegetatively, by rhizomes, and by seeds, which drop near the parent plant. Flowering typically occurs from late May to mid-July, but may extend into September in the Willamette Valley. Fruits have been observed as early as mid-June and as late as mid-October. Coast Range populations generally flower later and produce seed earlier, probably because of the shorter growing season. Seed production for a Nelson's checkermallow plant is typically high. An average plant may produce between 300 and 3000 seeds, but could potentially exceed 10,000 seed. The limiting factor of Nelson's checkermallow seed production is weevil damage. Weevils typically associated with the plants in the wild often infest flowers and eat flowers. Early in seed production, weevils often consume developing embryos and may

account for 80 to 100% loss of pre-dispersal seed. In the Willamette Valley, Nelson's checkermallow begins flowering as early as mid-May, and continues through August to early September, depending upon the moisture and climatic conditions of each site. Coast Range populations experience a shorter growing season and generally flower later and senesce earlier. Nelson's checkermallow inflorescences are indeterminate, and often simultaneously exhibit fruits, open flowers, and unopened buds. Seeds are deposited locally at or near the base of the parent plant and may be shed immediately or persist into winter within the dry flower parts that remain attached to the dead stems. Above-ground portions of the plant die back in the fall, usually followed by some degree of regrowth at the base, with the emergence of small, new leaves that persist through the winter directly above the root crown. It is not uncommon for some plants to continue producing some flowers into the fall and early winter, although this is usually limited to one or two small stems per plant, consequently with little seed production (USFWS 1998). Perfect-flowered Nelson's checkermallow are protandrous, with complete temporal separation of male and female phases in individual flowers (Gisler and Meinke 1998). This prevents self-fertilization. The bottom-to-top foraging observed among most bee visitors also encourages outcrossing because pollinators leave male-phase flowers at the top of one raceme and then fly to female phase flowers on the bottom of the next raceme. Nelson's checkermallow is pollinated by a variety of insects, including at least 17 species of bees, 3 species of wasps, 9 species of flies, 6 species of beetles, and 5 species of butterflies/moths (Gisler 2003). Pre-dispersal seed predation by weevils (*Macrorhoptus sidalceae*) is extremely high in many populations, and may severely curtail, if not virtually eliminate, seed survival in many populations (Gisler and Meinke 1998). The weevils appear to be restricted to Willamette Valley, southwestern Washington and lower Coast Range populations (around Grand Ronde), but do not infest the Coast Range populations in Yamhill, Tillamook, and Washington counties. The weevils are native, host-specific, and are themselves parasitized by tiny undescribed wasps (Gisler and Meinke 1998) (USFWS, 2016).

Habitat Type

Adult: Wet prairies and stream sides (USFWS, 2016)

Habitat Narrative

Adult: In the Willamette Valley, Nelson's checkermallow is known from wet prairies and stream sides (USFWS 2010). Nelson's checkermallow populations occur at low elevations (below 200 m (650 feet)) within a mosaic of urban and agricultural areas, with concentrations around the cities of Corvallis and Salem. Although occasionally occurring in the understory of *Fraxinus latifolia* (Oregon ash) woodlands or among woody shrubs, Willamette Valley populations usually occupy open habitats supporting early seral plant species. These native prairie remnants are frequently found at the margins of sloughs, ditches, and streams; roadsides; fence rows; drainage swales; and fallow fields. Soil textures of the occupied sites vary from gravelly, well drained loams to poorly drained, hydric clay soils (CH2MHill 1986, Glad et al.1994). Some of the native plants commonly associated with *Sidalcea nelsoniana* in the Willamette Valley include: *Achillea millefolium* (yarrow), *Juncus effusus* (common rush), *Carex* spp. (sedge), *Spiraea douglasii* (western spiraea), *Crataegus douglasii* (Douglas' hawthorn), *Geum macrophyllum* (large-leaved avens), and *Fraxinus latifolia* (Oregon Department of Agriculture 1995). Most sites have been densely colonized by invasive weeds, especially introduced forage grasses. Common non-native species found with Nelson's checkermallow include *Festuca arundinacea*, *Rosa* spp. (rose), *Cirsium arvense* (Canada thistle), *Hypericum perforatum* (common St. John's wort), *Rubus* spp. (blackberry), *Phleum pratense* (timothy), *Holcus lanatus* (velvet grass), *Vicia* spp.,

Chrysanthemum leucanthemum (oxeye-daisy), *Agrostis capillaris*, *Alopecurus pratensis*, *Phalaris arundinacea*, *Geranium* spp. (geranium), *Lotus corniculatus* (bird's-foot trefoil) and *Daucus carota* (Oregon Department of Agriculture 1995). Coast Range Nelson's checkermallow populations typically occur in open, wet to dry grassy meadows, intermittent stream channels, and along margins of coniferous forests, with clay to loam soil textures (Glad et al. 1987) at elevation ranging from 490 to 600 m (1,610 to 1,970 feet). These areas generally support more native vegetation than Willamette Valley sites. Native plants commonly associated with Nelson's checkermallow in the Coast Range include *Senecio triangularis* (spear-head senecio), *Fragaria Virginiana*, *Juncus* spp., *Carex* spp., and *Achillea millefolium*; non-native associated species often include *Senecio jacobaea* (tansy ragwort), *Holcus lanatus*, and *Phleum pratense*. A variety of animal species are associated with Nelson's checkermallow. Stems and inflorescences are commonly eaten by deer and elk. Nelson's checkermallow flowers are visited by a diverse assemblage of insects, including leafcutter bees (Megachilidae), honey bees (Apidae), bumble bees (Bombidae), hover flies (Syrphidae), butterflies (Hesperiidae), and pollen-foraging beetles (Cerambycidae and Meloidae). The species is also a host for various phytophagous insects such as aphids (Aphididae), stinkbugs (Pentatomidae), scentless plant bugs (Rhopalidae), spotted cucumber beetles (Chrysomelidae), plant bugs (Miridae), milkweed bugs (Lygaeidae), spittlebugs (Cercopidae), butterfly larvae (Lycaenidae: *Strymon melinus*; Nymphalidae: *Vanessa anabella*), and in the Willamette Valley, weevils (Curculionidae: *Macrohoptus sidalcae*) (USFWS, 2016).

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Unknown (USFWS, 2016)

Number of Populations:

~90 (USFWS, 2016)

Population Size:

10,000 - 100,000 individuals (NatureServe, 2015)

Population Narrative:

The species' high susceptibility to pre-dispersal seed predation by weevils may eventually lead to recruitment problems, particularly in small populations already subject to other stresses such as competition with dense stands of invasive species. However, the ease of propagating this species by both seeds and rhizomes (Gisler 2004) suggests that its rarity may be more related to the significant destruction and degradation of its habitat rather than to any intrinsic vulnerability of the plants themselves. Prior to European settlement, the moist, open habitats preferred by this species were likely maintained by natural wildfires, fires set by Native Americans, and sporadic flooding. These landscape processes have been dramatically suppressed since that time, resulting in successional woody overgrowth of many formerly open sites. In addition, livestock grazing, agricultural and urban land conversion, and stream channel alterations have greatly reduced the quantity and quality of this species' preferred habitat, especially in the Willamette Valley; Bartels and Wilson (2003) state that land use changes over the past 150 years have altered or destroyed more than 99% of Willamette Valley wetland habitats. Although there is no direct evidence of this species' abundance prior to European

settlement, the vast declines in its preferred habitat strongly suggest that plants historically occurred more extensively throughout native Willamette Valley grasslands. In the Coast Range, habitat decline since European settlement does not appear to have been as severe, although habitat quality impacts (e.g. aggressive introduced species) are still apparent. Interestingly, some sources have suggested that this species may have been more recently introduced into Coast Range mountain meadows via livestock feed originating in the Willamette Valley (CH2M Hill 1986 cited in USFWS 1998). Decline of >10% Many known occurrences contain few plants. Based on occurrence data, total population size appears to be approximately 20,000 - 35,000 individuals. Guerrant (2001) estimated a total of around 26,500 individuals as of 1997; since then, an additional 25 occurrences have been documented, but many of these are small. 85 occurrences are currently believed extant, 83 in Oregon and 2 in Washington. Of the 83 Oregon occurrences, 3 are re-introductions and 4 are introductions. In Oregon, an additional 13 occurrences are ranked as historical/unknown, and a further 4 are believed extirpated. (NatureServe, 2015). In the late 1990s, the species was known to occur in 65 occurrences within five relict population centers in Oregon and Washington and occupy approximately 273 acres (USFWS 1998). The 2010 Recovery Plan states that Nelson's checkermallow was known from about 90 sites, comprising about 1,277 acres of total cover (USFWS 2010). Data collection for a range-wide inventory of Nelson's checkermallow was completed in 2014 (Curran, Institute for Applied Ecology, pers. comm. 2015). Results indicated that 71 populations composed of 214,111 individual plants in Oregon that have potential to contribute towards achieving recovery goals. Other smaller populations exist, but are unlikely to contribute to recovery. Of the 71 populations, 21 populations were less than 100 plants; 36 populations had 100 to 2,499 plants; and 14 populations had more than 2500 plants. Of those 14 populations, five contained over 10,000 plants (USFWS, 2016).

Threats and Stressors

Stressor: Development (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Agricultural and urban development have modified and destroyed habitats, fragmenting populations into small, widely scattered patches (USFWS 2010). In the Willamette Valley, extirpation is an ongoing threat to many Nelson's checker-mallow occurrences on private lands, roadsides, and undeveloped lots zoned for industrial and residential development. Within the genus *Sidalcea*, the actual sex ratio (the number of functionally pistillate to perfect flowers) of a population may be a strong contributing factor to its genetic vigor or vulnerability such that the ratio of pistillate to perfect flowers may ultimately control the amount and quality of seeds produced regardless of habitat quality. Likewise, seed predation by weevils prior to seed dispersal may also be a factor controlling seed production (USFWS, 2016).

Stressor: Hybridization (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of individuals/extinction

Narrative: There is a strong potential for interspecific hybridization among Nelson's checkermallow and other species of checkermallows in the region, although there are some ecological and genetic reproductive barriers to prevent it from occurring (Gisler 2003, 2004).

Nelson's checkermallow flowers later in the year than sympatric populations of *Sidalcea malviflora* ssp. *virgata* (rose checkermallow), but allopatric populations sometimes overlap in flowering periods. The two species are sexually compatible, thus human-mediated movement of the plants could result in formation of hybrids. Nelson's checkermallow and *S. cusickii* (Cusick's checker-mallow) are also fully compatible, and they also share pollinators and flowering times, but their geographic ranges are parapatric, with nearest populations narrowly separated by less than 1.6 km (1 mile) at the south end of Finley National Wildlife Refuge (Gisler 2004). If these species come into contact through human-mediated dispersal, hybridization could easily occur. Nelson's checkermallow is frequently found growing together with *S. campestris*, and they also share pollinators and flowering times, but they exhibit very low sexual compatibility (Gisler 2004). Reproductive barriers among the checker-mallows in the Willamette Valley likely evolved in response to selective pressure against hybridization (Gisler 2003, 2004); managers should be aware of the potential for hybridization as plants are moved around within the region (USFWS, 2016).

Stressor: Fire suppression (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Suppression of natural fire regimes is a threat to this species (USFWS, 2016).

Stressor: Woody vegetation (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Woody vegetation (via succession) is listed as a threat to this species (USFWS, 2016)

Recovery

Reclassification Criteria:

Not applicable.

Delisting Criteria:

Delisting will be considered when all of the following conditions have been met: (USFWS, 2010)

1. Distribution and abundance. The distribution of populations should reflect the extent of the species' historical geographic distribution to the extent practicable. See Table IV-6 in the Recovery Plan for distribution and abundance goals for this species. (USFWS, 2010)

2. Population trend and evidence of reproduction. The area of foliar cover shall have been stable or increasing over a period of at least 15 years. Stable does not mean that the population size is static over time; over a period of 15 years, the number of individuals in the population may exhibit natural year-to-year variability, but the trend must not be declining. Populations must show evidence of reproduction by seed set or presence of seedlings. (USFWS, 2010)

3. Habitat quality and management. Sites supporting populations of listed plants considered in Criterion 2 above must meet these criteria: (a) Prairie quality. Same as Downlisting Criterion 1.

(b) Security of habitat. Same as Downlisting Criterion 1. (c) Management, monitoring, and control of threats. Same as Downlisting Criterion 1. (USFWS, 2010)

4. Genetic material is stored in a facility approved by the Center for Plant Conservation. The stored genetic material in the form of seeds must represent the species' geographic distribution and genetic diversity through collections across the full range of the species. Collections from large populations are particularly important as reservoirs of genetic variability within the species. (USFWS, 2010)

5. Post-delisting monitoring plans and agreements to continue post-delisting monitoring are in place and ready for implementation at the time of delisting. Monitoring of populations following delisting will verify the ongoing recovery of the species, provide a basis for determining whether the species should be again placed under the protection of the Endangered Species Act, and provide a means of assessing the continuing effectiveness of management actions. (USFWS, 2010)

Recovery Actions:

- Details of the Recovery Actions are available in the 2010 Recovery Plan. Presented below is the introductory paragraph only. (USFWS, 2010)
- 1. Preserve, restore, and manage populations and habitat for the listed prairie species covered by this plan. The listed prairie species of western Oregon and southwestern Washington addressed by this plan are now found only in small, highly fragmented upland and wet prairie habitat remnants. The first step in the recovery of these species is to identify and protect the remaining populations with the greatest potential for restoration. The next step is to augment and, if necessary, reintroduce populations to restore connectivity between those that are currently isolated from one another to restore gene flow and create a population structure that provides for resiliency in a dynamic natural environment. Recovery for all of these species will depend upon the successful establishment of a network of protected populations in managed, suitable prairie habitats distributed across their historical range. As a large portion of the remnant prairie habitats within the range of these species is in private ownership, recovery will to a large extent depend upon the successful development of partnerships with private landowners and support of their efforts to protect, restore and manage native prairie habitats in the region. (USFWS, 2010)
- 2. Coordinate recovery actions to benefit other listed species and nonlisted prairie species of conservation concern. The extensive loss of both wet and upland prairie habitats throughout the geographic region addressed by this draft recovery plan has resulted in the concurrent declines of many of the native plants and animals associated with these ecosystems. In this plan we have attempted to focus not only on the recovery of the listed prairie species, but to extend these recovery efforts to the ecosystems upon which they depend. The recommended actions for restoring and reconnecting prairie habitats in western Oregon and southwestern Washington are intended to extend benefits beyond the threatened or endangered species addressed in the plan to all of the native prairie species in these regions, including nonlisted prairie species that are recognized as in decline. Proactive efforts to restore prairie systems should contribute to the arrest or reversal of these declines, thereby preventing the need to list these species in the future. Particularly on sites where listed species co-occur with nonlisted species of conservation concern, landowners or managers should be made aware so as to tailor management actions to avoid inadvertent negative impacts on any such species. Coordination with other agencies, private

landowners, or other interested parties will help ensure that the recovery actions outlined in this plan benefit the habitat and populations of other native prairie species. (USFWS, 2010)

- 3. Promote protection of listed species and prairie restoration on private lands. More than 90 percent of the land in the Willamette Valley is in private ownership. The restoration of prairie systems and their native plant and animal communities can therefore only be successful with the participation of private landowners. Without active management, populations of both listed and nonlisted species endemic to prairie habitats are almost certain to experience further declines. Working with private landowners and providing incentives to participate in the recovery effort for these species are critical elements of the recovery strategy. (USFWS, 2010)
- 4. Cultivate partnerships with both public and private agencies and organizations to promote the conservation of prairie ecosystems and listed prairie species. A diverse group of agencies and organizations are involved in recovery activities for the native prairies in western Oregon and southwestern Washington, including, but not limited to, the U.S. Fish and Wildlife Service, the Willamette Valley National Wildlife Refuge Complex, the U.S. Bureau of Land Management, U.S. Army Corps of Engineers, Confederated Tribes of Grand Ronde, Oregon Department of Transportation, City of Eugene, The Nature Conservancy, Oregon State University, Institute for Applied Ecology, Greenbelt Land Trust, McKenzie River Land Trust, Oregon Oak Communities Working Group, Washington Native Plant Society, Oregon Native Plant Society, Heritage Seedlings, and Berry Botanic Garden. Information regarding the recovery efforts for the prairie species should be shared with city and county planning, parks, and natural resource departments throughout the region covered by this recovery plan. City and county governments are the primary agencies that determine future land uses, and their participation is important for the recovery and restoration of the prairies and their associated listed species. Some local agencies are already making significant contributions toward prairie restoration; the West Eugene Wetlands are an excellent example of a significant conservation accomplishment achieved through a partnership of federal and local governments and private landowners/organizations. Plans, data, and information pertinent to the recovery of the prairie species must be synthesized and shared effectively between all agencies, groups, and individuals to leverage collective conservation efforts and achieve recovery. (USFWS, 2010)
- 5. Revise and update recovery plan as needed. Based on the results of the recommended research and monitoring efforts and the evaluation of the relative success or failure of different management techniques, the recovery plan should be revised periodically as needed to reflect this increased knowledge and improve the efficacy of future recovery actions. The scientific validity of the recovery criteria should also be reviewed and refined, if necessary, as more accurate species-specific data become available to assist with refining recovery criteria. (USFWS, 2010)
- 6. Develop post-delisting monitoring plans for each listed species prior to delisting. To ensure the continuing recovery of the listed species and adequacy of management actions to maintain the species at viable levels into the foreseeable future, a post-delisting monitoring plan must be developed and ready for implementation prior to delisting of any threatened or endangered species. Such a monitoring plan must be designed to be continued for a minimum of 5 years following the delisting action. (USFWS, 2010)

Conservation Measures and Best Management Practices:

- All of the General Plant Conservation Measures (Section 3.13.1) apply for Nelson's checkermallow. Nelson's checkermallow does not senesce completely in the fall like many other prairie plant species, and additional protections include: Burning: at any site with a population of this species, no more than one half of the occupied habitat may be burned in any year (USFWS, 2016).
- Herbicide use: protect Nelson's checkermallow plants from herbicide drift or overspray:
 - o When treating target plants with triclopyr, glyphosate or 2,4-D amine, apply by hand (e.g., with a backpack sprayer wand) when working near Nelson's checker-mallow to ensure protection of the listed plant.
 - o For all herbicide applications not excluded below, cover or otherwise protect (e.g., by clipping leaves to remove exposed green tissue) individual Nelson's checker-mallow plants to ensure that no herbicide comes in contact with the plant. Means of coverage may include 5-gallon buckets, tree protection tubes or other suitable shielding or covering material. Immediately after herbicide treatment, remove coverings.
 - o When applying glyphosate with a weed wiper in areas with Nelson's checkermallow, no covering of individual Nelson's checker-mallow is necessary. Apply glyphosate at a height to target upper grass stems, and avoid shorter Nelson's checkermallow plants.
 - o No covering of Nelson's checkermallow is required if treating target plants with sethoxydim or clethodim.
 - o Broadcast application of grass-specific herbicides may be used in on up to half of an area occupied by Nelson's checkermallow between February 15 and April 15. If using a weed wiper to apply a grass-specific herbicide for a particular listed plant during the growing season, the herbicide will be applied to the upper grass stems of targeted non-native plants, thus avoiding the shorter listed plant species.
 - o All other broadcast applications will only occur after August 15.
 - o All other herbicides will only be applied from August 15 to October 31 when the species is dormant.

SPECIES ACCOUNT: *Sidalcea oregana ssp. valida* (Kenwood Marsh checker-mallow)

Species Taxonomic and Listing Information

Listing Status: Endangered; 11/21/1997; Pacific Southwest (R8)

Physical Description

A perennial herb in the mallow family (Malvaceae). The plants are 1 to 2 m (3 to 6 ft) tall. The leaves are rounded. Lower leaves have 5 to 7 shallow lobes; upper leaves are generally smaller and divided into 3 to 5 entire, lanceolate segments. The compound inflorescence consists of densely flowered, spike-like racemes 2 to 5 cm (0.8 to 2.0 in) long. Petals are 1.0 to 1.5 cm (0.4 to 0.6 in) long, notched at the apex, and deep pink-mauve. The flowers appear from late June to September. *Sidalcea oregana ssp. valida* differs from *S. oregana ssp. eximia* in having a hairless calyx. (USFWS, 1997)

Taxonomy

Edward L. Greene (1897) first described *Sidalcea oregana ssp. valida* in June, 1894, based on material he collected from Knight's Valley, Sonoma County, California. Since then, this taxon has been known as *S. maxima* (Baker), *S. oregana* var. *spicata* (Jepson), *S. eximia* (Baker) and *S. spicata ssp. valida* (Wiggins) (CNPS 1988b). C. L. Hitchcock (1957) studied the genus *Sidalcea* and recognized four subspecies, including *S. oregana ssp. valida*, a treatment accepted by Steven Hill (1993). (USFWS, 1997)

Historical Range

See current range/distribution.

Current Range

Freshwater marshes approximately 150 m (490 ft) in elevation, at Kenwood Marsh and Knight's Valley, Sonoma County, California. (USFWS, 1997)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Breeding Season

Adult: Flowers appear from late June to September (USFWS, 2009).

Reproduction Narrative

Adult: Flowers appear from late June to September (USFWS, 2009).

Habitat Type

Adult: Marsh (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Clumped (NatureServe, 2015)

Environmental Specificity

Adult: Narrow/specialist (NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: Low (inferred from NatureServe, 2015)

Site Fidelity

Adult: High (inferred from NatureServe, 2015)

Habitat Narrative

Adult: Species inhabits the edges of freshwater marsh. (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat needs of this species and the low number of known populations.

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Unknown (USFWS, 2019)

Number of Populations:

2 (USFWS, 2019)

Population Size:

Varies from 24 to 500 per population (USFWS, 2019)

Additional Population-level Information:

At the time of listing, two occurrences of Kenwood Marsh checker-mallow were known to exist with 130 plants between them. In 2018, biologists observed a small population (less than 100 individuals) at Deerfield Ranch Winery but no abundance survey was done (K. Symonds, pers. comm. 2018). Based on new observations from scientists and volunteers the threats to Kenwood Marsh Checker-mallow have marginally increased since the last status review. However, there has been no change to our understanding of threats to the species, or its distribution. (USFWS, 2019)

Population Narrative:

There are two locations with extant populations: Kenwood Marsh and Deerfield Ranch Winery. During the previous status review (2009) there were two main sites within Kenwood Marsh where the Kenwood Marsh checker-mallow remained extant: at Deerfield Ranch Winery and on an adjacent property. Today, the only confirmed, extant population exists at the Deerfield Ranch Winery. Botanists have not surveyed the additional population at Kenwood Marsh for nearly 20 years (Service 2009) and the status of the plant remains unknown at this location. Likewise, no botanical surveys have been done at Knight's Valley in 30 years. In 2009, only three colonies existed at the Deerfield Ranch Winery (USFWS; A. Rex, in litt. 2017). Kenwood Marsh checker-

mallow abundance at this location has continued to decline in recent years (A. Rex, in litt. 2017; Appendix A). Over the past 25 years, the abundance at the winery has fluctuated from as many as 550 individuals, to as few as 24 (Appendix B; CNDDDB 2018; USFWS 2009). (USFWS, 2019)

Threats and Stressors

Stressor: Grazing (USFWS, 1998)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: This species is adversely affected at both of its locations by reduced seed set resulting from cattle grazing (CNPS 1988b). Populations of *Lilium pardalinum* ssp. *pitkinense* have been enclosed with various types of wire fencing in an attempt to prevent grazing or browsing by cattle, horses, and deer, but most of the fences have failed to prevent grazing completely. The plants continue to suffer from herbivory by cattle, deer, and perhaps gophers and other herbivores, resulting in loss of flowers and seeds (L. Lozier, in litt. 1990). (USFWS, 1997)

Stressor: Water diversion (USFWS, 2009)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Both permitted and unauthorized water diversions are listed as a threat to this species (USFWS, 2009).

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2009)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Regulatory mechanisms are deemed as inadequate to protect this species. Including those that require a 10-day advance notice to officials before private landowners change the land use in areas populated with this species. (USFWS, 2009).

Stressor: Small population size (USFWS, 1997)

Exposure:

Response:

Consequence:

Narrative: The small population size of this plant species increases the susceptibility to extirpation from random events. Population sizes of 100 or fewer are known for one or more populations of *Sidalcea oregana* ssp. *valida*. This species may also be subject to increased genetic drift and inbreeding as a consequence of their small population sizes (Menges 1991, Ellstrand and Elam 1993). Increased homozygosity resulting from genetic drift and inbreeding may lead to a loss of fitness (ability of individuals to survive and reproduce) in small populations. In addition, reduced genetic variation in small populations may make any species less able to successfully adapt to future environmental changes (Ellstrand and Elam 1993). This species is threatened by potential loss of fitness and/or genetic variability associated with small population sizes. (USFWS, 1997)

Stressor: Naturally-occurring events (USFWS, 1997)

Exposure:**Response:****Consequence:**

Narrative: The potential for loss of the only population of *Sidalcea oregana* ssp. *valida* from naturally occurring events, because of the small population size, is exacerbated by drought and water diversions. In addition, this population is being encroached upon by invasive weeds, including yellow star-thistle and blackberry (A. Howald, pers. comm. 1993). One of the subpopulations was damaged by an off-road vehicle during maintenance of a local aqueduct, which passes through the marsh. The maintenance activity occurred late in the season when the soil was relatively dry, resulting in minimal damage to the plants. If such maintenance activities occur during a time when the soil is saturated, they pose a threat to the plants (A. Howald, pers. comm. 1993). (USFWS, 1997)

Stressor: Climate change (USFWS, 2009)

Exposure:**Response:****Consequence:**

Narrative: Climate change is listed as threat to this species. (USWS, 2009)

Recovery**Reclassification Criteria:**

Not defined. A Recovery Plan has not been prepared. (USFWS, 2019)

Delisting Criteria:

Not defined. A Recovery Plan has not been prepared. (USFWS, 2019)

Recovery Actions:

- Not defined. A Recovery Plan has not been prepared. (USFWS, 2019)

Conservation Measures and Best Management Practices:

- Removing thatch and invasive species from exclosures: Kenwood Marsh checker-mallows grow in full sun on the margins of riparian areas (K. Symonds, pers. comm. 2018). The species is currently threatened by thatch buildup from annual sedges, as well as invasive plants, both of which shade habitat (K. Symonds, pers. comm. 2018; R. Rex, pers. comm. 2018). Manual removal of invasive plants and thatch might be necessary to increase Kenwood Marsh checker-mallow survival. In 2018, Deerfield Ranch Winery staff and volunteers removed thatch and invasive plants from browsing exclosures (A. Rex, pers. comm. 2018). These efforts should take place annually to ensure the survival of Kenwood Marsh checker-mallow. (USFWS, 2019)
- Locate appropriate areas for new colony establishment: The Kenwood Marsh checker-mallow probably once existed in riparian zones between Kenwood Marsh and Knight's Valley. Today, the dispersal of this species is restricted by land-use conversion to agriculture and urban areas. However, there might be areas within the historical range where the species could be re-established with seeding and outplanting. Private landowners should be contacted and, if landowners are willing, a management plan should be developed and implemented by the Service or CDFW. Research and public outreach would be needed to determine the feasibility of establishing new colonies in the area. (USFWS, 2019)

- Population monitoring: Population estimates of Kenwood Marsh checker-mallow are sporadic (CNDDDB; Appendix B). Establishing a protocol for continual, annual population monitoring would help us better understand the species needs and recovery potential. (USFWS, 2019)

SPECIES ACCOUNT: *Sidalcea oregana* var. *calva* (Wenatchee Mountains checkermallow)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Region (R1) (USFWS, 2016)

Physical Description

Plant has several stems, 2-15 dm tall; leaves thick and fleshy, without hairs; flowers light to deep pink. Flowers June through July. (NatureServe, 2015)

Taxonomy

The taxon was first recognized as a distinct variety named *Sidalcea oregana* ssp. *oregana* var. *calva* by Hitchcock and Kruckeberg (1957). Hitchcock and Cronquist (1973) later simplified the nomenclature by eliminating the subspecies *oregana*, and all subordinate taxa of *S. oregana* became varieties of the species. No further revisions have been made for *S. oregana* var. *calva* related to either taxonomy or relevant nomenclature for the species (USFWS, 2011).

Current Range

Occurs in a small area within Chelan County, Washington.

Critical Habitat Designated

Yes; 9/6/2001.

Legal Description

On September 6, 2001, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Sidalcea oregana* var. *calva* (Wenatchee Mountains checkermallow) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in Washington (66 FR 76536-76548).

Critical Habitat Designation

The critical habitat designation for *Sidalcea oregana* var. *calva* includes one CHU in Chelan County, Washington. This species critical habitat encompasses approximately 6,135 acres (ac) (2,484 hectares (ha)) (66 FR 76536-76548).

Washington, Chelan County. From USGS 7.5' quadrangle maps Peshastin and Tip Top, Washington. T. 23 N., R 18 E., beginning at a point on Camas Creek in the NW1/4 of NW1/4 of section 35 at approximately 47°26'52" N latitude and 120°38'57" W longitude proceeding downstream (northwesterly), expanding in all directions to include the entire wetland complex that comprises the Camas Meadow Natural Area Preserve, to a point approximately 0.4 km (0.25 mi) from the confluence of Pendleton Creek and Peshastin Creek, located at 47°31'06" and 120°37'18" W longitude. From this last point, the western boundary of the designated critical habitat parallels Peshastin Creek to a point at the southwest of the designated area located at 47°28'46" N latitude and 120°38'57" W longitude. The maximum elevation of the designated critical habitat is 1,000 m (3,300 ft) and the lowest elevation is 488 m (1,600 ft). Critical habitat within this area includes watercourses and wetland habitat out to the beginning of upland vegetation.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Sidalcea oregana* var. *calva* critical habitat consists of three components (66 FR 76536-76548):

The known primary constituent elements of critical habitat for *Sidalcea oregana* var. *calva* include: surface water or saturated upper soil profiles; a wetland plant community dominated by native grasses and forbs, and generally free of woody shrubs and conifers that would produce shade and competition for *Sidalcea oregana* var. *calva*;

seeps and springs on fine-textured soils (clay loams and silt loams), which contribute to the maintenance of hydrologic processes necessary to support meadows that remain moist into the early summer;

and elevations of 488–1,000 m (1,600–3,300 ft).

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Insect (bee) pollinated. Other pollinators unknown (USFWS, 2004)

Breeding Season

Adult: Flowering begins in the middle of June and peaks in the middle to end of July, although some individuals may have flowers present in mid-August (USFWS, 2004).

Reproduction Narrative

Adult: Hymenoptera (NatureServe, 2015). Pollination of the species is not well understood. In her studies of *S. oregana* var. *calva*, Tara Goldsmith reported that the colonial ground-nesting bee *Diadasia nigrifrons* is most likely the dominant pollinating insect (Goldsmith 2003). Honey bees (*Apis mellifera*), although present, were not observed to visit *S. oregana* var. *calva*. Interestingly, Goldsmith found no significant difference in the rate of flower to fruit success (about 36 percent) between flowers that were excluded from insect pollination and those that were not, indicating that insects are not the sole vector for pollination. Goldsmith pointed to the need for further study of the pollination mechanisms of *S. oregana* var. *calva* to potentially improve the plant's reproductive output. The species likely reproduces only from seed and, based on examination of seed capsules, the production of seed appears to be high (Gamon 1987). The somewhat clumped distribution of mature *S. oregana* var. *calva* plants suggests that seed dispersal is restricted to the areas near mature plants, unless the seeds are moved by animals or transported by water (Caplow 2002). Reproductive individuals produce flowers on one to several stems. Flowering begins in the middle of June and peaks in the middle to end of July, although some individuals may have flowers present in mid-August. Welldeveloped fruits are present by early August (Hitchcock et al. 1961; Washington Natural Heritage Program and U.S. Bureau of Land Management 1998). Investigations have suggested the species is not rhizomatous (D. Wilderman, pers. comm. 2004). The species likely reproduces only from seed and, based on examination of seed capsules, the production of seed appears to be high (Gamon

1987). The somewhat clumped distribution of mature *S. oregana* var. *calva* plants suggests that seed dispersal is restricted to the areas near mature plants, unless the seeds are moved by animals or transported by water (Caplow 2002). (USFWS, 2004).

Habitat Type

Adult: Meadows (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Clumped (NatureServe, 2015)

Environmental Specificity

Adult: Narrow/specialist (NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: Low (NatureServe, 2015)

Site Fidelity

Adult: High (NatureServe, 2015)

Habitat Narrative

Adult: *S. oregana* var. *calva* is restricted to wetlands and moist meadows of the Wenatchee Mountains of central Washington on the east side of the Cascades. This species is found at midelevations, ranging from 488 to 1,000 meters (1,600 to 3,300 feet). Populations of *S. oregana* var. *calva* are generally concentrated in the wetter portions of open forest-moist meadow habitats, in slight topographic depressions. The plant may also be found in open conifer forests dominated by *Pinus ponderosa* (ponderosa pine) and *Pseudotsuga menziesii* (Douglas-fir), on the perimeter of shrub and hardwood thickets dominated by quaking aspen (*Populus tremuloides*), along permanent or intermittent streams in sparsely forested draws, and near seeps, springs, or small drainages. The presence of surface water or saturated upper soil profiles in the spring and early summer is the feature common to the variety of habitats where the species is found (USFWS, 2004). High ecological integrity of the community and site fidelity as well as low tolerance ranges are based on the low number of known populations and the relatively restricted range.

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: The somewhat clumped distribution of mature *S. oregana* var. *calva* plants suggests that seed dispersal is restricted to the areas near mature plants, unless the seeds are moved by animals or transported by water (Caplow 2002) (USFWS, 2004).

Population Information and Trends**Population Trends:**

Decreasing (NatureServe, 2015)

Resiliency:

Low (NatureServe, 2015)

Representation:

Low (NatureServe, 2015)

Redundancy:

Low (NatureServe, 2015)

Number of Populations:

1 - 5 (NatureServe, 2015)

Population Narrative:

The extremely small range and general lack of suitable habitat may make the taxon more vulnerable to chance environmental or human-caused events. The historic range of *Sidalcea oregana* var. *calva* was approximately 11 miles by 3 miles; there has been significant loss of potential habitat in this area due to agricultural and residential development (WANHP 1998; USFWS 2004). Of the five extant populations, one has approximately 11,000 individuals (estimated in 2000) but the rest are small (ranging from approximately 8 to 300 individuals each in 2001) (USFWS 2004). Five extant populations are known (USFWS 2004). There are approximately seven historic occurrences (NatureServe, 2015). Low resiliency, representation and redundancy are based on the species low number of known populations in a relatively restricted (small) geographic area.

Threats and Stressors

Stressor: Wetland conversion (USFWS, 2004)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: The primary threats to *S. oregana* var. *calva* include habitat fragmentation, degradation, or loss due to conversion of native wetlands to orchards and other agricultural uses and rural residential development (USFWS, 2004).

Stressor: Altered hydrology (USFWS, 2004)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Altered hydrology is considered a major threat to this species (USFWS, 2004).

Stressor: Competition from native and nonnative plants (USFWS, 2004)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Competition from native and nonnative plants is listed as a major threat to this species (USFWS, 2004).

Stressor: Recreational impacts (USFWS, 2004)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: Recreational impacts are considered a major threat to this species. Seeds of the full species *Sidalcea oregana* are collected by horticulturists. Some populations are small enough that even limited collecting pressure could have adverse impacts. *S. oregana* var. *calva* is an attractive plant and may be sought for collection. All perennial species in the genus are considered attractive plants with horticultural potential (Hitchcock and Cronquist 1961; Gamon 1987). Wild-collected seed of the species *S. oregana* (no variety given) is available through a seed exchange program offered by the International Gardening Society, North American Rock Garden Society (North American Rock Garden Society 1996). Although seed collection does not pose a key threat to *S. oregana* var. *calva* currently, the potential of harm through such activity should be considered when developing management plans for the species (USFWS, 2004)

Stressor: Woody plant encroachment (USFWS, 2004)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: In the absence of fire woody plant encroachment can happen as part of natural succession and is considered a major threat to this species (USFWS, 2004).

Stressor: Seed predation (USFWS, 2004)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Seed predation by weevils is considered a major threat to this species (USFWS, 2004).

Stressor: Fire suppression activities (USFWS, 2004)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: The Mountain Home Meadow site was adversely impacted by fire suppression activities associated with the Rat Creek Fire during 1994 (Harrod 1995). A fire line was constructed in the drainage area supporting a population of *S. oregana* var. *calva*. Blading of the area by a bulldozer destroyed approximately 50 percent of the population (more than 100 plants), disturbed the soil, and altered the hydrology of this wet meadow. This types of activity is considered a major threat to this species (USFWS, 2004).

Stressor: Road construction (USFWS, 2004)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Road construction may alter hydrology by modifying surface and subsurface runoff, changing water flows, and increasing the potential for erosion and sedimentation and is considered a threat to this species (USFWS, 2004).

Stressor: Timber harvest (USFWS, 2004)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Timber harvest may alter hydrology by modifying surface and subsurface runoff, changing water flows, and increasing the potential for erosion and sedimentation and is considered a threat to this species (USFWS, 2004).

Stressor: Naturally occurring events (flooding, land slides, etc.) (USFWS, 2004)

Exposure:

Response:

Consequence: Loss of habitat/extinction

Narrative: The species is highly vulnerable to extirpation from demographic factors or random, naturally occurring events due to the small size of most of the remaining populations (USFWS, 2004).

Recovery

Reclassification Criteria:

There are at least four stable, self-sustaining populations in each of the 5th field watersheds (Peshastin Creek and Icicle Creek) where the species currently occurs. Alternatively, there could be three stable, self-sustaining populations in each of these two watersheds and at least three stable, self-sustaining populations in another drainage if additional populations are discovered in the future. Additional populations may be identified through surveys or established through reintroductions. To be considered separate, each population must be geographically and hydrologically separated, such that events resulting in the extinction of one population are not likely to result in the extinction of another population. To be considered stable and self-sustaining, a population should maintain a 5-year average of at least 500 adult plants, show evidence of positive or neutral population growth over the same 5-year period, and show evidence of natural reproduction and establishment (USFWS, 2004).

2. All of the stable, self-sustaining populations are on protected sites secure from threats. For a site to be considered protected, it must be owned or managed by a government agency or private conservation organization that identifies perpetual maintenance of the species as the primary management objective for the site, or the site must be protected by a permanent conservation easement or covenant that commits present and future landowners to the conservation of the species (USFWS, 2004).

3. Genetic material is stored in a facility approved by the Center for Plant Conservation. The stored genetic material in the form of seeds must adequately represent the species' geographic distribution and genetic diversity (USFWS, 2004).

4. Adequate population and habitat monitoring has been established for all of the known populations. Population monitoring must be statistically sound and should be able to detect a 20 percent change in the population with a 90 percent degree of certainty. Habitat monitoring should include monitoring of shrub and tree cover, nonnative species, and hydrology (USFWS, 2004).

5. Management plans have been developed and implemented for all State and federally owned populations. Management plans will include provisions for monitoring, research, and habitat maintenance and restoration, including hydrologic restoration. These plans will also define actions designed to reduce or control threats to the species (USFWS, 2004).

Delisting Criteria:

Criteria for delisting the species remain the same as those for downlisting, with the following exceptions: 1. The populations that meet downlisting criterion #1 above will be naturally reproducing, stable or increasing in number with a minimum of 500 adult plants, secure from threats, and will have persisted an additional 5 years, for a total of 10 years. All other details of criterion #1 remain unchanged (USFWS, 2004).

One additional criterion is added for delisting: 6. Post-delisting monitoring plans and agreements to continue post-delisting monitoring are in place and ready for implementation at the time of delisting. Monitoring of populations following delisting will verify the ongoing recovery of the species and provide a means of assessing the continuing effectiveness of management actions (USFWS, 2004).

Conservation Measures and Best Management Practices:

- Collect, distribute, and store seed in an approved Center for Plant Conservation Seed Bank facility for later grow-out and reintroduction. The need for this action is considerable, given the current accessions are ageing, do not represent the Mountain Home population, and are located only in a single seed bank location, at the Berry Botanic Garden in Portland, Oregon. The currently stored collections date from 1986 to 1999. We would like to expand this to more than one seed bank location by adding the Miller Seed Vault at the University of Washington's Center for Urban Horticulture, Seattle, Washington (USFWS, 2011).
- Census and monitor all populations. Despite the best of intentions by responsible agencies, monitoring has been somewhat inconsistent between populations since publishing of the recovery plan. There has not been a full species census conducted in a single year to serve as a baseline for future comparisons and to allow the detection of trends. It is important to design a census that is efficient and comprehensive, yet be flexible to continue into the future in the face of uncertain funding. Cooperative development of a new monitoring plan is a challenge for the Technical Team (USFWS, 2011).
- Continue research into insect predation. Arnett and Birkhauser (2008) recommend repeating the proposed weevil protocol at several sites in order to develop an understanding of annual variation in level of insect infestation and to gain a better understanding of the annual variation in phenology. Trial runs early and late in the season may yield a better understanding of the different behavior of the two weevil species. A single late season monitoring was also suggested, as it may give the best estimate of the total level of insect damage, if it is conducted before seed dispersal begins. Arnett and Birkhauser (2008) suggested conducting prescribed fire at one of the *Sidalcea oregana* var. *calva* populations. This offers an opportunity to use this methodology to measure the effects of this action as a management treatment as the plant and the weevil likely evolved together under conditions of a higher fire frequency than current. Because *Sidalcea oregana* var. *calva* is historically located in areas where late season, low-intensity burns occurred frequently (Caplow 2003, Goldsmith 2005), it could be predicted that the plant species would respond positively to fire, as it would reduce competition with encroaching shrubs and trees and increase plant vigor, as well as possibly keep populations of the weevil and other harmful insects in check (USFWS, 2011).
- Complete hydrologic restoration in Camas Meadows. The success of a pilot hydrologic restoration project at Camas Meadows has improved wetland function and increased the amount of habitat in the largest population of *Sidalcea oregana* var. *calva*. In addition, the project was shown to improve native plant diversity and reduce the threat of altered hydrology within in the Camas Meadow population. This project demonstrated a successful method for restoring the hydrologic function to

the wetland and provided benefits to the species. Several areas of headcutting still require attention in remnant drainage ditches and should be completed to help alleviate threats to *Sidalcea oregana* var. *calva*. Invasive species control and native restoration planting should accompany any hydrologic restoration undertaken with *S. oregana* var. *calva* (USFWS, 2011).

- Reconsider value of Mountain Home population to survival and recovery With the discovery of a much larger, increasing and more stable Mountain Home population than previously thought, the Technical Team may reconsider the value of this population to the recovery of the species and we may elect to pursue a conservation agreement with the landowners. Such an action would allow the population to “count” toward recovery criteria # 1: a minimum of 500 plants, stable, and in a protected status; all for a period of at least five years. Additionally, this population is thought to represent a significant source of genetic variability for *S. oregana* var. *calva*, and therefore elevates its importance as a potential source of seed collection to propagate seedlings for reintroduction efforts or the species (USFWS, 2011).
- Complete and refine reintroduction planning In the Spotlight Species Action Plan (USFWS 2009) is a list of actions, that if implemented, would make substantial gains toward the recovery of *Sidalcea oregana* var. *calva*. The Technical Team should review this document, update it to reflect the new information and insight from this status review and use it to guide the reintroduction of the species. The Action Plan was developed primarily by using information and actions directly taken from the recovery plan (USFWS 2004), and would likely benefit from a revision (USFWS, 2011).

SPECIES ACCOUNT: *Sidalcea pedata* (Pedate checker-mallow)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Southwest (R8) (USFWS, 2015)

Physical Description

A perennial herb from a fleshy taproot. The inflorescence is spike-like with deep rose-pink flowers; the upper flowers are crowded. (NatureServe, 2015)

Taxonomy

The genus *Sidalcea*, of the mallow (Malvaceae) family, comprises approximately 22 species located throughout western North America, mostly Oregon and California. A thorough description of the perennial members of this genus can be found in Hitchcock (1957). The perennial herb of interest, *Sidalcea pedata* A. Gray, was first described by Asa Gray (1887) based on a 1886 collection made by Samuel B. Parish from "Bear Valley in the San Bernardino Mountains, S. California" (Parish 1917). Jepson (1925) relegated the taxon to the variation *Sidalcea spicata* var. *pedata*. However, C. L. Hitchcock (1957) returned the taxon to full species status as *Sidalcea pedata* in his revision of the perennial species of the genus *Sidalcea*. *Sidalcea pedata* is distinguished from other sister species by its smooth carpels, mostly leafless stem, and the three- to five-lobed leaves that are then dissected into short, linear segments. Additional species of *Sidalcea* that occur in the San Bernardino Mountains include *S. malvaeflora* ssp. *dolosa* (distinguished by the presence of additional stem leaves, few-flowered racemes, and net-veined carpels), *S. hicknianji* ssp. *parishii* (shallowly-lobed leaves and coarse, gray pubescence), and *S. neomexicana* (fleshy leaves and netveined carpels). Colloquial names commonly used for this species are pedate checkermallow, bird-footed checkerbloom, bird-footed checkermallow, and Bear Valley checkermallow. Voucher specimens of *Sidalcea pedata* are held at the University of California, Riverside Herbarium; Jepson Herbarium at the University of California, Berkeley; Pomona College Herbarium; and in the Dudley Stanford collection of the California Academy of Sciences.

Historical Range

See current range/distribution.

Current Range

California endemic, occurs in the Big Bear Basin of San Bernardino County, California. (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Insect pollinated (USFWS, 2011)

Reproduction Narrative

Adult: *Sidalcea pedata* is gynodioecious, meaning there are plants with both female and hermaphrodite flowers and plants with female flowers only. Research findings indicate that female and hermaphrodite plants differ substantially in their reproductive biology and pollination ecology (Leong 2006, p. 24). Hermaphrodites can produce seeds through outcrossing (pollen transfer between separate plants) and geitonogamy (pollen transfer between separate flowers on the same plant), whereas females appear to produce seeds solely through outcrossing. The most common visitors to *S. pedata* appear to be generalist bees, predominantly in the genus *Osmia*. *Sidalcea pedata* also attracts one specialist pollinator, the female of the bee species *Diadasia nigrifrons* (Anthrohoridae). Other visitors include flies, butterflies, and beetles. Bee visitors appear to distinguish between the two sex morphs and are more highly attracted to hermaphrodite flowers when initially flying to a new group of stems (Leong 2006, p. 24). Female plants also appear to be much more productive than hermaphrodites. *Sidalcea pedata* seeds are small and dispersal appears to be limited to the area surrounding the parent plant (USFS 2000a, p. 37). Research indicates that *S. pedata* does not reproduce in or near severely impacted areas and that noncompacted soils are important to the reproductive success and persistence of this species (Krantz 1981, p. VI) (USFWS, 2011).

Habitat Type

Adult: Meadows (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Clumped (inferred from NatureServe, 2015)

Environmental Specificity

Adult: Narrow/specialist (NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: Low (inferred from NatureServe, 2015)

Site Fidelity

Adult: High (inferred from NatureServe, 2015)

Habitat Narrative

Adult: Species inhabits loamy clay of annually-moist pebble plain meadows, and occasionally in dry meadows at 1600-2500 m (Pearson, 1989) (NatureServe, 2015). High ecological integrity of the community, site fidelity and low tolerance ranges are inferred based on the specific habitat needs of this species, the relatively small number of populations and its limited geographic range.

Dispersal/Migration**Dispersal**

Adult: Low (USFWS, 2011)

Dispersal/Migration Narrative

Adult: *Sidalcea pedata* seeds are small and dispersal appears to be limited to the area surrounding the parent plant (USFS 2000a, p. 37) (USFWS, 2011).

Population Information and Trends**Population Trends:**

Decreasing (NatureServe, 2015)

Resiliency:

Low (NatureServe, 2015)

Representation:

Low (NatureServe, 2015)

Redundancy:

Low (NatureServe, 2015)

Number of Populations:

6 - 20 (NatureServe, 2015)

Population Size:

1 - 1000 individuals (NatureServe, 2015)

Population Narrative:

Wetland plant in open, flat habitat (Bittman 1998). The majority of this taxon's habitat was flooded in the 1890s. More recent development continues to threaten the taxon. Decline of 70-90%. Not many plants left due to multiple threats (Bittman 1998). Known from ten recent occurrences (seen during the last 20 years) and four historical (NatureServe, 2015).

Threats and Stressors

Stressor: Development (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: The threat of development remains high because the majority of *Sidalcea pedata* occurrences are on private land (10 of 16 EOs). Two of these occurrences are currently posted for sale: Metcalf Creek at the Drive-in and Flea market (EO 17) and the YMCA camp at Bluff Lake (EO 6) (Eliason, pers. obs. 2010). Impacts of development pressures on private land are evident at a number of occurrences: the east side of Baldwin Lake (EO 9, 30) has been highly developed to the extent that populations may become extirpated or too small to persist, and populations at Metcalf Creek (EO 17), Eagle Point (EOs 19, 21), and the south shore of Baldwin Lake (EO 8) have also been impacted by development. The only *S. pedata* occurrence that is considered fully protected is at the north shore of Baldwin Lake (EO 1) on the Baldwin Lake Ecological Reserve (managed by CDFG). The direct threat of development to *S. pedata* habitat therefore remains substantial and is currently impacting habitat at 10 of the 16 extant occurrences (Appendix 1) (USFWS, 2011).

Stressor: Off-Highway Vehicles (USFWS, 2011)

Exposure:

Response:**Consequence:** Loss of individuals

Narrative: The listing rule indicated that OHV activity eliminated colonies and damaged *Sidalcea pedata* habitat (USFWS 1984, p. 34499). In 2000, a review by the USFS found that approximately 1.1 miles (1.7 kilometers (1.3 ha (3.3 ac))) of unauthorized roads bisect or are adjacent to known occupied meadow plant occurrences and that the unauthorized network of roads allow for an “unknown, though likely high, level of random and on-going impacts to threatened/endangered meadow plant habitat (USFS 2000a, p. 99).” OHV use continues to impact moist meadow habitat by altering hydrology, compacting soil, and degrading habitat. Preventing OHV use within *Sidalcea pedata* habitat has been difficult because much of the activity is either on private land or is unauthorized. Occurrences at the north and south shores of Baldwin Lake (EOs 1, 6) are particularly vulnerable to OHV use. At the south shore of Baldwin Lake (EO 6), OHV trails bisect the *S. pedata* occurrence, connecting private land to the shoreline (USFS 2000, p. 62). Fencing that may provide protection to the occurrence at the north shore of Baldwin Lake (EO 1)—at the side of State Route 18, which could prevent unauthorized OHVs from entering—has been knocked down or has fallen down due to heavy snow drifts (Eliason, pers. obs. 2010). In 2010, the USFS placed boulders at the entrance of these roads to prevent illegal OHV activity, which appears successful in reducing impacts from this threat (Eliason, pers. obs. 2010) on USFS land. Currently 10 of the 16 known extant occurrences are subject to impacts from OHV activity (USFWS, 2011).

Stressor: Alteration of hydrology (USFWS, 2011)**Exposure:****Response:****Consequence:** Loss of habitat

Narrative: Alteration of soil hydrology or existing drainage patterns may have impacted several *Sidalcea pedata* occurrences including Eagle Point (EO 21) and the north shore of Baldwin Lake (EO 1). At each of these locations, efforts were made to prevent hydrology-related impacts to the habitat and to the species. For instance, CDFG’s purchase of private lands containing the watershed for the north shore of the Baldwin Lake occurrence (EO 1; Baldwin Lake Ecological Reserve) in 1992 has helped to maintain natural hydrologic patterns. The Pan Hot Springs occurrence (EO 12) is found on deed restricted land; however, the water source for the habitat is not included in the deed restriction. Without control of water availability, the plants and their habitat at this occurrence remain threatened (USFS 2002, p. 25). While protection measures have lessened the threat of altered hydrology at several occurrences, it remains a rangewide threat to 14 of the 16 known extant occurrences (Appendix 1) (USFWS, 2011).

Stressor: Invasive nonnative plants (USFWS, 2011)**Exposure:****Response:****Consequence:** Loss of habitat

Narrative: *Thinopyrum intermedium* (previously *Elytrigia intermedia*) (intermediate wheatgrass) has been identified as a threat to occurrences at Baldwin Lake (EOs 1, 8, 9, 23, 24, 30), Eagle Point (EOs 19 and 21), and in the south of Pan Hot Springs (EO 12). An entire population at the northern end of the Pan Hot Springs occurrence (EO 12) has been extirpated from the meadow edge since the early 1990s by a dense invasion of *T. intermedium* (Krantz 2008, p. 11; Eliason, pers. comm. 2011). *Thinopyrum intermedium* invades *Sidalcea pedata* habitat and outcompetes it for space. It also produces a thatch that *S. pedata* seedlings cannot penetrate. Control methods

such as burning or mowing have proven ineffective as both grasses are perennial and that returns in subsequent years (Eliaison, pers. obs. 2010). Nonnative plants are a threat to 14 of the 16 known extant occurrences of *S. pedata* (Appendix 1) (USFWS, 2011).

Stressor: Predation (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Since the time of listing, horse grazing and pasturing activities have been identified as threats that are impacting occurrences at Pan Hot Springs (EO 12), Metcalf Creek (EO 17), and Bluff Lake (EO 6). Voluntary landowner agreements resulted in the relocation of equestrian activities away from rare plant habitat in the areas, and in 1987, horse corrals were removed from Pan Hot Springs. These efforts were successful and recovery of *Sidalcea pedata* populations has been observed at that location (USFS 2002, p. 19). Horse grazing and pasturing activities remains a threat to only 3 of 16 *S. pedata* occurrences at the east and south shores of Baldwin Lake (EOs 8, 9, 30). These occurrences are on private lands and there are no protective measures in place to reduce this threat (USFWS, 2011).

Stressor: Inadequacy of Existing Regulatory Mechanisms (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: In summary, the Act is the primary Federal law that has provided protection for *Sidalcea pedata* since its listing as endangered in 1984. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for *S. pedata* absent its status under the Act. One occurrence at Baldwin Lake (EO 1) is considered fully protected; however, even this population is impacted by recreational activities and illegal trespass. Two of the 16 extant *S. pedata* occurrences are afforded protection through local agencies by protecting land to conserve rare plant populations. There are also unresolved conflicts between State protections afforded under CESA and NPPA and county weed abatement provisions. Therefore, State and other Federal laws and regulations have limited ability to protect the species in absence of the Act. Inadequacies in provisions or implementation in regulatory mechanisms are not considered threats to the species, although these inadequacies may permit or precipitate actual threats that are described under Factors A, B, C, and E (USFWS, 2011).

Stressor: Recreational activities (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of individuals/loss of habitat

Narrative: Impacts associated with recreational activities have been identified as a rangewide threat to *Sidalcea pedata* (Appendix 1). Recreational activities include but are not limited to: hiking, camping, fishing, horse riding, mountain biking, and dog walking. The primary impact from recreational activities is trampling that can crush and kill individual plants. Additional impacts include soil compaction, devegetation, escaped campfire threats, introduction or spread of nonnative species, and burial of plants with litter (USFS 2002, p. 23). Fencing and signage indicating the presence of sensitive species have proven effective at reducing the threat of recreational activities at the north and south shore of Baldwin Lake. Moderate success has also

been made in educating the public and heightening the awareness of the need for the protection and recovery of *S. pedata* and numerous other listed and rare species near Big Bear Lake. The Big Bear Discovery Center at San Bernardino National Forest regularly presents public education programs on a variety of subjects, including threatened and endangered species (USFS 2000b, p. 80). Though recreational activities are a rangewide threat, the resulting impacts have been reduced at Pan Hot Springs (EO 12) and Bluff Lake (EO 6) through coordination with private landowners (USFS 2002, p. 23) (USFWS, 2011).

Stressor: Fire suppression measures (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Implementation of fire suppression measures has been identified as a threat at 11 of 16 extant *Sidalcea pedata* occurrences. The San Bernardino County Land Use/Fire Hazard Abatement Division (see Factor D discussion) requires that owners must remove weeds and grasses in areas where this vegetation acts as fuel that may pose a fire threat. Weeds and grasses are described by the County of San Bernardino generally as annuals that grow and dry out each year, and thus removal activities do not discriminate for rare plants (County of San Bernardino 2010). Weed and grass removal generally involves mowing, which damages or destroys individual *S. pedata* plants. If removal activities are conducted before or during *S. pedata* flowering and fruit development, the plants reproductive output and germination may be significantly impacted. While *S. pedata* appears to be a robust species and has been observed in mowed, vacant lots (Eagle Point (EO 21), Metcalf Creek (EO 17)), these populations (or in many cases just individual perennial plants) may be “hanging on” and not reproducing (Eliason, pers. obs. 2010). If mowing is to continue, effort should be made to time this activity to avoid impacting *S. pedata* germination and the persistence of the populations (USFWS, 2011).

Stressor: Reduced populations (USFWS, 2011)

Exposure:

Response:

Consequence: Lack of genetic variability

Narrative: Fragmentation and isolation can adversely impact small populations of plants that are already reduced in distribution such as *Sidalcea pedata* resulting in increased vulnerability to extirpation (Barrett and Kohn 1991, pp. 3–30). These effects may be the result of several factors, including small areas of suitable habitat, local extirpations, or ongoing natural or artificial factors limiting establishment and survival of the taxon. The small numbers of *Sidalcea pedata* occurrences is a concern because it increases the possibility that impacts from urban development or other activities near moist meadow habitat could destroy all or a significant portion of the species’ population. *Sidalcea pedata* is distributed on less than 8.1 ha (20 ac) of moist meadow habitat (USFWS 1998, p. iii). Stochastic events outside the natural range of frequency and severity (such as floods, fires, contamination, or drought) can substantially reduce or eliminate species such as *S. pedata* with a restricted range and small population, and increase the likelihood of its extinction (Lande 1993, p. 912). Genetic effects may further influence population demography via inbreeding depression and genetic drift (Barrett and Kohn 1991, pp. 3–30; Menges 1991, pp. 58–61). Allee (1931, pp. 17– 50) suggested small, single populations are vulnerable to extirpation when opportunities for reproduction diminish because of reduced opportunity of individuals to reproduce (Allee effect or depensation) (Courchamp et al. 2008, pp. vi–216). Stephens et al. (1999, pp. 185–190), Dennis (2002, pp. 389–401) and Courchamp et al.

(2008, pp. vi–216) suggest that the Allee effect is a density-dependent event that is inversely related to population size (USFWS, 2011).

Stressor: Climate change and drought (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to particular species (including *Sidalcea pedata*) or sites at this time. It seems likely that *S. pedata*, a species restricted to montane meadows in a single small portion of a mountain range found on clay soils with particular hydrological needs, would be threatened rangewide by any differences in climatic regimes brought on by changes to the climate. A changing climate with spatial and temporal shifting of temperature and precipitation may cause this species-specific adaptations to climate to work against its survival. A changing climate may also provide advantages to other native and nonnative plant species. Sharing information between scientists, land managers, and decision makers will increase our ability to address these threats. Increasing the success with which we address current threats to *S. pedata* will increase our success of handling the uncertain effects of future climate change (USFWS, 2011).

Recovery

Reclassification Criteria:

Populations of *Sidalcea pedata* and adjacent suitable habitat are fully protected through land management agreements, land ownership by resource agency or conservation organization, conservation easement, or other permanent means of protection (USFWS, 2011).

Populations are stable or increasing with allowances for natural fluctuations (USFWS, 2011).

Recovery Actions:

- Overall, while some steps have been made in achieving recovery, progress towards reclassifying and eventually delisting *Sidalcea pedata* has been largely unsuccessful and there are indications—such as two extirpations, and the significant habitat degradation at the east and south shores of Baldwin Lake (EOs 8, 9, 30), Metcalf Creek (EO 17) and Eagle Point (EO 21)—that *S. pedata* is facing an increasing threat of extirpation. The recovery plan was not threats based; consequently, action items necessary to meet the plan's recovery criteria are insufficient to reduce or eliminate the threats identified in the five-factor analysis and recover the species.

Conservation Measures and Best Management Practices:

- Work with partners, in particular private landowners, to help conserve *Sidalcea pedata*. Identify opportunities through the Service's Partners for Fish and Wildlife Programs to implement conservation opportunities on private lands (USFWS, 2011).
- Conduct monitoring to inventory actual occurrences and update the status of *Sidalcea pedata* occurrences throughout the species range. While the occurrences on the east side of Baldwin Lake (EOs 9, 30) are presumed extant, surveys should occur because they have not been conducted at this species location for many years (USFWS, 2011).

- Establish a seed bank focusing first on small, isolated populations that have the greatest potential to become extirpated (USFWS, 2011).
- Work with the State and San Bernardino County to resolve conflicts with the weed abatement plan (USFWS, 2011).
- Develop a threats-based recovery plan or outline to guide conservation actions for the species (USFWS, 2011).

SPECIES ACCOUNT: *Sideroxylon reclinatum* ssp. *austrofloridense* (Everglades bully)

Species Taxonomic and Listing Information

Listing Status: Threatened; 11/6/2017; Southeast Region (R4) (USFWS, 2017)

Physical Description

Everglades bully is a single to many-stemmed shrub, 3 to 6 feet (ft) (1 to 2 meters (m)) tall (Corogin and Judd 2014, pp. 410-412). The branches are smooth, slightly bent, and somewhat spiny. The leaves are thin, oval-shaped, 0.8 to 2 inches (in) (2 to 5 centimeters (cm)) long, evergreen, lance-shaped, and fuzzy on their undersides. The flowers are in axillary clusters. This subspecies is distinguished from the similar subspecies *S. reclinatum* ssp. *reclinatum* in Florida by its leaves, which are persistently pubescent (fuzzy) on their undersides, rather than smooth or pubescent only along the leaf midvein. In addition, the two subspecies are more reliably distinguished by differences in the micromorphology of the leaf epidermis. (USFWS, 2017)

Taxonomy

The genus *Sideroxylon* is represented by eight species in Florida. All of these plants were previously assigned to the genus *Bumelia*. *Sideroxylon reclinatum*, the Florida bully, is represented by three subspecies that range nearly throughout Florida and into neighboring states. The Everglades subspecies was first recognized by Whetstone (1985, pp. 544-547) as *Bumelia reclinata* var. *austrofloridense*, then transferred to the genus *Sideroxylon* (Kartesz and Gandhi 1990, pp. 421-427). *Sideroxylon reclinatum* ssp. *austrofloridense* was made a subspecies rather than a variety (Kartesz and Gandhi 1990, pp. 421-427); in plant nomenclature, the ranks of variety and subspecies are interchangeable. *Sideroxylon reclinatum* ssp. *austrofloridense* is used in the current treatment of the Florida flora (Wunderlin and Hansen 2016, p. 1). The online Atlas of Florida Vascular Plants (Wunderlin and Hansen 2016, p. 1), Integrated Taxonomic System (ITIS 2016, p. 1), NatureServe (2016, p. 1), and the Florida Department of Agriculture and Consumer Services (FDACS) (Coile and Garland 2003, p. 19) indicate that *Sideroxylon reclinatum* ssp. *austrofloridense* is the accepted taxonomic status. (USFWS, 2017)

Historical Range

The historical range of *Sideroxylon reclinatum* ssp. *austrofloridense* is limited to Collier, Miami-Dade, and Monroe Counties, Florida. In Miami-Dade County, the plant was known from central and southern Miami-Dade County along the Miami Rock Ridge, which extends from Long Pine Key in the Everglades northward through urban Miami to the Miami River. In Monroe County, the plant is known from Big Cypress National Preserve on the mainland, and was collected as far south as Key Largo, in the Florida Keys. In Collier County, the subspecies has been recorded only within Big Cypress National Preserve. The subspecies is apparently extirpated from Key Largo, and has not been found in surveys of pine rocklands on Key Largo, Big Pine Key, Cudjoe Key and Lower Sugarloaf Key. (USFWS, 2017)

Current Range

The current range of *Sideroxylon reclinatum* ssp. *austrofloridense* is in Miami-Dade and Monroe Counties, Florida, in Big Cypress National Preserve, the Long Pine Key region of Everglades

National Park, and pine rocklands adjacent to Everglades National Park. The current range is approximately 42 mi (67.5 km). (USFWS, 2017)

Critical Habitat Designated

Yes;

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Sexual (USFWS, 2017)

Reproduction Narrative

Adult: Little is known about the life history of *Sideroxylon reclinatum* ssp. *austrofloridense*, including pollination biology, seed production, or dispersal. Reproduction is sexual, with new plants generated from seeds. The subspecies produces flowers from April to May, and fruit ripens from June to July. (USFWS, 2017)

Habitat Type

Adult: Pine rockland habitat, marl prairie habitat, and within the ecotone between both habitats (USFWS, 2017)

Dependencies on Specific Environmental Elements

Adult: Periodic fire is extremely important to maintaining habitat for this subspecies (USFWS, 2017)

Tolerance Ranges/Thresholds

Adult: The plants can stand partial inundation with fresh water for a portion of the year, but do not tolerate salinity. (USFWS, 2017)

Dependency on Other Individuals or Species for Habitat

Adult: The species frequently has numerous stem galls, but these galls do not appear to cause mortality to the plant and may in fact be an important part of the subspecies' natural history. In addition, the stem galls are often inhabited by acrobat ants. (USFWS, 2017)

Habitat Narrative

Adult: *Sideroxylon reclinatum* ssp. *austrofloridense* grows in pine rockland habitat, marl prairie habitat and within the ecotone between both habitats. These habitats are maintained by regular fire, and are prone, particularly marl prairie, to annual flooding for several months during the wet season. The species also grows on the sunny edges of rockland hammock habitat, which is fire-resistant. Everglades bully occurs in sparsely vegetated, well-lit, open areas that are maintained by disturbance. (USFWS, 2017)

Dispersal/Migration**Dispersal**

Adult: Unknown (USFWS, 2017)

Population Information and Trends**Population Trends:**

Unknown (USFWS, 2017)

Number of Populations:

13 extant populations (USFWS, 2017)

Population Size:

10,000 to 100,000 plants, mostly occurring at Long Pine Key (USFWS, 2017)

Population Narrative:

The largest population occurs at Long Pine Key in Everglades National Park (ENP). The population at Long Pine Key is estimated at between 10,000-100,000 plants. Recent surveys of ENP have identified 14 occurrences of *Sideroxylon reclinatum* ssp. *austrofloridense* in Long Pine Key, expanding the known range in ENP. In Miami-Dade County, outside ENP, pine rocklands tracts are orders of magnitude smaller and exist in a matrix of agricultural, commercial, and residential development. Approximately 73 plants were observed at Larry and Penny Thompson Park, within the Richmond Pine Rocklands. Extant populations have been found at Quail Roost Pineland (two plants), Navy Wells Pineland Preserve (four plants), and Sunny Palms Pinelands (two plants). The subspecies has been observed in pine rocklands at Grant Hammock and Pine Ridge Sanctuary. The subspecies no longer occurs at the Nixon-Smilely Preserve. Surveys in the Gum Slough region of Lostmans Pines in Big Cypress National Park reported finding *Sideroxylon reclinatum* ssp. *austrofloridense* with limited distribution within the study area (USFWS, 2017)

Threats and Stressors

Stressor: Present or Threatened Destruction, Modification, or Curtailment of Its Habitat or Range

Exposure:

Response:

Consequence:

Narrative: Habitat loss, fragmentation and degradation, and associated pressures from increased human population are major threats this species. These threats are expected to increase as remaining pine rocklands and other habitats are lost to development, placing these plants at greater risk. This species may be impacted when pine rocklands are converted to other uses or when lack of fire causes the conversion to hardwood hammocks or other unsuitable habitats. On public lands, including National Park Service lands and Miami-Dade County-owned lands, implementation of prescribed fire has not been sufficient because of legal constraints (permitting requirements) and inadequate funding. Any populations of this species found on private property could be destroyed due to development. Although efforts are being made to conserve natural areas and apply prescribed fire, most pine rocklands remain in poor fire condition, and the long-term effects of large-scale and wide-ranging habitat modification, destruction, and curtailment will last into the future, while ongoing habitat loss due to population growth, development, and agricultural conversion continues to pose a threat to this species outside of conservation lands.

Stressor: Inadequacy of Existing Regulatory Mechanisms

Exposure:

Response:**Consequence:**

Narrative: This species is found on Federal, State and County lands. NPS regulations provide protection at Everglades National Park and Big Cypress National Preserve. These two sites continue to support the largest and best managed populations. State regulations provide protection against trade, but allow private landowners or their agents to clear or remove species on the Florida Regulated Plant Index. State Park regulations provide protection for plants within Florida State Parks. The Natural Forest Communities program in Miami is designed to protect rare and important upland (non-wetlands) habitats in south Florida; however, this regulatory strategy has several limitations that reduce its ability to protect this plant and its habitat. Although many populations of this species are afforded some level of protection because they are on public conservation lands, especially Federal lands, existing regulatory mechanisms vary in strength and scope, and do not provide substantive protection of habitat at this time. They have not led to a sufficient reduction of threats posed to these plants by a wide array of sources. (USFWS, 2017)

Stressor: Other Natural or Manmade Factors Affecting Its Continued Existence

Exposure:**Response:****Consequence:**

Narrative: Threats from other natural or manmade factors to this species include nonnative, invasive plants; management practices (such as mowing); recreation (including off-road vehicle use), effects from small population size and isolation; limited geographic range; and stochastic events including hurricanes, storm surges, and wildfires. Additionally, this plant is particularly vulnerable to the effects of climate change, including sea level rise, as changes in the water table, increased soil salinity from partial inundation, and storm surge will likely result in vegetation shifts in the decades prior to the fully anticipated sea level rise. Some of these threats (e.g., nonnative species) may be reduced on public lands due to active programs by Federal, State, and County land managers. Many of the remaining populations of this plant are small and geographically isolated, and genetic variability is likely low, increasing the inherent risk due to overall low resilience of these plants. The threats act together to impact populations of this species. (USFWS, 2017)

Recovery**Reclassification Criteria:**

Not defined.

Delisting Criteria:

Not defined.

Recovery Actions:

- Recovery actions have not been defined.

Conservation Measures and Best Management Practices:

- Conserve pine rocklands and suitable habitat through purchase or conservation easements.
- Provide regular prescribed burns to maintain suitable habitat conditions.
- Remove exotic plants and hardwoods to restore understories.

- Monitor and manage remaining small populations in Miami-Dade County.
- Locate new occurrences within Everglades National Park through additional surveys.
- Establish the limits of this species habitat requirements through additional surveys within Everglades National Park.
- Determine effects (positive or negative) from Everglades restoration and other hydrologic manipulations and changes through monitoring at Long Pine Key.

SPECIES ACCOUNT: *Silene alexandri* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/08/1992; Pacific Region (R1) (USFWS, 2016)

Physical Description

A subshrub 3-6 dm tall. Flowers are white. (NatureServe, 2015)

Taxonomy

Silene alexandri was described by Hillebrand (1888) based upon a specimen he discovered on Molokai (USFWS 1992) (USFWS, 1996).

Historical Range

See current range/distribution

Current Range

Current range: central Molokai; historically no additional range.

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Silene alexandri* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one detailed critical habitat unit (CHU), in Maui County in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Silene alexandri* includes one CHU in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Molokai—Lowland Mesic—Unit 1 (and) *Palmeria dolei*—Unit 37—Lowland Mesic (and) *Pseudonestor xanthophrys*—Unit 37— Lowland Mesic This area consists of 3,489 ac (1,412 ha) of State land, and 5,281 ac (2,137 ha) of privately owned land, from Waianui Gulch to Mapulehu, in central Molokai. These units are occupied by the plants *Alectryon macrococcus*, *Ctenitis squamigera*, *Cyanea dunbariae*, *C. mannii*, *C. profuga*, *Cyperus fauriei*, *Cyrtandra filipes*, *Gouania hillebrandii*, *Labordia triflora*, *Neraudia sericea*, *Santalum haleakalae* var. *lanaiense*, *Schiedea lydgatei*, *S. sarmentosa*, *Silene alexandri*, *S. lanceolata*, *Spermolepis hawaiiensis*, and *Zanthoxylum hawaiiense*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Lowland Mesic—Unit 1 is not known to be occupied by *Asplenium dielerectum*, *Bonamia menziesii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea procera*, *C. solanacea*, *Diplazium molokaiense*, *Festuca molokaiensis*, *Flueggea neowawraea*, *Isodendron pyriformis*, *Kadua laxiflora*, *Melicope mucronulata*, *M. munroi*, *M. reflexa*, *Phyllostegia haliakalae*, *P. mannii*, *P. pilosa*, *Sesbania*

tomentosa, *Stenogyne bifida*, or *Vigna o-wahuensis*, or the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Silene alexandri* critical habitat consists of one component. Lowland mesic (Molokai) (81 FR 17790-18110):

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further

degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkii*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History

Food/Nutrient Resources**Reproductive Strategy**

Adult: Unknown (USFWS, 1996)

Reproduction Narrative

Adult: Currently, no life history information is available for this species (USFWS, 1996).

Habitat Type

Adult: Shrubland/Dry forest (USFWS, 1996)

Habitat Narrative

Adult: Species inhabits moist shrublands on steep rocky slopes. (NatureServe, 2015). The two known populations are found in remnant dry forest and shrubland at an elevation between 610 and 760 meters (2,000 and 2,500 feet). Associated plant species include aalii, ohia, pukiawe, and uluhe (USFWS 1992) (USFWS, 1996).

Dispersal/Migration**Motility/Mobility**

Adult: Unknown (USFWS, 1996)

Dispersal/Migration Narrative

Adult: Currently, no life history information is available for this species (USFWS, 1996).

Population Information and Trends**Population Trends:**

Increasing (USFWS, 2014)

Resiliency:

Low (USFWS, 2014)

Representation:

Low (USFWS, 2014)

Redundancy:

Low (USFWS, 2014)

Number of Populations:

1 - 5 (NatureServe, 2015)

Population Size:

1 - 1000 individuals (NatureServe, 2015)

Population Narrative:

Fragility unknown. A total of fewer than 50 plants observed. 1 current (between 1982 and 1997) and 1 historical occurrence. (NatureServe, 2015). Surveys conducted by the Plant Extinction Prevention Program (2009) discovered four new individuals of *Silene alexandri* at Kewela in a population containing 17 individuals previously. In 2012, the single population contained 25 mature wild individuals of *S. alexandri* (PEPP 2012). Overall, the numbers of individuals have increased from approximately 6 individuals reported in the previous 5-year review to approximately 25 individuals in 2012 (PEPP 2012). The increase in numbers resulted from additional surveys (USFWS, 2014). Low resiliency, representation and redundancy are based on the species being known from a single population with few individuals and its specific habitat requirements.

Threats and Stressors

Stressor: Climate change (USFWS, 2014)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Climate change destruction or degradation of habitat – Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Silene alexandri* is highly vulnerable to the impacts of climate change. Therefore, additional management actions are needed to conserve this taxon into the future (USFWS, 2014).

Stressor: Feral deer (USFWS, 2014)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Ungulate degradation of habitat – Axis deer (*Axis axis*) populations have increased on Molokai and are now found in areas occupied by *S. alexandri* (PEPP 2011, 2013) (USFWS, 2014).

Stressor: Landslides/flooding (USFWS, 2014)

Exposure:

Response:

Consequence: Extinction

Narrative: Landslides and flooding destruction or degradation of habitat – The single population is threatened by landslides and erosion (PEPP 2009, 2013) (USFWS, 2014).

Stressor: Stochastic events (USFWS, 2014)

Exposure:

Response:

Consequence: Extinction/loss of habitat

Narrative: Stochastic events – Drought mortality or reduced viability – Drought may exacerbate the effects of ungulates and has direct adverse impacts on *S. alexandri* (PEPP 2013). In addition, fire is a threat to the single known population of this species (USFWS, 2014).

Stressor: Slug herbivory (USFWS, 2014)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Slug herbivory – Herbivory by slugs (unidentified species) have been reported as a new threat to this species (PEPP 2012, 2013) (USFWS, 2014).

Stressor: Rodent predation and herbivory (USFWS, 2014)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Rodent predation and herbivory – Rats (*Rattus* sp.) are considered a threat to *S. alexandri* (PEPP 2010, 2012) (USFWS, 2014).

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: We previously reported that climate change may pose a threat to this species, anticipating an analysis by 2013. The assessment conducted by Fortini et al. (2013) concluded that *S. alexandri* is extremely vulnerable to the impacts of climate change, with a vulnerability score of 0.991 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). In addition, this species has no overlap between current and future climate envelopes, and is unlikely to tolerate expected changes in climate at its current location. This means that this species must persist within suitable microrefugia, or move to newly available climate-compatible areas to avoid extinction. Therefore, additional management actions, including potential for assisted translocations, are needed to conserve this taxon into the future (USFWS, 2018).

Recovery

Reclassification Criteria:

For downlisting, a total of at least five populations, with at least 300 plants each (a total of 1,500 mature plants) must be sustained for five years (USFWS, 1996).

Delisting Criteria:

For delisting, a total of at least five populations, with at least 300 plants each (a total of 1,500 mature plants) must be sustained for ten years (USFWS, 1996).

Conservation Measures and Best Management Practices:

- Ungulate monitoring and control – Maintain fencing to exclude browsing by ungulates (USFWS, 2014).
- Invasive plant monitoring and control – Continue control of invasive introduced plant species within fenced areas (USFWS, 2014).
- Captive propagation for genetic storage and reintroduction o Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. o Evaluate genetic resources currently in storage to determine the need to place additional genetic resources in long-term storage due to this species' vulnerability to climate change (USFWS, 2014).

- Reintroduction/translocation – Augment populations as genetically appropriate individuals become available in nurseries and as habitat is protected (USFWS, 2014).
- Surveys / inventories – Survey the geographical and historical range of *Silene alexandri* for a thorough current assessment of the species' status (USFWS, 2014).
- Fire monitoring and control – Develop and implement a fire management plan at the existing exclosure (USFWS, 2014).
- Climate change adaptation strategy – Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change (USFWS, 2014).
- Alliance and partnership development – Initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon (USFWS, 2014).
- New Management Actions:
 - Captive propagation for genetic storage and reintroduction—
 - o The Lyon Arboretum Micropropagation Laboratory reported 164 containers of propagules representing seven individuals from Kawela. The Lyon Arboretum Seed Conservation Laboratory reported almost 22,000 seeds in storage representing 19 plants from one population at Kawela; almost 11,000 seeds in storage representing 11 plants from a second population at Kawela; and over 1,000 seeds representing crosses of individuals at Mākolelau (Lyon Arboretum 2017).
 - o The University of California—Irvine (2014) reported six plants in storage representing three wild individuals.
 - Stochastic events—Build resiliency and redundancy—In 2015, the Plant Extinction Prevention Program (PEPP) outplanted 28 individuals at Kawela and 13 individuals at Mākolelau. In 2016, PEPP outplanted 358 individuals at Kawela (21 founders represented). In 2017, PEPP outplanted 321 individuals at Kawela and 20 individuals at Kamiloloa gulch (PEPP 2015, 2016, 2017a, 2017b) (USFWS, 2018).

SPECIES ACCOUNT: *Silene hawaiiensis* (No common name)

Species Taxonomic and Listing Information

Listing Status: Threatened; 03/04/1994; Pacific Region (R1) (USFWS, 2016)

Physical Description

Silene hawaiiensis is in the Caryophyllaceae, or pink family. It is a sprawling, short-lived shrub with slanting or climbing stems approximately 15 to 40 centimeters (6 to 16 inches) long that arise from an enlarged root, and are generally covered with short, sticky hairs. Leaves are slender, often recurved, and stalkless. The stems are 6 to 15 millimeters (0.2 to 0.6 inch) long and 0.5 to 0.8 millimeters (0.02 to 0.03 inch) wide. Flowers are borne in loosely arranged, elongate, sticky clusters. The calyx is fused, five-toothed, purple-tinged, and 11 to 14 millimeters (0.02 to 0.03 inch) long. Petals are green-white above and sometimes maroon or maroon-streaked below. Each petal is divided into two parts, a two-lobed expanded blade and a long narrow, stalk-like base (U.S. Army 2003a).

Historical Range

See current range/distribution

Current Range

Silene hawaiiensis is endemic to the island of Hawaii. The species can be found on the western slopes of Mauna Kea; the Hualalai summit and Humuula saddle; the northern, western, and northwestern slopes of Mauna Loa; and near the Kilauea Crater. Currently more than 50 occurrences are known in a 200-square kilometer (77-square mile) area (U.S. Army 2003a).

Critical Habitat Designated

Yes; 2/27/2003.

Legal Description

On July 2, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Silene hawaiiensis* on the island of Hawaii (68 FR 39623 - 39722).

Critical Habitat Designation

The critical habitat designation for *Silene hawaiiensis* includes two units totaling 6,908 acres in Hawaii county, Hawaii. The units are Hawaii 25—*Silene hawaiiensis*—a and Hawaii 27—*Silene hawaiiensis*—b. Each unit is essential to the conservation of *S. hawaiiensis* because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population. Each unit provides habitat for a population that is geographically separated from other recovery populations of this islandendemic species within its historical range in order to reduce the likelihood of all recovery populations being destroyed by one naturally occurring catastrophic event. The two units designated provide habitat for a total of three populations, each with 300 mature, reproducing individuals. The excluded lands at PTA provide habitat for seven additional populations.

Hawaii 25—*Silene hawaiiensis*—a [854 ha (2,110 ac)]: This unit contains a portion of Kipuka Kulalio, it is completely within the Kapapala watershed, and it lies completely within HVNP. The

unit provides habitat for 1 population of 300 individuals of *S. hawaiiensis*, and is currently occupied by about 1,800 individuals.

Hawaii 27—*Silene hawaiiensis*—b [1,942 ha (4,798 ac)]: This unit contains Uwekahuna Bluff; portions of the lava flows of 1919, 1921, and 1961; a portion of Kilauea Crater; and all of Halemaumau Crater. The unit is entirely in the Kapapala watershed and lies completely within HVNP. This unit provides habitat for 2 populations of 300 individuals of *S. hawaiiensis* and is currently occupied by 3,851 to 3,951 individuals. This unit provides the southeasternmost critical habitat within the species' historical range.

Primary Constituent Elements/Physical or Biological Features

Habitat features that are essential for this species include, but are not limited to, montane and subalpine dry shrubland on weathered lava, on variously aged lava flows, and cinder substrates.

Special Management Considerations or Protections

The Service publishes this final rule acknowledging that they have incomplete information regarding many of the primary biological and physical requirements for this species. However, both the Act and the relevant court orders require the Service to proceed with designation at this time based on the best information available. As new information accrues, the Service may consider reevaluating the boundaries of areas that warrant critical habitat designation.

The following management actions are important in providing a conservation benefit to the species: feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: Life history information is limited. Flowering has been observed in August and September. Most plants surveyed have been adults. The species is considered short-lived; however, the plant may be longer lived than originally thought because it can sprout from a large, woody taproot. The species has also been documented to resprout following fire (U.S. Army 2003a).

Habitat Type

Adult: montane and subalpine dry shrublands

Habitat Narrative

Adult: *Silene hawaiiensis* typically grows in montane and subalpine dry shrublands on decomposed lava and ash, as well as on all ages of lava and cinder substrates at elevations from 900 to 1,300 meters (2,953 to 4,265 feet). The species is found on barren lava, on disturbed

sites, and in Sparse *Metrosideros* Treelands, Open *Metrosideros* Treelands with sparse shrub understory, Open *Metrosideros* Treelands with dense shrub understory, *Chenopodium* Shrublands, Open *Dodonaea* Shrublands, *Dodonaea* Mixed Shrublands, *Sophora-Myoporum* Shrublands with forb understory, *Leptecophylla-Dodonaea* Shrublands, and *Eragrostis* Grasslands.

Dispersal/Migration

Population Information and Trends

Population Size:

> 50

Population Narrative:

Currently more than 50 occurrences are known in a 200-square kilometer (77-square mile) area (U.S. Army 2003a).

Threats and Stressors

Stressor:

Exposure:

Response:

Consequence:

Narrative: Threats to *Silene hawaiiensis* include sheep, goats, and pigs browsing and trampling (browsing can be severe to the base of the plant, as mouflon sheep and feral pigs are known to root up and consume the fleshy taproot); competition by non-native plant species such as *Pennisetum setaceum*; disturbances associated with military exercises; fire; and property development (U.S. Army 2003a).

Stressor: Collecting impacts

Exposure:

Response:

Consequence:

Narrative: Illegal collection for scientific, horticultural or other purposes threatens the populations of *S. hawaiiensis*, as well as possible excessive visitation. For instance, in 2013, two reintroduced individuals of *S. hawaiiensis* were uprooted in the Mauna Kea area and those two plants were stolen along with other common and federally listed plants (P. Peshut and S. Evans, U.S. Army, pers. comm. 2013). This incident was reported to the State of Hawaii's Division of Conservation and Resource Enforcement (DOCARE) and the U.S. Fish and Wildlife Service's Office of Law Enforcement (OLE) (P. Peshut and S. Evans, pers. comm. 2013) (USFWS, 2015).

Recovery

Delisting Criteria:

To be considered for delisting, the taxon must be managed to control threats (e.g., fenced, weeding, etc.) in the five largest populations and be represented in an ex situ (off-site) collection. In addition, a minimum of eight to ten populations should be documented on island where the species now occur or occurred historically. Each of these populations must be

naturally reproducing and increasing in number, with a minimum of 300 mature individuals per population. Each population should persist at this level for a minimum of five consecutive years before delisting is considered. The delisting goals for this species have not been met, as only two of the known populations contain more than 300 mature individuals (Table 1). In addition, not all threats are being sufficiently managed throughout all of the populations (Table 2). This species is likely to become endangered in the foreseeable future throughout all or a significant portion of its range, and therefore, continues to meet the definition of threatened (USFWS, 2015).

Conservation Measures and Best Management Practices:

- Important conservation actions needed for *Silene hawaiiensis* include the following: construction of fenced exclosures around important occurrences to reduce impacts from feral ungulates and control and/or eradication of non-native plants, particularly *Pennisetum setaceum* to reduce threats from competition, habitat degradation, and fire (Service 1996a). In addition, a State-wide management plan that identifies areas and landscapes for the long-term conservation of all known occurrences of *S. hawaiiensis* is needed. As part of this management plan, landowners and managers should delineate management units to conserve this species and other native species through threat control and habitat restoration. Ongoing Conservation Actions: The Volcano Rare Plant Facility has 13 plants in cultivation that were propagated from a population at the Mauna Loa Radio Facility and about 100 seeds still germinating from that same location (Service 2003a). The Center of Environmental Management of Military Lands, Colorado State University is documenting all locations and condition (e.g., vigor, browse, disease) of this species. Research has been proposed to establish population distribution and genetic diversity of this species on the island of Hawaii (C. Bern, pers. comm.).
- Recommendations for Future Actions: ☐ Surveys / inventories – Survey geographical and historical range for a current assessment of the species' status. ☐ Captive propagation for genetic storage and reintroduction – Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. ☐ Ungulate monitoring and control – Maintain existing exclosures and monitor for potential incursions. ☐ Invasive plant monitoring and control – Eradicate invasive introduced plants within ungulate exclosures and maintain exclosures free of invasive plants. ☐ Population viability monitoring and analysis – Continue monitoring wild and reintroduced individuals. ☐ Fire monitoring and control – Develop and implement a fire management plan at the existing exclosures. ☐ Climate change adaptation strategy – Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change. ☐ Alliance and partnership development – Initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon (USFWS, 2015).

