Molokai—Coastal—Unit 7 consists of 49 ac (20 ha) of privately owned land from Alanuihipaka Ridge to Kalanikaula, on the northeastern coast of Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). Although Molokai—Coastal—Unit 7 is not known to be occupied by *Bidens wiebkii*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrnone*, *Marsilea villosa*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Lowland Wet—Unit 1 (and) *Palmeria dolei*—Unit 38—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 38—Lowland Wet This area consists of 2,195 ac (888 ha) of State land, and 754 ac (305 ha) of privately owned land (partly within The Nature Conservancy's Pelekunu Preserve), from Pelekunu Valley to Wailau Valley, in north-central Molokai. These units are occupied by the plant *Cyrtandra filipes*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Lowland Wet—Unit 1 is not known to be occupied by *Asplenium dielirectum*, *Bidens wiebkii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea dunbariae*, *C. grimesiana* ssp. *grimesiana*, *C. solanacea*, *Lysimachia maxima*, *Melicope reflexa*, *Peucedanum sandwicense*,

Phyllostegia hispida, *P. mannii*, *Plantago princeps*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Lowland Wet—Unit 2 (and) *Palmeria dolei*—Unit 39—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 39— Lowland Wet This area consists of 1,356 ac (549 ha) of State land and 594 ac (241 ha) of privately owned land, from Kahanui to Pelekunu Valley, in north-central Molokai. These units are occupied by the plant *Lysimachia maxima*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Lowland Wet—Unit 2 is not known to be occupied by *Asplenium dielerectum*, *Bidens wiebkkei*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea dunbariae*, *C. grimesiana* ssp. *grimesiana*, *C. solanacea*, *Cyrtandra filipes*, *Melicope reflexa*, *Peucedanum sandwicense*, *Phyllostegia hispida*, *P. mannii*, *Plantago princeps*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Lowland Wet—Unit 3 consists of 94 ac (38 ha) of State land, and 3,125 ac (1,265 ha) of privately owned land, from Waiahookalo gulch to Moaula stream and Puniuohua, on eastern Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). Although Molokai—Lowland Wet—Unit 3 is not known to be occupied by *Asplenium dielerectum*, *Bidens wiebkkei*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea dunbariae*, *C. grimesiana* ssp. *grimesiana*, *C. solanacea*, *Cyrtandra filipes*, *Lysimachia maxima*, *Melicope reflexa*, *Peucedanum sandwicense*, *Phyllostegia hispida*, *P. mannii*, *Plantago princeps*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Montane Wet—Unit 1 (and) *Palmeria dolei*—Unit 40—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 40— Montane Wet This area consists of 1,545 ac (625 ha) of State land, and 1,851 ac (749 ha) of privately owned land, from the headwaters of Waialeia Stream and above Pelekunu Valley, eastward along the summit area to Mapulehu, in northcentral Molokai. These units are occupied by the plants *Bidens wiebkkei*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea mannii*, *C. profuga*, *Phyllostegia hispida*, and *Pteris lidgatei*,