SPECIES ACCOUNT: *Silene lanceolata* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Region (R1) (USFWS, 2016)

Physical Description

Silene lanceolata, a member of the Caryophyllaceae (pink) family, is a short-lived perennial. Flowers are white with deeply lobed, clawed petals, and stems are 15 to 50 cm (6 to 20 in) long and woody at the base. Leaves are narrow, smooth and fringed with hairs. This species is distinguished from other Hawaiian members of the genus by its erect stem, terminal inflorescence, and length of the calyx, clawed petals, and carpophore (ovary structure) (Wagner et al 1999) (USFWS, 2016).

Historical Range

Historically, *Silene lanceolata* was found on Kauai, in Makua Valley on Oahu, below Puu Kolekole in east Molokai, Maunalei on Lanai, and on Mauna Kea on Hawaii (USFWS, 2016).

Current Range

Current range: Molokai, Oahu, and Hawaii (USFWS, 2016)

Critical Habitat Designated

Yes; 3/19/2003.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Silene lanceolata* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one detailed critical habitat units (CHUs), in Maui County in Hawaii (81 FR 17790-18110).

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Silene lanceolata* under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Silene lanceolata* (77 FR 57648-57862). The critical habitat designation includes 8 critical habitat units, which encompass approximately 1,449 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Silene lanceolata* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Silene lanceolata* includes one CHUs in Maui County, Hawaii with detailed unit information. There are also an unknown number of units on Lanai that contain this species (number of units is unknown because detailed unit descriptions for Lanai are not available) (81 FR 17790-18110).

Molokai—Lowland Mesic—Unit 1 (and) *Palmeria dolei*—Unit 37—Lowland Mesic (and) *Pseudonestor xanthophrys*—Unit 37— Lowland Mesic This area consists of 3,489 ac (1,412 ha) of

State land, and 5,281 ac (2,137 ha) of privately owned land, from Waianui Gulch to Mapulehu, in central Molokai. These units are occupied by the plants *Alectryon macrococcus*, *Ctenitis squamigera*, *Cyanea dunbariae*, *C. mannii*, *C. profuga*, *Cyperus fauriei*, *Cyrtandra filipes*, *Gouania hillebrandii*, *Labordia triflora*, *Neraudia sericea*, *Santalum haleakalae* var. *lanaiense*, *Schiedea lydgatei*, *S. sarmentosa*, *Silene alexandri*, *S. lanceolata*, *Spermolepis hawaiiensis*, and *Zanthoxylum hawaiiense*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Lowland Mesic—Unit 1 is not known to be occupied by *Asplenium dielirectum*, *Bonamia menziesii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea procera*, *C. solanacea*, *Diplazium molokaiense*, *Festuca molokaiensis*, *Flueggea neowawraea*, *Isodendrion pyriformis*, *Kadua laxiflora*, *Melicope mucronulata*, *M. munroi*, *M. reflexa*, *Phyllostegia haliakalae*, *P. mannii*, *P. pilosa*, *Sesbania tomentosa*, *Stenogyne bifida*, or *Vigna o-wahuensis*, or the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

The critical habitat designation for *Silene lanceolata* includes 8 critical habitat units, covering one ecosystem type, which encompasses approximately 1,449 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8.

Oahu—Dry Cliff—Unit 1 [49 ac (20 ha)]. This area consists of 49 ac (20 ha) in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the rim of Makua Valley. Oahu—Dry Cliff—Unit 2 [412 ac (167 ha)]. This area consists of 320 ac (130 ha) of State land and 91 ac (37 ha) of City and County of Honolulu land in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the ridge from Keaau to Ohikilolo. Oahu—Dry Cliff—Unit 3 [450 ac (182 ha)]. This area consists of 349 ac (141 ha) of City and County of Honolulu land and 101 ac (41 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the eastern rim of Makaha Valley along Kamaileunu Ridge. Oahu—Dry Cliff—Unit 4 [24 ac (10 ha)]. This area consists of 24 ac (10 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along Kauaopuu ridge, which divides Waianae Kai and Lualualei valleys. Oahu—Dry Cliff—Unit 6 [149 ac (60 ha)]. This area consists of 149 ac (60 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Lualualei Valley from Puukanehoa to Puukaua. Oahu—Dry Cliff—Unit 7a [68 ac (27 ha)]. This area consists of 68 ac (27 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley to Pohakea. Oahu—Dry Cliff—Unit 7b [38 ac (16 ha)]. This area consists of 38 ac (16 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley at Palikea. Oahu—Dry Cliff—Unit 8 [259 ac (105 ha)]. This area consists of 259 ac (105 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Nanakuli Valley from Palehua to Puumanawanua, and partially within the Nanakuli Forest Reserve.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Silene lanceolata* critical habitat consists of two components. Lowland dry (Lanai) and Lowland mesic (Molokai) (81 FR 17790-18110):

Ecosystem: Lowland Dry. Elevation: <3,300 ft (<1,000 m). Annual precipitation: <50 in (<130 cm). Substrate: Weathered silty loams to stony clay, rocky ledges, littleweathered lava. Canopy: *Diospyros*, *Myoporum*, *Pleomele*, *Santalum*. Subcanopy: *Chamaesyce*, *Dodonaea*, *Leptecophylla*, *Osteomeles*, *Psydrax*, *Scaevola*, *Wikstroemia*. Understory: *Alyxia*, *Artemisia*, *Bidens*, *Chenopodium*, *Nephrolepis*, *Peperomia*, *Sicyos*.

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Silene lanceolata* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Silene lanceolata* occurs within the indicated ecosystem in the Waianae Mountain caldera complex:

Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8. Dry Cliff. (A) Elevation: unrestricted. (B) Annual Precipitation: < 75 in (<190 cm). (C) Substrate: >65 degree slope, rocky talus. (D) Canopy: None. (E) Subcanopy: *Antidesma*, *Chamaesyce*, *Diospyros*, *Dodonaea*. (F) Understory: *Bidens*, *Eragrostis*, *Melanthera*, *Schiedea*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be

currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium*

molokaiense, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Silene lanceolata* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: Information on the reproductive cycles, longevity, specific environmental requirements, and limiting factors for this species are unknown (68 FR 35950) (USFWS, 2016).

Habitat Type

Adult: Cliff faces and ledges of gullies (USFWS, 2016)

Habitat Narrative

Adult: On Oahu, *Silene lanceolata* grows on cliff faces and ledges of gullies in dry to mesic shrublands at elevations between 351 and 978 m (1,151 to 3,208 ft). Associated native plant species include *Artemisia australis*, *Bidens* sp., *Carex* sp., *Chamaesyce* sp., *Dodonaea viscosa*, *Lysimachia* sp., *Osteomeles anthyllidifolia*, *Schiedea mannii*, or *Tetramolopium filiforme*. Information on the reproductive cycles, longevity, specific environmental requirements, and limiting factors for this species are unknown (68 FR 35950) (USFWS, 2016).

Dispersal/Migration

Population Information and Trends

Population Trends:

Unknown (USFWS, 2016)

Number of Populations:

6 (USFWS, 2016)

Population Size:

2,640 individuals (NatureServe, 2015)

Population Narrative:

Silene lanceolata is currently known from a total of 2,640 individuals on the islands of Molokai, Oahu, and Hawaii. On Molokai, a single occurrence of approximately 100 individuals was reported in 1987 on private land near Puu Kolekole. On Hawaii, it is found on the Army's Pohakuloa Training Area in Kipuka Kalawamauna, Puu KeeKee, and Kipuka Alala. These three occurrences are distributed over a distance of approximately 15 km (9 mi) and total more than 2,500 individuals. On Oahu, this species has increased from approximately 40 known individuals in five occurrences in mid to late 1990s to 157 known individuals in two occurrences in 2006 (U.S. Army Garrison 1999a, U.S. Army Garrison 2006c) (Table SB 37). Thus, *S. lanceolata* is characterized by two population units at low numbers, and an overall abundance on Oahu that appears to be increasing but is due in part to increased monitoring efforts.

Threats and Stressors

Stressor: Feral ungulates (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Habitat destruction by feral goats, pigs, and sheep is listed as a threat to this species (USFWS, 2016).

Stressor: Fire (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Fire from military activities is listed as a threat to this species (USFWS, 2016).

Stressor: Non-native plants (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Competition with non-native plants is listed as a threat to this species (USFWS, 2016).

Stressor: Low numbers (USFWS, 2016)

Exposure:

Response:

Consequence: Extinction/loss of populations

Narrative: Almost half of individuals (98 percent) are located outside the action area, *S. lanceolata* has a moderate background risk of species extinction range wide and high background risk of species extinction (because of low numbers of individuals) on Oahu without protection from existing and additional threats (USFWS, 2016).

Stressor: Climate Change

Exposure:

Response:

Consequence:

Narrative: Climate change adaptation strategy – Fortini et al. (2013) conducted a landscapebased assessment of climate change vulnerability for native plants of Hawaii using high resolution

climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *S. lanceolata* is moderately vulnerable to the impacts of climate change. Therefore, additional management actions are needed to conserve this taxon into the future (USFWS, 2015).

Stressor: Predator - Argentine Ants

Exposure:

Response:

Consequence:

Narrative: – In 2010, evidence of recent herbivory were present on approximately 9 percent of the monitored individuals of *S. lanceolata* at PTA, with the majority due to insect herbivory at 94 percent (U.S. Army 2010). Argentine ants (*Linepithema humile*) were noted once again in ASR 18; however, without further studies the direct and indirect impacts of Argentine ant to this species is unknown (U.S. Army 2010) (USFWS, 2015).

Recovery

Reclassification Criteria:

For downlisting, a total of five to seven populations of *Silene lanceolata* should be documented on islands where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered. The downlisting goals for this species have not been met, as only two of the known populations contain more than 300 mature individuals (Table 1). In addition, all threats are not being sufficiently managed throughout all of the populations (Table 2). Therefore, *Silene lanceolata* meets the definition of endangered as it remains in danger of extinction throughout its range (USFWS, 2015).

Delisting Criteria:

Due to the limited knowledge of life history requirements for short-term and long-term survival, the recovery plan for this species specifies interim objectives to downlisting and delisting that involve stabilization of all existing populations (Service 1999a). Conservation actions required for stabilization are described in the “Stabilization” section of the project description for this opinion. However, *S. lanceolata* is not included as a target taxon for stabilization under the Makua Implementation Plan Addendum. The Army does not actively manage this species on Oahu (Service 2003a) (USFWS, 2016).

Conservation Measures and Best Management Practices:

- The recovery plan for *Silene lanceolata* identifies several conservation actions that should be implemented for its recovery. Fenced exclosures should be constructed at all known occurrences to reduce impacts from ungulates. Subsequent control of ungulates and rats from all occupied sites will remove their impact on this species and its habitat. Control measures for non-native plant species that threaten *S. lanceolata* should be implemented. Augmentation of existing occurrences and the establishment of new occurrences should be done by outplanting when adequate propagated materials are available. Control of highly flammable vegetation and maintenance of fuelbreaks is also needed, for plant occurrences found growing in areas of high risk from fire (USFWS, 2016).

- A State-wide strategic plan is being developed by the Hawaii and Pacific Plants Recovery Coordinating Committee that will address the long-term conservation of *Silene lanceolata* (Hawaii and Pacific Plant Recovery Coordinating Committee 2007). This plan will include broader landscape actions that are needed for the recovery of this plant throughout its range. This species is also being propagated at Pahole Mid-Elevation Rare Plant Facility, Pohakuloa Training Area Plant Facility, and the Volcano Rare Plant Facility (Service 1999a; Service 2005b). In addition occurrences of this species occur in two management units where they may benefit from stabilization management of other species and/or ecosystem-level protection. The management units are Ohikilolo, which is fenced; and Waianae Kai Management Unit, which are not fenced (USFWS, 2016).
- Recommendations for Future Actions:
 - ▣ Surveys / inventories – Survey geographical and historical range for a current assessment of the species' status.
 - ▣ Captive propagation for genetic storage and reintroduction
 - o Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range.
 - o Evaluate genetic resources currently in storage to determine the need to place additional genetic resources in long-term storage due to this species' vulnerability to climate change.
 - ▣ Ungulate monitoring and control – Maintain existing exclosures and monitor for potential incursions.
 - ▣ Invasive plant monitoring and control – Eradicate invasive introduced plants within ungulate exclosures and maintain exclosures free of invasive plants.
 - ▣ Population viability monitoring and analysis – Continue monitoring wild and reintroduced individuals.
 - ▣ Fire monitoring and control – Develop and implement a fire management plan at the existing exclosures.
 - ▣ Climate change adaptation strategy – Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change.
 - ▣ Alliance and partnership development – Initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon (USFWS, 2015).

SPECIES ACCOUNT: *Silene perlmanii* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/29/1991; Pacific Region (R1) (USFWS, 2016)

Physical Description

A subshrub, usually many-branched from base, often forming clumps. Stems are erect to ascending, and 3-5 dm long. Flowers are white. (NatureServe, 2015)

Historical Range

See current range/distribution

Current Range

Current range: Waianae Mountains of Oahu; historically no additional range.

Critical Habitat Designated

Yes; 9/18/2012.

Legal Description

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Silene perlmanii* under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Silene perlmanii* (77 FR 57648-57862). The critical habitat designation includes 11 critical habitat units, which encompass approximately 7,332 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Silene perlmanii* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Silene perlmanii* includes 11 critical habitat units, covering two ecosystem types, which encompass approximately 7,332 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). Oahu—Lowland Mesic—Units 1, 2, 3; Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8.

Oahu—Lowland Mesic—Unit 1 [4,448 ac (1,800 ha)]. This area consists of 3,565 ac (1,443 ha) of State land, 583 ac (236 ha) of City and County of Honolulu land, 22 ac (9 ha) of Federal land, and 277 ac (112 ha) of privately owned land in the lowland mesic ecosystem in the Waianae Mountains, encompassing a large area including the north slopes of Mt. Kaala, from the Pahole NAR to the Kaala NAR, and south to the Waianae Kai Forest Reserve (FR). Oahu—Lowland Mesic—Unit 2 [1,063 ac (430 ha)]. This area consists of 1,063 ac (430 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Puuhapapa south to Puukaua. Oahu—Lowland Mesic—Unit 3 [353 ac (143 ha)]. This area consists of 353 ac (143 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Pohakea Pass to Kaiakuakai Gulch.

Oahu—Dry Cliff—Unit 1 [49 ac (20 ha)]. This area consists of 49 ac (20 ha) in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the rim of Makua Valley.

Oahu—Dry Cliff—Unit 2 [412 ac (167 ha)]. This area consists of 320 ac (130 ha) of State land and 91 ac (37 ha) of City and County of Honolulu land in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the ridge from Keaau to Ohikilolo.

Oahu—Dry Cliff—Unit 3 [450 ac (182 ha)]. This area consists of 349 ac (141 ha) of City and County of Honolulu land and 101 ac (41 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the eastern rim of Makaha Valley along Kamaileunu Ridge.

Oahu—Dry Cliff—Unit 4 [24 ac (10 ha)]. This area consists of 24 ac (10 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along Kauaopuu ridge, which divides Waianae Kai and Lualualei valleys.

Oahu—Dry Cliff—Unit 6 [149 ac (60 ha)]. This area consists of 149 ac (60 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Lualualei Valley from Puukanehoa to Puukaua.

Oahu—Dry Cliff—Unit 7a [68 ac (27 ha)]. This area consists of 68 ac (27 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley to Pohakea.

Oahu—Dry Cliff—Unit 7b [38 ac (16 ha)]. This area consists of 38 ac (16 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley at Palikea.

Oahu—Dry Cliff—Unit 8 [259 ac (105 ha)]. This area consists of 259 ac (105 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Nanakuli Valley from Palehua to Puumanawana, and partially within the Nanakuli Forest Reserve.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Silene perlmannii* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Silene perlmannii* occurs within the Lowland mesic and Dry cliff ecosystems in the Waianae Mountain caldera complex:

Oahu—Lowland Mesic—Units 1, 2, 3. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: Acacia, Diospyros, Metrosideros, Myrsine, Pouteria, Santalum. (E) Subcanopy: Dodonaea, Freycinetia, Leptecophylla, Melanthera, Osteomeles, Pleomele, Psydrax. (F) Understory: Carex, Dicranopteris, Diplazium, Elaphoglossum, Peperomia.

Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8. (A) Elevation: unrestricted. (B) Annual Precipitation: < 75 in (<190 cm). (C) Substrate: >65 degree slope, rocky talus. (D) Canopy: None. (E) Subcanopy: Antidesma, Chamaesyce, Diospyros, Dodonaea. (F) Understory: Bidens, Eragrostis, Melanthera, Schiedea.

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Silene perlmannii* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History**Food/Nutrient Resources****Breeding Season**

Adult: *Silene perlmanii* flowers in the spring, depending on climatic conditions (USFWS, 1998)

Reproduction Narrative

Adult: Early fruiting *Silenes* are disseminated by wind. Birds also disperse seeds of *Silene*. It is not clear if this is secondary dispersal (NatureServe, 2015). *Silene perlmanii* flowers in the spring, depending on climatic conditions. Flowers last for a day. Fruits develop in a few weeks (USFWS 1995) (USFWS, 1998).

Habitat Type

Adult: Mesic forest cliff face (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Clumped (USFWS, 1998)

Environmental Specificity

Adult: Narrow/specialist (USFWS, 1998)

Tolerance Ranges/Thresholds

Adult: Low (USFWS, 1998)

Site Fidelity

Adult: High (USFWS, 1998)

Habitat Narrative

Adult: Species inhabits cliff face in diverse mesic forest (NatureServe, 2015). *Silene perlmanii* typically grows on cliff faces in diverse mesic forest at an elevation of 790 meters (2,600 feet) (USFWS 1995; Wagner et al. 1990). Associated species include *Plantago princeps* (laukahi kuahiwi) (USFWS 1995) (USFWS, 1998). Species was presumed extirpated. In 2003 15 individuals were outplanted in the Honolulu preserve, as of 2007 only 3 were known to survive (USFWS, 2012).

Dispersal/Migration**Dispersal**

Adult: Wind and bird dispersal (USFWS, 1998)

Dispersal/Migration Narrative

Adult: Early fruiting *Silenes* are disseminated by wind. Birds also disperse seeds of *Silene*. It is not clear if this is secondary dispersal.; (NatureServe, 2015)

Population Information and Trends

Resiliency:

Fragility unknown. (NatureServe, 2015)

Representation:

Fragility unknown. (NatureServe, 2015)

Redundancy:

Fragility unknown. (NatureServe, 2015)

Number of Populations:

1 - 5 (NatureServe, 2015)

Population Size:

1 - 1000 individuals (NatureServe, 2015)

Adaptability:

Fragility unknown. (NatureServe, 2015)

Population Narrative:

Fragility unknown. Currently only two plants are known. One occurrence with 20 plants was discovered in 1987 and has since been reduced to a single plant. Two current (between 1982 and 1997) and no historical occurrences. (NatureServe, 2015)

Threats and Stressors

Stressor: Feral pigs (USFWS, 1998).

Exposure:

Response:

Consequence: Habitat loss/loss of individuals

Narrative: Habitat degradation and predation by feral pigs are a threat to this species (USFWS, 1998).

Stressor: Competition from invasive plants (USFWS, 1998).

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Competition from invasive plants is listed as a threat to this species (USFWS, 1998).

Stressor: Natural occurring event/reduced vegetative vigor (USFWS, 1998).

Exposure:

Response:

Consequence: Extinction

Narrative: Naturally occurring events (fire, landslides, etc) and reduced vegetative vigor are listed as threats to this species (USFWS, 1998).

Recovery

Reclassification Criteria:

For downlisting, a total of five to seven populations of each taxon should be documented on Oahu and at least one other island where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 1998).

Delisting Criteria:

A total of 8 to 10 populations of each taxon should be documented on Oahu and at least one other island where they now occur or occurred historically. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. Each population should persist at this level for a minimum of 5 consecutive years (USFWS, 1998).

Conservation Measures and Best Management Practices:

- Captive propagation for genetic storage and reintroduction - Collect cuttings or seed from tagged individuals, keeping close track of the maternal source for use in ex situ propagation (USFWS, 2013).
- Reintroduction / translocation o While surveying for new populations or reintroduced populations, determine which sites are least invaded by invasive introduced plant species and which appear to have the highest likelihood of maintaining new reintroductions. o Continue to reintroduce the species back into its known historical range (USFWS, 2013).
- Ungulate exclosures - Construct, maintain, and monitor ungulate-proof exclosures around each population (USFWS, 2013).
- Ungulate control – Protect all populations against disturbances from feral ungulates (USFWS, 2013).
- Ecosystem-altering invasive plant species control – Control invasive introduced plant species around all populations (USFWS, 2013).
- Surveys / inventories – Survey geographical and historical range for a thorough current assessment of the species status (USFWS, 2013).
- Alliance and partnership development - Enhance coordination and collaboration among other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2013).
- Genetic research – Assess genetic variability within extant individuals (USFWS, 2013).
- Population biology research – Study *Silene perlmannii* with regard to geographical distribution, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats (USFWS, 2013).
- Threats research – Assess the modeled effects of climate change on this species, and use the results to determine future landscape needed for the recovery of the species (USFWS, 2013).

SPECIES ACCOUNT: *Silene polypetala* (Fringed campion)

Species Taxonomic and Listing Information

Listing Status: Endangered; 2/19/1991; Southeast Region (R4)

Physical Description

Fringed campion is a perennial herb that forms mats by spreading vegetatively, with long, slender stolon-like rhizomes and leafy offshoots, both of which terminate in overwintering clusters of leaves (rosettes). Leaves of the rosette and stem are opposite, widest toward the tip, mostly 1-4 inches long. Each rosette produces one to several erect flowering shoots, each of which is unbranched or sparingly branched, up to 16 inches tall. The flowers are arranged in groups of 3-5 at the top of the flowering shoot. The calyx is tubular and covered with long, weak hairs. The 5 separate petals are each divided into a lower part about as long as the calyx and a triangular upper part that extends 1-11/2 inch from the calyx. The wide apex of each petal is divided into slender segments, giving the flower a fringed appearance. The petals are pink or white. Flowering is from late March to May (Kral 1983, Hitchcock and Maguire 1947, Faust 1981). The plant is easily recognized by its distinctive flowers. (USFWS, 1996)

Taxonomy

Research by Ward (2006) proposed an official change in nomenclature for the species, from *Silene polypetala* to *Silene catesbaei*. Ward's (2006) historical research found that the name *Silene polypetala*, formed in 1948 by Fernald and Schubert, based on their assessment of Thomas Walter's 1788 *Flora Caroliniana*, was erroneously applied to a fragmentary herbarium specimen they believed to be labeled by Walter as *Cucubalus polypetalus*. Ward (2006) proposes that the species and fragmentary herbarium specimen Thomas Walter referred to as *Cucubalus polypetalus* was either of two introduced species, *Silene cucubalus* or *Lychnis alba*--these two exotic species having been established in mountains of North Carolina by the eighteenth century. When Ward (2006) cross-referenced Thomas Walter's Latin prescriptions to specimen labels, he found a prescription for a new species termed by Walter as *Silene catesbaei*, a plant for which no herbarium specimen could be located in the *Flora Caroliniana*. Walter's Latin prescription appeared to Ward (2006) to be a better match to the species named by Fernald and Schubert and considered today as *Silene polypetala*. Since no type specimen matched Walter's prescription of *Silene catesbaei*, the International Code of Botanical Nomenclature guidelines allows for an author [Ward] to select a new type specimen, a neotype, to match the accepted name and prescription of *Silene catesbaei*, for which Ward (2006) did, selecting a specimen formerly and widely known as *Silene polypetala*. The neotype is a specimen of *Silene catesbaei*/*Silene polypetala* collected along Pobiddy Road in Talbot County, Georgia. USFWS accepts the name of *Silene catesbaei* for future documentation. However, to formally make this change in 50 CFR 17.12, it will require notice in the Federal Register (USFWS, 2015).

Historical Range

In six counties in Georgia: Bibb, Crawford, Decatur, Talbot, Taylor, and Upson Counties; in two counties in Florida: Gadsden and Jackson Counties. (USFWS, 1996)

Current Range

In eight counties in Georgia: Bibb, Crawford, Decatur, Houston, Talbot, Taylor, Twiggs, and Upson Counties; in two counties in Florida: Gadsden and Jackson Counties. (USFWS, 2015)

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Sexual and asexual (USFWS, 1996)

Breeding Season

Adult: Flowering begins in late March at the Florida locales, and ends sometime in May at the sites near the Fall Line in Georgia, with fruits maturing a month later (NatureServe, 2015).

Reproduction Narrative

Adult: Although no studies of the reproductive biology of *Silene polypetala* are known to the author, the large, showy, nectariferous flowers are indicative of a sexually reproducing species dependent on insects for pollination, perhaps supplemented by hummingbirds. In the genus *Silene*, the nectar is concealed at the base of the calyx tube, and the flowers are probed by larger bees and lepidoptera (Zomlefer 1994). Flowering begins in late March at the Florida locales, and ends sometime in May at the sites near the Fall Line in Georgia, with fruits maturing a month later. Some, if not all, plants in cultivation exhibit male sterility as evidenced by flattened anther sacs and the production of few, if any well-formed pollen grains. Lack of sexual reproduction may, therefore, be one reason for this species not persisting in cultivation. Sexual reproduction is supplemented by, and quite possibly exceeded by asexual reproduction. *Silene polypetala* produces runners, nearly leafless basal, procumbent stems terminating in rooted rosettes of leaves. In time, the rosettes produce flowering stems and the connection to the original plant decays. Thus a colony that appears to be composed of numerous individuals may, in fact, harbor only one or very few genetic individuals. The clonal nature of this species creates difficulties for monitoring its status and progress towards recovery. Counting individuals seems impossible without genetic testing. There is no clear reason to examine the genetic structures of the populations if they are stable. Possibly, the best approach for monitoring of populations is by detailed mapping using permanent stakes (metal stakes driven into the ground can be relocated with a metal detector) combined with geographic positioning systems, which are useful relocating populations. While plants can be mapped precisely, use of the mapping methods is limited by the need for trained individuals and costly equipment (USFWS, 1996). This species spreads vegetatively and the number of genotypes is far fewer than the number of clusters of plants at a site (USFWS 1991) (NatureServe, 2015).

Habitat Type

Adult: Deciduous woods

Habitat Narrative

Adult: *Silene polypetala* occurs in various situations within hardwood forests. It is often on fairly steep slopes of deep ravines or north-facing hillsides, sometimes on nearly level ground, particularly in flatwoods developed on Iredell soils. The great majority of populations of *Silene polypetala* occur in the watershed of the Apalachicola River and its- tributary, the Flint River.

One factor that the sites seem to have in common is a circumneutral soil reaction, due to the nature of the parent material. In the Coastal Plain occurrences (Florida and Decatur County, Georgia) the parent material is limestone. In the Piedmont localities the parent material is a magnesium-rich rock, hornblende gneiss. (USFWS, 1996)

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Stable short term population trend (NatureServe, 2015)

Number of Populations:

40 (USFWS, 2015)

Population Size:

1500 - 2000 plants in Florida; no estimate for Georgia, but most sites are more extensive than the Florida sites (USFWS, 2015)

Resistance to Disease:

Plants in the wild appear to exhibit no apparent symptoms of disease. (USFWS, 2015)

Population Narrative:

Silene catesbaei is currently known from 40 sites in Georgia and Florida. No comparable, long-term data exists to determine trends for the species, but overall, available habitat appears to be degrading over much of its range. Jenkins and Baker (2006) estimated that approximately 1500-2000 plants occurred among 12 element occurrences in Florida. No abundance estimates exist for Georgia but most of the central Georgia sites are more extensive in size, in both the area *Silene catesbaei* occupies and the numbers of plants present (Pete Pattavina, pers. obs. 2006). Many *Silene catesbaei* populations are composed of only a few patches, can be overlooked when plants are not in flower, and often occur over only a few acres. New populations are periodically discovered during field status surveys, when new areas are explored in the vicinity of known sites. However, without public ownership of sites to remove the primary threat of clear-cutting of forest, in concert with specific management to ensure habitat stability on existing sites, the periodic discovery of new populations will do little to offset the risk of extinction to this species. Three sites are considered extirpated: (1) Rivoli Lakes, Bibb County, Georgia; (2) Colaparchee Creek, Bibb County, Georgia; and (3) Lumpkin Road, Talbot County, Georgia. None of these sites was very large but each was situated at the fringes of the species' range and could have represented genetically unique populations. (USFWS, 2015)

Threats and Stressors

Stressor: Habitat loss and/or degradation (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Habitat loss continues for *Silene catesbaei* as areas are clear-cut and other forested parcels suffer from infestation by exotic, invasive plant species that out-compete *Silene*

catesbaei. The largest known site (40 acres) in the Ocmulgee River drainage (Piedmont area) is at risk of losing *Silene catesbaei*, if English ivy continues to spread up the small stream courses where the species grows. Hundreds of acres of habitat in the Apalachicola River drainage are being impacted by invasive plants, many sites where other endangered plants occur, such as *Torreya taxifolia*. (USFWS, 2015).

Stressor: Predation by herbivores (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: One increased threat to the species is the burgeoning population of white-tailed deer (*Odocoileus virginianus*) that, on some sites, excessively browse the plants, preventing fruit development and seed set (Steve Bowling, pers. comm. 2004)(Wilbur Duncan, pers. comm. 2004)(Pete Pattavina, pers. obs. 2004). Steve Bowling observed an increase in deer pressure on *Silene catesbaei* populations, beginning in the early-to-mid 1980s. This observation is supported by data that shows rapid expansion of Georgia's white-tailed deer population since 1972, when the State deer herd expanded from 253,000 to approximately 990,000 in 2013, peaking in 1997 at 1,460,000 individuals (GDNR 2014). Although no data is available to prove that the increase in deer population has a negative effect on *Silene catesbaei* populations, deer modified population structure and plant robustness in other forest herbs (Anderson 1994)(Leege et al. 2010), caused declines in species richness in forests, evenness and species diversity (Rawinski 2008)(Webster et al. 2005). (USFWS, 2015)

Stressor: Inadequacy of existing regulation (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: State laws do not restrict private landowners from any lawful activity that would modify or destroy threatened or endangered plants. Therefore neither the Preservation of Native Plants of Florida Act nor the Georgia Wildflower Preservation Act has had a significant effect in minimizing habitat degradation or fragmentation on private lands, the primary threat to the listed species. Georgia's Wildflower Preservation Act of 1973 provides protection for this species, especially on state-owned land. Sites owned by the U.S. Army Corps of Engineers should be considered protected, although close communication with land managers is necessary to ensure *Silene catesbaei*'s needs are included in approved management protocols. The Endangered Species Act prohibits deliberate removal of endangered plants from these areas, and all Federal agencies have a responsibility to conserve endangered plants. (USFWS, 2015)

Recovery

Reclassification Criteria:

1. Reclassification of *Silene polypetala* to Threatened will be considered if 10 viable and geographically distinct populations are protected from foreseeable threats (USFWS, 1996).

Delisting Criteria:

1. Delisting of *Silene polypetala* will be considered if 20 of the known populations (including at least 16 in Georgia and 4 in Florida) are protected. Population viability should be confirmed

through periodic monitoring for at least a 10-year period (including at least 5 years of monitoring after delisting) (USFWS, 1996).

Recovery Actions:

- 1. Protect populations. *Silene polypetala* has an inherently narrow geographic and ecological distribution. In the absence of active conservation efforts, sites with this plant will gradually be lost or degraded for reasons described above. This plan emphasizes the conservation of existing populations rather than the creation of new ones. The plan assumes that most owners of sites with this plant are interested in its conservation and that they may be receptive to offers of biological monitoring and assistance with conservation measures such as honeysuckle control. Planning of exotic pest plant control is important enough to be a separate recovery task (4). (USFWS, 1996)
- 2. Preserve genetic stock from acutely threatened populations. Due to the scarcity of extant populations, conservation of the genetic diversity that remains in the species is a high priority. Therefore, some living material of the species should be moved from any population facing imminent local extinction (i.e., where protection is not feasible or cannot be initiated in time to prevent extirpation). At the time of writing, this is necessary for the Crawford County, Georgia population. It is not known whether seed can be stored, which would be less costly than maintaining plants in cultivation. (USFWS, 1996).
- 3. Monitor populations to determine trends and developing threats. All sites supporting *Silene polypetala* should be monitored, if landowners grant permission. Arrangements with landowners to allow monitoring are included in Task 1. (USFWS, 1996)
- 4. Plan control of exotic pest plants. - Assess threats. When sites are visited, the nature and extent of pest plant infestations must be noted. Information from *Silene* sites must be combined with information from similar habitats in central Georgia and the Apalachicola Bluffs region of Georgia, Florida, and Alabama. - Identify control methods. A great deal of information is available on exotics control, as well as practical experience by land managers. As threats are identified, possible control methods need to be sought and tried, then modified with experience. Herbicide treatments have the potential to destroy native forest species. (USFWS, 1996)
- 5. Search for additional populations. As indicated above, this species has been searched for previously. However, additional potential habitat exists which has not been checked. Just one example: areas in Monroe County, Georgia indicated on the state geological map as underlain by hornblende gneiss, the same mapping unit as nearby Bibb County localities for the species. (USFWS, 1996)
- 6. Reestablish populations and augment populations at protected locations, if deemed necessary. The feasibility of (re)introduction has not been demonstrated, nor will introductions be necessary if other recovery actions are successful. (USFWS, 1996).
- 7. Manage sites to maintain and/or enhance populations. As *Silene polypetala* is adapted to an environment in which successional change is relatively slow, maintenance of populations chiefly requires protection from disturbance. Results of the monitoring program (Task 3) should indicate whether human manipulation might benefit *Silene polypetala* in certain natural or experimental microhabitats. Because exotic pest plants can invade otherwise pristine habitats, controlling them may become the main management action. (USFWS, 1996)
- 8. Educate the public about the value and fragility of this species and its habitat. Since most of the landscape of the Piedmont and Coastal Plain is developed, in cultivation, or in a

successional state, relatively undisturbed hardwood forest can provide an all-too-rare primeval experience. They also have the potential to serve as outdoor classrooms for studying important ecological and/or evolutionary concepts such as succession, competition, endemism, and ecotypic differentiation. (USFWS, 1996)

- 9. Apply laws protecting endangered plant species. Employ local, State, and Federal regulations when they are appropriate to protect the sites where this plant occurs. (USFWS, 1996)

Conservation Measures and Best Management Practices:

- Update the most recent, draft recovery plan (USFWS 1996b), to incorporate genetic information and new populations (USFWS, 2015).
- Revisit and assess all known sites for viability and other population variables at least every two years (USFWS, 2015).
- Promote and/or fund long-term population and/or demographic monitoring projects through partnerships (USFWS, 2015).
- Acquire private forestry tracts and bring into public ownership for proper management of the species and its habitat. Land tracts in the Chattahoochee River basin should be given top priority for purchase because of the genetic and habitat diversity found there. Since the species generally occurs over small areas, purchasing large portions of the global range would be relatively inexpensive, since only several thousand acres may require purchase to ensure long-term protection and survival of the species. Formal conservation agreements and conservation easements may also be effective at protecting *Silene catesbaei* habitat (USFWS, 2015).
- Perform new searches for the species in the Ocmulgee River basin and Chattahoochee River drainage. Habitat modeling using one-meter Lidar data may be useful for this exercise (USFWS, 2015).
- Continue to fund long-term invasive species control at sites in the Apalachicola and Ocmulgee sites (USFWS, 2015).
- Monitoring needs to be standardized for the species to ensure that data collected from different parties is comparable. *Silene catesbaei* is clonal and patch-forming, posing difficulties for estimating the number of plants at occupied sites (USFWS, 2015).
- Identify sites within the species range for establishment of new sites and/or population augmentation. (USFWS, 2015)

SPECIES ACCOUNT: *Silene spaldingii* (Spalding's Catchfly)

Species Taxonomic and Listing Information

Listing Status: Threatened; Pacific Region (R1) (USFWS, 2016)

Physical Description

A perennial herb with stout stems, 2-8 dm tall. White flowers, forming a tight, leafy flower head, bloom from late June to August. (NatureServe, 2015)

Taxonomy

Spalding's catchfly produce one to several vegetative or flowering stems that arise from a simple or branched persistent underground stem (caudex), which surmounts a long, narrow taproot. Plants range from 20 to 40 cm in height. Each stem typically bears 4 to 7 pairs of simple, opposite leaves that are 5 to 8 cm in length and 2 to 4 cm in width. Similar to the majority of plants in this family, Spalding's catchfly has distinctly swollen nodes located where the leaves are attached to the stem. Reproductive individuals produce 3 to 20 cream to pink or light green flowers that are borne in a branched, terminal inflorescence. All green portions of the plant (foliage, stem, and flower bracts) are covered in dense sticky hairs that frequently trap dust and insects, giving this species the common name 'catchfly' (USFWS, 2016).

Current Range

Regional endemic restricted to remnants of the Poulouse Prairie grasslands of eastern Washington, northeastern Oregon, northern Idaho, and western Montana (barely extending into British Columbia, Canada) (NatureServe, 2015). The species is endemic to the Palouse region of south-east Washington and adjacent Oregon and Idaho, and is disjunct in northwestern Montana and British Columbia, Canada (USFWS, 2016).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Food/Nutrient Narrative

Adult: All green portions of the plant (foliage, stem, and flower bracts) are covered in dense sticky hairs that frequently trap dust and insects, giving this species the common name 'catchfly' (USFWS, 2016).

Breeding Season

Adult: Flowering typically occurs from mid-July through August, but may occasionally continue into October (USFWS, 2016).

Reproduction Narrative

Adult: Plants (both vegetative and reproductive) emerge in mid- to late May. Flowering typically occurs from mid-July through August, but may occasionally continue into October. Rosettes are formed the first and possibly the second year, followed by the formation of vegetative stems.

Above-ground vegetation dies back at the end of the growing season and plants either emerge in the spring or remain dormant below ground for one to several consecutive years. Spalding's catchfly reproduces solely by seed. It lacks rhizomes or other means of reproducing vegetatively (USFWS, 2016). *Silene spaldingii* is a partially self-compatible, hermaphroditic perennial. Reproduction is apparently via seed only, as rhizomes or other means of vegetative propagation are lacking. Seeds appear to require cold stratification, so germination occurs mainly in the spring. Rosettes are formed the first year and flowering may occur during or after the second season. Flowers are protandrous (Lesica and Heidel 1996). Anthers mature and dehise pollen first. During this time, the styles are unexpanded, and the unexposed stigmatic surfaces are held well below the level of the anthers. After the anthers shrivel and fall from the filaments, the three styles expand and the stigmas become receptive. Each flower persists for two to several days, and two or more flowers may be in bloom on the same plant, so geitonogamous pollination is possible. This system promotes outcrossing while allowing the possibility of self-pollination (Lesica 1991; 1993). The bumblebee, *Bombus fervidus*, appears to be the only significant pollination vector for *S. spaldingii* throughout its range (Lesica and Heidel 1996). At least at some populations, *S. spaldingii* appears to be subject to pollinator limitations, inbreeding depression, and a large genetic load (Lesica 1991; 1993).; *Silene spaldingii* most frequently occurs in relatively intact climax or successional advanced mesic grassland communities (Lorain 1991). It does not occur at sites where the native vegetation has been displaced by aggressive weeds. It is apparently tolerant of light to moderate grazing (Schassberger 1988). In areas where grazing occurs, it does not appear to be preferred by cattle, but these populations also are much smaller than those in mature grassland habitats. Lesica (1994) found that prescribed burning at a site in Montana increased growth, recruitment and flowering of *Silene spaldingii*.; Perfect; Predominantly outcrossing; SEXUAL; ABIOTIC; Self-dispersing; Hymenoptera; (NatureServe, 2015)

Habitat Type

Adult: Palouse Prairie (NatureServe, 2015)

Habitat Narrative

Adult: The 2007 Recovery Plan describes occupied habitat within five physiographic regions; 1) the Palouse Grasslands in west-central Idaho and southeastern Washington; 2) the Channeled Scablands in eastern Washington; 3) the Blue Mountain Basins in northeastern Oregon; 4) the Canyon Grasslands of the Snake River and its tributaries in Idaho, Oregon, and Washington; and 5) the Intermontane Valleys of northwestern Montana. These regions are distinctive from one another in climate, plant composition, historical fire frequencies, and soil characteristics. These differences are significant in that they may translate into differences in life histories, habitat trends, consequences of fire suppression, and types of weed control as they apply to conservation of catchfly (USFWS, 2016). Restricted to Palouse Prairies, sometimes extending into areas where the grasslands are intermingled with ponderosa pine (*Pinus ponderosa*) woodlands. Soils are almost always a productive, deep loess. Elevation range is 580-1,220 m. *Silene spaldingii* is restricted to *Festuca idahoensis* habitat types and phases throughout its range. These areas are often referred to as Palouse prairie. Sites are often near lower treeline, or near scattered ponderosa pine trees. Populations have been found on all aspects, but there seems to be a preference for northerly-facing aspects. It occurs at elevations ranging from about 1,900 to 3,600 feet, and on flat to steep slopes. Soils are almost always productive silt/loams (loess) that are moderately deep and sometimes gravelly (Gamon 1991; Lorain 1991). The soils

are depositional materials from catastrophic floods of glacial Lake Missoula that extend from Montana across Idaho into eastern Oregon and Washington. (NatureServe, 2015)

Dispersal/Migration

Population Information and Trends

Population Trends:

Increasing (USFWS, 2016)

Number of Populations:

~99 (USFWS, 2016)

Population Size:

~28,750 (USFWS, 2016)

Population Narrative:

When catchfly was initially listed in 2001, it was known from 58 populations if the element occurrence records within 1.6 km (1 mile) of one another are grouped together (USFWS 2007). There were 7 populations in Idaho, 6.5 in Montana, 9 in Oregon, 35 in Washington, and 0.5 in British Columbia, Canada. Some 16,500 individual plants were estimated at the time of listing. As of 2007, there were 99 populations: 22 in Idaho, 10.33 in Montana, 17 in Oregon, 49 in Washington, and 0.66 in British Columbia, Canada (USFWS 2007). The number of individual plants in each population ranged from one to several thousand. Several new sites within the Canyon Grasslands have expanded our knowledge of the range of the species by 80.4 (50 miles) from those locations known in 2001. New occurrences are likely a result of increased survey effort, not an increase in actual plant distribution or vigor. In 2007, the estimated number of plants was approximately 28,750 individuals in the United States. The ten largest populations are each made up of more than 500 plants. Approximately 78% of the total known individuals of catchfly are found within these few large populations. Of the 99 known populations, two-thirds (66 populations, or 67%) are small populations, each made up of fewer than 100 individuals (USFWS 2007). Much of the remaining habitat occupied by Spalding's catchfly is fragmented by roads, agricultural fields, and other developments. Additional plants and populations have been found throughout its range since 2007, but range-wide population numbers and trends have not been summarized to date (K. Colson, USFWS, pers. comm. 2015). The 2007 Recovery Plan describes occupied habitat within five physiographic regions; 1) the Palouse Grasslands in west-central Idaho and southeastern Washington; 2) the Channeled Scablands in eastern Washington; 3) the Blue Mountain Basins in northeastern Oregon; 4) the Canyon Grasslands of the Snake River and its tributaries in Idaho, Oregon, and Washington; and 5) the Intermontane Valleys of northwestern Montana. These regions are distinctive from one another in climate, plant composition, historical fire frequencies, and soil characteristics. These differences are significant in that they may translate into differences in life histories, habitat trends, consequences of fire suppression, and types of weed control as they apply to conservation of catchfly. The long-lived nature of Spalding's catchfly, in conjunction with sporadic and rare recruitment, delayed maturity, cryptic rosettes that may disappear before monitoring, prolonged dormancy, and difficulties identifying seedlings, make it challenging to measure changes in numbers of individuals of this species (USFWS 2007). For plants exhibiting prolonged dormancy, population trend monitoring needs to occur for 3 or more consecutive

years every 5 to 20 years to adequately assess trends at a given site (USFWS 2007). Long-term demographic monitoring occurred at a number of sites, including two in eastern Washington, two in northwest Montana, and two in the canyon grasslands of the Snake and Salmon Rivers surrounding Craig Mountain, Idaho (USFWS 2007, Hill 2012, Lesica 2012, Hill et al. 2014). Population trend data is also still collected at numerous sites in Washington and Oregon (K. Colson, USFWS, pers. comm. 2015). In 2012, guidelines for monitoring trend of catchfly populations in Key Conservation Areas were developed to encourage the development of consistent and statistically relevant monitoring methodologies across the range of the species. Across the range of the species, the number of populations of Spalding's catchfly have increased since it was first listed. In Idaho, there are 34 populations; these populations vary from 1 to over 500 individuals (K. Colson, USFWS, pers. comm. 2015). In Montana, there are 15 populations, including the largest known population, which is over 16,000 plants (A. Pipp, Montana Natural Heritage Program, pers. comm. 2015). Many of these populations are relatively small, and only 2 populations exceed 500 plants. In Oregon, there are approximately 21 populations; these populations vary from a few to over 40,000 individual plants documented on the Zumwalt preserve (Sausen, USFWS, pers. comm. 2015; Taylor et al. 2012). On Federal lands in Oregon, this species occurs on the Wallowa-Whitman NF, BLM lands, and National Park Service Lands (Old Chief Joseph Gravesite and Cemetery). Of these 21 populations in Oregon, as of 2015, there are approximately 16 populations in the Blue Mountains Physiographic Region and approximately five populations in the Canyon Grasslands Physiographic Region. In Washington, there are 53 populations composed of 563 site locations as of 2013; these populations vary from just a few individuals to several thousand plants (Arnett, 2014). On Federal lands in Washington this species occurs on the Umatilla NF. (Sausen, USFWS, pers. comm. 2015). Overall, *Silene spaldingii* populations are not secure from threats identified in the Plan including invasive nonnative plants; problems associated with small, geographically isolated populations; changes in the fire regime and fire effects; land conversion associated with urban and agricultural development; adverse livestock grazing and trampling; adverse grazing (herbivory) and trampling by wildlife species; off-road vehicle use; insect damage and disease; impacts from prolonged drought and climate change; and the inadequacy of existing regulatory mechanisms (USFWS, 2016).

Threats and Stressors

Stressor: Development (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Human development (habitat loss) is listed as a threat to this species (USFWS, 2016).

Stressor: Grazing (USFWS, 2016)

Exposure:

Response:

Consequence: Habitat degradation

Narrative: Habitat degradation associated with adverse grazing and trampling by domestic livestock and wildlife is listed as a threat to this species (USFWS, 2016).

Stressor: Nonnative plants (USFWS, 2016)

Exposure:

Response:**Consequence:** Loss of habitat**Narrative:** Invasions of aggressive nonnative plants are listed as threats to this species (USFWS, 2016).**Stressor:** Loss of genetic variability (USFWS, 2016)**Exposure:****Response:****Consequence:** Extinction/loss of genetic variability**Narrative:** Loss of genetic fitness (the loss of genetic variability and effects of inbreeding) is a problem for many small, fragmented populations where genetic exchange is limited (USFWS, 2016).**Stressor:** Fire frequency and seasonality (USFWS, 2016)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:** Fire frequency and seasonality is listed as a threat to this species (USFWS, 2016).**Stressor:** Off-road vehicle use (USFWS, 2016)**Exposure:****Response:****Consequence:** Loss of individuals/habitat degradation**Narrative:** Off-road vehicle use is listed as a threat to this species (USFWS, 2016).**Stressor:** Herbicides (USFWS, 2016)**Exposure:****Response:****Consequence:** Loss of individuals**Narrative:** Herbicide spraying and drift is listed as a threat to this species (USFWS, 2016).**Recovery****Recovery Actions:**

- Ongoing conservation efforts include research, Palouse Grassland conservation actions, invasive nonnative plant control, and land acquisition. Monitoring efforts continue, the technical team has worked towards developing a standardized monitoring protocol, and new monitoring has been initiated (USFWS, 2016).

SPECIES ACCOUNT: *Solanum conocarpum* (Marron bacora)

Species Taxonomic and Listing Information

Listing Status: Proposed Endangered

Physical Description

Solanum conocarpum is a dry-forest shrub of the Solanaceae or tomato family, which may attain 3 m (9.8 ft) height. Its leaves are oblong-elliptic or oblanceolate (broader at the distal third than the middle), ranging from 3.5-7 cm (0.62-1.5 in) wide. The leaves are coriaceous (leathery texture) and glabrous (no hairs), and have a conspicuous yellowish mid-vein. The flowers are usually paired in nearly sessile (not stalked) lateral or terminal cymes (flat-topped flower cluster). The corolla consists of five separate petals that are light violet, greenish at the base, and about 2 cm (0.78 in) wide. The fruit, a berry, is ovoid-conical (teardrop shaped), 2-3 cm (0.78-1.2 in) long, and turns from green with white striations to golden yellow when ripe (Acevedo-Rodríguez 1996).

Taxonomy

Solanum conocarpum belongs to the Solanaceae family. The genus *Solanum* includes about 1,200 species mostly of herbs and shrubs with a worldwide distribution (Liogier and Martorell 1995). Liogier and Martorell (1982) recognized about 24 species of *Solanum* from the Puerto Rican platform, and 10 species occurring within the island of St. John (Acevedo-Rodríguez 1996).

Historical Range

U.S. Virgin Islands, Island of St. John. *Solanum conocarpum* was originally known from a type specimen collected by L.C. Richard at Coral Bay, St. John, USVI, in 1787 (Acevedo-Rodríguez 1996). No population estimates are available from Richards discovery, nor are there any known population estimates prior to 1992. However, the species was presumed to be near extinction, as two mature plants were believed to be the only specimens left in the wild, one in NPS land, and the other on private land (B. Kojis and R. Boulon, pers comm., 1996, Vilella and Palumbo 2010). The species was rediscovered in 1992 by P. Acevedo-Rodríguez on the island of St. John (Ray and Stanford 2003). After 1992, six additional populations of *Solanum conocarpum* were identified and reported to occur on dry, poor soils (Ray and Stanford 2005). Acevedo-Rodríguez (1996) referenced the possibility of the species being present on St. Thomas, and mentioned a collection of one sterile specimen from Virgin Gorda (British Virgin Islands; BVI). Pedro Acevedo-Rodríguez (pers comm., 2002) believes that the specimen from Virgin Gorda belongs to a different species, *Cestrum laurifolium*. Omar Monsegur, USFWS, conducted a site visit to the John Folly population in 2010 and identified several *C. laurifolium* adjacent to individuals of *S. conocarpum*. Both plants (*C. laurifolium* and *S. conocarpum*) look very similar and are easy to misidentify (O. Monsegur, pers comm., 2010).

Current Range

Solanum conocarpum is currently known from eight localities in the Island of St. John, USVI. Two locations are found in the north side of the Island (Base Hill and Brown Bay Trail), and six towards the southeast side Nanny Point, Friis Bay, Reef Bay, John Folly, Sabbath Point, and Europa Ridge). All of the eight known localities of *S. conocarpum* are wild populations each ranging from 1 to 144 individuals. The majority of individuals are found within the NPS

boundaries, leaving only two populations on private lands (Friis Bay and Sabbat Point). The largest population of *S. conocarpum* is located at Nanny Point. Due to potential urban and tourism development at Nanny Point, most of the natural population has been transferred to NPS lands. The owners of the private properties that harbor the Nanny Point natural population agreed to protect an additional area corresponding to Parcel 30-3 by donating it to the NPS (Carper and Selengut 2003, Ray and Carper 2009). Thus, the entire Nanny Point population now lies within a protected area. Populations located on Base Hill, Brown Bay Trail, Europa Ridge, and Reef Bay, lie within NPS lands.

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Obligate outcrosser

Dependency on Other Individuals or Species

Adult: Species requires other individuals of the same species to outcross (obligate outcrosser).

Reproduction Narrative

Adult: Little is known about the natural history, reproductive biology, and effects of herbivory on *S. conocarpum* (Ray and Stanford 2003). It has been suggested that this species might be functionally dioecious (requiring male and female flowers from different plants to outcross). However, P. Acevedo-Rodríguez (pers comm., 2002) documented flowers and fruits in a solitary wild plant he discovered in the White Cliff area (Reef Bay general area). He further suggested that *S. conocarpum* may have less reproductive fitness due to selfing (self-pollination). Later, Ray and Stanford (2005) conducted some pollination studies in a controlled environment, which indicated that the species might be an obligate outcrosser with complete self-incompatibility (plant has both male and female parts, but it needs to outcross with other individuals to produce fruits due to self-incompatibility). These studies were conducted because prior to 2003 a lack of natural recruitment was observed in the wild (Ray and Stanford 2003, J. Saliva, USFWS, pers obs., 2004, O. Monsegur, USFWS, pers obs., 2010, Vilella and Palumbo 2010). DNA sampling of the majority of *S. conocarpum* populations suggests that most populations have been long isolated (Ray and Stanford 2005). Additionally, genetic work performed at the University of the Virgin Islands by A. Stanford has shown low heterozygosity (a measure of the allele frequency or genetic diversity) (G. Ray, pers comm., 2010). Further, when compared with its close relative *S. polygamum*, it appears to show a significant reduction in genetic diversity (G. Ray, pers comm., 2010).

Habitat Narrative

Adult: Acevedo-Rodríguez (1996) described the habitat of *S. conocarpum* as a dry, deciduous forest. The species also has been reported to occur on dry, poor soils (Ray and Stanford 2005). It can be locally abundant in exposed topography on sites disturbed by erosion (depositional zones at the toe of the slopes), areas that have received moderate grazing, and around ridgelines as an understory component in diverse woodland communities (Carper and Ray 2008). A habitat

suitability model suggests that the vast majority of *S. conocarpum* habitat is found in the lower elevation coastal scrub forest (Vilella and Palumbo 2010).

Dispersal/Migration

Motility/Mobility

Adult: Sessile

Dispersal

Adult: Low due to a lack of seed dispersers and pollinators

Dependency on Other Individuals or Species for Dispersal

Adult: As an obligate outcrosser, the species requires seed dispersers and pollinators.

Dispersal/Migration Narrative

Adult: The nature of the relationships between *S. conocarpum* and different pollinators and seed dispersers that have interacted with the species over its evolutionary history, is an important factor to consider. Controlled pollination studies concluded that this species is an obligate outcrosser (reproduction requires pollen from another plant) with complete self-incompatibility (Ray and Stanford 2005). As plant populations become reduced and spatially segregated, important life-history needs provided by pollinators and seed dispersers may be compromised (Kearns and Inouye 1997). It is possible that natural fruit dispersers of *S. conocarpum* had targeted other food sources as the populations of this shrub became increasingly patchy, as a result of deforestation and introduction of exotic plant species. The absence of a fruit disperser may also indicate that the disperser of the species is extinct or that the populations are too small to attract the disperser (Roman 2006).

Population Information and Trends

Number of Populations:

8 site localities with populations ranging from 1-144 individuals.

Population Size:

~144 individuals

Population Narrative:

No population estimates of *S. conocarpum* are available prior to 1992. The species was presumed to be near extinction, as two mature plants were believed to be the only specimens left in the wild (B. Kojis and R. Boulon, pers comm., 1996, Vilella and Palumbo 2010). The known wild populations of currently occur in eight localities in the island of St. John, and range from 1 to 144 individuals. The original natural population of *S. conocarpum* located at Nanny Point consisted of 184 individuals. About 40 of these plants were located within a 30-ft access corridor to a private property and were transplanted to an adjacent location within the same population in the national park (property donated by Mike Carper to the NPS) to avoid potential impacts from development (M. Carper, pers comm., 2010). During a site visit to Nanny Point in May 2010 it was observed that approximately 90 percent of the transplanted material was dead or stressed due to lack of water (O. Monsegur, USFWS, unpubl. data, 2010). Death was also observed in the non-transplanted individuals (144), apparently resulting from competition with

edge vegetation (vines). Thus, the current number of natural individuals at Nanny Point is estimated at 144 individuals. Combined deaths (transplanted and competition) of plants has resulted in an overall population decline of 25 percent. The second largest natural population of *S. conocarpum* is located at Friis Bay and consists of 33 individuals (Ray and Stanford 2005). The natural populations found in Base Hill, Brown Bay Trail, Europa Ridge, and Sabbat Point consist of one individual each, whereas that in Reef Bay consists of six individuals. Though more recently, the population at Reef Bay has been reported as extirpated (G. Ray, pers comm., 2010), but no official confirmation of the extirpation has been made. The current status of introduced seedlings at Reef Bay, which initially experienced high rates of survival, is also unknown. The individual in Brown Bay is located on the edge of the Brown Bay Trail, and shows evidence of damage due to trail maintenance. A new population was recently recorded in Johns Folly Bay adjacent to Road 107, just along the boundaries of the NPS (M. Carper, pers comm., 2010). This population is approximately 11 adult individuals and shows signs of human disturbance (O. Monsegur, USFWS, unpubl. data, 2010). *Solanum conocarpum* suffers from the lack of natural recruitment, absence of dispersers, fragmented distribution, and lack of genetic variation. These factors are evidenced by the predominance of old individuals in the populations, reduced number of individuals, low number of populations, and lack of connectivity between populations, any or all of which may result in an increased risk of genetic drift. Furthermore, four of the currently known localities consist of a single individual, which may not be sustainable, as the species has been identified as an obligate outcrosser. One natural population has been reported as extirpated, the largest population has suffered a reduction of approximately 25 percent of the natural individuals, and low genetic variability has been reported for the species.

Threats and Stressors

Stressor: Human development

Exposure:

Response:

Consequence:

Narrative: Habitat modification may result in irreversible damage to the species natural habitat, decreasing the number of individuals of already small populations. In addition, the current sale of private housing lots adjacent to currently known populations suggests future urban developments that could lead to the extirpation of unknown populations.

Stressor: Non-native mammal species

Exposure:

Response:

Consequence:

Narrative: Exotic mammal browsers are found throughout the range of *S. conocarpum* in St. John Island. These include feral goats (*Capra aegagrus hircus*), pigs (*Sus scrofa*), Key deer (*Odocoileus virginianus clavium*), and donkeys (*Equus asinus*) (Vilella and Palumbo 2010; O. Monsegur, USFWS, pers obs., 2010). Feral donkeys, pigs, deer, and goats could directly and indirectly affect *S. conocarpum* populations by uprooting and eating seedlings, destabilizing slopes, and dispersing exotic plant species, thus preventing or reducing the sustainability of its populations. It is expected that these exotic mammals are modifying the structure of the vegetation, and therefore, the environmental conditions in these areas. This may imply changes on microhabitat conditions that are necessary for seed germination and seedling recruitment of *S. conocarpum*.

Stressor: Lack of natural recruitment

Exposure:

Response:

Consequence:

Narrative: Lack of natural recruitment represents one of the major threats to *S. conocarpum*. An example is the structure of the populations of Nanny Point and John Folly, which are predominantly comprised by old individuals. This is also true for the Brown Bay Trail individual. Seedling and sapling stages are missing in these populations, and old individuals are dying due to competition with other species such as vines. Without natural recruitment or successful augmentation from captive propagated individuals, these populations are likely to become extirpated as older individuals die.

Stressor: Absence of dispersers

Exposure:

Response:

Consequence:

Narrative: The nature of the relationships between *S. conocarpum* and different pollinators and seed dispersers that have interacted with the species over its evolutionary history, is an important factor to consider. Controlled pollination studies concluded that this species is an obligate outcrosser (reproduction requires pollen from another plant) with complete self-incompatibility (Ray and Stanford 2005). As plant populations become reduced and spatially segregated, important life-history needs provided by pollinators and seed dispersers may be compromised (Kearns and Inouye 1997). It is possible that natural fruit dispersers of *S. conocarpum* had targeted other food sources as the populations of this shrub became increasingly patchy, as a result of deforestation and introduction of exotic plant species. The absence of a fruit disperser may also indicate that the disperser of the species is extinct or that the populations are too small to attract the disperser (Roman 2006).

Stressor: Population fragmentation

Exposure:

Response:

Consequence:

Narrative: The loss of potential breeding partners, reduction or loss of pollinators, and the loss of seed dispersers are examples of negative impacts due to habitat fragmentation (Kearns and Inouye 1997, Murren 2002). As an obligate outcrosser, *S. conocarpum* encounters another challenge in that isolated and relic individuals may no longer reproduce unless enhancement and artificial propagation projects are conducted. Along with a decreasing population size, negative impacts of habitat fragmentation may result in erosion of genetic variation through the loss of alleles by random genetic drift (Honney and Jacquemyn 2007). Habitat fragmentation may also limit the ability of a species to respond to a changing environment (Booy et al. 2000).

Stressor: Lack of genetic variation

Exposure:

Response:

Consequence:

Narrative: Research conducted on *S. conocarpum* shows a reduction in its genetic diversity (Ray and Stanford 2005). The population with the greatest genetic diversity is the one located at

Nanny Point, which also has the largest number of individuals. In addition to attempts to safeguard the genetic diversity of the species, the survival of reintroduced individuals needs to be monitored as well as their development into mature individuals capable of contributing to the natural recruitment of the species. Consequently, the protection and monitoring of known adult individuals should be considered as a high priority for the conservation of the species.

Recovery

Recovery Actions:

- Surveys should continue to update status and distribution of the species, including in St. Thomas and the British Virgin Islands. Surveys should consider the habitat suitability model prepared by Vilella and Palumbo (2010).
- Threats to *S. conocarpum* as well as the magnitude or the imminence of such threats should be monitored on an annual basis.
- Attempts to safeguard the genetic diversity of the species, the survival of reintroduced individuals, as well as their development into mature individuals need to continue.
- Due to lack of natural recruitment, protection and monitoring of known adult individuals should be considered a high priority for the conservation of the species.
- Efforts to protect *S. conocarpum* populations on privately-owned lands should be initiated.
- Public education and outreach programs regarding the status of *S. conocarpum* should be reinforced.

Conservation Measures and Best Management Practices:

- Surveys should continue to update status and distribution of the species, including in St. Thomas and the British Virgin Islands. Surveys should consider the habitat suitability model prepared by Vilella and Palumbo (2010).
- Threats to *S. conocarpum* as well as the magnitude or the imminence of such threats should be monitored on an annual basis.
- Attempts to safeguard the genetic diversity of the species, the survival of reintroduced individuals, as well as their development into mature individuals need to continue.
- Due to lack of natural recruitment, protection (e.g., fencing) and monitoring of known adult individuals should be considered a high priority for the conservation of the species.
- Efforts to protect *S. conocarpum* populations on privately-owned lands should be initiated.
- Public education and outreach programs regarding the status of *S. conocarpum* should be reinforced.

SPECIES ACCOUNT: *Solanum drymophilum* (Erubia)

Species Taxonomic and Listing Information

Listing Status: Endangered; 8/26/1988; Southeast Region (R4) (USFWS, 2015)

Physical Description

A spiny shrub that may reach 18 feet (5.5 meters) in height. The leaves and petioles have minute, white, star-shaped hairs whereas young twigs, inflorescences and flowers have long, whitish star-shaped hairs. Spines, sharp and stiff, yellowish, 5/16 to 7/16 of an inch (.8 to 1.1 centimeters) long, are found primarily along the mid-vein of the leaves and occasionally along the twigs. The leaves, alternate, lanceolate to lanceolate-oblong and entire, are 5 1/2 to 7 1/2 inches (14 to 19 centimeters) long and 5/8 to 1 1/4 inches (1.5 to 3.2 centimeters) wide (Vivaldi and Woodbury 1981). Inflorescences are lateral, subterminal, many-flowered racemes which may reach 3 to 3 1/2 inches (8 to 9 centimeters) in length. The pedicels are slender and short when in flower but become longer and curved when in fruit. Flowers are perfect with a 5-lobed, bell-shaped calyx. The corolla is 5-lobed, white, folded like a fan, with the lobes united one-third to one-half of their length. The superior ovary is 2-celled and the ovules numerous. The fruit is a glabrous, round, shiny—black berry approximately 3/16 to 5/16 of an inch (5 to 8 centimeters) in diameter. Seeds are numerous, circular, creamy—yellow in color, and about 1/16 of an inch (1.5 millimeters) in diameter (USFWS, 1992).

Taxonomy

Solanum ensifolium has long been known as *S. drymophilum*, based on a misinterpretation of the original provenance of the type of *S. ensifolium*. Both names refer to the same species, but *S. ensifolium* is an older name (1852) than *S. drymophilum* (1909). However, *Solanum ensifolium* is the name that is accepted in the recent checklists for Puerto Rico (Axelrod 2011) and the West Indies (Acevedo-Rodríguez and Strong 2012) (USFWS, 2015).

Historical Range

Known from an area known as Piedras del Collado in the Sierra de Cayey, in Salinas in east-central Puerto Rico (USFWS, 1992). Believed to be extirpated from historic sites in Naguabo in eastern Puerto Rico, and Lares in the west-central mountain region of Puerto Rico (USFWS, 2015).

Current Range

Known from the Salinas site in east-central Puerto Rico, and at sites in the municipalities of Florida and Arecibo in northern Puerto Rico (USFWS, 2015). 2019 refinements: Currently, erubia is known from three (3) populations: Las Piedras def Collado (previously known as Las Tetas de Cayey) in the municipality of Salinas (this was the only known population at the time of listing); Rio Abaja Commonwealth Forest in the municipality of Arecibo; and two localities near road PR-140 in the municipality of Florida. (USFWS, 2019).

Critical Habitat Designated

Yes;

Life History

Food/Nutrient Resources**Reproductive Strategy**

Adult: Biotic (EPA, 2016)

Breeding Season

Adult: In flower and fruiting year-round (USFWS, 1992)

Key Resources Needed for Breeding

Adult: Insects for pollination (EPA, 2016)

Other Reproductive Information

Adult: Seed production is abundant (USFWS, 1992)

Reproduction Narrative

Adult: Species is insect-pollinated; potential fruit type is berry (sometimes enclosed by inflated persistent calyx)/ speticidal capsule (EPA, 2016). Little is known about the pollination mechanism. Species is in flower and fruiting throughout the year; seed production is abundant (USFWS, 1992).

Habitat Type

Adult: Terrestrial (USFWS, 1992)

Habitat Vegetation or Surface Water Classification

Adult: Subtropical wet forest life zone (USFWS, 1992)

Geographic or Habitat Restraints or Barriers

Adult: Elevation 1,000 - 3,000 ft (EPA, 2016)

Habitat Narrative

Adult: Erubia is endemic to evergreen forests of the subtropical wet forest life zone, on volcanic soils at elevations from 1,000 to 3,000 feet. The habitat has been described as subtropical wet forest in an area of volcanic outcrops (USFWS, 1992). The most recent information indicates that erubia occurs in disturbed sites with poor soils and exposed topography (USFWS, 2015).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Little is known about the dispersal mechanisms for this species (USFWS, 1992).

Population Information and Trends**Population Trends:**

Not available.

Species Trends:

Unknown (USFWS, 2015)

Number of Populations:

1 (USFWS 2015)

Population Size:

150 - 200 (USFWS, 2015)

Population Narrative:

No new comprehensive surveys of this plant have been completed since the 1992 recovery plan, which reported that 150 plants were known from one locality at Las Piedras del Collado (also known as Las Tetas de Cayey) in the municipality of Salinas. It was thought at that time that this plant occurred in the Lares area as well, but it could not be confirmed. Although other individuals have been documented in other municipalities, all populations have been poorly monitored and their current status is unknown (USFWS, 2015).

Threats and Stressors

Stressor: Habitat modification or destruction (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Although some erubia populations occur on protected areas, most of the known populations occur on privately-owned lands that could be affected directly or indirectly by urban development or lack of appropriate habitat management. Potential urban development or expansion of existing constructions, habitat modification caused by road maintenance, landslides, overgrowth of vegetation and the lack of site management are threats to erubia. However, these threats are non-imminent and of low magnitude (USFWS, 2015).

Stressor: Natural or manmade factors (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Due to its limited distribution and number of natural populations, the cumulative effects of human induced fire, exotic invasive plant species, and climate change are considered detrimental to erubia as a whole (USFWS, 2015)

Recovery**Reclassification Criteria:**

1. The privately-owned population site is given protected status (USFWS, 1992)
2. At least two new self-sustaining populations in Commonwealth forest units or otherwise protected lands have been established (USFWS, 1992)

Delisting Criteria:

1. The two (2) existing populations on privately owned lands (i.e., Salinas and Florida) are protected through conservation mechanisms (addresses Factors A and E). (USFWS, 2019).

2. Existing three (3) populations on Las Piedras de/ Collado, Rio Abajo Commonwealth Forest, and the municipality of Florida show a stable or increasing trend, evidenced by natural recruitment and multiple age classes (addresses Factors A and E). (USFWS, 2019).

3. Establish three (3) new populations on lands protected by conservation mechanisms within the known geographical range of the species that demonstrate a stable or increasing trend, evidenced by natural recruitment and multiple age classes (addresses Factors A and E). (USFWS, 2019).

4. Threat reduction and management activities have been implemented to a degree that the species will remain viable into the foreseeable future (addresses Factor E). (USFWS, 2019).

Recovery Actions:

- Protect the privately-owned “Tetas de Cayey” site (USFWS, 1992)
- Monitor all known individuals (USFWS, 1992)
- Enforce existing Commonwealth and Federal regulations (USFWS, 1992)
- Continue to search for new populations
- Assess habitat requirements (USFWS, 1992)
- Assess phenology and pollination mechanisms (USFWS, 1992)
- New in 2019: Develop and implement a monitoring protocol to adaptively manage the species and its habitat. Additional monitoring should occur after major disturbances (e.g., fires, hurricanes, and landslides) as recommended in the 2015 5-year review status. This recovery action should be coordinated with PRDNER and be included within Task 112: Monitor all known individuals of the approved recovery plan. (USFWS, 2019).

Conservation Measures and Best Management Practices:

- The recovery of the species should focus primarily on the protection of the known populations and their habitat. The area where erubia exists in Las Piedras del Collado should be incorporated into the already designated natural reserve.
- Comprehensive field surveys on erubia should be conducted within historical sites and in non-traditional sites with suitable habitat to determine the existence and distribution of the species and its current status.
- Enhance existing populations with propagated individuals.
- Studies should be conducted of the species’ phenology and reproductive biology to figure out another way to effectively propagate the species.
- Studies should be conducted on the patterns of genetic variation, in order to develop a plan to preserve the species’ germplasm.
- All the populations should be monitored on a regular basis, and additional visits should be made after fires, hurricanes, landslides, or other major disturbances.

SPECIES ACCOUNT: *Solanum guamense* (Berenghenas halomtano)

Species Taxonomic and Listing Information

Listing Status: Endangered; 11/02/2015; Pacific Region (R1) (USFWS, 2016)

Physical Description

Solanum guamense (Biringenas halumtanu, birengenas halom tano), a small shrub in the nightshade family (Solanaceae). (USFWS, 2015)

Historical Range

Historically, *S. guamense* was reported from Guam, Rota, Saipan, Tinian, Asuncion, Guguan, and Maug (Stone 1970, p. 521; GBIF 2012e—Online Database; Bishop Museum 2014—Online Database). (USFWS, 2015)

Current Range

Solanum guamense (Biringenas halumtanu, birengenas halom tano), is known only from the Mariana Islands (Merrill 1914, pp. 139–140; Stone 1970, p. 521; Costion and Lorence 2012, p. 89). (USFWS, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: Not available.

Habitat Type

Adult: Terrestrial (USFWS, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest (USFWS, 2015)

Habitat Narrative

Adult: Currently, *S. guamense* is known from a single occurrence of one individual on Guam, in the forest ecosystem (Perlman and Wood 1994, pp. 135–136) (USFWS, 2015)

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Not available.

Population Information and Trends

Population Trends:

Not available.

Resiliency:

Very low (USFWS, 2015)

Redundancy:

Very low (USFWS, 2015)

Number of Populations:

1 (USFWS, 2015)

Population Size:

1 (USFWS, 2015)

Population Narrative:

Currently, *S. guamense* is known from a single occurrence of one individual on Guam, in the forest ecosystem (Perlman and Wood 1994, pp. 135–136). (USFWS, 2015)

Threats and Stressors

Stressor: Alien species and fire (NatureServe, 2015)

Exposure:

Response:

Consequence:

Narrative: Major threats include alien species and fire. (NatureServe, 2015)

Stressor: Small population size (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: *Solanum guamense* is now highly vulnerable to extinction, as there is only one known extant individual of this species. (USFWS, 2015)

Stressor: Habitat loss and destruction from agriculture, urban development, animals, and typhoons (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: *Solanum guamense*, and habitat for its recovery on Guam, Rota, Saipan, and Tinian, are at risk, due to continued habitat loss and destruction from agriculture, urban development, nonnative animals and plants, and typhoons. (USFWS, 2015)

Stressor: Climate change (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: The Service anticipates the effects of climate change will further exacerbate many of these threats in the future. (USFWS, 2015)

Stressor: Herbivory by pigs and deer (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Herbivory by pigs and deer, combined with the effects of low numbers of individuals, which results in loss of vigor and genetic representation, and limits its ability to compete with other species and adapt to changes in environmental conditions, contribute to the decline of *S. guamense*. (USFWS, 2015)

Recovery

Reclassification Criteria:

Not available.

Delisting Criteria:

Not available.

Recovery Actions:

- Not available.

Conservation Measures and Best Management Practices:

- Not available.

SPECIES ACCOUNT: *Solanum incompletum* (Popolo ku mai)

Species Taxonomic and Listing Information

Listing Status: Endangered; 11/10/1994; Pacific Region (R1) (USFWS, 2016)

Physical Description

Solanum incompletum is a woody shrub which reaches heights of up to 3 meters (10 feet). Its stems and lower leaf surfaces are covered with prominent reddish prickles and, sometimes, on younger plants yellow fuzzy hairs. Leaf margins are one to four-lobed on each side. Leaves are oval to elliptic, 10 to 15 centimeters (4 to 6 inches) long and 7 centimeters (2.8 inches) wide and found on petioles of up to 7 centimeters (2.8 inches) in length. There are prominent veins on the lower leaf surface. Inflorescences are loose clusters of single-stalked flowers. The white petals form a star that is approximately 2 centimeters (0.8 inch) in diameter. Fruits are round berries, yellow-orange to black in color and approximately 1.5 centimeters (0.6 inch) in diameter (U.S. Army 2003a). *Solanum incompletum* differs from others in the genus by the presence of prickles, loose flower clusters, curved anthers, and berry size (U.S. Army 2003a)

Taxonomy

– *Solanum incompletum* is a member of the Solanaceae, or nightshade family. In 1888, two varieties, *S. incompletum* var. *glabrum* and *S. incompletum* var. *mauiense*, were described. In 1969 a collection from Maui was described and named as *S. haleakalaense*. *Solanum haleakalaense* and *S. incompletum* were synonymized by David Symon in the Manual of Flowering Plants of Hawaii (1999) into *S. incompletum*. No varieties of this species are now recognized.

Historical Range

Historically, *Solanum incompletum* was known from the islands of Lanai, Maui, and Hawaii. It is believed that the distribution of *S. incompletum* may also have included the islands of Kauai and Molokai.

Current Range

Currently, it is only known from the island of Hawaii at PTA (U.S. Army 2003a).

Critical Habitat Designated

Yes; 7/2/2003.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Solanum incompletum* (Popolo ku mai) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes five detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

On July 2, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Solanum incompletum* on the island of Hawaii (68 FR 39623 - 39722).

Critical Habitat Designation

The critical habitat designation for *Solanum incompletum* includes five CHUs in Maui County, Hawaii with detailed unit information. There are also an unknown number of units on Lanai that contain this species (number of units is unknown because detailed unit descriptions for Lanai are not available) (81 FR 17790-18110).

Maui—Lowland Dry—Unit 1 consists of 11,465 ac (4,640 ha) of State land, 2,069 ac (837 ha) of federally owned land, and 3 ac (1 ha) of privately owned land, from Kanaio to Kahualau Gulch on the southern slopes of east Maui. This unit is occupied by the plants *Bonamia menziesii*, *Cenchrus agrimonioides*, *Flueggea neowawraea*, *Melicope adscendens*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 1 is not known to be occupied by *Alectryon macrococcus*, *Bidens micrantha* ssp. *kalealaha*, *Canavalia pubescens*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Hibiscus brackenridgei*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Sesbania tomentosa*, *Solanum incompletum*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 2 consists of 1,851 ac (749 ha) of State land at Keokea on the southern slopes of east Maui. This unit is occupied by the plants *Bonamia menziesii*, *Canavalia pubescens*, and *Hibiscus brackenridgei*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 2 is not known to be occupied by *Alectryon macrococcus*, *Bidens micrantha* ssp. *kalealaha*, *Cenchrus agrimonioides*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Flueggea neowawraea*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Solanum incompletum*, *Spermolepis hawaiiensis*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 3 consists of 188 ac (76 ha) of privately owned land, at Keauhou on the southern slopes of east Maui. This unit is occupied by the plant *Canavalia pubescens*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 3 is not known to be occupied by *Bidens micrantha* ssp. *kalealaha*, *Bonamia menziesii*, *Cenchrus agrimonioides*, *Colubrina oppositifolia*,

Ctenitis squamigera, *Flueggea neowawraea*, *Hibiscus brackenridgei*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Solanum incompletum*, *Spermolepis hawaiiensis*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 4 consists of 1,266 ac (512 ha) of State land (including the Department of Land and Natural Resources) at Ahihi-Kinohiwa Natural Area Reserve on the southern slopes of east Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). Although Maui—Lowland Dry—Unit 4 is not currently occupied by *Bidens micrantha* ssp. *kalealaha*, *Bonamia menziesii*, *Canavalia pubescens*, *Cenchrus agrimonioides*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Flueggea neowawraea*, *Hibiscus brackenridgei*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Solanum incompletum*, *Spermolepis hawaiiensis*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Mesic—Unit 1 consists of 1,147 ac (464 ha) of State land, 241 ac (97 ha) of privately owned land, and 494 ac (200 ha) of federally owned land (Haleakala National Park), from Manawainui Valley to Kukuiula on the eastern slopes of east Maui. This unit is occupied by the plants *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, and *Huperzia mannii*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Mesic—Unit 1 is not known to be occupied by *Ctenitis squamigera* or *Solanum incompletum*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

The critical habitat designation for *Solanum incompletum* includes two units totaling 1,882 acres in Hawaii County, Hawaii. The units are Hawaii 10—*Solanum incompletum*—a and Hawaii 11—*Solanum incompletum*—b. Both units currently are unoccupied by this species. Each unit is essential to the conservation of the species because it supports habitat that is necessary for the establishment of additional populations in order to reach recovery goals. Each unit is geographically separated from other critical habitat for this multi-island species within its historical range in order to reduce the likelihood of all recovery populations being destroyed by

one naturally occurring catastrophic event. The two units designated provide habitat for a total of four populations, each with 300 mature, reproducing individuals.

Hawaii 10—*Solanum incompletum*— a [705 ha (1,741 ac)]: This unit contains no named natural features, it is entirely in the Kiholo watershed, and is completely within the Puuwaawaaa Wildlife Sanctuary; provides habitat for 3 populations of 300 individuals of *S. incompletum*; and is currently unoccupied.

Hawaii 11—*Solanum incompletum*— b [57 ha (141 ac)]: This unit contains no named natural features, it is entirely in the Waiaha watershed, and is completely within the Honuauulu Forest Reserve; provides habitat for 1 population of 300 individuals of *S. incompletum*; and is currently unoccupied. This unit provides the southernmost critical habitat within the species' historical range.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Solanum incompletum* critical habitat consists of two components. Lowland dry (east Maui and Lanai) and Lowland mesic (east Maui and Lanai)(81 FR 17790-18110):

Ecosystem: Lowland Dry. Elevation: <3,300 ft (<1,000 m). Annual precipitation: <50 in (<130 cm). Substrate: Weathered silty loams to stony clay, rocky ledges, littleweathered lava. Canopy: Diospyros, Myoporum, Pleomele, Santalum. Subcanopy: Chamaesyce, Dodonaea, Leptecophylla, Osteomeles, Psydrax, Scaevola, Wikstroemia. Understory: Alyxia, Artemisia, Bidens, Chenopodium, Nephrolepis, Peperomia, Sicyos.

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: Acacia, Diospyros, Metrosideros, Myrsine, Pouteria, Santalum. Subcanopy: Dodonaea, Freycinetia, Leptecophylla, Melanthera, Osteomeles, Pleomele, Psydrax. Understory: Carex, Dicranopteris, Diplazium, Elaphoglossum, Peperomia.

Habitat features that are essential for this species include, but are not limited to, dry to mesic forest, diverse mesic forest, and subalpine forest.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight

plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; MauiWet

Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

The Service publishes this final rule acknowledging that they have incomplete information regarding many of the primary biological and physical requirements for these species. However, both the Act and the relevant court orders require the Service to proceed with designation at this time based on the best information available. As new information accrues, the Service may consider reevaluating the boundaries of areas that warrant critical habitat designation.

The following management actions are important in providing a conservation benefit to the species: feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History

Food/Nutrient Resources

Habitat Narrative

Adult: Historically, *Solanum incompletum* occurred in dry to mesic forests, diverse mesic forests, and subalpine forests. On Army lands at the Pohakuloa Training Area (PTA) on the island of Hawaii, the species is found on lava flows of various ages in Sparse *Metrosideros* Treelands and *Myoporum* Shrublands at an elevation of 1,425 meters (4,675 feet). Associated species include *Sophora chrysophylla* and *Myoporum sandwicense* (U.S. Army 2003a).

Dispersal/Migration

Population Information and Trends

Number of Populations:

1 - 5 (NatureServe, 2015)

Population Size:

1 - 1000 individuals (NatureServe, 2015)

Population Narrative:

Fragility unknown. 6 individuals were recently rediscovered. Previous to this, the species was last seen in 1949 and thought possibly extinct. 1 current (between 1982 and 1997) and 13 historical occurrences. (NatureServe, 2015). New status information: ☐ In 2009, there were 14 individuals at Puu Anahulu on Hawaii Island (PEPP 2009). In 2010, there were 15 plants at Puu Anahulu and Puu Waawaa (PEPP 2010). In 2011, an estimated 75 individuals of *Solanum incompletum* was known from Pohakuloa Training Area (PTA), Puu Anahulu, and Puu Waawaa (PEPP 2011). However, approximately 10 individuals were lost in the Puu Waawaa region apparently due to drought conditions (PEPP 2011). In 2014, two populations containing approximately 30 to 75 mature wild individuals of *S. incompletum* were known (PEPP 2014). In 2014, there were five individuals at Puu Anahulu (PEPP 2014). ☐ In 2010, there were 158 wild individuals (72 mature and 86 immature) of *Solanum incompletum* at PTA (U.S. Army Garrison [U.S. Army 2010]). Quantifying abundance for this species has proven difficult at PTA given its tendency for below ground clonal reproduction and the formation of above ground root sprouts (U.S. Army 2010). When uncertainty exists as to whether an above ground structure is an individual or a clone from another individual, it is tagged and marked as a possible clone and tallied accordingly. Nevertheless, there is likely some error in counts representing the actual number of individual plants present in a given area. In August 2013, there were an estimated 81 individuals, including an estimate of all potential clones (U.S. Army 2014). ☐ Overall, the numbers of individuals have increased from the approximately 83 wild mature individuals reported in the previous 5-year review to approximately 86 wild individuals in 2015. The number of reintroduced individuals decreased from the estimated 950 individuals reported in the previous 5-year review to more than 554 individuals in 9 populations. Natural recruitment was observed at two reintroduced sites at PTA with a total of 46 mature and 68 immature individuals. Natural recruitment of approximately 68 mature and 121 immature individuals of *S. incompletum* was also observed at outplanting sites located on State-owned lands outside of PTA (USFWS, 2015).

Threats and Stressors**Stressor:****Exposure:****Response:****Consequence:**

Narrative: *Solanum incompletum* is threatened primarily by browsing and habitat degradation by feral ungulates, competition from non-native plant species, wildfire, reduced reproductive vigor (e.g., limited gene pool), and extinction as a result of a single environmental disturbance (U.S. Army 2003a).

Stressor: Climate change adaptation strategy

Exposure:

Response:

Consequence:

Narrative: Fortini et al. (2013) conducted a landscapebased assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *S. incompletum* has a low vulnerability to the impacts of climate change (USFWS, 2015).

Stressor: Stochastic events

Exposure:

Response:

Consequence:

Narrative: Drought mortality or reduced viability – Drought may exacerbate the effects of ungulates and has direct adverse impacts on *S. incompletum* (PEPP 2010, 2014; U.S. Army 2010) (USFWS, 2015).

Stressor: Collecting impacts

Exposure:

Response:

Consequence:

Narrative: Illegal collection for scientific, horticultural or other purposes threatens the populations of *S. incompletum*, as well as possible excessive visitation. For instance, on two incidents in 2013, seven reintroduced individuals of *S. incompletum* were uprooted in the Mauna Kea area and those plants were stolen along with other common and federally listed plants (P. Peshut and S. Evans, pers. comm. 2013) (USFWS, 2015).