and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Montane Wet—Unit 1 is not known to be occupied by *Adenophorus periens*, *Cyanea procera*, *C. solanacea*, *Hesperomannia arborescens*, *Lysimachia maxima*, *Melicope reflexa*, *Phyllostegia mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea laui*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Montane Wet—Unit 2 (and) *Palmeria dolei*—Unit 41—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 41—Montane Wet This area consists of 871 ac (353 ha) of State land, and 39 ac (16 ha) of privately owned land, from Honukaupu to Olokui (between Pelekunu and Wailau valleys), in north-central Molokai. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). Although Molokai—Montane Wet—Unit 2 is not known to be occupied by *Adenophorus periens*, *Bidens wiebkei*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea mannii*, *C. procera*, *C. profuga*, *C. solanacea*, *Hesperomannia arborescens*, *Lysimachia maxima*, *Melicope reflexa*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Pteris lidgatei*, *Schiedea laui*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Montane Wet—Unit 3 consists of 77 ac (31 ha) of State land, and 726 ac (294 ha) of privately owned land, above the east rim of Wailau Valley on eastern Molokai. This unit is occupied by the plant *Melicope reflexa*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Montane Wet—Unit 3 is not known to be occupied by *Adenophorus periens*, *Bidens wiebkei*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea mannii*, *C. procera*, *C. profuga*, *C. solanacea*, *Hesperomannia arborescens*, *Lysimachia maxima*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Pteris lidgatei*, *Schiedea laui*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Montane Mesic—Unit 1 (and) *Palmeria dolei*—Unit 42—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 42— Montane Mesic This area consists of 257 ac (104 ha) of State land, and 559 ac (226 ha) of privately owned land from Kamiloloa to Makolelau in central Molokai. These units are occupied by the plants *Alectryon macrococcus*, *Bidens wiebkiei*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Montane Mesic—Unit 1 is not known to be occupied by *Asplenium dielerectionum*, *Cyanea dunbariae*, *C. mannii*, *C. procera*, *C. solanacea*, *Cyperus fauriei*, *Kadua laxiflora*, *Melicope mucronulata*, *Neraudia sericea*, *Plantago princeps*, or *Stenogyne bifida*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Bidens wiebkiei* critical habitat consists of four components. Coastal (Molokai), Lowland wet (Molokai), Montane wet (Molokai) and Montane mesic (Molokai) (81 FR 17790-18110):

Ecosystem: Coastal. Elevation: <980 ft (<300 m). Annual precipitation: <20 in (<50 cm). Substrate: Well-drained, calcareous, talus slopes; dunes; weathered clay soils; ephemeral pools; mudflats. Canopy: *Hibiscus*, *Myoporum*, *Santalum*, *Scaevola*. Subcanopy: *Gossypium*, *Sida*, *Vitex*. Understory: *Eragrostis*, *Jacquemontia*, *Lyceum*, *Nama*, *Sesuvium*, *Sporobolus*, *Vigna*.

Ecosystem: Lowland Wet. Elevation: <3,330 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Ecosystem: Montane Wet. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: >75 in (>190 cm). Substrate: Well-developed soils, montane bogs. Canopy: *Acacia*, *Charpentiera*, *Cheirodendron*, *Metrosideros*. Subcanopy: *Broussaisia*, *Cibotium*, *Eurya*, *Ilex*, *Myrsine*. Understory: *Ferns*, *Carex*, *Coprosma*, *Leptecophylla*, *Oreobolus*, *Rhynchospora*, *Vaccinium*.

Ecosystem: Montane Mesic. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Deep ash deposits, thin silty loams. Canopy: *Acacia*, *Ilex*, *Metrosideros*, *Myrsine*, *Nestegis*, *Nothoecstrum*, *Pisonia*, *Pittosporum*, *Psychotria*, *Sophora*, *Zanthoxylum*. Subcanopy: *Alyxia*, *Charpentiera*, *Coprosma*, *Dodonaea*, *Kadua*, *Labordia*, *Leptecophylla*, *Phyllostegia*, *Vaccinium*. Understory: *Ferns*, *Carex*, *Peperomia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cooki*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant

species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D’Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History**Food/Nutrient Resources****Breeding Season**

Adult: Includes May (USFWS, 1996)

Reproduction Narrative

Adult: This species was observed in flower during May 1982 (HHP 1 990a). (USFWS, 1996)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland, shrubland/chaparral (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 250 and 1,050 meters (USFWS, 1996)

Spatial Arrangements of the Population

Adult: Scattered (USFWS, 1996)

Habitat Narrative

Adult: This species is found in moist shrublands and forests in gulches and on ridges. Four populations of this species are scattered along steep, exposed slopes (USFWS 1992) in *Metrosideros polymorpha* (ohia) dominated mesic shrublands and forests at 250 to 1,050 meters (820 to 3,450 feet) in elevation (USFWS 1992). Other associated plant taxa include *Antidesma* (hame), *Nestegis sandwicensis* (olopua), *Pisonia* (papala kepau), and *Scaevola gaudichaudii* (naupakakuahiwi) (USFWS 1992). (USFWS, 1996; NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

Low (inferred from USFWS, 2011)

Redundancy:

Low (inferred from USFWS, 2011)

Number of Populations:

6 occurrences (USFWS, 2018)

Population Size:

200 plants (USFWS, 2018)

Population Narrative:

At the time of listing in 1992 there were 5 populations of no more than 60 total individuals of *Bidens wiebkei* (USFWS 1992). Currently, there are at least 7 populations with as many as 500 individuals on East Molokai. (USFWS, 2011); In 2011, there were seven populations that totaled fewer than 250 individuals on Moloka'i. Currently, there are six populations totaling fewer than 200 individuals: below Pu'ukolekole Gulch in Kamakou Preserve and extending below (50 individuals) (NTBG 2014; PEPP 2017); 10 individuals at Kumu'eli (NTBG 2014); west of Waialua (10 individuals) (PEPP 2013, 2017); Waialua below Kahawaiiki Gulch (3 individuals) (NTBG 2006; Bakutis 2006, in litt.); Lamaloa Gulch (15 individuals) (PEPP 2013, 2017); and Kua Gulch (100 individuals) (PEPP 2017). There are no new observations of the 100s of individuals at Pāpalaua east to Puahanunui (last observed in 2010) (PEPP 2010). (USFWS, 2018)

Threats and Stressors

Stressor: Ungulates (USFWS, 2011)

Exposure:

Response:**Consequence:**

Narrative: Threats to *Bidens wiebkai* are feral ungulates, including pigs (*Sus scrofa*), goats (*Capra hircus*), and deer (*Ovis montanus*), which degrade the habitat. (USFWS, 2011)

Stressor: Invasive plant species (USFWS, 2011)

Exposure:**Response:****Consequence:**

Narrative: In addition, invasive introduced plant species that alter the habitat and compete for resources include *Buddleia asiatica* (dogtail), *Acacia confusa* (Formosan koa), *Ageratum conyzoides* (billygoat weed), *Ageratina riparia* (spreading mist flower), *Andropogon virginicus* (broomsedge), *Axonopus fissifolius* (narrow-leaved carpetgrass), *Chamaecrista nictitans* (partridge pea), *Christella dentata* (downy wood fern), *Drymaria cordata* (white snow), *Hypochoeris radicata* (hairy cat's ear), *Lantana camara* (lantana), *Melinis minutiflora* (molasses grass), *Pluchea carolinensis* (fleabane), *Rubus rosifolius* (thimbleberry), *Sacciolepis indica* (Glenwood grass), *Schinus terebinthifolius* (Christmas berry), and *Setaria parviflora* (yellow foxtail). (USFWS, 2011)

Stressor: Fire (USFWS, 2011)

Exposure:**Response:****Consequence:**

Narrative: At Halawa and Makakupaia, within the Molokai Forest Reserve, *Melinis minutiflora* creates a fire hazard (USFWS 1996). Part of the Makakupaia area burned in a fire in September 2009 (Kubota 2009). (USFWS, 2011)

Stressor: Rats (USFWS, 2011)

Exposure:**Response:****Consequence:**

Narrative: Rats (*Rattus* spp.) are believed to be predators of this species (Listing Factor C) (Wood and Perlman 2002). Spittle bugs (species unknown) have been observed on other native species of *Bidens* (Listing Factor C) (H. Oppenheimer, pers. comm. 2009). (USFWS, 2011)

Stressor: Climate change (USFWS, 2011; USFWS, 2018)

Exposure:**Response:****Consequence:**

Narrative: Climate change may also pose a threat to this species. However, current climate change analyses in the Pacific Islands lack sufficient spatial resolution to make predictions on impacts to this species. The Pacific Islands Climate Change Cooperative (PICCC) has currently funded climate modeling that will help resolve these spatial limitations. The Service anticipates high spatial resolution climate outputs by 2013. (USFWS, 2011); habitat—Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawai'i using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by

Fortini et al. (2013) concluded that *Bidens wiebkei* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.735 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2018)

Stressor: Landslides and erosion (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Botanists noted that landslides are a threat to individuals of *Bidens wiebkei* at Kumu'eli, below Pu'ukolekole, and Lamaloa (NTBG 2002, 2005; PEPP 2013). In addition, erosion of sea cliffs is a threat to *B. wiebkei* that occurs east of Pāpalaua (PEPP 2010). Landslides and erosion due to natural weathering destabilizes substrates, alters hydrological patterns, and damages and destroys individual plants (Stearns 1985). (USFWS, 2018)

Recovery

Reclassification Criteria:

1. A total of five to seven populations of each taxon should be documented on Maui and at least one other island where they now occur or occurred historically. (USFWS, 1996)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1996)
3. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered. (USFWS, 1996)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Maui and at least one other island where they now occur or occurred historically. (USFWS, 1996)
2. Each population must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1996)
3. Each population should persist at this level for a minimum of five consecutive years. (USFWS, 1996)

Recovery Actions:

- Protect habitat and control threats. (USFWS, 1996)
- Expand existing wild populations. (USFWS, 1996)
- Conduct essential research. (USFWS, 1996)
- Develop and implement detailed monitoring plans for all species. (USFWS, 1996)
- Establish new populations as needed to reach recovery objectives. (USFWS, 1996)

- Validate and revise recovery criteria. (USFWS, 1996)
- Ungulate monitoring and control—Continue to construct and maintain fenced exclosures to protect individuals from the negative impacts of feral ungulates. Protect all occurrences against browsing and habitat disturbances from feral ungulates. (USFWS, 2018)
- Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations. Control invasive nonnative species that compete with the species around all populations. (USFWS, 2018)
- Captive propagation for genetic storage and reintroduction—Continue propagation efforts for maintenance of genetic stock. (USFWS, 2018)
- Reintroduction and translocation—Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. (USFWS, 2018)
- Fire monitoring and control—Develop and implement fire prevention management plans. (USFWS, 2018)
- Predator and herbivore monitoring and control—Implement effective control methods for rodents. (USFWS, 2018)
- Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from landslides and erosion. (USFWS, 2018)
- Alliance and partnership development—Continue to work with partners in planning and implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2018)
- Climate change adaptation strategy—Assess the modeled effects of climate change on this species, and determine future landscape needed for the recovery of the species. (USFWS, 2018)

Conservation Measures and Best Management Practices:

- Fence to exclude feral ungulates. (USFWS, 2011)
- Control introduced invasive plant species. (USFWS, 2011)
- Collect seed from all seven populations for genetic storage and reintroduction. (USFWS, 2011)
- Propagate for augmentation of smaller wild populations when threats are abated. (USFWS, 2011)
- Work with Hawaii Division of Forestry and Wildlife and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species. (USFWS, 2011)
- Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species. (USFWS, 2011)

SPECIES ACCOUNT: *Blennosperma bakeri* (Sonoma sunshine)

Species Taxonomic and Listing Information

Listing Status: Endangered; 1/2/1992; Pacific Southwest (R8)

Physical Description

Blennosperma bakeri plants are less than 30 centimeters (cm) (11.8 inches (in)) tall with alternate, linear leaves (Ornduff 1977a, Baldwin 2012). The leaves have smooth margins and are 5.1 to 15.2 cm (2.0 to 6.0 in) long with zero to five lobes (Baldwin 2012). From March to May, the plants have a butter-yellow, daisy-like flower head at the tip of each branch. Each flower head is less than 1.5 cm (0.6 in) across. The 6 to 15 outer petals are 5 to 7 millimeters (mm) (0.20 to 0.28 in) long. Occasionally the flowers may be white instead of yellow. The pollen is white. The flowers produce tapered achenes (dry, one-seeded fruits) that are 3 to 4 mm (0.12 to 0.16 in) long and have 4 to 6 sharp angles along the sides. The achenes are covered with tiny bumps and become slimy when wet giving the species one of its common names, “Baker’s sticky seed” (Ornduff 1963, Munz and Keck 1968, Ornduff 1977a, Baldwin 2012). (USFWS, 2016)

Taxonomy

Blennosperma bakeri is an annual plant in the aster family. It has been known by the scientific name *Blennosperma bakeri* (Heiser) since it was first described by Heiser (1947). Two other species are recognized in this genus; *B. nanum* (dwarf blennosperma) grows in California and *B. chilense* (Chilean blennosperma) occurs in Chile (Baldwin 2012). (USFWS, 2016)

Historical Range

Sonoma County, California. (USFWS, 2016)

Current Range

Sonoma County, California. (USFWS, 2019)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual: cross-pollination (USFWS, 2016)