Recovery

Conservation Measures and Best Management Practices:

- The Seed Storage Facility at Lyon Arboretum and the University of Kentucky, School of Biological Sciences are conducting research on the seed storage requirements of an unspecified number of seeds of *Solanum incompletum* collected from PTA. Additionally, the Lyon Micropropagation Facility has, in vitro, tissue collected from plants at PTA. This material, to date, has not produced any plants. At PTA, the propagation facility has 160 plants that were propagated from two individuals collected at this installation. In addition, there are also 5,000 seeds in storage that were collected from eight individuals at PTA. Two hundred *S. incompletum* were outplanted in Kipuka Alala; however, only six have survived. Twenty-one plants outplanted by the State of Hawaii are surviving on Puu Huluhulu (Service 2003a; S. Gleason pers. comm., 2003).
- New management actions:
 - Surveys / inventories o A single new location of *S. incompletum* was recorded within the installation wide survey area in the Kipuka Kalawamauna West Fence Unit (U.S. Army 2014). This new discovery significantly benefits this species because there are only four known locations of this species at PTA (U.S. Army 2014).
 - Ungulate monitoring and control o In 2009, seven fenced enclosures approximately 3 meters by 3 meters (10 feet by 10 feet) were constructed to protect wild individuals of *S. incompletum* at Puu Anahulu (PEPP 2009).
 - In 2010, extreme drought conditions throughout PTA led to an increase in ungulate pressure to rare plants and their habitat. Consequently, emergency fences constructed of lightweight materials (plastic orange fencing) were breached and significant browse damage was observed on individuals of *S. incompletum* within Areas of Species Recovery (ASRs) 24 and 40 (U.S. Army 2010). The emergency fences were replaced with small-scale fences constructed from metal t-posts and hog wire fencing

to ensure the plants were protected from ungulates. o The *Solanum incompletum* Fence Unit and the external perimeter of the Mixed Tree Fence Unit were completed in 2010 (U.S. Army 2010). All known individuals of *S. incompletum* at PTA are protected by large-scale fence units and ungulate control commenced in 2011. As of 2013, the *Solanum incompletum* Fence Unit was ungulate-free (U.S. Army 2014). o In May 2014, a damaged 10-acre enclosure in Upper Puu Anahulu/Puuwaawaa was repaired (State of Hawaii Department of Land and Natural Resources [DLNR] 2014). The enclosure will provide protected habitat for outplanting the following endangered species *Zanthoxylum hawaiiense*, *Neraudia ovata*, *Solanum incompletum*, *Haplostachys haplostachya*, *Stenogyne angustifolia*, *Portulaca sclerocarpa*, and other dry to mesic species (DLNR 2014). □

Invasive plant monitoring and control – Manual hand clearing and maintenance spraying of weeds is ongoing around individuals of *S. incompletum* at PTA (U.S. Army 2010, 2014). □

Rodent predation or herbivory control – Snap traps and rodenticides are used to control rodents at PTA (U.S. Army 2010). As of 2013, rodent control was suspended pending a review of control methods and efficacy (U.S. Army 2014). In 2014, primarily work will identify which rodent species is responsible for damaging plants, and species-specific control methods will be developed and implemented (U.S. Army 2014). □

Captive propagation for genetic storage and reintroduction o The Volcano Rare Plant Facility (2013) had 10 individuals growing in their nursery from the Puu Anahulu population and propagated 11 plants for reintroductions next year. The Volcano Rare Plant Facility (2014) had 10 individuals growing in their nursery from the Puu Anahulu population. o The Lyon Arboretum's Seed Conservation Laboratory (2014) has 550 seeds in storage. o The National Tropical Botanical Garden (2014) propagated 37 seeds in 2012 from PTA. There are three plants outplanted at the Visitor's Center in Lawai and one plant at McBryde Lower Valley Conservation and Horticulture Center (National Tropical Botanical Garden 2015) for genetic storage and education. o In 2010, four more founders of *S. incompletum* were added to the three founders already in cultivation at the Rare Plant Propagation Facility at PTA (U.S. Army 2010). Two of the seven founders at the Rare Plant Propagation Facility are no longer extant at PTA. o In 2013, there were more than 13,000 seeds from 117 accessions representing three groups and 57 founders of *S. incompletum* in long-term storage at PTA (U.S. Army 2014). In 2015, nine fruits from four founders were collected and placed into long-term storage at PTA (U.S. Army 2015). o In 2014, fruit from *S. incompletum* was collected from Upper Puu Anahulu and Puu Waawaa Forest Reserve (DLNR 2014). □

Captive propagation protocol development – Propagation trials were conducted to determine appropriate storage and propagation techniques for *S. incompletum*. The trials indicated that seeds from *S. incompletum* had a low germination rate over an extended period of years (the number of years was not specified) and the seeds remained viable for more than 15 years (U.S. Army 2015). □

Population viability monitoring and analysis o In 2009, 13 of the 14 known wild individuals at Puu Anahulu were monitored for reproductive development (PEPP 2009). Fruit was collected from one founder and delivered to Volcano Rare Plant Facility. o In 2010, the populations at Puu Anahulu and Puu Waawaa were monitored for reproductive development and overall health of the plants (PEPP 2010). Fifteen plants were observed and cuttings were collected from five individuals. Most of the plants were noted as wilting from the effects of severe drought. o In 2010, no mature plants were reproductively active at the time of monitoring (U.S. Army 2010). This differs from 2009 when more than half (58%) of mature individuals were reproductive. Based on field observations, this may be driven primarily by drought conditions experienced in 2010. o In 2011, there was a substantial decline of 10 plants in the Puu Waawaa region, apparently due to the recent droughts (PEPP 2011). It is likely this species suffered similar declines across its entire range, including on adjacent federal lands at PTA (PEPP 2011). o Careful and closer analysis is needed to determine whether wild individuals are indeed separate individuals or are they actually attached underground and the root shoots represent a single individual (PEPP 2014). If this is true, staff at PTA estimated that they may have 25 distinct

individuals with an additional 5 plants located outside PTA (PEPP 2014). o In 2013, five of the 12 known individuals at Puu Anahulu were monitored (PEPP 2014). Fruit was collected from a single individual and four cuttings were collected (PEPP 2014). In 2014, the five individuals were monitored again (PEPP 2014). o At site 209 in the Kipuka Kalawamauna east fence unit, 27 reintroduced individuals (84 percent) survived of the 32 planted in 2003 (U.S. Army 2015). Although a few seedlings have been observed over the last 4 years, none have persisted (U.S. Army 2015). This may be due to insufficient rain or insect predation. In 2014, eight naturally recruited seedlings were observed at the site (U.S. Army 2015). o At site 214 within the Kipuka Alala South fence unit, monitoring of the site in 2014 tallied 123 reintroduced individuals and 46 naturally recruited mature and approximately 60 immature individuals at the site (U.S. Army 2015). o Near Saddle Road on State-owned lands, natural recruitment of 30 seedlings and/or suckers was observed in 2014 (U.S. Army 2015). o In North Kona on State-owned lands, natural recruitment of three adults and two immature individuals were observed in 2014 (U.S. Army 2015). o At Puu Waawaa Cone Unit on State-owned lands monitoring conducted in 2014 revealed natural recruitment of 19 mature and 21 immature individuals (U.S. Army 2015). □ Reintroduction / translocation o In 2010, 10 individuals of *S. incompletum* were reintroduced at three sites at PTA (U.S. Army 2010). o In 2014, 8 individuals were added to site 209 of the Kipuka Kalawamauna east fence unit (U.S. Army 2015). o In 2014, 16 individuals of *S. incompletum* were reintroduced at Mixed Tree fence unit (U.S. Army 2015). o During 2002 to 2012 at site 214 within the Kipuka Alala south fence unit, 152 individuals were reintroduced to the site (U.S. Army 2015). In 2014, an additional 18 individuals were reintroduced to the site. o At site 219 within the Kipuka Alala South fence unit, four individuals were reintroduced in 2014 (U.S. Army 2015). o In 2014, at site 220 within the Kipuka Kalawamauna north fence unit three individuals were reintroduced (U.S. Army 2015). o Near Saddle Road on State-owned lands, 445 individuals were reintroduced during 2002 to 2012, 10 individuals were added in 2014, and 209 plants remained in 2014 (U.S. Army 2015). o In North Kona on State-owned lands, 225 individuals were outplanted during 2004 to 2009 and only 4 individuals remained in 2014 (U.S. Army 2015). o At Puu Waawaa Cone Unit on State-owned lands, 391 individuals were reintroduced during 2005 to 2012 and additional 15 individuals were reintroduced in 2014 (U.S. Army 2015). In 2014, 138 reintroduced individuals remained. o On County-owned lands in North Kona, nine individuals were reintroduced during 2008 to 2012 with an additional two individuals reintroduced in 2014. Only four plants survived in 2014 (U.S. Army 2015). □ Stochastic events – Build resilience and redundancy – In 2010, all individuals of *S. incompletum* within ASRs 24 and 40 at PTA were watered (U.S. Army 2010). Plants located in ASR 24 were visited monthly, due to its remote location, and provided approximately 0.5 gallons of water. Plants located in ASR 40 were visited once a week and each plant was given approximately 0.5 gallons of water. The frequency of watering in ASR 40 was reduced to once every two weeks, then once every four weeks. Supplemental monitoring was conducted following the watering and plants were photo documented. After supplemental watering was initiated in ASR 40, invasive ants and scale were observed on and around individuals of *S. incompletum*. As a result, ant control was implemented at six of the seven plant locations (one location was excluded because the plant had died). □ Listing and critical habitat designation – Seven units of critical habitat for *S. incompletum* was proposed in the lowland dry, lowland mesic, and subalpine ecosystems on Maui (USFWS 2012). On Lanai, critical habitat for *S. incompletum* was proposed in six units in the coastal, lowland dry, lowland mesic, and dry cliff ecosystems. The final rule for critical habitat designations has not been published at the time of this review (USFWS, 2015).

- Recommendations for Future Actions: • Surveys / inventories – Survey geographical and historical range for a current assessment of the species' status. • Captive propagation for genetic storage and reintroduction – Continue collection of genetic resources for storage, propagation, and

reintroduction into protected suitable habitat within historical range. • Ungulate monitoring and control – Maintain existing exclosures and monitor for potential incursions. • Invasive plant monitoring and control – Eradicate invasive introduced plants within ungulate exclosures and maintain exclosures free of invasive plants. • Population viability monitoring and analysis – Continue monitoring wild and reintroduced individuals. • Fire monitoring and control – Develop and implement a fire management plan at the existing exclosures. • Alliance and partnership development – Initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon (USFWS, 2015).

SPECIES ACCOUNT: *Solanum nelsonii* (Popolo (Nelson's Horse-nettle))

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/31/2016; Pacific Region (R1) (USFWS, 2016)

Physical Description

Solanum nelsonii is a sprawling or trailing shrub which grows up to 3.3 feet (ft) (1 meter (m)) tall, forming clumps up to 4.9 ft (1.5 m) in diameter. Young stems and leaves are densely pubescent and do not have spines. Leaves are grayish green, have entire margins, are arranged alternately along the stems, and are broadly ovate. Flowers are perfect and have a white tubular corolla that is tinged with lavender to pale purple. Round berries are usually black when mature with numerous seeds. *S. nelsonii* is unusual in the genus with its doubly curved, purple anthers, which possibly suggest different pollinators than bees (Symon 1999, pp. 1,273-1,274).

Taxonomy

Kingdom: Plantae; Phylum: Anthophyta; Class: Dicotyledoneae; Family: Solanaceae (potatoes). *Solanum nelsonii* was described by Dunal (1852). This species is recognized as a distinct taxon in the Manual of Flowering Plants of Hawaii (Symon 1999, pp. 1,273-1,274), the most recently accepted Hawaiian plant taxonomy.

Historical Range

Historically, *Solanum nelsonii* was known from the island of Hawaii at South Point and South Kona; the island of Niihau at Kealea Bay, Kawaewaae, and Leahi; Pearl and Hermes on North Island, Seal-Kittery Island, and Grass Island; and on Green Island (Kure). This species was last collected on Niihau in 1949 (HBMP 2008). The only plant on Maui was reported to have disappeared in the mid-1990s after cattle had been allowed to graze in its last known habitat (HBMP 2008).

Current Range

The species is known from populations on the islands of Molokai and Hawaii, and the northwestern Hawaiian Islands (NWHI), Hawaii. The current populations in the NWHIs are found on Kure, Midway (Sand, Eastern, and Spit islands), Laysan, Pearl and Hermes, and Nihoa (Vanderlip, in litt. 2010).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Habitat Type

Adult: Typical habitat is coral rubble or sand in coastal sites up to 490 ft (150 m) in elevation (Symon 1999, p. 1,273).

Habitat Vegetation or Surface Water Classification

Adult: Grassland/herbaceous, Sand/dune, Shrubland/chaparrall

Environmental Specificity

Adult: Unknown

Habitat Narrative

Adult: The species is found on the main Hawaiian Islands and on all of the Northwestern Hawaiian Islands except Nihoa in coastal dry shrublands and grasslands on unconsolidated coral sand dunes, lithified dunes, or in coral rubble. On Niho, it is found on rocky ridges and in gulches with soil of basaltic (volcanic rock) origin (NatureServe 2014).

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Decline (NatureServe 2014)

Species Trends:

Decline (NatureServe 2014)

Number of Populations:

Represented on 7 of the Hawaiian islands (Molokai, Hawaii, Kure, Midway, Laysan, Pearl and Hermes, and Nihoa)

Population Size:

Molokai, including Ilio Point (~47) and Moomomi Preserve (4); Hawaii (5); Kure (?); Midway (~260); Laysan (~490); Pearl and Hermes (?); and Nihoa, including (8,000 to 15,000); also represented in ex situ collections.

Population Narrative:

Solanum nelsonii is known from populations in the Northwestern Hawaiian Islands on Kure (unknown number of individuals), Midway (approximately 260 plants), Laysan (approximately 490 plants), Pearl and Hermes (unknown number of individuals), Nihoa (8,000 to 15,000 adult plants); in the main Hawaiian Islands from an unknown number of plants on Molokai including Ilio Point (47 individuals) and Moomomi Preserve (4 individuals down from 50 known previously); and from individuals seen at Kaalualu, Kamilo, and Kaulana Bay, South Point (5 fence-enclosed individuals) on the island of Hawaii (Bio, in litt. 2008; Tangalin, in litt. 2006; Rehkemper, in litt. 2006; Aruch, in litt. 2006; Moses, in litt. 2005; Vanderlip, in litt. 2010; Conry, in litt. 2012; Plant Extinction Prevention Program (PEPP), in litt. 2013). We are unaware of additional surveys conducted to date.

Threats and Stressors

Stressor: Feral ungulates (pigs, goats, cattle, sheep, deer)

Exposure: Habitat degradation and destruction

Response:

Consequence:

Narrative: On Molokai, *S. nelsonii* is moderately threatened by feral ungulates that degrade and destroy habitat.

Stressor: Human impacts

Exposure: Habitat degradation and destruction

Response:

Consequence:

Narrative: On Hawaii, human impacts from four-wheel drive and all-terrain vehicles continue to be the biggest threat to the population at South Point (Agorastos, in litt. 2011).

Stressor: Nonnative plants

Exposure: Competition and displacement

Response:

Consequence:

Narrative: On Molokai and the NWHI, this species is exposed to threats from nonnative plants that outcompete and displace it.

Stressor: Feral ungulates and a nonnative grasshopper

Exposure: Predation

Response:

Consequence:

Narrative: On Molokai, *S. nelsonii* is moderately threatened by feral ungulates that may eat individuals. In the NWHI, the species is exposed to threats by herbivory by a nonnative grasshopper (*Schistocera nitens*). Its presence on Pearl and Hermes is unknown. This insect is a recent invader in the northwestern Hawaiian Islands, and was observed to cause widespread destruction of native plants on Nihoa by defoliation (Wegman et al. 2002).

Stressor: Tsunamis

Exposure: Habitat and population destruction

Response:

Consequence:

Narrative: Overwash from tsunami is a potential threat to populations on Kure, Midway (Sand, Eastern, and Spit Islands), Laysan, Pearl, and Hermes, and other low-lying coastal areas occupied by *S. nelsonii*. The Pacific tsunami generated by the magnitude 9.0 earthquake off the northeast coast of Japan on March 11, 2011, resulted in overwash 100 feet inland on Kure, complete overwash of Spit Island, over 60 percent overwash of Eastern Island, and overwash of the entire coastline of Sand Island (FWS 2011; Starr, in litt. 2011; Vanderlip, in litt. 2011). Tsunami waves may dislodge *S. nelsonii* individuals; however, the impacts of brief submergence in sea water alone may not result in the loss of *S. nelsonii* individuals or its habitat requirements. Starr (in litt. 2011) estimates that the 2011 tsunami swept over almost all of the *S. nelsonii* plants mapped on Midway in 2008.

Stressor: Climate change

Exposure: Habitat degradation and destruction

Response:

Consequence:

Narrative: Climate change may pose a threat to the ecosystem that supports this species. Fortini et al. (2013, pp. 1134) conducted a landscape-based assessment of climate change vulnerability

for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013, p. 89) concluded that *Solanum nelsonii* is extremely vulnerable to the impacts of climate change. Therefore, additional management actions may be needed to conserve this taxon into the future.

Recovery

Recovery Actions:

- Build ungulate exclusion fencing and conduct routine fence monitoring and maintenance.
- Conduct nonnative plant control using physical, mechanical, and biological control methods, as well as herbicides when necessary.
- Develop and implement a grasshopper control program on the northwestern Hawaiian Islands.
- Conduct propagation in ex situ collections for maintenance of genetic stock.
- Survey for populations of *Solanum nelsonii* in historical locations on Maui and the island of Hawaii.
- Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species.

Conservation Measures and Best Management Practices:

- Build ungulate exclusion fencing and conduct routine fence monitoring and maintenance.
- Conduct nonnative plant control using physical, mechanical, and biological control methods, as well as herbicides when necessary.
- Develop and implement a grasshopper control program on the northwestern Hawaiian Islands.
- Conduct propagation in ex situ collections for maintenance of genetic stock.
- Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species.

SPECIES ACCOUNT: *Solanum sandwicense* (ʻAiakeakua, popolo)

Species Taxonomic and Listing Information

Listing Status: Endangered; 02/25/1999; Pacific Region (R1) (USFWS, 2016)

Physical Description

A sprawling shrub up to 5 m tall. All parts are covered with yellowish brown hairs. Flowers are white and faint purple (NatureServe, 2015).

Taxonomy

A member of the nightshade family (Solanaceae) (USFWS, 2003). The genus is cosmopolitan, this species is endemic to Kauai & Oahu. Original taxonomy maintained by Wagner et al. (NatureServe, 2015).

Historical Range

Historically, *Solanum sandwicense* was known from both Kauai and Oahu. On Kauai, it was historically reported from locations in the Kokee region bounded by Kalalau Valley, Milolii Ridge, and Kawaikoi, and extending to the Hanapepe River. On Oahu, *S. sandwicense* occurred in both the Waianae and Koolau Ranges (USFWS 1994; 2009).

Current Range

This species was last seen on Oahu in 2000 (USFWS, 2003). It currently occurs in Kokee State Park, Kuia Natural Area Reserve, and Na Pali-Kona Forest Reserve at Kahuamaa Flats, Honopu, Awaawapuhi, Nualolo, Kumuwela Ridge, Kawaiiki, Waialae Valley, and Mokuone Stream (Kauai) (USFWS, 2009).

Critical Habitat Designated

Yes; 6/17/2003.

Legal Description

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Solanum sandwicense* (ʻAiakeakua, popolo) under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Solanum sandwicense* (77 FR 57648-57862). The critical habitat designation includes 7 critical habitat units, which encompass approximately 7,823 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Solanum sandwicense* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

On February 27, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Solanum sandwicense* on the island of Kauai, Hawaii (68 FR 9116 - 9479).

Critical Habitat Designation

The critical habitat designation for *Solanum sandwicense* includes 7 critical habitat units, covering one ecosystem type, which encompasses approximately 7,823 acres on the Island of

Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Mesic—Units 1, 2, 3, 4, 5, 6, 7.

Oahu—Lowland Mesic—Unit 1 [4,448 ac (1,800 ha)]. This area consists of 3,565 ac (1,443 ha) of State land, 583 ac (236 ha) of City and County of Honolulu land, 22 ac (9 ha) of Federal land, and 277 ac (112 ha) of privately owned land in the lowland mesic ecosystem in the Waianae Mountains, encompassing a large area including the north slopes of Mt. Kaala, from the Pahole NAR to the Kaala NAR, and south to the Waianae Kai Forest Reserve (FR). Oahu—Lowland Mesic—Unit 2 [1,063 ac (430 ha)]. This area consists of 1,063 ac (430 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Puuhapapa south to Puukaua. Oahu—Lowland Mesic—Unit 3 [353 ac (143 ha)]. This area consists of 353 ac (143 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Pohakea Pass to Kaiakuakai Gulch. Oahu—Lowland Mesic—Unit 4 [20 ac (8 ha)]. This area consists of 20 ac (8 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, between the Waipilopilo and Hanaimoa gulches, on State-owned land within the Hauula Forest Reserve. Oahu—Lowland Mesic—Unit 5 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, in Maakua Gulch and ridge; is State-owned; and within the Hauula FR. Oahu—Lowland Mesic—Unit 6 [247 ac (100 ha)]. This area consists of 12 ac (5 ha) State land and 235 ac (95 ha) of privately owned land in the lowland mesic ecosystem on the windward side of the Koolau Mountains, inland of Kaaawa Point, and is partially within Ahupuaa O Kahana State Park. Oahu—Lowland Mesic—Unit 7 [1,669 ac (676 ha)]. This area consists of 681 ac (276 ha) of State land, 129 ac (52 ha) of City and County of Honolulu land, and 852 ac (345 ha) of privately-owned land in the lowland mesic ecosystem on the leeward side of the Koolau Mountains, on Waialae Nui ridge.

The critical habitat designation for *Solanum sandwicense* includes two units totaling 6,651 acres in Kauai County, Hawaii. The units are Kauai 11—*Solanum sandwicense*—a, b.

Kauai 11—*Solanum sandwicense*—a: This unit is critical habitat for *Solanum sandwicense* and is 2,442 ha (6,039 ac) on State land (Kuia NAR, Kokee and Na Pali Coast State Parks). This unit contains portions of the Awaawapuhi, Berry Flat, Nualolo and Honopu Trails, Kahuamaa Flat, Kainamanu and Kalahu Summits, and Kaunuohua and Kumuwela Ridges. This unit provides habitat for five populations of 300 mature, reproducing individuals of the short-lived perennial *Solanum sandwicense* and is currently occupied with eight to nine plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable. It provides habitat for the westernmost range of the species that is unique to Kauai. The habitat features contained in this unit that are essential for this species include, but are not limited to, forest canopies in diverse lowland or montane *Acacia koa* or *Acacia koa*-*Metrosideros polymorpha* mesic or wet forests. This unit provides for five populations within this multiisland species' historical range on Kauai that are some distance away from the other critical habitat for this species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophic event.

Kauai 11—*Solanum sandwicense*—b: This unit is critical habitat for *Solanum sandwicense* and is 249 ha (614 ac) on State land, containing portions of Kawaiiki Ridge. This unit provides habitat for one population of 300 mature, reproducing individuals of the short-lived perennial *Solanum sandwicense* and is currently unoccupied. This unit is essential to the conservation of the taxon

because it supports habitat that is important to the establishment of additional populations on Kauai in order to reach recovery goals. It provides habitat for the westernmost range of the species that is unique to Kauai. The habitat features contained in this unit that are essential for this species include, but are not limited to, forest canopies in diverse lowland or montane *Acacia koa* or *Acacia koa*-*Metrosideros polymorpha* mesic or wet forests. This unit provides for one population within this multi-island species' historical range on Kauai that is some distance away from the other critical habitat for this species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophic event.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Solanum sandwicense* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Solanum sandwicense* occurs was known historically (last observed > 20 yrs ago) from the Lowland mesic ecosystem in the Koolau Mountain caldera complex and the Waianae caldera complex:

Oahu—Lowland Mesic—Units 1, 2, 3, 4, 5, 6, 7. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. (E) Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. (F) Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Within these units, the currently known primary constituent elements of critical habitat include, but are not limited to, the habitat components provided by:

(i) Under forest canopies in diverse lowland or montane *Acacia koa* or *Acacia koa*-*Metrosideros polymorpha* mesic or wet forests and containing one or more of the following associated plant species: *Alphitonia ponderosa*, *Athyrium sandwicense*, *Bidens* spp., *Carex meyenii*, *Coprosma* spp., *Cryptocarya mannii*, *Dianella sandwicensis*, *Dicranopteris linearis*, *Dubautia* spp., *Hedyotis* spp., *Ilex anomala*, *Melicope* spp., *Poa* spp., *Pouteria sandwicensis*, *Psychotria* spp., *Syzygium sandwicensis*, or *Xylosma hawaiiense*; and

(ii) Elevations between 540 and 1,290 m (1,770 and 4,232 ft).

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Solanum sandwicense* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Existing manmade features and structures within the boundaries of the mapped areas, such as buildings; roads; aqueducts and other water system features, including but not limited to pumping stations, irrigation ditches, pipelines, siphons, tunnels, water tanks, gaging stations, intakes, reservoirs, diversions, flumes, and wells; existing trails; campgrounds and their

immediate surrounding landscaped area; scenic lookouts; remote helicopter landing sites; existing fences; telecommunications equipment towers and associated structures and equipment; electrical power transmission lines and distribution, and communication facilities and regularly maintained associated rights-of-way and access ways; radars, telemetry antennas; missile launch sites; arboreta and gardens; heiau (indigenous places of worship or shrines), and other archaeological sites; airports; other paved areas; and lawns and other rural residential landscaped areas do not contain one or more of the primary constituent elements described for each species and therefore are not included in the critical habitat designations.

The following management actions are important: Feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas deemed essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas deemed essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual: self-pollination (USFWS, 2009)

Lifespan

Adult: 4 - 8 years (USFWS, 2009)

Breeding Season

Adult: February - March, May - September (USFWS, 2009)

Reproduction Narrative

Adult: Herbarium vouchers at Bernice P. Bishop Museum (C. Imada, pers. comm. 2008), the herbarium database at the National Tropical Botanical Garden (2008a), and data from Hawaii Biodiversity and Mapping Program (2007) reveal that the species was observed in flower on Kauai from February to March and from May to September; fruiting was observed in all months except for April and November. TNC (2006) reports that plants appear quite capable of self-fertilization, and that plants are relatively short-lived, with outplants and nursery stock surviving for only three years in less-than-ideal habitat. However, the last wild plant on Oahu was at least six years old, and wild plants probably live for four to eight years. Outplantings start producing large amounts of fruit in about two years, but under nursery conditions with heavy fertilization can mature and produce fruit in five months (USFWS, 2009).

Habitat Type

Adult: Terrestrial (NatureServe, 2015); riparian (USFWS, 2003)

Habitat Vegetation or Surface Water Classification

Adult: Diverse lowland to montane mesic and wet forest (USFWS, 1995)

Dependencies on Specific Environmental Elements

Adult: Oahu: open sunny areas (USFWS, 2003)

Geographic or Habitat Restraints or Barriers

Adult: Oahu: 430 - 3,300 ft. elevation (USFWS, 2003); 2,500 - 4,000 ft. elevation (USFWS, 1995)

Habitat Narrative

Adult: Inhabits moist forest in gulches and on flats (NatureServe, 2015). *Solanum sandwicense* was found on Oahu on talus slopes and in streambeds in open, sunny areas at elevations between 131 and 1,006 m (430 and 3,300 ft.) (USFWS, 2003). This species is typically found in open, sunny areas at elevations between 760 and 1,220 meters (2,500 and 4,000 feet) in diverse lowland to montane mesic forests and occasionally in wet forests (USFWS, 1995).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: The genus is bird dispersed (NatureServe, 2015).

Population Information and Trends**Population Trends:**

Not available

Species Trends:

Number of individuals stable, number of populations declining (USFWS, 2009)

Resiliency:

Low (inferred from USFWS, 2009; see current range/distribution)

Redundancy:

Low (inferred from USFWS, 2009)

Number of Populations:

12 (USFWS, 2017)

Population Size:

24-36 wild (USFWS, 2017)

Population Narrative:

Currently, there are five wild populations on Kauai. There are 18 - 20 wild individuals and 446 outplanted individuals. When *S. sandwicense* was federally listed as endangered, only four of 12 known populations were still extant on both islands (one on Oahu and three on Kauai), totaling about 20 individuals (USFWS 1994) (USFWS, 2009). At the time of the last 5-year review in 2009 there were five populations totaling 18 to 20 individuals from Kahuamaa Flats, Honopu, Awaawapuhi, Nualolo, Kumuwela ridge, Kawaiiki, Waialae Valley, Mokuone stream on the island of Kauai. The last known individual at Palawai Gulch on Oahu died in the 1990s. Currently, there

are seven to 12 wild populations totaling 24 and 36 individuals on Kauai (NTBG 2010a-b, 2012a-d, 2014a-c, 2015a; PEPP 2010, 2011, 2012, 2013, 2014, 2015, 2016, 2017) (USFWS, 2017).

Threats and Stressors

Stressor: Ungulates (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Habitat degradation by feral pigs (*Sus scrofa*), goats (*Capra hircus*), mule deer (*Odocoileus hemionus*) (USFWS, 2009).

Stressor: Predation (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: On Kauai: predation from rats (*Rattus* spp.). On Oahu: predation on seedlings by various species of introduced invasive slugs (USFWS, 2009).

Stressor: Invasive plants (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: On Kauai: competition with introduced invasive plant species such as *Hedychium gardnerianum* (kalihi ginger), *Lonicera japonica* (Japanese honeysuckle), *Passiflora tarminiana* (banana poka), *Psidium cattleianum* (strawberry guava), *Kalanchoe pinnata* (air plant), *Erigeron karvinskianus* (daisy fleabane), *Grevillea robusta* (silk oak), *Myrica faya* (fire tree), *Mariscus meyenianus* (Meyen's flatsedge), *Lantana camara* (lantana), *Setaria parviflora* (perennial foxtail), and *Rubus argutus* (Florida prickly blackberry). On Oahu: competition with the introduced invasive plant species *Passiflora suberosa* (corky passionflower), *Clidemia hirta* (Koster's curse), *Toona ciliata* (Australian red cedar), *Lantana camara*, *Psidium* spp. (guavas), and *Schinus terebinthifolius* (Christmasberry) (USFWS, 2009).

Stressor: Fire (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Because Hawaiian plants were subjected to fire during their evolution only in areas of volcanic activity and from occasional lightning strikes, they are not adapted to recurring fire regimes and are unable to recover well following a fire. The most prominent threat is fires caused by people pursuing recreational activities, and prevailing winds spreading fires to inland areas. Fire could destroy seeds as well as plants, even on steep cliffs (Clarke and Cuddihy 1980, Corn et al. 1979, Cuddihy and Stone 1990) (USFWS, 1995).

Stressor: Human activity (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Collection, disturbance, development (USFWS, 2009).

Stressor: Small population size (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: The species continues to be vulnerable to extinction caused by randomly occurring natural events (e.g., landslides or hurricanes) or reduced reproductive vigor due to small population size and a limited number of populations (USFWS, 2009).

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Solanum sandwicense* is vulnerable to the impacts of climate change, with a vulnerability score of 0.563 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions are needed to conserve this taxon into the future (USFWS, 2017).

Recovery

Reclassification Criteria:

1. A total of five to seven populations should be documented on Kauai and at least one other island where they now occur or occurred historically (USFWS, 1995).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population for short-lived perennials (USFWS, 1995).
3. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered (USFWS, 1995).

Delisting Criteria:

1. A total of eight to ten populations should be documented on Kauai and at least one other island where they now occur or occurred historically (USFWS, 1995).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population for short-lived perennials (USFWS, 1995).
3. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered (USFWS, 1995).

Recovery Actions:

- Protect current populations, control threats and monitor (USFWS, 1995).
- Expand current populations (USFWS, 1995).
- Conduct research essential to conservation of the species (USFWS, 1995).
- Establish new populations as needed to reach recovery objectives (USFWS, 1995).
- Validate and revise recovery objectives (USFWS, 1995).
- Devise and implement a public education program (USFWS, 1995).
- In order to prevent this taxon from going extinct, propagation efforts and the maintenance of adequate genetic stock ex situ should be undertaken immediately, as well as the protection of remaining wild individuals from feral pigs and alien weed threats (USFWS, 1995).
- Management actions necessary to protect the remaining wild individual on Oahu include selective weeding of Christmas berry and *Passiflora suberosa*, as well as regular monitoring (J. Crummer, personal communication 1995) (USFWS, 1995).

Conservation Measures and Best Management Practices:

- Continue collection of fruit and plant material from wild individuals on Kauai and reintroduced individuals on Oahu for future reintroductions (USFWS, 2009).
- Construct enclosure fences to protect individuals from the negative impacts of feral ungulates on Kauai, and eradicate invasive introduced plant species within the enclosures on Kauai and Oahu (USFWS, 2009).
- Establish reintroduced populations within protected habitats (USFWS, 2009).
- Augment current natural populations (USFWS, 2009).
- Initiate planning and contribute to implementation of ecosystem-level management and restoration to benefit this species (USFWS, 2009).
- Survey geographical and historical range for a thorough current assessment of the species (USFWS, 2009).
- Assess genetic variability within extant populations (USFWS, 2009).
- Study *Solanum sandwicense* populations with regard to population size and structure, geographical distribution, flowering cycles, pollination vectors, seed dispersal agents, specific environmental requirements, limiting factors, and threats (USFWS, 2009).
- New Management Actions: • PEPP botanists collected seeds and cuttings for propagation at Lyon Arboretum, DOFAW, and NTBG (PEPP 2010, 2011, 2012, 2013, 2014, 2015, 2016). NTBG has seeds from 15 collections from Makaha (at least three founders), Puu o Kila (at least one founder), and Berry Flats (at least two founders). NTBG also has over a hundred plants in their nursery and dozens of plants throughout their gardens (NTBG 2017). Kokee Rare Plant Facility has 60 plants representing two founders from Kaunuohua and one founder from Berry Flats. Seven founders from Waialae are currently being established at the Lyon Arboretum Micropropagation Lab. There is one founder in the Lyon Arboretum seed bank from Mohihi, two founders from Berry Flats, one founder from Puu o Kila, three founders from Waialae, and one founder from Nualolo Trail (Lyon Arboretum 2017). • Waimea Arboretum has six plants from the Oahu *S. sandwicense* (2017). Pahole Rare Plant Facility on Oahu has four potted plants (PEPP 2016). There are thousands of seeds representing the Oahu founder via fruit collected from outplants (Lyon Arboretum 2017). • PEPP, NTBG, and The Nature Conservancy outplanted *Solanum sandwicense* into monitored enclosures at Limahuli (65 individuals), Lapa (35 individuals), Nualolo (30 individuals) and Kalalau (16 individuals) on Kauai (PEPP 2015, 2017). • PEPP on Oahu have been outplanting in three locations. Currently there are 29 outplants in Makaha, 97 outplants in Palikea, and 20 outplants in Pualii, all representing the last wild plant on Oahu (PEPP 2017). • PEPP on Kauai monitors wild populations of *Solanum sandwicense* at

Kumuwela, Berry Flats, Puu o Kila, Mohihi-Waialae Trail, Kawaiiki, Kaunuohua, and Makaha ridge (PEPP 2010, 2011, 2012, 2013, 2014, 2015). • In 2015, this species was not recorded from the Kaluaa and Waieli Management Units on Oahu where it had been previously recorded in 2010 (US Army Garrison 2016) (USFWS, 2017).

- Recommendations for Future Actions: No new threats and no other significant new information regarding the species' biological status have been reported since the last 5-year review in 2009. Therefore, the following recommendations for future actions are reiterated for the 5-year review for 2017. • Surveys and inventories—Survey geographical and historical range for a thorough assessment of the species. • Ungulate monitoring and control—Continue to construct enclosure fences to protect individuals from the negative impacts of feral ungulates. • Invasive plant monitoring and control— o Control established ecosystem-altering nonnative invasive plant species around all populations. o Control nonnative plant species in the immediate vicinity of *Solanum sandwicense* populations that compete with this species. • Captive propagation for genetic storage and reintroduction—Continue collection of seeds and cuttings, and propagation for reintroduction. • Reintroduction and translocation— o Continue to reintroduce individuals into suitable habitat within historical range that is being managed for known threats to this species. o Augment current natural populations. • Population biology research— o Study *Solanum sandwicense* populations to determine viable population size and structure, geographical distribution, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. o Assess genetic variability within extant populations (USFWS, 2017).

SPECIES ACCOUNT: *Solidago houghtonii* (Houghton's goldenrod)

Species Taxonomic and Listing Information

Listing Status: Threatened; 07/18/1988; Great Lakes-Big Rivers Region (R3) (USFWS, 2016)

Physical Description

A perennial herb. Stems are frequently tufted or clumped, up to 7.5 dm high. Leaves become linear upwards on the stems. The inflorescence is a terminal, more-or-less flat-topped cluster of relatively few, large flower heads, each consisting of about 6-9 pale to bright yellow ray flowers and several yellow disk flowers. The branches of the inflorescence are smooth, but the stalks of the flower heads are finely but distinctly hairy. Blooms in August. (NatureServe, 2015)

Taxonomy

FNA (vol. 20, 2006) transfers *Oligoneuron houghtonii* to *Solidago houghtonii*. The disagreements concerning the origin of *S. houghtonii* and, more importantly, the true identities of populations within the currently circumscribed range, argue strongly for considering the species in the broad sense now (USFWS, 1997; NatureServe, 2015)

Current Range

Solidago houghtonii is primarily an endemic of the Upper Great Lakes region, occurring principally on the northern shores of Lakes Michigan and Huron in Michigan and Ontario; peripheral range extends north to Canadian shores of Georgian Bay, also 1 disjunct site in New York. (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Dependency on Other Individuals or Species

Adult: Jolls' preliminary findings from the 1993 research indicate that *S. houghtonii* is self-incompatible and thus dependent on insect vectors for successful pollination. Potential pollen vectors include bees (Hymenoptera), butterflies (Lepidoptera), flies (Diptera), moths (Lepidoptera), and wasps (Hymenoptera). (USFWS, 1997)

Breeding Season

Adult: August to October (USFWS, 1997)

Reproduction Narrative

Adult: Flowering occurs primarily in August and early September but may occur as early as late July and not uncommonly well into October. Fruiting and seed dispersal appears to occur mostly from August through November and undoubtedly later (MNH 1993). Jolls' preliminary findings from the 1993 research indicate that *S. houghtonii* is self-incompatible and thus dependent on insect vectors for successful pollination. Potential pollen vectors include bees

(Hymenoptera), butterflies (Lepidoptera), flies (Diptera), moths (Lepidoptera), and wasps (Hymenoptera). (USFWS, 1997)

Habitat Type

Adult: Terrestrial and palustrine (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Bog/fen, herbaceous wetland, riparian, barrens, sand/dune (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Prefers cool, moist areas (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found in sparsely vegetated areas at elevations between 100 and 400 m (NatureServe, 2015)

Environmental Specificity

Adult: Narrow. Specialist or community with key requirements common. (NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: Medium (USFWS, 1997)

Habitat Narrative

Adult: *Solidago houghtonii* occurs primarily along the northern shores of Lakes Huron and Michigan and is restricted to calcareous beach sands, rocky and cobbly shores, beach flats, edges of marl ponds, and especially the shallow, trough-like interdunal wetlands that parallel shoreline areas (MNEI 1993). Much less commonly, *S. houghtonii* occurs in wet prairie-like habitats in Lower Michigan and locally in a New York marl fen. It also occurs on seasonally wet limestone pavement, which is the species' more typical habitat in the eastern portion of its range. *S. houghtonii* was collected from open limestone pavements in moist rock crevices (D.F. Brunton 3352, CAN). In sand dune areas, it tends to occur on the lee side of low foredunes and on low stabilized dunes adjacent to interdunal wetlands, especially in moist to saturated sands within and around interdunal depressions. The restriction of *S. houghtonii* to calcareous sands and dolomitic limestone areas of the Niagaran Escarpment suggests that the species requires a relatively high amount of calcium and magnesium (and possibly sodium and potassium) in its substrate. Dune sands in the region of the Niagaran Escarpment generally have a calcareous component of about 1 to 5 percent that is composed primarily of ground mollusk shells (Collins 1989). The sands in which it grows are circumneutral (pH 7.0) to alkaline (pH 8.0) and may occasionally have a thin covering of organic material (Collins 1989). *Solidago houghtonii* usually occurs where there is a relatively low density of competing vegetation at elevations between 100 and 400 meters. The species' apparent establishment in the better drained portions of dunes, such as along the backside of foredunes, may indicate it has some resistance to desiccation. Often associated with *Solidago ohioensis*, *Lobelia kalmii*, and other calciphiles; occasionally associated with two other rare species: Pitcher's thistle (*Cirsium pitcherii*) and dwarf lake iris (*Iris lacustris*). (USFWS, 1997; NatureServe, 2015)

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Not available.

Population Information and Trends**Population Trends:**

Long-term trends suggest declines of 30-70%, whereas short-term trends indicate a decline of <30% to relatively stable (NatureServe, 2015)

Resiliency:

Medium (inferred from USFWS, 1997)

Representation:

Low (inferred from USFWS, 1997)

Redundancy:

Medium (inferred from USFWS, 1997)

Population Growth Rate:

Slowly declining (NatureServe, 2015)

Number of Populations:

~90 (NatureServe, 2015)

Population Narrative:

Long-term population trends suggest declines of 30-70%, whereas short-term trends indicate a decline of <30% to relatively stable. There are approximately 90 occurrences known (Penskar et al. 1996). (NatureServe, 2015)

Threats and Stressors

Stressor: Narrow habitat range (USFWS, 1997)

Exposure:

Response:

Consequence:

Narrative: *Solidago houghtonii*, like several of its associated endemics, is particularly vulnerable to extirpation because of its restriction to narrow shoreline habitats of the Great Lakes. In a 1981 status survey, D.C. Nepstad considered habitat destruction to be the greatest threat to populations of *S. houghtonii* and cited the desirability of shoreline areas for residential housing and the escalating pressure for this type of development as a principal cause of this habitat destruction. The rate of residential development continues to accelerate, and it is highly unlikely that there will be any abatement of this trend in the near future. Nepstad (1981) also noted that some major occurrences of *S. houghtonii* have been considerably altered and fragmented by private development such that their long-term viability has been severely diminished. This has been a view supported by subsequent field surveys (MNFI 1993). There are many causes of habitat alterations that have adversely affected *S. houghtonii* populations. Construction of beach retaining walls and other emergency erosion control measures (e.g. rip-rap and bulkhead installation) prevents or inhibits dune formation. Excessive foot and off-road vehicle (ORV) traffic

destabilizes dune and beach flats. Marina construction, road construction, sand mining, and home and cottage construction where improved lake views are desired, have resulted in leveling of dune ridges (Collins 1989). Driveway installation or permitted work performed by utilities and railroads near interdunal wetlands have fragmented colonies and altered the hydrology. Residential development further potentially threatens habitat by altering hydrology with the placement and construction of septic systems whose nutrient loading degrade adjacent interdunal wetlands. Finally, both foot and ORV traffic have caused the direct destruction of plants. (USFWS, 1997)

Stressor: Modification of groundwater (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Disjunct populations, located in calcareous fens and dependent upon calcium rich groundwater flowing through them, face additional threats. Modifications or contamination of the groundwater could cause these sites to become unsuitable for Houghton's goldenrod and could lead to extirpation of this species. As such, this species could be also be threatened by off-site activities. (USFWS, 2011)

Stressor: Invasive species (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Invasive species control efforts are underway in three of the four Michigan State Parks with Houghton's goldenrod. New York has had limited success with control efforts at Bergen Swamp. Common reed grass (*Phragmites australis*) is the non-native invasive species most likely to affect Houghton's goldenrod at Bergen Swamp (Drake, pers. comm. 2010), although encroachment by false brome (*Brachypodium sylvaticum*) may pose a threat to Houghton's goldenrod also (Steve Young, NYNHP, pers. comm., 2010). Almost all occurrences are threatened by the increase in invasive plant species, such as baby's breath (*Gypsophila paniculata*), *Phragmites australis*, purple loosestrife (*Lythrum salicaria*) and false brome (*Brachypodium sylvaticum*). If not removed or controlled, these invasive species may threaten the Houghton's goldenrod habitat by outcompeting native species, shading the habitat or altering the hydrology. (USFWS, 2011)

Stressor: Climate change (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Climate change models predict the climate of the Great Lakes region will grow warmer and drier over the next century, with precipitation increasing in winter and decreasing in summer (AMEC 2006; Anton Reznicek, University of Michigan, pers. comm. 2004; Kling et al. 2003). Average temperatures in the Great Lakes region could increase by 3 to 7°C in winter and 3 to 11°C in summer by the year 2100. While average annual precipitation could increase by 10–20 percent, significant changes in the seasonal precipitation cycle are likely, with winter and spring rain increasing and summer rain decreasing by up to 50 percent (Kling et al. 2003). A warmer, drier summer will affect surface and groundwater levels, as well as soil moisture, which is projected to decrease by 30 percent in summer (Kling et al. 2003). Increased water temperatures

will also result in decreased ice cover that when combined with an expected intensity of winter storms, will leave coastal areas more vulnerable to the effects of winter storms and flooding (Fang and Stefan 2000; AMEC 2006), altering Houghton's goldenrod habitat. A warmer climate could also bring about a northward shift and an even greater increase in invasive species that may be more problematic in the dunes and lakeshore systems, thus increasing competition with native plant species (Malcolm et al. 2002; AMEC 2006; Penskar, pers. comm. 2009). (USFWS, 2011)

Stressor: Roads and highways (USFWS, 1997)

Exposure:

Response:

Consequence:

Narrative: Several *S. houghtonii* occurrences in Michigan are within or along rights-of-way administered by MDOT. Records in the MNFI show that there are at least 11 occurrences partially within or along MDOT rights-of-way, representing nearly 20 percent of the known occurrences in Michigan. Kim D. Herman (1988) notes that *S. houghtonii* is more vulnerable to disturbance than two other endemics of Great Lakes shorelines, dwarf lake iris and Pitcher's thistle, because of its restriction to narrow bands of interdunal wetland habitats, many of which occur between coastal roads and lakeshores. In some of these sites, highways may be severely fragmenting *S. houghtonii* populations or preventing them from expanding and colonizing suitable habitat available further inland. Herman (1988) further states that the MDOT activities which resulted in the most adverse effects to this species and other Great Lakes endemics are projects along two major State roadways, US-2 and US-23, located in the Upper Peninsula and Lower Peninsula, respectively. These activities included culvert extensions, pavement recycling, shoulder widening, and other types of safety work. (USFWS, 1997)

Stressor: Road maintenance (USFWS, 1997)

Exposure:

Response:

Consequence:

Narrative: A number of common road maintenance activities, including emergency repairs on eroding shoreline areas, herbicide application, mowing, road salting, shoulder grading, snow removal, and tree removal, have affected populations of *S. houghtonii* (Herman 1988). A number of illegal activities which have occurred on or near MDOT rights-of-way have also affected this species and its habitat. Illegal use of sites by commercial fishermen and encroachments by ORV operators and other recreationists have had adverse effects (MNFI 1993). (USFWS, 1997)

Stressor: Off-road vehicles (ORVs) (USFWS, 1997)

Exposure:

Response:

Consequence:

Narrative: Habitat damage resulting from ORV traffic is one of the major threats to *S. houghtonii*. The restriction of this species to a very limited, narrow expanse of shoreline habitat renders it particularly vulnerable to destruction and habitat fragmentation. Off-road-vehicles are in widespread use and are very difficult to exclude from most kinds of natural areas, particularly beaches and coastal dunes. Their use and resulting effects on these sites are well documented throughout Michigan (MNFI 1993). Off-road-vehicle traffic or evidence of it has been observed in areas of exemplary *S. houghtonii* occurrences, such as Crow River Mouth (Mackinac County),

Grass Bay (Cheboygan County), and Wilderness State Park (Emmet County) (MNFI 1993), and probably occurs in many and perhaps most other sites throughout the range of the species. (USFWS, 1997)

Stressor: Natural disturbances (USFWS, 1997)

Exposure:

Response:

Consequence:

Narrative: The restriction of *S. houghtonii* to low-lying, linear coastal zone habitats also causes it to be highly susceptible to natural disturbance. Rises in lake levels, such as the record highs attained in 1986, may severely reduce population numbers throughout the entire range of the species (Voss 1987). It is thus very important that destructive human activities are minimized or eliminated so as not to exacerbate the effects of natural disturbance (Voss 1987). (USFWS, 1997)

Stressor: Artificial stabilization of lake levels (USFWS, 1997)

Exposure:

Response:

Consequence:

Narrative: It is unlikely that the range of *S. houghtonii* will expand because of the accelerating habitat loss and fragmentation due to development, increasing human-caused habitat disturbance, and the restriction of nearly all individuals of the species to shores of the Great Lakes. Therefore, essential habitat must be protected. Any artificial stabilization of Great Lakes levels could markedly change the natural dynamics of shoreline habitats and be highly detrimental to *S. houghtonii*, as well as to many other sensitive species and significant natural communities. Stabilization of the Great Lakes at low water levels might initially benefit *S. houghtonii* by temporarily exposing maximum suitable habitat. However, unless lake levels are continually lowered, stabilized *S. houghtonii* habitat is likely to be altered and will become unsuitable through plant succession. As a relatively poor competitor restricted to dynamic shoreline areas, this species depends on the cyclical fluctuations of the Great Lakes. It suffers local extirpations during high water years, but later exploits and colonizes newly exposed habitat as it becomes available again. (USFWS, 1997)

Stressor: Over-collection (USFWS, 1997)

Exposure:

Response:

Consequence:

Narrative: Like many rare species, *S. houghtonii* can potentially be over-collected by individuals with legal collecting permits, such as those who desire specimens for herbaria in which this taxon is poorly represented. Despite the good intentions of removing live plants for propagation and exhibition in rare plant collections, such activities, if done excessively or without proper permits, also represent a threat to populations. Permits granted for the taking of this species should be issued only after careful consideration and consultation with appropriate, knowledgeable individuals. Permits should stipulate that collections may be made only when an occurrence (i.e., a "population") would not be significantly diminished or adversely affected by removal of individuals. (USFWS, 1997)

Recovery

Reclassification Criteria:

Reclassification criteria are not available.

Delisting Criteria:

1. Protect a minimum of 30 of the most viable occurrences of Houghton's goldenrod and preserve the species' essential habitat and the natural environmental processes that maintain it. (USFWS, 1997)

Recovery Actions:

- Protect all known occurrences, with priority given to the most viable occurrences and the species' essential habitat. (USFWS, 1997)
- Survey suitable habitat for additional occurrences and verify the status of historic occurrences. (USFWS, 1997)
- Educate and notify land managers and the public. (USFWS, 1997)
- Monitor occurrences for population demographics, viability, and threats. (USFWS, 1997)
- Conduct biosystematic research throughout the species' range. (USFWS, 1997)

Conservation Measures and Best Management Practices:

- Report survey results and habitat and population conditions to the Michigan Natural Features Inventory and the East Lansing Field Office and update element occurrence records. (USFWS, 2011)
- Plan and implement regular surveys and monitoring of occurrences, including better documentation of habitat conditions and populations trends. (USFWS, 2011)
- Reassess ranks of known occurrences. (USFWS, 2011)
- Provide education and outreach to stakeholders and the public. (USFWS, 2011)
- Monitor approach of non-native species and control as appropriate. (USFWS, 2011)

SPECIES ACCOUNT: *Solidago shortii* (Short's goldenrod)

Species Taxonomic and Listing Information

Listing Status: Endangered; 9/5/1985; Southeast Region (Region 4) (USFWS, 2016)

Physical Description

A perennial herb with one to several erect or ascending stems 0.5 to 1.3 m tall, arising from a creeping rhizome. Stems are terete in cross section, slightly ribbed, and minutely scabrid-puberulent at least above the middle. Leaves are alternate, crowded, 5-10 cm long and 0.6 to 1.5 cm wide. Individual leaves are firm, oblong-lanceolate to narrowly elliptic, remotely serrulate and glabrous on both sides. The leaves are largest near the middle of the stem and become progressively smaller towards the inflorescence. Lower leaves are reduced and usually absent during flowering time. The inflorescence is terminal and ranges from racemose to paniculate with divergent, secund branches. Heads are 10-14 flowered on puberulent stalks usually 5 mm or less in length. The involucre is 4-6 mm long and 3 mm wide with imbricate, coriaceous and glabrous phyllaries. Ray florets number from 4 to 8 and are 2.5-3.0 mm long. The corollas are elliptic-linear with bright yellow ligules about 2 mm long. The disc florets are also bright yellow with a short tube, funnel form throat and five linear spreading lobes about equaling the throat in length. The white papus is capillary and about 2 mm long. Achenes are cuneate-cylindric, about 2 mm long, and pale brown with appressed, silky pubescence (USFWS, 1988).

Taxonomy

In the Aster family (Asteraceae)(USFWS, 1988).

Historical Range

Historically known from Jefferson, Robertson, Nicholas, and Fleming Counties in Kentucky (USFWS, 1988).

Current Range

Known from Robertson, Nicholas, and Fleming Counties in Kentucky (the vicinity of Blue Licks, Kentucky) and along the Blue River in Harrison County, Indiana (USFWS, 2007).

Critical Habitat Designated

Yes;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Insect (USFWS, 1988)

Breeding Season

Adult: Flowers from mid-August to early November (USFWS, 1988).

Key Resources Needed for Breeding

Adult: Insects for pollination, probably bees (USFWS, 1988)

Reproduction Narrative

Adult: Flowers from mid-August to early November, and fruits mature several weeks after the flowers wither. Specific pollinators have not been documented; sweat bees have been observed visiting the flowers. Germination rates in the field are unknown (USFWS, 1988).

Habitat Type

Adult: Terrestrial (USFWS, 1988)

Habitat Vegetation or Surface Water Classification

Adult: A variety of dry, mostly open habitats, in full sun or partial shade (USFWS, 1988).

Dependencies on Specific Environmental Elements

Adult: Natural disturbance (USFWS, 1988)

Environmental Specificity

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

Habitat Narrative

Adult: Habitat is full sun or partial shade in a variety of dry, mostly open habitats. These include limestone cedar glades, open eroded areas, edges of dry, open oak-hickory woods, cedar thickets, pastures, old fields, power rights-of-way, and rock ledges along highway rights-of-way. This species does not appear to compete well and does best in areas with a low density of other plants. It will not grow in full shade (as in closed canopy woods). Soils are described as flaggy, silty clay texture with 20-30% rock fragments, and slightly acid to moderately alkaline, with slow permeability and rapid runoff (USFWS, 1988). In the long term, it appears that the species can survive only in early successional, short-term habitats (resulting from some disturbance), natural openings associated with animal movements or rock outcrops, or dynamic rocky shorelines along rivers (Indiana occurrence) (USFWS, 2007).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Although goldenrod fruits are normally wind dispersed, there is no evidence that this species is expanding its range by this method. It has been suggested that bison may be a dispersal vector (USFWS, 1988).

Population Information and Trends**Population Trends:**

Stable to declining (USFWS, 2007)

Species Trends:

Decline of 10-30% (NatureServe, 2015)

Resiliency:

Medium (inferred from USFWS, 2007)

Representation:

Medium (inferred from USFWS, 2007)

Redundancy:

Low (inferred from USFWS, 2007)

Number of Populations:

14 (USFWS, 2007)

Population Size:

1 - 1000 individuals (NatureServe, 2015)

Adaptability:

The plant is clonal and is capable of persisting after some disturbance. Survivorship curves are typical of other herbaceous perennials (Walck et al. 1999b). Does not produce a long-lived seed bank (Walck et al. 1999a) (NatureServe, 2015).

Population Narrative:

Based on the results of numerous surveys and investigations over the past 25 years, the current distribution of *S. shortii* is restricted to 13 occurrences within a 2-mile radius of Blue Licks Battlefield State Resort Park in Fleming, Nicholas, and Robertson counties, Kentucky and one occurrence along the Blue River in Harrison County, Indiana (Harrison-Crawford State Forest). Despite numerous, intensive searches of similar habitats, only two occurrences (one within Sho1i's Goldenrod SNP in Fleming County, Kentucky and the Indiana occurrence) have been discovered since completion of the recovery plan in 1988. At present, eight Kentucky occurrences (numbers 1, 2, 5, 7a, Sa, 11, 12a, and Short's Goldenrod SNP) and the Indiana occurrence appear to be stable, and some level of protection has been achieved for all but one of these occurrences (number 11). The remaining Kentucky occurrences have shown declines in the number of stems and surface area since 1989 (Smith et al. 2004; Buchele et al. 1989). The reason for these declines is unknown, but competition from exotics and land-clearing activities on private property appear to be the primary causes (USFWS, 2007).

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: The Kentucky occurrences are most threatened by competition from exotics such as crown vetch, tall fescue, and other species described above, habitat disturbance on private property, and highway and powerline maintenance activities. The Indiana occurrence is most threatened by competition from exotics. The potential raising of the Ohio River's pool level is a possible threat but is unlikely to occur (USFWS, 2007).

Stressor: Overutilization for commercial, recreational, scientific, or educational purposes (USFWS, 2007)

Exposure:

Response:**Consequence:**

Narrative: Recent park improvements in Blue Licks Battlefield State Resort Park are expected to increase the recreational use of the park and could lead to adverse impacts to *S. shortii* individuals if recreational activities (e.g., hiking) are not directed away from *S. shortii* occurrences. The species' small range and low number of individual plants makes it vulnerable to overcollecting for scientific purposes. Plants within Blue Licks Battlefield State Resort Park cannot be collected without a permit from the Kentucky Department of Parks and KSNPC; these permits are only issued for valid scientific purposes. Plants occurring on private property are not afforded this protection. The Indiana occurrence is also potentially threatened by recreational use (trampling by fishermen, canoeists, hikers). At present, though, recreational use does not appear to be a significant threat in Indiana. In addition, these plants occur on state property and cannot be collected without a permit (USFWS, 2007).

Stressor: Predation (USFWS, 2007)

Exposure:**Response:****Consequence:**

Narrative: Over-grazing by cattle on private property has the potential to adversely affect the species by eliminating flower production, but this effect has not been observed directly (USFWS, 2007).

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2007)

Exposure:**Response:****Consequence:**

Narrative: Occurrences at Blue Licks Battlefield State Resort Park are protected from unauthorized taking; permits administered by the Kentucky Department of Parks and KSNPC are only issued for valid scientific purposes. Portions of occurrences 7a and 12a are protected through an MOU between KSNPC and KYTC (KSNPC 1989) that restricts habitat disturbance within these road rights-of-way. The Indiana occurrence occurs on state property (Harrison-Crawford State Forest) and is also protected from unauthorized taking. No such protection is available for occurrences located on private property in Kentucky or Indiana (USFWS, 2007).

Stressor: Other natural and manmade factors affecting its continued existence (USFWS, 2007)

Exposure:**Response:****Consequence:**

Narrative: The species has been reduced to a small number of occurrences with a limited number of individuals. Consequently, the species is vulnerable to natural or human-induced factors (fire suppression) that might directly destroy individuals and further reduce population size (Federal Register 1985). Natural (secondary) succession can eliminate potential habitat for *S. shortii* through changes in vegetational composition. As old-field habitats and closed canopy woodlands develop, potential *S. shortii* habitat is lost (USFWS, 2007).

Recovery**Reclassification Criteria:**

1. Adequate protection is obtained for the nine high priority occurrences and the habitat they occur in (USFWS, 1988).
2. Protected occurrences are determined to be self-sustaining and maintaining current population levels or above (USFWS, 1988).
3. Species biology and ecological requirements are sufficiently understood to determine and implement long-term management strategies (USFWS, 1988).

Delisting Criteria:

1. Adequate protection is obtained for the nine high priority occurrences and the habitat they occur in (USFWS, 1988).
2. Protected occurrences are determined to be self-sustaining and maintaining current population levels or above (USFWS, 1988).
3. Species biology and ecological requirements are sufficiently understood to determine and implement long-term management strategies (USFWS, 1988).
4. At least nine additional protected occurrences, equal in size and significance to the high priority occurrences mentioned above, are discovered in the vicinity of the Blue Licks population or at a currently unknown location (USFWS, 1988).

Recovery Actions:

- Protect existing occurrences and essential habitat. Prioritize occurrences for protection. Contact landowners and negotiate highest or most appropriate level of protection possible (USFWS, 1988).
- Conduct systematic searches for additional occurrences and populations. Identify potential habitat. Conduct ground searches (USFWS, 1988).
- Conduct studies of life history and ecological requirements. Delineate existing occurrences and establish permanent study plots. Analyze physical habitat and characterize habitat factors. Study phenology, pollination, and seed dispersal. Perform ex situ germination study and long-term demographic study. Determine management practices and develop recommendations to maintain health, vigor, and survivability of species (USFWS, 1988).
- Develop management plan and implement recommended management practices if determined beneficial. Conduct controlled burns, if determined beneficial. Remove overstory and/or aggressive competing vegetation if determined beneficial. Implement controlled rotational grazing system, if determined beneficial. Monitor results of management practices and re-evaluate needs as data on management results are obtained (USFWS, 1988).
- Maintain viable seeds. Collect and deposit seeds into seed banks. Make seeds available to organizations or institutions for propagation (USFWS, 1988).
- Continue management and monitoring of naturally occurring and reintroduced occurrences in Kentucky and Indiana, with consideration of intensified management at selected sites (USFWS 2017).
- Consider expansion of reintroduction efforts, with careful consideration of seed origin and genetics (USFWS 2017).

- Investigate and compare the genetic diversity/structure of Kentucky and Indiana populations, including the reintroduced occurrences in Harrison County, Kentucky (USFWS 2017).
- Investigate potential impacts of the bacterial leaf spot observed on occurrences in the Blue Licks area of Kentucky (USFWS 2017).
- Explore the potential threat posed by the horticultural cultivar *S. shortii* 'Solar Cascade' (USFWS 2017).

Conservation Measures and Best Management Practices:

- Continue searches for new occurrences in the Blue Licks area, especially near known buffalo traces (USFWS, 2007).
- Conduct searches for new occurrences in riparian outcrop habitats of central Kentucky and southern Indiana or in upland areas of the region with suitable habitat (USFWS, 2007).
- Continue to investigate the life history and ecological requirements of the species (e.g., seedling establishment, seed and pollen dispersal distances) (USFWS, 2007).
- Continue to pursue permanent protection (through registry agreements, easements, or land purchases) of occurrences located on private property (USFWS, 2007).
- Expand the size of extant occurrences through habitat management and augmentation (USFWS, 2007).
- Establish viable occurrences in areas within the historical range that have suitable habitat, especially the Blue Licks Area of Fleming, Nicholas, and Robertson counties; develop criteria for establishing experimental populations in Kentucky (USFWS, 2007).
- Acquire potentially suitable but currently unoccupied habitat for the species where the species can be introduced and managed (USFWS, 2007).
- Continue implementation of management actions for permanently protected occurrences; develop a management strategy for the Indiana occurrence (USFWS, 2007).
- Revise the recovery plan (USFWS, 2007).

SPECIES ACCOUNT: *Solidago spithamea* (Blue Ridge goldenrod)

Species Taxonomic and Listing Information

Listing Status: Threatened; Southeast Region (R4) 03/28/1985

Physical Description

A perennial herb with solitary or tufted, erect, unbranched stems, usually 1-3 dm tall. A flat- or round-topped terminal cluster of yellow flower heads, each containing 20-30 flowers, blooms from July to September. This is 1 of only a few southern goldenrods with close affinities to plants now abundant in more northern areas. Populations are thought to be relict in nature, persisting on mountain-tops as the regional climate became warmer and drier. (NatureServe, 2015)

Taxonomy

Blue Ridge goldenrod is a member of a large and taxonomically complex genus which contains over 100 species native chiefly to North America, reaching its greatest complexity in the Eastern United States. The name of the genus comes from the Latin solidus and ago meaning solid and firm, referring to the healing qualities of the members of this genus (Britton and Brown 1970). The genus is within the large and complex family (Asteraceae) (USFWS, 1987).

Historical Range

Only three populations of Blue Ridge goldenrod are known to exist; two are in Avery County, North Carolina, on Grandfather Mountain and Hanging Rock, and one is on the border between Mitchell County, North Carolina, and Carter County, Tennessee, on Roan Mountain (USFWS, 1987).

Current Range

Endemic to three mountains, Grandfather Mountain and Hanging Rock Mountain in North Carolina, and Roan Mountain on the North Carolina-Tennessee border (Weakley 2008) (NatureServe, 2015).

Critical Habitat Designated

Yes;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: rhizomes and seeds? Pollinators unknown (USFWS, 1987)

Breeding Season

Adult: Flowering occurs from July to September (USFWS, 1987).

Reproduction Narrative

Adult: Flowering occurs from July to September. The fruit, which is present from July to October, is a cypsela (referred to by some as an achene or nutlet) 2.5 to 3 millimeters long (Kral 1979, Massey et al, 1980, Cronquist 1980). Various hymenopterns have been seen visiting the flowers,

but pollinators have not been identified. The plants appear to spread vegetatively by extending rhizomes and presumably reproduce by seed; however, the importance of each mode of reproduction to the species is unknown. Information on seed set, germination and survival of seedlings, flowering frequency, and response of populations to climatic extremes and various forms of disturbance are not available for this species (USFWS, 1987).

Habitat Type

Adult: Rocky outcrops, ledges, cliffs and balds (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Rocky places such as outcrops, ledges, cliffs, and balds at elevations above 1400 m (NatureServe, 2015).

Environmental Specificity

Adult: Narrow/specialist (NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: High (NatureServe, 2015)

Site Fidelity

Adult: High (NatureServe, 2015)

Habitat Narrative

Adult: Rocky places such as outcrops, ledges, cliffs, and balds at elevations above 1400 m. Sites occupied by the species are generally exposed to full sun. Common associates include grasses and sedges, as well as other rare, high-elevation species such as Heller's blazing star (*Liatris helleri*), Roan Mountain bluet (*Houstonia montana*) and spreading avens (*Geum radiatum*) (NCHP 2001) (NatureServe, 2015).

Dispersal/Migration**Motility/Mobility**

Adult: Low (inferred from USFWS, 1987)

Dispersal

Adult: Low/Slow (inferred from USFWS, 1987)

Population Information and Trends**Population Trends:**

Three historical populations were extirpated by extensive recreational and residential development (NatureServe, 2015).

Resiliency:

Low (inferred from NatureServe, 2015)

Representation:

Low (inferred from NatureServe, 2015)

Redundancy:

Low (inferred from NatureServe, 2015)

Number of Populations:

1 - 5 (NatureServe, 2015)

Population Size:

over 1,800 total 'clumps' (NatureServe, 2015)

Additional Population-level Information:

Stable. The known range of *Solidago spithamaea* (Hanging Rock, Roan Mountain, and Grandfather Mountain) has remained the same since the species was listed in 1985 (Service 1985). As stated in the 2012 5-year review, the Hanging Rock population may consist of fewer than 10 clumps, the Roan Mountain population consists of several hundred clumps, and the Grandfather Mountain population consists of several hundred to 1,000 clumps (Service 2012). It should be noted, at the time of the 2012 population estimate, the species had not been monitored since 2001 and determining consistency of monitoring methods among observers was not possible (Service 2012). A recent range-wide survey, conducted in 2016 and 2017, noted 24 clumps at Hanging Rock, 420 clumps at Roan Mountain, and 1,814 clumps at Grandfather Mountain (Thompson 2018b). Inconsistent and infrequent monitoring prior to 2016 increases uncertainties associated with the species' status and trends; however, current population estimates are consistent with estimates derived from 2001 monitoring which indicates stability from 2001 to 2016. (USFWS 2019)

Population Narrative:

Three historical populations were extirpated by extensive recreational and residential development. As of 2009 (USFWS), two populations contained no more than 300 and 1500 patches respectively, and no estimates were available for two populations (USFWS 2009). Estimating population size is difficult due to clonal growth (USFWS 2009). Five populations known in North Carolina. (NatureServe, 2015). Low resiliency, representation and redundancy are inferred based on specific habitat requirements and low population numbers for this species.

Threats and Stressors

Stressor: Recreational Use (USFWS, 2012)

Exposure:

Response:

Consequence: Degradation of habitat

Narrative: The principal source of habitat destruction affecting *S. spithamaea* is recreational use by people who venture out into the species' habitat in search of high-elevation views or adventurous rock climbing, boulder hopping, or other activities. Trampling compacts the plant's rhizome and can shear plants from the rocks in which they are anchored. In the process, fragile soils that have developed over geologic time frames can also be destroyed, making recolonization of these sites by *S. spithamaea* exceedingly difficult. Trampling has contributed to declines in at least one subpopulation of the species² and continues to threaten the long-term viability of several others (USFWS, 2012).

Stressor: Development (USFWS, 2012)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: A related concern stems from the construction of facilities intended to control or direct visitor use. These facilities must be sited and constructed appropriately in order to avoid impacts to *S. spithamea* (USFWS, 2012).

Stressor: Woody succession (USFWS, 2012)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: The listing rule identified woody succession as a threat to this species. As soils accumulate and other types of vegetation are able to populate areas where *S. spithamea* had been growing, the taller successional species may outcompete *S. spithamea*, which would negatively impact its ability to thrive (USFWS, 2012).

Stressor: Rock slides (USFWS, 2012)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Natural rock slides were also described as an additional threat to the species, but natural rock slides may also serve to open up additional areas of newly available habitat for an early-successional species like *S. spithamea*. Thus, as with many factors, the frequency and severity of these disturbance events needs to be better understood for a meaningful evaluation of their effects on the continued existence of this species (USFWS, 2012).

Stressor: Climate Change (USFWS, 2012)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Accelerated global climate change is likely to disrupt patterns of climate variability to which *S. spithamea* has become adapted; thus, it is likely to exacerbate the threats already mentioned. However, the current scale of most global models of climate change offers little insight into the changes that will likely occur on the high peaks of the Southern Appalachians (USFWS, 2012).

Recovery

Delisting Criteria:

Criterion 1: The three populations at Roan Mountain, Grandfather Mountain, and Hanging Rock are protected (USFWS, 2012).

Criterion 2: Any necessary management actions have been undertaken for these populations by landowners or cooperating agencies and it has been documented that this management is successfully ensuring the continued survival of these populations (USFWS, 2012).

Criterion 3: Through introduction and/or discovery of new populations, two additional self-sustaining populations exist within the species' historical range (it is believed that at least two additional populations are required to ensure that the species will not become extinct in the foreseeable future) (USFWS, 2012).

Criterion 4: All five populations and their habitat are protected from present and foreseeable human-related and natural threats that may interfere with the survival of any of the population (USFWS, 2012).

Recovery Actions:

- The population at Grandfather Mountain occurs on property that, until 2009, was owned by Grandfather Mountain, Inc., a private corporation with a long history of working with the USFWS and other conservation partners toward the conservation of the rare species and habitats found there. The first measures of formal protection occurred in 1979, when this landowner placed portions of its land on a voluntary Registry of Natural Heritage Areas maintained by the North Carolina Natural Heritage Program (NCNHP) (The Nature Conservancy 1996). The landowner signed a Cooperative Agreement with the USFWS and the North Carolina Department of Agriculture in 1983; in 1991, this owner granted the North Carolina Chapter of The Nature Conservancy a perpetual conservation easement on more than 1,000 acres of the property. In 2009, the State of North Carolina announced the purchase of 2,456 acres formerly owned by Grandfather Mountain, Inc., for inclusion in the North Carolina State Park system. Some portions of the *S. spithamaea* population were retained by Grandfather Mountain, Inc., which has converted to a nonprofit organization--the Grandfather Mountain Stewardship Foundation--and is devoted to education, outreach and environmental stewardship (Jesse Pope, Grandfather Mountain Stewardship Foundation, 2009, personal communication). The population at Roan Mountain occurs on land managed by the U.S. Forest Service (USFS), Pisgah and Cherokee National Forests. This population receives protection under provisions of the Endangered Species Act that require federal agencies to assist in recovery efforts for federally listed species and to consult with the USFWS before undertaking actions which may affect the continued existence of such species. The USFWS has a long history of working with the USFS toward the conservation of Roan Mountain and the rare species that occur there (including six federally listed plants and animals). The Grandfather Mountain and Roan Mountain populations are protected from overt forms of habitat destruction, such as land-use conversion and large-scale commercial or residential development. However, both areas are open to the public and managed (at least in part) for recreational uses, which is an acknowledged threat to *S. spithamaea*. Additional comments on this threat and efforts to manage it are provided below. The population at Hanging Rock is in private ownership and remains unprotected. (USFWS, 2012).
- Grandfather Mountain, Inc., has a long history of implementing appropriate management actions on behalf of the rare species that occur on its properties. The numerous rock cliffs and outcrops which support *S. spithamaea* and numerous other rare and endemic plant species have long been closed to climbing and rappelling. Another site was formally closed to the public (and specifically to hang gliding activities) in the early 1990s, due in large part to concerns over impacts to rare species (including *S. spithamaea*). However, portions of the Grandfather Mountain *S. spithamaea* population occur in areas that receive considerable visitation by the public for recreational purposes. Documentation that management actions are effectively controlling impacts to *S. spithamaea* is currently lacking. The USFS closed two

Roan Mountain sites containing this species (protecting five of the six *S. spithamea* subpopulations supported there) to the public in the early 1990s, primarily in response to concerns that public access was or could result in impacts to the rare species found there. The one Roan Mountain subpopulation that is not closed to the public is in Tennessee, is not visible from a trail, and does not appear to be impacted by recreational visitors (Gary Kauffman, USFS, 2012, personal communication). The population at Hanging Rock is not protected and is not receiving any form of management (USFWS, 2012).

- One additional population has been tentatively identified at The Peak in Ashe County, North Carolina. No other new populations have been discovered or introduced (USFWS, 2012).
- To date, there are three extant populations of the species and a fourth population awaits further confirmation. Threats related to trampling are being managed at the two largest populations of the species (Grandfather Mountain and Roan Mountain); however, some impacts continue to occur at both populations as a result of recreational visitors who disregard signs and established barricades. Vegetation succession and habitat desiccation (both of which may be exacerbated by accelerated global climate change) remain as threats to all populations (USFWS, 2012).
- *Solidago spithamea* co-occurs with other federally listed species. Impacts from monitoring could inadvertently occur if field staff conducting monitoring are unaware of other species present or how to identify them. Pre-monitoring, tailgate meetings should occur prior to each monitoring event when species co-occur. Field staff should be briefed on species present, how to identify them, and strategies for avoidance. (USFWS 2019)
- Work with Thompson to document the monitoring protocol and threats assessment used during the 2016 and 2017 field seasons. Share this information with land managers and property owners to ensure consistency during future monitoring events. (USFWS 2019)
- Work with Thompson, or find an appropriate partner, to continue range-wide monitoring and threats assessment according to the protocol used in 2016 and 2017 so that consistent data can be meaningfully compared. (USFWS 2019)

Conservation Measures and Best Management Practices:

- Confirm the taxonomic identity of the putative population of *S. spithamea* reported at The Peak, in Ashe County, North Carolina (Recovery Task 1.2) (USFWS, 2012).
- Develop a taxonomic key distinguishing co-occurring immature *S. glomerata* from *S. spithamea* (Recovery Task 1.2) (USFWS, 2012).
- Work with appropriate partners to evaluate protection alternatives at Hanging Rock, including the use of voluntary landowner agreements (Recovery Task 1.4) (USFWS, 2012)
- Develop interim research and management plans in conjunction with the USFS; North Carolina Division of Parks and Recreation; and Grandfather Mountain, Inc. (Recovery Task 1.1) (USFWS, 2012).
- Implement monitoring at a representative number of subpopulations across Grandfather Mountain and Roan Mountain (and The Peak, if confirmed) (Recovery Tasks 2, 2.1, 2.3, and 2.6) (USFWS, 2012).
- Compile quantitative data summarizing transplant survivorship across all previously attempted introduction or augmentation efforts involving this species, and evaluate causes for success/failure (Recovery Task 2.8) (USFWS, 2012).
- Evaluate long-term storage requirements for this species, and work with appropriate partners to place representative genetic material in long-term storage (Recovery Task 3) (USFWS, 2012).

- Collaborate with appropriate partners to begin stepping down global climate change models to a meaningful scale for purposes of projecting impacts to high-elevation Southern Appalachian rocky summit and cliff habitats, then devise and evaluate potential adaptation scenarios for *S. spithamea* (Recovery Tasks 1.3 and 1.4) (USFWS, 2012).

SPECIES ACCOUNT: *Spermolepis hawaiiensis* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Region (R1) (USFWS, 2016)

Physical Description

Spermolepis hawaiiensis, a member of the Apiaceae (parsley) family, is a slender annual herb with few branches. Its leaves are dissected into narrow, lance-shaped divisions. *Spermolepis hawaiiensis* is the only member of the genus native to Hawaii. It is distinguished from other members of the family by being a non-succulent annual with an umbrella-shaped inflorescence (68 FR 35950) (USFWS, 2016).

Historical Range

Historically, *Spermolepis hawaiiensis* was known from (Waimea) Kauai, (Koko Head) Oahu, (Paomai and Kahinahina) Lanai, and (Apua) Hawaii (USFWS, 2016).

Current Range

Currently, a total of 12 occurrences of *S. hawaiiensis* are known on Kauai, Oahu, Molokai, Lanai, West Maui, and Hawaii (USFWS, 2016)

Critical Habitat Designated

Yes; 6/17/2003.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Spermolepis hawaiiensis* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes eight detailed critical habitat units (CHUs), in Maui County in Hawaii (81 FR 17790-18110).

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Spermolepis hawaiiensis* under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Spermolepis hawaiiensis* (77 FR 57648-57862).

The critical habitat designation includes 15 critical habitat units, which encompass approximately 2,225 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Spermolepis hawaiiensis* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

On February 27, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Spermolepis hawaiiensis* on the island of Kauai, Hawaii (68 FR 9116 - 9479).

Critical Habitat Designation

The critical habitat designation for *Spermolepis hawaiiensis* includes eight CHUs in Maui County, Hawaii with detailed unit information. There are also an unknown number of units on Lanai that

contain this species (number of units is unknown because detailed unit descriptions for Lanai are not available) (81 FR 17790-18110).

Molokai—Lowland Mesic—Unit 1 (and) *Palmeria dolei*—Unit 37—Lowland Mesic (and) *Pseudonestor xanthophrys*—Unit 37— Lowland Mesic This area consists of 3,489 ac (1,412 ha) of State land, and 5,281 ac (2,137 ha) of privately owned land, from Waianui Gulch to Mapulehu, in central Molokai. These units are occupied by the plants *Alectryon macrococcus*, *Ctenitis squamigera*, *Cyanea dunbariae*, *C. mannii*, *C. profuga*, *Cyperus fauriei*, *Cyrtandra filipes*, *Gouania hillebrandii*, *Labordia triflora*, *Neraudia sericea*, *Santalum haleakalae* var. *lanaiense*, *Schiedea lydgatei*, *S. sarmentosa*, *Silene alexandri*, *S. lanceolata*, *Spermolepis hawaiiensis*, and *Zanthoxylum hawaiiense*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Lowland Mesic—Unit 1 is not known to be occupied by *Asplenium dielerectum*, *Bonamia menziesii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea procera*, *C. solanacea*, *Diplazium molokaiense*, *Festuca molokaiensis*, *Flueggea neowawraea*, *Isodendron pyriformis*, *Kadua laxiflora*, *Melicope mucronulata*, *M. munroi*, *M. reflexa*, *Phyllostegia haliakalae*, *P. mannii*, *P. pilosa*, *Sesbania tomentosa*, *Stenogyne bifida*, or *Vigna o-wahuensis*, or the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 1 consists of 11,465 ac (4,640 ha) of State land, 2,069 ac (837 ha) of federally owned land, and 3 ac (1 ha) of privately owned land, from Kanaio to Kahualau Gulch on the southern slopes of east Maui. This unit is occupied by the plants *Bonamia menziesii*, *Cenchrus agrimonoides*, *Flueggea neowawraea*, *Melicope adscendens*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 1 is not known to be occupied by *Alectryon macrococcus*, *Bidens micrantha* ssp. *kalealaha*, *Canavalia pubescens*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Hibiscus brackenridgei*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Sesbania tomentosa*, *Solanum incompletum*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 2 consists of 1,851 ac (749 ha) of State land at Keokea on the southern slopes of east Maui. This unit is occupied by the plants *Bonamia menziesii*, *Canavalia pubescens*, and *Hibiscus brackenridgei*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or

biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 2 is not known to be occupied by *Alectryon macrococcus*, *Bidens micrantha* ssp. *kalealaha*, *Cenchrus agrimonioides*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Flueggea neowawraea*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Solanum incompletum*, *Spermolepis hawaiiensis*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 3 consists of 188 ac (76 ha) of privately owned land, at Keauhou on the southern slopes of east Maui. This unit is occupied by the plant *Canavalia pubescens*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 3 is not known to be occupied by *Bidens micrantha* ssp. *kalealaha*, *Bonamia menziesii*, *Cenchrus agrimonioides*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Flueggea neowawraea*, *Hibiscus brackenridgei*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Solanum incompletum*, *Spermolepis hawaiiensis*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 4 consists of 1,266 ac (512 ha) of State land (including the Department of Land and Natural Resources) at Ahihi-Kinau Natural Area Reserve on the southern slopes of east Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). Although Maui—Lowland Dry—Unit 4 is not currently occupied by *Bidens micrantha* ssp. *kalealaha*, *Bonamia menziesii*, *Canavalia pubescens*, *Cenchrus agrimonioides*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Flueggea neowawraea*, *Hibiscus brackenridgei*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Solanum incompletum*, *Spermolepis hawaiiensis*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 5 consists of 3,615 ac (1,463 ha) of State land, and 43 ac (17 ha) of privately owned land, from Panaewa to Manawainui on the western and southern slopes of west

Maui. This unit is occupied by the plants *Asplenium dielerectum*, *Bidens campylotheca* ssp. *pentamera*, *Cenchrus agrimonioides*, *Gouania hillebrandii*, *Kadua coriacea*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and *Tetramolopium capillare*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 5 is not known to be occupied by *Ctenitis squamigera*, *Cyanea obtusa*, *Hesperomannia arbuscula*, *Hibiscus brackenridgei*, *Lysimachia lydgatei*, *Neraudia sericea*, *Schiedea salicaria*, *Sesbania tomentosa*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 6 consists of 3 ac (1 ha) of State land, and 237 ac (96 ha) of privately owned land, from Paleaahu Gulch to Puu Hona on the southern slopes of west Maui. This unit is occupied by the plants *Hibiscus brackenridgei* and *Schiedea salicaria*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 6 is not known to be occupied by *Asplenium dielerectum*, *Bidens campylotheca* ssp. *pentamera*, *Cenchrus agrimonioides*, *Ctenitis squamigera*, *Cyanea obtusa*, *Gouania hillebrandii*, *Hesperomannia arbuscula*, *Kadua coriacea*, *Lysimachia lydgatei*, *Neraudia sericea*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Spermolepis hawaiiensis*, *Tetramolopium capillare*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Montane Mesic—Unit 1 (and) *Palmeria dolei*—Unit 42—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 42— Montane Mesic This area consists of 257 ac (104 ha) of State land, and 559 ac (226 ha) of privately owned land from Kamiloloa to Makolelau in central Molokai. These units are occupied by the plants *Alectryon macrococcus*, *Bidens wiebkei*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Montane Mesic—Unit 1 is not known to be occupied by *Asplenium dielerectum*, *Cyanea dunbariae*, *C. mannii*, *C. procera*, *C. solanacea*, *Cyperus fauriei*, *Kadua laxiflora*, *Melicope mucronulata*, *Neraudia sericea*, *Plantago princeps*, or *Stenogyne bifida*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations

within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

The critical habitat designation for *Spermolepis hawaiiensis* includes 15 critical habitat units, covering two ecosystem types, which encompass approximately 2,225 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Dry—Units 1, 2, 7, 8, 9, 10, 11; Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8.

Oahu—Lowland Dry—Unit 1 [102 ac (41 ha)]; This area consists of 49 ac (20 ha) of State land and 53 ac (22 ha) of privately owned land in the Waianae Mountains, extending from Haili Gulch to Kawaipahai. Oahu—Lowland Dry—Unit 2 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland dry ecosystem in the Waianae Mountains, on Federal land within Kaena Point State Park. Oahu—Lowland Dry—Unit 7 [15 ac (6 ha)]. This area consists of 15 ac (6 ha) of State land in the lowland dry ecosystem, in Leahi (Diamond Head) Crater within Diamond Head State Monument. Oahu—Lowland Dry—Unit 8 [99 ac (40 ha)]. Oahu—This area consists of 96 ac (40 ha) of privately owned land and 3 ac (1 ha) of State land as part of the old railroad right-of-way in the lowland dry ecosystem, at the Kalaeloa Barber's Point Harbor area. Oahu—Lowland Dry—Unit 9 [37 ac (15 ha)]. This area consists of 17 ac (7 ha) of City and County land, 3 ac (1 ha) of privately owned land, 1 ac (0.5 ha) of State land, and 16 ac (6 ha) of Federal (Pearl Harbor NWR) land in the lowland dry ecosystem at Kalaeloa. Oahu—Lowland Dry—Unit 10 [43 ac (17 ha)]. This area consists of 43 ac (17 ha) of State land (DHHL) in the lowland dry ecosystem at Kalaeloa. Oahu—Lowland Dry—Unit 11 [166 ac (67 ha)]. This area consists of 166 ac (67 ha) of federal land (U.S. Navy) in the lowland dry ecosystem at Kalaeloa.

Oahu—Dry Cliff—Unit 1 [49 ac (20 ha)]. This area consists of 49 ac (20 ha) in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the rim of Makua Valley. Oahu—Dry Cliff—Unit 2 [412 ac (167 ha)]. This area consists of 320 ac (130 ha) of State land and 91 ac (37 ha) of City and County of Honolulu land in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the ridge from Keaau to Ohikilolo. Oahu—Dry Cliff—Unit 3 [450 ac (182 ha)]. This area consists of 349 ac (141 ha) of City and County of Honolulu land and 101 ac (41 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the eastern rim of Makaha Valley along Kamaileunu Ridge. Oahu—Dry Cliff—Unit 4 [24 ac (10 ha)]. This area consists of 24 ac (10 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along Kauaopuu ridge, which divides Waianae Kai and Lualualei valleys. Oahu—Dry Cliff—Unit 6 [149 ac (60 ha)]. This area consists of 149 ac (60 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Lualualei Valley from Puukanehoa to Puukaua. Oahu—Dry Cliff—Unit 7a [68 ac (27 ha)]. This area consists of 68 ac (27 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley to Pohakea. Oahu—Dry Cliff—Unit 7b [38 ac (16 ha)]. This area consists of 38 ac (16 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley at Palikea. Oahu—Dry Cliff—Unit 8 [259 ac (105 ha)]. This area consists of 259 ac (105 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Nanakuli Valley from Palehua to Puumanawanua, and partially within the Nanakuli Forest Reserve.

The critical habitat designation for *Spermolepis hawaiiensis* includes two units totaling 452 acres in Kauai County, Hawaii. The units are Kauai 11—*Spermolepis hawaiiensis*— a, Kauai 13—*Spermolepis hawaiiensis*— b.

Kauai 11—*Spermolepis hawaiiensis*—a: This unit is critical habitat for *Spermolepis hawaiiensis* and is 95 ha (237 ac) on State land (Puu Ka Pele Forest Reserve), containing portions of Kawaiiki Valley. This unit provides habitat for one population of 500 mature, reproducing individuals of the annual *Spermolepis hawaiiensis* and is currently occupied with two plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable. It provides habitat for the westernmost range of the species that is unique to Kauai. The habitat features contained in this unit that are essential for this species include, but are not limited to, *Metrosideros polymorpha* forests or *Dodonaea viscosa* lowland dry shrubland. This unit provides for one population within this multi-island species' historical range on Kauai that is some distance away from the other critical habitat for this species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophic event.

Kauai 13—*Spermolepis hawaiiensis*—b: This unit is critical habitat for *Spermolepis hawaiiensis* and is 87 ha (215 ac) on State land, containing portions of Waimea Canyon. This unit provides habitat for one population of 500 mature, reproducing individuals of the annual *Spermolepis hawaiiensis* and is currently occupied with three plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable. It provides habitat for the westernmost range of the species that is unique to Kauai. The habitat features contained in this unit that are essential for this species include, but are not limited to, *Metrosideros polymorpha* forests or *Dodonaea viscosa* lowland dry shrubland. This unit provides for one population within this multi-island species' historical range on Kauai that is some distance away from the other critical habitat for this species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophic event.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Spermolepis hawaiiensis* critical habitat consists of two components. Lowland dry (east Maui, west Maui and Lanai) and Lowland mesic (Lanai and Molokai) (81 FR 17790-18110):

Ecosystem: Lowland Dry. Elevation: <3,300 ft (<1,000 m). Annual precipitation: <50 in (<130 cm). Substrate: Weathered silty loams to stony clay, rocky ledges, littleweathered lava. Canopy: *Diospyros*, *Myoporum*, *Pleomele*, *Santalum*. Subcanopy: *Chamaesyce*, *Dodonaea*, *Leptecophylla*, *Osteomeles*, *Psydrax*, *Scaevola*, *Wikstroemia*. Understory: *Alyxia*, *Artemisia*, *Bidens*, *Chenopodium*, *Nephrolepis*, *Peperomia*, *Sicyos*.

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Molokai—Montane Mesic: The physical and biological features of critical habitat are: (A) Elevation: 3,300 to 6,500 ft (1,000 to 2,000 m). (B) Annual precipitation: 50 to 75 in (130 to 190 cm). (C) Substrate: Deep ash deposits, thin silty loams. (D) Canopy: *Acacia*, *Ilex*, *Metrosideros*, *Myrsine*, *Nestegis*, *Nothocestrum*, *Pisonia*, *Pittosporum*, *Psychotria*, *Sophora*, *Zanthoxylum*. (E) Subcanopy: *Alyxia*, *Charpentiera*, *Coprosma*, *Dodonaea*, *Kadua*, *Labordia*, *Leptecophylla*, *Phyllostegia*, *Vaccinium*. (F) Understory: *Ferns*, *Carex*, *Peperomia*.

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Spermolepis hawaiiensis* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Spermolepis hawaiiensis* occurs within the Lowland dry and Dry cliff ecosystems in the Waianae Mountain caldera complex and the Lowland dry ecosystem in the Koolau Mountain caldera complex:

Oahu—Lowland Dry—Units 1, 2, 7, 8, 9, 10, 11. (A) Elevation: <3,300 ft (<1,000 m). (B) Annual Precipitation: <50 in (<130 cm). (C) Substrate: Weathered silty loams to stony clay, rocky ledges, little weathered lava. (D) Canopy: *Diospyros*, *Myoporum*, *Pleomele*, *Santalum*, *Sapindes*. (E) Subcanopy: *Chamaesyce*, *Dodonaea*, *Leptecophylla*, *Osteomeles*, *Psychotria*, *Scaevola*, *Wikstroemia*. (F) Understory: *Alyxia*, *Artemisia*, *Bidens*, *Chenopodium*, *Nephrolepis*, *Peperomia*, *Plumbago*, *Sicyos*, *Sida*, *Waltheria*.

Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8. (A) Elevation: unrestricted. (B) Annual Precipitation: < 75 in (<190 cm). (C) Substrate: >65 degree slope, rocky talus. (D) Canopy: None. (E) Subcanopy: *Antidesma*, *Chamaesyce*, *Diospyros*, *Dodonaea*. (F) Understory: *Bidens*, *Eragrostis*, *Melanthera*, *Schiedea*.

Within these units, the currently known primary constituent elements of critical habitat include, but are not limited to, the habitat components provided by:

(i) *Metrosideros polymorpha* forests or *Dodonaea viscosa* lowland dry shrubland and containing one or more of the following associated plant species: *Bidens sandwicensis*, *Doryopteris* spp., *Eragrostis variabilis*, *Erythrina sandwicensis*, *Lipochaeta* spp., *Schiedea spargulifolia*, or *Sida fallax*; and

(ii) Elevations between 56 and 662 m (184 and 2,172 ft).

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for

125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–

66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Spermolepis hawaiiensis* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

The following management actions are important: Feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas deemed essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas deemed essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: Associated plant species include *Doryopteris* sp., *Gouania hillebrandii*, and *Sida fallax*.

This species is an annual, and numbers fluctuate greatly from year to year, depending on climatic conditions and other unknown factors. Little else is known about the life history of this taxon. Reproductive cycles, specific environmental requirements, and limiting factors are unknown (Makua Implementation Team 2003) (USFWS, 2016).

Habitat Type

Adult: Lowland dry shrubland, cultivated fields, and pastures (USFWS, 2016)

Habitat Narrative

Adult: *Spermolepis hawaiiensis* is known from various vegetation types, including *Metrosideros polymorpha* forests, *Dodonaea viscosa* lowland dry shrubland, cultivated fields, and pastures between about 300 and 600 m (1,000 and 2,000 ft) in elevation (USFWS, 2016).

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Unknown (USFWS, 2016)

Number of Populations:

12 (USFWS, 2016)

Population Size:

5,000 - 10,000 individuals (USFWS, 2016)

Population Narrative:

Currently, a total of 12 occurrences of *S. hawaiiensis* are known on Kauai, Oahu, Molokai, Lanai, West Maui, and Hawaii. The total number of individuals State-wide is estimated between 5,000 and 10,000 individuals. On Kauai, this species has been observed in the Koaie branch and other unspecified locations within Waimea Canyon, Hanapepe at Kapahili Gulch, and Hipalau on State and private land. The total number of plants on Kauai is a few thousand. On Oahu, this species is known from a total of fewer than 60 individuals at Diamond Head and Makua-Keaau ridge on State and Federal lands, respectively. On Molokai, about 600 plants were reported from Kamalo, on private land. On Lanai, two occurrences of *S. hawaiiensis* are known: east of Puu Manu with 50 to 100 individuals and Kaa Gulch with about 300 individuals, both on private lands. On West Maui, *S. hawaiiensis* is known from two occurrences in the Lihau section of the West Maui Natural Area Reserve with 60 to 100 individuals and several hundred to thousands of plants, respectively; and, above Lahainaluna School with about 100 individuals. On the island of Hawaii, three occurrences of about 500 individuals are found on the U.S. Army's Pohakuloa Training Area in Kipuka Alala, Puu Anahulu, and an unnamed kipuka within the 1859 lava flow (Makua Implementation Team 2003) (Table SB 38) (USFWS, 2016).

Threats and Stressors

Stressor: Feral ungulates (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Habitat degradation by feral goats, axis deer, and mouflon sheep is listed as a threat to this species (USFWS, 2016).

Stressor: Non-native plants (USFWS, 2016)

Exposure:**Response:****Consequence:** Loss of habitat**Narrative:** Competition with various non-native plants is listed as a threat to this species (USFWS, 2016).**Stressor:** Fire (USFWS, 2016)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:** Fire is listed as a threat to this species (USFWS, 2016).**Stressor:** Military activities (USFWS, 2016)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:** Military activities are listed as a threat to this species (USFWS, 2016).**Stressor:** Habitat destruction (USFWS, 2016)**Exposure:****Response:****Consequence:** Loss of habitat**Narrative:** Habitat destruction is listed as a threat to this species (USFWS, 2016).**Stressor:** Stochastic events (USFWS, 2016)**Exposure:****Response:****Consequence:** Loss of individuals**Narrative:** Direct destruction of individual plants by erosion, landslides, and rockslides are listed as threats to this species (Service 1999a; 68 FR 35950) (USFWS, 2016).***Recovery*****Delisting Criteria:**

Due to the limited knowledge of life history requirements for short-term and long-term survival, the recovery plan for this species specifies interim objectives to downlisting and delisting that involve stabilization of all existing populations (Service 1999a). However, *S. hawaiiensis* is not included as a target taxon for stabilization pursuant to the Makua Implementation Plan Addendum. The Army does not actively manage this species in the Makua action area (Service 2003a) (USFWS, 2016)

Conservation Measures and Best Management Practices:

- The recovery plan for this species identifies the following important conservation actions. Fenced exclosures should be constructed around all known occurrences to reduce impacts from feral ungulates. Control of non-native plant species within the exclosures is also needed. Collection, storage, and propagation of representative genetic stock are needed, as well as augmentation of existing occurrences and establishment of additional occurrences (Service 1999a) (USFWS, 2016).

- Ongoing Conservation Actions A State-wide strategic plan is being developed by the Hawaii and Pacific Plants Recovery Coordinating Committee that will address the long-term conservation of *Spermolepis hawaiiensis*. This plan will also include broader landscape actions that are needed for the recovery of this plant throughout its range. This species is being propagated at the Pohakuloa Training Area Rare Plant Facility. Currently, no other management actions are known for this species (Service 1999b; Service 2005b; Durand, pers. comm. 2004, Koob1996) (USFWS, 2016).
- New management actions:
 - ▣ Surveys / inventories
 - o In 2009, a new population containing several 100 individuals of *S. hawaiiensis* was found in Olowalu Valley on West Maui while surveying for *Tetramolopium capillare* (Plant Extinction Prevention Program [PEPP] 2009).
 - o In 2009, a new population of *S. hawaiiensis* (number of individuals not provided) was discovered on Molokai while surveying for *Pritchardia munroi* (PEPP 2010).
 - o During 2011 to 2012, approximately 18.25 square kilometers (300 acres) were surveyed at PTA (U.S. Army 2013). Surveys were completed within the following fence units: *Haplostachys haplostachya* (67 hectares [165 acres]), *Kadua coriacea* (393 hectares [969 acres]), Kipuka Alala North (431 hectares [1,066 acres]), Puu Nohona O Hae (79 hectares [195 acres]), Puu Papapa (28 hectares [68 acres]), and *Silene hawaiiensis* (18 hectares [44 acres]). During that survey, approximately 389 locations were recorded of *Spermolepis hawaiiensis* (U.S. Army 2013).
 - o The survey of the Infantry Platoon Battle Course alternative was completed in September 2012 and 332 locations of *S. hawaiiensis* were recorded (U.S. Army 2012).
 - o Approximately 173 locations of *S. hawaiiensis* were recorded within the installation wide survey area (U.S. Army 2014). Most of the locations were found within the Kipuka Alala Fence Units. Additionally, approximately 302 new locations were recorded within the impact area during surveys for the U.S. Army's proposed Infantry Platoon Battle Area (U.S. Army 2014). These new locations greatly increase the previously documented distribution for this species.
 - o In 2014, surveys conducted in previously un-surveyed areas and previously surveyed areas discovered approximately 160 locations of *S. hawaiiensis* (U.S. Army 2015).
 - ▣ Ungulate monitoring and control
 - o All known individuals of *S. hawaiiensis* at PTA are protected within the Kipuka Alala north and south fence units and the Puu Papapa fence unit (U.S. Army 2010, 2014). The Kipuka Alala north and south fence units are considered ungulate-free (U.S. Army 2014).
 - o The fences at Puu Waawaa Forest Reserve were monitored in 2013 (State of Hawaii Department of Land and Natural Resources [DLNR] 2014). Additional fencing was added to gates to prevent the ingress of ungulates into the fenced unit (DLNR 2014).
 - ▣ Invasive plant monitoring and control
 - o A management plan for control of *Passiflora tarminiana* (banana poka) in habitat occupied by *S. hawaiiensis* within the Kipuka Alala south fence unit was developed and implemented in 2008 at PTA (U.S. Army 2010). In 2010, transects were surveyed and all individuals of *P. tarminiana* located along transects were controlled.
 - o During 2013 to 2014 at the Puu Waawaa Forest Reserve, invasive plants removed around reintroduced plants included *Cenchrus setaceus* (fountain grass), *Lantana camara* (lantana), *Ricinus communis* (castor bean), and *Chenopodium murale* (nettleleaf goosefoot) (DLNR 2014). Small invasive tree seedlings were also removed, including *Grevillea robusta* (silver oak), *Schinus molle* (pepper tree), *Olea europaea* subsp. *europaea* (European olive), and *Jacaranda mimosifolia* (jacaranda) (DLNR 2014).
 - ▣ Captive propagation for genetic storage and reintroduction
 - o There are three individuals and one seed flat containing numerous individuals of *S. hawaiiensis* in the nursery at Hawaii Volcanoes National Park (2014).
 - o There are hundreds of seeds in storage and 23 plants growing at Maui Nui Botanical Gardens (2014).
 - o The Lyon Arboretum's Seed Conservation Laboratory (2014) has more than 3,500 seeds in storage.
 - o The Lyon Arboretum's Micropropagation Laboratory (2013) has approximately 56 propagules in storage.
 - o The National Tropical Botanical Garden (2014) has approximately 1,495 seeds in storage from Kauai and Maui.
 - o There are more than 5,000 seeds in storage at the Volcano Rare Plant Facility from founders at PTA (2014).
 - o During 2011 to 2012, 132 seeds were collected from a single founder located within the Infantry Platoon Battle Area at PTA

for genetic storage (U.S. Army 2013). o During 2012 to 2013, more than 29,000 seeds from 5 accessions representing 3 groups and 5 founders of *S. hawaiiensis* were collected and placed in long-term storage at PTA (U.S. Army 2014). There are now more than 559,000 seeds in storage from 69 accessions representing 3 groups and 42 founders in long-term storage at PTA (U.S. Army 2014). Field collections of genetic resources at PTA are usually small and infrequent due to the ephemeral nature of the species. The vast majority of seed in ex situ storage is from plant growing in the greenhouse (U.S. Army 2014). ¶ Captive propagation protocol development – Propagation trials were conducted at PTA to determine appropriate storage and propagation techniques for *S. hawaiiensis*. The trials indicated that seeds of *S. hawaiiensis* germinate readily at a rate of more than 50 percent (U.S. Army 2015). Seed longevity for *S. lanceolata* is unknown (U.S. Army 2015). ¶ Population viability monitoring and analysis o In 2010, a new monitoring methodology was implemented at PTA where previously known locations of *S. hawaiiensis* were sampled on a monthly basis to determine if there is a seasonal component that leads to this species germination or if there are specific moisture availability thresholds that elicit germination (U.S. Army 2010). If plants were found during the monthly sampling period a more intensive distributional survey would be conducted to determine the extent of the species' occurrence and to estimate abundance. Unfortunately, no plants were found in 2010 and the new monitoring methodology was not utilized. The lack of plants may have been due to prolonged drought conditions that have affected most species at PTA throughout 2010 (U.S. Army 2010). o At site 214 within the Kipuka Alala South fence unit, monitoring of the site in 2014 tallied a single reintroduced individual and approximately 10 naturally recruited immature individuals (U.S. Army 2015). o Near Saddle Road on State-owned lands, natural recruitment of approximately 25 mature individuals was observed in 2014 (U.S. Army 2015). o At Puu Waawaa Cone Unit on State-owned lands monitoring conducted in 2014 recorded natural recruitment of more than 500 mature individuals of *S. hawaiiensis* (U.S. Army 2015). o On County-owned lands in North Kona, natural recruitment was not observed at this site in 2014 (U.S. Army 2015). ¶ Reintroduction / translocation o In 2013, approximately 4,300 seeds were broadcasted at Puu Waawaa Cone Unit on State-owned lands (U.S. Army 2014). o During 2002 to 2012 at site 214 within the Kipuka Alala south fence unit, 20 individuals were reintroduced to the site (U.S. Army 2015). In 2014, a single individual of *S. hawaiiensis* was reintroduced at the site (U.S. Army 2015). o Near Saddle Road on State-owned lands, 4 individuals were reintroduced during 2002 to 2012, no individuals were added in 2014, and no plants remained in 2014 (U.S. Army 2015). o At Puu Waawaa Cone Unit on State-owned lands, three individuals were reintroduced during 2005 to 2012 (U.S. Army 2015). In 2014, no reintroduced individuals remained. o On County-owned lands in North Kona, eight individuals were reintroduced during 2008 to 2012 and no reintroduced individuals remained in 2014 (U.S. Army 2015). o During 2013 to 2014, 118 individuals of *S. hawaiiensis* were reintroduced at Puu Waawaa Forest Reserve (DLNR 2014). ¶ Listing and critical habitat designation o Sixteen units of critical habitat were designated in the lowland dry and dry cliff ecosystems on Oahu for *S. hawaiiensis* (USFWS 2012a). o Two units of critical habitat for *S. hawaiiensis* were proposed in the lowland mesic and montane mesic ecosystems on Molokai (USFWS 2012b). On Maui, critical habitat for *S. lanceolata* was proposed in six units in the lowland dry ecosystem. On Lanai, three units of critical habitat for *S. hawaiiensis* were proposed in the lowland dry and lowland mesic ecosystems. The final rule for critical habitat designations has not been published at the time of this review. ¶ Climate change adaptation strategy – Fortini et al. (2013) conducted a landscapebased assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *S. hawaiiensis* has a low vulnerability to the impacts of climate change (USFWS, 2015).

SPECIES ACCOUNT: *Sphaeralcea gierischii* (Gierisch mallow)

Species Taxonomic and Listing Information

Listing Status: Endangered; 09/12/2013; Southwest Region (Region 2) (USFWS, 2016)

Physical Description

A perennial herb with few to many stems from a woody caudex (short, thickened, woody stem, subterranean or at ground-level). Stems are 43-103 cm tall, sparingly leafy, often dark red-purple, and in tall, open clumps. The foliage is bright green and essentially hairless. The leaf blades are 1.2-4 cm long, 1-5 cm wide; usually longer than wide. The leaves are egg-shaped or somewhat heart-shaped, the base heart-shaped to even-ended, with 3-5 lobes. The flowering stem is open, usually with more than one flower per node. The calyx is 5-10 mm long, green, essentially hairless, and the orange petals are 15-25 mm long (Atwood and Welsh 2002 cited in Falk 2008). Blooms April - early June. (NatureServe, 2015)

Taxonomy

Sphaeralcea gierischii is a species described in 2002 from Utah and Arizona (Atwood and Welsh 2002. Novon 12: 159-166). This species is similar to *S. rusbyi* but has glabrous or glabrescent herbage with few or no stellate hairs. (NatureServe, 2015)

Current Range

Endemic to a small area straddling the Utah-Arizona state line, in northwestern Mohave County, Arizona (vicinity of Black Rock Gulch, Black Knolls, and Pigeon Canyon) and closely adjacent Washington County, Utah (Little Round Valley). (USFWS 2010).

Critical Habitat Designated

Yes; 8/13/2013.

Legal Description

On August 13, 2013, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Sphaeralcea gierischii* (Gierisch mallow) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes two critical habitat units (CHUs), in Arizona and Utah (78 FR 49165-49183).

Critical Habitat Designation

The critical habitat designation for *Sphaeralcea gierischii* includes two CHUs in Mohave County, Arizona, and Washington County, Utah. This species critical habitat encompasses approximately 12,822 acres (ac) (5,189 hectares (ha)) (78 FR 49165-49183).

Unit 1: Starvation Point: This unit consists of 1,339 ha (3,308.7492 ac) in Arizona and Utah, and occurs on land managed by Arizona BLM (220.31 ha; 544.40 ac) and Utah BLM (802.11 ha; 1,982.07 ac), SITLA in Utah (67.73 ha; 167.38 ac), and ASLD in Arizona (248.83 ha; 614.87 ac). This unit was occupied at the time of listing and contains the features essential to the conservation of the species. Unit 1 contains two Gierisch mallow populations, including the second largest population. Unit 1 is located west of I-15 as this highway crosses the State line of Arizona and Utah, and is bounded by the Virgin River to the west and I-15 to the south and east. The features essential to the conservation of the species may require special management considerations or

protection to control invasive plant species, to control habitat degradation due to the recreation and mining activities that disrupt the soil composition, and to maintain the identified associated vegetation and pollinators essential to the conservation of the species. The portion of habitat that occurs on ASLD occurs within the footprint of the Georgia-Pacific Mine, which could resume gypsum mining operations in the near future. Grazing, which can modify the primary constituent elements and may require special management, typically occurs outside of the growing season for Gierisch mallow in the one pasture on Utah BLM and SITLA lands within this unit; however, recent wildfires in adjacent pastures in this allotment have resulted in livestock grazing occurring into the spring growing season for Gierisch mallow. These recently burned pastures have since been rehabilitated, and livestock grazing is anticipated to return to its normal grazing rotation of November 1 to February 28 in the future (Douglas 2012, p. 1).

Unit 2: Black Knolls This unit consists of approximately 3,850 ha (9,513 ac) in Arizona, and occurs on land managed by both Arizona BLM (3,586.28 ha; 8,861.90 ac) and ASLD (263.62 ha; 651.41 acres). This unit is occupied at the time of listing and contains the features essential to the conservation of the species. Unit 2 contains the remaining 16 Gierisch mallow populations, including the largest population. Unit 2 is located south of I-15 as this highway crosses the State line of Arizona and Utah, and is bounded by Black Rock Gulch to the west and Mokaac Mountain to the south and east. The features essential to the conservation of the species may require special management considerations or protection to control invasive plant species, to control habitat degradation due to mining activities that disrupt the soil composition, and to maintain the identified associated vegetation and pollinators essential to the conservation of the species. The largest population of Gierisch mallow occurs in the area of the proposed expansion of the Black Rock Gypsum Mine. As described in the final listing rule published elsewhere in today's Federal Register, grazing on BLM lands in Arizona typically occurs during the growing season for Gierisch mallow on all three BLM allotments within this critical habitat designation and is expected to modify the primary constituent elements, although some of the pastures are in a rest/rotation system in which a pasture may see an entire year of rest before being grazed again.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Sphaeralcea gierischii* critical habitat consists of five components (78 FR 49165-49183):

- (i) Appropriate geological layers or gypsiferous soils, in the Harrisburg Member of the Kaibab Formation, that support individual Gierisch mallow plants or their habitat, within the elevation range of 775 to 1,148 meters (2,477 to 3,766 feet). Appropriate soils are defined as: (A) Badland, (B) Fluvaquents and Torrifluvents, (C) Riverwash, (D) Cave-Harrisburg-Grapevine complex, (E) Grapevine-Hobcan complex, (F) Nikey-Ruesh complex, (G) Gypill-Hobog complex, (H) Hobog-Tidwell complex, (I) Hobog-Grapevine complex, (J) Grapevine-Shelly complex, and (K) Hindu-Rock outcrop-Gypill complex.
- (ii) Appropriate Mojave desert scrub plant community and associated native species for the soil types at the sites listed in paragraph (2)(i) of this entry.
- (iii) Biological soil crusts within the soil types listed in paragraph (2)(i) of this entry.

(iv) The presence of insect visitors or pollinators, such as the globemallow bee and other solitary bees. To ensure the proper suite of pollinators are present, this includes habitat that provides nesting substrate for pollinators in the areas described in paragraph (2)(ii) of this entry.

(v) Areas free of disturbance and areas with low densities or absence of nonnative, invasive plants, such as red brome and cheatgrass.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographic area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. The features essential to the conservation of this species may require special management considerations or protection to reduce the direct and indirect effects associated with the following threats: Habitat loss and degradation from mining operations; livestock grazing; recreation activities; and invasive plant species. Please refer to the final listing rule published elsewhere in today's Federal Register for a complete description of these threats. Special management to protect the features essential to the conservation of the species from the effects of gypsum mining include creating managed plant preserves and open spaces, limiting disturbances to and within suitable habitats, and evaluating the need for (and conducting restoration or revegetation of) native plants in open spaces or plant preserves containing similar gypsum soils. Management activities that could ameliorate these threats include (but are not limited to) seed collection from the Gierisch mallow throughout its range, including those plants within the footprint of each mine. These seeds could be used to begin propagation studies to determine the long-term viability of plants growing in reclaimed soils. Additionally, these seeds could be used to begin propagating plants to be planted in other gypsum deposits and to augment existing populations. In addition to collecting seeds directly from plants, the seed bank could be collected from the top 1 inch of soil before the surface disturbance occurs as long as soils are properly handled during seed bank collection (Scoles-Sciulla and DeFalco 2009, entire). Special management may be necessary to protect features essential to the conservation of the Gierisch mallow from livestock grazing, including fencing populations; avoiding activities, such as water trough placement, that might concentrate livestock near or in occupied habitat; and removing livestock from critical habitat during the species' growing and reproductive seasons, especially during periods of flowering and fruiting. Special management that may be necessary to protect the features essential to the conservation of the Gierisch mallow from recreational activities includes directing recreational use away from and outside of critical habitat, fencing small populations, removing or limiting access routes, ensuring land use practices do not disturb the hydrologic regime, and avoiding activities that might concentrate water flows or sediments into critical habitat. Additionally, threats related to both control of nonnative, invasive species and fire suppression and fire-related activities resulting from the spread of nonnative, invasive species include: • Crushing and trampling of plants from fire suppression and treatment activities; • Damage to seedbank as a result of fire severity; • Soil erosion; and • An increase of invasive plant species that may compete with native plant species as a result of wildfires removing non-fire-adapted native plant species or as a result of fire suppression equipment introducing invasive plant species.

Life History

Food/Nutrient Resources

Breeding Season

Adult: April to early June (NatureServe, 2015)

Reproduction Narrative

Adult: Flowers bloom between April and early June. The Service does not know how the flowers are pollinated, the pollination system (self-pollinated or obligate out crosser), seed dispersal mechanisms, or the conditions under which seeds germinate. (NatureServe, 2015)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Desert (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Occurs at elevations between 700 to 1,300 m (NatureServe, 2015)

Environmental Specificity

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

Habitat Narrative

Adult: Found mainly on gypsiferous outcrops of the Harrisburg Member of the Kaibab Formation (considered to be essentially an obligate gypsophile); also collected on the Moenkopi Formation and on limestone rock/soil. Tends to occur on low terraces with clay to gravelly soil, on north-facing slopes of 5-30% at elevations between 700 and 1,300 m. Plant community is warm desert shrub (Mohave desertscrub), with dominants including creosote bush (*Larrea tridentata*), blackbrush (*Coleogyne ramosissima*), saltbush (*Atriplex* sp.), *Yucca* sp., *Ambrosia* sp., and *Ephedra* sp. Other associated genera and species include: *Chrysothamnus*, *Dalea* (prairie-clover), *Hilaria jamesii* (James' galleta), *Hymenoclea salsola* (burrow-brush), *Lycium andersonii* (desert-thorn), *Opuntia*, *Petalonyx* (sandpaper-plant), *Psoralea* (indigo bush), *Purshia* (cliffrose), and gypsiferous biological soil crust species. (NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Long-term trends are unknown but short-term trends indicate a decline of 10-30% (NatureServe, 2015)

Resiliency:

Low (inferred from NatureServe, 2015)

Representation:

Low (inferred from NatureServe, 2015)

Redundancy:

Low (inferred from NatureServe, 2015)

Population Growth Rate:

Unknown (NatureServe, 2015)

Number of Populations:

5 (NatureServe, 2015)

Population Size:

16,000 to 26,000 (NatureServe, 2015)

Population Narrative:

Long-term population trends are unknown but short-term trends indicate a decline of 10-30%. A plant of limited range and distribution, including being found in a specific soil composition (gypsum outcrops), it is highly susceptible to habitat destruction and modification. Surveys by Hughes (2012a in USFWS 2013) estimate total population size to be between 11,000 and 18,000 individuals in Arizona. Hughes (2008a, p. 12; Highes 2009, p. 15; in USFWS 2013) conducted more extensive surveys of gypsiferous soils in Utah and estimated the population to be between 5,000 and 8,000 individuals. There are 4 occurrences in a small area of northwest Mohave County, Arizona, while 1 occurrence occurs across the border in Utah. All occurrences are restricted to less than approximately 186 ha (460 ac). Since surveys began, no new populations have been found outside of known areas. (USFWS, 2013). (NatureServe, 2015)

Threats and Stressors

Stressor: Climate change and drought (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Because of the threats of mining, grazing during drought years, recreation, and nonnative species, the cumulative effects of climate change and drought may be of concern for this species in the future. At this time, the state of knowledge concerning the localized effects of climate change and drought is too speculative to determine whether climate change and drought are a threat to these species in the future (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation (herbivory, along with some related trampling) by livestock is a threat that has moderate impacts only during drought years or during the reproductive period. Livestock herbivory during the reproductive period can lead to the flowering stalks being eaten, thus preventing adult Gierisch mallow plants from reproducing (USFWS, 2013).

Stressor: Habitat destruction and modification (USFWS, 2013)

Exposure:**Response:****Consequence:**

Narrative: Factors adversely affecting habitat of Gierisch mallow, which are anticipated to result in a significant decrease in both the range of the species and the size of the population of the species, include mining activities, livestock grazing, nonnative plant species, and fire. All of the populations and most of the habitat are located on BLM and ASLD lands, which have an extensive history of, and recent successful exploration activities for, gypsum mining. Although livestock do not typically eat Gierisch mallow, livestock grazing can affect Gierisch mallow habitat more significantly during drought years, as livestock move into the Gierisch mallow habitat searching for forage. Additionally, livestock have been implicated in spreading nonnative, invasive species, such as red brome and cheatgrass, although the extent to which livestock contribute to the spread of these two nonnative grasses is not known. Red brome and cheatgrass are documented to occur in all 18 populations of the Gierisch mallow, although mostly after wet years. The threat of fire caused by annual invasions of nonnative species is exacerbated by mining activities, livestock grazing, and recreation activities (USFWS, 2013).

Stressor: Small populations (USFWS, 2013)

Exposure:**Response:****Consequence:**

Narrative: Small population size and restricted range intrinsic vulnerabilities to the Gierisch mallow that may not rise to the level of a threat on their own. However, the small population sizes and restricted range of this species increase the risk of extinction to the Gierisch mallow populations in conjunction with the effects of global climate change and the potential for stochastic extinction events such as mining and invasive species. Therefore, the small, localized population size are considered to exacerbate the threats of mining, invasive species, and climate change to the species (USFWS, 2013).

Recovery**Reclassification Criteria:**

Reclassification criteria are not available.

Delisting Criteria:

Delisting criteria are not available.

Recovery Actions:

- Recovery actions are not available.

Conservation Measures and Best Management Practices:

- Conservation measures are not available.

SPECIES ACCOUNT: *Spigelia gentianoides* (Gentian pinkroot)

Species Taxonomic and Listing Information

Listing Status: Endangered; 12/26/1990; Southeast Region (R4)

Physical Description

This small perennial herbaceous species possesses a single, erect, sharply ridged stem 10-30 centimeters (cm) (3.9-11.8 inches (in.)) long. The leaves are opposite, sessile, and in pairs at right angles to the next set of leaves. The leaves are largest at the top of the stem, 3-5 cm long, with lower leaves smaller. Flowers are borne in a short, few-flowered, terminal, determinate cyme. The flower consists of a narrow corolla tube of about 2.5-5 cm long, with five triangular lobes, each 5-6 mm long. The corolla is pale to dark pink; slightly darker at the margins of the lobes for the var. *gentianoides*. The stamens are within the flower, and the pollen grains are deposited along the bristles of the style (secondary pollen presentation). At anthesis, the corolla lobes of var. *gentianoides* are partially open, occasionally fully reflexed; whereas the corolla lobes of var. *alabamensis* are always fully reflexed. The green sepals are 4-6 cm long. The fruit is a capsule with two conspicuous round lobes. Peak flowering season occurs between May and June, however, plants have been seen flowering as early as April and as late as October. In a greenhouse, individual flowers last 2 to 5 days before wilting. Most seeds can be collected in June or July. (USFWS, 2012)

Taxonomy

At the time the Recovery Plan was issued, the species was comprised of two varieties located in Jackson and Calhoun counties (Florida), and Geneva and Bibb counties (Alabama). Morphological and molecular studies reassessed the appropriate ranks of these varieties and elevated variety *alabamensis* to species (USFWS 2018, Weakley et al. 2011). Consequently, *Spigelia gentianoides alabamensis* is now a different species. (USFWS, 2019) *Spigelia gentianoides* var. *gentianoides* was first collected in north Florida by Alvan Wentworth Chapman in 1837, probably from the west side of the Apalachicola River, in either Jackson or Calhoun counties. He identified the plant as *S. floridana*, later Alphonse de Candolle (1845) established the current epithet, *S. gentianoides*. *S. gentianoides alabamensis* was first found in 1992 by James R. Allison (Georgia Natural Heritage Program, Georgia Department of Natural Resources) with Timothy Stevens, Jim Rodgers, and Debbie Rodgers while exploring the Little Cahaba River in Bibb County, Alabama. (USFWS, 2012)

Historical Range

Var. *gentianoides*: Washington, Calhoun, and Jackson counties in Florida, and Geneva County in Alabama. Var. *alabamensis*: Bibb County, Alabama. (USFWS, 2012)

Current Range

Spigelia gentianoides var. *gentianoides* is present in Washington, Calhoun, and Jackson counties in Florida, and Geneva County in Alabama. *Spigelia gentianoides* var. *alabamensis* is present in Bibb County, Alabama. (USFWS, 2019)

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Abiotic, Biotic, Self-pollination

Breeding Season

Adult: Peak flowering season occurs between May and June; However, plants have been seen flowering as early as April and as late as October. (USFWS, 2018)

Other Reproductive Information

Adult: *Spigelia gentianoides* can be propagated vegetatively and from seeds. Affolter (2005) successfully propagated *S. alabamensis*: by transplanting entire plants from the field to well drained potting mix; from stem cuttings, and by germinating seeds using cold stratification (2°C) or gibberellic acid (500-1000 ppm) treatments. Eight weeks of cold stratification provided excellent germination rates. (USFWS, 2018)

Reproduction Narrative

Adult: Secondary pollen presentation, a mechanism presenting the pollen on a structure other than the anther, appears to be present in *S. gentianoides* (Negrón-Ortiz, 2007, pers. observ.) and *S. alabamensis*; pollen was observed in the short bristles of the style. At the Geneva SF population, small Halictidae bees (sweat bees) were observed entering and exiting the flower of the *S. gentianoides*. (USFWS, 2018)

Habitat Type

Adult: Terrestrial (USFWS, 2012)

Habitat Vegetation or Surface Water Classification

Adult: well drained upland pinelands (var. *gentianoides*); glades (var. *alabamensis*) (USFWS, 2012)

Dependencies on Specific Environmental Elements

Adult: Fire-dependent ecosystems (USFWS, 2012)

Spatial Arrangements of the Population

Adult: Solitary individual or in small clumps (USFWS, 2012)

Habitat Narrative

Adult: *Spigelia alabamensis* is found in glades (open, almost treeless areas within woodland) that have developed over an ancient rock formation known as Ketona Dolomite. The Ketona formation contains a pure form of dolomite, crystalline in texture with only about 2% of siliceous impurities (Garland 2008). The glades vary in size from about 0.1 to 5 hectares with soil high in magnesium and calcium, low in phosphorus and potassium, and a pH ranging from 7.4 to 7.6 (Grossman et al. 1994). The topography varies from flat to sometimes very strongly sloping. There are patches of exposed rock and thin-soiled areas dominated by grasses and other herbaceous vegetation. The plants in these glades are exposed to extreme heat and drought. At

these sites, plants are quite abundant, and mainly found in small clumps adjacent to rocks.
(USFWS, 2018)

Dispersal/Migration

Dispersal/Migration Narrative

Adult: The mechanism of seed dispersal is unknown, but the fruit does not appear to be adapted for long-distance dispersal (USFWS, 2009).

Population Information and Trends

Population Trends:

Unknown (USFWS, 2018)

Number of Populations:

Var. gentianoides: 7; var. alabamensis: 17 (USFWS, 2018)

Population Size:

Var. gentianoides: ~3,900 individuals; var. alabamensis: unknown ("seems to be abundant")
(USFWS, 2018)

Additional Population-level Information:

Very narrow distribution, low population density. (USFWS, 2018)

Population Narrative:

Spigelia gentianoides var. *gentianoides* is currently restricted to seven extant sites within four counties west of the Apalachicola River: Calhoun, Jackson, and Washington counties in Florida, and Geneva County in Alabama. These sites support about 3,900 plants. The species was originally recorded from nine sites but two sites are considered extirpated. Of the seven extant sites, two new were noted in 2013. *Spigelia alabamensis* (*S. gentianoides* var. *alabamensis*, sensu Gould 1996) is restricted to the Ketona Dolomite formation and glades of Bibb County, AL. This species seems to be abundant but the current number of individuals at these glades is unknown; therefore, population trends are also unknown for *S. alabamensis*. Some of the 17 glades where this species is found are owned and protected by TNC. (USFWS, 2018)

Threats and Stressors

Stressor: Habitat loss or modification (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Conversion of much of the upland forest land in the four counties to pulpwood plantations (clearcutting, mechanical site preparation, and pine plantations) has possibly extirpated other populations. Clearcutting and/or selective thinning are of concern since typical silviculture operations often result in soil disturbance and compaction. In particular, site preparation practices resulting in soil disturbance, change in canopy cover from tree harvest, and change in fire frequency and seasonality are of concern. Land conversion coupled with disruption of pre-historical and historical fire regimes of the longleaf pine-wiregrass ecosystem is

responsible for the rapid decline of the ecosystem where *S. gentianoides* is found. Several studies have shown that frequent prescribed fire regimes are important for maintenance of longleaf pine-wiregrass ecosystem (Hiers et al. 2007). Prescribed burnings at 3 – 5 year intervals seem to maintain optimal *S. gentianoides* populations. However, areas at Apalachee WMA are on a 2-year fire rotation where the largest population of *S. gentianoides* appears to be stable (A. Jenkins, FNAI, 8/15/2018, pers. comm.). However, it is unknown 1) if frequent fires is detrimental to recruitment, and 2) the implications of fire seasonality to *S. gentianoides* survival. Habitats converted to pine plantation, and managed without fire have created a shaded canopy. In addition, pine plantation management induces severe soil disturbance. According to Kral (1983), *S. gentianoides* would not survive the mechanical site preparation used in pine monoculture. This observation seems accurate due to the fragile nature of these plants, but the population located at the Spigelia Preserve seems to have survived, at least over the short term, after cutting and planting. Nevertheless, the population exhibited a decline immediately after the last timber harvest. Similarly, the population in Jackson Co. on land owned by Guy Anglin emerged in a former pine plantation. Urban development also threaten *S. gentianoides*. Conversion of much of forest land to residential development has possibly extirpated many populations. More than a third of Florida's land is projected to be developed by 2070 along with a growth of about 33.7 million residents—almost 15 million more people than in 2010 (University of Florida GeoPlan Center 2017). *Spigelia alabamensis* is restricted to one county in northern Alabama. It is found in 17 glades, and TNC owns and protects about a dozen larger glades and some smaller glades. Populations on private property are threatened by future development for home-sites, agriculture, logging of associated hardwoods, recreational facilities, or other purposes. (USFWS, 2018)

Stressor: Disease or Predation (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Neither diseases nor predation are currently known to be major threats to *S. gentianoides* or *S. alabamensis*. However, minor herbivore damage was noted at Three Rivers SRA and Geneva SF (B. Chowdhury, AU, 6/11/2018, pers. comm.) populations. (USFWS, 2018)

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: The Endangered Species Act (Act) of 1973, as amended prohibits the removal of federally listed threatened and endangered plants or the malicious damage of such plants on areas under federal jurisdiction, or the destruction of endangered plants on non-federal areas in violation of state law or regulations or in the course of any violation of a state criminal trespass law. However, the Act does not provide protection for plants on non-federal lands unless it is in violation of state law. In Florida, *S. gentianoides* is listed as endangered under the Preservation of Native Plant Flora of Florida Act (PNPFF Act) (Rule: 5B-40.0055, Section 581.185-187, Florida Statutes; <https://www.flrules.org/gateway/RuleNo.asp?ID=5B-40.0055>). The PNPFF Act addresses the protection of endangered, threatened, or "commercially exploited" plants (http://www.sfrc.ufl.edu/Extension/florida_forestry_information/planning_and_assistance/threatened_and_endangered_species.html). The removal of protected plants from a property, whether for transplant, sale, or any other purpose, requires both the written permission of the

landowner and a permit from the Florida Department of Agriculture and Consumer Services. In Alabama, the Alabama State Constitution provided the necessary authority to add plants to Alabama's section 6 cooperative agreement. Department of Conservation and Natural Resources has a policy to protect, conserve and increase the wildlife of the state [Ala. Code 9-2-2 (1)], but provides little direction as to how this is to be accomplished. While the state's Natural Heritage Program maintains lists of non-game species considered endangered, threatened, of special concern or poorly known, it does not apply penalties for taking listed species or for altering their habitats. The Nongame Wildlife Program, which was started in 1984, helps administer endangered and threatened species projects on federally and state-listed species, and also issues scientific collecting permits to enable a wide range of projects and collect the data for fishes, amphibians, reptiles, birds, and mammals (USFWS, 2018)

Stressor: Non-native plant interactions (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Currently, non-indigenous plants within or near extant populations of *S. gentianoides* do not pose a threat. However, *Lygodium japonicum* (Thunb. ex Murr.) Sw. (Japanese climbing fern) and *Lonicera japonica* Thunb. (Japanese honeysuckle) have been found in the vicinity of *S. gentianoides*, and both are becoming problematic in areas of the Southeast. (USFWS, 2018)

Recovery

Reclassification Criteria:

Downlisting of *S. gentianoides* from endangered to threatened status will be considered when (Criterion 5 was removed per USFWS 2019): (USFWS, 2012; USFWS, 2019)

1. Extant populations and newly discovered sites are identified and mapped (USFWS, 2012; USFWS, 2019).
2. Inventories (i.e., the total number of individuals, number of flowering vs. non-flowering plants, presence of pollinators, and whether seedling recruitment is occurring) have been conducted across the species' historic sites and/or on new locations; (USFWS, 2012)
3. Monitoring programs and management protocols on selected populations (e.g., largest populations) are established for 15 years to track threats to the species and its habitat (e.g., control exotic species, minimize site disturbance, urban development); (USFWS, 2012)
4. For var. *alabamensis*: the extant populations (including subpopulations at the Ketona Glades, Bibb Co., Alabama) located on public land are stable. (USFWS, 2012)
6. Research on key aspects related to demography (e.g., density, effect of fire on seedling establishment), reproductive biology, and seed ecology is accomplished (USFWS, 2012)
7. Viable germplasm representing > 50% of the populations for each variety is maintained in ex-situ. (USFWS, 2012)

Var. *gentianoides*: (1) sizes of populations in the Apalachee WMA, Three Rivers State Park, Calhoun Spigelia Preserve in Florida and the Geneva State Forest in Alabama are increased via prescribed burns until plant numbers are stabilized over a period of 15 years; (2) at least one new population is found, and; (3) at least one population is re-established within the historic range, specifically at sites where the plants are currently known to be extirpated. (USFWS, 2012)

Var. *alabamensis*: (1) 50 % the Bibb Co. glades known to support the variety on private land are protected through conservation agreements, easements, and/or land acquisition. (USFWS, 2012)

Delisting Criteria:

The following Delisting Criteria are applicable to var. *gentianoides*: (USFWS, 2019)

1. Existing core populations [Apalachee WMA, TNC Spigelia Preserve, Three Rivers SRA, Rock Hill TNC Preserve, and Geneva SF] are restored and properly managed, and monitoring demonstrates that the populations are stable or increasing over multiple prescribed burn cycles, evidenced by a type of natural recruitment and/or multiple size-classes (addresses Factors A, D, and E). (USFWS, 2019)
2. At least five (5) new populations are discovered or established within the historic range of the species on lands protected by a conservation mechanism. These populations should exhibit stable or increasing trends over multiple prescribed burn cycles, evidenced by a type of natural recruitment and/or multiple size-classes (addresses Factors A and E). (USFWS, 2019)
3. Threats to *S. gentianoides* and its habitat (e.g., exotic species, site disturbance, urban development, hurricanes) have been managed and reduced to ensure the persistence of *S. gentianoides* into the foreseeable future (addresses Factors A, D, and E). (USFWS, 2019)

Delisting criteria for var. *alabamensis* have not been developed. (USFWS, 2012)

Recovery Actions:

- 1. Protect, manage, and secure existing populations and habitat. The distribution of *Spigelia gentianoides* is limited to a few areas in Northwest Florida extending into central Alabama (Fig. 2), thus it is important to secure and stabilize current and any newly discovered populations to prevent further decline of this plant. (USFWS, 2012).
- 2. Conduct surveys/inventories. Inventory of current and new populations; field surveys and species distribution modeling to determine survey sites. (USFWS, 2012).
- 3. Establish new occurrences within the historic range of var. *gentianoides*, specifically in the sites where the plants are known to be extirpated (USFWS, 2012).
- 4. Maintain the species ex-situ in a protected facility. Ex-situ populations will serve as an important component for storage of germplasm and reintroducing *S. gentianoides* populations within the species range. (USFWS, 2012).
- 5. Conduct long-term monitoring and research; establish and implement a long-term monitoring program on selected sites, to include population biology/demographic studies and phenological studies. Conduct research into reproduction, pollination ecology, and breeding systems. Conduct research on seed bank, germination, and seedling survival. Conduct taxonomic and genetic studies. (USFWS, 2012)

- 6. Outreach: Develop and distribute information to the general public about *S. gentianoides*, how to protect and manage it for its recovery, and how lands can be managed to benefit the plant along with meeting landowner needs. Promote the implementation of the recovery actions via private landowners, academia, and public agencies. (USFWS, 2012)
- 7. Review and track recovery progress. (USFWS, 2012)
- Recommended Action from 2018 5-Year Review: Establish protection and management agreements with landowners. (USFWS, 2018)
- Recommended Action from 2018 5-Year Review: Conduct surveys/inventories on each known population. For each extant population, the following data should be collected once a year: the total number of individuals, number of flowering vs. non-flowering plants, presence of visitors to the flowers, and whether seedling recruitment is occurring. (USFWS, 2018)
- Conduct a long-term study using populations distributed throughout the species' historical range Recommended Action from 2018 5-Year Review: for 10 years to document both distribution and abundance changes. Observations of flowering and fruiting are important and should be integrated with variables such as plant size and seedling data. Since gentian pinkroot occurs in fire prone habitats, the effect of this disturbance (including winter vs. growing season prescribed fire, fire frequency, intensity, duration, and timing) on survival and fecundity should be also monitored. Such studies should be conducted on large populations. Plants should be monitored several times during a 12-month cycle (e.g., flowering and fruiting seasons) the first year, then annually or biannually over an extended number of years. (USFWS, 2018)
- Recommended Action from 2018 5-Year Review: Investigate if there is a soil seed bank persistence of *S. gentianoides* seeds throughout the species' geographic range. (USFWS, 2018)
- Recommended Action from 2018 5-Year Review: Conduct germination studies and investigate whether seedling recruitment is occurring. (USFWS, 2018)
- Recommended Action from 2018 5-Year Review: Monitoring and managing for invasive species: Frequent inventories or surveys of the Florida populations for invasive plant species should be established, which will help with the early detection and eradication of small patches of exotic invasive plants within the sites. This is an ongoing action for the Three Rivers SRA population conducted by the Park staff. (USFWS, 2018)
- Recommended Action from 2018 5-Year Review: Conduct surveys/inventories on potentially new sites in Northern Florida and Alabama. This action can include the use of aerial photographs and species distribution models to determine potential sites, with subsequent field inventory of the site using a consistent, statistically valid, repeatable inventory method. If new populations are discovered, protection should be sought. (USFWS, 2018)
- Recommended Action from 2018 5-Year Review: Reintroduce plants within the historic range, specifically in the sites where the plants have been extirpated. (USFWS, 2018)
- Recommended Action from 2018 5-Year Review: Conduct reproductive studies Since site disturbance occurs within the populations of *S. gentianoides*, it may pose problems to pollinator diversity (Kevan and Phillips 2001). Therefore, it is important to determine which insects are pollinators, and understand the value and pollinators' requirements so that actions can be taken to incorporate specific management or protection plans. Knowledge of the type of mating systems is essential for conservation of rare plant taxa because mating systems affect genetic diversity within and among populations (Navarro and Guitian 2002).

- Therefore, floral morphological analysis and experimental hand-pollinations are all recommended. (USFWS, 2018)
- Recommended Action from 2019 Amended Recovery Plan: Conduct research on key aspects related to (1) demography (e.g., density, effect of fire on seedling establishment), (2) reproductive biology, (3) levels and distribution of genetic diversity, (4) seed ecology to facilitate better understanding of this species' biology and potential impacts of threats such as low density, and changes in fire regime and (5) effects of catastrophic events such as hurricanes on populations and habitat of *S. gentianoides* (addresses Factor E, and resiliency, and inform representation). (USFWS, 2019)
 - Recommended Action from 2019 Amended Recovery Plan: The effects of forest management practices (e.g., logging) on long-term persistence of *S. gentianoides* is assessed and a standardized monitoring technique is in place (addresses Factor D and resiliency). (USFWS, 2019)
 - Recommended Action from 2019 Amended Recovery Plan: Inventories (i.e., the total number of individuals, number of flowering vs. non-flowering plants, presence of pollinators, and whether seedling recruitment is occurring) have been conducted across the species' historic sites and/or on new locations where appropriate habitat exists (addresses Factors A and D). (USFWS, 2019)
 - Recommended Action from 2019 Amended Recovery Plan: A living collection of viable germplasm, collected from genetically distinct sites, is maintained in protected facilities (ex-situ) for research, recovery, and public outreach (addresses Factors A and E, and representation). (USFWS, 2019)

SPECIES ACCOUNT: *Spiraea virginiana* (Virginia spiraea)

Species Taxonomic and Listing Information

Listing Status: Threatened; 06/15/1990; Northeast Region (Region 5) (USFWS, 2015)

Physical Description

Colonial shrub up to 1.2 m high; largest stems 3-4 cm in diameter, dark gray, often arching or nearly horizontal; young stems upright, greenish-yellow to reddish-brown; branching often profuse in older specimens; leaves alternate, very variable in shape, size and degree of serration, generally mucronate-tipped, glaucous beneath, simply and singly serrate to entire, ranging from ovate to lanceolate; flowers 6 mm wide, bright to creamy white in tightly packed corymbs; corymbs variable in size, ranging from 5-22 cm, wide; follicles small, 2.0 mm long, 1.5 mm wide; seeds rarely produced. Fruit is a follicle. Flowering in June and July. Fruiting in August and September. (NatureServe, 2015)

Taxonomy

The two varieties sometimes recognized (var. *serrulata* and var. *virginiana*) are not maintained by Kartesz (1994 and 1999), nor are they recognized by any Heritage Program in the species' range, or by the U.S. Fish and Wildlife Service. *Spiraea virginiana* is distinguished from most other *Spiraea* by its creamy white flowers in corymbs, and its leaves which have an acute apex (Weakley 2004). (NatureServe, 2015)

Historical Range

Known historically in Pennsylvania. (NatureServe, 2015)

Current Range

Pennsylvania and Ohio south to Georgia and Tennessee. Records for Pennsylvania are historic. It occurs on streams that drain into the Ohio River and primarily within the Appalachian (Cumberland) Plateau and Blue Ridge physiographic regions, with at least one outlier in the Bluegrass Region of Kentucky. (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Asexual (vegetative) and sexual (NatureServe, 2015)

Breeding Season

Adult: June to July (NatureServe, 2015)

Key Resources Needed for Breeding

Adult: The species' flowers are visited by a host of insects, most commonly beetles. Identified insects, which are common and widespread, include flower long—horn beetles, a flower beetle, and a soldier beetle (R.L. Hoffman pers. comm.). (USFWS, 1992)

Reproduction Narrative

Adult: Although this element may flower profusely, it is clonal and almost exclusively reproduces vegetatively. Sexual reproduction will occur when genets are placed in close proximity but is rare in the native habitat (D.W. Ogle, pers. comm., 1996). Flowers bloom in June and July. The species' flowers are visited by a host of insects, most commonly beetles. Identified insects, which are common and widespread, include flower long—horn beetles, a flower beetle, and a soldier beetle (R.L. Hoffman pers. comm.). (USFWS, 1992)

Habitat Type

Adult: Riverine, Palustrine, and terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: High gradient, herbaceous wetland, riparian, scrub-scrub wetland, bare rock/talus/scree (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 850 to 2,400 feet (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Colonies (USFWS, 1992)

Environmental Specificity

Adult: Very narrow. Specialist or community with key requirements scarce. (NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: High (USFWS, 1992)

Habitat Narrative

Adult: *Spiraea virginiana* is found at elevations between 850 to 2,400 feet in periodically flood-scoured banks of high-gradient mountain streams, meander scrolls, point bars, natural levees, and braided features of lower stream reaches, and occasionally near disturbed rights-of-way (Ogle 1992). Plants often found on geologically active areas with erosion, deposition, and slumping, along rivers with dynamic flooding regimes, sandbars, scoured river shore and flatrock habitat with crevices. These areas also are associated with cobbles, boulders, and massive rock outcrops with sandy or clay soils. The areas can be periodically xeric. Plants are often seen in silt mud and sand. The growth, spread, and subsequent fragmentation of modular colonies are important processes in moving individuals within the environment. *S. virginiana* survives several types of stochastic events, and its phenotypic plasticity has much to tell us about temporal adaptation. (NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Seeds seem to be rarely produced. The seeds are very small (> 2 mm long x ca. 0.5 mm wide) and could be dispersed by wind or water. (USFWS, 1992)

Population Information and Trends

Population Trends:

Short-term trends indicate a decline of 10 to 30% (NatureServe, 2015)

Resiliency:

High (USFWS, 1992)

Representation:

Moderate (USFWS, 1992)

Redundancy:

Moderate (USFWS, 1992)

Number of Populations:

31 (NatureServe, 2015)

Adaptability:

Moderate (USFWS, 1992)

Population Narrative:

Shor-term population trends indicate a 10 to 30% decline. There are approximately 31 populations in seven states, down from 39 populations in eight states (Ogle 1992). *S. virginiana* survives several types of stochastic events, and its phenotypic plasticity has much to tell us about temporal adaptation. (NatureServe, 2015)

Threats and Stressors

Stressor: Impoundments (USFWS, 1992)

Exposure:

Response:

Consequence:

Narrative: Impoundments are a double threat to the species: clones are not only destroyed by rising water, but the impoundment may also serve as a “death trap” for propagules washed down-stream. The probability of being washed into a suitable habitat may decrease from slim to none, thus breaking any possible continuity in downstream motility. (USFWS, 1992)

Stressor: Road-building and water release regulation (USFWS, 1992)

Exposure:

Response:

Consequence:

Narrative: A site on the Cheoah River in Graham County, North Carolina was probably destroyed by road-building and water release regulation (erosion control) below a dam. (USFWS, 1992)

Stressor: Industry development (USFWS, 1992)

Exposure:**Response:****Consequence:**

Narrative: Areas along Hominy Creek in Buncombe County, North Carolina have been extensively developed by industries. (USFWS, 1992)

Stressor: Watershed management (USFWS, 1992)

Exposure:**Response:****Consequence:**

Narrative: Cumulative and more subtle problems could occur from lack of watershed management and uncontrolled development of rivers. Bowles and Apfelbaum (1989) illustrate the effects of stochastic environmental events on another riverine species and graphically describe necessary conditions for survival. "Extinction possibility is increased by low disturbance, which favors plant succession and competition, or by high disturbance, which exceeds levels of ... population maintenance." (USFWS, 1992)

Stressor: Reproduction and genetics (USFWS, 1992)

Exposure:**Response:****Consequence:**

Narrative: "Weak points" in the species' biology may be a threat to its survival. Paucity of sexual reproduction dramatically decreases the intrinsic rate of reproduction and the dispersal potential of the plant's small seeds. Genetic "fixation" of the clonal material may have adverse effects on the future breeding potential of the species, and the small number of genetically different individuals may constitute a threat. (USFWS, 1992)

Stressor: Insect predation (USFWS, 1992)

Exposure:**Response:****Consequence:**

Narrative: Various insect pests have been seen on virginiana plants. Aphids of several types cluster at the rapidly growing shoot tips. Most of these are tended by ants, which move the aphids from place to place on the same plant, or from plant to plant. Aphids are most common on plants growing away from the water's edge. On the beneficial side, lady bug beetles are regularly seen on these same stem tips. In another case, K. Walton (pers. comm.) identified a copper underwing moth caterpillar, a common and widespread species, that was doing damage in one population. However, for the most part, there is little evidence of anything other than local damage by insect pests. (USFWS, 1992)

Stressor: Introduced plants (USFWS, 1992)

Exposure:**Response:****Consequence:**

Narrative: Introduced alien plant species (e.g., *Polygonatum cuspidatum*, *Liquidum sinense*, *Spiraea japonica*, and *Rosa multiflora*) are another, almost uncontrollable, detriment. (USFWS, 1992)

Recovery**Reclassification Criteria:**

Reclassification criteria are not available.

Delisting Criteria:

1. Three stable populations are permanently protected in each drainage where populations are currently known. (USFWS, 1992)
2. Stable populations are established on protected sites in each drainage where documented vouchers have been collected. (USFWS, 1992)
3. Potential habitat in the states with present or past collections has been searched for additional populations. (USFWS, 1992)
4. Representatives of each genotype are cultivated in a permanent collection. (USFWS, 1992)

Recovery Actions:

- Protect existing populations and essential habitat through landowner cooperation and land acquisition. (USFWS, 1992)
- Search for additional populations. (USFWS, 1992)
- Conduct site-specific habitat manipulation as needed to maintain populations. (USFWS, 1992)
- Distinguish between N and n individuals and identify genetically different populations. (USFWS, 1992)
- Maintain cultivated sources for reproduction studies as well as conservation and reintroduction activities. (USFWS, 1992)
- Study the species' environmental tolerances and habitat characteristics. (USFWS, 1992)
- Re-establish populations within the historic range of the species. (USFWS, 1992)
- Inform land owners and managers about the plant's recovery needs. (USFWS, 1992)
- Monitor populations and evaluate effectiveness of recovery efforts. (USFWS, 1992)

Conservation Measures and Best Management Practices:

- Protect existing populations and essential habitat. (USFWS, 1992)
- Conduct rangewide searches in areas of suitable habitat for additional populations. (USFWS, 1992)
- Conduct site-specific manipulation to maintain existing populations. (USFWS, 1992)
- Distinguish between N and n individuals. (USFWS, 1992)
- Maintain representative material from each known genotype in permanent cultivation. (USFWS, 1992)
- Investigate the species environmental tolerances and habitat characteristics. (USFWS, 1992)
- As appropriate, reintroduce *S. virginiana* in additional drainage systems within the species' historical range. (USFWS, 1992)
- Develop an information packet for landowners and land managers. (USFWS, 1992)
- Evaluate the effectiveness of protection and management programs and redirect efforts as necessary. (USFWS, 1992)

SPECIES ACCOUNT: *Stahlia monosperma* (Cobana negra)

Species Taxonomic and Listing Information

Listing Status: Threatened; Southeast Region (R4) 04/05/1990

Physical Description

Stahlia monosperma (cobana negra) is a medium-sized, evergreen tree that reaches 25 to 50 feet in height, and 1 to 1.5 feet in diameter. It is a member of the Family Fabaceae, easily identified by (1) pinnately compound leaves with 6 to 12 opposite, lance-shaped to ovate leaflets on red stalks and with scattered black raised dots on lower surface; (2) clusters of pale yellow flowers about one-half of an inch across the five petals; (3) odd. elliptic, thick and fleshy, red pods 2 inches or less in length; and (4) yellow-green and slightly pendulous foliage (Little and Wadsworth 1964). Flowers are yellow and are produced between March and May, depending on rainfall. Flower clusters are terminal, 3 to 6 inches long, and unbranched. The slightly hairy flowers have a funnel-shape, broad base, 10 stamens and a one-celled, slender and curved ovary. A thin, red, fleshy fruit is produced during late June and mid-July. Fruit pods are about 1.5 inches broad and three-fourths of an inch thick, with an odor of ripe apples, light brown tasteless flesh, and one large seed (Little and Wadsworth 1964). Fruits mature in summer and fall. The sapwood is light brown, and the heartwood is dark brown. The wood is very hard, heavy, strong, durable, and resistant to attack by dry wood termites (USFWS, 1996).

Taxonomy

Stahlia monosperma belongs to a monotypic Genus endemic to Puerto Rico and Hispaniola (USFWS, 1996).

Historical Range

Stahlia monosperma (cobana negra) is a tree currently known from parts of the southwestern and northeastern coasts of Puerto Rico and the island of Vieques (USFWS, 1996).

Current Range

At present, natural populations of Cóbana negra are found in nine areas: Punta Ventana, Punta Guaniquilla, Laguna Joyuda, Punta Melones, Road PR 307 (Boquerón Country Club), near Villa Taina, Sierra Bermeja, Punta Picúa, and Vieques Island (Table 2). Additionally, based on a propagation effort conducted for more than 13 years, the species has been planted at least 18 municipalities throughout Puerto Rico (Figure 3). This information does not include those individuals that have been planted as part of reforestation efforts and public education, and those that have been planted island-wide around public parks, and along state and rural roads and private parcels (USFWS, 2014).

Population Information and Trends**Population Trends:**

Increasing (USFWS, 2014)

Resiliency:

Low (inferred from USFWS, 2014)

Representation:

Low (inferred from USFWS, 2014)

Redundancy:

Low (inferred from USFWS, 2014)

Number of Populations:

Nine (USFWS, 2014)

Population Size:

~200 total individuals (USFWS, 2014)

Population Narrative:

There are three known populations and a total of 34 individuals. Population level trends tend to be increasing due to re-introduction (USFWS, 2014). Low resiliency, redundancy and representation are inferred based on the low number of populations and the specific habitat needs of the species.

Threats and Stressors

Stressor: Illegal dumping (USFWS, 2014)

Exposure:

Response:

Consequence: Loss/degradation of habitat

Narrative: Some of the wetland areas are commonly used as illegal dumping sites where used tires, mattresses, refrigerators, and other kind of trash are left in suitable areas for the species (USFWS, 2014).

Stressor: Human development (USFWS, 2014)

Exposure:

Response:

Consequence: Loss/degradation of habitat

Narrative: The development of these areas has resulted in habitat modification and fragmentation, and has limited the natural expansion of currently known populations of *Cóbana negra* (USFWS, 2014).

Stressor: Predation (USFWS, 2014)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: At the time of listing, browsing of seedlings was considered a threat to the species especially in the first year following establishment. Currently, Sierra Bermeja, Villa Taina and Laguna Joyuda, are areas where livestock may still graze on Cóbana negra. The individuals in grazing areas grow sparse and only reach adulthood where cattle are limited. (USFWS, 2014). Because most of the wild individuals are in protected areas restricted from livestock, and some have conservation measures for the protection of the species, we believe that the threat of predation is low (USFWS, 2014).

Stressor: Lack of individual recruitment (USFWS, 2014)

Exposure:

Response:

Consequence: Limited population growth

Narrative: The Cóbana negra populations have been affected by lack of natural recruitment despite the abundant fruit production and the fact that seeds germinate very well under nursery conditions. The best information available indicates that little recruitment is occurring on natural populations, and when present, seedlings and saplings are located just below the parent tree, suggesting problems of seed dispersal. Due to the lack of long term monitoring efforts, it remains unknown if these individuals will develop as mature plants capable of reproduction. Thus, the Service is unable to determine if the natural populations are actually stable or improving. In the case of reintroduced material, a rapid assessment conducted by the Service on individuals planted since 1998 at Laguna Cartagena NWR, identified several size classes, which suggests some recruitment (USFWS 2014a). However, a thorough assessment of the entire population at Laguna Cartagena is needed to determine if natural recruitment is actually occurring. Also, other reintroduced individuals have been planted in private and public lands, which are not suitable natural habitats for the species (e.g. pasturelands and urban areas). Hence, we do not consider these plantings self-sustaining and the chances for these populations to be expanding are very limited. Therefore, we believe that the factors mentioned above are a threat to the species (USFWS, 2014).

Stressor: Hurricanes and climate change (USFWS, 2014)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Disturbances such as hurricanes may affect small relic populations of Cóbana negra. These populations are very important as they may harbor an important genetic stock of the species. Cóbana negra may be further threatened by climate change, which is predicted to increase the frequency and strength of tropical storms and can cause severe droughts (Hopkinson et al. 2008). Even if Cóbana negra resists adverse effects of hurricanes, the cumulative effects of severe storms, soil erosion and increased sediment runoff may compromise the establishment of seedlings along drainages, which usually provide suitable habitat for the species. Habitat modification may result in irreversible damage to the species' natural habitat, decreasing the number of individuals in already small populations. However, the current frequency of severe hurricanes is low, therefore, the Service considers severe tropical storms as a low and non-imminent threat to the species (USFWS, 2014).

Stressor: Human induced fires (USFWS, 2014)

Exposure:

Response:**Consequence:**

Narrative: Caribbean ecosystems are vulnerable to natural and anthropogenic events. Native plants and endemic species with limited distribution are particularly susceptible to human induced fires. Restoring native plant communities is challenging where invasive plants have altered fire regimes and ecosystem properties (Brooks et al. 2004). In Puerto Rico, the native plant community of subtropical dry forests is not fire-adapted; hence, it has been affected by human induced fires (Wolfe 2008). These fires may lead to destruction of the native vegetation seed bank, and usually favor conditions for the establishment of exotic plant species (e.g., *Leucaena leucocephala* and *Megathyrus maximus*). Moreover, exotic plants increase direct competition for resources and limit native plant species recruitment in highly degraded areas (Wolfe 2008). The possibility of severe droughts triggered by climate change may contribute to an increase in the number and frequency of fires on Puerto Rico. These cumulative factors may reduce the number of individuals and further reduce populations of *Cóbana negra*. The Service is aware of natural populations of *Cóbana negra* being directly affected by human induced fires and the associated habitat modification in the area of Sierra Bermeja (USFWS 2014b). Moreover, areas managed for conservation, and where the species have been widely planted, have been recently affected by fires (i.e., Cabo Rojo NWR and Laguna Cartagena NWR). Nonetheless, we consider the threat of human-induced fires to be low and non-imminent because their effect is local and they do not threaten all populations of *Cóbana negra* at once (USFWS, 2014).

Stressor: Genetic variation (USFWS, 2014)

Exposure:**Response:**

Consequence: Limited population viability

Narrative: *Cóbana negra* occurs in small natural populations with a limited geographic distribution. These factors along with habitat fragmentation, and the fact that planted individuals come from propagated material from the same seed source, may result in the erosion of genetic variation of the species (Honnay and Jacquemyn 2007). Such genetic erosion also may limit the species' ability to respond to environmental changes (Booy et al. 2000). As previously mentioned under the section about new genetic information, *Cóbana negra* may be facing a population bottleneck due to a severe reduction in population size in the recent past. Based on the above information, we consider the low genetic variation as a high, but non-imminent threat to the species (USFWS, 2014).

Recovery**Delisting Criteria:**

1. Self-sustaining new populations (following the appropriate ecological and genetic studies to determine self-sustainability) are established within protected areas (USFWS, 2014).
2. Specimens or populations found on privately-owned lands are placed under protective status (USFWS, 2014).

Recovery Actions:

- Criteria 1 has been initiated with the introduction of individuals in protected areas (USFWS, 2014).

- Criteria 2 has been partially met as most natural individuals (80%) are in areas managed for conservation by governmental and non-governmental organizations (USFWS, 2014).

Conservation Measures and Best Management Practices:

- The Service, in cooperation with PRDNER and academia, needs to determine how many individuals constitute a self-sustaining population. After this work, the recovery plan should be revised to establish objective, measurable delisting criteria (USFWS, 2014).
- Genetic studies should be conducted to determine the genetic variation of planted individuals (USFWS, 2014).
- Efforts to protect privately-owned populations should be started. Areas like Punta Melones, near Villa Taina, Laguna Joyuda and Sierra Bermeja are susceptible to development. Hence, working with the private landowners to conserve these natural areas is essential. Private-lands initiatives such as Partners for Fish and Wildlife and Coastal Programs are needed to further protect the areas where Cóbana negra is known to occur naturally (USFWS, 2014).
- The Service should continue the efforts to promote the collection of seed material from natural populations and not from plantations. This actions help to increase the genetic variation of Cóbana negra (USFWS, 2014).
- Conduct periodic surveys of introduced populations to assess the success of planting efforts and determine if recovery actions are effective (USFWS, 2014).

SPECIES ACCOUNT: *Stenogyne angustifolia angustifolia* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 11/29/1979; Pacific Region (R1) (USFWS, 2016)

Physical Description

Stenogyne angustifolia is a member of the Lamiaceae, or mint family. Although six varieties have been described, none are currently accepted by Weller and Sakai in the Manual of Flowering Plants of Hawaii (Wagner et al. 1999). It is a prostrate, trailing plant with four-sided, smooth stems which are occasionally pubescent at the nodes. Leaves are undivided, contracted at the base into a petiole approximately one centimeter (0.4 inch) in length, and smooth. The leaf blade is oblong to linear, wavy to serrate, and between 2 and 6 centimeters (0.8 and 2.4 inches) long and 6 and 12 millimeters (0.2 and 0.5 inch) wide. Flowers are tubular, distinctly veined, and 8 to 13 millimeters (0.3 to 0.5 inch) long. The upper lip of the flower is twice as long as the lower and petals are yellow to dull brownish-pink and finely pubescent (U.S. Army 2003a).

Historical Range

Historically, *Stenogyne angustifolia* was known from the islands of Molokai, Maui, and Hawaii.

Current Range

Currently, an estimated 5,000 to 7,500 individuals occur only on the island of Hawaii (U.S. Army 2003a).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Habitat Type

Adult: Semi-arid shrublands and *Metrosideros* Woodlands

Habitat Narrative

Adult: *Stenogyne angustifolia* grows on relatively flat, ash-veneered lava and shallow soils in semi-arid shrublands and *Metrosideros* Woodlands at an elevation of 1,555 meters (5,102 feet). The species also occurs at an elevation of 1,035 meters (3,396 feet) in the transition zone between pastureland and the Keamuku lava flow. The species has been described as abundant on various-aged lava or rock outcrops that support the following diversity of plant communities: *Eragrostis* Grassland, *Chenopodium* Shrubland, *Chamaesyce* Treelands, Open *Metrosideros* Treelands with sparse and dense shrub understory, Intermediate *Metrosideros* Mixed Treelands, Open and Mixed *Dodonaea* Shrublands, *Myoporum*-*Dodonaea* Shrublands, *Myoporum*-*Sophora* Mixed Shrublands, *Myoporum* Shrublands, and *Leptecophylla* Mixed Shrublands (U.S. Army 2003a).

Dispersal/Migration***Population Information and Trends*****Number of Populations:**

6 - 20 (NatureServe, 2015)

Population Size:

1 - 1000 individuals (NatureServe, 2015)

Population Narrative:

Population estimates are difficult to make because of vegetative reproduction. 9 CURRENT POPULATIONS; APPROXIMATELY 12 HISTORICAL RECORDS. (NatureServe, 2015)

Threats and Stressors**Stressor:****Exposure:****Response:****Consequence:**

Narrative: The threats to *Stenogyne angustifolia* include habitat competition from non-native plants, particularly *Pennisetum setaceum*; and conversion of habitat to a fire-based vegetation community. Army training such as mounted and dismounted off-road maneuvers, bivouac, and live-fire training increase the risk of fire, habitat fragmentation and alien plant seed spread. Off-road and on-road driving and training increases the level of dust (which can compromise plant health and vigor) due to the fine soils in the northern Pohakuloa Training Area (PTA) on the island of Hawaii. In addition, due to the very limited distribution of this species, a single natural or human-caused environmental disturbance could be catastrophic. The taxon does not appear palatable to feral sheep and goats, and appears to be consumed only during dry periods or after a fire (U.S. Army 2003a).

Recovery***Conservation Measures and Best Management Practices:***

- Important conservation actions needed for *Stenogyne angustifolia* include the following: control of non-native plant species and feral ungulates; reduction of fire; and research on habitat requirements, population structure, reproductive biology, and seed biology. Multiple occurrences that replicate the existing density and distribution for *S. angustifolia* should be established to increase species abundance and density (U.S. Army 2003a). In addition, a State-wide management plan that identifies areas and landscapes for the long-term conservation of all known occurrences of *S. angustifolia* is needed. As part of this management plan, landowners and managers should delineate management units to conserve this species and other native species through threat control and habitat restoration. Ongoing Conservation Actions: Aside from specific actions occurring at PTA (and discussed in a subsequent section), the Service is unaware of species-specific conservation actions being conducted for *Stenogyne angustifolia*.

SPECIES ACCOUNT: *Stenogyne bifida* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/08/1992; Pacific Region (R1) (USFWS, 2016)

Physical Description

A trailing perennial herb. Flowers are pale yellowish green and pale brown. (NatureServe, 2015)

Taxonomy

Stenogyne bifida, a nonaromatic member of the mint family (Lamiaceae), is a climbing, short-lived perennial herb, with smooth or slightly hairy, four-angled stems. The long, narrow calyx teeth and the deep lobe in the upper lip of the yellow corolla separate this species from others of the genus (Weller and Sakai 1999) (USFWS, 2003).

Historical Range

See current range/distribution

Current Range

Current range: Eastern Molokai; also known historically from western Molokai (NatureServe, 2015).

Critical Habitat Designated

Yes; 3/16/2016.

Legal Description

On March 18, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Stenogyne bifida* (no common name) under the Endangered Species Act of 1973, as amended (Act) (68 FR 12982 13141). On March 30, 2016, the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Stenogyne bifida* (81 FR 17789-18110). The critical habitat designation includes 11 critical habitat units, which encompass approximately 27,051 acres on the Island of Molokai, Hawaii.

The critical habitat designation for *Stenogyne bifida* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Stenogyne bifida* includes 11 critical habitat units, covering four ecosystem types, which encompass approximately 27,051 acres on the Island of Molokai, Hawaii (81 FR 17789 - 18110). The designated critical habitats include: Molokai - Lowland Mesic - Unit 1; Molokai--Lowland Wet - Unit 1, 2, 3; Molokai - Montane Wet--Unit 1, 2, 3; Molokai--Montane Mesic--Unit 1; Molokai - Wet Cliff - Unit 1, 2, 3.

Molokai—Lowland Mesic—Unit 1 [8,770 ac (3,549 ha)]: This area consists of 3,489 ac (1,412 ha) of State land, and 5,281 ac (2,137 ha) of privately owned land, from Waianui Gulch to Mapulehu, in central Molokai.

Molokai—Lowland Wet—Unit 1 [2,949 ac (1,193 ha)]: This area consists of 2,195 ac (888 ha) of State land, and 754 ac (305 ha) of privately owned land (partly within The Nature Conservancy's Pelekunu Preserve), from Pelekunu Valley to Wailau Valley, in north-central Molokai. Molokai—Lowland Wet—Unit 2 [1,950 acres (789 ha)]: This area consists of 1,356 ac (549 ha) of State land and 594 ac (241 ha) of privately owned land, from Kahanui to Pelekunu Valley, in north-central Molokai. Molokai—Lowland Wet—Unit 3 [3,219 acres (1,303 ha)]: This area consists of 94 ac (38 ha) of State land, and 3,125 ac (1,265 ha) of privately owned land, from Waiahookalo gulch to Moaula stream and Puniuohua, on eastern Molokai.

Molokai—Montane Wet—Unit 1 [3,397 ac (1,375 ha)]: This area consists of 1,545 ac (625 ha) of State land, and 1,851 ac (749 ha) of privately owned land, from the headwaters of Waialeia Stream and above Pelekunu Valley, eastward along the summit area to Mapulehu, in northcentral Molokai. Molokai—Montane Wet—Unit 2 [910 ac (368 ha)]: This area consists of 871 ac (353 ha) of State land, and 39 ac (16 ha) of privately owned land, from Honukaupu to Olokui (between Pelekunu and Wailau valleys), in north-central Molokai. Molokai—Montane Wet—Unit 3 [803 ac (325 ha)]: This area consists of 77 ac (31 ha) of State land, and 726 ac (294 ha) of privately owned land, above the east rim of Wailau Valley on eastern Molokai.

Molokai - Montane Mesic - Unit 1 [816 ac (330 ha)]: This area consists of 257 ac (104 ha) of State land, and 559 ac (226 ha) of privately owned land from Kamiloloa to Makolelau in central Molokai.

Molokai—Wet Cliff —Unit 1 [1,607 ac (651 ha)]: This area consists of 1,395 ac (565 ha) of State land, and 212 ac (86 ha) of privately owned land, and encircles the plateau between Pelekunu and Wailau valleys, in north-central Molokai. Molokai—Wet Cliff —Unit 2 [1,268 ac (513 ha)]: This area consists of 462 ac (187 ha) of State land, and 806 ac (326 ha) of privately owned land (partly within The Nature Conservancy's Pelekunu Preserve), along the rim of Pelekunu Valley from Kipapa Ridge to Mapulehu, in central Molokai. Molokai—Wet Cliff —Unit 3 [1,362 ac (551 ha)]: This area consists of 1,137 ac (460 ha) of State land, and 225 ac (91 ha) of privately owned land, along the rim of Wailau Valley from Mapulehu to Kahiwa Gulch, in eastern Molokai.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Stenogyne bifida* critical habitat consists of the following components according to ecosystem type (81 FR 17789 - 18110):

"(i) Molokai - Lowland Mesic - Unit 1(A) Elevation: Less than 3,300 ft (1,000 m).(B) Annual precipitation: 50 to 75 in (130 to 190 cm).(C) Substrate: Shallow soils, little to no herbaceous layer.(D) Canopy: Acacia, Diospyros, Metrosideros, Myrsine, Pouteria, Santalum.(E) Subcanopy: Dodonaea, Freycinetia, Leptecophylla, Melanthera, Osteomeles, Pleomele, Psydrax.(F) Understory: Carex, Dicranopteris, Diplazium, Elaphoglossum, Peperomia."

(ii) Molokai - Lowland Wet - Units 1, 2, 3 (A) Elevation: Less than 3,300 ft (1,000 m). (B) Annual precipitation: Greater than 75 in (190 cm). (C) Substrate: Clays; ashbeds; deep, well-drained soils; lowland bogs. (D) Canopy: Antidesma, Metrosideros, Myrsine, Pisonia, Psychotria. (E) Subcanopy: Cibotium, Claoxylon, Kadua, Melicope. (F) Understory: Alyxia, Cyrtandra, Dicranopteris, Diplazium, Machaerina, Microlepidia.

(iii) Molokai - Montane Wet - Units 1, 2, 3 (A) Elevation: 3,300 to 6,500 ft (1,000 to 2,000 m). (B) Annual precipitation: Greater than 75 in (190 cm). (C) Substrate: Well-developed soils, montane bogs. (D) Canopy: Acacia, Charpentiera, Cheiropendron, Metrosideros. (E) Subcanopy: Broussaisia, Cibotium, Eurya, Ilex, Myrsine. (F) Understory: Ferns, Carex, Coprosma, Leptecophylla, Oreobolus, Rhynchospora, Vaccinium.

(iv) Molokai - Montane Mesic - Unit 1 (A) Elevation: 3,300 to 6,500 ft (1,000 to 2,000 m). (B) Annual precipitation: 50 to 75 in (130 to 190 cm). (C) Substrate: Deep ash deposits, thin silty loams. (D) Canopy: Acacia, Ilex, Metrosideros, Myrsine, Nestegis, Nothocestrum, Pisonia, Pittosporum, Psychotria, Sophora, Zanthoxylum. (E) Subcanopy: Alyxia, Charpentiera, Coprosma, Dodonaea, Kadua, Labordia, Leptecophylla, Phyllostegia, Vaccinium. (F) Understory: Ferns, Carex, Peperomia.

(v) Molokai - Wet Cliff - Units 1, 2, 3 (A) Elevation: Unrestricted. (B) Annual precipitation: Greater than 75 in (190 cm). (C) Substrate: Greater than 65 degree slope, shallow soils, weathered lava. (D) Canopy: None. (E) Subcanopy: Broussaisia, Cheiropendron, Leptecophylla, Metrosideros. (F) Understory: Bryophytes, ferns, Coprosma, Dubautia, Kadua, Peperomia.

Special Management Considerations or Protections

For all plants and remaining snails: Special management considerations or protections are necessary throughout the critical habitat areas designated for *Stenogyne bifida* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of this species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Unknown (USFWS, 2003)

Reproduction Narrative

Adult: Little is known about the life history of this species. Its flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors are unknown (Service 1996a) (USFWS, 2003).

Habitat Type

Adult: moist-wet forests (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Wet and moist-wet forests on gulch slopes and on ridgetops. (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Wet and moist-wet forests on gulch slopes and on ridgetops. (NatureServe, 2015)

Habitat Narrative

Adult: Wet and moist-wet forests on gulch slopes and on ridgetops. (NatureServe, 2015)

Dispersal/Migration**Motility/Mobility**

Adult: Unknown (USFWS, 2003)

Dispersal/Migration Narrative

Adult: Little is known about the life history of this species. Its flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors are unknown (Service 1996a) (USFWS, 2003).

Population Information and Trends**Population Trends:**

Unknown (NatureServe, 2015)

Number of Populations:

1 - 5 (NatureServe, 2015)

Population Size:

1 - 1000 individuals (NatureServe, 2015)

Adaptability:

Fragility unknown. (NatureServe, 2015)

Population Narrative:

Fragility unknown. Currently about 9 plants observed, estimate less than 100 plants. 3 current and 9 historical occurrences. (NatureServe, 2015). New Status Information: • *Stenogyne bifida* may be extinct in the wild. The last known individual died in 2013 (PEPP 2014). • In 2016, 11 critical habitat units in five ecosystems (lowland mesic, lowland wet, montane wet, montane mesic, and wet cliff) were designated on Moloka'i for *S. bifida* (27,050 ac; 10,948 ha) (81 FR 17790, March 30, 2016) (USFWS, 2018).

Threats and Stressors

Stressor: Habitat destruction and modification (USFWS, 2014)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (deer, goats, and pigs), nonnative plants, human activities, and landslides. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative

plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). The remaining population of *Stenogyne bifida* is located near a hiking trail at Kawela and has the potential of being trampled or collected. Landslides destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. In addition, climate change may pose a threat (USFWS, 1996 and 2012).

Stressor: Limited populations (USFWS, 1996)

Exposure:

Response:

Consequence:

Narrative: The Recovery Plan reported a single population of *Stenogyne bifida* consisting of 12 plants. The small number of populations and individual plants increases the potential for extinction from random naturally occurring events. The limited gene pool may depress reproductive vigor, or a single human-caused or natural environmental disturbance could destroy a significant percentage of the individuals or the only extant population. The remaining population of *Stenogyne bifida* is located near a hiking trail at Kawela and has the potential of being trampled or collected (USFWS, 1996).

Stressor: Predation (USFWS, 2014)

Exposure:

Response:

Consequence:

Narrative: Predation by rats is reported as a threat to this species by the Plant Extinction Prevention Program (USFWS, 2014).

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: An assessment conducted by Fortini et al. (2013) concluded that *S. bifida* is vulnerable to the impacts of climate change, with a vulnerability score of 0.564 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions may be needed to conserve this taxon into the future (USFWS, 2018).

Recovery

Reclassification Criteria:

Downlisting criteria for this species is at least five populations of at least 300 plants each (1,500 mature plants) sustained for 5 years (USFWS, 1996).

Delisting Criteria:

Downlisting criteria for this species is at least five populations of at least 300 plants each (1,500 mature plants) sustained for 10 years (USFWS, 1996).

Conservation Measures and Best Management Practices:

- Continue to collect seeds and/or cuttings from cultivated individuals for genetic storage and propagation (USFWS, 2010).

- Treat plants with systemic fungicide and pesticide solution, if the plants can tolerate it, before reintroducing into natural habitat settings (USFWS, 2010).
- Grow a percentage of the plants to maturity in a nursery setting before reintroduction to improve survival and shorten time until flowering and to generate additional seeds, if possible (USFWS, 2010).
- As adequate material becomes available, outplant propagules into a minimum of two reintroduction sites and an easily accessible site where the plants can be intensively managed for threats from invasive introduced plants, disease, and insects (USFWS, 2010).
- Monitor all wild and reintroduced individuals frequently to discover any negative impacts and manage them as quickly as possible (USFWS, 2010).
- Continue to propagate from cuttings, leaving some plants in ex situ collections to maintain material for replacement plants (USFWS, 2010).
- Work with Hawaii Division of Forestry and Wildlife and The Nature Conservancy to contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2010).
- New Management Actions:
 - Captive propagation for genetic storage and reintroduction—The Lyon Arboretum Micropropagation Laboratory reported 250 containers of propagules representing at least four individuals of *S. bifida* from Kawela (Lyon Arboretum 2017) (USFWS, 2018).
- Recommendations for Future Actions: We are not aware of any new threats or significant new information regarding the species' biological status since the last 5-year review 2014. Thus, the following recommendations for future actions are reiterated for the 5-year review for 2018.
 - Surveys and inventories—Survey geographical and historical range for a current assessment of the species' status.
 - Ungulate monitoring and control—Fence any new occurrences to protect them from the impacts of feral ungulates.
 - Invasive plant monitoring and control—Control established ecosystemaltering nonnative invasive plant species around all populations of *S. bifida*.
 - Landslides and flooding destruction or degradation of habitat—Build resilience and redundancy with propagation and reintroduction.
 - Captive propagation for genetic storage and reintroduction—
 - o Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range.
 - o Evaluate genetic resources currently in storage to determine the need to place additional resources in long-term storage due to this species' vulnerability to climate change.
 - Reintroduction and translocation—Reintroduce individuals into suitable habitat protected from threats.
 - Rodent predation and herbivory—Control rats in the vicinity of all individuals.
 - Invertebrate predation and herbivory—Develop and implement methods to control slugs.
 - Climate change adaptation strategy—Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change.
 - Alliance and partnership development—Initiate planning and contribute to ecosystem-level restoration and management to benefit this species (USFWS, 2018).

SPECIES ACCOUNT: *Stenogyne campanulata* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 05/13/1992; Pacific Region (R1) (USFWS, 2016)

Physical Description

Stenogyne campanulata is a member of the mint family (Lamiaceae), described as a vine with four-angled, hairy stems. The hairy leaves are broadly oval, about 5 centimeters (2 inches) long and 3 centimeters (1 inch) wide. The flowers occur in clusters of about six per leaf axil. The very broadly bell-shaped, hairy calyces are about 13 millimeters (0.5 inches) long, with teeth that are 3 millimeters (0.1 inches) long and 5 millimeters (0.2 inches) wide at the base. The petals are fused into a straight, hairy, white tube about 13 millimeters (0.5 inches) long, with short purple lobes. The fruits of this species have not been seen, but the fruit of all other members of this genus are fleshy nutlets. *Stenogyne campanulata* is distinguished from closely related species by its large and very broadly bell-shaped calyces that nearly enclose the relatively small, straight corollas, and by small calyx teeth that are half as long as wide (Weller and Sakai 1990) (USFWS, 1995).

Taxonomy

Stenogyne campanulata was discovered in 1986 by Steven Montgomery on sheer, virtually inaccessible cliffs below the upper rim of Kalalau Valley on Kauai. In 1989, Stephen Weller and Ann Sakai described the plant as a new species, naming it for the flowers' bell-shaped calyces (USFWS, 1995).

Current Range

Stenogyne campanulata is known only from the single population which was originally discovered on the cliffs of Kalalau to below Puu o Kila (USFWS, 1995).

Critical Habitat Designated

Yes; 2/27/2003.

Legal Description

On February 27, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Stenogyne campanulata* on the island of Kauai, Hawaii (68 FR 9116 - 9479).

Critical Habitat Designation

The critical habitat designation for *Stenogyne campanulata* includes one unit totaling 1,050 acres in Kauai County, Hawaii. The unit is Kauai 11—*Stenogyne campanulata*—a.

Kauai 11—*Stenogyne campanulata*—a: This unit is critical habitat for *Stenogyne campanulata* and is 424 ha (1,050 ac) on State land (Kokee and Na Pali Coast State Parks). This unit contains the Kahuamaa Flats. This unit provides habitat for three populations of 300 mature, reproducing individuals of the short-lived perennial *Stenogyne campanulata* and is currently occupied with 51 to 66 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable. The habitat features contained in this unit

that are essential for this species include, but are not limited to, rock faces of nearly vertical, northfacing cliffs in diverse lowland or montane mesic forest. Although the service does not feel that there is enough habitat that currently exists to reach the recovery goal of 8 to 10 populations for this species, this unit is at an appropriate size to avoid their destruction by one naturally occurring catastrophic event.

Primary Constituent Elements/Physical or Biological Features

Within this unit, the currently known primary constituent elements of critical habitat include, but are not limited to, the habitat components provided by:

- (i) Rock faces of nearly vertical, northfacing cliffs in diverse lowland or montane mesic forest and containing one or more of the following associated native plant species: *Lepidium serra*, *Lobelia niihauensis*, *Lysimachia* spp., *Melicope pallida*, *Metrosideros polymorpha*, *Neraudia kauaiensis*, *Nototrichium divaricatum*, *Poa mannii*, *Remya montgomeryi*, or *Wilkesia gymnoxiphium*; and
- (ii) Elevations between 335 and 1,290 (1,100 and 4,232 ft).