Lifespan

Adult: ~ 1 year (USFWS, 2016)

Dependency on Other Individuals or Species

Adult: Pollinators, such as *Andrena blennospermatis* (USFWS, 2016)

Breeding Season

Adult: March - April (USFWS, 2016)

Key Resources Needed for Breeding

Adult: Heavy fall rains, insect pollinators (USFWS, 2016)

Reproduction Narrative

Adult: Flower from March through April. The flowers of *B. bakeri* are self-incompatible, meaning that they can set seed only when fertilized by pollen from a different plant (USFWS, 2016). *Blennosperma bakeri* is an annual; its entire life cycle from seed germination to seed set is completed in a single growing season. In nature, *B. bakeri* seeds germinate in the fall following heavy rains, and the plants can grow even when submerged (Patterson et al. 1994). The most abundant native pollinator of *B. bakeri* was the solitary bee, *Andrena blennospermatis*. Other pollinators that visited *B. bakeri* included *Apis mellifera* (European honeybee), four species of generalist native bees, and syrphid flies. Under dry conditions, or in dense populations, *B. bakeri* may bear only a single flower head per plant (Patterson et al. 1994), thus producing a maximum of 15 achenes. However, when pools dry and fill repeatedly in a single growing season, each plant may produce as many as 20 flower heads (Patterson et al. 1994), with potential for 300 achenes per plant (USFWS, 2016).

Habitat Type

Adult: Wetland, aquatic (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Vernal pool, wet grassland (USFWS, 2016)

Geographic or Habitat Restraints or Barriers

Adult: Occurs < 330 ft. elevation (USFWS, 2016)

Habitat Narrative

Adult: Occurs predominantly on the Santa Rosa Plain, which is located in central Sonoma County, California, and is characterized by seasonal wetlands, predominately in the form vernal pools, and associated upland grassland habitat. Vernal pools form in depressions having a shallow, impermeable soil layer that restricts the downward movement of water. The pools have an outlet barrier that further causes ponding (CH2M Hill 1995) and may be connected and fed by shallow drainage pathways called "swales." Vernal pools generally fill during winter rains and dry in late spring or summer. "Natural" vernal pools are those that are found occurring naturally in the landscape. "Created" vernal pools are those that have been constructed in an area that was not a vernal pool in the recent past (within the last 100 to 200 years) and that is isolated from existing vernal pools (Gwin et al. 1999 and Lewis 1989). This species grows only in seasonal wetlands. (USFWS, 2016)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Dispersal mechanisms for the achenes have not been studied. However, seed dispersal of *B. nanum* var. *nanum*, a species that occupies similar habitat to *B. bakeri*, was found by Ornduff (1964) to be within a small radius of the parent plants based on the area occupied by flower-color variants. (USFWS, 2016)

Population Information and Trends**Population Trends:**

Unknown (USFWS, 2016)

Species Trends:

Decreasing (USFWS, 2016)

Number of Populations:

18 (USFWS, 2016)

Population Size:

Variable among years; < 100 to > 1.5 million (USFWS, 2016)

Population Narrative:

After listing, the number of sites with many individuals decreased, and the number with less than 10 individuals increased. The percentage of sites with fewer than 10 individuals increased by 15 percent between the time of listing and 1994 (USFWS, 2008). The most current occurrence information documents the presence of 18 extant occurrences. Populations exhibit extreme fluctuations in size among years, often varying by one or two orders of magnitude (CNDDDB 2013). Individual occurrence sizes ranged over time from fewer than 100 plants to more than 1.5 million plants (CNDDDB 2013). Collection of annual abundance data has been sporadic; therefore, determination of population trends is difficult. A 2009 study by Sloop and Ayres found that moderate genetic diversity existed among the occurrences of *Blennosperma bakeri* on the Santa Rosa Plain (USFWS, 2016).