Special Management Considerations or Protections

Existing manmade features and structures within the boundaries of the mapped areas, such as buildings; roads; aqueducts and other water system features, including but not limited to pumping stations, irrigation ditches, pipelines, siphons, tunnels, water tanks, gaging stations, intakes, reservoirs, diversions, flumes, and wells; existing trails; campgrounds and their immediate surrounding landscaped area; scenic lookouts; remote helicopter landing sites; existing fences; telecommunications equipment towers and associated structures and equipment; electrical power transmission lines and distribution, and communication facilities and regularly maintained associated rights-of-way and access ways; radars, telemetry antennas; missile launch sites; arboreta and gardens; heiau (indigenous places of worship or shrines), and other archaeological sites; airports; other paved areas; and lawns and other rural residential landscaped areas do not contain one or more of the primary constituent elements described for each species in paragraph (b) of this section and therefore are not included in the critical habitat designations.

The following management actions are important: Feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas deemed essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas deemed essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Unknown (USFWS, 1995)

Reproduction Narrative

Adult: Little is known about the life history of *Stenogyne campanulata*. Flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors are unknown (USFWS, 1995).

Habitat Type

Adult: Moist forest cliff (NatureServe, 2015)

Habitat Narrative

Adult: Species inhabits moist forests on steep rocky slopes. (NatureServe, 2015). *Stenogyne campanulata* grows on the rock face of a nearly vertical, north-facing cliff at an elevation of 1,085 meters (3,560 feet). The associated shrubby vegetation includes native species such as *ahinahina*, *Lepidium serra* (anaunau), *Lysimachia glutinosa*, *olomea*, and *Remya montgomeryi*, and alien species such as prickly Florida blackberry and daisy fleabane (USFWS 1992a) (USFWS, 1995).

Dispersal/Migration**Motility/Mobility**

Adult: Unknown (USFWS, 1995)

Dispersal/Migration Narrative

Adult: Little is known about the life history of *Stenogyne campanulata*. Flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors are unknown (USFWS, 1995).

Population Information and Trends**Population Trends:**

Unknown (NatureServe, 2015)

Resiliency:

Low (NatureServe, 2015)

Representation:

Low (NatureServe, 2015)

Redundancy:

Low (NatureServe, 2015)

Number of Populations:

1 (USFWS, 2017)

Population Size:

20 (USFWS, 2017)

Population Narrative:

Fragility unknown. About 50 plants known. 5 current (between 1982 and 1997) and no historical occurrences. (NatureServe, 2015). Low resiliency, representation and redundancy are based on the fact that this species has one known population with ~50 individuals and a restricted habitat type (NatureServe, 2015). New Status Information: In addition to those populations cited in the previous 5-year review, new observations include the following: • At the time of the last 5-year review in 2009 there was assumed to be one population with an unknown number of individuals on inaccessible cliffs at Kalalau on the island of Kauai. Currently, it is estimated that there are 20 individuals in the same area (PEPP 2014; Clark 2016) (USFWS, 2017).

Threats and Stressors

Stressor: Feral goats and pigs (USFWS, 2009)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Herbivory and habitat degradation by feral goats and habitat disturbance by feral pigs is listed as a major threat to this species (USFWS, 2009).

Stressor: Invasive plants (USFWS, 2009)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Competition from introduced invasive plant species is listed as a major threat to this species (USFWS, 2009).

Stressor: Small population size (USFWS, 2009)

Exposure:

Response:

Consequence: Extinction

Narrative: Species like *Stenogyne campanulata* that are endemic to small portions of a single island are inherently more vulnerable to extinction than widespread species because of the higher risks posed to a few populations and individuals by random demographic fluctuations and localized catastrophes such as hurricanes, flooding and disease outbreaks (Factor E) (USFWS, 2009).

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: —Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Stenogyne campanulata* is extremely vulnerable to the impacts of climate change, with a vulnerability score of 0.83 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions are needed to conserve this taxon into the future (USFWS, 2017).

Recovery**Reclassification Criteria:**

Stenogyne campanulata is a shortlived perennial, and to be considered stabilized, which is the first step in recovering the species, the taxon must be managed to control threats (e.g., fenced) and be represented in an ex situ (off-site) collection (USFWS, 2009).

A minimum of three populations should be documented on the island of Kauai. Each of these populations must be naturally reproducing and increasing in number, with a minimum of 50 mature individuals per population (USFWS, 2009).

Recovery Actions:

- Recommendations for Future Actions: No new threats and no other significant new information regarding the species' biological status have been reported since the last 5-year review in 2009. Therefore, the following recommendations for future actions are reiterated for the 5-year review for 2017.
- Surveys and inventories—Survey geographical and historical range for a thorough current status of the species.
- Ungulate monitoring and control—Protect all occurrences against browsing and disturbances from feral ungulates. Construct and maintain small-scale fenced exclosures around all populations to prevent imminent extinction.
- Invasive plant monitoring and control—
 - o Control established ecosystem-altering nonnative invasive plant species around all populations.
 - o Control invasive nonnative plant species around all populations that compete with the species.
- Captive propagation for genetic storage and reintroduction—Continue propagation efforts for maintenance of genetic stock.
- Reintroduction and translocation—Continue to reintroduce individuals into suitable habitat within historical range that is being managed for known threats to this species.
- Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered throughout historic range to reduce impacts from landslides.
- Population biology research—Study *Stenogyne campanulata* populations to determine viable population size and structure, geographical distribution, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats (USFWS, 2017).

Conservation Measures and Best Management Practices:

- Continue collection of genetic resources for storage, future propagation and reintroducing into protected suitable habitat within historical range (USFWS, 2009).
- Construct exclosure fences to protect individuals from the negative impacts of feral pigs, and eradicate introduced invasive plant species within the exclosures (USFWS, 2009).
- Enhance current natural populations with appropriate genetic individuals (USFWS, 2009).
- Monitor success or failure of reintroductions (USFWS, 2009).
- Work with the Hawaii Division of Forestry and Wildlife to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species in Kalalau Valley (USFWS, 2009).
- Survey geographical and historical range for a thorough current status of the species (USFWS, 2009).
- Assess genetic variability within extant and ex situ populations (USFWS, 2009).
- Study *Stenogyne campanulata* populations with regard to population size and structure, geographical distribution, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats (USFWS, 2009).

- New Management Actions: • Individuals were outplanted in a fenced enclosure at Kalalau in 2012 and 2013 (PEPP 2012, 2013). Cuttings were taken for propagation at the Kokee Rare Plant Facility, which currently propagates six plants in its nursery (Clark 2016; DOFAW 2016; PEPP 2016). • NTBG has two individuals outplanted (which produce seeds) at the garden as a living collection. Three of these seeds are in the NTBG seed bank (NTBG 2008, 2017) (USFWS, 2017).

SPECIES ACCOUNT: *Stenogyne cranwelliae* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 11/29/2013; Pacific Region (R1) (USFWS, 2016)

Physical Description

A creeping vine. Leaves are ovate to suborbicular, 1.8 - 2.7 cm long. Flowers are 6 per verticillaster. Corollas are very pale pink (NatureServe, 2015).

Taxonomy

A member of the mint family (Lamiaceae) (USFWS, 2013). Belongs to the Hawaiian endemic genus of 20 species, this species is endemic to island of Hawaii (NatureServe, 2015).

Historical Range

Endemic to the Kohala Mountains on the island of Hawaii, Hawaiian islands (NatureServe, 2015). Historically, *S. cranwelliae* was known from the Kohala Mountains, in the montane wet and wet cliff ecosystems (Weller and Sakai 1999, p. 837) (USFWS, 2013).

Current Range

It currently occurs in the Kohala Mountains: roughly 1.5 sq. mi (2.5 sq. km) around the border between the Puu O Umi NAR and Kohala FR; Opaeha, in the Puu O Umi NAR; Puukapu, in the Puu O Umi NAR (6-by-6-ft (2-by-2- m) "patch" of individuals); the rim of Kawainui Gulch; along Kohakohau Stream, in the Puu O Umi NAR; and Waimanu Bog Unit in the Puu O Umi NAR (USFWS, 2013).

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Not available

Habitat Type

Adult: Terrestrial, riparian (USFWS, 2013)

Habitat Vegetation or Surface Water Classification

Adult: Montane wet forest, wet cliff forest (USFWS, 2013; NatureServe, 2015)

Environmental Specificity

Adult: Unknown (NatureServe, 2015)

Habitat Narrative

Adult: Inhabits wet forests. The environmental specificity is unknown (NatureServe, 2015). It occurs in the montane wet and wet cliff ecosystems, near streams and bogs (Perlman and Wood 1996, pp. 1–14; HBMP 2010k) (USFWS, 2013).

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Not available

Population Information and Trends

Population Trends:

Unknown; rediscovered in 1995 (NatureServe, 2015)

Resiliency:

Very low (inferred from USFWS, 2013; see current range/distribution)

Redundancy:

Low (inferred from USFWS, 2013)

Number of Populations:

6 (USFWS, 2013)

Population Size:

< 160 (USFWS, 2013)

Population Narrative:

The long term population trend is unknown; this species was thought to be extinct until rediscovered during surveys of the Kohala Mountains in 1995 (USFWS 2004) (NatureServe, 2015). Currently, there are 6 occurrences of *S. cranwelliae* totaling fewer than 160 individuals (USFWS, 2013).

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (pigs), nonnative plants, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by

nonnative pest species. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (pigs, rats, and slugs) is considered an ongoing threat to *Stenogyne cranwelliae* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

Stressor:

Exposure:

Response:

Consequence:

Narrative:

Stressor:

Exposure:

Response:

Consequence:

Narrative:

Recovery

Reclassification Criteria:

Not available - this species does not have a recovery plan.

Delisting Criteria:

Not available - this species does not have a recovery plan.

Recovery Actions:

- Not available - this species does not have a recovery plan.

Conservation Measures and Best Management Practices:

- The State's PEP Program identified *Stenogyne cranwelliae* as priority species for collection, propagation, and outplanting; however, due to other workload priorities and limited funding, they have not been able to carry out all of these actions (PEPP 2012, pp. 1–169). While the actions they have been able to implement are a step toward increasing the overall numbers and populations in the wild, these actions are insufficient to eliminate the threat of limited numbers at this time (USFWS, 2013).

SPECIES ACCOUNT: *Stenogyne kaalae* ssp. *sherffii* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/31/2016; Pacific Region (R1) (USFWS, 2016)

Physical Description

A climbing vine. Stems are quadrangular, 3 to 7 ft. (1 to 2 m) long, either glabrous or pubescent in grooves. Leaves are glossy and 5 in (12 cm) long. Flowers are very dark maroon and narrowly bell-shaped. Nutlets are 0.2 in (4 mm) long, fleshy, and dark purple (Weller and Sakai 1999, p. 838; Wagner and Weller 1999, pp. 448–449) (USFWS, 2015).

Taxonomy

A member of the mint family (Lamiaceae) (USFWS, 2015). New combination published in Novon 9: 448-449. 1999. Previously, *Stenogyne sherffii* was treated as a full species, but Wagner and Weller treat as a subspecies of *S. kaalae*. Kartesz (1999) included *S. sherffii* in the synonymy of *S. kaalae* without recognizing any infraspecific taxa in that species (NatureServe, 2015).

Historical Range

It is historically known from diverse mesic forest in the Waianae Mountains of Oahu and from the lowland wet ecosystem of the Koolau Mountains (although it was believed to be a different species, *S. sherffii*, until the mid-1990s). This subspecies occurred within a very small range in the northern Koolau Mountains, at Opaepa and Kawaihoa, but is now extinct in the wild (USFWS, 2015).

Current Range

Stenogyne kaalae ssp. *sherffii* occurs in the Koolau Mountains of Oahu (USFWS, 2015).

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Not available

Habitat Type

Adult: Terrestrial (USFWS, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Wet forest (USFWS, 2015)

Dependencies on Specific Environmental Elements

Adult: Lowland wet ecosystem (USFWS, 2015)

Geographic or Habitat Restraints or Barriers

Adult: 1,500 - 1,600 ft. elevation (USFWS, 2015)

Habitat Narrative

Adult: It occurs in diverse wet forest at 1,500 to 1,600 ft. (450 to 490 m), in the lowland wet ecosystem (Wagner and Weller 1999, pp. 448–449; HBMP 2010; U.S. Army 2014 database; TNCH 2007) (USFWS, 2015).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

No individuals are known to exist in the wild (USFWS, 2015)

Number of Populations:

1 outplanted (USFWS, 2014)

Population Size:

76 outplants (USFWS, 2014)

Population Narrative:

There are no known wild individuals; this species only exists in propagation (USFWS, 2015). Currently, *Stenogyne kaalae* ssp. *sherffii* is known only from cultivation at the Pahole Rare Plant Facility on Oahu and the University of California; and 76 outplanted individuals at Opaepa on Oahu (PEPP 2013, p. 194) (USFWS, 2014).

Threats and Stressors

Stressor: Feral pigs (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Feral pigs modify and destroy the habitat of *Stenogyne kaalae* ssp. *sherffii* on Oahu, with evidence of the activities of these animals reported in the areas where this subspecies occurred (HBMP 2010; PEPP 2014, p. 169) (USFWS, 2015).

Stressor: Nonnative plants (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Nonnative plants destroy and modify the native habitat of *S. kaalae* ssp. *sherffii*, and displace this subspecies and other native Hawaiian plants by competing for water, nutrients, light, and space, or they may produce chemicals that inhibit the growth of other plants (Smith 1985, pp. 180–250; Vitousek et al. 1987 in Cuddihy and Stone 1990, p. 74; HBMP 2010) (USFWS, 2015).

Stressor: Reduced reproductive vigor (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: This subspecies may experience reduced reproductive vigor due to low levels of genetic variability, leading to diminished capacity to adapt to environmental changes, thereby lessening the probability of its long-term persistence (Barrett and Kohn 1991, p. 4; Newman and Pilson 1997, p. 361) (USFWS, 2015).

Stressor: Climate change (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Climate change may result in alteration of the environmental conditions and ecosystems that support this species. *Stenogyne kaalae* ssp. *sherffii* may be unable to tolerate or respond to changes in temperature and moisture, or may be unable to move to areas with more suitable climatic regimes (Fortini et al. 2013, p. 90) (USFWS, 2015).

Stressor: Small population size/stochastic events (USFWS, 2014)

Exposure:

Response:

Consequence:

Narrative: *Stenogyne kaalae* ssp. *sherffii* is threatened by having a small number of individuals and populations. Species that are endemic to single islands or small island groups are inherently more vulnerable to extinction than are widespread species, because of the increased risk of genetic bottlenecks, random demographic fluctuations, climate change effects, and localized catastrophes such as hurricanes, drought, rockfalls, landslides, and disease outbreaks (Pimm et al. 1988, p. 757; Mangel and Tier 1994, p. 607). These problems are further magnified when populations are few and restricted to a very small geographic area, and when the number of individuals in each population is very small. Populations with these characteristics face an increased likelihood of stochastic extinction due to changes in demography, the environment, genetics, or other factors (Gilpin and Soule 1986, pp. 2434) (USFWS, 2014).

Recovery

Reclassification Criteria:

Not available - this species does not have a recovery plan.

Delisting Criteria:

Not available - this species does not have a recovery plan.

Recovery Actions:

- Not available - this species does not have a recovery plan.

Conservation Measures and Best Management Practices:

- PEPP efforts currently include propagation of *Stenogyne kaalae* ssp. *sherffii* for the purpose of restoration outplanting in its native range (PEPP 2013, pp. 8, 25, 194). Monitoring of habitat that could support this species is ongoing (PEPP 2013, pp. 8, 25, 194) (USFWS, 2014).
- Continue to survey for populations of *Stenogyne kaalae* ssp. *sherffii* in areas of potentially suitable habitat (USFWS, 2014).
- Continue propagation efforts for maintenance of genetic stock (USFWS, 2014).
- Reintroduce individuals into suitable habitat within historic range that is being managed for additional known threats (e.g., nonnative animals and plants) to this species (USFWS, 2014).

SPECIES ACCOUNT: *Stenogyne kanehoana* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 05/13/1992; Pacific Region (R1) (USFWS, 2016)

Physical Description

A perennial rambling vine with 1 - 2 m long stems. Flowers are whitish or pale yellow, with pinkish-purple lips (NatureServe, 2015).

Taxonomy

A member of the mint family (Lamiaceae) (USFWS, 2003).

Historical Range

Stenogyne kanehoana was known from the east ridge of Puu Kanehoa in the Waianae Mountains, near the summit of the ridge connecting Puu Kanehoa with Puu Hapapa to the north and Puu Kaua to the south, a distance totaling approximately 2.8 km (1.7 mi) (USFWS, 2003).

Current Range

Occurs in the southern Waianae Mountains (NatureServe, 2015). The population near the summit of Puu Kanehoa on privately owned land was found dead recently. An additional occurrence in Kaluaa Gulch was discovered in 2000 by Joan Yoshioka of TNCH (USFWS, 2003).

Critical Habitat Designated

Yes; 6/17/2003.

Legal Description

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Stenogyne kanehoana* under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Stenogyne kanehoana* (77 FR 57648-57862). The critical habitat designation includes 3 critical habitat units, which encompass approximately 5,884 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Stenogyne kanehoana* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Stenogyne kanehoana* includes 3 critical habitat units, covering one ecosystem type, which encompasses approximately 5,884 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Mesic—Units 1, 2, 3.

Oahu—Lowland Mesic—Unit 1 [4,448 ac (1,800 ha)]. This area consists of 3,565 ac (1,443 ha) of State land, 583 ac (236 ha) of City and County of Honolulu land, 22 ac (9 ha) of Federal land, and 277 ac (112 ha) of privately owned land in the lowland mesic ecosystem in the Waianae Mountains, encompassing a large area including the north slopes of Mt. Kaala, from the Pahole

NAR to the Kaala NAR, and south to the Waianae Kai Forest Reserve (FR). Oahu—Lowland Mesic—Unit 2 [1,063 ac (430 ha)]. This area consists of 1,063 ac (430 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Puuhapapa south to Puukaua. Oahu—Lowland Mesic—Unit 3 [353 ac (143 ha)]. This area consists of 353 ac (143 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Pohakea Pass to Kaiakuakai Gulch.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Stenogyne kanehoana* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Stenogyne kanehoana* occurs within the indicated ecosystem in the Waianae Mountain caldera complex:

Oahu—Lowland Mesic—Units 1, 2, 3. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. (E) Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. (F) Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Stenogyne kanehoana* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Asexual: vegetative (USFWS, 2013)

Lifespan

Adult: 7 - 12 (USFWS, 2003)

Breeding Season

Adult: Primarily February - March, sometimes January - April (USFWS, 2003)

Key Resources Needed for Breeding

Adult: Precipitation (USFWS, 2003)

Reproduction Narrative

Adult: This species is not setting seed or at least is not successfully reproducing (Herbst, 1992) (NatureServe, 2015). It is a short-lived perennial (fewer than 10 years). Three factors were

identified as affecting the rarity of *Stenogyne kanehoana*: Vegetative reproduction of *S. kanehoana* by long, rambling stems, which may root when contacting the ground, leading to the formation of additional plants; infrequent or inconsistent flowering; a large percentage of non-flowering or non-fruiting plants (U.S. Army Garrison 2008) (USFWS, 2013). *Stenogyne kanehoana* generally flowers from February through March, but flowering depends on precipitation, and flowers have been noted from January to as late as April. Fruits mature within six weeks. The lifespan of this species appears to be about seven to 12 years (USFWS, 2003).

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Low mesic *Metrosideros*, *Eugenia*, *Osmanthus* and *Myrsine* forest (NatureServe, 2015; USFWS, 2003)

Geographic or Habitat Restraints or Barriers

Adult: 1,834 - 3,831 ft. elevation (USFWS, 2003)

Habitat Narrative

Adult: Inhabits diverse mesic forest under canopy of *Metrosideros*, *Eugenia*, *Osmanthus* and *Myrsine* (NatureServe, 2015). It is found in lowland mesic forest between 559 and 1,168 m (1,834 and 3,831 ft.) elevation (USFWS, 2003).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Not available

Resiliency:

Very low (inferred from USFWS, 2013)

Representation:

Very low (inferred from USFWS, 2013)

Redundancy:

Very low (inferred from USFWS, 2013)

Number of Populations:

1 (USFWS, 2013)

Population Size:

1 (USFWS, 2013)

Population Narrative:

There is one wild individual and 124 outplanted individuals (USFWS, 2013).

Threats and Stressors

Stressor: Climate change (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Climate change may also pose a threat to this species. However, current climate change analyses in the Pacific Islands lack sufficient spatial resolution to make predictions on impacts to this species (USFWS, 2013).

Stressor: Disease (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: An undetermined species of powdery mildew has been identified as a new threat to *Stenogyne kanehoana* (U.S. Army Garrison 2008) (USFWS, 2013).

Stressor: Predation (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Invasive slugs have negatively impacted the regeneration of *Stenogyne kanehoana* (U.S. Army Garrison 2010) (USFWS, 2013).

Stressor: Nonnative plants (USFWS, 2003)

Exposure:

Response:

Consequence:

Narrative: Competition for space, water, light, and nutrients by the nonnative species *Clidemia hirta*, *Paspalum conjugatum*, *Passiflora suberosa*, *Psidium cattleianum*, and *Schinus terebinthifolius* (USFWS, 2003).

Stressor: Small population size (USFWS, 2003)

Exposure:

Response:

Consequence:

Narrative: The extremely small number of individual plants and their restricted distribution increases the potential for extinction from naturally occurring events (USFWS, 2003).

Stressor: Habitat degradation (USFWS, 2003)

Exposure:

Response:

Consequence:

Narrative: Habitat degradation by feral pigs, predation by the two spotted leafhopper, and trampling by hikers are also thought to be threats to this species (HINHP Database 2001; Service 1998b; 57 FR 20592) (USFWS, 2003).

Recovery

Reclassification Criteria:

1. A total of five to seven populations should be documented on Oahu and at least one other island where they now occur or occurred historically (USFWS, 1998).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure, with a minimum of 300 mature individuals per population (for short-lived perennials) (USFWS, 1998).
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 1998).

Delisting Criteria:

1. A total of 8 to 10 populations should be documented on Oahu and at least one other island where they now occur or occurred historically (USFWS, 1998).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure, with a minimum of 300 mature individuals per population (for short-lived perennials) (USFWS, 1998).
3. Each population should persist at this level for a minimum of 5 consecutive years (USFWS, 1998).

Recovery Actions:

- Protect habitat and control threats (USFWS, 1998).
- Expand existing wild populations (USFWS, 1998).
- Conduct essential research (USFWS, 1998).
- Develop and maintain monitoring plans (USFWS, 1998).
- Reestablish wild populations within historic range (USFWS, 1998).
- Validate and revise recovery criteria (USFWS, 1998).
- Conduct surveys (USFWS, 1998).
- Maintain adequate genetic stock (USFWS, 1998).
- Enhance wild populations and establish of new populations (USFWS, 1998).

Conservation Measures and Best Management Practices:

- Captive propagation for genetic storage and reintroduction: Collect cuttings or seed from tagged individuals, keeping close track of the maternal source for use in ex situ propagation. Manage nursery collections to promote flowering. Continue research in pollination and continue to hand-pollinate. This includes collecting pollen, testing pollen viability, and pollinating all flowering plants, both in situ and ex situ (USFWS, 2013).
- Reintroduction / translocation: While surveying for new populations or reintroduced populations, determine which sites are least invaded by invasive introduced plant species and which appear to

have the highest likelihood of maintaining new reintroductions. Continue to reintroduce the species back into its known historical range (USFWS, 2013).

- Ungulate exclosures – Construct, maintain, and monitor ungulate-proof exclosures around each population (USFWS, 2013).
- Ecosystem-altering invasive plant species control – Control invasive introduced plant species around all populations. Continue to target all canopy weeds along the catchment ridge of Kalauu to maintain native dominated matrix with care to avoid damaging the *Dicranopteris linearis* (uluhe) understory which is needed for successful growth of *Stenogyne kanehoana* (U.S. Army Garrison 2011) (USFWS, 2013).
- Threats research: Invasive slugs negatively impacted the regeneration of *Stenogyne kanehoana* (U.S. Army Garrison 2010). In 2009, slug control research using Sluggo, a slug and snail bait, began in the field at the Kahanahaiki population unit on U.S. Army lands (U.S. Army Garrison 2009, 2010). In October 2010, Sluggo was registered for use by the Hawaii Department of Agriculture (U.S. Army Garrison 2010) for control of slugs and nonnative snails in forested areas for the protection of native, threatened, and endangered plants of Hawaii. However, since native snails also exist in areas where threatened and endangered plants occur, additional research is need to find a control method that can be used in areas where native snail species co-occur with listed plants (USFWS, 2013).
- Surveys / inventories – Survey geographical and historical range for a thorough current assessment of the species status (USFWS, 2013).
- Site / area / habitat protection – Develop and implement effective measures to reduce the impact of military activities and hikers (USFWS, 2013).
- Fire protection – Develop and implement fire management plans for all wild and reintroduced populations (USFWS, 2013).
- Alliance and partnership development - Enhance coordination and collaboration among other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2013).
- Population biology research – Study *Stenogyne kanehoana* with regard to population size and structure, geographical distribution, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats (USFWS, 2013).
- Threats research: Assess the modeled effects of climate change on this species, and use the results to determine future landscape needed for the recovery of the species. Investigate appropriate controls for powdery mildew outbreaks. Implement controls for invasive slugs around *Stenogyne kanehoana* populations (USFWS, 2013).

SPECIES ACCOUNT: *Stenogyne kauaulaensis* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 06/27/2013; Pacific Region (R1) (USFWS, 2016)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Stenogyne kauaulaensis* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes four detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Stenogyne kauaulaensis* includes four CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Montane Mesic—Unit 2 (and) *Palmeria dolei*—Unit 19—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 19— Montane Mesic This area consists of 124 ac (50 ha) of State land at Helu and the upper reaches of Puehuhunui on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plants *Ctenitis squamigera*, *Cyanea magnicalyx*, *Diplazium molokaiense*, *Lysimachia lydgatei*, *Remya mauiensis*, and *Santalum haleakalae* var. *lanaiense*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 2 is not known to be occupied by the plants *Geranium hillebrandii*, *Huperzia mannii*, *Stenogyne kauaulaensis*, or *Zanthoxylum hawaiiense*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 3 (and) *Palmeria dolei*—Unit 20—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 20— Montane Mesic This area consists of 174 ac (70 ha) of State land at Lihau on the southwestern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plant *Geranium hillebrandii*, and contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 3 is not known to be occupied by the plants *Ctenitis squamigera*, *Cyanea magnicalyx*, *Diplazium molokaiense*, *Huperzia mannii*, *Lysimachia lydgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Stenogyne kauaulaensis*, or *Zanthoxylum hawaiiense*, or by the forest birds, the

akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 4 (and) *Palmeria dolei*—Unit 21—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 21— Montane Mesic This area consists of 72 ac (29 ha) of State land at Halepohaku on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5).

Although Maui—Montane Mesic—Unit 4 is not known to be occupied by the plants *Ctenitis squamigera*, *Cyanea magnicalyx*, *Diplazium molokaiense*, *Geranium hillebrandii*, *Huperzia mannii*, *Lysimachia lydgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Stenogyne kauaulaensis*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 5 (and) *Palmeria dolei*—Unit 22—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 22— Montane Mesic This area consists of 170 ac (69 ha) of State land at the upper reaches of Manawainui Gulch on the southeastern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plants *Remya mauiensis* and *Santalum haleakalae* var. *lanaiense*, and contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 5 is not known to be occupied by the plants *Ctenitis squamigera*, *Cyanea magnicalyx*, *Diplazium molokaiense*, *Geranium hillebrandii*, *Huperzia mannii*, *Lysimachia lydgatei*, *Stenogyne kauaulaensis*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 3 (and) *Palmeria dolei*—Unit 20—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 20— Montane Mesic This area consists of 174 ac (70 ha) of State land at Lihau on the southwestern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plant *Geranium hillebrandii*, and contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 3 is not known to be occupied by the plants *Ctenitis squamigera*, *Cyanea magnicalyx*, *Diplazium*

molokaiense, *Huperzia mannii*, *Lysimachia lydgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Stenogyne kauaulaensis*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Stenogyne kauaulaensis* critical habitat consists of one component. Montane mesic (west Maui) (81 FR 17790-18110):

Ecosystem: Montane Mesic. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Deep ash deposits, thin silty loams. Canopy: *Acacia*, *Ilex*, *Metrosideros*, *Myrsine*, *Nestegis*, *Nothocestrum*, *Pisonia*, *Pittosporum*, *Psychotria*, *Sophora*, *Zanthoxylum*. Subcanopy: *Alyxia*, *Charpentiera*, *Coprosma*, *Dodonaea*, *Kadua*, *Labordia*, *Leptecophylla*, *Phyllostegia*, *Vaccinium*. Understory: Ferns, *Carex*, *Peperomia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent

elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkii*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: No information found

Habitat Type

Adult: Montane mesic ecosystem (USFWS, 2016)

Habitat Narrative

Adult: *Stenogyne kauaulaensis* (NCN), a short-lived perennial vine in the mint family (Lamiaceae), occurs on Maui. This recently described (2008) plant is found only along the southeastern rim of Kauaula Valley, in the montane mesic ecosystem on west Maui (USFWS, 2016).

Dispersal/Migration**Motility/Mobility**

Adult: No information found

Population Information and Trends**Population Trends:**

No information found.

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative plants, fire, drought, landslides, rockfalls, and hurricanes. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Fire can destroy dormant seeds and plants, even in steep and inaccessible areas. Successive fires can remove habitat for native species by altering microclimate conditions favorable to alien plants. Drought, landslides, and rockfalls destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:**Consequence:**

Narrative: Predation and herbivory by nonnative animal species (slugs) is considered an ongoing threat to *Stenogyne kauaulaensis* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

Stressor: Small populations (USFWS, 2013)

Exposure:**Response:****Consequence:**

Narrative: *Stenogyne kauaulaensis* faces the threat of limited numbers (i.e., there are fewer than 50 individuals in the wild). *Stenogyne kauaulaensis* is only known from three individuals. These plants face imminent threats from landslides and rockfalls because of their location on steep slopes, and from drought and fire in the montane mesic ecosystem on west Maui (USFWS, 2013).

Recovery**Recovery Actions:**

- There is no recovery plan for this species.

SPECIES ACCOUNT: *Stenogyne kealiae* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 05/13/2010; Pacific Region (R1)

Physical Description

A trailing vine. Leaves are thinly to moderately coriaceous, broadly lanceolate to elliptic-lanceolate, 8 - 15 cm long. Flowers are 3 - 5 per verticillaster. Corollas are deep pinkish purple (NatureServe, 2015).

Taxonomy

A member of the mint family (Lamiaceae) (USFWS, 2010b). The supplement to the revised Manual of the Flowering Plants of Hawaii (Wagner et al. 1999) resurrects this species from synonymy of *S. purpurea*. Kartesz lists it in synonymy of *S. purpurea* in his 1994 checklist, but recognizes it as distinct in the 1999 Synthesis (NatureServe, 2015).

Historical Range

Historically, this species occurred at Pohakupili near Kealia in the Kealia Forest Reserve on the island of Kauai (USFWS, 2010b).

Current Range

Currently, this species occurs at Honopu, Kalalau, Malamalamaiki, Pohakupili, and Wainiha (Kauai) (USFWS, 2010b).

Critical Habitat Designated

Yes; 4/13/2010.

Legal Description

On April 13, 2010, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Stenogyne kealiae* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes 11 critical habitat units (CHUs), in Hawaii (75 FR 18960-19165).

Critical Habitat Designation

The critical habitat designation for *Stenogyne kealiae* includes 11 CHUs in Kauai County, Hawaii (75 FR 18960-19165).

Kauai—Lowland Wet—Section 1: Lowland Wet—Section 1 consists of 1,164 ac (471 ha) in the lowland wet ecosystem (117 ac (47.4 ha) on State land; 1,047 ac (424 ha) on private land), including wet forest extending from Kulanalilia into Limahuli Valley to Honoanapali, in the Halelea Forest Reserve (Figure 2-A). The section includes 1,099 ac (445 ha) of State and privately owned land within previously designated critical habitat and 65 ac (26 ha) of newly designated critical habitat on private land. The area that falls within designated critical habitat lies within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and newly designated Critical Habitat Unit 20, Map 217c. This section is occupied by the plants *Chamaesyce remyi* var. *remyi*, *Charpentiera densiflora*, *Labordia helleri*, and *Phyllostegia renovans*. This section also contains unoccupied habitat that is essential to the conservation of these four species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section

includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet–Section 1 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhliewa*, *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Melicope paniculata*, *M. puberula*, *Platydesma rostrata*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 2: Lowland Wet–Section 2 consists of 172 ac (70 ha) in the lowland wet ecosystem, including wet forest extending from Alealau to Pohakea, within the Hono o Na Pali NAR and the Na Pali Coast State Park (Figure 2-A, above). The entire section is State-owned and within previously designated critical habitat; it falls within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and is occupied by the plant *Melicope puberula*. This section also contains unoccupied habitat that is essential to the conservation of this species by providing the physical and biological features necessary for the expansion of the existing wild population. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet–Section 2 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *C. remyi* var. *remyi*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhliewa*, *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Labordia helleri*, *Melicope paniculata*, *Phyllostegia renovans*, *Platydesma rostrata*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 3: Lowland Wet–Section 3 consists of 756 ac (306 ha) in the lowland wet ecosystem, including wet forest in upper Wainiha Valley, on privately owned land in the Halelea Forest Reserve (Figure 2-B). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and is occupied by the plants *Chamaesyce remyi* var. *kauaiensis*, *Cyrtandra oenobarba*, *Melicope puberula*, *Phyllostegia renovans*, and *Stenogyne kealiae*. This section also contains unoccupied habitat that is essential to the conservation of these five species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet–Section 3 is not known to be occupied by the species *Chamaesyce remyi* var. *remyi*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhliewa*, *Dubautia imbricata* ssp. *imbricata*, *Labordia helleri*, *Melicope paniculata*, *Platydesma rostrata*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 4: Lowland Wet—Section 4 consists of 591 ac (239 ha) in the lowland wet ecosystem, including wet forest at the head of Lumahai Valley, on State (10 ac, 4.1 ha) and privately owned (581 ac, 235 ha) land in the Halelea Forest Reserve (Figure 2-B, above). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and is occupied by the plants *Chamaesyce remyi* var. *remyi*, *Cyrtandra oenobarba*, *Melicope paniculata*, *Phyllostegia renovans*, and *Platydesma rostrata*. This section also contains unoccupied habitat that is essential to the conservation of these five species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet—Section 4 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhliewa*, *Dubautia imbricata* ssp. *imbricata*, *Labordia helleri*, *Melicope puberula*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population numbers of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 5: Lowland Wet—Section 5 consists of 1,541 ac (624 ha) in the lowland wet ecosystem, including wet forest extending from the headwaters of the Wailua River at “Blue Hole” south to Iole, on State (442 ac, 179 ha) and privately owned (1,099 ac, 445 ha) land in the Lihue-Koloa Forest Reserve (Figure 2-C). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 10 of 50 CFR 17.99(a)(1), Map 36a, and is occupied by the plants *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Melicope paniculata*, *Phyllostegia renovans*, and *Platydesma rostrata*. This section also contains unoccupied habitat that is essential to the conservation of these five species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet—Section 5 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *C. remyi* var. *remyi*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhliewa*, *Labordia helleri*, *Melicope puberula*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 6: Lowland Wet—Section 6 consists of 789 ac (319 ha) in the lowland wet ecosystem, including wet forest extending from Kapalaoa to Kanaele Bog and Lauahihaihai in the Wahiawa Mountains, on State (134 ac, 54 ha) and privately owned (655 ac, 265 ha) land in the Lihue-Koloa Forest Reserve (Figure 2-D). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 10 of 50 CFR 17.99(a)(1), Map 36a, and is occupied by the plants *Chamaesyce remyi* var. *remyi*, *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Platydesma rostrata*, and *Tetraplasandra bisattenuata*. This

section also contains unoccupied habitat that is essential to the conservation of these five species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet—Section 6 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhliewa*, *Labordia helleri*, *Melicope paniculata*, *M. puberula*, *Phyllostegia renovans*, *Stenogyne kealiae*, and *Tetraplasandra flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Montane Mesic—Section 1: Montane Mesic—Section 1 consists of 2,423 ac (980 ha) in the montane mesic ecosystem, including the area above Honopu Valley to Mahanaloa Valley, on State owned land in Kokee State Park, the Na Pali-Kona Forest Reserve, and Kuia NAR (Figure 3-A). The entire section is within previously designated critical habitat for the plant species, falling within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70c, and is occupied by the plants *Chamaesyce remyi* var. *remyi*, *Labordia helleri*, *Myrsine knudsenii*, *Platydesma rostrata*, *Psychotria grandiflora*, *Stenogyne kealiae*, and *Tetraplasandra flynnii*. This section is also occupied by the akekee and the picture-wing fly; maps of critical habitat for these species can be found at 50 CFR 17.95(b) for the akekee and akikiki (Unit 1—Montane Mesic), and at 50 CFR 17.95(i) for the picture-wing fly (Unit 1—Montane Mesic). This section also contains unoccupied habitat that is essential to the conservation of these nine species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the montane mesic forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the montane mesic ecosystem (Table 3), as well as species-specific PCEs for the akekee and akikiki (arthropod prey) and picture-wing fly (the larval-stage host plants, *Cheirodendron* sp. and *Tetraplasandra* sp.). Although Montane Mesic—Section 1 is not known to be occupied by the species *Diellia mannii*, *Myrsine mezii*, and the akikiki, we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Montane Mesic—Section 2: Montane Mesic—Section 2 consists of 376 ac (152 ha) in the montane mesic ecosystem and includes a portion of the area surrounding a tributary of Nawaimaka Stream east to Kumuwela Ridge (Figure 3-A, above). The entire section is State-owned within Kokee State Park, and includes 8 ac (3 ha) of newly designated critical habitat. This section is occupied by *Diellia mannii* and the picture-wing fly *Drosophila sharpi*, and includes the montane mesic forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the montane mesic ecosystem (Table 3), as well as the larval-stage host plants (*Cheirodendron* sp. and *Tetraplasandra* sp.) associated with the picture-wing fly. This section also contains unoccupied habitat that is essential to the conservation of these two species by providing the physical and biological features necessary for the expansion of the existing wild populations. Although Montane Mesic—Section 2 is not known to be occupied by the

plants *Chamaesyce remyi* var. *remyi*, *Labordia helleri*, *Myrsine knudsenii*, *Myrsine mezii*, *Platydesma rostrata*, *Psychotria grandiflora*, *Stenogyne kealiae*, and *Tetraplasandra flynnii*, or by the birds the akekee and akikiki, we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historical range, as well as species-specific PCEs for the akekee and akikiki (arthropod prey). Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery. For the plants, that portion of the section that overlies previously designated critical habitat falls within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70c. The previously undesignated land comprises Critical Habitat Unit 21 of 50 CFR 17.99(a)(1), Map 217d. Maps of critical habitat for the akekee and akikiki can be found at 50 CFR 17.95(b) (Unit 2—Montane Mesic), and for the picture-wing fly at 50 CFR 17.95(i) (Unit 2—Montane Mesic).

Kauai—Montane Mesic—Section 3: Montane Mesic—Section 3 consists of 139 ac (56 ha) in the montane mesic ecosystem, including the upper portion of the Nawaimaka Valley up to Kapukapaia Ridge, on State-owned land in the Na Pali-Kona Forest Reserve (Figure 3-B). This section is not in previously designated critical habitat and includes the only montane mesic forest occupied by the plant *Myrsine mezii*, and the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the montane mesic ecosystem (Table 3). This section also contains unoccupied habitat that is essential to the conservation of this species by providing the physical and biological features necessary for the expansion of the existing wild population. Although Montane Mesic—Section 3 is not known to be occupied by the plants *Chamaesyce remyi* var. *remyi*, *Labordia helleri*, *Myrsine knudsenii*, *Myrsine mezii*, *Platydesma rostrata*, *Psychotria grandiflora*, *Stenogyne kealiae*, and *Tetraplasandra flynnii*; by the birds the akekee and akikiki; or by the picturewing fly *Drosophila sharpi*, we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. It also provides for the species-specific PCEs for the akekee and akikiki (arthropod prey) and the larval-stage host plants (*Cheirodendron* sp. and *Tetraplasandra* sp.) associated with *D. sharpi*. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery. For the plants, this section comprises Critical Habitat Unit 22 of 50 CFR 17.99(a)(1), Map 217e. Maps of critical habitat for the akekee and akikiki can be found at 50 CFR 17.95(b) (Unit 3—Montane Mesic), and for the picturewing fly at 50 CFR 17.95(i) (Unit 3—Montane Mesic).

Kauai—Dry Cliff—Section 1: Dry Cliff—Section 1 consists of 404 ac (163 ha) in the dry cliff ecosystem, along cliffs from Kalanu to Pihea peak, within the Na Pali Coast State Park (Figure 5). The entire section is within previously designated critical habitat and is State-owned; it falls within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 67a. This section is occupied by the plants *Chamaesyce eleanoriae*, *Lysimachia scopulensis*, *Schiedea attenuata*, and *Stenogyne kealiae*. This section includes the dry cliffs, the moisture regime, and subcanopy and understory plant species identified as PCEs in the dry cliff ecosystem (Table 3).

Kauai—Dry Cliff—Section 2: Dry Cliff—Section 2 consists of 309 ac (125 ha) in the dry cliff ecosystem, including cliffs and ridges extending from Kanakou to Keanapuka and along Manono Ridge, surrounding the hanging valley Pohakuao, in the Na Pali Coast State Park (Figure 5, above).

The entire section is State-owned and within previously designated critical habitat; it falls within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 67a. This section is occupied by the plant *Chamaesyce eleanoriae* and includes the dry cliffs, the moisture regime, and subcanopy and understory plant species identified as PCEs in the dry cliff ecosystem (Table 3). Although Dry Cliff - Section 3 is not known to be occupied by the plants *Lysimachia scopulensis*, *Schiedea attenuata*, and *Stenogyne kealiae*, we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range of the species. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Stenogyne kealiae* critical habitat consists of three components (Lowland wet, Montane mesic and Dry cliff) (75 FR 18960-19165):

Ecosystem: Lowland Wet. Elevation: <3,000 ft (<914 m). Annual precipitation: >75 in (>190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Ecosystem: Montane Mesic. Elevation: 3,300–5,243 ft (914–1,598 m). Annual precipitation: 50–75 in (127–190 cm). Substrate: weathered aa lava, rocky mucks, thin silty loams, deep volcanic ash soils. Canopy: *Acacia*, *Metrosideros*, *Psychotria*, *Tetraplasandra*, *Zanthoxylum*. Subcanopy: *Cheirodendron*, *Coprosma*, *Kadua*, *Ilex*, *Myoporum*, *Myrsine*. Understory: *Bidens*, *Dryopteris*, *Leptecophylla*, *Poa*, *Scaevola*, *Sophora*.

Ecosystem: Dry Cliff. Elevation: unrestricted. Annual precipitation: < 75 in (<190 cm). Substrate: >65 degree slope, rocky talus. Canopy: None. Subcanopy: *Antidesma*, *Chamaesyce*, *Diospyros*, *Dodonaea*. Understory: *Bidens*, *Eragrostis*, *Melanthera*, *Schiedea*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contains the physical or biological features essential to the conservation of the species that may require special management considerations or protection. It is recognized that activities in and adjacent to areas designated as critical habitat may affect one or more of the PCEs found in these areas. Special management is needed throughout each of the designated critical habitat units. The following discussion of special management needs is applicable to each of the 47 Kauai species for which we are designating critical habitat. These 47 Kauai species include 41 species that are currently found in the wild, and 6 species that are not currently extant in the wild. For each of the 41 Kauai species found in the wild, we have determined that the features essential to their conservation are primarily dependent on maintaining the successful functioning of the ecosystem(s) in which they occur (Tables 3 and 4). In some cases, additional species-specific primary constituent elements have also been identified (Table 4). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical and biological features essential to the conservation of all of these species include

habitat destruction and modification by feral ungulates, predation by nonnative species, competition with nonnative species, hurricanes, landslides, flooding, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by feral ungulates (pigs, goats, and black-tailed deer). Feral ungulates also impact the habitat through predation and trampling. The State of Hawaii provides game mammal (feral pigs and goats, and black-tailed deer) hunting opportunities on one or more State-designated public hunting areas on the islands of Kauai, Oahu, Maui, Molokai, Lanai, and Hawaii (Hawaii Administrative Rules 13-123; DLNR 2009a). Management of game animals by the State ranges from providing maximal sustained public hunting opportunities and benefits (e.g., “sustained yield”) in some areas to game animal removal by State staff, or their designees, in other areas (DLNR 2009b). Public hunting areas are not fenced, and game mammals have unrestricted access to most areas across the landscape, regardless of the underlying land use designation. While fences are sometimes built to provide protection from game mammals to the natural resources within the fenced area, the current number and locations of fences are not sufficient to prevent habitat destruction and degradation. Without special management, the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new alien plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species will help to address the threat presented by fire to three critical habitat areas in particular (Kauai—Lowland Mesic— Section 1, Kauai—Montane Mesic— Section 2, and Kauai—Dry Cliff— Section 1; see Table 5 for corresponding CFR unit numbers). This threat is primarily due to the presence of nonnative species, such as the grasses *Andropogon* sp. and *Setaria* sp., which increase the fuel load and quickly regenerate after a fire. These species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D’Antonio and Vitousek 1992, pp. 64– 66; Brooks et al. 2004, p. 680). In addition, five sections (Kauai—Dry Cliff—Section 1, Kauai—Dry Cliff— Section 2, Kauai—Wet Cliff—Section 1, Kauai—Wet Cliff—Section 2, and Kauai—Wet Cliff—Section 3; see Table 5 for corresponding CFR unit numbers) may require special management to reduce the threat of landslides and flooding, which threaten to further degrade the habitat conditions and have the potential to eliminate some species in their entirety (e.g., *Schiedea attenuata*). In summary, we find that each of the areas we are designating as critical habitat contains features essential to the conservation of the species that may require special management considerations or protection to ensure the conservation of the 47 Kauai species. These special management considerations and protections are required to preserve and maintain the essential features provided to these species by the ecosystems upon which they depend. A more detailed discussion of each of these threats is presented above, under the Summary of Factors Affecting the Species section.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: Not available

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Mesic to wet shrublands and forests (NatureServe, 2015); dry cliff, lowland wet, and montane mesic ecosystems (USFWS, 2010b)

Geographic or Habitat Restraints or Barriers

Adult: 2,231 - 4,100 ft. elevation (USFWS, 2010b)

Habitat Narrative

Adult: Inhabits mesic to wet shrublands and forests (NatureServe, 2015). It occurs in the dry cliff, lowland wet, and montane mesic ecosystems, in *Metrosideros polymorpha* forest, *M. polymorpha*-*Acacia koa* forest, and *M. polymorpha*-*Dicranopteris linearis* shrubland, at elevations between 3,550 and 4,100 ft. (1,082 and 1,250 m) (Wagner and Weller 1991, p. 51; TNCH 2007). One population (Wainiha), however, is reported between 2,231 and 2,707 ft. (680 and 825 m) elevation (HBMP 2007) (USFWS, 2010b).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Unknown (NatureServe, 2015)

Species Trends:

Declining (NatureServe, 2015)

Resiliency:

Low (inferred from USFWS, 2010b; see current range/distribution)

Redundancy:

Low (inferred from USFWS, 2010a)

Number of Populations:

5 (USFWS, 2010a)

Population Size:

18 (USFWS, 2017)

Population Narrative:

The long term population trend is unknown. Known declining due to numerous threats, exact percentage is unknown (HBMP 2007) (NatureServe, 2015). There are currently 18 wild individuals of *Stenogyne kealiae* in four locations. Propagation and outplanting efforts are ongoing (USFWS, 2017).

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from non-native plants, pigs, goats, deer, fire, hurricanes, landslides, and climate change. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Landslides destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. Fire can destroy dormant seeds and plants, even in steep in inaccessible areas. Successive fires can remove habitat for native species by altering microclimate conditions favorable to alien plants.

Stressor: Predation and herbivory (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species present an immediate and significant threat to *Stenogyne kealiae* throughout its range due to documented browsing and trampling by pigs, goats, and deer, and documented mechanical damage by rats (USFWS, 2010).

Response:**Consequence:****Narrative:*****Recovery*****Reclassification Criteria:**

Not available - recovery plan not yet developed.

Delisting Criteria:

Not available - recovery plan not yet developed.

Recovery Actions:

- Assess the distribution, current status, and potential future distribution of existing ecosystems and determine the most important sites for ecosystem management. Make use of landscape modeling, spatial analysis, remote sensing technology, and existing survey data to better understand species distributions and priority ecosystem areas for targeting future surveys (USFWS, 2010a).
- Initiate control of ecosystem-modifying threats, such as ungulates and invasive introduced plant species, as soon as possible within the highest priority management units (USFWS, 2010a).
- Stabilize and protect remaining extant populations of the 45 plants and 2 bird species. Conduct systematic, island-wide surveys for additional populations. Make use of landscape modeling, spatial analysis, remote sensing technology, and existing survey data to better understand distributions and priority areas for targeting future surveys (USFWS, 2010a).
- Restore and maintain multiple viable populations of the 45 plants and 2 bird species by protecting, restoring, and maintaining existing habitats or areas with potential for restoration that are within their historical range (USFWS, 2010a).
- Conduct research on control methods for introduced slugs and avian malaria (USFWS, 2010a).
- Develop an augmentation plan to collect and propagate seed from the 45 plant species that can later be utilized for population restoration, augmentation, and reintroduction (USFWS, 2010a).
- Prevent the influx of new pests and invasive species into recovery areas. Increase the efforts of the Kauai Invasive Species Committee and improve border security (USFWS, 2010a).
- Prioritize research studies that will provide information and tools aiding in the mitigation of known threats and limiting factors of the species and ecosystems (USFWS, 2010a).
- Increase outreach effort and coordination with State agencies and private landowners regarding ecosystem conservation. Promote opportunities to assist in the recovery of these species through Habitat Conservation Plans, Safe Harbor Agreements, and through various conservation partnerships funded by State and Federal agencies and private organizations (USFWS, 2010a).
- RECOMMENDATIONS FOR FUTURE ACTIONS: • Surveys and inventories—Continue to survey for populations of *Stenogyne kealiae* in areas of potentially suitable habitat. • Ungulate monitoring and control—Protect all occurrences against browsing and disturbances from feral ungulates. Construct and maintain fenced exclosures around existing populations to prevent imminent extinction. • Invasive plant monitoring and control

o Control established ecosystem-altering nonnative invasive plant species around all populations. o Control invasive nonnative plant species around all populations that compete with the species. • Predator and herbivore monitoring and control—Implement effective measures to control rodents around all populations. • Invertebrate predation or herbivory control—Study *Stenogyne kealiae* populations to determine level of threat from invertebrate predation or herbivory, effective control actions, and any additional needed recovery actions. • Captive propagation for genetic storage and reintroduction—Continue collection and propagation efforts for maintenance of genetic stock. • Reintroduction and translocation—Continue reintroduction of individuals into suitable habitat within historic range that is being managed for known threats to this species. • Population biology research—Study *Stenogyne kealiae* populations to determine viable population size and structure, geographical distribution, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. • Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered throughout historic range to reduce impacts from landslides and storms. • Based on the recovery criteria above, consider development of a recovery plan (USFWS, 2017).

Conservation Measures and Best Management Practices:

- This species is monitored by the Plant Extinction Prevention Program, which focuses on those plant species with fewer than 50 individuals remaining in the wild. The goal of the program is to achieve the general interim recovery guidelines set by the Hawaii and Pacific Plants Recovery Coordinating Committee (1994), which are: 3 populations of 25 (long-lived species), 50 (short-lived), or 100 (annual) mature, reproducing individuals; all threats to those populations being managed; and all individuals are represented in genetic storage (USFWS, 2010a).
- This species is currently in controlled propagation for genetic storage and/or reintroduction efforts (USFWS, 2010a).

SPECIES ACCOUNT: *Stephanomeria malheurensis* (Malheur wire-lettuce)

Species Taxonomic and Listing Information

Listing Status: Endangered; 12/10/1982; Pacific Region (R1) (USFWS, 2016)

Physical Description

Stephanomeria malheurensis is an annual up to 50 cm tall, with a basal rosette of glabrous leaves; stem single, much branched, with scale-like leaves; heads numerous clustered or single on short peduncles; florets 5-11 per head, the ligules pink, white, or rarely orange-yellow. Pappus bristles are connate in groups of 2 to 4 at the base. (USFWS, 1990)

Taxonomy

At the time of listing, the Malheur wire lettuce was considered to be the species *S. malheurensis*. Malheur wire lettuce was first discovered in 1966 and subsequently described by Gottlieb in 1978 (Gottlieb 1978). Gottlieb used prior publications (Gottlieb 1973, 1973a, 1974, 1977, and 1978) to support the hypothesis that the diploid annual plant referred to as “*malheurensis*” evolved from the population of *S. exigua* subsp. *coronaria* (Greene). Gottlieb examined morphometric and meristic characters in samples and determined that the data supports classification of Malheur wire lettuce as a distinct species (Gottlieb 1978). Additional research and published results support the classification of Malheur wire lettuce as a species (Gottlieb 1977a, 1991, 2003, Gottlieb and Bennett 1983, Brauner and Gottlieb 1987, Brauner and Gottlieb 1989, and Joongku Lee et al. 2002). Malheur wire lettuce is accepted as a species by Integrated Taxonomic Information System (ITIS) and The International Compositae Alliance through the Smithsonian Institution in collaboration with the USDA National Plant Data Center and is listed on the ITIS website (Integrated Taxonomic Information System 2011). (USFWS, 2011)

Historical Range

The maximum historical range is unknown, (USFWS, 2011)

Current Range

Endemic to central Harney Co., Oregon, U.S.A., in an area called the Narrows, near Malheur and Harney lakes. (USFWS, 2011). Specifically, it is found on a broad hill top on BLM lands near Narrows, Oregon (south of Burns in Harney County), and has never been found outside of this one site despite efforts to locate potential additional populations. Critical habitat is designated on a 160-acre (65-hectare) area at this site, within what is now the South Narrows Area of Critical Environmental Concern. (USFWS, 2019).

Critical Habitat Designated

Yes; 12/10/1982.

Legal Description

On November 10, 1982, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective December 10, 1982), for *Stephanomeria malheurensis* (Malheur wire-lettuce) under

the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in Oregon (47 FR 50881-50886).

Critical Habitat Designation

The critical habitat designation for *Stephanomeria malheurensis* includes one CHU in Harney County, Oregon. A description is presented below; a map is available in the Final Rule. This species' critical habitat encompasses approximately 160 acres (47 FR 50881-50886).

In Harney County, Oregon: the lands west of Highway 205 within the SE $\frac{1}{4}$ of the NE $\frac{1}{4}$ and the NE $\frac{1}{4}$ of the SE $\frac{1}{4}$, Section 11; and the W $\frac{1}{2}$ of the SW $\frac{1}{4}$ of the NW $\frac{1}{4}$, and the SE $\frac{1}{4}$ of the NE $\frac{1}{4}$ of the SW $\frac{1}{4}$, and the NW $\frac{1}{4}$ of the SW $\frac{1}{4}$ Section 12, T27S. R30E. Willamette Meridian.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Stephanomeria malheurensis* critical habitat consists were not defined in the Final Rule (47 FR 50881-50886).

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Self-pollinating (USFWS, 2010)

Lifespan

Adult: Annual plant (USFWS, 2010)

Breeding Season

Adult: Flowering typically occurs in July and August (USFWS, 2010).

Other Reproductive Information

Adult: Since the time of its discovery, Malheur wire-lettuce has been held forth as a rare example of sympatric speciation (e.g., Gottlieb 1973, p. 552; Gottlieb 1991, pp. 11-12). The species *Stephanomeria malheurensis* is thought to have arisen by way of a mutation event in a single plant from the obligate outcrossing parent species, *Stephanomeria exigua* subsp. *coronaria*, resulting in an individual capable of self-pollination. Originally differentiated from its putative progenitor by only a single allele, chromosomal rearrangement in the descendent inbreeding lineage likely resulted in reproductive isolation between the two *Stephanomeria* despite their lack of geographic isolation (Gottlieb 1973, pp. 550, 552; Gottlieb 1977, p. 879; Gottlieb 1978, entire). Malheur wire-lettuce was accepted as a valid species at the time of listing due to the combination of reproductive isolation and distinctive morphological characters (e.g., Gottlieb 1973, p. 552; Gottlieb 1978, entire; Gottlieb and Bennett 1983, p. 276), but it appears that the species was discovered in its nascency. The genome of Malheur wire-lettuce is a slender subset of the variability observed in the parent species, and its original discoverer, Dr. Leslie Gottlieb, described the species as "still within a bottleneck state having to do with its recent origin" (Gottlieb 1973, p. 553). Furthermore, the recently evolved species displayed several characteristics that Gottlieb (1973, p. 553) and later Sherman (2009, p. 81) described as "maladaptive." These include, among others, a relaxation of seed germination requirements

that can result in Malheur wire-lettuce sprouting in the fall rather than spring, with consequent high levels of seedling mortality over the cold winters (Gottlieb 1973, p. 553). Citing to the perennially low numbers of Malheur wire-lettuce and its potentially maladaptive traits, Sherman (2009, p. 81) states that the species “may be predisposed to extinction, as is the case with many neospecies.” Even relatively soon after its initial discovery, Dr. Gottlieb reflected “without additional genetic augmentation stemming from mutation or hybridization, and in its present harsh environment, the probability that “Malheurenensis” will persist seems small” (Gottlieb 1973, p. 553). (USFWS, 2019). All of these considerations pose a dilemma in the conservation of Malheur wire-lettuce. The researcher most intimately familiar with the species questioned its ability to survive over the long term, and another considered it predisposed to extinction. Concerted efforts over the years to reintroduce the species to its type locality after it has repeatedly gone extinct in the wild have failed, as have attempts to introduce the species to similar habitat nearby. We are thus left with a species that is of scientific interest as it represents one of the only known examples of sympatric speciation of a diploid species, but that species persists only in the form of stored seed, and it appears incapable of surviving independently in its natural habitat. (USFWS, 2019).

Reproduction Narrative

Adult: Malheur wirelettuce is an annual plant in the composite family (Asteraceae). It can reach 5 dm (20 inches) in height. This species forms a rosette of hairless leaves that arise from its base. The single stems are many-branched with scale-like leaves. Flower heads are either numerous and clustered, or solitary on short stems. The strap-shaped petals are pink, white, or rarely orange-yellow. Flowering typically occurs in July and August. The Malheur wirelettuce is co-located with an ancestral relative, small wirelettuce (*Stephanomeria. exiqua* ssp. *coronaria*); however, the two species do not interbreed. While the Malheur wirelettuce is self-pollinating, its ancestral relative is not (USFWS, 2010).

Habitat Type

Adult: Desert hill top (USFWS, 2010)

Spatial Arrangements of the Population

Adult: Clumped (USFWS, 2010)

Environmental Specificity

Adult: Narrow/specialist (USFWS, 2010)

Tolerance Ranges/Thresholds

Adult: Low (USFWS, 2010)

Site Fidelity

Adult: High (USFWS, 2010)

Habitat Narrative

Adult: Species inhabits a broad hilltop composed of volcanic tuff (in contrast to soils in the surrounding flats, which are primarily derived from basalt). The native vegetation is dominated by big sagebrush (*Artemesia tridentata*) and rabbit-brush (*Chrysothamnus* spp.). (NatureServe, 2015). Malheur wirelettuce occurs in the high desert of the northern portion of the Great Basin and is located in an area south of Burns, Oregon. It occurs on top of a dry, broad hill on volcanic

soil intermixed with layers of limestone. Dominant plants at the site are big sagebrush (*Artemisia tridentata*), gray rabbitbrush (*Chrysothamnus nauseosus*), green rabbitbrush (*Chrysothamnus viscidiflorus*), and, more recently, cheatgrass. Malheur wirelettuce may be one of the few species able to survive on and around the otherwise barren harvester ant hills at the site (USFWS, 2010). The species narrow environmental specificity, clumped spatial arrangement of the population, high ecological integrity of the community and site fidelity as well as low tolerance ranges are based on the narrow geography this species inhabits and its specific habitat requirements, as well as the few known populations that are known to occur.

Dispersal/Migration

Dispersal

Adult: Harvester ants appear to be a dispersal agent (USFWS, 2011)

Dispersal/Migration Narrative

Adult: Observations made by Brauner (1988, pp. 15, 16, and 20) and BLM (1987, no pagination) indicate harvester ants (*Pogonomyrmex owyheei*) contribute to loss of seed through granivory, but also may to a lesser extent contribute to seed dispersal. Additional observations of harvester ants collecting seed have been made by ODA staff during the ongoing restoration activity (Currin et al. 2009, pp. 29-30). Granivory could be a hindrance to seed recruitment, but it is possible that harvester ants facilitate seed burial or possibly facilitate seed germination. Further investigation on harvester ant influence on Malheur wire lettuce is recommended (Currin et al. 2009, p. 30) (USFWS, 2011).

Population Information and Trends

Population Trends:

Decreasing (NatureServe, 2015)

Resiliency:

Low ((USFWS, 2011)

Representation:

Low ((USFWS, 2011)

Redundancy:

Low ((USFWS, 2011)

Number of Populations:

1 - 5 (NatureServe, 2015)

Population Size:

250 - 1000 individuals (NatureServe, 2015)

Population Narrative:

Does not appear to compete well with exotic annual taxa. Presumed extinct in the wild in 1985. Decline of >90% 1028 plants transplanted in 2008, though the trend has been for these reintroduced populations to fail in a matter of years. Recruitment from previous years' seed is

low. Two EOs, one presumed extinct in the wild and another a novel reintroduction site. Both populations are maintained by transplants. (NatureServe, 2015). The Malheur wire lettuce population continues to be small and remains vulnerable to natural fluctuations. Cheat grass that invaded Malheur wire lettuce habitat in the early 1970s persists within the habitat and likely affects the site conditions for re-establishing Malheur wire lettuce (BLM 2005 and 2006). Between 1986 and 1990, over 1,300 seedlings were planted within the ACEC and designated critical habitat in an attempt to restore the plant in the wild. As of 1989, there were 939 seedlings established through these efforts. After 1990, the population was left to persist on its own and was extirpated in the wild after 13 years (Currin et al. 2007). The restoration project being implemented by the ODA has made progress toward meeting the recovery criteria for establishment of Malheur wire lettuce at a minimum of four locations within the designated critical habitat area described in the recovery plan (Fish and Wildlife Service 1991). Narrows 1, Narrows 2, and Narrows 3 sites have been installed, and currently support Malheur wire lettuce within the designated critical habitat (see section 2.3.1.1.). Over the past four years, nearly 4,000 seedlings have been planted, and 46,000 seeds have been sown within the Narrows ACEC. ODA estimates the planted seedlings have contributed over 154,000 seeds to the soil seed bank at the Narrows restoration sites (Currin and Meinke 2010, p. 33). Whether the seeds are able to successfully germinate, grow, reproduce and ultimately create a self-sustaining population of Malheur wire lettuce over time (for at least 15 years) without human assistance remains to be seen. The additional site known as the "Dunes" site was planted in 2007 and 2008, but is not within the designated critical habitat. An additional 5,000 seeds have been added to the conservation seed bank at Berry Botanical Garden (USFWS, 2011). Low resiliency, representation and redundancy are based on the species becoming extinct in the wild and having to be re-introduced. The re-introductions have resulted in three new populations that are being monitored. Between 2007 and 2011, an intensive multi-year restoration program for Malheur wire-lettuce took place in the protected 160-acre critical habitat location. More than 4,500 seedlings were planted and hand-watered for 8 weeks following planting. Approximately 46,000 seeds were directly sown, and more than 150,000 seeds produced by transplants were estimated to have been contributed to the soil seed bank at the restoration site (U.S. Fish and Wildlife Service 2011, p. 17; Oregon Department of Agriculture 2012, entire). Despite these efforts, annual surveys in 2016 found only three individuals in poor condition, leading the ODA to declare the species "functionally extinct" (Oregon Department of Agriculture 2017, p. 2). In a subsequent visit by Service biologists in 2017, again no representatives of the species were observed (Brumbelow and Mauer, pers. obs. 2017). (USFWS, 2019).

Threats and Stressors

Stressor: Surface mining (USFWS, 1991)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: The lone population of this species is vulnerable to any substantial habitat alteration and faces the potential threat of surface mining for zeolites on and near the site where it occurs (USFWS, 1991).

Stressor: Cheat grass (USFWS, 1991)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: It is immediately threatened by competition with an exotic grass, *Bromus tectorum* (USFWS, 1991).

Stressor: Grazing (USFWS, 1991)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: It is immediately threatened by grazing of native herbivores (probably black—tailed jackrabbits) (USFWS, 1991).

Stressor: Insect predation (USFWS, 1991)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: The larvae of an unidentified insect may be foraging on the plant (USFWS, 1991).

Stressor: Small population size (USFWS, 1991)

Exposure:

Response:

Consequence: Extinction

Narrative: Natural fluctuations in small population size may lead to extinction (USFWS, 1991).

Stressor: Invasive plants, allelopathic affects (USFWS, 1991)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Possible allelopathic (inhibitory) affects by introduced plants, i.e. cheatgrass, (*Bromus tectorum*) (USFWS, 1991).

Recovery

Reclassification Criteria:

The 160-acre Critical Habitat is secure from the threats of fire (USFWS, 2011).

The 160-acre Critical Habitat is secure from the threats of mining (USFWS, 2011).

The 160-acre Critical Habitat is secure from the threats of grazing (USFWS, 2011).

The 160-acre Critical Habitat is secure from the threats of introduced exotic species for five years (USFWS, 2011).

Flowering plants produce seeds in at least four separate locations within the designated critical habitat (USFWS, 2011).

Recovery Actions:

- A buffer zone or fire lane was established and is being maintained around the critical habitat of Malheur wire lettuce to enhance the plant's survival (Fish and Wildlife Service 1991, p.

- 12). The BLM currently maintains native surface roads which roughly follow the boundary of the South Narrows Area of Critical Environmental Concern (ACEC) on three sides, with State highway 205 on the fourth side. Fire lines are generally successful in holding a fire (Meinick 2011) (USFWS, 2011).
- The ACEC was designated to incorporate the designated critical habitat into BLM management. All present and future mining claims have been withdrawn (Fish and Wildlife Service 1991, p. 12). All mining claim activity within the ACEC remains inactive (Meinick 2011) (USFWS, 2011).
 - The area was fenced to keep livestock from the ACEC. The fence is maintained by BLM. Plantings of Malheur wire lettuce conducted within the ACEC in 1987 and 1989 were protected by rodent proof fencing (Fish and Wildlife Service 1991, p. 12). Transplanting seedlings into plots surrounded by rabbit exclosure fencing had little effect on the survival and reproduction of the seedling transplants (Currin et al. 2007, p 47 and Currin and Meinke 2008, p. 15). The livestock fence is still maintained, but current restoration efforts do not rely on rodent fencing to protect seedlings from natural herbivory (Currin and Meinke 2008, p. 15; and Currin et al. 2009, p. 14) (USFWS, 2011).
 - Cheatgrass (*Bromus tectorum*), an exotic species, was identified as a threat to Malheur wire lettuce that competes for water, and is possibly allelopathic (inhibition of growth in one species of plant by chemicals produced by another species of plant). Reducing its influence was considered necessary in the recovery plan. The recovery plan recommended a study of allelopathy to determine the extent of impact cheat grass has on Malheur wire lettuce. A study was initiated in 1987 and preliminary results indicted a slight allelopathic affect from cheat grass on lettuce seeds, used as a proxy rather than using seeds of Malheur wire lettuce, and recommended continued investigation using Malheur wire lettuce seeds to test significance of allelopathy (Davidson and Bargaen 1987, pp. 4-5). No additional studies of allelopathy have been conducted for Malheur wire lettuce. The recovery plan also recommended rogueing (weeding out) of cheatgrass throughout the growing season within 1-2 ft. radius of existing Malheur wire lettuce plants. Before the Narrows fire in 1972, Malheur wire lettuce inhabited the open areas between shrubs and bunchgrasses (Currin and Meinke 2007, p. 8). After the fire, cheatgrass invaded the site and at times formed an almost complete groundcover in the open areas. Higher levels of cheatgrass corresponded with a decline in Malheur wire lettuce (Brauner 1988, pp. 4 and 21-23). Several treatments to reduce cheatgrass were conducted with varying results (Gottlieb 1991, p. 12). According to Taylor (1997), the act of weeding may have negative impacts on Malheur wire lettuce plants due to disturbance during weeding activities. No additional cheatgrass removal activities have been conducted (Fish and Wildlife Service 1991, p. 12). The BLM reported a reduction in the amount of cheat grass plants present at the designated critical habitat area in comparison with the amount reported after the Narrows Fire in 1972, but also noted an increase in other exotic annual forbs including burr buttercup (*Ranunculus testiculatus*), jagged chickweed (*Holosteum umbellatum*), pale alyssum (*Alyssum alyssoides*), and tumble mustard (*Sisymbrium altissimum*) (BLM 2005). During the restoration activities conducted from 2007 to present, selection of transplant site plots were located in areas observed to have reduced amounts of cheatgrass present. The designated critical habitat is not free from exotic species at this time. Additional restoration work, monitoring, and analysis is needed to determine if the exotic plants present at the site constitute a continued threat to Malheur wire lettuce (USFWS, 2011).
 - No Malheur wire lettuce plants were observed in surveys conducted in 2004 through 2007. The restoration efforts have focused on planting seedlings in plots scattered in two different

areas within the ACEC and the designated critical habitat. The success of the planting has varied from year to year and among the various plots. Currently there are three plots with reproducing plants located within the ACEC and designated critical habitat boundary (See section 2.3.1.1) (USFWS, 2011).

- 2019 recommended action 1: Continue seed bulking to retain current seed supply. (USFWS, 2019).
- 2019 - 2: Halt seedling planting at designated sites until we gain an improved understanding of habitat needs for the species. (USFWS, 2019).
- 2019 - 3: Monitor habitat of Malheur wire-lettuce for signs of survival of the species in the wild. (USFWS, 2019).
- 2019 - 4: Cooperate with The Nature Conservancy to develop an experimental seed planting of Malheur wire-lettuce using novel techniques they are developing for restoration in the harsh desert environments of the Great Basin. For example, they have developed a variety of “seed pods” that are designed to give plants a boost to overcome multiple barriers preventing establishment. (USFWS, 2019).
- 2019 - 5: Monitor planting of “seed pods” or other novel techniques to determine seed to maturation success at the native site. (USFWS, 2019).
- 2019 - 6: Continue “conservation reliant” management and restoration once experimental tactics are validated. (USFWS, 2019).
- 2019 - 7: Adapt techniques and reassess recovery goals as needed. (USFWS, 2019).

Conservation Measures and Best Management Practices:

- Continue to work with ODA, BLM, and Native Plant Society to accomplish restoration and monitoring activities benefitting Malheur wire lettuce. Plant seedlings and supplement seed on four sites within the designated critical habitat and ACEC site (recovery plan objectives 1 and 5) (USFWS, 2011).
- Continue to bulk seed for use in implementation of future recovery efforts as well as to increase and replace stored seed of Malheur wire lettuce (recovery plan objective 51) (USFWS, 2011).
- Continue annual census of Malheur wire lettuce. Sampling should occur starting in April when rosettes are observable and continue through July to detect flowering plants. Additional monitoring should be conducted during flowering to estimate seed production. Continuation of monitoring is needed to observe the demography of the species and to assess its responses to climate changes, particularly drought conditions, over time (USFWS, 2011).
- Work with the BLM and ODA to develop a long-term management and monitoring plan for the Malheur wire lettuce and its habitat. The plan should address the threats described in the original listing (restricted range, mining, herbivores, limited population, and cheatgrass) and recovery plan. Monitoring should be sufficient to track fluctuations in available habitat, and abundance of nonnative or invasive plant species (USFWS, 2011).
- Evaluate the potential for control of introduced non-native and competing plant species particularly cheat grass. Also consider potential for preventing introduction and spread of other invasive species (USFWS, 2011).
- Evaluate granivore – seed interactions related to harvester ants and dispersal of seed. Determine whether harvester ants are a hindrance to restoration or if they aid in recovery through caching and dispersal of viable seed (USFWS, 2011).

SPECIES ACCOUNT: *Streptanthus albidus* ssp. *albidus* (Metcalf Canyon jewelflower)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Southwest (R8) (USFWS, 2015)

Physical Description

An annual herb, up to 1+ m tall. Basal leaves are narrow, coarsely toothed, the upper leaves not toothed and becoming linear. Flowers (April-July) are borne in leafless terminal clusters; they have white to whitish-green sepals and white petals with purple-brown veins. The erect, flattened seed pods are 3-8 cm long. (NatureServe, 2015)

Taxonomy

Streptanthus albidus ssp. *albidus* (Metcalf Canyon jewelflower) was first collected in 1887 by Volney Rattan, a botany teacher and author, from hillsides a few miles south of San Jose (Greene 1887). Edward Greene described *Streptanthus albidus* ssp. *albidus* in 1887 (Greene 1887); later he redefined the limits of *Euclisia*, formerly a subgenus of *Streptanthus*, treating it as a genus in its own right (Greene 1904). *Streptanthus albidus* ssp. *albidus*, as a member of the *Euclisia* group, was included in this change. Jepson (1925) returned *Euclisia* to subsection status, and later authors followed his treatment. Jepson (1925) also treated *Streptanthus albidus* ssp. *albidus* as a subspecies of *Streptanthus glandulosus*. Kruckeberg published a revision of the *Streptanthus glandulosus* complex in which he recognized the close relationships among *Streptanthus glandulosus*, *Streptanthus albidus*, and *Streptanthus niger* (Kruckeberg 1958). In this paper, he notes that the “sharp genetic discontinuity between *Streptanthus albidus* and all other populations, coupled with the morphological distinctness and regional restriction of *Streptanthus albidus* warrant the restoration of this Greeneian species.” He recognized two subspecies: *Streptanthus albidus* ssp. *albidus* and *Streptanthus albidus* ssp. *perarnoenus* (Kruckeberg 1958). Recent research affirms the distinctiveness of *Streptanthus albidus* ssp. *albidus*. *Streptanthus albidus* ssp. *perarnoenus*, and *Streptanthus niger* (M. Mayer. in litt., 1998) (USFWS, 1998).

Current Range

Santa Clara county, California. (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Breeding Season

Adult: *Streptanthus albidus* ssp. *albidus* flowers April to June (Kruckeberg 1977) (USFWS, 1998).

Reproduction Narrative

Adult: *Streptanthus albidus* ssp. *albidus* flowers April to June (Kruckeberg 1977). No detailed data on its reproductive biology or demography are available. Nine populations totaling approximately 20,000 to 25,000 plants have been recorded (McCarten 1992b) (USFWS, 1998).

Habitat Type

Adult: Outcrops

Spatial Arrangements of the Population

Adult: clumped (NatureServe, 2015)

Environmental Specificity

Adult: Narrow/specialist (inferred from NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: Low (inferred from NatureServe, 2015)

Site Fidelity

Adult: High (inferred from NatureServe, 2015)

Habitat Narrative

Adult: Species inhabits serpentine outcrops with shallow soils (NatureServe, 2015). High ecological integrity and site fidelity as well as low tolerance ranges are inferred based on this species restricted habitat requirements and geography.

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Not available

Population Narrative:

Known from 22 total occurrences, but only nine presumed extant (NatureServe, 2015)

Threats and Stressors

Stressor: Development (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: At the time of listing, there were 13 documented sites, 9 of which still harbored plants. Two occurrences were known from herbarium records only. One of the historical records was visited in 1990, but no plants were found. *Streptanthus albidus* ssp. *albidus* was last observed at the other historical site in 1895. One population consisting of approximately 9,000 plants, approximately 45 percent of all known plants, occurred on the proposed site of the Cerro Plata residential and golf course project (also known as Ranch on Silver Creek Development). Although no direct destruction of any plants were planned at the time of listing, it was thought that construction activities, human disturbance, and habitat fragmentation would result in

significant impacts to the population. There was a proposed Valley Christian School and South Valley Christian Church that would destroy 61 percent of the 2,700 plants occurring on the site. The remaining 7 populations were also threatened by impending or potential development. The Ranch on Silver Creek Development (Cerro Plata) has been constructed since the time of listing. Although all direct impacts to *Streptanthus albidus* ssp. *albidus* were avoided as described in the biological opinion (Service 2000), the populations within the 580 acre parcel are intermixed with residential homes, golf course, and facilities. Ten years of monitoring (2001-2010) of the preserved populations within the on-site Hassler Ranch Preserve show that the Plant Conservation Areas are still occupied by *Streptanthus albidus* ssp. *albidus*. The total area occupied within the Plant Conservation Areas has increased slightly by 3.65 acres. The numbers of plants have drastically reduced from 75,000 plants in 1998 to an average of 11,266 plants over 10 years (2001-2010). This is a reduction of 85% percent of the baseline prior to construction of the Silver Creek Development. One location at Tulare Hill was covered by fill during construction of a housing development (CNDDDB 2012). Three sites within the Metcalf Energy Center Ecological Preserve are proposed for reintroduction (Whittall 2011). The reintroduction plan includes monitoring and preparation of a management plan (USFWS, 2013).

Stressor: Predation (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Herbivory was observed on approximately 8 individuals of *Streptanthus albidus* ssp. *albidus* at the Metcalf Motorcycle County Park. The herbivory was likely due to invertebrate herbivores since aphids and Pierid caterpillars have been observed in the populations there previously (Whittall, 2011) (USFWS, 2013).

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: In summary, the Endangered Species Act is the primary Federal law that provides protection for these species since their listing as endangered in 1995. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for the species absent its status under the Act. Therefore, we continue to believe other laws and regulations have limited ability to protect the species in absence of the Endangered Species Act (USFWS, 2013).

Stressor: Nitrogen deposition (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: A relatively recently identified threat is nitrogen deposition into grasslands from air pollution sources and the resultant increase in productivity of the soils has facilitated increased invasion of nonnative species (ICF 2012). The main effect for Santa Clara Valley dudleya and Metcalf Canyon jewelflower is their vulnerability to annual grass overgrowth. Nonnative annuals are much less dominant in serpentine areas, although increasing nitrogen deposition from air pollution has increased the productivity of serpentine soils and allowed a greater number of nonnatives to invade (Evens and San 2004; Harrison et al. 2003; Weiss 1999). Santa Clara Valley

dudleya (*Dudleya setchellii*) lives on rock outcrops and is relatively immune from grass invasions except when extremely tall grasses smother small rock outcrops. The species persists on medium to large rock outcrops in ungrazed areas. Metcalf Canyon jewelflower can be a poor competitor against dense annual grasses, and some degree of grazing appears necessary to maintain populations (ICF 2012). Livestock grazing is an important management tool to combat increased invasive nonnative plants in serpentine grasslands due to atmospheric nitrogen deposition (Weiss 1999) (USFWS, 2013).

Stressor: Climate change (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: ICF (2012) summarized the potential effects of climate change to serpentine plant species and its relationship to the proposed permitted activities during the Santa Clara Valley Habitat Plan's proposed 50 year permit span. Serpentine plant distribution is restricted to highly specialized and localized habitat requirements that include species-specific microclimate conditions coincident with serpentine soil occurrence. Restriction to serpentine soils limits species range and distribution to this soil type. Climate change could change microclimate conditions so that species can no longer persist within their current range. Increase in favorable microclimate conditions could lead to an expansion of distribution and increase in abundance, both in terms of number of populations and number of plants within each population. Change in timing or intensity of seasonal events could have an effect on pollinator reproductive and plant flowering periods leading to phenological mismatches. The Santa Clara Habitat Plan (ICF 2012) includes a conservation strategy reserve design to reduce species vulnerability and provides opportunities for species and natural communities to adapt in response to climate changes (USFWS, 2013)

Recovery

Reclassification Criteria:

Secure and protect specified recovery areas. Occupied habitat along with adjacent unoccupied habitat and a 150-meter (500- foot) buffer at nine known sites. Management plan approved and implemented for recovery areas, including survival of the species as an objective. For all populations and any occupied or unoccupied habitat identified as essential to survival.

Delisting Criteria:

Secure and protect specified recovery areas. 18 populations representing entire historic range of the species. from incompatible uses:

Recovery Actions:

- Population monitoring in specified recovery areas shows: Downlist: Stable or increasing for a period of 20 years that include the normal precipitation cycle (or longer if suggested by the results of demographic monitoring). Delist: No decline after downlisting; if declining, determine cause and reverse trend.

Conservation Measures and Best Management Practices:

- Preserve, protect, manage, and monitor *Dudleya setchellii* CNDDb occurrence number 43. Occurrence number 43 was found in the year 2005, subsequent to listing of the species and the

Recovery Plan. The occurrence represents the most southwesterly extent of its current known range (USFWS, 2013).

- Confirm if the historic and current westernmost and southernmost occurrences for *Streptanthus albidus* ssp. *albidus* are valid. Perform additional surveys in suitable habitat around CNDDDB number 6 and 21 to confirm if the range of the species is smaller than previously understood (USFWS, 2013).
- Conservation measures should include focus on preserving, monitoring, and managing pollinator fauna as it appears to be essential for any significant fruit set in *Streptanthus albidus* ssp. *Albidus* (USFWS, 2013).
- *Streptanthus albidus* ssp. *albidus* plant numbers can fluctuate drastically from year to year (Whittall 2011). Reliable methods should be developed to evaluate when a population should be considered as stable and viable. The methods should include ways to measure and evaluate natural and human influenced variables

SPECIES ACCOUNT: *Streptanthus bracteatus* (Bracted twistflower)

Species Taxonomic and Listing Information

Listing Status: Candidate; (USFWS, 2016); Proposed Threatened

Physical Description

Bracted twistflower (*Streptanthus bracteatus*) is a herbaceous annual plant of the Mustard Family (Brassicaceae) currently reported from five counties of south-central Texas. The seeds germinate in response to fall and winter rainfall, forming basal rosettes (clusters of leaves that radiate from the root crown); the young plants resemble radish seedlings. The waxy bluish-green basal leaves, up to 15 centimeters (cm) (5.9 inches (in)) long, have broadly lobed margins. Flower stalks emerge the following spring bearing showy lavender-purple flowers; often these stalks are un-branched and 46 to 61 cm (18 to 24 in) tall, but may reach 137 cm (54 in) in height, and have several long branches. The lower stem leaves have an elongated heart shape and the upper leaves are progressively shorter, ultimately reduced to very short, triangular bracts (modified leaves) at the base of each flower stem. Thin seed pods, known as siliques, are up to 12 cm (4.7 in) long and 4 millimeters (mm) (0.15 in) wide; they mature and dry during the summer, finally splitting open to release flattened seeds with narrow wings. The foliage withers as the fruits mature, and the plants die during the blazing heat of summer.

Taxonomy

Family: Brassicaceae (mustards). About 100 species of *Streptanthus* have been described, although many of these have more recently been placed in *Caulanthus*, *Boechera*, *Thelypodium*, or other genera (Tropicos 2011a, pp. 12). Gray (1848, p. 146) described *Streptanthus bracteatus* as a new species, based on specimens collected by Ferdinand Lindheimer near New Braunfels, Texas, in 1846. Kuntze (1891, p. 933, cited in Tropicos 2011c, p. 1) classified this taxon as *Erysimum bracteatum* (A. Gray) Kuntz. Nevertheless, the Flora of North America (Al-Shehbaz 2011, p. 706), Tropicos (2011b, p. 1), the Integrated Taxonomic Information Service (2011, p. 1), the International Plant Names Index (2011, p. 1), and the Plants Database (Natural Resources Conservation Service 2011, p. 1) treat this taxon as a valid species with the name *Streptanthus bracteatus*. Pepper (2010, p. 14) concluded that *S. bracteatus* is a morphologically and evolutionarily distinct species; its closest extant relative is the broadpod jewelflower, *S. platycarpus*, a west Texas endemic. Poole et al. (2007, p. 470) list bracted twistflower and bracted jewelflower as common names for this species. While the latter is also used by the Plants Database, the botanists and conservation organizations who work with this species primarily use the former name. For the purposes of this document, we will refer to *Streptanthus bracteatus* as bracted twistflower.

Historical Range

U.S., Texas. Historic collection records where the species has not been observed since 1989: Comal, Bandera/Kerr, Real, Bexar counties.

Current Range

U.S., Texas. Bexar, Hays, Medina, Travis, and Uvalde counties. Endemic to a small area of the Edwards Plateau of Texas.

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Breeding Season

Adult: Bloom April and may continue to May and early June

Reproduction Narrative

Adult: Rosettes have been reported in October, November, and March, and presumably can be seen throughout the winter months. The relatively few rosette observations (five) reflects the difficulty of positive species identification at this life stage; prior to flowering, bracted twistflower is easily confused with another member of the mustard family, rock cress (*Arabis petiolaris*) (Damude and Poole 1990, p. 6). From 79 to 90 percent of seed germination occurs during October and November (Zippin 1997, p. 222). Flowering peaks in April and may continue into May and June. Fruits have been observed from April through June. Mature seeds have been collected most often in June, but occasionally as late as August. Dieringer (1991, pp. 341343) investigated the pollination ecology of one population of bracted twistflower. He determined that it is primarily an outcrossing species, although 6.3 percent of self-pollinated flowers set fruit. A locally common species of leafcutter bee, *Megachile comata* (family Megachilidae), was an effective pollinator. About 29 percent of un-manipulated flowers set fruit, 12 percent of fruiting plants were eaten by deer, and 11 percent of fruit capsules were damaged by seed-eating insects.

Habitat Type

Adult: Primarily in oak-juniper woodlands and associated openings on slopes and in canyon bottoms with shallow, well drained, gravelly clays and clay loams over limestone. Often found amid dense shrub growth where some protection from browsing animals is afforded, but is not ideal habitat.

Habitat Vegetation or Surface Water Classification

Adult: Forest/Woodland; Shrubland/Chaparral, Woodland - Mixed

Habitat Narrative

Adult: Bracted twistflowers are best adapted to sites with less than 50 percent cover of woody plants, and that severe herbivory by dense populations of white-tailed deer has largely extirpated the plant from its optimal habitats. It may persist for a time in the protection of dense thickets, or it may gradually decline. In addition, the germination of seeds and reproduction of bracted twistflower in the wild appears to respond to as-yet unknown triggers. This compels us to consider how historic vegetation changes may have affected bracted twistflower populations. Bray (1904, pp. 14, 22) described a very apparent, ongoing transition of Edwards Plateau uplands from grassland to woodland at the beginning of the twentieth century. At that time, the well-watered canyons supported dense forests with trees over 500 years old; stunted but continuous forest covered hills and bluffs; sparse trees were found on loose, stony slopes in the eastern Edwards Plateau (precisely where bracted twistflower populations currently occur); and trees were then invading the open prairies on the level plateau divides (uplands), which previously were free of woody vegetation (Bray 1904, pp. 1415). He attributed

this change to overgrazing and the consequent depletion of grasses, erosion, and cessation of wildfires, and stated that open prairies had been converted to dense oak scrub in a span of 25 years (Bray 1904, pp. 1415, 2223). These historic descriptions support a hypothesis that bracted twistflower is a relict of a woodland-grassland ecotone (transition zone) that occurred at or near the confluence of loose, stony slopes and prairie uplands. This savanna, in the broad sense of the term, would have been influenced periodically by wildfires of varying intensity and frequency. Some *Streptanthus* species, such as *S. heterophyllus* (San Diego wild cabbage), germinate following wildfires (Moreno and Oechel 1991, pp. 1999-2000), thus, fire may also be a trigger of bracted twistflower emergence.

Dispersal/Migration

Population Information and Trends

Number of Populations:

13 EOs (=populations); 9 with intact habitat, 4 with degraded or partially destroyed habitat

Population Size:

~6,200 individuals

Population Narrative:

Of the 16 EOs (Element Occurrences=geographic sites) observed since 1989, 9 EOs remain with intact habitat, 2 EOs are partially intact, 2 are on managed rights-of-way, and 3 sites have been developed and the populations are presumed extirpated. Only 7 of the intact EOs and portions of 2 EOs, representing 2,502 individuals (33 percent of the maximum populations observed since 1989), are on protected natural areas. Four EOs with 3,708 individuals (48 percent of the maximum populations) are intact but vulnerable to development and other impacts. Five EOs have been partially or completely developed, resulting in the loss of 1,449 individuals (19 percent of the maximum populations). Two EOs were destroyed in 2012 and 2013.

Threats and Stressors

Stressor: Urban development

Exposure: Degradation and destruction of habitat

Response:

Consequence:

Narrative: The greatest threat to bracted twistflower is habitat loss due to urban and residential land development (McNeal 1989, p. 17; Damude and Poole 1990, p. 51; Zippin 1997, p. 229; Fowler 2010, p. 2; Pepper 2010, p. 5). Our analysis of the 16 EOs reported since 1989 indicates that 3 have been extirpated, portions of 2 have been extirpated, 2 are in disturbed habitat, and 9 are intact. Of the intact EOs, 2 are vulnerable to development, and 7 intact EOs and portions of 2 EOs, representing 33 percent of the maximum populations recorded since 1989, occur in protected natural areas. The Rough Hollow population in Hays County was discovered in 2010; by 2012, the site had been bulldozed. The Cat Mountain population in Travis County, which was a core reservoir of the species genetic diversity (Pepper 2010, p. 12), was located on private land that was sold in 2011 (Bracted Twistflower Working Group 2010, pp. 34; Stewart 2012); this site was completely bulldozed in 2013 (Fowler 2014, p. 16). Habitat loss is an imminent threat

throughout the species range to the populations not on protected natural areas and is likely to continue.

Stressor: White-tailed deer, small mammals, exotic ungulates

Exposure: Browsing

Response:

Consequence:

Narrative: Severe herbivory by white-tailed deer is a major, imminent threat to bracted twistflower throughout the species' range, except where populations are protected from deer by fencing or intensive herd management (hunting) (McNeal 1989, p. 17; Damude and Poole 1990, pp. 5253; Dieringer 1991, p. 341; Zippin 1997, pp. 39197, 227; Leonard 2010a, pp. 3643; Fowler 2014, pp. 17, 19) and is exacerbated by the extremely high deer densities in the Edwards Plateau of Texas (Zippin 1997, p. 227). The foliage of bracted twistflower is very palatable to many browsing animals, including squirrels (Fowler 2010, p. 7), and even humans (Kral 1990 cited in Damude and Poole 1990, p. 51). Exotic ungulate species such as aoudad (*Ammotragus lervia*), which have been widely introduced on game ranches and now exist in self-sustaining feral populations in central Texas, present an additional potential threat (Damude and Poole 1990, pp. 52 - 53). It is also likely that bracted twistflower populations were impacted during historic periods of poor rangeland management in central Texas, particularly by herds of goats and sheep.

Stressor: Woody plant density

Exposure: Decreased habitat

Response:

Consequence:

Narrative: Changes in vegetation structure and composition, specifically the increased density of woody plant cover, appear to be detrimental to bracted twistflower (Pepper 2010, p. 5). The species benefits from higher light intensity and duration than it receives in many of the extant populations; its persistence in dense thickets may be due to increased herbivory of the plants growing in more open vegetation (Leonard 2010a, p. 63; Ramsey 2010, p. 22). The positive reproductive response of bracted twistflower to higher light levels is consistent with the hypothesis that it may also be a fire-adapted species (Fowler 2010, pp. 3, 10). Bray (1904, pp. 1415, 2324) documented the rapid transition of grasslands to woodlands in the Edwards Plateau occurring more than a century ago; he attributed this change to over-grazing, the depletion of grasses, and the cessation of wildfires. We conclude that bracted twistflower habitats were probably influenced by frequent wildfires and that the frequency of wildfires has decreased greatly since pre-settlement times; therefore, bracted twistflower may be a fire-adapted species, and the lack of wildfire may have contributed to its decline. The increase in density of woody plant cover has occurred incrementally over a span of decades, but affects most bracted twistflower populations, including those on protected natural areas, and may also have caused a gradual decline in population sizes. In addition, optimal vegetation management of bracted twistflower populations may be incompatible with the management of nesting habitat of the endangered golden-cheeked warbler.

Stressor: Powdery mildew fungus

Exposure: Disease infestation

Response:

Consequence:

Narrative: Bracted twistflower is highly susceptible to attack from a powdery mildew fungus (Ascomycota, family Erysiphaceae) which may be more severe when plants grow in dense, shaded thickets (Ramsey 2010, p. 21; Leonard 2010a, p. 53). The species of fungus has not yet been identified; it may be an introduced pathogen to which bracted twistflower has no resistance (Bracted Twistflower Working Group 2010, p. 2). We do not yet know the magnitude of this threat. However, Fowler (2014, p. 17) found that, contrary to expectation, the incidence of powdery mildew was positively associated with reproductive output (plants with greater degrees of powdery mildew infestation produced more viable seed).

Stressor: Recreation

Exposure: Erosion and trampling

Response:

Consequence:

Narrative:

Recovery

Recovery Actions:

- Search for new populations on public conservation land as well as private lands (with landowner permission).
- Provide technical guidance and material support to private landowners who voluntarily wish to conserve the species on their land.
- Manage the existing populations on protected natural areas more rigorously, including installation of deer exclosures, closing illicit foot and mountain bike trails, enforcing applicable regulations that protect the habitats on public property, and conducting public outreach.
- Maintain less than 50 percent cover of woody plants at occupied habitats to the extent allowed under the existing habitat management plans or applicable regulations.
- Protect multiple populations within each area of the species genetic diversity in Medina and Travis counties.
- Investigate the species ecology and optimal habitat requirements, particularly the fire ecology, geology, and associated vegetation structure.
- Conduct pilot reintroductions to determine effective methods of population reintroduction and augmentation. Reintroduction and augmentation must use seeds from ecotypes adapted to the sites. Avoid translocating propagules of an ecotype into sites that support a genetically distinct ecotype.
- Collect seeds from extant populations for seed bank storage and propagation. Propagate plants from the representative genetic ecotypes (genotypes that are specifically adapted to a specific ecological area) and produce seed for experimental and reintroduction efforts (to prevent excessive collection from wild sources and depletion of the soil seed bank at extant populations).

Conservation Measures and Best Management Practices:

- Manage the existing populations on protected natural areas more rigorously, including installation of deer exclosures, closing illicit foot and mountain bike trails, enforcing applicable regulations that protect the habitats on public property, and conducting public outreach.

- Maintain less than 50 percent cover of woody plants at occupied habitats to the extent allowed under the existing habitat management plans or applicable regulations.
- Protect multiple populations within each area of the species genetic diversity in Medina and Travis counties.
- Investigate the species ecology and optimal habitat requirements, particularly the fire ecology, geology, and associated vegetation structure.
- Conduct pilot reintroductions to determine effective methods of population reintroduction and augmentation. Reintroduction and augmentation must use seeds from ecotypes adapted to the sites. Avoid translocating propagules of an ecotype into sites that support a genetically distinct ecotype.
- Collect seeds from extant populations for seed bank storage and propagation. Propagate plants from the representative genetic ecotypes (genotypes that are specifically adapted to a specific ecological area) and produce seed for experimental and reintroduction efforts (to prevent excessive collection from wild sources and depletion of the soil seed bank at extant populations).

SPECIES ACCOUNT: *Streptanthus niger* (Tiburon jewelflower)

Species Taxonomic and Listing Information

Listing Status: Endangered; 3/6/1995; Pacific Southwest (R8)

Physical Description

An annual herb of the mustard family (Brassicaceae) that reaches 30 to 60 centimeters (1 to 2 feet) in height. The lower leaves are toothed, the upper leaves less toothed or not at all. The sepals are a very dark purple; the petals have a purple claw and a white blade with a purple midvein. The pods are erect, almost straight and 4 to 7 centimeters (1.5 to 2.75 inches) long (Kruckeberg and Etienne 1977). The zig-zag inflorescence pattern (Kruckeberg and Etienne 1977) and the lack of hairs (Greene 1886b) distinguish *Streptanthus niger* from its near relative *Streptanthus glandulosus* (bristly jewelflower). (USFWS, 1998)

Taxonomy

Streptanthus niger was described by Edward L. Greene, from a type specimen he collected at St. Hilary's Church in the town of Tiburon in Marin County (Greene 1886). Greene later changed the genus to *Euclisia* (Greene 1904), but Jepson (1925) returned the genus to *Streptanthus*, and others followed. In 1959, Munz and Keck referred to the plant as a subspecies of *Streptanthus glandulosus*, but in 1968, Munz returned it to *S. niger*, following Kruckeberg (1958). Molecular genetic research in the 1990s concluded that *S. niger*, while genetically distinct, did not form a reciprocally monophyletic unit and was nested within the larger and more widespread *S. glandulosus* clade (Mayer and Soltis 1999). Based on these results, Al-Shehbaz and Mayer (2008) proposed a reclassification of *S. niger* to *Streptanthus glandulosus niger*. We originally listed the species as endangered under the name *S. niger* (U.S. Fish and Wildlife Service 1995). However, to remain up-to-date with current nomenclature, we will recommend that an amendment be submitted to change the listing to *Streptanthus glandulosus niger*. (USFWS, 2010)

Historical Range

Marin County, California. (USFWS, 2010)

Current Range

In California, on southwest facing slopes on the Tiburon Peninsula of Marin County. (USFWS, 2010)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Self-pollinated (USFWS, 1998)

Breeding Season

Adult: Seedlings of *Streptanthus niger* appear in March and April (Hunter 1 989b), and the plants flower from May to June (Kruckeberg and Etienne 1977) (USFWS, 1998).

Reproduction Narrative

Adult: Seedlings of *Streptanthus niger* appear in March and April (Hunter 1 989b), and the plants flower from May to June (Kruckeberg and Etienne 1977). The species is self-pollinated (Kruckeberg 1957). The seed capsules open in late June (Hunter 1989b). Populations have fluctuated from 50 to 2,000 plants (Hunter 1989b, A. Allen, in litt., 1991). A 1990 survey found a total of approximately 800 plants in the two occurrences together (E. Buxton, pers. comm. as cited in Morey and Hunter 1990). The known occurrences combined comprise approximately 5 hectares (12 acres) of habitat (Morey and Hunter 1990). No detailed data are available on the reproductive biology or demography of the species (USFWS, 1998).

Habitat Type

Adult: Grasslands (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Serpentine slopes (NatureServe, 2015)

Habitat Narrative

Adult: *Streptanthus niger* occurs at elevations of approximately 100 meters (350 feet) on the slopes of the southern Tiburon Peninsula on shallow rocky serpentine soils, which are formed from weathered volcanic (ultramafic) rocks such as serpentinite, dunite, and peridotite (Service 1998). These soils provide a harsh environment for plant growth, however, this species has adapted to this harsh environment and requires it for survival. Associated federally listed species are *Hesperolinon congestum* (Marin dwarf-flax) and *Castilleja affinis* ssp. *neglecta* (Tiburon paintbrush). Other associated plants include *Nassella lepida* (foothill needlegrass), *Eriophyllum confertiflorum* (golden yarrow), *Hemizonia congesta* ssp. *congesta* (hayfield tarweed), *Nassella pulchra* (purple needlegrass), *Calamagrostis ophitidis* (serpentine reedgrass), *Calycadenia multiglandulosa* (sticky calycadenia), and *Eriogonum luteolum* var. *caninum* (Tiburon buckwheat) (Service 1998). (USFWS, 2010)

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Decreasing (NatureServe, 2015)

Number of Populations:

1 - 5 (NatureServe, 2015)

Population Size:

250 - 2500 individuals (NatureServe, 2015)

Population Narrative:

Two populations are known from the southern end of the peninsula where they occur within 3 kilometers (2 miles) of one another (CNDDB, 2009). One is at the tip of the peninsula at Old St.

Hilary's Church Preserve (Preserve), and the other is along the Middle Ridge of the peninsula. No historical occurrences are known outside of the Tiburon Peninsula, and it is likely *S. niger* never occurred elsewhere (Morey and Hunter 1989). Both of the reported localities were known at the time of listing, and both populations are currently extant. However, population numbers fluctuate yearly and have been reported to include lows of 50 individuals and highs of 2,000 plants per population (Hunter 1989, Service 1998). During favorable growing conditions in 2009 the Middle Ridge site had a population of approximately 2,000 individuals (R. Brittman, California Department of Fish and Game, in litt. 2010). Current abundance information is not available for the Preserve site (E. Buxton, California Native Plant Society, in litt. 2010). (USFWS, 2010)

Threats and Stressors

Stressor: Residential development (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Of the two *Streptanthus niger* records present in the CNDDDB (2009), one is protected by Town of Tiburon Open Space (Middle Ridge) and the other is partially protected by Marin County Open Space (Old St. Hilary's Church Preserve) but a portion at the top of the hill is proposed for development (E. Buxton, California Native Plant Society, in litt. 2010) (Table 1). LSA Associates, Inc. (LSA) is currently writing a vegetation and fire management plan for the Town of Tiburon which includes conservation measures for this species in the area (USFWS, 2010).

Stressor: Foot traffic (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: The threat of trampling has intensified since the time of listing. Currently, *Streptanthus niger* is threatened by trampling from hikers, joggers, dog walkers, and off-trail bicyclists. The Middle Ridge and Preserve occurrences are adjacent to the Ring Mountain open space managed by the Marin Open Space District. Ring Mountain is a very popular site and heavily visited by the public whose activities extend into *S. niger* habitat. Dog walkers and off-leash dogs currently create the greatest impact, followed by hikers, joggers, and mountain bicyclists (G. Ngarangad, Marin County Open Space District, pers. comm. 2010). The Middle Ridge site is used extensively by professional dog walkers and dogs are frequently off-leash resulting in additional trampling of *S. niger* habitat (R. Brittman, California Department of Fish and Game, in litt. 2010; E. Buxton, California Native Plant Society, in litt. 2010). Trampling has also increased due to off trail hikers and illegal bicycle trails. Rangers from the Marin County Open Space District and a contracted Sheriff's deputy patrol the area and both educate individuals about the environment and issue citations (G. Ngarangad, Marin County Open Space District, pers. comm. 2010) (USFWS, 2010).

Stressor: Road construction (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Road construction is listed as a threat to this species (USFWS, 2010)

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: At the time of listing, regulatory mechanisms thought to have some potential to protect *Streptanthus niger* included: (1) listing under the California Endangered Species Act (CESA); (2) the California Environmental Quality Act (CEQA) and the National Environmental Protection Act (NEPA); and (3) the Federal Endangered Species Act in those cases where *S. niger* occurs and is incidentally protected in habitat occupied by a listed wildlife species. The listing rule (60 FR 6671) provides an analysis of the level of protection that was anticipated from those regulatory mechanisms. This analysis appears to remain currently valid.(USFWS, 2010)

Stressor: Non-native plant species (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Competition with introduced species continues to be a serious threat to serpentine native plants (Service 1995, Service 1998). Competition and displacement from invasive plant species poses a potential threat to *Streptanthus niger*. Exotic and/or invasive, weedy plant species reduce native plant diversity and diminish the habitat suitability for native species; this is particularly the case in sensitive habitats (G. Cooley, California Department of Fish and Game, pers. comm. 2008). The consistent pattern of heavy growth of nonnative grasses when not controlled by grazing or other management can ‘smother’ native plants, resulting in the subsequent crowding out, outcompeting, or overshadowing of native annuals. A common consequence of such heavy annual grass growth is development of thatch, which adds to the strong smothering effect by inhibiting annuals’ germination and growth (Weiss et al. 2007). *S. niger* is particularly threatened by nonnative invasive species such as *Genista monspessulana* (French broom), *Cytisus scoparius* (Scotch broom), *Avena fatua* (wild oats), and *Cortaderia selloana* (pampas grass) (USFWS, 2010).

Stressor: Restricted range (USFWS, 2010)

Exposure:

Response:

Consequence: Extinction/lack of genetic variability

Narrative: *Streptanthus niger* is extremely restricted in its range, and known from only two occurrences on the Tiburon Peninsula in Northern California, each of which fluctuates between 50 and 2,000 individuals between years. The small population sizes and the restricted range of the species places *S. niger* at risk from catastrophic or stochastic events and loss of genetic variability. Potential future development of the areas surrounding the Preserve, and on the top of the hill at Old St. Hilary’s Church would have direct negative effects on this species and exacerbate the threat from low numbers of individuals. Since the total number of individuals per year fluctuates drastically (from 50 to 2000 individuals per locality), these populations are at risk of extirpation by a random event such as a disease outbreak, drought, fire, or other natural or human-caused factors. Additionally, few populations, low population numbers and, large population fluctuations among years increase the likelihood of loss of genetic variability which may lead to a decrease in average fitness and reduced resilience to environmental stressors such as disease and alterations in habitat (USFWS, 2010).

Stressor: Climate change (USFWS, 2010)

Exposure:

Response:

Consequence: Loss of habitat/extinction

Narrative: A modeling study completed by Loarie et al. (2008) provides an evaluation of potential trends to California's floristic communities under climate change scenarios. In general, plant diversity will shift in two divergent directions: along the coast and northwards at higher elevations; and southwards at higher elevations of the Sierra Nevada. The models suggest that climate change has the potential to break up local floras, resulting in new species combinations, with new patterns of competition and biotic interactions (Loarie et al. 2008). Based on these modeling results, *Streptanthus niger* may be unable to shift its range because of isolated, small populations, whose growth depend upon particular hydrological regimes and soil characteristics, and the limited available, suitable habitat surrounding extant occurrences (USFWS, 2010).

Recovery

Reclassification Criteria:

A/1: Occupied habitat at the Old St. Hilary's Preserve and Middle Ridge site is fully protected and managed with the primary intention of preserving the populations in perpetuity. In addition, secure and protect adjacent unoccupied habitat and a 150-meter (500- foot) buffer around protected occupied habitat, where possible. If additional individuals or populations are discovered on private lands that are not part of the Old St. Hilary's Preserve or protected land at Middle Ridge, they are secured through voluntary land acquisitions, conservation easements, or other means. (USFWS, 2019)

A/2: Management plan(s), approved by the Service, are developed and implemented for populations at Old St. Hilary's Preserve and Middle Ridge, and any other location(s) where the species may be discovered (see A/1). Management plans will include survival of the species as an objective and will include any adjacent occupied or unoccupied habitat identified as essential to survival. The plans include provisions for annual standardized monitoring of each population to determine demographic trends and actions to control invasive plant species. Adequate funding must be dedicated in order to implement the management plan in perpetuity. (USFWS, 2019)

E/1: As described in A/2, standardized population monitoring at Old St. Hilary's Preserve, Middle Ridge and any other location(s) where the species may be discovered (see A/1) shows stable or increasing populations over a period of 20 years that include two normal precipitation cycles (or longer if suggested by the results of demographic monitoring). If monitoring shows any population is declining, determine the cause of decline and reverse the trend. (USFWS, 2019)

E/2: Unless research shows otherwise, the St. Hilary's Preserve and any other population that may be discovered (see A/1) contain an average of at least 3,000 flowering individuals, and the Middle Ridge population contain an average of at least 2,000 flowering individuals. This will allow each population to maintain its breadth of genetic diversity and adaptive potential over the long-term, attract sufficient pollinators, and maintain a stable or increasing population. (USFWS, 2019)

E/3: Seeds stored in at least two Center for Plant Conservation certified facilities⁴⁸ and reliable seed germination and propagation techniques are understood. (USFWS, 2019)

Delisting Criteria:

A/1: A minimum of one new population is established in an area on the Tiburon peninsula that contains suitable protected habitat and appropriate plant associates. Each introduced population is maintained over a 20-year period that includes two normal precipitation cycles (or longer if suggested by the results of demographic monitoring). (USFWS, 2019)

A/2: Service-approved management plan(s) are developed and implemented for the introduced population(s) from A/1. Management plan(s) include survival of the species as an objective and include any adjacent occupied or unoccupied habitat identified as essential to survival. The plans include provisions for annual standardized monitoring to determine demographic trends and control invasive species. Adequate funding is dedicated to implement the management plan in perpetuity. (USFWS, 2019)

A/3: The population(s) described in A/1 is secured and protected, along with adjacent unoccupied habitat and a 150-meter (500- foot) buffer, where possible. The introduced population(s) is secured through voluntary land acquisitions, conservation easements, or other means. (USFWS, 2019)

E/1: Unless research shows otherwise, the introduced population described in A/1 contains an average of at least 3,000 plants. This will allow the introduced population to maintain its breadth of genetic diversity and adaptive potential over the long-term, attract sufficient pollinators, and to maintain a stable or increasing population. (USFWS, 2019)

E/2: Population monitoring of introduced populations under A/1 shows evidence of natural recruitment and contain a stable or increasing population over a 20-year monitoring period that include two normal precipitation cycles (or longer if suggested by the results of demographic monitoring). The other populations are stable or increasing after downlisting. (USFWS, 2019)

Recovery Actions:

- 1. Introduce and maintain one new Tiburon jewelflower population in an area on the Tiburon peninsula that contains suitable protected habitat and the appropriate plant associates. (Priority 1) (USFWS, 2019)
- 2. Work with Marin County Parks and Open Space to update their current management plan to include the Tiburon jewelflower. Institute a species-specific management plan to ensure a self-sustaining population over the long-term. (Priority 1) (USFWS, 2019)
- 3. Conduct research to better understand the relationship between genetic diversity and the species capacity for adaptive evolution (Priority 1). (USFWS, 2019)
- 4. Store seeds in at least two Center for Plant Conservation certified facilities. Unless storage techniques and/or research show otherwise, replenish seed stock every 10 years to ensure seed viability. (Priority 2) (USFWS, 2019)
- 5. Establish a Service-approved monitoring plan to cover a minimum of 5 years post-delisting of Tiburon jewelflower. The plan will be ready for implementation at the time of delisting to ensure the ongoing conservation of the species and the continued effectiveness of management actions. Adequate funding must be dedicated in order to implement the delisting management plan. (Priority 3) (USFWS, 2019)

SPECIES ACCOUNT: *Styrax portoricensis* (Palo de jazmin)

Species Taxonomic and Listing Information

Listing Status: Endangered; 04/22/1992; Southeast Region (R4) (USFWS, 2016)

Physical Description

Styrax portoricensis is an evergreen tree of 10-12 m in height. The leaves are simple, alternate, exstipulate, and glabrous, measuring 6-12 cm long, and 3-5 cm wide. The leaf blades are elliptic, with a cuneate base, and an acute or acuminate apex; the petiole is 6- 12 long and lepidote. Both surfaces are finely reticulate-veined; the upper side is shiny dark green, the lower surface is pale green with scattered stellate scales. The axillary or terminal flower racemes are 2-5 cm long, bearing three to six perfect flowers with ferrugineolepidote, curved pedicles of 10-15 mm long. The calyx is cup-shaped, ferrugineo-lepidote, with five 4-5 mm long sepals. The white corolla is valvate, with five 12-25 mm long petals which are silvery lepidote inside. The 10 stamens present are free, with filaments as long as anthers, and with long stellate hairs at the base. The superior ovary contains numerous ovules. The pistil is as long as the corolla lobes, with a three-lobed stigma. The fruit is one-seeded, oblong-elliptic, lepidote, drupe of 2.5-3.5 cm long and 1.3-1.5 cm in diameter. The fruit apex is acuminate, and the fruit base maintains the calyx (persistent). The fruit bear only one seed, 19 mm long and 8-10 mm wide, which is pale reddish brown (USFWS, 1993).

Taxonomy

Styrax portoricensis (palo de jazmin) was described in 1892 by Krug and Urban from specimens collected by Sintenis in 1885 in the Sierra de Naguabo and Sierra de Yabucoa of eastern Puerto Rico. In October of 1935, the species was collected somewhere in the Luquillo Mountains by C. Horn and L. Holdridge (Vivaldi et al. 1981c). Fruits of the species were collected in 1954 in the El Verde area of the Luquillo Mountains (Little et al. 1974). Besides the collections mentioned, no record of the species was made until the early 1980's, when it was rediscovered in the Luquillo Mountains, being known at present from a single individual (USFWS, 1993).

Historical Range

See current range/distribution.

Current Range

All the currently known localities of *Callicarpa ampla*, *Ilex sintenisii*, *Styrax portoricensis*, *Ternstroemia luquillensis*, and *Ternstroemia subsessilis* occur within the Caribbean National Forest, which is administered by the USDA Forest Service. The following are known sites for the species: Barrio Guzman Arriba. Rio Grande municipality. Only a single tree is known, growing west of El Cacique (USFWS, 1993). Currently, palo de jazmin is only known to naturally occur within the palo colorado forest type at EYNF where 19 individuals have been documented at five locations (USFWS 2015). Palo de jazmin has been planted on other sites within EYNF, and in a land managed for conservation by Para La Naturaleza in the municipality of Barranquitas (USFWS 2015). (USFWS, 2019).

Critical Habitat Designated

Yes;

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Unknown (USFWS, 2015)

Reproduction Narrative

Adult: Little is known about the reproductive biology of this species. Fruits are present in Sintenis herbarium specimen number 1169 of *Styrax portoricensis*, collected on April 26, 1885 (Vivaldi and Woodbury 1981c) (USFWS, 1993).

Habitat Type

Adult: Palo colorado forest (USFWS, 1993)

Habitat Vegetation or Surface Water Classification

Adult: Palo colorado forest (USFWS, 1993)

Tolerance Ranges/Thresholds

Adult: Low (inferred from USFWS, 1993)

Site Fidelity

Adult: High (inferred from USFWS, 1993)

Habitat Narrative

Adult: The Luquillo Mountains region is of volcanic origin and of a rough topography, with cliffs and rock exposures at high elevations. Six major rivers are born in the mountains and waterfalls are numerous. Nineteen soils belonging to four soil associations have been identified within the Caribbean National Forest (Silander et al. 1986), of which the Los Guineos-Guayabota-Rock land association constitutes the most extensive one (USDA 1977). This association contains acidic, shallow to deep, well drained to poorly drained steep soils. The Caribbean National Forest holds four vegetation types: tabonuco forest, palo colorado forest, palma de sierra forest, and dwarf or elfin forest. All the known localities of *Callicarpa ampla* and *Styrax portoricensis*, and some localities of *Ternstroemia luquillensis* and *Ternstroemia subsessilis* occur within the palo colorado vegetation type. Some localities of *Ternstroemia luquillensis* and *Ternstroemia subsessilis*, and all the localities of *Ilex sintenisii* occur in the dwarf forest vegetation type (USFWS, 1993). High ecological integrity and site fidelity as well as low tolerance ranges are inferred based on species specific habitat needs and low number of populations.

Dispersal/Migration**Motility/Mobility**

Redundancy:

Low (inferred from USFWS, 2015)

Number of Populations:

One (USFWS, 2015)

Population Size:

~19 individuals (USFWS, 2015)

Population Narrative:

Styrax portoricensis: Palo de jazmín is a tree only known from the Luquillo Mountains in eastern Puerto Rico (Liogier and Martorell 2000). At the time of listing (1992) palo de jazmín was known from a single individual growing in the Palo Colorado forest west of El Cacique in the Luquillo Mountains. The current number of individuals in the wild (natural populations) is estimated at about 19 trees (Table 2) within the following areas of El Yunque National Forest: Monte Cacique area (1-3 ind.), Río Espiritu Santo (2 ind.), Palo Hueco (8 ind.), Arboretum (2 ind.), and Cristal Trail (4 ind.) (Luis Rivera, USFS, 2011, pers. comm.). The USFS also reported a single planted individual in the Catalina area (USFS office at El Yunque National Forest). There are also unconfirmed records of the species in the area surrounding the Puerto Rican Parrot Aviary (Anastacio Gómez, USFS, 2012, pers. comm.). In addition, the PRCT planted about 5 individuals of this species within a property they manage in the municipality of Barranquitas. These trees have developed as reproductive individuals and are managed for conservation purposes. Despite the historical information, during the 2011 surveys no individuals of natural populations mentioned above were located at El Yunque National Forest. Since there is no long term monitoring of the natural populations and some of the historical populations seem to be lost or probably extinct, it is not possible to establish any trend about the population's status or demography (USFWS, 2015). In addition, Low resiliency, representation and redundancy are inferred based on low number of populations and individuals.

Threats and Stressors

Stressor: Forest management (USFWS, 2015)

Exposure:**Response:****Consequence:** Loss of habitat/Loss of individuals

Narrative: At the time of listing, forest management practices such as the establishment and maintenance of plantations, selective cutting, trails and roads construction and maintenance, and shelter construction may have affected these trees. Furthermore, the proposed reconstruction and reopening of Road PR 191 was considered as a direct threat to some populations of these species. The destruction of the dwarf or elfin forests for the construction and/or expansion of communication facilities by the U.S. Navy and private entities were also considered a threat. Based on the available information, the core of the known populations of *I. sintenisii*, *S. portoricensis*, *C. ampla*, *T. subsessilis*, and *T. luquillensis* occur within the boundaries of El Yunque National Forest. Since the time of listing the USFWS has not documented any case of an individual of an endangered species being affected by forest management practices (management of plantations, trail maintenance or road construction). Moreover, the plans to reopen Road PR 191 have been abandoned due to the potential for further landslides that may compromise the project. Nonetheless, the USFS consults with the Service under Section 7 of the ESA when proposing actions within the forest to ensure that possible adverse effects to listed species are avoided or minimized before any such project is implemented. In addition, the USFS conduct environmental reviews documents under NEPA for all actions in the forest. These consultation mechanisms are effective tools to minimize possible effects of management activities on species and their habitats. Based on the above, we consider the present or threatened destruction, modification, or curtailment of the species habitat or range as low in magnitude and not imminent threat to these species (USFWS, 2015).

Stressor: Overutilization (USFWS, 2015)**Exposure:****Response:****Consequence:** Loss of individuals

Narrative: Despite the fact that plant collection in El Yunque National Forest is prohibited, when the five species were listed, collection was considered a threat due to the ornamental potential of these species. However, there is no evidence indicating that the species has been affected by these factors. Based on the above, we believe that overutilization for commercial, scientific or educational purposes is no longer a threat to these species (USFWS, 2015).

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2015)**Exposure:****Response:****Consequence:** Loss of habitat/Loss of individuals

Narrative: Since the currently known populations of these species are mostly restricted to El Yunque National Forest, and there are appropriate Commonwealth and Federal laws and regulations protecting these five species, we believe that the inadequacy of existing regulatory mechanisms should no longer be considered a threat to them. However, historical collections indicate that suitable habitat may extend to private properties adjacent to El Yunque. In fact, some of the known populations that occur within El Yunque National Forest are located just along the boundaries of the forest. Thus, it is important to note that enforcement on private lands continues to be a challenge as accidental damage or extirpation of individuals has occurred with other federally listed species due to lack of knowledge of the species by private land owners and law enforcement officers (USFWS, 2015).

Stressor: Hurricanes (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: Due to the low number of populations and individuals, hurricanes were identified as a threat to *I. sintenisii*, *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis* in the final rule. As endemic to the Caribbean, these tree species should be well adapted to tropical storms disturbance. However, the low number of populations and individuals pose a threat to the species by making them more susceptible to stochastic events such as hurricanes. In fact, it is not clear to what extent populations of these species may have been affected by Hurricane Hugo (which devastated El Yunque National Forest in 1989) or Hurricane Georges (in 1998). The heavy rains associated with tropical storms and hurricanes in the mountains of Puerto Rico often lead to landslides. Despite the low number of populations and individuals, the USFWS considers hurricanes, landslides and climate change as a moderate and non-imminent threat to these species (USFWS, 2015).

Stressor: Landslides (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: Natural landslides are common as part of the forest dynamics of El Yunque and it is expected that the frequency of this disturbance increases as a result of severe extreme rain events or droughts. Given the steep slopes on which most of these species grow, massive landslides may extirpate entire populations. The USFWS is aware that an area of road PR 191 that formerly connected the municipalities of Río Grande and Naguabo, and that run across the forest has historically been affected by landslides. This area was the site of some populations that were not located by the interagency group in 2011. Due to the severity of landslides, it was determined that it was not logistically and economically feasible to repair this road. Based on the 2011 surveys, *I. sintenisii* seems to be the only species that is not imminently threatened by hurricanes and landslides. The prime habitat for *I. sintenisii* is associated with dwarf forest vegetation. Due to the low agricultural value and inaccessibility of this habitat, this vegetation was not cleared during the peak of the deforestation of the island, and thus some of the highest parts of El Yunque remain as pristine forest. This explains the relative abundance of the species along the summits of Pico El Yunque and Pico del Este. Despite the low number of populations and individuals, the USFWS considers hurricanes, landslides and climate change as a moderate and non-imminent threat to these species (USFWS, 2015).

Stressor: Climate change (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: This species may be further threatened by climate change, which is predicted to increase the frequency and strength of tropical storms and can cause severe droughts (Hopkinson et al. 2008). Vulnerability to climate change impacts is a function of sensitivity to those changes (e.g., changes rain regime and moisture availability), exposure to those changes, and adaptive capacity (Glick et al. 2011). Despite the relative abundance and apparently stability of the populations of *I. sintenisii*, its habitat is considered rare in Puerto Rico. These areas (dwarf

forest vegetation) are ecological islands that harbor unique vegetation and environmental conditions. Shifts of vegetation communities are expected as temperatures and moisture regimes are altered by climate change. Under this scenario populations of *I. sintenisii* as well as *S. portoricensis*, *C. ampla*, *T. subsessilis*, and *T. luquillensis* may be displaced or outcompeted by native or exotic species with wider environmental plasticity. Despite the low number of populations and individuals, the USFWS considers hurricanes, landslides and climate change as a moderate and non-imminent threat to these species (USFWS, 2015).

Stressor: Genetic variation (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of viability

Narrative: Along with a decreasing population size, negative impacts of habitat fragmentation may result in erosion of genetic variation through the loss of alleles by random genetic drift (Honnay and Jacquemyn 2007) and may also limit the ability of a species to respond to a changing environment (Booy et al. 2000). Given the extremely small population size and lack of connectivity between populations of *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis* in Puerto Rico, it is highly likely that their genetic variability is extremely low. Based on the above, we consider the lack of genetic variation a high and imminent threat to *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis*. Overall, we consider hurricanes, landslides, climate change and genetic variation as threats to *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis*. Due to the small number of populations, the USFWS considers the above mentioned threats as high in magnitude and imminent for those species. In the case of *I. sintenisii*, the species is at least stable and probably improving, thus we consider the above mentioned threats as low and non-imminent (USFWS, 2015).

Recovery

Reclassification Criteria:

An agreement between the Fish and Wildlife Service and the USDA Forest Service concerning the protection of *Callicarpa ampla*, *Ilex sintenisii*, *Styrax portoricensis*, *Ternstroemia luquillensis*, and *Ternstroemia subsessilis* within the Caribbean. National Forest property has been prepared and implemented (USFWS, 1993).

An agreement between the Fish and Wildlife Service and the Department of Natural and Environmental Resources (DNER) concerning the protection of the three species in Commonwealth forests has been prepared and implemented, if the species is found within DNER properties (USFWS, 1993).

New populations (the number of which should be determined following the appropriate studies) capable of self perpetuation have been established within protected areas (USFWS, 1993).

Delisting Criteria:

1. Existing natural populations exhibit a stable or increasing trend, evidenced by natural recruitment, and multiple age classes (addresses Factors E). (USFWS, 2019).

2. Establish or discover four (4) additional populations within the current range at EYNF that exhibit a stable or increasing trend, evidenced by natural recruitment, and multiple age classes (addresses Factors A and E). (USFWS, 2019).
3. Establish or discover two (2) new populations outside the current range but within the historical range (e.g., Carite, Guilarte or Toro Negro Commonwealth Forests) that exhibit a stable or increasing trend, evidenced by natural recruitment, and multiple age classes (addresses Factors A and E). (USFWS, 2019).
4. Threats have been addressed and/or managed to the extent that the species will remain viable into the foreseeable future (addresses Factor A and E). (USFWS, 2019).

Recovery Actions:

- Criterion 1 has been partially met. There is no formal agreement between the USFS and the USFWS for the implementation of a management plan to protect these five species. However, the El Yunque National Forest is managed by the USFS for conservation, and has an approved “Revised Land and Resource Management Plan” (1997), which is currently under revision. Moreover, Federal agencies are mandated to carry out programs for the conservation of endangered species under Section 7 of the Endangered Species Act (ESA) to ensure that any action authorized, funded or carried out by a Federal agency is not likely to jeopardize the continued existence of a federally listed species. Thus, the USFS continually consults with the USFWS to avoid and minimize impacts to listed species and their habitat at El Yunque National Forest. In addition, on July 26, 2005, the U.S. Congress enacted the Caribbean National Forest Act to designate approximately 10,000 acres of land in the El Yunque National Forest as wilderness and as a component of the National Wilderness Preservation System in accordance with the Wilderness Act (16 U.S.C. 1131 et seq.). This Act prohibits certain activities (e.g., timber harvest) within wilderness designated areas, although it does not preclude the installation and maintenance of facilities (e.g., data collection and remote transmission facilities) essential to the scientific and conservation purposes of the Forest Service. Therefore, the majority of the habitat upon which these species depend upon is essentially protected (USFWS, 2015).
- Criterion 2 has been partially met. Although there is no specific agreement between USFWS and the PRDNER concerning the protection of these three species in Commonwealth forests, there is an agreement between the two agencies under Section 6 of the Endangered Species Act, in which the PRDNER carries out conservation activities for the benefit of threatened and endangered species. Furthermore, these five species are listed by the PRDNER as endangered, and thus are protected by regulations of the Commonwealth of Puerto Rico (See factor D.). Therefore, special consideration is taken when considering actions within areas that harbor suitable habitat for these species (USFWS, 2015).
- Criterion 3 has been initiated. The Puerto Rico Conservation Trust (PRCT) is successfully propagating *Styrax portoricensis*. The USFWS has utilized some of this material and begun planting this species (approximately 50 individuals) at El Yunque National Forest. In addition, the PRDNER began planting *Styrax portoricensis* (approximately 5 individuals) in the Carite Commonwealth Forest. Furthermore, the USFS has propagated *Callicarpa ampla* by air layering (cloning by promoting rooting of branches using hormones), and has planted about three individuals at El Portal in El Yunque National Forest. However, little information is available about the reproductive biology and the ecology of these species. Further research and monitoring of reintroduced individuals is required to determine the success of these

actions. There is no information about the propagation of any of the remaining three species (*Ilex sintenisii*, *Ternstroemia luquillensis* and *Ternstroemia subsessilis*) (USFWS, 2015).

- New in 2019: 1. Establish long-term conservation mechanisms (e.g., land conservation easements and conservation agreements) for private lands outside/bordering EYNF since these lands share similar vegetation and habitat characteristics. This new action should be included within Recovery Task 11. (USFWS, 2019).
- 2019 - 2. A protocol for the propagation and reintroduction of all five species should be developed in collaboration with partners (e.g., University of Puerto Rico, KEW, Fairchild Tropical Botanic Garden, PRDNER, Para La Naturaleza and Natural Resources Conservation Service). The protocol should address the feasibility of seed banking these species, and if deemed necessary, seed material should be stored at the Millennium Seed Bank (KEW) and USDA National Laboratory for Genetic Resources Preservation in Ft. Collins. This new action should be included within Recovery Task 33. (USFWS, 2019).
- 2019 - 3. Studies in the species' population genetics should be conducted to determined patterns of genetic diversity across the species natural distribution, and to provide baseline information for sound management of these species. This new action should be included within Recovery Task 3. (USFWS, 2019).

Conservation Measures and Best Management Practices:

- 1. The USFS should establish a long term monitoring program for the populations of listed plants at El Yunque National Forest to determine population trends for these species. The guidelines for these monitoring should be included as part of the El Yunque National Forest Management Plan (USFWS, 2015).
- 2. Develop a comprehensive survey and assessment of the population of *I. sintenisii*. This survey must be standardized to ensure that the habitat (dwarf forest) is efficiently surveyed (USFWS, 2015).
- 3. Molecular studies should be conducted to determine the relationships within the genus *Ilex* in Puerto Rico (USFWS, 2015).
- 4. The USFS, PRDNER and the USFWS should develop an intensive survey program to inventory areas within and outside El Yunque National Forest with potential habitat for these species. This program should include training to field biologists to allow personnel to recognize listed species in the field (USFWS, 2015).
- 5. The populations that are actively producing seeds need to be identified and monitored to collect seed material for recovery purposes. A protocol to collect seed should be developed and implemented to avoid altering the natural recruitment of the species (USFWS, 2015).
- 6. Enhancement of natural populations should be considered a priority, particularly for *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis*. The development of adequate propagation techniques is essential for the recovery of these species (USFWS, 2015).
- 7. Studies should be conducted to determine the patterns of genetic variation within and among populations, in order to develop a plan to preserve the species genetic variability (USFWS, 2015).
- 8. The recovery plan should be revised to establish measurable delisting criteria, including how many individuals constitute a self-sustainable population and how many populations would be needed to delist the species (USFWS, 2015).

SPECIES ACCOUNT: *Styrax texanus* (Texas snowbells)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/12/1984; Southwest Region (Region 2) (USFWS, 2016)

Physical Description

A shrub, usually with several stems from the base, up to 4 m tall. The leaves are alternative, suborbicular, 4-8 cm long, and about as broad. The leaf margins are entire and the leaf bases are cuneate to truncate or rounded. The upper leaf surface is glabrous, bright green and smooth and the lower leaf surface is conspicuously white with a very fine and dense silky tomentum. Flowers are axillary, solitary or in 2-5 flowered racemes with puberulent pedicles 10-12 mm long. The calyx is 4-6 mm long, pale, densely puberulent, apex grandular, and 5-7 toothed. There are 10 stamens with bright orange-yellow anthers. Fruits are dry, globose to subglobose, 7-8 mm in diameter (Gonsoulin, 1974). Produces showy white flowers borne in clusters among the rounded, bright green leaves with white undersurfaces. Blooms primarily in April. (USFWS, 1987; NatureServe, 2015)

Taxonomy

Fritsch (1996, 1997) completed isozyme analysis and DNA sequencing on Texas snowbells. These two studies in addition to others completed on *Styrax* morphology by Fritsch led to the designation of *S. texana* as a subspecies of *S. platanifolius*, along with four other subspecies: *platanifolius*, *stellatus*, *youngiae*, and *mollis* (Fritsch 1997). Fritsch (1997) considered the morphological variation recognized by Cory (1943) and Gonsoulin (1974) to be taxonomically unreliable or inconsequential. Fritsch (1997) confirmed the ranges of three of the subspecies (*platanifolia*, *stellata*, and *texana*) did overlap, but genetically they are different enough to be subspecies. USFWS currently recognizes this plant as *S. platanifolius* ssp. *texanus* (USFWS, 2008; 2018).

Historical Range

At the time of listing, 25 Texas snowbell plants were known from Edwards, Real, and Kimble Counties, Texas however, a report of four individuals from Kimble County was later determined to be incorrect. Other plants thought to be Texas snowbells were reported in 1942 from Val Verde County, Texas, but have not been reconfirmed (49 FR 40036-40037, TPWD circa 1995). (USFWS, 2008)

Current Range

Endemic shrub of the Edwards Plateau of Texas. Since 1986, field surveyors have documented 400 mature and 452 immature Texas snowbells plants in 22 naturally occurring sites in Real, Edwards, and Val Verde counties (USFWS, 2018)

Critical Habitat Designated

Yes;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Obligate out-crosser; fertilization requires transfer of pollen between individuals that are not too closely related (USFWS, 2018).

Dependency on Other Individuals or Species

Adult: The known pollinators include native species of bumblebee and carpenter bee and the introduced honey bee (USFWS, 2018).

Breeding Season

Adult: Texas snowbells usually flowers in April, and if fertilized, flowers produce a typically single-seeded dry fruit that matures in August (USFWS, 2018).

Other Reproductive Information

Adult: Fruits usually have one seed, but may have up to four under the most favorable conditions (Poole et al. 2007, p. 476 in USFWS, 2017).

Reproduction Narrative

Adult: Texas snowbells usually flowers in April, and if fertilized, flowers produce a typically single-seeded dry fruit that matures in August. However, investigations of the breeding system of Texas snowbells and another closely related species of *Styrax* indicate that it is an obligate out-crosser; fertilization requires transfer of pollen between individuals that are not too closely related. The known pollinators include native species of bumblebee and carpenter bee and the introduced honey bee. High rates of fertilization probably require that Texas snowbells plants are separated by no more than 0.5 to 1.0 km (0.3 to 0.6 mi). Almost all documented reproduction of Texas snowbells in the wild, as indicated by the presence of immature plants, occurs among populations that have at least 56 mature individuals dispersed over a distance of 1.6 km (1.0 mi) or less. Little or no reproduction occurs among isolated individuals and small populations. Reproductive success depends on the size and distribution of populations for two reasons: , Texas snowbells is very likely to be obligately xenogamous and pollen must be transferred between genetically compatible individuals that are within the foraging range of suitable bee or butterfly pollinators (USFWS, 2017; 2018a).

Habitat Type

Adult: Populations occur in limestone bluffs, boulder slopes, cliff faces, and gravelly stream-beds, usually along perennial streams or intermittent drainages in canyon bottoms, in full sun or in partial shade of cliffs and/or sycamore-little walnut woodlands, oak-juniper woodlands, or mixed oak-shrublands (Poole et al., 2007 in USFWS, 2017).

Habitat Vegetation or Surface Water Classification

Adult: Sycamore-little walnut, oak, oak-juniper woodland; near river drainages, canyons, and draws (USFWS, 2008; NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Annual precipitation ranges from 51.3 centimeters (cm) (20.2 inches [in]) to 69.5 cm (27.4 in); average temperatures range from a minimum of 0.9° Celsius (C) (33.6° Fahrenheit [F]) in January to a maximum of 36.3° C (97.3° F) in July (USFWS, 2018b).

Geographic or Habitat Restraints or Barriers

Adult: Elevations range from 372 to 579 m (1,220 to 1,900 ft) (USFWS, 2018b).

Environmental Specificity

Adult: Narrow (USFWS, 2018b)

Habitat Narrative

Adult: Pockets of rocky clay soils or crevices in limestone cliffs, bluffs, and ledges above permanent streams or rivers or above rocky stream beds with high water tables. (The steep areas are probably not the plant's primary habitat, but are refuges from extreme livestock grazing pressure.) Texas snowbells occur in moist habitats such as river drainages, canyons, and draws, which are abundant in the Edwards Plateau (Correll and Johnston 1970, Vines 1984, Poole and Birnbaum 2005, Riskind and Diamond 1988). Most plants occur in areas where they receive at least partial shade from surrounding vegetation during the day (Poole and Cook 1996). This species is found at elevation ranges from 372 to 579 m (1,220 to 1,900 ft). The surrounding vegetation is sycamore-little walnut (*Platanus occidentalis*-*Juglans microcarpa*), oak, or oak-juniper woodland. Average precipitation ranges from 51.3 centimeters (cm) (20.2 inches [in]) to 69.5 cm (27.4 in); average temperatures range from a minimum of 0.9° Celsius (C) (33.6° Fahrenheit [F]) in January to a maximum of 36.3° C (97.3° F) in Jul. (NatureServe, 2015; USFWS, 2018b)

Dispersal/Migration**Dispersal**

Adult: Low (USFWS, 2008)

Dispersal/Migration Narrative

Adult: Most Texas snowbell seeds fall directly beneath the parent plant (Poole 1993). Those seeds may stay where they fall on the ground, be moved by water if growing over a stream or creek, or be carried off by small mammals such as rock squirrels (*Spermophilus variegates*) or wood rats (*Neotoma* sp.) (TPWD 1990, Poole 1993). (USFWS, 2008)

Population Information and Trends**Population Trends:**

Stable to increasing (USFWS, 2017)

Species Trends:

Stable to increasing (USFWS, 2017)

Resiliency:

Low (USFWS, 2018a)

Representation:

Low (USFWS, 2018a)

Redundancy:

Low (USFWS, 2018b)

Number of Populations:

22 (USFWS, 2018a)

Population Size:

<1,000 (USFWS, 2008a)

Minimum Viable Population Size:

900-1,200 individuals (USFWS, 2018a)

Population Narrative:

Since 1986, field surveyors have documented 400 mature and 452 immature Texas snowbells plants in 22 naturally occurring sites in Real, Edwards, and Val Verde counties. Fifteen of the documented sites had fewer than 10 individuals and 2 had at least 100. Fifteen naturally occurring populations are on private land, 5 are on private conservation land (Dolan Falls Preserve and conservation easements managed by The Nature Conservancy), and 2 are on public conservation land (Devil's River State Natural Area). The subspecies has also been reintroduced in 22 sites on private land and 2 sites at Dolan Falls Preserve. By comparing with other plant species that have similar, well-studied life histories, we estimate that the minimum viable size of metapopulations is from 900 to 1,200 individuals. The global population spans a range of 121 km (75 mi) east to west and 35 km (22 mi) north to south. The known populations occur along watercourses, on or near steep slopes, in exposed limestone and gravel of the upper reaches of the Nueces, West Nueces, and Devils River watersheds. We estimate that about 15,043 ha (37,172 ac) of potential habitat exist in these watersheds. An unconfirmed population has also been reported from the lower West Frio River. The number of mature, naturally occurring Texas snowbells plants documented in 2013 was 8 times greater than in 1984 when it was federally listed as an endangered species. However, this increase primarily reflects new discoveries of individuals and populations rather than actual population growth. Texas snowbells has a low level of resilience because all known populations are far below the estimated minimum viable population level. There are few populations, hence redundancy is low. The subspecies is endemic to a small area with little ecological differentiation, and has little genetic diversity and therefore has low representation. In synthesis, the viability of Texas snowbells is low (USFWS, 2017; 2018a; 2018b).

Threats and Stressors

Stressor: Browsing by white-tailed deer, goats, and introduced ungulates (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: White-tailed deer population density is very high in much of the Edwards Plateau. In addition, ranchers introduced large numbers of goats in Real County (and elsewhere) beginning in the early 20th century; by 1930 there were 137,000 goats in the county (Minton 2010, pp. 3-4). More recently, the introduction of exotic ungulates has been promoted as an economic opportunity for Texas landowners (Mungall and Sheffield 1994, pp. 188-194). Some introduced ungulates, including aoudads, blackbuck antelope (*Antelope cervicapra*), axis deer, and fallow deer (*Dama dama*), have escaped and established large breeding populations in the wild. All of these ungulates browse to some degree on woody plants (Huerta-P. et al. 2005, pp. 239-242). In many parts of the Edwards Plateau an abrupt browse line in trees and shrubs provides stark

evidence of the intensity of ungulate browsing. Poole (1993) demonstrated that browsing is a major cause of mortality to Texas snowbells seedlings. Fulton (2010, attachment) provided photographic documentation of feral aoudads eating Texas snowbells plants. Successful recruitment and reintroduction of Texas snowbells occurs where plants are protected from browsers with fencing or other barriers, or where population densities of ungulate browsers are lower. Barriers are useful, short-term solutions to the browsing problem; full recovery of Texas snowbells will require better management of deer and feral ungulate populations (USFWS, 2017).

Stressor: Severe floods (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: The steep, rocky terrain of the Edwards Plateau and frequent occurrence of heavy rainfall contribute to the severity of the region's flash floods (Eckhardt 2015, pp. 1-2). Texas snowbells seeds often fall on dry stream beds and may germinate and establish there, only to be swept away during flash floods. The vulnerability of young Texas snowbells plants was demonstrated when a flood washed away the seedlings that were initially planted at EO2. The incidence of flash flooding is a natural and unavoidable feature of the narrow riparian habitats of Texas snowbells. However, flash flooding could become more frequent or more severe as a result of climate change (USFWS, 2017).

Stressor: Drought (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Tree ring data indicate that severe, extended droughts have occurred repeatedly in the Edwards Plateau since the year 1500 (Cleaveland et al. 2011, all). At EO17, average annual mortality of Texas snowbells was 6%, but increased to about 22% during the exceptional drought of 2011 (Reemts et al. 2016, p. 1). Therefore, the intensity and duration of drought are factors that affect the survival of Texas snowbells. Since it is likely that the intensity and/or duration of droughts will increase on a regional to global scale due to climate changes (IPCC 2013, p. 23), the viability of Texas snowbells may decline as a result (USFWS, 2017).

Stressor: Land ownership (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: A large portion of the known individuals and populations of Texas snowbells occurs on privately owned land. This does not constitute a threat to the subspecies, and in fact many landowners have demonstrated interest and enthusiasm for conservation of Texas snowbells. However, private ownership makes conservation more challenging for several reasons. Access to populations and habitats is subject to the interests of hundreds of individual landowners. Consequently, our knowledge of the subspecies' actual status is far from complete. Establishing and maintaining cooperative relationships with large numbers of private landowners is time-consuming, and these important relationships may lapse when personnel of conservation organizations retire or pursue other career choices. The ownership of private lands changes hands over time, and future owners may choose not to continue conservation efforts that were supported by previous owners. Hence, it is difficult to assure permanent conservation on private

lands. These challenges underscore the importance of effective landowner outreach in the conservation of Texas snowbells (USFWS, 2017).

Stressor: Small population size (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Texas snowbells has been documented in 22 sites; 15 of these sites had less than 10 individuals. The entire global population of about 400 mature, reproductive individuals is less than an estimated MVP of 900 to 1,200 individuals. In addition to the lack of reproduction, small populations are more vulnerable to extirpation from stochastic (random) events. For example, it is more likely that a single landslide or flood could wipe out every individual of a small colony of Texas snowbells than a larger population with colonies spread out over a wider area (USFWS, 2017).

Stressor: Lack of genetic diversity (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Fritsch (1996, p. 350) found low levels of genetic diversity among the Texas subspecies of *Styrax platanifolius*, suggesting that the group had undergone a genetic bottleneck. Adams and Poole (2011, pp. 200-202) also found very little evidence of variation between individuals or among populations of Texas snowbells. This lack of genetic diversity may reduce the potential to adapt to new or existing diseases and parasites, extreme weather, and climate changes. Low genetic diversity may also reduce fertilization and seed production if remaining individuals are too closely related for out-crossing (USFWS, 2017).

Stressor: Population fragmentation and isolation (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Successful fertilization probably requires the transfer of pollen between individuals that are not closely related. In addition to low population size, the fragmentation and isolation of individuals and small colonies decreases the likelihood of successful reproduction. The progeny of small colonies may be too closely related to fertilize each other, so small colonies are more likely to die out than larger ones. An important factor for long-term management of the subspecies is the effective pollination range of its insect pollinators. We estimate that genetically diverse individuals should be not more than about 0.5 to 1.0 km (0.3 to 0.6 mi) apart for high fertilization rates to occur (USFWS, 2017).

Stressor: Pollinator deficiency (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: We currently do not have information on the population statuses of the known pollinators of Texas snowbells. However, many pollinator species, including bumblebees (Williams and Osborne 2009, pp. 368-374), have declined in many parts of the world. Since fertilization of Texas snowbells probably requires outcrossing, and depends on bumblebees and

other insect pollinators, declines in populations of these pollinators within the subspecies' habitats represents a potential threat to its viability (USFWS, 2017).

Stressor: Climate change (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: The Fifth Assessment Report of the Intergovernmental Panel on Climate Change (IPCC) (IPCC 2013, p. 23) projects the following changes by the end of the 21st century, relative to the 1986 to 2005 averages: It is virtually certain that most land areas will experience warmer and/or fewer cold days and nights; it is virtually certain that most land areas will experience warmer and/or more frequent hot days and nights; it is very likely that the frequency and/or duration of warm spells and heat waves will increase in most land areas; it is very likely that the frequency, intensity, and/or amount of heavy precipitation will increase in mid-latitude land masses; it is likely that the intensity and/or duration of droughts will increase on a regional to global scale. The magnitude of projected changes varies widely, depending on which scenario of future greenhouse gas emissions is used. These scenarios are called Representative Concentration Pathways (RCPs). Under the best-case scenario of RCP2.6, the combined emissions of carbon dioxide, methane, and nitrous oxide, expressed as the carbon dioxide equivalent, will stabilize at 475 parts per million (ppm) by the year 2100. This figure rises to 630, 800, and 1,313 ppm under the RCP4.5, RCP6.0, and RCP8.5 scenarios, respectively (IPCC 2013, p.22). The report also states, "In many mid-latitude and subtropical dry regions, mean precipitation will likely decrease..." (p. 16). However, the Fifth Assessment does not simulate regional precipitation patterns well (p. 11). Furthermore, we do not know how Texas snowbells would respond to changes in temperatures and rainfall amounts and patterns. Since these changes could be detrimental to the subspecies, climate change represents a potential threat to its continued survival (USFWS, 2017).

Stressor: Endemism (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Texas snowbells is endemic to a very limited area. We estimate that only about 15,043 ha (37,172 ac) of potential habitat exist in the upper portions of three watersheds; the subspecies' global range spans 121 km (75 mi) east to west and 35 km (22 mi) north to south. While endemism is not a threat, per se, it increases the subspecies' vulnerability to other threats. For example, climate change could further reduce the amount of potential habitat, or a single prolonged drought or catastrophic rainfall and flooding could increase mortality throughout the subspecies' range (USFWS, 2017).

Recovery

Reclassification Criteria:

Texas snowbells may be reclassified as a threatened species when the following conditions have been met: Self-sustaining metapopulations have reached the MVP level of at least 500 individuals of reproductive age in each recovery unit (occupied watershed): The upper Nueces, West Nueces, and Devils River. If wild populations are discovered in other watersheds, this criterion must also be met in those watersheds. MVP is based only on mature, reproductive individuals since mortality of young Texas snowbells plants is very high, and apparent population

sizes can fluctuate wildly if immature plants are included. Metapopulations may be considered self-sustaining when: a) Unaided recruitment equals or exceeds mortality over a 10-year span, which is the expected minimum time to complete an entire generation (as defined in III.7); b) facilitated population augmentation and reintroduction are no longer necessary for successful recruitment; and c) fenced exclosures or other types of barriers are no longer necessary to reduce mortality from ungulate browsing. However, we anticipate that population management of white-tailed deer and introduced ungulates, pollinator conservation, and other habitat management practices will continue to be necessary in this region. The continuation of these practices will not preclude the attainment of this criterion (USFWS, 2018b).

Delisting Criteria:

Recovery will be signified by: Resilient, redundant, viable metapopulations in the Nueces, West Nueces, and Devils River watersheds (and possibly other watersheds, if other naturally-occurring populations are discovered), where spontaneous recruitment over time equals or exceeds mortality; and the conservation of its ecological and genetic representation through the restoration of gene flow throughout each extant metapopulation (USFWS, 2018b).

Texas snowbells may be removed from the endangered species list when: All downlisting criteria (IV.1.a, b, and c) have been met and sustained, and self-sustaining metapopulations have been established in each recovery unit (occupied watershed) and have remained stable or increasing for 20 additional years (2 additional generations, as described in III.7); this is a total of at least 30 years (3 generations). The completion of 3 generations would likely span multiple periods of high and low precipitation. This represents the minimum number of generations required to detect demographic trends; however, a longer time frame may be necessary if a clear trend has not yet been observed (USFWS, 2018b).

Recovery Actions:

- Priority 1(1): Promote awareness and conservation of Texas snowbells on private lands in the upper Nueces, West Nueces, and Devils River watersheds, as well as other watersheds if natural populations are discovered there (USFWS, 2018b).
- Priority 1(2). Protect remnant populations and individuals of Texas snowbells from ungulate browsers, and reduce browse intensity through population management of native white-tailed deer and introduced ungulates in the upper Nueces, West Nueces, and Devils River watersheds (USFWS, 2018b).
- Priority 1(3). Conduct scientific investigations to guide conservation efforts (USFWS, 2018b).
- Priority 2(4). Augment small populations and isolated individuals to increase reproductive rates, and reintroduce populations to restore gene flow between and among remnant populations in the upper watersheds of the Nueces, West Nueces, and Devils Rivers. Augmentation and reintroduction may also be appropriate in the Frio, West Frio, Dry Frio, and Sycamore Creek watersheds if natural populations are confirmed there, but is contraindicated if other subspecies of *Styrax platanifolius* occur there, since this could lead to hybridization between subspecies (USFWS, 2018b).
- Priority 3(5). Search for new populations in potential habitats throughout the subspecies' range. In particular, the discovery or confirmation of populations in the Frio, West Frio, Dry Frio, or Sycamore Creek watersheds would increase our knowledge of the subspecies' geographic range and adaptability, and might confer greater ecological and genetic diversity (representation) to the subspecies as a whole (USFWS, 2018b).

- Priority 3(6). Promote conservation and management of native bees, butterflies, and other pollinators in the upper Nueces, West Nueces, and Devils River watersheds (USFWS, 2018b)
- Priority 3(7). Verify that viable, self-sustaining populations occur within each recovery unit and have maintained stable or increasing population sizes for three or more generations (a minimum of 30 years). One generation has passed when individuals are successfully recruited through seed germination within habitats, survive to maturity, produce viable seed, and the second-generation seed germinates in the same habitats. Based on observed growth rates in the wild, a single generation takes at least 10 years to complete (USFWS, 2018b).

Conservation Measures and Best Management Practices:

- Update the Recovery Plan to include objective and measurable recovery criteria that address all of the five listing factors that are relevant to the species. (USFWS, 2008)
- Obtain information on all natural and reintroduced populations to adequately assess the status of the species. (USFWS, 2008)
- Map the amount and distribution of potential Texas snowbell habitat across the range. (USFWS, 2008)
- Conduct a population viability analysis. (USFWS, 2008)
- Draft a reintroduction plan to maximize efficiency and success for meeting recovery criteria. (USFWS, 2008)

SPECIES ACCOUNT: *Suaeda californica* (California seablite)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Southwest (R8) (USFWS, 2015)

Physical Description

An evergreen shrub that forms low mounds, leafy with fleshy, narrow leaves, each 5-35 mm long. The tiny flowers (2-3 mm across) are borne July-October. (NatureServe, 2015)

Taxonomy

Suaeda californica was first described by Sereno Watson in 1874, based on type material collected by Bolander and Kellogg in San Francisco Bay tidal marshes. Amos Heller published the name *Dondia californica* in 1898, recognizing the genus name used by Michel Adanson in 1763. However, the name *Suaeda* has been conserved (Abrams 1944). Munz (1959) recognized several previously recognized taxa as subspecies of *S. californica*, and described the range as extending from San Francisco Bay south to Lower (Baja) California. Ferren and Whitmore (1983) noted that much of what had been identified as *S. californica* in southern California was a distinct taxon, which they named *S. esteroa*. Further study revealed that the only extant populations of *Suaeda* that resemble the type specimen of *S. californica* are those that occur in the vicinity of Morro Bay. In his revision of the genus, Ferren (1993) recognized *S. californica* as a full species (USFWS, 2013).

Historical Range

See Current

Current Range

Extirpated from the San Francisco Bay area; now known only from Morro Bay, San Luis Obispo County. May have once occurred in Sonoma County as well (Skinner and Pavlik 1994). Does NOT occur in southern California or Baja California - plants of these areas are referable to *S. esteroa* &/or *S. taxifolia* (Skinner and Pavlik 1994, USFWS 1994). (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Wind pollinated? (USFWS, 2013)

Breeding Season

Adult: Flowers typically appear from May to October, but mostly in late summer. Occasional flowers may be found at other times of the year, sometimes emerging as early as late spring (McMinn 1939, Baye pers. observ.) (USFWS, 2013).

Reproduction Narrative

Adult: *Suaeda californica* produces seeds throughout its lifespan. Reproduction appears to be entirely by seed (sexual); there are no known reports of natural regeneration from vegetative fragments. The spread of individual plants can be extensive, and sometimes resembles clonal populations. However, they have not been observed to spread clonally. Vegetative stem cuttings of *S. californica* treated with synthetic auxins (hormones) are easily rooted for artificial propagation (P. Baye pers. observ. 1991-1999). Reproductive maturity may in some cases be reached in as little as one year (P. Baye unpubl. data 1998). Flowering occurs on portions of the current year's shoot growth, usually on lateral branches of older wood. Flowers typically appear from May to October, but mostly in late summer. Occasional flowers may be found at other times of the year, sometimes emerging as early as late spring (McMinn 1939, Baye pers. observ.). Differences in flowering phenology may be an indication of genetic variation. One entire colony of *Suaeda californica* on Pickleweed Island, Morro Bay, was observed to flower precociously in April, while adjacent plants and all other colonies were entirely vegetative (P. Baye unpubl. data 2000). The longevity of individual plants is unknown, but large woody plants in stable substrate appear to live for over a decade. Very little information is available on the breeding system of *Suaeda californica*; however, a predominantly outcrossing breeding system would be expected for this wind-pollinated, often colonial, shrub. Abundant seed (many hundreds per plant) is produced on fruiting plants at Morro Bay. The ability of isolated plants in cultivation to produce seed (P. Baye pers. observ. 1998) suggests that at least some individuals possess a degree of self-compatibility. Abundant seed set occurred spontaneously in outdoor container-grown nursery plants at the Golden Gate National Recreation Area nursery in San Francisco in 1998. These seeds were viable and produced vigorous seedlings (E. Heimbinder pers. comm. 1999). Based on observations by marsh ecologist Peter Baye, abundant seedling establishment at Morro Bay appears to be episodic, corresponding to storm events that cause both vegetation gaps and deposits of driftline debris with seeds. Seedlings were widespread and abundant along the backbarrier shoreline following the erosive winter storms of 1998. Many thousands of seedlings and multiple-branched juvenile plants had established in the erosion zone in driftlines and litter rafts by late April 1998. Seedlings rooted in debris rafts without roots in the marsh substrate were subject to high mortality. No evidence of long distance dispersal and colonization was observed. Re-survey of the extensive 1998 seedling colonies in April of 1999 and 2000 revealed only regeneration of remnant mature shrubs that survived erosion. No juvenile or young mature plants were detected, indicating extremely high mortality of the post-storm cohort of seedlings. In contrast, the colonies of mature *Suaeda californica* at the north end of Morro Bay were mostly unaffected by the 1998 storm. These narrow, dense colonies acted as a significant refugia for survival and seed production during the catastrophic mortality that affected most of the population along the bayshore of the central sand spit (USFWS, 2013).

Habitat Type

Adult: Salt marsh (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Clumped (NatureServe, 2015)

Environmental Specificity

Adult: Narrow/specialist (NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: Low (inferred from NatureServe, 2015)

Site Fidelity

Adult: High (inferred from NatureServe, 2015)

Habitat Narrative

Adult: Species is restricted to the upper intertidal zone of a coastal salt marsh along the perimeter of a bay (NatureServe, 2015). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species and the relatively low number of known populations.

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Seeds of *Suaeda californica* are somewhat hard-coated, and are enclosed in fleshy calyces that become spongy and buoyant upon drying, and which remain attached to the fruits after dehiscence and dispersal (USFWS, 2010).

Population Information and Trends**Population Trends:**

Not available

Resiliency:

Low (inferred from NatureServe, 2015 and USFWS, 2013)

Representation:

Low (inferred from NatureServe, 2015 and USFWS, 2013)

Redundancy:

Low (inferred from NatureServe, 2015 and USFWS, 2013)

Number of Populations:

Nine (USFWS, 2013)

Population Size:

1 - 1000 individuals (NatureServe, 2015); ~500 (NatureServe, 2015)

Population Narrative:

< 500 genetic individuals estimated by McLeod (1991) as cited in USFWS 1994. (NatureServe, 2015). USFWS (2013) notes that there are nine known occurrences of this species 5 naturally occurring in Morro Bay and 4 re-introduced locations in San Francisco Bay. Low Resiliency, representation and redundancy are inferred based on the low number of occurrences and individuals as well as the small geographic range this species inhabits.

Threats and Stressors

Stressor: Alteration and Loss of Habitat (USFWS, 2013)

Exposure:

Response:**Consequence:** Loss of habitat

Narrative: The historical rarity of *Suaeda californica* in San Francisco Bay may have been due in part to the natural rarity of its sandy high marsh and beach habitat, but its extirpation seems related to the early spread of urban and port development over the East Bay shoreline from Richmond to Alameda, centered around Oakland (P. Baye pers. comm. 2004). This heavily urbanized area was the center of both the bay's sandy shorelines and *S. californica* distribution. Oakland and Alameda Marshes were filled and urbanized before the 20th century, eliminating populations there, but it was the destruction of Bay Farm Island for the construction of the Oakland International Airport in the 1950s and 1960s that probably destroyed the only remaining viable population in San Francisco Bay. Other species with affinity for sandy tidal marsh edges, such as *Atriplex californica*, were also described as occurring either along sandy beaches or sandy marsh edges within San Francisco Bay (Brewer et al. 1880, Jepson 1911, Greene 1894). These, too, have become extirpated. The Morro Bay population has suffered little habitat loss compared with San Francisco Bay, and has relatively abundant habitat there, despite declines following El Niño winter storm erosion. However, it is subject to strong fluctuations in abundance due to natural disturbances, particularly dune migration and shoreline erosion, and its regeneration following disturbance is vulnerable to numerous threats. Though the population has in the past been threatened by strong residential and commercial real estate development pressures on the east shore of Morro Bay, centered at Baywood Park and Los Osos, these pressures have been reduced drastically (J. Vanderweir pers. comm. 2009). Loss of habitat and individuals, and failed regeneration after natural catastrophes could cause extirpation of this population. Other threats include interference by non-native vegetation, trampling, oil spills, sea level rise associated with climate change, excessive dune mobilization, and alteration of shoreline dynamics due to stabilization and shoreline repair projects (USFWS, 2013).

Stressor: Recruitment failure (USFWS, 2013)**Exposure:****Response:****Consequence:** Loss of individuals/Weakening population

Narrative: Trampling of seedlings in Morro Bay may contribute to the failure of *Suaeda californica* regeneration following catastrophic shoreline erosion caused by major storms. Trampling results from both recreational activities (hiking) and by black-tail deer (*Odocoileus hemionus*) populations on the sand spit, and represents a relatively infrequent threat. However since seedling recruitment is episodic and local, impacts to seedlings (which are difficult to detect) could be severely detrimental at times. This is indicated by tracks and footprints along the Morro Bay shoreline in a devegetated zone nearly 0.5 meter (0.55 yd) wide (P. Baye pers. observ. 1997-1999). As recreational pressure on the Morro Bay shoreline increases with local residential population and increased visitor use at Montaña de Oro and Morro Bay State Parks, this impact is likely to become more severe (USFWS, 2013).

Stressor: Competition with non-native species (USFWS, 2013)**Exposure:****Response:****Consequence:** Loss of habitat

Narrative: Exotic invasive vegetation, primarily *Carpobrotus edulis* X *chilensis* hybrids (iceplant), *Eucalyptus globulus* (blue gum), and *Cupressus macrocarpa* (Monterey cypress; a native to the Monterey peninsula only), cause significant damage to *Suaeda californica* by direct interference

and indirect adverse habitat modification. *Carpobrotus edulis* establishes clonal colonies in adjacent uplands above saline influence, and can encroach by transporting nonsaline soil moisture from portions of the clone above the high tide line (P. Baye unpubl. data 1997). Most stands of *S. californica* along the perimeter road to Morro Beach State Park have been partially smothered by *C. edulis*, which grows through and over the *S. californica* colonies there. *Carpobrotus edulis* impacts are particularly significant for seedling regeneration along the backbarrier shore of Morro Bay spit. As the sandy backbarrier shoreline retreats into dense continuous stands of *C. edulis* on the dunes, *C. edulis* overhangs the erosional scarp and forms a canopy that drapes over the base of the scarp and upper shoreline. This sharply reduces or eliminates open seedling habitat for *S. californica*—its regeneration niche. It may also inhibit regeneration of storm-eroded remnants of *S. californica*. Therefore, spread of *C. edulis* along the dunes of the backbarrier shoreline is likely to reduce population resilience of *S. californica*. In fact, removal of *C. edulis* near *S. californica* populations has had a striking effect of recovery of the later (Baye in litt. 2009). Heavy leaf litter and canopy shade from non-native trees, *Cupressus macrocarpa* and *Eucalyptus globulus*, are detrimental to seedling habitats for *Suaeda californica*, and apparently cause decline in vigor of remnant stands of mature plants (e.g., near the entrance of Morro Bay State Park and in Baywood Park). Degradation of the ecological niche for seedling regeneration is probably a more severe long-term threat to the viability of the *S. californica* population than local disturbance of existing mature colonies. Stands of *S. californica* have been damaged directly by broken and fallen limbs of *E. globulus* adjacent to Morro Beach State Park (P. Baye unpubl. data 1997-2000). The persistence of suitable and restorable habitat for reintroduction of *Suaeda californica* to San Francisco Bay is also threatened by non-native vegetation. In San Francisco Bay, the spread of invasive *Spartina* (Daehler and Strong 1996) caused the conversion of open mudflat into stabilized tidal marsh that traps sediment and moderates estuarine wave energy. This invasive vegetation intercepted alongshore transport of sand in the middle and lower intertidal zone, and inhibited the wave deposition of the sandy higher elevation marsh-beach ecotone that is important for establishment of *S. californica*. Invasive *Spartina* eradication efforts have likely eliminated the further spread of the species which could have precluded the long-term viability of *S. californica* reintroduction (USFWS, 2013).

Stressor: Dredging (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Navigational dredging may threaten stands of *Suaeda californica* that have colonized the marina shoreline at Morro Bay State Park. Dredging of the inlet channel steepens the subtidal shore profile, probably resulting in shoreline erosion along the unarmored eroding south shore of the interior shoreline of the marina, which could threaten the *S. californica* colony there. The marina subpopulation of *S. californica* is particularly significant to the species' conservation because it is highly sheltered from storm wave erosion that threatens the main population along the spit's backbarrier shoreline (USFWS, 2013).

Stressor: Predation (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: In the absence of natural predators, hunting, or management in Morro Bay, deer populations are likely to forage intensively along the backbarrier shoreline where seeps provide fresh water, soft herbaceous vegetation, and flat travel corridors (USFWS, 2013).

Stressor: Small number of populations (USFWS, 2013)

Exposure:

Response:

Consequence: Extirpation

Narrative: *Suaeda californica* is vulnerable to extinction in the wild largely because it has been reduced to a very small number of populations distributed in a very narrow zone of the Morro Bay and San Francisco Bay shorelines. In Morro Bay, most of the colonies occur along the erodible backbarrier shore of the Morro Bay sand spit, which is susceptible to erosion by occasional extreme storm tides and high wind-generated waves, and rapid burial by migrating dunes. Severe storm erosion occurred along this shoreline in the winter of 1997-1998, creating an extensive erosional scarp in the narrow *S. californica* zone. The population has not yet rebounded from this event. Although this was a natural catastrophe and rebound may occur in time, erosion events may become a recurrent threat if climate change increases storm intensity, frequency, and sea level rise rates (USFWS, 2013).

Stressor: Climate change (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat/extirpation

Narrative: Extreme local fluctuations of climate (winter storms, high winds, summer drought) may be associated with global climate change. A series of severe winter storms followed by years of drought could cause catastrophic reproductive failure of the species. Global climate change and associated sea level rise may also cause long-term changes in the stability of sand beach and dune shorelines (SCOR Working Group 1991), such as those of Morro Bay spit. *Suaeda californica* occurs in abundance only where the backbarrier shoreline is adjacent to dune scrub vegetation that stabilizes dunes. It is sparse or absent where bare mobile dunes retreat over the backbarrier shoreline. Many of the remaining colonies are being encroached on by mobile dunes, and are not expected to survive more than a few years. The formation of new "marsh coves" (potential *S. californica* habitat) in the lee of stabilizing dunes may occur in the future, but none are foreseeable now. A combination of shoreline retreat and increased dune movement could significantly reduce the largest subpopulation of *S. californica*. Accelerated sea level rise and shoreline retreat could also force conflicts between natural movement of the *Suaeda californica* zone on the east shore of Morro Bay and landowner needs. Where costly residential developments are threatened by shoreline retreat, response typically involves armoring (structural stabilization) of the shoreline (e.g., revetments, seawalls, rip-rap, etc.). Currently, *S. californica* appears to be able to migrate with the slowly retreating shorelines of eastern Morro Bay (Baywood Park, heron rookery) (USFWS, 2013).

Stressor: Oil spills (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat/extirpation

Narrative: Oil spills and clean-up operations may have significant adverse effects on *Suaeda californica* populations at Morro Bay, particularly on seedlings. Spilled oil tends to accumulate

near the high tide line, the narrow marsh zone in which *S. californica* is largely restricted. Oil would probably cause high mortality of seedlings and juvenile plants during years of seedling regeneration by coating and smothering small plants with oil, and possibly by direct toxicity. Oil clean-up operations involving mechanical removal (raking, excavation) of oiled sand would also cause significant disturbance of *S. californica* habitat. Direct toxic effects of oil on older woody *S. californica* are uncertain, but are probably less damaging than effects of clean-up operations (USFWS, 2013).

Recovery

Delisting Criteria:

1) protection of the population at Morro Bay to ensure its long-term survival (USFWS, 2013).

2) re-establishment of suitable habitat with new populations in San Francisco Bay, the historical range of the species

Conservation Measures and Best Management Practices:

- 1. Any person collecting information on *Suaeda californica* as part of field surveys or research should be encouraged to submit occurrence information to the CNDDDB to provide a more comprehensive picture of this species distribution and status throughout its range (USFWS, 2010).
- 2. Potential re-introduction sites for *Suaeda californica* within the San Francisco Bay area and other sites within its historic range should continue to be evaluated by the Service (USFWS, 2010).
- 3. Land managers and the Service should work cooperatively to begin population surveys in all potentially suitable and legally-accessible habitat along the central coast to determine if there are yet undiscovered occurrences of *Suaeda californica* and to update the status of known occurrences (USFWS, 2010).
- 4. The CDPR and the Service should continue monitoring of existing outplanting efforts and seek to identify additional sites for outplanting of *Suaeda californica* on Federal, State, or otherwise conserved lands along the coastline in San Luis Obispo County (USFWS, 2010).
- 5. Establish site-specific and species monitoring protocols to identify potential impacts of sea-level rise and storm surge associated with climate change. This will assist in determining the effects of projected sea level rise and increased storm surge events on *Suaeda californica* and its habitat (USFWS, 2010).
- 6. The CDPR and Morro Coast Audubon Society should develop and implement active nonnative invasive species eradication programs for those occurrences of *Suaeda californica* under their management authority. Post-eradication, sites should be evaluated for their potential to re-establish occurrences of *S. californica* (USFWS, 2010).

SPECIES ACCOUNT: *Tabernaemontana rotensis* (No common name)

Species Taxonomic and Listing Information

Listing Status: Threatened; 11/02/2015; Pacific Region (R1) (USFWS, 2016)

Physical Description

A small to medium-sized tree (USFWS, 2015). It grows to heights of perhaps 6 m (20 ft.) and is rather weak and spindly in appearance, with large, yellow-green to dark-green leaves and thin, milky sap. The inflorescence consists of a few to over 30 flowers with 5 spirally arranged, united white petals that appear slightly folded until they flare at the tips. The fruits occur singly or twinned and have one to three ridges. Each fruit is relatively small, 3 to 7 cm (1.2 to 2.8 in) long, dehiscent (they open at maturity) (USFWS, 2000).

Taxonomy

A member of the dogbane family (Apocynaceae). The genus is widespread throughout tropical and subtropical regions (USFWS, 2015). Kanehira (1936) first described the species as *Ervatamia rotensis* from his type collection from Rota (Kanehira 3666). Stone (1965, 1970) recognized the species from the Rota and Guam collections (Stone 5256, Kanehira 3666, Hosokawa 9832) as *Tabernaemontana rotensis* (USFWS, 2000).

Historical Range

It is historically known from Guam and Rota (USFWS, 2015). Historically, *Tabernaemontana rotensis* was known from lowland dry forest on Rota; on Guam, *T. rotensis* was known from individual specimens in the limestone forests along cliffhills at Asanite, on the University of Guam campus, and at the "Japanese Overlook" of the Naval Magazine (Raulerson and Rinehart 1997) (USFWS, 2000).

Current Range

It currently occurs on Guam and Rota (Mariana Islands) (USFWS, 2015).

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Sexual (inferred from USFWS, 2000)

Breeding Season

Adult: Guam: January, May, July (herbarium specimens); Rota: October - November (herbarium specimens) (USFWS, 2000)

Reproduction Narrative

Adult: Each fruit contains 4 to 10 seeds in a red pulp. Herbarium specimens show flowering in Guam plants has occurred in January, May, and July; specimens collected on Rota were in flower in October and November (USFWS, 2000).

Habitat Type

Adult: Terrestrial (USFWS, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest (USFWS, 2015)

Habitat Narrative

Adult: It occurs in the forest ecosystem (USFWS, 2015).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: On Guam, seeds have been observed to mold in the seed case without separating from the fruit, indicating that birds may be useful in distributing the seeds (G. Wiles, in litt. 1998) (USFWS, 2000).

Population Information and Trends**Population Trends:**

Not available

Species Trends:

Increasing (USFWS, 2015)

Resiliency:

Low (inferred from USFWS, 2015)

Redundancy:

Low (inferred from USFWS, 2015)

Number of Populations:

Guam: 6; Rota: 1 (USFWS, 2015)

Population Size:

Guam: 21,000; Rota: 9 wild, 30 outplanted (USFWS, 2015)

Population Narrative:

In 2004, *T. rotensis* was known from 8 individuals on Rota, and at least 250 individuals on Guam (69 FR 1560; January 9, 2004). The best scientific data currently available indicate that on Guam, *T. rotensis* is known from 6 occurrences totaling approximately 21,000 individuals (M and E Pacific, Inc. 1998, p. 61; UOG 2007, pp. 32–42), and on Rota, *T. rotensis* is known from 9 individuals (CNMI DLNR 2014, in litt.). Additionally, there are 30 surviving outplanted individuals on Rota (USFWS, 2015).

Threats and Stressors

Stressor: Development, military training, urbanization (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: In their 2015 Final SEIS ([http:// guambuildupeis.us/](http://guambuildupeis.us/)) (see “Historical and Ongoing Human Impacts,” above), the U.S. Department of Navy states that approximately 5,000 Marines will be relocated from Okinawa to Guam, accompanied by approximately 1,300 dependents, with a concurrent introduction of support staff and development of infrastructure, and increased use of resources such as water (Berger et al. 2005, p. 347; JGPO– NavFac, Pacific 2015, p. ES–3). The current preferred alternative sites on Guam for cantonment and live-fire training include the Naval Computer and Telecommunications Station Finegayan and Northwest Field on Andersen AFB, where this species occurs. In November 2007, the people of Rota voted to legalize casino gambling to increase tourism, and two development projects have been proposed. Development around and within forested areas on Rota will also directly impact the forest habitat and individuals of this species (USFWS, 2015).

Stressor: Ungulates (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Several herds of Asiatic water buffalo or carabao roam southern Guam and the Naval Magazine area, and cause damage to the ecosystem that supports this species. Philippine deer have caused extensive damage resulting in changes in the forest structure, including erosion, grazing to the point of clearing the entire herbaceous understory, consumption of seeds and seedlings preventing regeneration of native plants and the spread of invasive plant species, and other physical damage (e.g., trunk rubbing) (Schreiner 1997, pp. 179–180; Wiles et al. 1999, pp. 193–215; Berger et al. 2005, pp. 36, 45–46, 100; CNMI– SWARS 2010, p. 24; JGPO–NavFac, Pacific 2010b, p. 3–33; SWCA 2011, pp. 35, 42; Harrington et al. 2012, in litt.). Feral pigs are extremely destructive and have both direct and indirect impacts on native plant communities. While rooting in the earth in search of invertebrates and plant material, pigs directly impact native plants by disturbing and destroying vegetative cover, and trampling plants and seedlings. Pigs may also reduce or eliminate plant regeneration by damaging or eating seeds and seedlings (USFWS, 2015).

Stressor: Fire (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Fire is a human-exacerbated threat to native species and native ecosystems throughout the Mariana Islands, particularly on the island of Guam. Fire can destroy dormant seeds of native species as well as plants themselves, even in steep or inaccessible areas. Successive fires that burn farther and farther into native habitat destroy native plants and remove habitat for native species by altering microclimate conditions to those favorable to alien plants (USFWS, 2015).

Stressor: Small population size/lack of reproduction (USFWS, 2000)

Exposure:**Response:****Consequence:**

Narrative: The primary threat to *Tabernaemontana rotensis* is the lack of reproductive vigor and seed distribution due to reduced numbers of individuals. This situation includes a lack of observed seed production on Rota, which may be due to either the lack of a pollinator or predation by insects, mice, or rats (G. Hughes, pers. comm. 1998) (USFWS, 2000).

Stressor: Nonnative plants (USFWS, 2000)

Exposure:**Response:****Consequence:**

Narrative: Competition with the nonnative vines *Momordica charantia* (balsam pear), *Mikania scandens* (mile-a-minute vine), and *Passiflora suberosa* (wild passionfruit) may threaten seedlings and saplings (G. Wiles, in litt. 1998) (USFWS, 2000).

Recovery**Reclassification Criteria:**

Not available - this species does not have a recovery plan.

Delisting Criteria:

Not available - this species does not have a recovery plan.

Recovery Actions:

- Not available - this species does not have a recovery plan.

Conservation Measures and Best Management Practices:

- Area 50, a 59-ac (24-ha) enclosure on Andersen AFB on Guam containing a relictual patch of limestone forest, was created to exclude ungulates and the brown treesnake (Hess and Pratt 2006, p. 2). This enclosure was maintained for ecosystem and species experimental research. Several individuals of the tree *Tabernaemontana rotensis* occur within the enclosure, and would benefit from protection from predators and habitat disturbance (Hess and Pratt 2006, p. 7). However, researchers found the enclosure in a state of neglect, and invaded by nonnative plant species and pigs, with only 20 ac (8 ha) of undisturbed primary forest remaining by 2006 (Hess and Pratt 2006, p. 24) (USFWS, 2015).
- In 2014, the Navy funded a project to examine the distribution and abundance of *Tabernaemontana rotensis* on Joint Regional Marianas (JRM) lands (DON 2014, in litt.) (USFWS, 2015).
- Rota's Department of Fish and Wildlife constructed enclosures for two occurrences of *Tabernaemontana rotensis* in the Sabana Conservation Area, but only one enclosure remains, as the other burned in a fire (Hess and Pratt 2006, p. 33; 65 FR 35029, June 1, 2000) (USFWS, 2015).

USFWS. 2000. Endangered and Threatened Wildlife and Plants

SPECIES ACCOUNT: *Taraxacum californicum* (California taraxacum)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Southwest (R8) (USFWS, 2015)

Physical Description

A perennial herb from a taproot. Leaves are all basal. Flower heads (May-August) are pale yellow, borne on leafless, hollow stalks, about 5-20 cm tall. (This species differs from the ubiquitous dandelion, *T. officinale*, in several ways including paler foliage and flower color and less deeply lobed leaves.) (NatureServe, 2015)

Taxonomy

Generally accepted as a distinct species endemic to California (San Bernardino Mountains only); accepted by all pertinent references: Munz (Flora of California, 1959), Stebbins in Jepson manual (Hickman, 1993), California Native Plant Society list (Skinner and Pavlik, 1994), California Natural Diversity Database (1999), and Kartesz (1994 checklist and 1999 Floristic Synthesis). Formally listed in 1998 as an endangered species by U.S. Fish and Wildlife Service. (NatureServe, 2015)

Historical Range

See current range/distribution.

Current Range

Endemic to the San Bernardino Mountains, ranging from the Holcomb and Bear Valleys to South Fork Meadows in the Santa Ana River watershed (USFWS, 2013)

Critical Habitat Designated

Yes; 8/14/2008.

Legal Description

On August 14, 2008, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Taraxacum californicum* (California taraxacum) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes eleven critical habitat units (CHUs), in California (73 FR 47706-47767).

Critical Habitat Designation

The critical habitat designation for *Taraxacum californicum* includes eleven CHUs in San Bernardino County, California. This species critical habitat encompasses approximately 1,914 acres (775 ha) (73 FR 47706-47767).

Unit 2: North Baldwin Meadow We are designating Unit 2 as critical habitat for both *Poa atropurpurea* and *Taraxacum californicum*. Unit 2 consists of approximately 177 ac (72 ha) of non-degraded meadow occupied by both species at the time of listing; both species continue to occur within this unit. Unit 2 contains all of the features essential to the conservation of both species. It is located within the SBNF, on the north shore of Baldwin Lake, and northeast of Big Bear Lake. Approximately half of Unit 2 is federally owned and half is owned by CDFG. Habitat in Unit 2 was historically impacted by authorized and unauthorized vehicle use, mining activity, residential development, and grazing by burros (CNDDDB 2006a, p. 1; SBNF 2002a, p. 33; SBNF

2002b, p. 57). The meadow is protected, but it is adjacent to State Route 18 and accessible to the public (SBNF 2000, p. 57). Disruption of the hydrologic regime by upstream development, trampling during illegal woodcutting, and quartzite theft activities were identified as past threats in this unit (CNDDDB 2006b, p. 16). Additionally, *Poa atropurpurea* and *Taraxacum californicum* and their essential features are threatened in this unit by competition from invasion of nonnative, herbaceous annuals, and *T. officinale* has been reported to occur in this meadow (Krantz 2007, p. 2). Therefore, special management considerations or protection may be required to restore, protect, and maintain the essential features in Unit 2 due to the threats from upstream development, nonnative species invasion, hybridization, and human disturbance.

Unit 3: Belleville Meadow We are designating Unit 3 as critical habitat for both *Poa atropurpurea* and *Taraxacum californicum*. Unit 3 consists of an approximately 414-ac (168-ha) meadow occupied by both species at the time of listing; both species continue to occur within this unit. Unit 3 (also referred to as Upper Holcomb Valley) contains all of the features essential to the conservation of both species. Although most individuals of *P. atropurpurea* observed were reported to be male, both sexes are present (SBNF 2000, p. 47). In 1999, the *T. californicum* population in Unit 3 was reported to be “large” and “healthy” with no apparent *T. officinale* hybrids (SBNF 2000, p. 56). Although no hybrid individuals are reported from this meadow, recent reports indicate that *T. officinale* is present at this location and the two species could hybridize (Krantz 2007, p. 2). Unit 3 is located within the SBNF, north of Big Bear Lake, and east of Hitchcock Meadow (Unit 4). The majority of lands within this unit are federally owned (409 ac (166 ha)), with only 5 ac (2 ha) of meadow habitat privately owned by the Lithuanian Scouts Association. Meadow habitat in this Unit 3 may be impacted by recreational activities and nearby diffuse mining operations (CNDDDB 2006a, p. 6; Eliason 2007b); and placement of USFS roads has resulted in habitat loss and effects to meadow hydrology. Several areas of Belleville Meadow are currently heavily utilized for dispersed recreation, including vehicle use along the classified roads through the site, hiking and mountain biking along the Gold Fever Trail, and use of Holcomb Valley Campground near the western portion of the meadow. Additionally, several mining claims also exist in the meadow. Unauthorized vehicle activity and mountain biking off of classified roads and trails have caused devegetation and alteration of surface hydrology in some areas (SBNF 2002a, p. 36). Finally, *Poa atropurpurea* and *Taraxacum californicum* and their physical and biological features are threatened in this unit by invasion of nonnative, herbaceous annuals, and *T. officinale* has been reported to occur in this meadow (Krantz 2007, p. 2). The USFS erected signs and fencing and conducted outreach to protect occurrences in Unit 3 (SBNF 2002a, p. 37). For example, to reduce impacts to *Poa atropurpurea*, trails within Holcomb Valley Campground were disguised and rehabilitated, and the area was protected through barricading and signing (SBNF 2002a, p. 5). Nearby trails that did not pass through listed plant habitat were delineated and signed to encourage visitors to use those trails (SBNF 2002a, p. 5). However, special management considerations or protection may still be required to restore, protect, and maintain the essential features in Unit 3 due to the threats from human disturbance; current nearby mining activities; hybridization; and invasive, nonnative plant species.

Unit 4: Hitchcock Meadow We are designating Unit 4 as critical habitat for both *Poa atropurpurea* and *Taraxacum californicum*. Unit 4 consists of an approximately 497-ac (201-ha) meadow occupied by both species at the time of listing; both species continue to occur within this unit. Although *T. officinale* is present, no apparent hybrids have been reported (SBNF 2000, p. 56). We do not have any information about the ratio of male to female *P. atropurpurea* plants in this meadow. Unit 4 contains all of the features essential to the conservation of both species

and is located within the SBNF, north of Big Bear Lake, and west of Belleville Meadow (Unit 3). The majority of Unit 4 (also referred to as Holcomb Valley) is privately owned by the Boy Scouts of America (BSA) and used as a recreational and educational activity camp (BSA 2007, p. 1). Unit 4 has been historically impacted by OHV use, horse grazing, and other human disturbance (CNDDDB 2006b, p. 18). It is currently impacted by recreational and educational activities and horse grazing (SBNF 2000, p. 56; SBNF 2002a, p. 51). Additionally, *Poa atropurpurea* and *Taraxacum californicum* and their physical and biological features are threatened in this unit by invasion of nonnative, herbaceous annuals. Therefore, special management considerations or protection may be required to restore, protect, and maintain the essential features in Unit 4 due to the threats from past human disturbance; current camp activities; and invasive, nonnative plant species.

Unit 5: Bluff Meadow We are designating Unit 5 as critical habitat for both *Poa atropurpurea* and *Taraxacum californicum*. Unit 5 consists of an approximately 205-ac (83-ha) meadow occupied by both species at the time of listing; both species continue to occur within this unit. Although *T. officinale* is present, no hybrids are reported (SBNF 2000, p. 56). We do not have any information about the ratio of male to female *P. atropurpurea* plants in this meadow. Unit 5 contains all of the features essential to the conservation of both species. It is located within the SBNF, south of the west end of Big Bear Lake. The majority of Unit 5 is privately owned by the Wildlands Conservancy, and currently leased to the San Bernardino County Regional Parks Division as an outdoor science education camp (Wildlands Conservancy 2005). Unit 5 has been historically impacted by recreational activities, cattle grazing, and other human disturbance (CNDDDB 2006b, p. 12), although impacts are limited to recreational and educational activities (Eliason 2007b; SBNF 2000, p. 57; SBNF 2002a, p. 42). *Poa atropurpurea* and *Taraxacum californicum* and their physical and biological features are also threatened in this unit by invasion of nonnative, herbaceous annuals, including potential hybridization of *T. californicum* with *T. officinale* (SBNF 2000, p. 57; SBNF 2002a, p. 42). Therefore, special management considerations or protection may be required to restore, protect, and maintain the essential features in Unit 5 due to the potential impacts of past human disturbance; current camp activities; hybridization; and invasive, nonnative plant species.

Unit 6: North Shay Meadow We are designating Unit 6 as critical habitat for *Taraxacum californicum* only. Unit 6 consists of an approximately 21-ac (8-ha) meadow occupied by the species at the time of listing; the species continues to occur within this unit. Although occupancy of Unit 6 was documented one year after listing, we consider Unit 6 to be occupied at the time of listing because it contains approximately 12 percent of the total number of individuals reported since 1999 and has the second highest number of total individuals reported from any one unit, and therefore, we believe this area has been occupied for several years despite having been discovered in 1999 (see "Criteria Used to Identify Critical Habitat" section). Although *T. officinale* is present, no hybrids are reported (SBNF 2000, p. 56). This unit contains all of the features essential to the conservation of the species. It is located within the SBNF, east of Big Bear Lake, on the southern shore of Baldwin Lake, and north of Shay Road. The land in this unit is federally owned. This northern portion of Shay Meadow has been isolated by development from the southern meadow adjacent to East Big Bear Boulevard. Lakeshore habitat within Unit 6 is currently impacted by recreational activities due to the use of trails connecting private land to the lakeshore for OHV use, hiking, mountain biking, and horseback riding (SBNF 2000, p. 57; SBNF 2002a, p. 23). Additionally, *Taraxacum californicum* and features essential to its conservation are threatened in this unit by invasion of nonnative, herbaceous annuals, including potential

hybridization with *T. officinale* (CNDDDB 2006b, p. 36; SBNF 2000, p. 57). Therefore, special management considerations or protection may be required to restore, protect, and maintain the essential features in Unit 6 due to the impacts of human disturbance; hybridization; and invasive, nonnative plant species.

Unit 7: Horse Meadow We are designating Unit 7 as critical habitat for *Taraxacum californicum* only. Unit 7 consists of an approximately 74-ac (30-ha) meadow occupied by the species at the time of listing; the species continues to occur within this unit. Occupancy throughout the meadow was confirmed as recently as 2002 (Denslow et al. 2002, pp. 12 and 13). Although *T. officinale* is present, no hybrids have been reported (SBNF 2000, p. 56). Unit 7 contains all of the features essential to the conservation of the species. It is located within the SBNF, southwest of Big Bear Lake, and northwest of San Gorgonio Mountain. Unit 7 is federally owned and located in the San Gorgonio Wilderness Area of the SBNF. Recreational impacts from foot-traffic are reported in Unit 7 (Denslow et al. 2002, pp. 12 and 13; CNDDDB 2006b, p. 5; SBNF 2000, p. 57; SBNF 2002a, p. 54). Additionally, *Taraxacum californicum* and features essential to its conservation are threatened in this unit by invasion of nonnative, herbaceous annuals, including potential hybridization with *T. officinale* (SBNF 2000, p. 57). Therefore, special management considerations or protection may be required to restore, protect, and maintain the essential features in Unit 7 due to threats from human disturbance; hybridization; and invasive, nonnative plant species.

Unit 8: Fish Creek Meadow We are designating Unit 8 as critical habitat for *Taraxacum californicum* only. Unit 8 consists of an approximately 89-ac (36-ha) meadow occupied by the species at the time of listing; the species continues to occur within this unit. Although *T. officinale* is present, no hybrids are reported (SBNF 2000, p. 56). Unit 8 contains all of the features essential to the conservation of the species. It is located within the SBNF, southwest of Big Bear Lake, and northeast of San Gorgonio Mountain. Unit 8 is federally owned and occurs within the San Gorgonio Wilderness Area of the SBNF. Habitat conditions in Unit 8 are reported to be undisturbed, although diffuse recreational use impacts are likely due to trails around meadow in forested area (CNDDDB 2006b, p. 6; SBNF 2002a, p. 52). Additionally, *Taraxacum californicum* and features essential to its conservation are threatened in this unit by invasion of nonnative, herbaceous annuals, including potential hybridization with *T. officinale* (SBNF 2000, p. 58). Therefore, special management considerations or protection may be required to restore, protect, and maintain the essential features in Unit 8 due to the threats from human disturbance; hybridization and invasive; nonnative plant species.

Unit 9: Broom Flat Meadow We are designating Unit 9 as critical habitat for *Taraxacum californicum* only. Unit 9 consists of an approximately 188-ac (76-ha) meadow occupied by the species at the time of listing; the species continues to occur within this unit. Although *T. officinale* is present, no hybrids are reported (SBNF 2000, p. 56). Although occupancy of Unit 9 was documented 2 years after listing, we consider it to have been occupied at the time of listing because Unit 9 supports approximately 9 percent of the total number of *T. californicum* individuals reported since 1999, which is the fifth largest recorded population out of 35 and more than double the average recorded population size. This unit contains all of the features essential to the conservation of the species. Unit 9 is federally owned and located within the SBNF southeast of Big Bear Lake. Unit 9 is historically impacted by OHV activity, cattle and burro grazing, and other human disturbance (CNDDDB 2006b, p. 28; SBNF 2002b, p. 64). This unit and essential features therein are currently impacted by diffuse recreational activities and cattle

grazing (SBNF 2000, p. 58; SBNF 2002a, p. 46) and by invading, nonnative, herbaceous annuals, including potential hybridization with *T. officinale* (CNDDDB 2006b, p. 28; SBNF 2002a, p. 45). Therefore, special management considerations or protection may be required to restore, protect, and maintain the essential features in Unit 9 due to the potential impacts of human disturbance; hybridization; and invasive, nonnative plant species.

Unit 10: Wildhorse Meadow We are designating Unit 10 as critical habitat for *Taraxacum californicum* only. Unit 10 consists of an approximately 52-ac (21-ha) meadow occupied by the species at the time of listing; the species continues to occur within this unit. Although *T. officinale* is present, no hybrids are reported (SBNF 2000, p. 56). Although occupancy of Unit 10 was documented 1 year after listing, we consider Unit 10 to have been occupied at the time of listing because Unit 10 has the highest number of total documented individuals since the time of listing among all the units (SBNF 2000, p. 56; CNDDDB 2006b, pp. 30 and 31) and hosts approximately 20 percent of the total number of individuals reported since 1999, and therefore, we believe that this area was occupied for several years despite having been discovered in 1999 (see “Criteria Used to Identify Critical Habitat” section). Unit 10 was also reported to be occupied by *Poa atropurpurea* in 1981, although surveys in 1999 and 2000 did not locate any individuals (SBNF 2000, p. 47). Therefore, this unit is designated as critical habitat for *T. californicum* only. This unit contains all of the features essential to the conservation of the species. The land in this unit is federally owned and is located within the SBNF southeast of Big Bear Lake. Habitat in Unit 10 is reported to be of “excellent” quality and well protected, although some diffuse recreation impacts have been reported (SBNF 2000, pp. 56 and 58; SBNF 2002a, p. 69). *Taraxacum californicum* and features essential to its conservation are threatened in this unit by invasion of nonnative, herbaceous annuals, including potential hybridization with *T. officinale* (CNDDDB 2006b, p. 31; SBNF 2000, p. 56 and 58). Therefore, special management considerations or protection may be required to restore, protect, and maintain the essential features in Unit 10 due to the potential impacts of invasive, nonnative plant species; hybridization; and diffuse recreation impacts.

Unit 11: Cienega Seca Meadow We are designating Unit 11 as critical habitat for both *Poa atropurpurea* and *Taraxacum californicum*. Unit 11 consists of an approximately 81-ac (33-ha) meadow occupied by both species at the time of listing; both species continue to occur within this unit. Although *T. officinale* is present, no hybrids are reported (SBNF 2000, p. 56). We do not have any information about the ratio of male to female *P. atropurpurea* plants in this meadow. Unit 11 contains all of the features essential to the conservation of both species. It is located within the SBNF adjacent to State Route 38, southeast of Big Bear Lake, and northeast of San Geronio Mountain. The majority of Unit 11 (also referred to Blue Sky Meadow) is privately owned by the Los Angeles County Education Foundation (LACEF), and currently used as an outdoor science education camp (Wildlands Conservancy 2007; LACEF 2007). Unit 11 has been historically impacted by changes in the hydrologic regime due to recreational activities, cattle grazing, and other human disturbance (CNDDDB 2006a, p. 2, 2006b, p. 2). Water usage from a well and vehicle use on some access roads are current threats to meadow habitat (SBNF 2002a, p. 77). *Poa atropurpurea* and *Taraxacum californicum* and their essential features are also threatened in this unit by invasion of nonnative, herbaceous annuals, including potential hybridization of *T. californicum* with *T. officinale* (CNDDDB 2006b, p. 2; SBNF 2000, p. 58). Therefore, special management considerations or protection may be required to restore, protect, and maintain the essential features in Unit 11 due to the threats from past human disturbance; current camp activities; hybridization; and invasive, nonnative plant species.

Unit 12: South Fork Meadow We are designating Unit 12 as critical habitat for *Taraxacum californicum* only. Unit 12 consists of approximately 116-ac (47-ha) of meadows occupied by the species at the time of listing; the species continues to occur within this unit. Although *T. officinale* is present, no hybrids have been reported (SBNF 2000, p. 56). Unit 12 contains all of the features essential to the conservation of the species. It is located on Federal lands within the San Gorgonio Wilderness Area of SBNF, southwest of Big Bear Lake on the northern slope of San Gorgonio Mountain. Habitat in Unit 12 is reported to be virtually undisturbed, but possibly impacted by irregular and recreational use (CNDDDB 2006b, p. 1; Krantz 2007, p. 2; SBNF 2000, pp. 56 and 58). Threats include impacts of hikers, horseback riding, and camping; however, the meadows are minimally disturbed (SBNF 2002a, p. 66). Additionally, *Taraxacum californicum* and features essential to its conservation are threatened in this unit by invasion of nonnative, herbaceous annuals, including potential hybridization with *T. officinale* (SBNF 2000, pp. 56 and 58). Therefore, special management considerations or protection may be required to restore, protect, and maintain the essential features in Unit 12 due to the threats from human disturbance; hybridization; and invasive, nonnative plant species.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Taraxacum californicum* critical habitat consists of two components (73 FR 47706-47767):

- (i) Wet meadows subject to flooding during wet years and forest openings with seeps, springs, or creeks in the San Bernardino Mountains in San Bernardino County located at elevations of 6,700 to 9,000 feet (2,000 to 2,800 meters), that provide space for individual and population growth, reproduction, and dispersal; and
- (ii) Well-drained, loamy alluvial to sandy loam soils occurring in the wet meadow system or forest openings with seeps, springs, or creeks, with a 0 to 46 percent slope, to provide water, air, minerals, and other nutritional or physiological requirements to the species.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the areas occupied at the time of listing contain the features essential to the conservation of the species that may require special management considerations or protection. Major threats to *Poa atropurpurea* and *Taraxacum californicum*, and, therefore, to the features essential to their conservation, include development on private lands, grazing, off-highway vehicle (OHV) use, road maintenance activities, ground disturbance that affects surface hydrology, mining activities, recreational activities, habitat fragmentation, and the invasion of nonnative herbaceous plants. Please refer to the unit descriptions in the "Final Critical Habitat Designations" section for further discussion of special management considerations or protection of the physical and biological features related to geographically specific threats to *P. atropurpurea* and *T. californicum*. Special management considerations or protection of the wet meadows may be needed to address concerns such as reducing nonnative plant invasions and maintaining populations. Control and monitoring of nonnative, invasive plant species may be required to maintain wet meadows and or forest openings such that they can continue to support populations of *Poa atropurpurea* and or *Taraxacum californicum*. Nonnative species alter the meadow habitat by creating mats of thatch which cover bare ground needed for *P. atropurpurea* and *T. californicum* to become established,

and also use water resources that could be used by *P. atropurpurea* and *T. californicum*. The growth of nonnative species may adversely impact and change the physical and biological features of the meadow habitat. Implementing management actions that support fertilization and seed set of *P. atropurpurea* (Curto 1992, p. 11; Soreng 2000, pp. 1–4), and provide monitoring and protection of male *P. atropurpurea* clones may be required to maintain populations of *P. atropurpurea*. Special management considerations or protections for wet meadow habitat may need to be implemented to control the impacts associated with direct competition and hybridization caused by the nonnative *Taraxacum officinale*. This nonnative species occupies open niches, which can reduce the bare ground needed for *T. californicum* to become established, and may alter the physical and biological features of the meadow habitat. Management may include the removal of *T. officinale* from montane meadows where this species co-occurs with *T. californicum*. Additionally, it may be appropriate to remove hybridized individuals; however, we believe this course of action warrants further investigation. There are two USFS management guides that address conservation of *Poa atropurpurea* and *Taraxacum californicum*: (1) The CNF Habitat Management Guide for the Sensitive Plant Species: *Delphinium hesperium* ssp. *cuyamaca*, *Lilium parryi*, *Limnanthes gracilis* var. *parishii*, and *P. atropurpurea*, in Riparian Montane Meadows (CNF 1991, pp. 1–36) addresses conservation of *P. atropurpurea*; and (2) the SBNF Meadow Habitat Management Guide (SBNF 2002a pp. 1–155) addresses conservation of both species. In some cases, significant management actions have been implemented by the USFS (for example, cattle exclosures in Laguna Meadow (CNF 1991, p. 17), recreational trail closures in Belleville Meadow near Big Bear Lake (SBNF 2002a, p. 5)).

Life History**Food/Nutrient Resources****Habitat Type**

Adult: Alpine meadows (NatureServe, 2014)

Spatial Arrangements of the Population

Adult: Clumped (NatureServe, 2015)

Environmental Specificity

Adult: Narrow/specialist (inferred from NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: Low (inferred from NatureServe, 2015)

Site Fidelity

Adult: High (inferred from NatureServe, 2015)

Habitat Narrative

Adult: Species inhabits edges of moist meadows at 1620–2800 m elevation (NatureServe, 2015). *Taraxacum californicum* occurs in moist meadow habitats in the San Bernardino Mountains at elevations from 2,000 to 2,800 m (6,700 to 9,000 ft) and is often associated with *Poa atropurpurea*. These taxa are restricted to the relatively open edges apart from more mesic plants such as *P. pratensis*, *Carex* spp. or *Juncus* spp. (Krantz 1981b). The perimeter of such meadows often intergrades with sagebrush scrub dominated by sagebrush or pine forest (Krantz

1981b) (USFWS, 1998). High ecological integrity of the community and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species and it's the relatively narrow geographic range it inhabits.

Dispersal/Migration

Dispersal/Migration Narrative

Adult: We have no information on age class structure, pollen and seed dispersal, seedling establishment, persistence of seed in the soil, or adult mortality of any of the occurrences (USFWS, 2013).

Population Information and Trends

Population Trends:

Decreasing (NatureServe, 2015)

Resiliency:

Low (inferred from USFWS, 2013)

Representation:

Low (inferred from USFWS, 2013)

Redundancy:

Low (inferred from USFWS, 2013)

Population Growth Rate:

Decline of 10-90% (NatureServe, 2015)

Number of Populations:

20 (USFWS, 2013)

Population Size:

2 to 300 individuals/occurrence (USFWS, 2013)

Population Narrative:

Decline of 10-90% (NatureServe, 2015). Low resiliency, representation and redundancy are inferred based on the small number of occurrences and individual plants known to exist. USFWS (2013) notes that there are 20 known occurrences with each occurrence having between 2 and 300 individuals.

Threats and Stressors

Stressor: Alteration of hydrological conditions (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: The listing rule identified alteration of hydrological conditions as a significant threat to *Taraxacum californicum* habitat, noting potential impacts from roads and OHV activity (USFWS

1998, pp. 49012–49013). As discussed in the 2008 review, the SBNF identified alteration of hydrological conditions as a threat in their Meadow Habitat Management Guide (SBNF 2002). According to the management guide, meadows exist as a function of hydrology. Alteration of the local hydrology is, therefore, perhaps the greatest threat to this type of habitat. Any activities that affect site hydrology (e.g., lowering of water table, water diversion, overgrazing, off-road driving, roads, trails, mining, and historical or recent grazing) pose threats to meadow habitat and meadow plants (SBNF 2002, pp. 22, 24) (USFWS, 2013).

Stressor: Urbanization (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: The listing rule identified the relatively unrestricted development of privately-owned parcels in the Big Bear area outside the boundaries of the SBNF as a continuing threat. Half of the *Taraxacum californicum* occurrences at the time of listing—10 out of 20—were reported to be located within, or adjacent to, urbanized areas such as Big Bear City, Big Bear Lake Village, and Sugarloaf (USFWS 1998, p. 49009). Of these, four occurrences located at Metcalf Meadows (north occurrence), China Gardens/Eagle Point Meadows, Pan Hot Springs Meadow, and Rathbun (also known as Moonridge) Meadow fell within areas depicted as residential, commercial, or flood plain on a zoning map for the City of Big Bear Lake (USFWS 1998, p. 49013). The listing rule noted the apparent extirpation of the occurrence at Rathbun Meadow (T. Krantz, Environmental Consultant, 1993, pers. comm.). Development currently remains a threat to meadow habitat of five *Taraxacum californicum* occurrences on private land in the Big Bear area. Another six *T. californicum* occurrences are located in meadow habitat adjacent to developed areas and are threatened by indirect effects related to urbanization. In addition to directly removing meadow habitat, development degrades meadow habitat by altering site hydrology, increasing access to foot and vehicular traffic, and introducing nonnative plant species (USFWS, 2013).

Stressor: Roads and unauthorized Off Highway Vehicular (OHV) Use (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat/Habitat degradation

Narrative: Roads and unauthorized OHV use has been ameliorated at two occurrences through management actions of the SBNF (fencing, etc.), but continues to be a moderate threat to meadow habitat at 13 of 23 *Taraxacum californicum* occurrences. Nine of these occurrences are within or partially within CDFW and SBNF lands, though they continue to pose management challenges. Four occurrences entirely within private land in the Big Bear area are threatened by roads and unauthorized OHV use due to lack of protection and close proximity to roads (USFWS, 2013).

Stressor: Developed and dispersed recreation (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat/Habitat degradation

Narrative: Developed and dispersed recreation remains a moderate threat to meadow habitat at 17 of 23 *Taraxacum californicum* occurrences (Appendix 1). Since listing, developed and dispersed recreation due to close proximity to campgrounds has been identified as a threat at five additional meadows (in addition to North Shore Meadows identified at listing): Bluff

Meadow, Hitchcock Meadow and Belleville Meadow in Holcomb Valley, Red Ant Meadow, and Merriman Meadow. Additionally, a popular dispersed campsite on the SBNF (referred to as Yellow Post Site 25) threatens adjacent *T. californicum* habitat in Metcalf Meadow. Dispersed recreation has the potential to affect all occurrences of *T. californicum*, including occurrences entirely within private land in the Big Bear area. Seven, or nearly one-third of *T. californicum* occurrences, are recognized by the SBNF as particularly vulnerable to these threats due to their close proximity to campgrounds and concentrated use areas (USFWS, 2013).

Stressor: Mining activities (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat/Habitat degradation

Narrative: We have not received any new information to change our conclusion from the 2008 5-year review that mining is a current threat to *Taraxacum californicum* habitat at one occurrence (USFWS 2008a, p. 14) (USFWS, 2013).

Stressor: Grazing (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat/Habitat degradation/Loss of individuals

Narrative: Grazing is a moderate threat to 26 percent (6 of 23) of *Taraxacum californicum* occurrences. Horse grazing continues to threaten *T. californicum* and its habitat at three occurrences on private land. Significant steps were taken by the BLM and SBNF to reduce cattle and wild burro grazing within habitat occupied by *T. californicum* such that cattle grazing is not a substantial threat at this time. Although burro grazing has been reduced, it still threatens *T. californicum* and its habitat at four occurrences (USFWS, 2013).

Stressor: Competition with other plant species (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Alteration of habitat, through competition with other plant species continues to be a rangewide and moderate threat to meadow habitat at all 23 *Taraxacum californicum* occurrences (USFWS, 2013).

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: In summary, the Act provides the greatest regulatory protection to *Taraxacum californicum*. Many occurrences (13 in whole and 4 in part) are on USFS lands, and 1 occurrence is on both USFS and State land, where protection is afforded through land management plans. The NFMA in conjunction with the requirements of NEPA provides important guidance and policy for maintaining ecosystem and species-specific biodiversity on USFS lands via the development and implementation of land management plans (and environmental impact statements). This includes amendments or revisions to the land management plans, as well as conservation recommendations provided in the Meadow Habitat Management Guide (SBNF 2002). CDFW manages one occurrence within the Baldwin Lake Ecological Reserve. Finally, one occurrence on

private land is owned and managed by TWC in their Bluff Lake Reserve. Thus, 15 occurrences in whole and 4 in part currently have some protections provided by Federal and State agencies, and private organizations. However, these protections are discretionary and subject to funding availability (USFS 2012a, p. 93). Therefore, current conservation measures are not sufficient to reduce all threats and are largely dependent on the federally listed status of *T. californicum*. As a result, regulatory mechanisms provided by other Federal, State, and local laws and ordinances do not independently or collectively provide adequate regulatory protection to *T. californicum* (USFWS 2013).

Stressor: Hybridization (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of genetic viability

Narrative: Since our 2008 review, we received information indicating that hybridization with another nonnative dandelion, *Taraxacum erythrospermum* (red-seeded dandelion), may be a threat. Similar to *T. officinale*, it has a range of chromosome counts, including a count of 16 ($2n=16$, 32) (Brouillet 2006, pp. 245–246). This species has been identified at three occurrences in Big Meadow, Horse Meadow, and Holcomb Valley (CCH 2011, pp. 1–3; Eliason 2011a, pers. comm.) (USFWS, 2013).

Stressor: Limited numbers of *Taraxacum californicum* individuals (USFWS, 2013)

Exposure:

Response:

Consequence: Lack of genetic diversity

Narrative: In the listing rule, we identified the limited number of *Taraxacum californicum* individuals as a threat to *T. californicum*; however, no specific meadow areas or population densities were identified (USFWS 1998, pp. 49016–49017). Barrett and Kohn (1991) have discussed the consequences of small population size in plants. They stress the need for maintaining genetic diversity, especially for rare alleles (different forms of a gene). Maintaining diversity of alleles in self-incompatible (outcrossing) plants is important to ensure production of fertile seeds, and thus is important for the survival of plant populations. The likelihood of maintaining diversity decreases in smaller populations (Barrett and Kohn 1991, pp. 9, 10, 13). Thus, factors that negatively affect *Taraxacum californicum* individuals are more likely to threaten the survival of the species as a whole. The limited number of *Taraxacum californicum* individuals is a substantial threat of particular concern at 18 of 23 occurrences (78 percent), and possibly rangewide (USFWS, 2013).

Stressor: Fire suppression measures (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Since 2008, implementation of fire suppression measures has been identified as a new threat at 9 of 23 extant *Taraxacum californicum* occurrences. The San Bernardino County Land Use/Fire Hazard Abatement Division (see FACTOR D discussion) requires that owners must remove weeds and grasses in areas where this vegetation acts as a fuel that may pose a fire threat. Weeds and grasses are described by the County of San Bernardino generally as annuals that grow and dry out each year, and they did not discriminate for rare plants (County of San Bernardino 2011a, pp. 3–4; County of San Bernardino 2011b, p. 1). Weed and grass removal

generally involves mowing, which damages or destroys individual *T. californicum* plants. If removal activities are conducted before or during *T. californicum* flowering and fruit development, the plants reproductive output and germination may be significantly impacted (USFWS, 2013).

Stressor: Climate change and drought (USFWS, 2013)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Although there is uncertainty in climate change projections and the effects of climate change on this particular species, it seems likely that *Taraxacum californicum*, a species restricted to montane meadows in a single small portion of a mountain range found on particular soils with particular hydrological needs, would be threatened rangewide by differences in climatic regimes brought on by changes to the climate in the future. Therefore, based on the best available scientific data at this time, we believe climate change and drought is likely a significant threat to this species (USFWS, 2013).

Recovery

Recovery Actions:

- No recovery plan (USFWS, 2013)

Conservation Measures and Best Management Practices:

- 1. Continue to work with the State to purchase *Taraxacum californicum* habitat from willing sellers (e.g., Shay Meadow, Metcalf Meadow) (USFWS, 2013).
- 2) Continue to work with the Big Bear City Community Services District to adopt and implement the draft Pan Hot Springs Habitat Management Plan and record the Restrictive Covenant per the plan (USFWS, 2013).
- 3) Continue to work with local partners to identify an appropriate entity or entities to hold and manage conservation easements that protect *Taraxacum californicum* habitat (USFWS, 2013).
- 4) Expand the existing seed bank at Rancho Santa Ana Botanic Garden to include samples from populations determined to be key by the SBNF and the Service to buffer the species from genetic loss, should small populations become extirpated (USFWS, 2013).
- 5) Recommendation specific to threats from limited numbers of *Taraxacum californicum* individuals and hybridization: 1) Determine the breeding system of *T. californicum* and confirm the nature and extent of introgression with *T. officinale* and *T. erythrospermum*. Determine accurate rangewide chromosome counts of *T. californicum*, local *T. officinale* and *T. erythrospermum*. 2) Support SBNF efforts to conduct a prescribed burn of Juniper Meadow and study whether this burn will facilitate germination of any existing *T. californicum* seed in the soil (USFWS, 2013).
- 6) Recommendation specific to threats from competition with other plant species: Promote research and work with partners to determine the extent to which buildup of thatch contributes to the decline of *Taraxacum californicum* and to conduct comparative work on thatch removal methods (i.e., study the benefits and risks of fire, mowing, and any other thatch removal methods). Support SBNF efforts to conduct a prescribed burn of Juniper Meadow (USFWS, 2013).
- 7) Recommendation specific to threats from roads and unauthorized OHV use, and developed and dispersed recreation: Support SBNF efforts to identify additional key areas to close to human access (e.g., Yellow Post Site YP25 at Metcalf Meadows) (USFWS, 2013).

- 8) Recommendation specific to threats from inadequacy of existing regulatory mechanisms: Work with the State and San Bernardino County to help facilitate implementation of the weed abatement plan while minimizing impacts to rare plants including *Taraxacum californicum*. (USFWS, 2013).

SPECIES ACCOUNT: *Ternstroemia luquillensis* (Palo colorado)

Species Taxonomic and Listing Information

Listing Status: Endangered; Southeast Region (R4) 04/22/1992

Physical Description

Ternstroemia luquillensis is an evergreen tree of up to 20 meters in height, with dark gray smooth bark. The elliptic to oblong-elliptic entire, extipulate, and coriaceous leaves are about 6-12 cm long and 2.5-4 cm wide. The leaves are acute at both ends, with the midvein sunken; they are black punctate below, with stout petioles of 6-12 mm long. The perfect, actinomorphic flowers are fragrant and solitary, congregating at the end of the branches. The flowers measure about 2.5 cm in diameter, with a slender pedicel of 2.5-9 cm long. The flowers contain five 9 mm long imbricated sepals, and five 12 mm long creamy white petals. Flowers bear numerous stamens, adnate to the base of the corolla, and a two-celled superior ovary with 16-20 ovules in each cell. The fruit is an ovoid capsule with a persistent style, which contain several small bright red seeds of 3 mm long (USFWS, 1993).

Historical Range

See current range/distribution.

Current Range

Ternstroemia luquillensis (palo colorado) is an evergreen tree only known from six individuals within the palo colorado and dwarf forests of the Luquillo Mountains (USFWS, 1993). As of 2019, there is a botanical voucher that reports the presence of palo colorado in the municipality of Maricao on the opposite side of the Island (interior west of Puerto Rico; USFWS 2015). However, no further information is known from this site. (USFWS, 2019).

Critical Habitat Designated

Yes;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Unknown (USFWS, 2015)

Reproduction Narrative

Adult: Little is known about the reproductive biology. *Ternstroemia luquillensis* has been collected with flowers in June and July (USFWS, 1993).

Habitat Type

Adult: Palo colorado forest (USFWS, 1993)

Habitat Vegetation or Surface Water Classification

Adult: Palo colorado forest; dwarf/elfin forest (USFWS, 1993)

Tolerance Ranges/Thresholds

Adult: Low (inferred from USFWS, 1993)

Site Fidelity

Adult: High (inferred from USFWS, 1993)

Habitat Narrative

Adult: The Luquillo Mountains region is of volcanic origin and of a rough topography, with cliffs and rock exposures at high elevations. Six major rivers are born in the mountains and waterfalls are numerous. Nineteen soils belonging to four soil associations have been identified within the Caribbean National Forest (Silander et al. 1986), of which the Los Guineos-Guayabota-Rock land association constitutes the most extensive one (USDA 1977). This association contains acidic, shallow to deep, well drained to poorly drained steep soils. The Caribbean National Forest holds four vegetation types: tabonuco forest, palo colorado forest, palma de sierra forest, and dwarf or elfin forest. All the known localities of *Callicarpa ampla* and *Styrax portoricensis*, and some localities of *Ternstroemia luquillensis* and *Ternstroemia subsessilis* occur within the palo colorado vegetation type. Some localities of *Ternstroemia luquillensis* and *Ternstroemia subsessilis*, and all the localities of *Ilex sintenisii* occur in the dwarf forest vegetation type (USFWS, 1993). High ecological integrity and site fidelity as well as low tolerance ranges are inferred based on species specific habitat needs and low number of populations.

Dispersal/Migration**Motility/Mobility**

Adult: Low (Inferred from USFWS, 1993)

Dispersal

Adult: Low (inferred from USFWS, 1993)

Dependency on Other Individuals or Species for Dispersal

Adult: Low/Slow (inferred from USFWS, 1993)

Population Information and Trends**Population Trends:**

Unknown (USFWS, 2015)

Species Trends:

Unknown (USFWS, 2015)

Resiliency:

Low (inferred from USFWS, 2015)

Representation:

Low (inferred from USFWS, 2015)

Redundancy:

Low (inferred from USFWS, 2015)

Number of Populations:

Four (USFWS, 2015)

Population Size:

Six total individuals (USFWS, 2015)

Population Narrative:

When the recovery plan was approved in 1995, the number of individuals of *T. luquillensis* was known to be 6 individuals in 4 populations, and 37 individuals in 4 populations for *T. subsessilis*, all within the Luquillo Mountains (USFWS 1995) In addition to the populations of El Yunque National Forest, there are two specimen collections of *T. luquillensis* at the herbarium of the University of Puerto Rico at Mayaguez (MAPR) that were collected within the Maricao Commonwealth Forest. However, the herbarium specimens do not contain any information about the abundance of the species in the area. Based on the above, the USFWS does not have enough data to accurately determine the status of these two species at this time. Because of the absence of sightings, it is possible that the species' status may be declining or that some of their populations are extinct, but further monitoring is needed to support this conclusion (USFWS, 2015). In addition, Low resiliency, representation and redundancy are inferred based on low number of populations and individuals.

Threats and Stressors

Stressor: Forest management (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: At the time of listing, forest management practices such as the establishment and maintenance of plantations, selective cutting, trails and roads construction and maintenance, and shelter construction may have affected these trees. Furthermore, the proposed reconstruction and reopening of Road PR 191 was considered as a direct threat to some populations of these species. The destruction of the dwarf or elfin forests for the construction and/or expansion of communication facilities by the U.S. Navy and private entities were also considered a threat. Based on the available information, the core of the known populations of *I. sintenisii*, *S. portoricensis*, *C. ampla*, *T. subsessilis*, and *T. luquillensis* occur within the boundaries of El Yunque National Forest. Since the time of listing the USFWS has not documented any case of an individual of an endangered species being affected by forest management practices (management of plantations, trail maintenance or road construction). Moreover, the plans to reopen Road PR 191 have been abandoned due to the potential for further landslides that may compromise the project. Nonetheless, the USFS consults with the Service under Section 7 of the ESA when proposing actions within the forest to ensure that possible adverse effects to listed species are avoided or minimized before any such project is implemented. In addition, the USFS conduct environmental reviews documents under NEPA for all actions in the forest. These consultation mechanisms are effective tools to minimize possible effects of management activities on species and their habitats. Based on the above, we consider the present or threatened destruction, modification, or curtailment of the species habitat or range as low in magnitude and not imminent threat to these species (USFWS, 2015).

Stressor: Overutilization (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Despite the fact that plant collection in El Yunque National Forest is prohibited, when the five species were listed, collection was considered a threat due to the ornamental potential of these species. However, there is no evidence indicating that the species has been affected by these factors. Based on the above, we believe that overutilization for commercial, scientific or educational purposes is no longer a threat to these species (USFWS, 2015).

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: Since the currently known populations of these species are mostly restricted to El Yunque National Forest, and there are appropriate Commonwealth and Federal laws and regulations protecting these five species, we believe that the inadequacy of existing regulatory mechanisms should no longer be considered a threat to them. However, historical collections indicate that suitable habitat may extend to private properties adjacent to El Yunque. In fact, some of the known populations that occur within El Yunque National Forest are located just along the boundaries of the forest. Thus, it is important to note that enforcement on private lands continues to be a challenge as accidental damage or extirpation of individuals has occurred with other federally listed species due to lack of knowledge of the species by private land owners and law enforcement officers (USFWS, 2015).

Stressor: Hurricanes (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: Due to the low number of populations and individuals, hurricanes were identified as a threat to *I. sintenisii*, *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis* in the final rule. As endemic to the Caribbean, these tree species should be well adapted to tropical storms disturbance. However, the low number of populations and individuals pose a threat to the species by making them more susceptible to stochastic events such as hurricanes. In fact, it is not clear to what extent populations of these species may have been affected by Hurricane Hugo (which devastated El Yunque National Forest in 1989) or Hurricane Georges (in 1998). The heavy rains associated with tropical storms and hurricanes in the mountains of Puerto Rico often lead to landslides. Despite the low number of populations and individuals, the USFWS considers hurricanes, landslides and climate change as a moderate and non-imminent threat to these species (USFWS, 2015).

Stressor: Landslides (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: Natural landslides are common as part of the forest dynamics of El Yunque and it is expected that the frequency of this disturbance increases as a result of severe extreme rain events or droughts. Given the steep slopes on which most of these species grow, massive

landslides may extirpate entire populations. The USFWS is aware that an area of road PR 191 that formerly connected the municipalities of Río Grande and Naguabo, and that run across the forest has historically been affected by landslides. This area was the site of some populations that were not located by the interagency group in 2011. Due to the severity of landslides, it was determined that it was not logistically and economically feasible to repair this road. Based on the 2011 surveys, *I. sintenisii* seems to be the only species that is not imminently threatened by hurricanes and landslides. The prime habitat for *I. sintenisii* is associated with dwarf forest vegetation. Due to the low agricultural value and inaccessibility of this habitat, this vegetation was not cleared during the peak of the deforestation of the island, and thus some of the highest parts of El Yunque remain as pristine forest. This explains the relative abundance of the species along the summits of Pico El Yunque and Pico del Este. Despite the low number of populations and individuals, the USFWS considers hurricanes, landslides and climate change as a moderate and non-imminent threat to these species (USFWS, 2015).

Stressor: Climate change (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: This species may be further threatened by climate change, which is predicted to increase the frequency and strength of tropical storms and can cause severe droughts (Hopkinson et al. 2008). Vulnerability to climate change impacts is a function of sensitivity to those changes (e.g., changes rain regime and moisture availability), exposure to those changes, and adaptive capacity (Glick et al. 2011). Despite the relative abundance and apparently stability of the populations of *I. sintenisii*, its habitat is considered rare in Puerto Rico. These areas (dwarf forest vegetation) are ecological islands that harbor unique vegetation and environmental conditions. Shifts of vegetation communities are expected as temperatures and moisture regimes are altered by climate change. Under this scenario populations of *I. sintenisii* as well as *S. portoricensis*, *C. ampla*, *T. subsessilis*, and *T. luquillensis* may be displaced or outcompeted by native or exotic species with wider environmental plasticity. Despite the low number of populations and individuals, the USFWS considers hurricanes, landslides and climate change as a moderate and non-imminent threat to these species (USFWS, 2015).

Stressor: Genetic variation (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of viability

Narrative: Along with a decreasing population size, negative impacts of habitat fragmentation may result in erosion of genetic variation through the loss of alleles by random genetic drift (Honnay and Jacquemyn 2007) and may also limit the ability of a species to respond to a changing environment (Booy et al. 2000). Given the extremely small population size and lack of connectivity between populations of *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis* in Puerto Rico, it is highly likely that their genetic variability is extremely low. Based on the above, we consider the lack of genetic variation a high and imminent threat to *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis*. Overall, we consider hurricanes, landslides, climate change and genetic variation as threats to *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis*. Due to the small number of populations, the USFWS considers the above mentioned threats as high in magnitude and imminent for those species. In the case of *I. sintenisii*, the species is at least stable

and probably improving, thus we consider the above mentioned threats as low and non-imminent (USFWS, 2015).

Recovery

Reclassification Criteria:

An agreement between the Fish and Wildlife Service and the USDA Forest Service concerning the protection of *Callicarpa ampla*, *Ilex sintenisii*, *Styrax portoricensis*, *Ternstroemia luquillensis*, and *Ternstroemia subsessilis* within the Caribbean. National Forest property has been prepared and implemented (USFWS, 1993).

An agreement between the Fish and Wildlife Service and the Department of Natural and Environmental Resources (DNER) concerning the protection of the three species in Commonwealth forests has been prepared and implemented, if the species is found within DNER properties (USFWS, 1993).

New populations (the number of which should be determined following the appropriate studies) capable of self perpetuation have been established within protected areas (USFWS, 1993).

Delisting Criteria:

1. Existing natural populations exhibit a stable or increasing trend, evidenced by natural recruitment, and multiple age classes (addresses Factors E). (USFWS, 2019).
2. Establish or discover four (4) additional populations within the current range at EYNF that exhibit a stable or increasing trend, evidenced by natural recruitment, and multiple age classes (addresses Factors A and E). (USFWS, 2019).
3. Establish or discover two (2) new populations outside the current range but within the historical range (e.g., Carite, Guilarte or Toro Negro Commonwealth Forests) that exhibit a stable or increasing trend, evidenced by natural recruitment, and multiple age classes (addresses Factors A and E). (USFWS, 2019).
4. Threats have been addressed and/or managed to the extent that the species will remain viable into the foreseeable future (addresses Factor A and E). (USFWS, 2019).

Recovery Actions:

- 1. Establish long-term conservation mechanisms (e.g., land conservation easements and conservation agreements) for private lands outside/bordering EYNF since these lands share similar vegetation and habitat characteristics. This new action should be included within Recovery Task 11. (USFWS, 2019).
- 2. A protocol for the propagation and reintroduction of all five species should be developed in collaboration with partners (e.g., University of Puerto Rico, KEW, Fairchild Tropical Botanic Garden, PRDNER, Para La Naturaleza and Natural Resources Conservation Service). The protocol should address the feasibility of seed banking these species, and if deemed necessary, seed material should be stored at the Millennium Seed Bank (KEW) and USDA National Laboratory for Genetic Resources Preservation in Ft. Collins. This new action should be included within Recovery Task 33. (USFWS, 2019).

- 3. Studies in the species' population genetics should be conducted to determined patterns of genetic diversity across the species natural distribution, and to provide baseline information for sound management of these species. This new action should be included within Recovery Task 3. (USFWS, 2019).

SPECIES ACCOUNT: *Ternstroemia subsessilis* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; Southeast Region (R4) 04/22/1992

Physical Description

Ternstroemia subsessilis is an evergreen shrub or small tree of up to 5 m height. The leaves are alternate, exstipulate, and thick, measuring 3-7 cm long and 1.5-2.8 wide. The leaf blade is obovate to oblanceolate, with an obtuse and sometimes apiculate apex, and a cuneate base. The leaves are revolute, with a punctate lower leaf surface. Petioles are stout, measuring 6.6 mm long. The flower is perfect, actinomorphic and solitary, growing axillary from the end of the branches. The short pedicel, of 1-2 mm long, makes the flower appear sessile or subsessile, as the specific epithet of this plant suggests. The calyx consists of five glandular, imbricate sepals, 2-5 mm long. The corolla contains five white, connate, orbicular or concave petals, 10 mm long. The stamens are numerous, being adnate at the base of the corolla. The ovary is superior and probably two-celled. The fruit is an ovoid-conical capsule of 10 mm long, with a sharp point (USFWS, 1993).

Historical Range

Ternstroemia subsessilis (no common name) is an evergreen shrub or small tree which has been reported from the Luquillo Mountains and the Maricao Forest. It is currently known only from a population that consists of 37 individuals from nine sites at the Luquillo Mountains (USFWS, 1993).

Current Range

USFWS (2015) notes that there are 4 populations, all within the Luquillo Mountains.

Critical Habitat Designated

Yes;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Unknown (USFWS, 2015)

Reproduction Narrative

Adult: Little is known about the reproductive biology of this species. Ripe fruits were observed on various individuals of *Ternstroemia subsessilis* in May 1991 (Garcia and Laboy 1991) (USFWS, 1993).

Habitat Type

Adult: Palo colorado forest (USFWS, 1993)

Habitat Vegetation or Surface Water Classification

Adult: Palo colorado forest; dwarf/elfin forest (USFWS, 1993)

Tolerance Ranges/Thresholds

Adult: Low (inferred from USFWS, 1993)

Site Fidelity

Adult: High (inferred from USFWS, 1993)

Habitat Narrative

Adult: The Luquillo Mountains region is of volcanic origin and of a rough topography, with cliffs and rock exposures at high elevations. Six major rivers are born in the mountains and waterfalls are numerous. Nineteen soils belonging to four soil associations have been identified within the Caribbean National Forest (Silander et al. 1986), of which the Los Guineos-Guayabota-Rock land association constitutes the most extensive one (USDA 1977). This association contains acidic, shallow to deep, well drained to poorly drained steep soils. The Caribbean National Forest holds four vegetation types: tabonuco forest, palo colorado forest, palma de sierra forest, and dwarf or elfin forest. All the known localities of *Callicarpa ampla* and *Styrax portoricensis*, and some localities of *Ternstroemia luquillensis* and *Ternstroemia subsessilis* occur within the palo colorado vegetation type. Some localities of *Ternstroemia luquillensis* and *Ternstroemia subsessilis*, and all the localities of *Ilex sentenisi* occur in the dwarf forest vegetation type (USFWS, 1993). High ecological integrity and site fidelity as well as low tolerance ranges are inferred based on species specific habitat needs and low number of populations.

Dispersal/Migration**Motility/Mobility**

Adult: Low (Inferred from USFWS, 1993)

Dispersal

Adult: Low (inferred from USFWS, 1993)

Dependency on Other Individuals or Species for Dispersal

Adult: Low/Slow (inferred from USFWS, 1993)

Population Information and Trends**Population Trends:**

Unknown (USFWS, 2015)

Species Trends:

Unknown (USFWS, 2015)

Resiliency:

Low (inferred from USFWS, 2015)

Representation:

Low (inferred from USFWS, 2015)

Redundancy:

Low (inferred from USFWS, 2015)

Number of Populations:

Four (USFWS, 2015)

Population Size:

37 total individuals (USFWS, 2015)

Population Narrative:

There are four known populations with a total of 37 individuals. Species level and population level trends are unknown based on lack of data (USFWS, 2015). In addition, Low resiliency, representation and redundancy are inferred based on low number of populations and individuals.

Threats and Stressors

Stressor: Forest management (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: At the time of listing, forest management practices such as the establishment and maintenance of plantations, selective cutting, trails and roads construction and maintenance, and shelter construction may have affected these trees. Furthermore, the proposed reconstruction and reopening of Road PR 191 was considered as a direct threat to some populations of these species. The destruction of the dwarf or elfin forests for the construction and/or expansion of communication facilities by the U.S. Navy and private entities were also considered a threat. Based on the available information, the core of the known populations of *I. sintenisii*, *S. portoricensis*, *C. ampla*, *T. subsessilis*, and *T. luquillensis* occur within the boundaries of El Yunque National Forest. Since the time of listing the USFWS has not documented any case of an individual of an endangered species being affected by forest management practices (management of plantations, trail maintenance or road construction). Moreover, the plans to reopen Road PR 191 have been abandoned due to the potential for further landslides that may compromise the project. Nonetheless, the USFS consults with the Service under Section 7 of the ESA when proposing actions within the forest to ensure that possible adverse effects to listed species are avoided or minimized before any such project is implemented. In addition, the USFS conduct environmental reviews documents under NEPA for all actions in the forest. These consultation mechanisms are effective tools to minimize possible effects of management activities on species and their habitats. Based on the above, we consider the present or threatened destruction, modification, or curtailment of the species habitat or range as low in magnitude and not imminent threat to these species (USFWS, 2015).

Stressor: Overutilization (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Despite the fact that plant collection in El Yunque National Forest is prohibited, when the five species were listed, collection was considered a threat due to the ornamental potential of these species. However, there is no evidence indicating that the species has been affected by

these factors. Based on the above, we believe that overutilization for commercial, scientific or educational purposes is no longer a threat to these species (USFWS, 2015).

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: Since the currently known populations of these species are mostly restricted to El Yunque National Forest, and there are appropriate Commonwealth and Federal laws and regulations protecting these five species, we believe that the inadequacy of existing regulatory mechanisms should no longer be considered a threat to them. However, historical collections indicate that suitable habitat may extend to private properties adjacent to El Yunque. In fact, some of the known populations that occur within El Yunque National Forest are located just along the boundaries of the forest. Thus, it is important to note that enforcement on private lands continues to be a challenge as accidental damage or extirpation of individuals has occurred with other federally listed species due to lack of knowledge of the species by private land owners and law enforcement officers (USFWS, 2015).

Stressor: Hurricanes (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: Due to the low number of populations and individuals, hurricanes were identified as a threat to *I. sintenisii*, *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis* in the final rule. As endemic to the Caribbean, these tree species should be well adapted to tropical storms disturbance. However, the low number of populations and individuals pose a threat to the species by making them more susceptible to stochastic events such as hurricanes. In fact, it is not clear to what extent populations of these species may have been affected by Hurricane Hugo (which devastated El Yunque National Forest in 1989) or Hurricane Georges (in 1998). The heavy rains associated with tropical storms and hurricanes in the mountains of Puerto Rico often lead to landslides. Despite the low number of populations and individuals, the USFWS considers hurricanes, landslides and climate change as a moderate and non-imminent threat to these species (USFWS, 2015).

Stressor: Landslides (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: Natural landslides are common as part of the forest dynamics of El Yunque and it is expected that the frequency of this disturbance increases as a result of severe extreme rain events or droughts. Given the steep slopes on which most of these species grow, massive landslides may extirpate entire populations. The USFWS is aware that an area of road PR 191 that formerly connected the municipalities of Río Grande and Naguabo, and that run across the forest has historically been affected by landslides. This area was the site of some populations that were not located by the interagency group in 2011. Due to the severity of landslides, it was determined that it was not logistically and economically feasible to repair this road. Based on the 2011 surveys, *I. sintenisii* seems to be the only species that is not imminently threatened by hurricanes and landslides. The prime habitat for *I. sintenisii* is associated with dwarf forest

vegetation. Due to the low agricultural value and inaccessibility of this habitat, this vegetation was not cleared during the peak of the deforestation of the island, and thus some of the highest parts of El Yunque remain as pristine forest. This explains the relative abundance of the species along the summits of Pico El Yunque and Pico del Este. Despite the low number of populations and individuals, the USFWS considers hurricanes, landslides and climate change as a moderate and non-imminent threat to these species (USFWS, 2015).

Stressor: Climate change (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: This species may be further threatened by climate change, which is predicted to increase the frequency and strength of tropical storms and can cause severe droughts (Hopkinson et al. 2008). Vulnerability to climate change impacts is a function of sensitivity to those changes (e.g., changes rain regime and moisture availability), exposure to those changes, and adaptive capacity (Glick et al. 2011). Despite the relative abundance and apparently stability of the populations of *I. sintenisii*, its habitat is considered rare in Puerto Rico. These areas (dwarf forest vegetation) are ecological islands that harbor unique vegetation and environmental conditions. Shifts of vegetation communities are expected as temperatures and moisture regimes are altered by climate change. Under this scenario populations of *I. sintenisii* as well as *S. portoricensis*, *C. ampla*, *T. subsessilis*, and *T. luquillensis* may be displaced or outcompeted by native or exotic species with wider environmental plasticity. Despite the low number of populations and individuals, the USFWS considers hurricanes, landslides and climate change as a moderate and non-imminent threat to these species (USFWS, 2015).

Stressor: Genetic variation (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of viability

Narrative: Along with a decreasing population size, negative impacts of habitat fragmentation may result in erosion of genetic variation through the loss of alleles by random genetic drift (Honnay and Jacquemyn 2007) and may also limit the ability of a species to respond to a changing environment (Booy et al. 2000). Given the extremely small population size and lack of connectivity between populations of *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis* in Puerto Rico, it is highly likely that their genetic variability is extremely low. Based on the above, we consider the lack of genetic variation a high and imminent threat to *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis*. Overall, we consider hurricanes, landslides, climate change and genetic variation as threats to *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis*. Due to the small number of populations, the USFWS considers the above mentioned threats as high in magnitude and imminent for those species. In the case of *I. sintenisii*, the species is at least stable and probably improving, thus we consider the above mentioned threats as low and non-imminent (USFWS, 2015).

Recovery

Reclassification Criteria:

An agreement between the Fish and Wildlife Service and the USDA Forest Service concerning the protection of *Callicarpa ampla*, *Ilex sintenisii*, *Styrax portoricensis*, *Ternstroemia luquillensis* ,

and *Ternstroemia subsessilis* within the Caribbean. National Forest property has been prepared and implemented (USFWS, 1993).

An agreement between the Fish and Wildlife Service and the Department of Natural and Environmental Resources (DNER) concerning the protection of the three species in Commonwealth forests has been prepared and implemented, if the species is found within DNER properties (USFWS, 1993).

New populations (the number of which should be determined following the appropriate studies) capable of self perpetuation have been established within protected areas (USFWS, 1993).

Delisting Criteria:

1. Existing natural populations exhibit a stable or increasing trend, evidenced by natural recruitment, and multiple age classes (addresses Factors E). (USFWS, 2019).
2. Establish or discover four (4) additional populations within the current range at EYNF that exhibit a stable or increasing trend, evidenced by natural recruitment, and multiple age classes (addresses Factors A and E). (USFWS, 2019).
3. Establish or discover two (2) new populations outside the current range but within the historical range (e.g., Carite, Guilarte or Toro Negro Commonwealth Forests) that exhibit a stable or increasing trend, evidenced by natural recruitment, and multiple age classes (addresses Factors A and E). (USFWS, 2019).
4. Threats have been addressed and/or managed to the extent that the species will remain viable into the foreseeable future (addresses Factor A and E). (USFWS, 2019).

Recovery Actions:

- Criterion 1 has been partially met. There is no formal agreement between the USFS and the USFWS for the implementation of a management plan to protect these five species. However, the El Yunque National Forest is managed by the USFS for conservation, and has an approved "Revised Land and Resource Management Plan" (1997), which is currently under revision. Moreover, Federal agencies are mandated to carry out programs for the conservation of endangered species under Section 7 of the Endangered Species Act (ESA) to ensure that any action authorized, funded or carried out by a Federal agency is not likely to jeopardize the continued existence of a federally listed species. Thus, the USFS continually consults with the USFWS to avoid and minimize impacts to listed species and their habitat at El Yunque National Forest. In addition, on July 26, 2005, the U.S. Congress enacted the Caribbean National Forest Act to designate approximately 10,000 acres of land in the El Yunque National Forest as wilderness and as a component of the National Wilderness Preservation System in accordance with the Wilderness Act (16 U.S.C. 1131 et seq.). This Act prohibits certain activities (e.g., timber harvest) within wilderness designated areas, although it does not preclude the installation and maintenance of facilities (e.g., data collection and remote transmission facilities) essential to the scientific and conservation purposes of the Forest Service. Therefore, the majority of the habitat upon which these species depend upon is essentially protected (USFWS, 2015).
- Criterion 2 has been partially met. Although there is no specific agreement between USFWS and the PRDNER concerning the protection of these three species in Commonwealth forests,

there is an agreement between the two agencies under Section 6 of the Endangered Species Act, in which the PRDNER carries out conservation activities for the benefit of threatened and endangered species. Furthermore, these five species are listed by the PRDNER as endangered, and thus are protected by regulations of the Commonwealth of Puerto Rico (See factor D.). Therefore, special consideration is taken when considering actions within areas that harbor suitable habitat for these species (USFWS, 2015).

- Criterion 3 has been initiated. The Puerto Rico Conservation Trust (PRCT) is successfully propagating *Styrax portoricensis*. The USFWS has utilized some of this material and begun planting this species (approximately 50 individuals) at El Yunque National Forest. In addition, the PRDNER began planting *Styrax portoricensis* (approximately 5 individuals) in the Carite Commonwealth Forest. Furthermore, the USFS has propagated *Callicarpa ampla* by air layering (cloning by promoting rooting of branches using hormones), and has planted about three individuals at El Portal in El Yunque National Forest. However, little information is available about the reproductive biology and the ecology of these species. Further research and monitoring of reintroduced individuals is required to determine the success of these actions. There is no information about the propagation of any of the remaining three species (*Ilex sintenisii*, *Ternstroemia luquillensis* and *Ternstroemia subsessilis*) (USFWS, 2015).
- New in 2019: 1. Establish long-term conservation mechanisms (e.g., land conservation easements and conservation agreements) for private lands outside/bordering EYNF since these lands share similar vegetation and habitat characteristics. This new action should be included within Recovery Task 11. (USFWS, 2019).
- 2019 - 2. A protocol for the propagation and reintroduction of all five species should be developed in collaboration with partners (e.g., University of Puerto Rico, KEW, Fairchild Tropical Botanic Garden, PRDNER, Para La Naturaleza and Natural Resources Conservation Service). The protocol should address the feasibility of seed banking these species, and if deemed necessary, seed material should be stored at the Millennium Seed Bank (KEW) and USDA National Laboratory for Genetic Resources Preservation in Ft. Collins. This new action should be included within Recovery Task 33. (USFWS, 2019).
- 2019 - 3. Studies in the species' population genetics should be conducted to determined patterns of genetic diversity across the species natural distribution, and to provide baseline information for sound management of these species. This new action should be included within Recovery Task 3. (USFWS, 2019).

Conservation Measures and Best Management Practices:

- 1. The USFS should establish a long term monitoring program for the populations of listed plants at El Yunque National Forest to determine population trends for these species. The guidelines for these monitoring should be included as part of the El Yunque National Forest Management Plan (USFWS, 2015).
- 2. Develop a comprehensive survey and assessment of the population of *I. sintenisii*. This survey must be standardized to ensure that the habitat (dwarf forest) is efficiently surveyed (USFWS, 2015).
- 3. Molecular studies should be conducted to determine the relationships within the genus *Ilex* in Puerto Rico (USFWS, 2015).
- 4. The USFS, PRDNER and the USFWS should develop an intensive survey program to inventory areas within and outside El Yunque National Forest with potential habitat for these species. This program should include training to field biologists to allow personnel to recognize listed species in the field (USFWS, 2015).

- 5. The populations that are actively producing seeds need to be identified and monitored to collect seed material for recovery purposes. A protocol to collect seed should be developed and implemented to avoid altering the natural recruitment of the species (USFWS, 2015).
- 6. Enhancement of natural populations should be considered a priority, particularly for *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis*. The development of adequate propagation techniques is essential for the recovery of these species (USFWS, 2015).
- 7. Studies should be conducted to determine the patterns of genetic variation within and among populations, in order to develop a plan to preserve the species genetic variability (USFWS, 2015).
- 8. The recovery plan should be revised to establish measurable delisting criteria, including how many individuals constitute a self-sustainable population and how many populations would be needed to delist the species (USFWS, 2015).

SPECIES ACCOUNT: *Tetramolopium arenarium* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 03/04/1994; Pacific Region (R1) (USFWS, 2016)

Physical Description

Tetramolopium arenarium ssp. *arenarium* is an erect tufted shrub 0.8 to 1.3 meters (2.6 to 4.3 feet) tall. Plants are covered with tiny glands and straight hairs. Leaves are alternate, shallowly toothed (or toothless), and lance-shaped. They range in length from 15 to 35 millimeters (0.6 to 1.5 inches) and in width from 3 to 9 millimeters (0.1 to 0.4 inch). Inflorescences are terminal with 5 to 10 heads. Each head has 20 to 34 bracts beneath a single series of white florets (male ray florets) on the outside and fewer than 15 inner bisexual maroon-petalled disk florets. The fruits are compressed achenes (U.S. Army 2003a).

Taxonomy

Tetramolopium arenarium is a member of the Asteraceae, or sunflower family. Current classification recognizes three intraspecific taxa: *T. arenarium* ssp. *arenarium* var. *arenarium*, *T. arenarium* ssp. *arenarium* var. *confertum*, and *T. arenarium* ssp. *laxum*. These are distinguished from other members of the genus by its erect habit; presence and types of glands and hairs on the plant; few-flowered head clusters; large male ray florets; few, bisexual, maroon-petalled disk florets; and wide achenes (U.S. Army 2003a).

Historical Range

Historically, *Tetramolopium arenarium* ssp. *arenarium* was known from the islands of Maui and Hawaii.

Current Range

Currently, between 292 and 296 individuals occur only on the island of Hawaii (see Figure 49 in the Transformation Biological Assessment) (U.S. Army 2003a).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Habitat Type

Adult: Shrublands

Habitat Narrative

Adult: *Tetramolopium arenarium* ssp. *arenarium* occurs in *Dodonaea viscosa* dominated lowland and montane dry shrublands at elevations from 800 and 1,500 meters (2,625 and 4,921 feet). At the Pohakuloa Training Area (PTA) on the island of Hawaii the species is found in the *Dodonaea* Mixed Shrubland at elevations between 1,300 and 1,700 meters (4,265 and 5,577 feet). *Tetramolopium arenarium* ssp. *arenarium* is extremely rare on very old Mauna Kea flows (greater than 10,000 years old) (U.S. Army 2003a).

Threats and Stressors**Stressor:****Exposure:****Response:****Consequence:**

Narrative: The primary threats to *Tetramolopium arenarium* ssp. *arenarium* are feral ungulates that browse on the plant; rooting by feral pigs; competition from non-native plant species such as *Pennisetum setaceum*; and conversion of habitat to a fire-based vegetation community. Army training such as mounted and dismounted off-road maneuvers, bivouac, and live-fire training, increase the risk of fire, habitat fragmentation and alien plant seed spread. Off-road and on-road driving and training increases the level of dust (which can compromise plant health and vigor) due to the fine soils in northern PTA. In addition, due to the very limited distribution of this species, a single natural or human-caused environmental disturbance could be catastrophic (U.S. Army 2003a).

Stressor:**Exposure:****Response:****Consequence:**

Narrative: If the species is still extant in the general area in which it was originally collected, it is threatened by alien plants, introduced ungulates, and fire. (NatureServe, 2015)

Stressor:

Exposure:

Response:

Consequence:

Narrative: Threats include fire, military activities, sheep, goats, and pigs. (NatureServe, 2015)

Recovery

Conservation Measures and Best Management Practices:

- The following important conservation actions are needed for *Tetramolopium arenarium* ssp. *arenarium*: control of non-native plant species and feral ungulates; reduction of fire risk; and research on habitat requirements, population structure, reproductive biology, and seed biology. Augmentation of small populations and re-establishment of new populations within the historical range of the species are also expected to benefit the species (U.S. Army 2003a). In addition, a State-wide management plan that identifies areas and landscapes for the long-term conservation of all known occurrences of *T. arenarium* ssp. *arenarium* is needed. As part of this management plan, landowners and managers should delineate management units to conserve this species and other native species through threat control and habitat restoration. Ongoing Conservation Actions: Aside from specific actions occurring at PTA (and discussed below), the Service is unaware of species-specific conservation actions being conducted for *Tetramolopium arenarium* ssp. *arenarium*.

SPECIES ACCOUNT: *Tetramolopium capillare* (Pamakani)

Species Taxonomic and Listing Information

Listing Status: Endangered; 09/30/1994; Pacific Region (R1) (USFWS, 2016)

Physical Description

Tetramolopium capillare are is a slender, low-growing or sprawling shrub in the aster family (Asteraceae). Stems are 50-80 cm (19.7-31.5 in) long and densely glandular when young. The leaves are slender (10-25 x 0.3-0.4 mm [0.4-1x 0.01-0.02 in]) with pointed tips. The leaves are involute—that is, the leaf edges strongly roll toward the top surface of the leaf. The leaves, attached directly to the main stem of the plant, are firm and resistant to signs of wilting. The leaves are hairless or with small hairs near the base. Glandular flower heads occur singly on stalks and measure 7-10 mm (0.3-0.4 in) in diameter with 30-50 petal-like white, 3.5-4.3 mm (0.1-0.2 in) ray florets and 15-25 red-tinged greenish-yellow 3.6 mm (0.1 in) disk florets; the bases of the heads are covered with 45-50 small grasslike appendages (bracts). The dry fruits (achenes) are under 3 mm (0.1 in) long and under 1 mm (0.04 in) wide. (USFWS, 1997)

Taxonomy

This taxon can be readily distinguished from the apparently related *Tetramolopium remyi* by its shorter flower stalk, smaller heads, and lax or sprawling habit (Wagner et al. 1990). Despite the close relationship with *Tetramolopium remyi*, *T. capillare* is readily distinguished by its shorter peduncle, smaller heads, and lax or sprawling habit (Wagner et al. 1990). (USFWS, 1997)

Historical Range

Regarding *Tetramolopium capillare*, Lowrey in Wagner et al. (1990) states, “known only from dry forest and shrubland among rocks in the foothills, West Maui from Lahainaluna to Wailuku. (USFWS, 1997)

Current Range

Endemic to West Maui. Thus, *Tetramolopium capillare* is currently known only from Halepohaku and Kauaula Valley, West Maui. (USFWS, 1997)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Tetramolopium capillare* (Pamakani) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes seven detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Tetramolopium capillare* includes seven CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Lowland Dry—Unit 5 consists of 3,615 ac (1,463 ha) of State land, and 43 ac (17 ha) of privately owned land, from Panaewa to Manawainui on the western and southern slopes of west

Maui. This unit is occupied by the plants *Asplenium dielerectum*, *Bidens campylotheca* ssp. *pentamera*, *Cenchrus agrimonoides*, *Gouania hillebrandii*, *Kadua coriacea*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and *Tetramolopium capillare*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 5 is not known to be occupied by *Ctenitis squamigera*, *Cyanea obtusa*, *Hesperomannia arbuscula*, *Hibiscus brackenridgei*, *Lysimachia lydgatei*, *Neraudia sericea*, *Schiedea salicaria*, *Sesbania tomentosa*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 6 consists of 3 ac (1 ha) of State land, and 237 ac (96 ha) of privately owned land, from Paleaahu Gulch to Puu Hona on the southern slopes of west Maui. This unit is occupied by the plants *Hibiscus brackenridgei* and *Schiedea salicaria*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 6 is not known to be occupied by *Asplenium dielerectum*, *Bidens campylotheca* ssp. *pentamera*, *Cenchrus agrimonoides*, *Ctenitis squamigera*, *Cyanea obtusa*, *Gouania hillebrandii*, *Hesperomannia arbuscula*, *Kadua coriacea*, *Lysimachia lydgatei*, *Neraudia sericea*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Spermolepis hawaiiensis*, *Tetramolopium capillare*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Dry Cliff—Unit 5 (and) *Palmeria dolei*—Unit 29—Dry Cliff (and) *Pseudonestor xanthophrys*—Unit 29— Dry Cliff This area consists of 1,298 ac (525 ha) of State land, from Helu and across Olowalu to Ukumehame Gulch, on west Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 5). They are occupied by the plant *Tetramolopium capillare*, and contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Dry Cliff—Unit 5 is not currently occupied by the plants *Bonamia menziesii*, *Diplazium molokaiense*, *Hesperomannia arbuscula*, *Isodendron pyriformum*, *Kadua laxiflora*, or *Neraudia sericea*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Dry Cliff—Unit 6 consists of 279 ac (113 ha) of State land along the east wall of Ukumehame Gulch on west Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 5). Although Maui—Dry Cliff—Unit 6 is not currently occupied by the plants *Bonamia menziesii*, *Diplazium molokaiense*, *Hesperomannia arbuscula*, *Isodendron pyriformis*, *Kadua laxiflora*, *Neraudia sericea*, or *Tetramolopium capillare*, we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 6 (and) *Palmeria dolei*—Unit 35—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 35—Wet Cliff This area consists of 1,858 ac (752 ha) of State land, and 253 ac (102 ha) of privately owned land, at the summit ridges of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). They are occupied by the plants *Alectryon macrococcus*, *B. conjuncta*, *Ctenitis squamigera*, *Cyrtandra munroi*, *Remya mauiensis*, and *Santalum haleakalae* var. *lanaiense*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Wet Cliff—Unit 6 is not known to be occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Bonamia menziesii*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Isodendron pyriformis*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, or *Tetramolopium capillare*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 7 (and) *Palmeria dolei*—Unit 36—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 36—Wet Cliff This area consists of 556 ac (225 ha) of State land along Honokowai ridge on the northwestern side of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). These units are occupied by the plants *Cyrtandra filipes* and *C. munroi*, and contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Wet Cliff—Unit 7 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. conjuncta*, *Bonamia menziesii*, *Ctenitis squamigera*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Isodendron pyriformis*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Tetramolopium capillare*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation

and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 8 consists of 337 ac (137 ha) of State land along Kahakuloa ridge on the north side of west Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). Although Maui—Wet Cliff— Unit 8 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. conjuncta*, *Bonamia menziesii*, *Ctenitis squamigera*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Isodendrion pyrifolium*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Tetramolopium capillare*, we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Tetramolopium capillare* critical habitat consists of three components. Lowland dry (west Maui), Dry cliff (west Maui) and Wet cliff (west Maui)(81 FR 17790-18110):

Ecosystem: Lowland Dry. Elevation: <3,300 ft (<1,000 m). Annual precipitation: <50 in (<130 cm). Substrate: Weathered silty loams to stony clay, rocky ledges, littleweathered lava. Canopy: *Diospyros*, *Myoporum*, *Pleomele*, *Santalum*. Subcanopy: *Chamaesyce*, *Dodonaea*, *Leptecophylla*, *Osteomeles*, *Psydrax*, *Scaevola*, *Wikstroemia*. Understory: *Alyxia*, *Artemisia*, *Bidens*, *Chenopodium*, *Nephrolepis*, *Peperomia*, *Sicyos*.

Ecosystem: Dry Cliff. Elevation: unrestricted. Annual precipitation: <75 in (<190 cm). Substrate: >65 degree slope, rocky talus. Canopy: None. Subcanopy: *Antidesma*, *Chamaesyce*, *Diospyros*, *Dodonaea*. Understory: *Bidens*, *Eragrostis*, *Melanthera*, *Schiedea*.

Ecosystem: Wet Cliff. Elevation: unrestricted. Annual precipitation: >75 in (>190 cm). Substrate: >65 degree slope, shallow soils, weathered lava. Canopy: None. Subcanopy: *Broussaisia*, *Cheirodendron*, *Leptecophylla*, *Metrosideros*. Understory: *Bryophytes*, *Ferns*, *Coprosma*, *Dubautia*, *Kadua*, *Peperomia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is

not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species

such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylothea* ssp. *pentamera*, *B. campylothea* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mcelandowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Not available.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Shrubland/chaparral (NatureServe, 2015)

Habitat Narrative

Adult: Presumably, the species grew in dryland forest and shrubland of lowland, leeward West Maui. Associated species within the presumed potential habitat of this species include *Metrosideros polymorpha*, *Styphelia tameiameia*, *Dodonaea viscosa*, *Machaerina angustifolia*, *Gahnia gahniiformis*, *Dubautia scabra*, *Lysimachia remyi*, *Deschampsia nubigena*, *Bidens menziesii*, *Lipochaeta lavarum*, *Heteropogon contortus*, *Dubautia linearis*, *Myoporum sandwicensis*, *Achyranthes splendens*, *Argemone glauca*, and *Waltheria indica* (HPCC 1994). Associated alien species include *Leucaena leucocephala*, *Conyza*, *Buddleja asiatica*, *Prosopis pallida*, and *Rhynchetrum repens* (HPCC 1994). (USFWS, 1997)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends

Population Trends:

Not available.

Resiliency:

Very low (inferred from USFWS, 2012)

Redundancy:

Very low (inferred from USFWS, 2012)

Number of Populations:

1-5 (NatureServe, 2015)

Population Size:

<200 (USFWS, 2012)

Population Narrative:

In 2010, there were no known genuine populations of *Tetramolopium capillare* (USFWS 2010). Meanwhile, population numbers for *Tetramolopium* species stands at around 120 individuals, with 19 individuals located at Hahakea and about 100 individuals at the lower (north fork) Kauaula Valley site (Plant Extinction Prevention Program 2010). A revisit of the upper Kauaula site in 2010 revealed no individuals of *T. capillare*, despite the presence of good habitat (H. Oppenheimer, pers. comm. 2010). (USFWS, 2012). New Status Information: • *Tetramolopium capillare* may be extinct in the wild (Oppenheimer 2018, in litt.). • In 2016, seven critical habitat units in three ecosystems (lowland dry, dry cliff, and wet cliff) were designated on west Maui for *T. capillare* (8,479 ac; 3,431 ha) (81 FR 17790, March 30, 2016) (USFWS, 2018).

Threats and Stressors

Stressor: Non-native plants (USFWS, 1997)

Exposure:

Response:

Consequence:

Narrative: Non-native plants threatening this species include *Leucaena leucocephala*, *Conyza*, *Buddleja asiatica*, *Prosopis pallida*, and *Rhynchetrum repens* (HPCC 1994). Established ecosystem-altering invasive plant species degradation of habitat (Plant Extinction Prevention Program 2008, 2009; Oppenheimer 2006; USFWS 1994, 1997, 2003) results from *Cortaderia jubata* (pampas grass), *Erigeron karvinskianus* (daisy fleabane), *Lantana camara* (lantana), *Leucaena leucocephala* (koa haole), *Melinis repens* (natal redtop), and *Rubus rosifolius* (thimbleberry). Established invasive plant species compete for resources including (Oppenheimer 2006; H. Oppenheimer, pers. comm. 2010; USFWS 1994, 1997, 2003) *Adiantum raddianum* (maidenhair fern), *Blechnum appendiculatum* (palm fern), *Buddleia asiatica* (dog tail), *Lythrum maritimum* (loosestrife), *Sonchus oleraceus* (sow thistle), and *Verbena litoralis* (seashore verbena). (USFWS, 1997; USFWS, 2012)

Stressor: Fire (USFWS, 1997)

Exposure:

Response:

Consequence:

Narrative: Fire is a continuing threat to this species and its habitat. (USFWS, 1997)

Stressor: Small population size (USFWS, 1997)

Exposure:

Response:

Consequence:

Narrative: Because this species occurs at such low population levels and in such a restricted area, a single severe environmental disturbance could result in its extinction. (USFWS, 1997)

Stressor: Degradation of habitat by ungulates (USFWS, 1997)

Exposure:

Response:

Consequence:

Narrative: Ungulate degradation of habitat (Hawaii Biodiversity and Mapping Program 2010; Plant Extinction Prevention Program 2008, 2009) from axis deer (*Axis axis*) and feral goats (*Capra hircus*). (USFWS, 2012)

Stressor: Climate change (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. However, current climate change analyses in the Pacific Islands lack sufficient spatial resolution to make predictions on impacts to this species. The Pacific Islands Climate Change Cooperative (PICCC) has currently funded climate modeling that will help resolve these spatial limitations. We anticipate high spatial resolution climate outputs by 2013. (USFWS, 2012)

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: We previously reported that climate change may pose a threat to this species, anticipating an analysis by 2013. The assessment conducted by Fortini et al. (2013) concluded that *T. capillare* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.61 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions may be needed to conserve this taxon into the future (USFWS, 2018).

Recovery

Reclassification Criteria:

1. A total of five to seven populations of each taxon should be documented on Maui and at least one other island where they now occur or occurred historically. (USFWS, 1997)

2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1997)

3. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered. (USFWS, 1997)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Maui and at least one other island where they now occur or occurred historically. (USFWS, 1997)

2. Each population must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1997)

3. Each population should persist at this level for a minimum of five consecutive years. (USFWS, 1997)

Recovery Actions:

- Use seed from existing (and any additionally discovered) populations to outplant into protected areas on West Maui, such as at Lihauor Manawainui Plant Sanctuary, providing necessary management to maximize chances of successful establishment and long-term survival. (USFWS, 1997)
- Recommendations for Future Actions: We are not aware of any new threats or significant new information regarding the species' biological status since the last 5-year review in 2012. Thus, the following recommendations for future actions are reiterated for the 5-year review for 2018. • Surveys and inventories—Continue to conduct thorough surveys of the Halepōhaku area in habitat where *Tetramolopium capillare* was last observed, especially within *Dodonaea* dry shrubland and *Heteropogon* grassland. • Ungulate monitoring and control—Fence any new occurrences to protect them from the impacts of feral ungulates. • Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around any new populations of *T. capillare*. • Fire destruction or degradation of habitat—Develop and implement a fire management plan for any wild or reintroduced populations. • Landslides and flooding destruction or degradation of habitat—Build resilience and redundancy with propagation and reintroduction. • Captive propagation for genetic storage and reintroduction—
 - o Propagate seeds collected from the Halepohaku population.
 - o Collect soil from areas of previously known individuals for germination trials. • Reintroduction and translocation—Reintroduce individuals into suitable habitat protected from threats. • Taxonomy research—Determine the taxonomic status of the Kaua'ula and Hāhākea populations. • Climate change adaptation strategy—Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change. • Alliance and partnership development—Initiate planning and contribute to ecosystem-level restoration and management to benefit this species (USFWS, 2018).

Conservation Measures and Best Management Practices:

- Propagate a portion of the 140 seeds from the Hale Pohaku population in genetic storage at National Tropical Botanical Garden. (USFWS, 2012)
- If sites are relocated, collect soil from known locations of *T. capillare* and take to the Olinda Rare Plant Facility in the hope of germinating a seed bank that will include sprouts of the taxon. (USFWS, 2012)
- Continue to conduct thorough surveys of the Hale Pohaku area in habitat where *Tetramolopium capillare* was last seen, especially in *Dodonaea* dry shrubland and *Heteropogon* grassland. (USFWS, 2012)
- Monitor the taxonomic status of the Kauaula and Hahakea populations. If not classifiable under *T. capillare*, it may be described as a new taxon that will need to be tracked. (USFWS, 2012)
- Continue to construct fenced enclosure around existing and reintroduced populations to provide protection from feral ungulates. (USFWS, 2012)
- Monitor fenced enclosures for evidence of breaching by feral ungulates. (USFWS, 2012)
- Develop and implement fire management plans for all wild and reintroduced populations. (USFWS, 2012)
- Work with Hawaii Division of Forestry and Wildlife and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species. (USFWS, 2012)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Region (R1) (USFWS, 2016)

Physical Description

A dwarf shrub 5-15 cm tall. The flowers are maroon or rarely yellow. (NatureServe, 2015)

Historical Range

See current range/distribution

Current Range

Current range: northern Waianae Mountains, Oahu; historically no additional range.

Critical Habitat Designated

Yes; 6/17/2003.

Legal Description

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Tetramolopium filiforme* under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Tetramolopium filiforme* (77 FR 57648-57862). The critical habitat designation includes 8 critical habitat units, which encompass approximately 1,499 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Tetramolopium filiforme* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Tetramolopium filiforme* includes 8 critical habitat units, covering one ecosystem type, which encompasses approximately 1,449 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8.

Oahu—Dry Cliff—Unit 1 [49 ac (20 ha)]. This area consists of 49 ac (20 ha) in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the rim of Makua Valley.

Oahu—Dry Cliff—Unit 2 [412 ac (167 ha)]. This area consists of 320 ac (130 ha) of State land and 91 ac (37 ha) of City and County of Honolulu land in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the ridge from Keaau to Ohikilolo.

Oahu—Dry Cliff—Unit 3 [450 ac (182 ha)]. This area consists of 349 ac (141 ha) of City and County of Honolulu land and 101 ac (41 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the eastern rim of Makaha Valley along Kamaileunu Ridge.

Oahu—Dry Cliff—Unit 4 [24 ac (10 ha)]. This area consists of 24 ac (10 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along Kauaopuu ridge, which divides Waianae Kai and Lualualei valleys.

Oahu—Dry Cliff—Unit 6 [149 ac (60 ha)]. This area consists of 149 ac (60 ha) in the dry

cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Lualualei Valley from Puukanehoa to Puukaua. Oahu—Dry Cliff—Unit 7a [68 ac (27 ha)]. This area consists of 68 ac (27 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley to Pohakea. Oahu—Dry Cliff—Unit 7b [38 ac (16 ha)]. This area consists of 38 ac (16 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley at Palikea. Oahu—Dry Cliff—Unit 8 [259 ac(105 ha)]. This area consists of 259 ac (105 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Nanakuli Valley from Palehua to Puumanawanua, and partially within the Nanakuli Forest Reserve.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Tetramolopium filiforme* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Tetramolopium filiforme* occurs within the indicated ecosystem in the Waianae Mountain caldera complex:

Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8. (A) Elevation: unrestricted. (B) Annual Precipitation: < 75 in (<190 cm). (C) Substrate: >65 degree slope, rocky talus. (D) Canopy: None. (E) Subcanopy: *Antidesma*, *Chamaesyce*, *Diospyros*, *Dodonaea*. (F) Understory: *Bidens*, *Eragrostis*, *Melanthera*, *Schiedea*.

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Tetramolopium filiforme* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Capable of self-pollination/probably is insect-pollinated (USFWS, 2016)

Breeding Season

Adult: Flowering usually occurs in the late winter and spring (USFWS, 2016).

Reproduction Narrative

Adult: Flowering usually occurs in the late winter and spring. Although capable of self-pollination, *T. filiforme* probably is insect-pollinated, as are most species in the sunflower family with conspicuous flowers. The seeds of *T. filiforme* are presumed to be wind-dispersed, as bristle-bearing achenes also are characteristic of wind-dispersed members of the sunflower family. Birds may also disperse the seeds because the bristles may adhere the achenes to their

feathers (Makua Implementation Team 2003). This species is relatively short-lived, usually less than five years. Other demographic information for *T. filiforme* in the wild is unknown, including number of seeds produced, age at sexual maturity, survivorship to sexual maturity, number of years in reproductive condition, survivorship during reproductive life, pollination and seed dispersal, vegetative reproduction and specific environmental requirements (USFWS, 2016).

Habitat Type

Adult: Rocky ridges/vertical cliffs (USFWS, 2016)

Habitat Narrative

Adult: *Tetramolopium filiforme* occurs in dry habitat at the seaward end of the Ohikilolo population unit and in dry-mesic and mesic habitats at higher, more inland locations. In general, the plants are found on exposed rocky ridges and sparsely vegetated, nearly vertical cliffs, often rooted in cracks in the rock, at elevations of 340 to 900 m (1,116 to 2,953 ft) (Makua Implementation Team 2003) (USFWS, 2016).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: The seeds of *T. filiforme* are presumed to be wind-dispersed, as bristle-bearing achenes also are characteristic of wind-dispersed members of the sunflower family. Birds may also disperse the seeds because the bristles may adhere the achenes to their feathers (Makua Implementation Team 2003) (USFWS, 2016).

Population Information and Trends**Population Trends:**

Decreasing (USFWS, 2016)

Number of Populations:

7 (USFWS, 2016)

Population Size:

~3,500 (USFWS, 2016)

Population Narrative:

Three of the existing population units have exceeded minimum criteria for stabilization population (at least 50 mature, reproducing individuals for short-lived perennials). Trends in numbers since listing indicate increases until 2003 and decreasing numbers since then in all population units except Keaau and Waianae Kai. In 2003, the last plant in the Waianae Kai population unit was reported as dead (Makua Implementation Team 2003). By 2004, a new population had appeared there, presumably from viable seeds in the soil seed bank (U.S. Army Garrison 2004a). Plants in the Kahanahaiki, Keaau, Makaha/Ohikilolo Ridge, and Ohikilolo population units are located in zones at risk from training-related wildfire. Thus, *T. filiforme* is characterized by seven population units and an overall decreasing trend in numbers since 2003, including three stabilization population units with relatively large numbers that are located in all fire risk zones (USFWS, 2016).

Threats and Stressors

Stressor: Fire (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of habitat/loss of individuals

Narrative: Fire is listed as a threat to this species (USFWS, 2016).

Stressor: Non-native insects (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Infestations of at least two species of non-native scale insects have been observed on *T. filiforme* and need further research (Makua Implementation Plan 2003) (USFWS, 2016).

Recovery**Delisting Criteria:**

Due to limited knowledge of life history requirements for short-term and long-term survival, the recovery plan for this species specifies interim objectives to downlisting and delisting that involve management of stabilization populations and abatements to threats (Service 1995a, 1998a) (USFWS, 2016).

Conservation Measures and Best Management Practices:

- The Makua Implementation Team (2003) has developed stabilization protocols for *Tetramolopium filiforme*, which are incorporated in the Army's Makua Implementation Plan Addendum (U.S. Army Garrison 2005a). In addition, this species occurs in two management units where it will benefit from population unit and/or ecosystem-level protection. The management units include Puu Kumakalii, which is not fenced and for which no fence construction is planned, and Ohikilolo, which is fenced. *Tetramolopium filiforme* seeds store well for several years, but viability is poor. The Army is focusing on collecting seed from fire-threatened sites in the lower Ohikilolo population unit. Plants can be propagated from both seed and cuttings. Cuttings are more than 90 percent successful, and The Nature Conservancy of Hawaii has successfully propagated the related *T. lepidotum* from seed. Outplanting has yet been attempted for *T. filiforme* in the wild because this species commonly grows in shallow cracks on exposed rocky ledges and cliffs; transitioning greenhouse plants to such sites may be difficult (U.S. Army Garrison 2005b). Current ex situ collections for this species include 31,000 seeds in seed storage (Lyon Arboretum Seed Storage Facility) (Service 2005b) (USFWS, 2016).

SPECIES ACCOUNT: *Tetramolopium lepidotum* ssp. *lepidotum* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/29/1991; Pacific Region (R1) (USFWS, 2016)

Physical Description

A shrub 12-36 cm tall. Flower heads with center maroon to pale salmon, and rays white to pinkish lavender. (NatureServe, 2015)

Historical Range

Historically, *Tetramolopium lepidotum* ssp. *lepidotum* was known from nearly the entire length of the Waianae Mountains, from Makua Valley to Cachexia Ridge, as well as from the island of Lanai (Lowrey 1990, USFWS 1995). (USFWS, 1998)

Current Range

Range includes Waianae Mountains, Oahu. (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Tetramolopium lepidotum* ssp. *lepidotum* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes two critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Tetramolopium lepidotum* ssp. *lepidotum* under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Tetramolopium lepidotum* ssp. *lepidotum* (77 FR 57648-57862). The critical habitat designation includes 11 critical habitat units, which encompass approximately 7,332 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Tetramolopium lepidotum* ssp. *lepidotum* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Tetramolopium lepidotum* ssp. *lepidotum* includes two CHUs in Maui County, Hawaii. Approximately 10,705 ac (4,332) ha) of private land on the Island of Lanai are being designated as critical habitat for *Tetramolopium lepidotum* ssp. *lepidotum*. (81 FR 17790-18110).

Both Critical Habitat Units are on Lanai and no data is specified except that they are owned by Lanai Resorts, LLC and Castle and Cooke Properties, Inc.

The critical habitat designation for *Tetramolopium lepidotum* ssp. *lepidotum* includes 11 critical habitat units, covering two ecosystem types, which encompass approximately 7,332 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Mesic—Units 1, 2, 3; Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8.

Oahu—Lowland Mesic—Unit 1 [4,448 ac (1,800 ha)]. This area consists of 3,565 ac (1,443 ha) of State land, 583 ac (236 ha) of City and County of Honolulu land, 22 ac (9 ha) of Federal land, and 277 ac (112 ha) of privately owned land in the lowland mesic ecosystem in the Waianae Mountains, encompassing a large area including the north slopes of Mt. Kaala, from the Pahole NAR to the Kaala NAR, and south to the Waianae Kai Forest Reserve (FR). Oahu—Lowland Mesic—Unit 2 [1,063 ac (430 ha)]. This area consists of 1,063 ac (430 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Puuhapapa south to Puukaua. Oahu—Lowland Mesic—Unit 3 [353 ac (143 ha)]. This area consists of 353 ac (143 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Pohakea Pass to Kaiakuakai Gulch.

Oahu—Dry Cliff—Unit 1 [49 ac (20 ha)]. This area consists of 49 ac (20 ha) in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the rim of Makua Valley. Oahu—Dry Cliff—Unit 2 [412 ac (167 ha)]. This area consists of 320 ac (130 ha) of State land and 91 ac (37 ha) of City and County of Honolulu land in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the ridge from Keaau to Ohikilolo. Oahu—Dry Cliff—Unit 3 [450 ac (182 ha)]. This area consists of 349 ac (141 ha) of City and County of Honolulu land and 101 ac (41 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the eastern rim of Makaha Valley along Kamaileunu Ridge. Oahu—Dry Cliff—Unit 4 [24 ac (10 ha)]. This area consists of 24 ac (10 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along Kauaopuu ridge, which divides Waianae Kai and Lualualei valleys. Oahu—Dry Cliff—Unit 6 [149 ac (60 ha)]. This area consists of 149 ac (60 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Lualualei Valley from Puukanehoa to Puukaua. Oahu—Dry Cliff—Unit 7a [68 ac (27 ha)]. This area consists of 68 ac (27 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley to Pohakea. Oahu—Dry Cliff—Unit 7b [38 ac (16 ha)]. This area consists of 38 ac (16 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley at Palikea. Oahu—Dry Cliff—Unit 8 [259 ac (105 ha)]. This area consists of 259 ac (105 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Nanakuli Valley from Palehua to Puumanawanua, and partially within the Nanakuli Forest Reserve.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Tetramolopium lepidotum* ssp. *lepidotum* critical habitat consists of one component (81 FR 17790-18110):

Lowland Dry Ecosystem: Elevation: <3,300 ft (<1,000 m). Annual precipitation: <50 in (<130 cm). Substrate: Weathered silty loams to stony clay, rocky ledges, littleweathered lava. Canopy: *Diospyros*, *Myoporum*, *Pleomele*, *Santalum*. Subcanopy: *Chamaesyce*, *Dodonaea*, *Leptecophylla*, *Osteomeles*, *Psydrax*, *Scaevola*, *Wikstroemia*. Understory: *Alyxia*, *Artemisia*, *Bidens*, *Chenopodium*, *Nephrolepis*, *Peperomia*, *Sicyos*.

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Tetramolopium lepidotum* ssp. *lepidotum* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Tetramolopium lepidotum* ssp. *lepidotum* occurs within the Lowland mesic and Dry cliff ecosystems in the Waianae Mountain caldera complex:

Oahu—Lowland Mesic—Units 1, 2, 3. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. (E) Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. (F) Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Oahu—Dry Cliff—Units 1, 2, 3, 4, 6, 7a, 7b, 8. (A) Elevation: unrestricted. (B) Annual Precipitation: < 75 in (<190 cm). (C) Substrate: >65 degree slope, rocky talus. (D) Canopy: None. (E) Subcanopy: *Antidesma*, *Chamaesyce*, *Diospyros*, *Dodonaea*. (F) Understory: *Bidens*, *Eragrostis*, *Melanthera*, *Schiedea*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further

degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkii*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Tetramolopium lepidotum* ssp. *lepidotum* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Sexual: self-pollination (USFWS, 1998; 2009)

Lifespan

Adult: 2-4 years (USFWS, 2009)

Breeding Season

Adult: April through July (USFWS, 1998)

Reproduction Narrative

Adult: *Tetramolopium lepidotum* ssp. *lepidotum* is a short-lived perennial that has been observed producing fruit and flowers from April through July (USFWS 1995). *Tetramolopium lepidotum* ssp. *lepidotum* is a short-lived perennial, with a two- to four-year lifespan (The Nature Conservancy 2006). The taxon is capable of self-fertilization, with high rates of viable seed set. (USFWS, 1998; USFWS, 2009)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Rocky ridges, shrublands, cliffs, (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations from 370 to 940 meters (1,200 to 3,000 feet) (USFWS, 1998)

Habitat Narrative

Adult: This species is found on windswept, dry rocky ridges on steep, exposed slopes. On Oahu, moist shrublands on ridgecrests and cliffs. On Lanai, dry shrublands on plateau lands. (NatureServe, 2015) *Tetramolopium lepidotum* ssp. *lepidotum* typically grows on grassy ridgetops, slopes, or west-facing cliffs in mesic forest at an elevation of 370 to 940 meters (1,200 to 3,100 feet) (USFWS 1995). Associated species include kookoolau, and ohia (USFWS 1995). (USFWS, 1998)

Dispersal/Migration

Dispersal

Adult: Low (USFWS, 2009)

Dispersal/Migration Narrative

Adult: Seeds have the potential for being wind-dispersed, but tend to fall near the parent plants. (USFWS, 2009)

Population Information and Trends**Population Trends:**

Declining (USFWS, 2013)

Resiliency:

Very low (inferred from USFWS, 2009)

Redundancy:

Very low (inferred from USFWS, 2009)

Number of Populations:

1 (USFWS, 2009)

Population Size:

147 (USFWS, 2013)

Population Narrative:

Overall, this represents a decline from the approximately 250 individuals reported in the last five year review to 147 individuals currently (USFWS, 2013). Previously, about 250 individuals, consisting of 75 mature and 175 seedlings, are within a single population located along the Ekahanui crestline (The Nature Conservancy 2006; USFWS 2008). The Nature Conservancy of Hawaii surveyed historical locations of the taxon in 2006, but only found new individuals at the extant Ekahanui crestline area (The Nature Conservancy 2006). Six individuals, resulting from previous outplantings, are also known to occur near a fenced exclosure within Honouliuli Preserve (USFWS 1998, 2008). (USFWS, 2009)

Threats and Stressors

Stressor: Trampling (NatureServe, 2015)

Exposure:

Response:

Consequence:

Narrative: Threats include trampling near trail and invasion by alien vegetation. (NatureServe, 2015)

Stressor: Climate change (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Climate change may also pose a threat to this species. However, current climate change analyses in the Pacific Islands lack sufficient spatial resolution to make predictions on impacts to this species. The Pacific Islands Climate Change Cooperative (PICCC) funded climate modeling that will help resolve these spatial limitations. High spatial resolution climate outputs are expected in 2013. (USFWS, 2013)

Stressor: Invasive introduced plants (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: The primary threat to the habitat of the taxon is competition from invasive introduced plant species such as *Melinis minutiflora* (molasses grass), and secondarily from *Conyza bonariensis* (horsetail weed), *Schinus terebinthifolius* (Christmasberry) and *Erigeron karvinskianus* (daisy fleabane) (The Nature Conservancy 2006). (USFWS, 2009)

Stressor: Habitat degradation by ungulates (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Feral ungulates, namely goats (*Capra hircus*) and pigs (*Sus scrofa*) also continue to threaten the taxon and its surrounding habitat through their degradation of habitat. (USFWS, 2009)

Stressor: Ants (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Young seedlings of the taxon are susceptible to scales spread by various species of ants (The Nature Conservancy 2006). (USFWS, 2009)

Stressor: Rockslides and landslides (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: The only extant population of *Tetramolopium lepidotum* ssp. *lepidotum* is susceptible to rockslides and large landslides (The Nature Conservancy 2006). (USFWS, 2009)

Stressor: Drought (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Drought is a major limiting factor for recruitment and survival of mature plants. (USFWS, 2009)

Stressor: Fire (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Fire is a low threat risk given the remote location, moisture level and ongoing grass control in the area. (USFWS, 2009)

Recovery

Reclassification Criteria:

1. A total of five to seven populations of each taxon should be documented on Oahu and at least one other island where they now occur or occurred historically. (USFWS, 1998)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1998)
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered. (USFWS, 1998)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Oahu and at least one other island where they now occur or occurred historically. (USFWS, 1998)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1998)
3. Each population should persist at this level for a minimum of 5 consecutive years. (USFWS, 1998)

Recovery Actions:

- Construct enclosures or strategic barrier fence to protect populations against feral ungulates. (USFWS, 1998)
- Control competing alien plant species within enclosures. Populations that have only a few remaining individuals (Kuma Kakii and Waianae Kai Forest Reserve) should immediately be weeded and protected where accessible. (USFWS, 1998)
- A coordinated fire protection plan for endangered plant species on State forest reserves (Waianae Kai), Federal (Schofield Barracks—West Range), and private lands (Honouliuli Preserve) should be developed and implemented. (USFWS, 1998)

Conservation Measures and Best Management Practices:

- Continue collection of genetic resources for storage, future propagation and reintroducing into protected suitable habitat within historical range. (USFWS, 2009)
- Establish additional populations within protected historical range and suitable habitat. (USFWS, 2009)
- Expand enclosure fences to protect all individuals from the negative impacts of feral ungulates, and eradicate introduced invasive plant species within the enclosures. (USFWS, 2009)
- Determine impacts from and control methods for ant predation. (USFWS, 2009)

- Survey geographical and historical range for a thorough current assessment of the species. (USFWS, 2009)
- Assess genetic variability within wild and outplanted individuals. (USFWS, 2009)
- Collect cuttings or seed from tagged individuals, keeping close track of the maternal source for use in ex situ propagation. (USFWS, 2013)
- While surveying for new populations or reintroduced populations, determine which sites are least invaded by invasive introduced plant species and which appear to have the highest likelihood of maintaining new reintroductions. (USFWS, 2013)
- Reintroduce the species back into its known historical range. (USFWS, 2013)
- Construct, maintain, and monitor ungulate-proof exclosures around each population. (USFWS, 2013)
- Control invasive introduced plant species around all populations. (USFWS, 2013)
- Implement effective control methods for rodents. (USFWS, 2013)
- Survey geographical and historical range for a thorough current assessment of the species status. (USFWS, 2013)
- Develop and implement effective measures to reduce the impact of landslides and flooding and military activities. (USFWS, 2013)
- Develop and implement fire management plans for all wild and reintroduced populations. (USFWS, 2013)
- Initiate planning and contribute to implementation of ecosystem-level management and restoration to benefit this species. (USFWS, 2013)
- Implement genetic studies to assess viability of remaining populations. (USFWS, 2013)
- Study *Tetramolopium lepidotum* subsp. *lepidotum* with regard to population size and structure, geographical distribution, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. (USFWS, 2013)
- Assess the modeled effects of climate change on this species, and use the results to determine future landscape needed for the recovery of the species. (USFWS, 2013)

SPECIES ACCOUNT: *Tetramolopium remyi* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 09/20/1991; Pacific Region (R1) (USFWS, 2016)

Physical Description

A decumbent or occasionally erect shrub, 1-4 dm tall. Flower heads are solitary on long, leafless stalks. (NatureServe, 2015)

Historical Range

It was known historically from dry exposed ridges and flats in the foothills of southwest Maui, but has not been reported from there in many years. It was last seen on Maui in 1944 (USFWS 2003b). (USFWS, 2011)

Current Range

Tetramolopium remyi was listed as endangered in 1991. At that time, it was known from a single population of 35 plants on Lanai (USFWS 1991). (USFWS, 2011)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Tetramolopium remyi* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes two detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Tetramolopium remyi* includes two CHUs in Maui County, Hawaii with detailed unit information. There are also an unknown number of units on Lanai that contain this species (number of units is unknown because detailed unit descriptions for Lanai are not available) (81 FR 17790-18110).

Maui—Lowland Dry—Unit 5 consists of 3,615 ac (1,463 ha) of State land, and 43 ac (17 ha) of privately owned land, from Panaewa to Manawainui on the western and southern slopes of west Maui. This unit is occupied by the plants *Asplenium dielerectum*, *Bidens campylotheca* ssp. pentamera, *Cenchrus agrimonioides*, *Gouania hillebrandii*, *Kadua coriacea*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and *Tetramolopium capillare*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 5 is not known to be occupied by *Ctenitis squamigera*, *Cyanea obtusa*, *Hesperomannia arbuscula*, *Hibiscus brackenridgei*, *Lysimachia lydgatei*, *Neraudia sericea*, *Schiedea salicaria*, *Sesbania tomentosa*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations

within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 6 consists of 3 ac (1 ha) of State land, and 237 ac (96 ha) of privately owned land, from Paleaahu Gulch to Puu Hona on the southern slopes of west Maui. This unit is occupied by the plants *Hibiscus brackenridgei* and *Schiedea salicaria*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 6 is not known to be occupied by *Asplenium dielerectum*, *Bidens campylotheca* ssp. *pentamera*, *Cenchrus agrimonoides*, *Ctenitis squamigera*, *Cyanea obtusa*, *Gouania hillebrandii*, *Hesperomannia arbuscula*, *Kadua coriacea*, *Lysimachia lydgatei*, *Neraudia sericea*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Spermolepis hawaiiensis*, *Tetramolopium capillare*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Tetramolopium remyi* critical habitat consists of one component. Lowland dry (west Maui and Lanai) (81 FR 17790-18110):

Ecosystem: Lowland Dry. Elevation: <3,300 ft (<1,000 m). Annual precipitation: <50 in (<130 cm). Substrate: Weathered silty loams to stony clay, rocky ledges, littleweathered lava. Canopy: *Diospyros*, *Myoporum*, *Pleomele*, *Santalum*. Subcanopy: *Chamaesyce*, *Dodonaea*, *Leptecophylla*, *Osteomeles*, *Psydrax*, *Scaevola*, *Wikstroemia*. Understory: *Alyxia*, *Artemisia*, *Bidens*, *Chenopodium*, *Nephrolepis*, *Peperomia*, *Sicyos*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The

125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant

species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Food/Nutrient Resources

Dependency on Other Individuals or Species

Adult: Pollination is hypothesized to be possibly by butterflies, bees, or flies (Lowrey 1986). (USFWS, 1994)

Breeding Season

Adult: April to January (USFWS, 1994)

Key Resources Needed for Breeding

Adult: Precipitation (USFWS, 1994)

Reproduction Narrative

Adult: *Tetramolopium remyi* flowers between April and January (Lowrey 1986). Field observations suggest that the population size of the species can be profoundly affected by variability in annual precipitation; the adult plants may succumb to prolonged drought, but apparently there is a seedbank in the soil that can replenish the population during favorable conditions (Lowrey 1986; T. Lowrey, personal communication 1992). Pollination is hypothesized to be possibly by butterflies, bees, or flies (Lowrey 1986). (USFWS, 1994)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Shrubland/chaparral (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 150 to 770 meters (500 to 2,500 feet) (USFWS, 2011)

Environmental Specificity

Adult: Low, with few key requirements (USFWS, 2011)

Habitat Narrative

Adult: The habitat where *Tetramolopium remyi* occurs is lowland dry shrubland on dry, exposed ridges or flats at 150 to 770 meters (500 to 2,500 feet) elevation. The only known extant population occurs at about 200 meters (660 feet) elevation, on nearly barren red soils in a highly overgrazed area in *Heteropogon contortus* (pili grass) and *Dodonaea viscosa* (aalii) shrubland. Associated native plant species include *Argemone glauca* (pua kala), *Bidens mauiensis* (kookoolau), *Doryopteris decipiens* (kumuniu), *Eragrostis variabilis* (kawelu), *Heteropogon contortus* (pili grass), *Lipochaeta heterophylla* (nehe), *L. lavarum* (nehe), *Myoporum sandwicense* (naio), *Panicum fauriei* (no common name [NCN]), *Sida fallax* (ilima), *Waltheria indica* (uhaloa), and *Wikstroemia oahuensis* (akia) (Oppenheimer 2010; USFWS 1995; Wood 2010). (USFWS, 2011)

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Not available.

Population Information and Trends

Population Trends:

Not available.

Resiliency:

Very low (inferred from USFWS, 2011)

Redundancy:

Very low (inferred from USFWS, 2011)

Number of Populations:

1 (USFWS, 2011)

Population Size:

<10 (USFWS, 2011)

Population Narrative:

In March 2008, only three mature individuals and 10 seedlings were observed (Perlman 2010). In May 2008, all the seedlings were reported dead due to drought conditions. In January 2009, the three adults were still alive. During the same year in July, there were only two adults and approximately 15 seedlings. As of March 2010, a single adult and a single seedling remains, despite efforts of hand watering each individual two to three times a year in 2008, 2009, and continuing into 2010 (Oppenheimer 2010). (USFWS, 2011). New Status Information: • There are 147 individuals of *Tetramolopium remyi* in one population on Lānaʻi (Oppenheimer 2018, in litt.; PEPP 2017a, 2018). • In 2012, the Service revised critical habitat for *Tetramolopium remyi*, and the proposed rule identified two critical habitat units on Lānaʻi in the lowland dry ecosystem (10,705 ac, 4,332 ha) (77 FR 34464, July 11, 2012). In the final rule, the Service excluded critical habitat for this species on the island of Lānaʻi because, as demonstrated by the ongoing conservation activities by the private landowner, their commitment to develop the Lānaʻi Natural Resources Plan, and a memorandum of understanding with the Service, exclusion from critical habitat would provide greater long-term benefits to the species than designation of

critical habitat (USFWS 2015; 81 FR 17790, March 30, 2016). • In 2016, two critical habitat units in the lowland dry ecosystem designated on west Maui for *T. remyi* (8,479 ac; 3,431 ha) (81 FR 17790, March 30, 2016) (USFWS, 2018).

Threats and Stressors

Stressor: Trampling by deer and sheep (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Trampling by feral axis deer (*Axis axis*) and mouflon sheep (*Ovis musimon*) is a threat to the habitat of *Tetramolopium remyi*. The area where *T. remyi* occurs was severely degraded by grazing and browsing of livestock in the past. Much of the native vegetation was removed because of grazing, thus increasing wind erosion of the fragile soils and creating opportunities for invasion by introduced plant species. (USFWS, 2011)

Stressor: Introduced invasive plants (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: These introduced invasive plant species include *Vachellia farnesiana* (klu), *Acacia mearnsii* (black wattle), *Andropogon virginicus* (broomsedge), *Cenchrus ciliaris* (buffelgrass), *Chamaecrista nictitans* (partridge pea), *Conyza bonariensis* (hairy horseweed), *Grevillea robusta* (silk oak), *Lantana camara* (lantana), *Melinis minutiflora* (molasses grass), *Melinis repens* (Natal grass), *Opuntia ficus-indica* (panini), *Pennisetum setaceum* (fountain grass), *Pluchea carolinensis* (marsh fleabane), *Prosopis pallida* (kiawe), and *Urochloa maxima* (Guinea grass). (USFWS, 2011)

Stressor: Fires (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: These introduced plant species also creates a fuel load, which increases the risk of fires (Oppenheimer 2010; USFWS 1995; Wood 2010). (USFWS, 2011)

Stressor: Drought (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Drought is a serious threat to this species (Oppenheimer 2010). (USFWS, 2011)

Stressor: Climate change (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Climate change may also pose a threat to *Tetramolopium remyi*. However, current climate change analyses in the Pacific Islands lack sufficient spatial resolution to make predictions on impacts to this species. The Pacific Islands Climate Change Cooperative (PICCC) has currently

funded climate modeling that will help resolve these spatial limitations. The Service anticipates high spatial resolution climate outputs by 2013. (USFWS, 2011)

Stressor: Stochastic events (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: In addition to all of the other threats, species like *Tetramolopium remyi* that are endemic to small portions of a single island are inherently more vulnerable to extinction than widespread species because of the higher risks posed to a few populations and individuals by random demographic fluctuations and localized catastrophes such as hurricanes, landslides, flooding, and disease outbreaks. (USFWS, 2011)

Stressor: Habitat loss from human development and introduced species (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: The extent of these natural processes on this single island endemic are exacerbated by anthropogenic threats, such as habitat loss for human development or predation by introduced species (USFWS 2010). (USFWS, 2011)

Stressor: Climate change loss or degradation of habitat

Exposure:

Response:

Consequence:

Narrative: We previously reported that climate change may pose a threat to this species, anticipating an analysis by 2013. The assessment conducted by Fortini et al. (2013) concluded that *T. remyi* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.868 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). In addition, this species has no overlap between current and future climate envelopes, and is unlikely to tolerate expected changes in climate at its current location. This means that this species must persist within suitable microrefugia, or move to newly available climate-compatible areas to avoid extinction. Therefore, additional management actions are needed to conserve this taxon into the future, such as locating key microsites that overlap with current and future climate envelopes for outplanting efforts.

Recovery

Reclassification Criteria:

1. A total of five to seven populations are documented on Lanai and at least one other island where they now occur or occurred historically. (USFWS, 1994)

2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1994)

3. Each of these populations must persist at this level for at least 5 consecutive years before downlisting is considered. (USFWS, 1994)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Lanai and at least one other island where they now occur or occurred historically. (USFWS, 1994)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1994)
3. Each population should persist at this level for at least 5 consecutive years before delisting is considered. (USFWS, 1994)

Recovery Actions:

- Secure and manage current populations and their habitat. (USFWS, 1994)
- Conduct essential research to the conservation of the species. (USFWS, 1994)
- Expand current populations. (USFWS, 1994)
- Establish new populations as needed to reach recovery objectives. (USFWS, 1994)
- Validate and revise recovery objectives. (USFWS, 1994)
- Recommendations for Future Actions: We are not aware of any new threats or significant new information regarding the species' biological status since the last 5-year review in 2011. Thus, the following recommendations for future actions are reiterated for the 5-year review for 2018. • Surveys and inventories—Continue to conduct thorough surveys to determine the current status of the species and for additional populations. • Ungulate monitoring and control—Construct and maintain enclosure fencing at all occurrences to protect them from the impacts of feral ungulates. • Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around populations of *T. remyi*. • Drought and fire destruction or degradation of habitat—Develop and implement a fire management plan for any wild or reintroduced populations. • Captive propagation for genetic storage and reintroduction—
 - o Collect fruit from any wild and reintroduced individuals that set seed to add to the genetic diversity collections. Propagate seeds collected from the Halepōhaku population.
 - o Collect soil from areas of previously known individuals for germination trials.
 - o Test the viability of the seeds in storage at the National Tropical Botanical Garden and Lyon Arboretum and determine if storage methods need modification.• Reintroduction and translocation—Reintroduce individuals into suitable habitat protected from threats. • Climate change adaptation strategy—Assess the modeled effects of climate change on this species and use to determine future landscape needed for the recovery of the species. • Alliance and partnership development—Work with the Hawai'i Division of Forestry and Wildlife, the PEPP, and other land managers to initiate planning and contribute to ecosystem-level restoration and management to benefit this species (USFWS, 2018).

Conservation Measures and Best Management Practices:

- Continue monitoring and watering individual wild plants. (USFWS, 2011)

- Maintain the small fence around the last mature individual at the Mauna o Umi to prevent trampling by axis deer and mouflon sheep. (USFWS, 2011)
- Construct large-scale fences around all naturally occurring and reintroduced individuals to control feral ungulates. (USFWS, 2011)
- Collect material for genetic storage and propagation for reintroduction. (USFWS, 2011)
- Test the viability of the seeds in storage at National Tropical Botanical Garden and Lyon Arboretum and determine if storage method needs to be modified. (USFWS, 2011)
- Reintroduce into protected suitable habitat within the species historical range. (USFWS, 2011)
- Collect fruit from any reintroduced individuals that set seed to add to the genetic diversity of the ex situ material. (USFWS, 2011)
- Control introduced invasive plant species around all populations. (USFWS, 2011)
- Conduct surveys to determine the current status of the species and for additional populations. (USFWS, 2011)
- Develop and implement a wildfire management plan. (USFWS, 2011)
- Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species. (USFWS, 2011)
- Work with Hawaii Division of Forestry and Wildlife, Plant Extinction Prevention Program, and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species. (USFWS, 2011)
- New Management Actions: • Surveys and inventories—The Plant Extinction Prevention Program (PEPP) surveys for new populations and monitors the known population of *Tetramolopium remyi* on Lānaʻi (PEPP 2010, 2011, 2012, 2013, 2016, 2017b, 2018). Soil samples are tested for a possible seed bank. • Ungulate monitoring and control—The only known population of *T. remyi* may be provided protection by construction of fencing by Pūlama Lānaʻi planned to begin in 2017 (Donoho 2016, in litt.; USFWS 2015). • Invasive plant monitoring and control—PEPP monitors the known population of *T. remyi* (2010, 2011, 2012, 2013, 2016, 2017a, 2018). • Captive propagation for genetic storage and reintroduction— o The Lyon Arboretum Seed Conservation Laboratory reported 281 seeds in storage from the ʻĀwehi population in 2012; 30,349 seeds in storage in 2016; and 17,279 seeds in storage in 2018, for a total of over 50,000 seeds likely representing over a dozen founders (Lyon Arboretum 2018). o The Olinda Rare Plant Facility (ORPF) reported four plants in propagation representing three individuals from ʻĀwehi (ORPF 2013, 2014, 2017). o The National Tropical Botanical Garden (NTBG) has seeds from five different collections from ʻĀwehi, but these collections are old (from 2001-2006) and it is uncertain how many individuals are represented and how many viable seeds remain (NTBG 2018).

Species Taxonomic and Listing Information

Listing Status: Threatened; 10/08/1992; Pacific Region (R1) (USFWS, 2017)

Physical Description

Tetramolopium rockii, a member of the aster family, is a glandular, hairy, prostrate shrub, which forms complexly branching mats 5 to 10 cm (2 to 4 in) tall and 8 to 40 cm (3 to 16 in) in diameter. Leaves of variety *calcisabulorum* are 2 to 3 cm (0.8 to 1.2 in) long and 5 to 7 mm (0.2 to 0.3 in) wide, have slightly inrolled edges, and are whitish due to the long silky hairs on their surfaces. Variety *rockii* has smaller, less hairy, flat, yellowish-green leaves, 1.5 to 2.1 cm (0.6 to 0.8 in) long and about 0.4 to 0.6 cm (0.2 in) wide. The leaves of both varieties are spatula shaped with glands and smooth margins. Flowerheads, arranged singly at the ends of flowering stalks 4 to 12 cm (1.6 to 4.7 in) long, have a hemispherical involucre 4 to 8 mm (0.2 to 0.3 in) high and 10 to 18 mm (0.4 to 0.7 in) in diameter. Approximately 60 to 100 white ray florets, 3 to 4.5 mm (0.1 to 0.2 in) long and 0.5 to 1 mm (0.02 to 0.04 in) wide, surround 30 to 55 functionally male, yellow, funnel-shaped disk florets. Fruits are achenes, 2 to 2.5 mm (0.08 to 0.1 in) long and about 0.7 to 0.9 mm (0.03 in) wide when fertile, and are topped with white bristles 2.5 to 4 mm (0.1 to 0.2 in) long. This species differs from others of the genus by its growth habit, its hairy and glandular surfaces, its spatulate leaf shape, and its yellow disk florets (USFWS 1992). (USFWS, 1996)

Taxonomy

A member of the sunflower family (Asteraceae) (USFWS, 2016). St. John (1974) described a new genus, *Luteidiscus*, for the species of *Tetramolopium* with yellow disk flowers. He transferred *T. rockii* to the new genus and also described a new species, *L. calcisabulorum*. The current treatment reduces St. John's two species to varieties of *Tetramolopium rockii*: the nominative variety and var. *calcisabulorum* (USFWS 1992). (USFWS, 1996)

Historical Range

Tetramolopium rockii var. *rockii* was first discovered on West Molokai at Moomomi about 80 years ago. (USFWS, 2011)

Current Range

Tetramolopium rockii var. *rockii* remains in two areas: from Kapalauoa to Kahinaakalani on West Molokai, and north of Kalawao on Kalaupapa Peninsula on East Molokai. (USFWS, 1996)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Tetramolopium rockii* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes seven detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Tetramolopium rockii* includes seven CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Molokai—Coastal—Unit 1 consists of 70 ac (28 ha) of privately owned land, and 54 ac (22 ha) of federally owned land (U.S. Coast Guard) at Laau Point, from Kahaiawa to Keawakalani, along the western coast of Molokai. This unit is occupied by the plant *Marsilea villosa*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 1 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 2 consists of 263 ac (106 ha) of State land, and 710 ac (287 ha) of privately owned land, from Ilio Point to Kaa Gulch, along the northwestern coast of Molokai. This unit is occupied by the plant *Marsilea villosa* and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 2 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 3 consists of 794 ac (321 ha) of State land, and 3 ac (1 ha) of federally owned land (Kalaupapa National Historical Park), from Kahi Point to Wainene, along the north-central coast of Molokai. This unit is occupied by the plants *Pittosporum halophilum*, *Schenkia sebaeoides*, and *Tetramolopium rockii*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 3 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Marsilea villosa*, *Peucedanum sandwicense*, or *Sesbania tomentosa*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small

numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 4 consists of 10 ac (4 ha) on Mokapu Island on the northern coast of Molokai. This area is State-owned, and is classified as a State Seabird Sanctuary. This unit is occupied by the plants *Peucedanum sandwicense* and *Pittosporum halophilum*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 4 is not known to be occupied by *Bidens wiebkii*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Marsilea villosa*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 5 consists of 1 ac (0.5 ha) on Huelo islet on the northern coast of Molokai. This area is State-owned, and is classified as a State Seabird Sanctuary. This unit is occupied by the plants *Brighamia rockii*, *Peucedanum sandwicense*, and *Pittosporum halophilum*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 5 is not known to be occupied by *Bidens wiebkii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Marsilea villosa*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 6 consists of 190 ac (77 ha) of State land, and 1,685 ac (682 ha) of privately owned land, from Kaholaiki Bay to Halawa Bay, on the northeastern coast of Molokai. This unit is occupied by the plants *Bidens wiebkii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, and *Ischaemum byrone*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 6 is not known to be occupied by *Brighamia rockii*, *Hibiscus brackenridgei*, *Marsilea villosa*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low

population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 7 consists of 49 ac (20 ha) of privately owned land from Alanuihipaka Ridge to Kalanikaula, on the northeastern coast of Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). Although Molokai—Coastal—Unit 7 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrnei*, *Marsilea villosa*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Tetramolopium rockii* critical habitat consists of one component. Coastal (Molokai) (81 FR 17790-18110):

Ecosystem: Coastal. Elevation: <980 ft (<300 m). Annual precipitation: <20 in (<50 cm). Substrate: Well-drained, calcareous, talus slopes; dunes; weathered clay soils; ephemeral pools; mudflats. Canopy: *Hibiscus*, *Myoporum*, *Santalum*, *Scaevola*. Subcanopy: *Gossypium*, *Sida*, *Vitex*. Understory: *Eragrostis*, *Jacquemontia*, *Lyceum*, *Nama*, *Sesuvium*, *Sporobolus*, *Vigna*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be

currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mcelandowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium*

molokaiense, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Not available.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Shrubland/chaparral (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Coastal ecosystem (USFWS, 2016)

Geographic or Habitat Restraints or Barriers

Adult: Found between 10 to 200 meters (30 and 650 feet) in elevation (USFWS, 1996)

Environmental Specificity

Adult: Medium, with some key requirements (USFWS, 1996)

Habitat Narrative

Adult: Inhabits dry coastal shrubland on solidified calcareous sand dunes (NatureServe, 2015). *Tetramolopium rockii* is restricted to hardened calcareous sand dunes or ash-covered basalt in the coastal spray zone or Coastal Dry Shrublands and Grasslands between 10 to 200 meters (30 and 650 feet) in elevation. Associated native species such as *Boerhavia repens* (alena), *Cassytha filiformis* (kaunaoa pehu), *Chenopodium oahuense* (aheahea), *Cuscuta sandwichiana* (kaunaoa), *Euphorbia degeneri* (akoko), *Euphorbia skottsbergii* var. *skottsbergii* (akoko), *Heliotropium anomalum* var. *argenteum* (hinahina-ku-kahakai), *Ipomoea indica* (koali awa), *Ipomoea pes-caprae* subsp. *brasiliensis* (pohuehue), *Jacquemontia ovalifolia* subsp. *sandwicensis* (pau-o-Hiiaka), *Melanthera integrifolia* (nehe), *Scaevola taccada* (naupaka), *Sesbania tomentosa* (ohai), *Sesuvium portulacastrum* (akulikuli), and *Waltheria indica* (uhaloa) with various lichens including *Buellia* sp. and *Caloplaca* sp. and grasses and sedges including *Fimbristylis cymosa* (mauu aki aki), *Panicum torridum* (kakonakona), and *Sporobolus virginicus* (aki aki) (Canfield 1990; Perlman 2010; Tangalin 2009). (USFWS, 1996; USFWS, 2011) Occurrences are in the coastal ecosystem (USFWS, 2016).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends

Population Trends:

Stable (USFWS, 2016)

Resiliency:

Medium (NatureServe, 2015)

Redundancy:

Low (inferred from USFWS, 2015)

Number of Populations:

4 (USFWS, 2016)

Population Size:

~94,000 (NatureServe, 2015)

Population Narrative:

In 2003, *T. rockii* was known from four occurrences totaling thousands of individuals (68 FR 12982, March 18, 2003). *Tetramolopium rockii* var. *calcisabulorum* was reported from Kaiehu Point to Kapalauoa, intergrading with var. *rockii*. *Tetramolopium rockii* var. *rockii* occurred from Kalawao to Kahinaakalani, Kaiehu point to Kapalauoa, and Moomomi to Kahinaakalani. Currently, numbers fluctuate considerably from year to year but remain in the thousands (USFWS, 2016). Approximately 94,000 plants known. There are 3 current (between 1982 and 1997) and no historical occurrences. (NatureServe, 2015). New Status Information: • There are at least 10,000 individuals of *Tetramolopium rockii* var. *rockii*, and 2,000 of variety *calcisabulorum* along the northwest coast of Moloka'i from Ka'a Gulch to Kahina'akalani, and from 'Ālau to Makali'i in the Kalaupapa National Historical Park. Numbers vary widely depending on rainfall (Bakutis 2018a, in litt.; Bakutis 2018b, in litt.; Haase 2018, in litt.; National Park Service (NPS) 2015). • In 2016, the IUCN reported extreme fluctuations in population size for both varieties (Chau 2016). • In 2016, seven critical habitat units in the coastal ecosystem designated on Moloka'i for *T. rockii* (4,222 ac; 1,549 ha) (81 FR 17790, March 30, 2016) (USFWS, 2018).

Threats and Stressors

Stressor: Trampling by deer (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Feral deer (*Axis axis*) trample native plants including *Tetramolopium rockii* var. *calcisabulorum* at Moomomi Preserve (Ed Misaki, The Nature Conservancy Hawaii, pers. comm. 2010). Deer are also a threat to *Tetramolopium rockii* var. *rockii* wherever the species is not protected by fenced exclosures at Kalaupapa (G. Hughes, pers. comm. 2010). (USFWS, 2011)

Stressor: Invasive introduced plants (USFWS, 2011)

Exposure:**Response:****Consequence:**

Narrative: Invasive introduced plant species modify the habitat and compete for resources with both varieties of the species. These invasive plants include *Atriplex semibaccata* (Australian saltbush), *Cenchrus ciliaris* (buffelgrass), *Chenopodium murale* (lamb's quarters), *Cynodon dactylon* (Bermuda grass), *Dactyloctenium aegyptium* (beach wiregrass), *Digitaria ciliaris* (Henry's crabgrass), *Lantana camara* (lantana), *Leucaena leucocephala* (haole koa), *Urochloa maximum* (Guinea grass), *Melinis repens* (Natal redtop), *Prosopis pallida* (kiawe), *Setaria parviflora* (perennial foxtail), and *Sporobolus indicus* (smutgrass). *Lantana camara* grows in dense patches. *Prosopis pallida* forms dense thickets in this coastal zone. Weedy grasses can also out-compete *Tetramolopium rockii* (Canfield 1990; Perlman 2010; Tangalin 2009). The introduced invasive plant species are a threat to *Tetramolopium rockii* because they compete with the species for water, light, and nutrients. (USFWS, 2011)

Stressor: Browsing by deer, rats, goats, and cattle (USFWS, 2011)

Exposure:**Response:****Consequence:**

Narrative: Deer, rats (*Rattus* spp.), and feral goats (*Capra hircus*) are considered threats at Moomomi, and deer are considered a threat at Kalaupapa (Perlman 2010; E. Misaki, pers. comm. 2010). Although deer have not been observed to directly browse on this species, however deer do browse on other native plants at Moomomi, including the endangered *Sesbania tomentosa*, and trample all native plants (E. Misaki, pers. comm. 2010). Cattle (*Bos taurus*) browsing was reported to be a threat to *Tetramolopium rockii* in 1991 (Wood 2010) but cattle have since been removed from Moomomi Preserve (E. Misaki, pers. comm. 2010). (USFWS, 2011)

Stressor: Climate change (USFWS, 2011)

Exposure:**Response:****Consequence:**

Narrative: Climate change may also pose a threat to this species. However, current climate change analyses in the Pacific Islands lack sufficient spatial resolution to make predictions on impacts to this species. The Pacific Islands Climate Change Cooperative has currently funded climate modeling that will help resolve these spatial limitations. The Service anticipates high spatial resolution climate outputs by 2013. (USFWS, 2011)

Stressor: Climate change loss or degradation of habitat

Exposure:**Response:****Consequence:**

Narrative: We previously reported that climate change may pose a threat to this species, anticipating an analysis by 2013. The assessment conducted by Fortini et al. (2013) concluded that *Tetramolopium rockii* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.893 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). In addition, this species has no overlap between current and future climate envelopes, and is unlikely to tolerate expected changes in climate at its current location. This means that this species must persist within suitable microrefugia, or move to newly available

climate-compatible areas to avoid extinction. Therefore, additional management actions are needed to conserve this taxon into the future, such as locating key microsites that overlap with current and future climate envelopes for outplanting efforts (USFWS, 2018).

Stressor: Hybridization

Exposure:

Response:

Consequence:

Narrative: This species may hybridize in a narrow zone of contact along the dunes (Lowrey in Wagner et al. 1999).

Recovery

Reclassification Criteria:

1. A total of five to seven populations of each taxon should be documented on Molokai and at least one other island where they now occur or occurred historically. (USFWS, 1996)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1996)
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered. (USFWS, 1996)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Molokai and at least 1 other island where they now occur or occurred historically. (USFWS, 1996)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1996)
3. Each population should persist at this level for a minimum of 5 consecutive years. (USFWS, 1996)

Recovery Actions:

- The highest priority for the recovery of the Molokai plant cluster taxa is the implementation of immediate recovery actions needed to keep “on-the-brink” species (those that number fewer than 100 individuals in the wild) from going extinct. These actions include propagation and maintenance of genetic stock ex situ, and protection of remaining wild individuals from threats. (USFWS, 1996)
- Secondly, the plan proposes the delineation of management units to conserve not only these taxa, but their habitats as well. These units should be managed to preserve as many native species (flora and fauna) as possible, through threat-control and forest-restoration programs. (USFWS, 1996)

- The next step in the recovery of these species is augmentation of small populations and re-establishment of new populations within the historical range of the species. This includes selection of areas for augmentation and reestablishment, determination of the best methods for ex situ propagation and transplanting, selection of the best genetic stock for each area, propagation of suitable stock, preparation of sites for seeding and/or transplanting, and monitoring and maintenance of new individuals and populations as they are established. (USFWS, 1996)
- A research program is also recommended to study the growth and reproductive viability of each taxon, determine the parameters of viable populations of each taxon, study the reproductive strategy and pollinators of each taxon, and study possible pests and diseases. (USFWS, 1996)
- Finally, the recovery criteria should be refined and revised as new information becomes available. (USFWS, 1996)
- Recommendations for Future Actions: Hybridization is reported as a possible threat to these varieties; however, we are not aware of any significant new information regarding the species' biological status since the last 5-year review in 2011. Thus, the following recommendations for future actions are added or reiterated for the 5-year review for 2018.
 - Surveys and inventories—Continue to monitor populations using the baseline survey to track how the populations change over time.
 - Ungulate monitoring and control—Remove feral ungulates from within existing large-scale fences surrounding naturally occurring individuals.
 - Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around populations of *T. rockii*.
 - Captive propagation for genetic storage and reintroduction—
 - o Collect material for genetic storage and propagation for reintroduction.
 - o Propagate for augmentation of existing populations if needed.
 - Reintroduction and translocation—
 - o Reintroduce individuals into suitable habitat protected from threats.
 - o Research weather conditions and possible conservation actions most favorable for natural regeneration in the wild.
 - o Research effects of possible hybridization between the two varieties.
 - Climate change adaptation strategy—Assess the modeled effects of climate change on this species and use to determine future landscape needed for the recovery of the species.
 - Alliance and partnership development—Work with land managers to initiate planning and contribute to ecosystem-level restoration and management to benefit this species (USFWS, 2018).

Conservation Measures and Best Management Practices:

- Collect material for genetic storage and propagation for reintroduction. (USFWS, 2011)
- Propagate for augmentation of existing populations if needed. (USFWS, 2011)
- Research weather conditions and possible conservation actions most favorable for natural regeneration in the wild. (USFWS, 2011)
- Establish a baseline survey to determine the current population census of the species and track, if and how, the populations are changing over time. (USFWS, 2011)
- Control introduced invasive plant species around wild plants. (USFWS, 2011)
- Control rats in the vicinity of these populations. (USFWS, 2011)
- Remove feral ungulates from within existing large-scale fences surrounding naturally occurring individuals. (USFWS, 2011)
- Conduct taxonomic study to determine if this is a valid species. (USFWS, 2011)
- Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species. (USFWS, 2011)

- New Management Actions: • Surveys and inventories—PEPP (Plant Extinction Prevention Program) and The Nature Conservancy (TNC) conducted recent surveys to determine the approximate range and numbers of individuals of both varieties of *Tetramolopium rockii* (Bakutis 2018b, in litt.). • Ungulate monitoring and control— o A portion of the known population at Mo'omomi Preserve area is within the fence; however, axis deer are still present within the fenced area (TNC 2018; Bakutis 2018, in litt.). o Individuals are within a fence in the Kalaupapa National Historical Park (NHP) (NPS 2015). • Invasive plant monitoring and control—Both the Mo'omomi Preserve and Kalaupapa NHP are monitored with nonnative plant removal (NPS 2015; TNC 2018). • Captive propagation for genetic storage and reintroduction— o Kalaupapa NHP reported thousands of seeds in storage (Kalaupapa NHP 2014). o The National Tropical Botanical Garden (NTBG) reported 2,000 seeds collected from Mo'omomi in 1990; 100 seeds collected from plants east of Mo'omomi in 2009, and 250 seeds collected from plants along the coastal strand of Kalaupapa peninsula in 2001 (NTBG 2017). • Stochastic events—Build resiliency and redundancy— o Currently, no individuals will be reintroduced in Mo'omomi Preserve until all axis deer are removed from the fenced area (TNC 2018). o Mokio Land Trust plans to outplant *Tetramolopium rockii* into the Mokio management area in the near future (Haase 2018, in litt.). o Kalaupapa NHP reported reintroduction of five individuals and dispersal of seeds at five locations in 2014.

SPECIES ACCOUNT: *Thalictrum cooleyi* (Cooley's meadowrue)

Species Taxonomic and Listing Information

Listing Status: Endangered; 02/07/1989; Southeast Region (R4) (USFWS, 2017)

Physical Description

A small, rhizomatous, perennial herb with erect to lax stems, up to 1 m tall. Loose clusters of flowers are borne in June. The unisexual flowers lack petals, but the sepals are white, pale yellow, or pale green with lavender filaments. The leaves are narrow and lance-shaped. The fruits are single-seeded and winged. Phenology: Flowers appear mid to late June and fruit mature in August or September (NatureServe, 2015).

Taxonomy

Thalictrum cooleyi is distinguished from other such members of the genus, *Thalictrum revolutum* in particular, by the combination of leaflet narrowness (4 to 26 times as long as wide), lack of lobing in the majority of the leaflets, and absence of hairs, glands, or papillae on lower leaflet surfaces, petioles, peduncles, and achenes (Park 1992) (USFWS, 1994).

Historical Range

Three historic North Carolina populations--Brunswick, Columbus, and Pender Counties--are assumed extirpated, because recent surveys showed habitat destruction at the sites and no plants were found (North Carolina Natural Heritage Program 1992). Cooley's meadowrue has been reported from New Hanover County, North Carolina (Radford et al. 1968), but without documentation (USFWS, 1994).

Current Range

All of the known *Thalictrum cooleyi* populations occur in the Coastal Plain Province in NC, GA, and FL (USFWS, 2009).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual, wind- and insect-pollinated (NatureServe, 2015)

Breeding Season

Adult: Flowering in June (Radford et al, 1968) (NatureServe, 2015)

Reproduction Narrative

Adult: Flowering in June (Radford et al, 1968). The winged, single-seeded fruits mature in August and September (Lowe et al. 1990), but the seed life is presumably short. A dioecious species, *Thalictrum cooleyi* has separate male and female flowers that are wind- and insect-pollinated (NatureServe, 2015).

Habitat Type

Adult: Pine Savanna (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Wetlands/intermittent fire (NatureServe, 2015; USFWS, 1994); soil pH 5.8-6.6 (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Clumped (Inferred from NatureServe, 2015 and USFWS, 1994)

Environmental Specificity

Adult: Narrow/specialist (NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: Low (Inferred from NatureServe, 2015 and USFWS, 1994)

Site Fidelity

Adult: High (NatureServe, 2015)

Habitat Narrative

Adult: Sunny, moist places such as open, savanna-like forest edges and clearings, wet savannas over calcareous clays, and ecotones between wet savannas and non-riverine swamp forests. Soils are basic, sandy loams. Also on roadsides and power line rights-of-way in former savannas. It grows on circumneutral soils in wet pine savannas, grass-sedge bogs, and savanna-like areas, often at the border of intermittent drainages or swamp forests. Boggy savannah-like borders of low woodlands, roadside ditches, and power line rights-of-way. Usually associates with some type of disturbance, e.g., clearings, the edges of frequently burned savannas, power line right-of ways which are maintained either by fire or mowing, and roadside edges. Typically on Grifton soil. This plant is found on fine sandy loams that are at least seasonally (winter) moist or saturated and are only slightly acidic (pH 5.8-6.6). Sufficient moisture is critical to plant vigor and reproductive effort. This plant occupies a narrow hydrological niche, where soil is moist to saturated but water does not stand above the soil surface. This species occurs in moist to wet bogs and savannas and savanna-like openings on circumneutral soils and is dependent upon some form of disturbance to maintain the open quality of its habitat. Currently, artificial disturbances, such as power line and road right-of-way maintenance, and plowed firebreaks, are maintaining some of the openings historically provided by naturally occurring periodic fires (Murdock 1989). This species grows in circumneutral soil in moist to wet savannas and savanna-like areas kept open by frequent fire or other disturbance. "This borderline type of habitat would have been disturbed historically by naturally occurring savanna fires moving through at 1- to 5-year intervals, clearing litter from the soil surface and causing the cyclical advance and retreat of woody growth. A typical population of Cooley's meadowrue has robust reproductive plants among shrubs and in adjacent open savanna and repressed individuals in nearby dense shade" (Boyer 1994) (NatureServe, 2015; USFWS, 1994). Low tolerance range and clumped spatial arrangement are inferred based on the specific habitat needs of this species and the relatively low number of populations (NatureServe, 2015; USFWS, 1994).

Dispersal/Migration

Motility/Mobility

Adult: Low (USFWS, 1994)

Dispersal/Migration Narrative

Adult: Possibly propagate by breaking off and dispersal of vegetative parts in aquatic habitat (USFWS, 1994).

Population Information and Trends**Population Trends:**

Decreasing (NatureServe, 2015)

Species Trends:

Stable (USFWS, 2009)

Resiliency:

Moderate (inferred from USFWS, 2009)

Representation:

Low (inferred from NatureServe, 2015)

Redundancy:

Moderate (inferred from USFWS, 2009)

Number of Populations:

12 (USFWS, 2009)

Population Size:

1 - 1000 total individuals (NatureServe, 2015)

Population Narrative:

Thalictrum cooleyi is intrinsically vulnerable in several ways. It is rhizomatous, so the number of ramets is far greater than the number of genets. It is dioecious, so the populations where only one sex persists are particularly vulnerable. It produces few seeds and apparently does not have a seed dispersal mechanism (USFWS 1989). (NatureServe, 2015) The total number of individuals is estimated at between 1 and 1000 and the number of populations between 6 and 20. In addition, the short-term population trend indicates a decline of 10-30% (NatureServe, 2015). Low representation, resiliency and redundancy are inferred based on species specific habitat needs, low number of populations and fragmentation of suitable habitat (NatureServe, 2015). In the 2008 Recovery Data Call, the status of *Thalictrum cooleyi* was listed as stable. Between 2005 and 2007, NCNHP staff or other knowledgeable botanists have visited 12 of 25 North Carolina subpopulations (representing 10 populations) of *Thalictrum cooleyi*. As of 2008, there were 9 extant populations in NC; 2 in GA; and 1 in FL (USFWS, 2009).

Threats and Stressors

Stressor: Agriculture (USFWS, 1994)

Not available

Delisting Criteria:

Cooley's meadowrue (*Thalictrum cooleyi*) will be considered for delisting when there are at least 16 self-sustaining, geographically distinct populations in existence that are protected to such a degree that the species no longer qualifies for protection under the Endangered Species Act (see criteria below). A self-sustaining population is a reproducing population that is large enough to maintain sufficient genetic variation to enable it to survive and respond to natural habitat changes. The number of individuals necessary and the quantity and quality of habitat needed to meet this criterion will be determined as one of the recovery tasks (USFWS, 1994).

Recovery Actions:

- Protect existing populations and essential habitat. Develop interim research and management plans in conjunction with landowners and managers. Search for additional populations and potential habitat. Rank populations for focus of protection efforts. Evaluate habitat protection alternatives (USFWS, 1994).
- Determine and implement management necessary for long-term reproduction, establishment, maintenance, and vigor. Determine population size, stage-class distribution and sex ratios for all populations. Study abiotic and biotic features of the species' habitat. Conduct long-term demographic studies. Determine the effects of past and ongoing habitat disturbance. Define criteria for self-sustaining populations and develop appropriate habitat management guidelines based upon the data obtained from Tasks 2.2 through 2.4. Implement appropriate management techniques as they are developed from previous tasks. Develop techniques and reestablish populations in suitable habitat within the species' historic range (USFWS, 1994).
- Maintain and expand cultivated sources for the species and provide for long-term maintenance of selected populations in cultivation (USFWS, 1994).

Conservation Measures and Best Management Practices:

- Revisit known populations that have not been visited in the past three years; monitor the habitat condition of each site including threats; discuss conservation options with landowners where appropriate; update Natural Heritage Program files with this information (USFWS, 2009).
- Search for additional populations (USFWS, 2009).
- Prioritize known sites for protection (USFWS, 2009).
- Protect additional populations (USFWS, 2009).
- Develop management plans for all protected populations (USFWS, 2009).
- Develop monitoring protocols, initiate long term population monitoring and determine the criteria for sustaining populations (USFWS, 2009).
- Conduct research on general biology of the species including life history and reproductive biology (breeding systems, seed production and seedling survivorship) (USFWS, 2009).
- Compare, genetically, the populations of questionable taxonomy in Georgia with those known from North Carolina and Florida (USFWS, 2009).
- Work with North Carolina Botanical Garden to conserve seeds and develop propagation protocols (USFWS, 2009).

SPECIES ACCOUNT: *Thelypodium howellii spectabilis* (Howell's spectacular thelypody)

Species Taxonomic and Listing Information

Listing Status: Threatened; Pacific Region (R1) (USFWS, 2016)

Physical Description

Howell's spectacular thelypody is an herbaceous biennial that reaches approximately 60 cm (24 inches) tall, with branches arising from near the base of the stem. The basal leaves are approximately 5 cm (2 inches) long with wavy edges and are arranged in a rosette. Stem leaves are shorter, narrow, and have smooth edges. It is a root forming plant and is pollinated by insects. Flowers appear in loose spikes at the ends of the stems. Flowers have four purple petals approximately 1.9 cm (0.75 inches) in length, each of which is borne on a short stalk. Fruits are long, slender pods (Kagan 1986). The plant begins actively growing in April, flowers in May, fruits in June and goes dormant in August (USFWS, 2016).

Current Range

Endemic to the northeastern corner of Oregon, occurring in the Baker-Powder River valley in Baker and Union Counties (Fish and Wildlife Service 1999). Generalized current range of about 175 sq. km.

Critical Habitat Designated

Yes;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Insect pollinated (USFWS, 2016)

Breeding Season

Adult: Flowers in May (USFWS, 2016)

Reproduction Narrative

Adult: It is a root forming plant and is pollinated by insects. Flowers appear in loose spikes at the ends of the stems. Flowers have four purple petals approximately 1.9 cm (0.75 inches) in length, each of which is borne on a short stalk. Fruits are long, slender pods (Kagan 1986). The plant begins actively growing in April, flowers in May, fruits in June and goes dormant in August (USFWS, 2016).

Habitat Type

Adult: Wet alkaline meadows (USFWS, 2016)

Habitat Narrative

Adult: The thelypody occurs in wet alkaline meadows in valley bottoms, usually in and around woody shrubs that dominate the habitat on the knolls and along the edge of the wet meadow habitat between the knolls. Soils are pluvial-deposited alkaline clays mixed with recent alluvial silts, and are moderately well-drained (Kagan 1986). Associated species include *Sarcobatus vermiculatus* (greasewood), *Distichlis stricta* (alkali saltgrass), *Elymus cinereus* (giant wild rye), *Spartina gracilis* (alkali cordgrass), and *Poa juncifolia* (alkali bluegrass) (Kagan 1986). The thelypody may be dependent on periodic flooding since it appears to rapidly colonize areas adjacent to streams that have flooded (Kagan 1986). Abundance fluctuates widely from year to year in response to annual climate and soil moisture (USFWS 2010, p. 4). Thelopody is readily consumed by cows. Thus, thelopody is typically only found under shrubs in areas that are intensively grazed during the growing season (USFWS 2010). In addition, this taxon does not compete well with encroaching weedy vegetation such as *Dipsacus fullonum* (teasel) (Davis and Youtie 1995) (USFWS, 2016).

Dispersal/Migration

Population Information and Trends

Population Trends:

Unknown (USFWS, 2016)

Number of Populations:

~16 (USFWS, 2016)

Population Size:

10,000 - 100,000 individuals (USFWS, 2016)

Population Narrative:

This taxon was thought to be extinct until rediscovered by Kagan in 1980 near North Powder (Kagan 1986a). The Recovery Plan identifies 11 different occurrences that are grouped into five separate “populations” The labeling of these geographically-clustered occurrences as “populations” is a loose application of the term, since we do not know the extent of genetic interchange among occurrences. The 2008 update of the Oregon Natural Heritage Information Center’s (ORNHC) database documents 15 Howell’s thelypody occurrences (USFWS 2010). The known occurrences vary substantially in size and plant abundance. Some are small patches just several hundred square feet in size, while others extend over 10 to 20 acres. One additional population has been established since the subspecies was listed. Staff from ODA’s Native Plant Conservation Program translocated thelypody plants to three locations near Baldock Slough on a property that has a permanent conservation easement through the Wetland Reserve Program (Currin et al.2008). All of the known thelypody occurrences are on private land and many are not accessible for monitoring. Since Federal listing in 1999, population monitoring efforts have focused on three sites where there are mechanisms in place that allow for thelypody monitoring: 1) the Haines Rodeo Grounds site, 2) the Miles Ranch Easement, and 3) the Baldock Slough introduction site (USFWS 2010). At all of the monitored sites, the number of flowering plants tends to vary widely from year-to-year. The amount of early spring precipitation appears to be an important driver of annual abundance, with high precipitation levels correlated with increased plant abundance. The biennial habit of thelypody also appears to play a role, with spikes in abundance tending to occur every two years (J. Stephenson, USFWS, pers. comm.,

2015). In one ½-acre plot at the Haines Rodeo Grounds that was intensively monitored from 2008 to 2010, thelypody abundance fluctuated from 3,011 plants in 2008 to 25,600 plants in 2009, and back down to 3,135 plants in 2010 (EcoWest Consulting 2011). As this is a protected site, no livestock grazing or other land use activities occur that might negatively affect plant development. The inherent year-to-year variability in plant numbers make it difficult to assess long-term population trends, particularly since quantitative surveys are not conducted every year (J. . Stephenson, USFWS, pers. comm., 2015). During good years, the Haines Rodeo Grounds population is quite large (> 50,000 plants in 2009), however few plants were found during qualitative surveys in June 2014 leading to concerns that this population is declining. There is concern that the spread of invasive weeds, particularly cheatgrass, is outcompeting thelypody in this area. There is less quantitative survey data for the Miles Ranch Easement, but it is also a large population in good years (> 35,000 plants in 2009). The Baldock Slough introduced population contained approximately 400 plants in 2009, distributed in 7 small areas. By 2013, plants were found at only 3 of the 7 areas, and a survey in June 2014 tallied only 20 plants in those 3 remaining areas (D. Trochlell, Natural Resource Conservation Service, pers. comm. 2014). The other known thelypody locations are all located on private lands have either very limited or no access to the occupied sites (USFWS 2010). Where occurrences are visible from public roads, occasional presence/absence surveys have been done in June/early July (when flowering plants are highly visible) to document that the occurrence is still extant, while the less visible sites have not been observed in many years. Much uncertainty remains given the inability to access and monitor the majority of populations on private lands that have no special management protections. However, the overall status of thelypody has improved since listing because additional populations have been found and 3 populations have some protections in place for thelypody. The protection of these sites and some modest progress in developing compatible livestock grazing management practices have moved these subspecies further away from the threat of extinction (USFWS 2010) (USFWS, 2016). Surveys 0 Additional population information was collected in 201 1 (Oregon Department of Transportation 2013), where State highway crews documented approximately 35 plants growing on the side of Highway 84. This population had been documented previously in 2009, 1997 and 1996, is within the previously described range, and is located 0.15 miles from another population. 0 USDA-NRCS conducted a survey of seven sites on June 25, 2014. In four of the . seven experimental sites where the Oregon Department of Agriculture Native Plant Conservation Program had conducted transplants in 2002 and 2007, no *T. howellii* ssp. *spectabilis* were found. USDA-NRCS attributed this decline to a competition from nonnative species including intermediate wheatgrass (*Thinopyrum intermedium*) and whitetop (*Cardaria draba*), which were thought to be outcompeting *T. howellii* ssp. *spectabilis* (U.S. Department of Agriculture- Natural Resource Conservation Service 2014) (USFWS, 2018). Research 0 In 2014, EcoWest Consulting Inc. and the USFWS finished an experiment titled “The influence of Population Dynamics, Grazing, and Precipitation Patterns on the Restoration of a Threatened Riparian Mustard to Former Habitat” (2014). *Thelypodium howellii* ssp. *spectabilis* was the subject of this Before/After Control/Impact (BACI) design study, which began in 2008 and concluded in 2014. The results of the study were largely inconclusive due to the life history and moisture and soil sensitivity of *T. howellii* ssp. *spectabilis*, which resulted in highly variable results. However, the researchers suggest that changes in grazing practice to late season grazing after post-seed dispersal may allow these plants to expand into other areas (USFWS, 2018).

Threats and Stressors

Stressor: Development (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Habitat loss due to urban and agricultural development is listed as a threat to this species (USFWS, 2016).

Stressor: Habitat degradation (USFWS, 2016)

Exposure:

Response:

Consequence: Habitat loss/habitat degradation

Narrative: Habitat degradation due to livestock grazing and hydrological modification is listed as a threat to this species (USFWS, 2016).

Stressor: Grazing (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Consumption by livestock is listed as a threat to this species (USFWS, 2016).

Stressor: Herbicides (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Use of herbicides or mowing during the growing season is listed as a threat to this species (USFWS, 2016).

Stressor: Competition (USFWS, 2016)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Competition with exotic species such as teasel (*Dipsacus fullonum*), bull thistle (*Cirsium vulgare*), Canada thistle (*C. canadensis*), and yellow sweet clover (*Melilotus officinalis*) is listed as a threat to this species (USFWS, 2016).

Recovery

Delisting Criteria:

The thelpody recovery plan calls for the protection of five self-sustaining thelpody populations throughout its extant and historic range. Each of the five populations should have management plans providing for the plant's long-term protection and have stable or increasing trends for 10 years. Currently, three populations of thelpody receive some level of protection from development and are managed for conservation (USFWS 2010). The Haines Rodeo Grounds is a purchased mitigation site specifically for thelpody conservation, and has a completed management plan for this species. The other two sites (the Miles Ranch Easement and the Baldock Slough introduction site) are easements managed for wetlands protection. While the Baldock slough will remain protected in the Wetland Reserve Program, it is not clear if the reintroduced population will become self-sustaining. In addition, there are also three small

roadside populations managed by ODOT under a State Management Area. In the past, there were two populations on private lands near North Powder that were managed via conservation easements: the BLM has managed a population for several years until about 2006, and the TNC managed another population for 15 years. At this time there are no agreements for the management of these two populations and their status is unknown (USFWS, 2016).

Recovery Actions:

- Landowner Outreach — Work with local officials in Baker and Union counties to develop a Thelypody Conservation Proposal that includes participation incentives that would then be taken to landowners in thelypody habitat for their consideration. Such a proposal would likely include provisions for establishment of pastures with special management elements for thelypody conservation (e.g., rest or reduced grazing during the growing season) (USFWS, 2018).
- Grazing Research — Continue controlled studies to determine the response of thelypody to livestock grazing outside the plant's primary growing season, as well as the potential to use grazing as a tool to control competing vegetation (USFWS, 2018).
- Manage Haines Rodeo Grounds Site — Work with the Baker County Road Department to reinstate implementation of the management plan for this site. Of particular concern at this site is control of competing vegetation in thelypody-occupied areas (USFWS, 2018).
- Management Plan for Miles Easement — Finalize a management plan for the Miles Easement and actively pursue its successful implementation (USFWS, 2018).
- Succeed at Baldock Slough — Continue the effort to successfully establish a thelypody population at Baldock Slough. Control of invasive weeds will need to be a key component of this effort (USFWS, 2018).
- Monitoring Plan — Develop and use a practical, standardized methodology for monitoring thelypody populations so that we can obtain comparable data across sites and across years. This methodology would also serve as the basis for a subsequent Post Delisting Monitoring Plan, satisfying one of the delisting criteria in the Recovery Plan (USFWS, 2018).

Conservation Measures and Best Management Practices:

- All of the General Plant Conservation Measures (Section 3.13.1) apply for thelypody. In addition, livestock grazing will not be used to control or remove invasive and non-native vegetation at project sites occupied by Howell's spectacular thelypody, unless approved by the local Service office (USFWS, 2016).

SPECIES ACCOUNT: *Thelypodium stenopetalum* (Slender-petaled mustard)

Species Taxonomic and Listing Information

Listing Status: Endangered; Pacific Southwest (R8) (USFWS, 2015)

Physical Description

A biennial herb, glabrous, glaucous. Basal leaves oblanceolate to oblong, entire or wavy-margined, thickish; cauline leaves ascending, sessile, oblong-lanceolate, sagittate, entire to few-toothed or shallowly lobed. Petals linear, lavender, rarely white, blades crinkled at base. (NatureServe, 2015)

Taxonomy

Thelypodium, a genus in the mustard family (Brassicaceae), contains approximately 20 species located throughout western North America, with 8 species occurring in California (Rollins 1993). The biennial *Thelypodium stenopetalum* S. Wats., was first described in 1887 by Sereno Watson from a collection made by Samuel B. Parish the same year from Bear Valley, San Bernardino Mountains, California (Watson 1887). Schulz (1933) transferred the taxon into the genus *Thelypodopsis*, subsequently changing the name to *Thelypodopsis stenopetala*. *Thelypodium stenopetalum* is distinguished from other members of the genus by the sessile (attached directly to the stem), clasping leaves, paired filaments that are free, and the linear petals. No other species of *Thelypodium* occur within the range of *Thelypodium stenopetalum* (USFWS, 1998).

Historical Range

See current range/distribution.

Current Range

California endemic, restricted to meadows of Big Bear Basin in San Bernardino County (Skinner, 1997). The full range extent covers no more than 49 sq mi. (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Lifespan

Adult: 2 years? (USFWS, 2011)

Breeding Season

Adult: Mature plants produce an inconspicuous flower stalk with flowers arranged in an open raceme in May or June; flowers may be present on the stalk through July (USFWS, 2011).

Reproduction Narrative

Adult: Thelypodium stenopetalum is typically considered to be a biennial species, although this has not been verified (see Species-specific research section below) (Henderson 2003, p. 57), with individual plants completing their life cycle in 2 years. First year plants generally produce leaf rosettes only and rarely flower that year. Observations of T. stenopetalum during drier years have found that with less water the species can act as an annual and produce smaller flowers that fall off the plant earlier than during wet years (S. Eliason, U.S. Forest Service, pers. obs. 2010). Mature plants produce an inconspicuous flower stalk with flowers arranged in an open raceme in May or June; flowers may be present on the stalk through July. Pollination studies have not been conducted on this species. No information is available on seed dispersal though it appears that the small seeds do not disperse very far from the parent plant (USFS 2000b, p. 41) (USFWS, 2011).

Habitat Type

Adult: Meadow (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Clumped (USFWS, 2011)

Environmental Specificity

Adult: Narrow/specialist (Natureserve, 2015)

Tolerance Ranges/Thresholds

Adult: Low (inferred from NatureServe, 2015 and USFWS, 2011)

Site Fidelity

Adult: High (inferred from NatureServe, 2015 and USFWS, 2011)

Habitat Narrative

Adult: Species inhabits mesic, alkaline meadows (Skinner, 1997) (NatureServe, 2015). Thelypodium stenopetalum is primarily found on vernal moist alkaline meadows at elevations. High ecological integrity of the population and site fidelity as well as low tolerance ranges are inferred based on the specific habitat requirements of this species and restricted range in which it is found. from 1,600 to 2,500 meters (m) (5,250 to 8,200 feet (ft)) in the Big Bear Valley, San Bernardino Mountains of California. Alkaline flats and lakeshores are also considered suitable habitat (USFS 2000b, p. 41) (USFWS, 2011).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: No information is available on seed dispersal though it appears that the small seeds do not disperse very far from the parent plant (USFS 2000b, p. 41) (USFWS, 2011).

Population Information and Trends**Population Trends:**

Decreasing (NatureServe, 2015)

Resiliency:

Low (inferred form NatureServe, 2015)

Representation:

Low (inferred form NatureServe, 2015)

Redundancy:

Low (inferred form NatureServe, 2015)

Number of Populations:

6 - 20 (NatureServe, 2015)

Population Size:

2500 - 10,000 individuals (NatureServe, 2015)

Population Narrative:

Extremely fragile due to occurrence in only a few wet meadows in one area (Bittman 1998). Long term trend is probably one of moderate decline. Decline of <50% to Relatively Stable Only a few occurrences have population numbers and they add up to 7470 plants (CNDDDB 2005). Known from three recent and seven historical occurrences (Bittman 1998) (NatureServe, 2015). Low resiliency, representation and redundancy are inferred based on the relatively low number of known populations and individuals and the limited geography within which this species occurs.

Threats and Stressors

Stressor: Development (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Development of the Big Bear Lake Reservoir (1884) and the Big Bear Dam (1911) destroyed almost all of the natural meadowland within Big Bear Valley. As a result, habitat occupied by *Thelypodium stenopetalum* was reduced from 2,800 ha (7,000 ac) to about 400 ha (1,000 ac) (USFWS 1984, p. 34498). This construction appears to have affected the extinction of some of the plants, which formerly grew in the valley (Parish 1917, p. 164) and likely eliminated some *T. stenopetalum* populations. Residential and commercial development led to the extirpation of three known historical occurrences of *T. stenopetalum* (EOs 8, 9, and 11) in the decades prior to listing (Appendix 1). At the time of listing, about 80 percent of the remaining *T. stenopetalum* habitat (approximately 400 ha (1,000 ac)) was considered vulnerable to development (USFWS 1984, p. 34499). The threat of development remains high because the majority of *Thelypodium stenopetalum* occurrences are on private land (four of six EOs). Impacts of development pressures on private land are evident at a number of occurrences: the subdivision and development of the land for the Hamilton Ranch Erwin Lake Estates at the east end of Erwin Lake (EO 3) has significantly impacted *T. stenopetalum* and its habitat, some *T. stenopetalum* habitat east of Eagle Point (EO 2 not in parcel K) has been lost to housing development, the occurrence at the south shore of Baldwin Lake (EO 6) has been impacted by development, and the Belleville Meadow occurrence (EO 10) has been impacted by upstream development. The only *T. stenopetalum* occurrence that is considered fully protected from development impacts is at the north shore of Baldwin Lake (EO 1) on the Baldwin Lake Ecological

Reserve (managed by CDFG), and residential construction activities are occurring adjacent to this reserve. There are no conservation measures in place that offer protection of these occurrences on private land from future development. The direct threat of development to *T. stenopetalum* therefore remains substantial and is currently impacting habitat at four of six extant occurrences (Appendix 1) (USFWS, 2011).

Stressor: Off-highway vehicles (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: The listing rule indicated that OHV activity eliminated colonies and damaged *Thelypodium stenopetalum* habitat (USFWS 1984, p. 34499). In 2000, a review by the Forest Service found that approximately 1.1 miles (1.7 kilometers) (1.3 ha (3 ac)) of unauthorized roads bisect or are adjacent to known occupied meadow plant occurrences and that the unauthorized network of roads allow for an “unknown, though likely high, level of random and on-going impacts to threatened/endangered meadow plant habitat” (USFS 2000b, p. 99). Unauthorized routes are closed when they are found; however, illegal OHV use continues to impact moist meadow habitat by altering hydrology, compacting soil, and degrading habitat. Controlling OHV use within *Thelypodium stenopetalum* habitat has been difficult because much of the activity is either on private land or is unauthorized. Occurrences at the north and south shores of Baldwin Lake (EOs 1, 6) are particularly vulnerable to OHV use. At the south shore of Baldwin Lake (EO 6), OHV trails bisect the *T. stenopetalum* occurrence, connecting private land to the shoreline (USFS 2000b, p. 62). Fencing that may have provided protection to the occurrence at the north shore of Baldwin Lake (EO 1)—at the side of State Route 18, which could prevent unauthorized OHVs from entering—has been knocked down or has fallen down due to heavy snow drifts (Eliason, pers. obs. 2010). In 2010, the Forest Service placed boulders at the entrance of these roads to preclude OHV activity, which appears to be successful in reducing this threat on Forest Service lands (Eliason, pers. obs. 2010). At Belleville Meadow (EO 10), OHV activity in unauthorized areas has been observed on a closed road that bisects the area (USFS 2000b, p. 62) and has caused devegetation and alteration of surface hydrology in some areas (USFS 2005, p. 37). The Forest Service has closed and rehabilitated unauthorized roads at this occurrence (USFWS 2005, p. 220). Despite fencing and barriers, unauthorized OHV use still occurs at Belleville Meadow (USFWS 2005, p. 37). Currently, we believe OHV activity is negatively impacting *T. stenopetalum* rangewide (USFWS, 2011).

Stressor: Alteration of hydrology (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: *Thelypodium stenopetalum* is susceptible to changes of the natural hydrological conditions within its habitat due to its apparent dependence on soil moisture (USFS 2000b, p. 37). Alteration of hydrology poses a threat to all *T. stenopetalum* occurrences (Eliason, pers. obs. 2010). Alteration of drainages and swales, depletion of groundwater, and conversion of drainages to flood control channels all have the potential to significantly impact populations of *T. stenopetalum*. In extreme cases, alteration of hydrology may result in the dewatering of the habitat by lowering the water table (USFS 2000b, p. 43). An increase in residential development and the subsequent installation of a large number of private wells has the potential to lower the water table and thereby alter the hydrology of moist meadow habitat (Krantz 1979, p. iv; Eliason,

pers. obs. 2010). Additionally, development, roads, and OHV activity may alter the hydrology of an area by creating gullies, which can cut off the water supply to a meadow aquifer downstream by intercepting, concentrating, and diverting runoff (USFS 2002 p. 22). Alteration of soil hydrology or existing drainage patterns may have impacted several *Thelypodium stenopetalum* occurrences including Eagle Point (EO 2) and the north shore of Baldwin Lake (EO 1). At each of these locations, efforts were made to prevent hydrology-related impacts to the habitat and to the species. For instance, CDFG's purchase of private land containing the watershed for the north shore of the Baldwin Lake occurrence (EO 1; Baldwin Lake Ecological Reserve) in 1992 has helped to maintain natural hydrologic patterns. The Pan Hot Springs occurrence (EO 7) is found on deed restricted land; however, the water source for the habitat is not included in the deed restriction. Without control of water availability, the plants and their habitat at this occurrence remain threatened (USFS 2002, p. 25). While protection measures have lessened the threat of altered hydrology at several occurrences, it remains a rangewide threat to five of six extant occurrences (Appendix 1) (USFWS, 2011).

Stressor: Invasive nonnative plants (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Since listing, invasive nonnative plants have been identified as a threat to five of six *Thelypodium stenopetalum* occurrences (Appendix 1). Nonnative species of grasses and forbs invade many plant communities often as an indirect result of habitat disturbance (Vitousek et al. 1997, p. 1). Development, roads, and other threats that disturb moist meadow habitat allow invasive nonnative plants to occupy and replace *T. stenopetalum*, and may decrease the amount of soil nutrients available to co-existing *T. stenopetalum* and eliminate natural pollinators (Levine et al. 2003, p. 777). Nonnative grasses may impact *T. stenopetalum* habitat by decreasing community water availability, which is often mediated by the displacement of species that use more water (Levine et al. 2003, p. 778). Invasion by nonnative grasses, may make it more difficult for *T. stenopetalum* to thrive because these grasses have a highly diffuse root system that is well positioned in the soil horizon to remove moisture that otherwise could support seedlings of *T. stenopetalum* (Levine et al. 2003, p. 778). Additionally, dead grasses may create a mat or thatch that impedes or prevents seedlings from becoming established. *Thinopyrum intermedium* (previously *Elytrigia intermedia*) (intermediate wheatgrass) has been identified as a threat to occurrences at the north and south shores of Baldwin Lake (EOs 1, 6), East of Eagle point (EO 2), Erwin meadows (EO 3), and in the south end of Pan Hot Springs (EO 7) (Eliaison pers. comm. 2011). *Thinopyrum intermedium* invades *T. stenopetalum* habitat and outcompetes it for space. It also produces a thatch that *T. stenopetalum* seedlings cannot penetrate. Control methods, such as burning or mowing, have proven ineffective because the grass is a perennial that returns in subsequent years (Eliaison pers. obs. 2010) (USFWS, 2011).

Stressor: Grazing/herbivory (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Since the time of listing, horse grazing and pasturing activities have been identified as threats that are impacting occurrences at Pan Hot Springs (EO 7), the south shore of Baldwin Lake (EO 6), and the east end of Erwin Lake (EO 3). Voluntary landowner agreements resulted in the relocation of equestrian activities away from rare plant habitat at Pan Hot Springs. These

efforts were successful and recovery of *Thelypodium stenopetalum* populations has been observed at this location (USFS 2002, p. 19). Horse grazing and pasturing activities remain a threat at the east end of Erwin Lake (EO 3) and south Baldwin Lake (EO 6). These occurrences are on private lands and there is no formal protection in place to control this threat. As described in the species biology, Andrew's marble butterfly feed on members of Brassicaceae (mustard family) including *Thelypodium stenopetalum*. The extent that feeding by Andrew's marble butterfly impacts *T. stenopetalum* populations is unknown. Further research is necessary to determine the status of this threat (USFWS, 2011).

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: In summary, the Act is the primary Federal law that has provided protection for *Thelypodium stenopetalum* since its listing as endangered in 1984. Other Federal and State regulatory mechanisms provide discretionary protections for the species based on current management direction, but do not guarantee protection for *T. stenopetalum* absent its status under the Act. There are also unresolved conflicts between State protections afforded under CESA and NPPA and county weed abatement provisions. Therefore, we believe that State and other Federal laws and regulations have limited ability to protect the species in absence of the Act. Two of the six extant *T. stenopetalum* occurrences are however, afforded protection through local agencies by protecting land to conserve rare plant populations. Inadequacies in provisions or implementation in regulatory mechanisms are not considered threats to the species, although these inadequacies may permit or precipitate actual threats that are described under Factors A, B, C, and E (USFWS, 2011).

Stressor: Recreational activities (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Impacts associated with recreational activities have been identified as a rangewide threat to *Thelypodium stenopetalum* (Appendix 1). Recreational activities include, but are not limited to: hiking, dispersed camping, fishing, horse riding, mountain biking, and dog walking. The primary impact from recreational activities is trampling, which can crush and kill individual plants. Additional impacts include soil compaction, devegetation, escaped campfire threats, introduction or spread of nonnative species, and burial of plants with litter (USFS 2002, p. 23). Fencing and signage indicating the presence of sensitive species have proven effective at reducing the threat of recreational activities at the north and south shore of Baldwin Lake (EOs 1, 6). Moderate success has also been made in educating the public and heightening the awareness of the need for the protection and recovery of *T. stenopetalum* and numerous other listed and rare species in the vicinity of Big Bear Lake. The Big Bear Discovery Center at San Bernardino National Forest regularly presents public education programs on a variety of subjects, including threatened and endangered species (USFS 2000b, p. 80) (USFWS, 2011).

Stressor: Fire suppression measures (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: Implementation of fire suppression measures has been identified as a threat at four of six extant *Thelypodium stenopetalum* occurrences. The San Bernardino County Land Use/Fire Hazard Abatement Division (see Factor D discussion) requires that owners must remove weeds and grasses in areas where this vegetation acts as a fuel that may pose a fire threat. Weeds and grasses are described by the County of San Bernardino generally as annuals that grow and dry out each year, and they did not discriminate for rare plants (County of San Bernardino 2010a, 2010b). Weed and grass removal generally involves mowing, which damages or destroys individual *T. stenopetalum* plants. If removal activities are conducted before or during *T. stenopetalum* flowering and fruit development, the plants reproductive output and germination may be significantly impacted (USFWS, 2011).

Stressor: Reduced populations (USFWS, 2011)

Exposure:

Response:

Consequence: Localized extinction and lack of genetic variability

Narrative: Fragmentation and isolation can adversely impact small populations of plants that are already reduced in distribution such as *Thelypodium stenopetalum* resulting in increased vulnerability to extirpation (Barrett and Kohn 1991, pp. 3–30). These effects may be the result of several factors, including small areas of suitable habitat, local extirpations, or ongoing natural or artificial factors limiting establishment and survival of the taxon. The small number of *Thelypodium stenopetalum* occurrences is a concern because it increases the possibility that impacts from urban development or other activities near moist meadow habitat could destroy all or a significant portion of the species' population. *Thelypodium stenopetalum* is distributed on less than 8.5 ha (21 ac) of moist meadow habitat (USFWS 1998, p. iii). Stochastic events outside the natural range of frequency and severity (such as floods, fires, contamination, or drought) can substantially reduce or eliminate species such as *T. stenopetalum* with a restricted range and small population, and increase the likelihood of extinction (Lande 1993, p. 912). Genetic effects may further influence population demography via inbreeding depression and genetic drift (Barrett and Kohn 1991, pp. 3–30; Menges 1991, pp. 58–61). Allee (1931, pp. 17– 50) suggested small, single populations are vulnerable to extirpation when opportunities for reproduction diminish because of reduced opportunity of individuals to reproduce (Allee effect or depensation) (Courchamp et al. 2008, pp. vi–216). Stephens et al. (1999, pp. 185–190), Dennis (2002, pp. 389–401) and Courchamp et al. (2008, pp. vi–216) suggest that the Allee effect is a density-dependent event that is inversely related to population size (USFWS, 2011).

Stressor: Climate change and drought (USFWS, 2011)

Exposure:

Response:

Consequence: Loss of habitat

Narrative: While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to particular species (including *Thelypodium stenopetalum*) or sites at this time. It seems likely that *T. stenopetalum*, a species restricted to montane meadows in a single small portion of a mountain range found on particular soils with particular hydrological needs, would be threatened rangewide by any differences in climatic regimes brought on by changes to the climate. A changing climate with spatial and temporal shifting of temperature and precipitation may cause this species specific adaptations to climate to work against its survival. A changing climate may also provide advantages to other native and nonnative plant species.

Sharing information between scientists, land managers, and decision makers will increase our ability to address these threats. Increasing the success with which we address current threats to *T. stenopetalum* will increase our success of handling the uncertain effects of future climate change (USFWS, 2011).

Recovery

Reclassification Criteria:

Six populations of *Thelypodium stenopetalum* and adjacent suitable habitat are fully protected through land management agreements, land ownership by resource agency or conservation organization, conservation easement, or other permanent means of protection (USFWS, 2011).

Populations are stable or increasing with allowances for natural fluctuations (USFWS, 2011).

Recovery Actions:

- Four of the six extant occurrences are located, in part, on private land and receive no formal protection. Development on private land remains the predominant threat to *Thelypodium stenopetalum*. As the majority of occurrences receive no protection, the conservation efforts described above are not enough to meet reclassification criterion 1 for *T. stenopetalum* from endangered to threatened status (USFWS, 2011).
- The populations of *Thelypodium stenopetalum* are declining overall, with extirpation of two occurrences (EOs 4 and 5) since listing. All occurrences are impacted by multiple threats and though some populations are presumed extant, surveys are needed to verify their status (e.g., east end of Erwin Lake (EO 3)). Surveys are necessary to determine the status of all occurrences on private land, but observations in the field suggest that *T. stenopetalum* are not increasing and may be declining; therefore, reclassification criterion 2 has not been met (USFWS, 2011).

Conservation Measures and Best Management Practices:

- Work with partners, in particular private landowners, to help conserve *Thelypodium stenopetalum*. Identify opportunities through the Service's Partners for Fish and Wildlife Programs to implement conservation opportunities on private lands (USFWS, 2011).
- Conduct monitoring to inventory actual occurrences and update the status of *Thelypodium stenopetalum* occurrences throughout the species range. While the occurrence on the east end of Erwin Lake (EO3) is presumed extant, surveys should occur because they have not been conducted at this species location for many years (USFWS, 2011).
- Conduct research on life history characteristics (e.g., pollination studies) and more specific habitat requirements. This information may be used for unoccupied habitat identification and potential reintroduction experiments (USFWS, 2011).