Threats and Stressors

Stressor: Development and conversion to agriculture (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: Today, the largest continuing threats to this species are urban development and land conversion to agriculture (such as vineyards) and associated agricultural activities and wastewater irrigation. The most recent estimates from the California Department of Conservation (2002) are that about 71,000 acres of Sonoma County have been converted to urban uses (Sonoma County Permit and Resource Management Department 2014). The threat of urban development to these species in the Santa Rosa Plain is expected to continue. In addition to urban development, land conversion to agriculture and associated agricultural activities has reduced occurrences of these plants (CNDDDB 2014). In 1991, at the time of the listing, approximately 34,500 acres of land were in wine grape production in Sonoma County (Sonoma County Agricultural Commissioner 1991). As of 2012, the acreage of wine grapes in Sonoma County had increased to approximately 58,400 acres (Sonoma County Agricultural Commissioner 2013). Additionally, irrigation with recycled water, a practice that began in the Santa Rosa Plain in the 1970s, has emerged as a major threat. Although the California Regional Water Quality Control Board regulations (Water Quality Control Plan for the North Coast Region) prohibit discharge of recycled water to surface waters during the summer, the regulations did not contemplate that recycled water would be used to irrigate vernal pools and other types of

seasonal wetlands (J. Short, pers. comm., 2007). Recycled water, as opposed to wastewater, is tertiary-treated (City of Santa Rosa, in litt. 2015** [comment letter]). Wastewater, however, can come from many sources including livestock waste ponds and runoff from agricultural fields (City of Santa Rosa, in litt. 2015** [comment letter]). (USFWS, 2016)

Stressor: Alteration of hydrology (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: Some actions, such as runoff from irrigation or irrigation with recycled water, can result in increased water on the landscape. The vernal pool habitat may receive more water than it normally would or receive it at an inappropriate time, resulting in flooding and death of listed plant seedlings. If water from urban or agricultural runoff continues to fill pools during spring and summer months, the listed plants will disappear because they cannot tolerate permanent inundation; invasion by plant species adapted to permanent inundation will occur. Additionally, irrigation with recycled water and runoff from irrigation can contain chemicals, such as herbicides, and other nutrients (Pereira et al. 1996) that can alter the vernal pool plant community, prevent germination, or kill seedlings. Nitrogen deposition from automobile traffic may also modify habitat by increasing soil nutrients, thus posing a continuing threat to remnant habitat that might otherwise be suitable for these species. Weiss and Luth (2003, p. 1) conducted research on the effects of nitrogen deposition along a highway south of the San Franciscan peninsula in San Francisco County. They found that nitrogen deposition within 100 m to 400 m from the highway was correlated with increased nonnative grass cover within these areas, resulting in competition for space with native plants. An increase in nonnative grass cover through changed habitat conditions could threaten the three plant species by competing for soil moisture and nutrients and inhibiting successful germination. (USFWS, 2016)

Stressor: Off-highway vehicles (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: Damage by off-highway vehicles was noted as a threat to *Blennosperma bakeri*. Currently, on Department-owned properties that support the listed plants, some damage to preserves from vehicle trespass does occur, but without damage to the vernal pools. The most significant damage to vernal pools from vehicles has resulted from a Mosquito Vector Control vehicle driving through the vernal pools to spray for mosquitoes during the time when the pools were wet in 2014. Disturbance to the pools included physical damage to the pools and swales from tire ruts and crushing and uprooting the plants (S. Martinelli, CDFW, in litt. 2014). The level of this threat is likely to be variable and is difficult to predict or monitor. (USFWS, 2016)

Stressor: Grazing management and thatch accumulation (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: Appropriate levels of grazing may provide some control of weedy plants, reduce competition between native plants and invasive plants, and can provide some bare soil for germination of native plants, all of which may provide opportunities for native plants to germinate. Cessation of cattle grazing has been found to exacerbate the negative effects of

invasive nonnative plants on vernal pool inundation period. If grazing is removed, areas of bare soil can be quickly occupied by nonnative, invasive plants. Removal of grazing from vernal pool grasslands where grazing is the traditional land use practice may have devastating impacts on vernal pool habitat, particularly on upland habitat surrounding vernal pools (G. Cooley, in litt., 2014). For example, non-native grasses increased and native grasses decreased in vernal pools when grazing was discontinued at a site in the Southeastern Sacramento Valley, resulting in a 50 to 80 percent reduction in vernal pool inundation (Marty 2005). Since the time of listing, grazing has been removed at many locations and has resulted in thatch build-up. Anecdotal evidence supports the theory that thatch build-up of nonnative vegetation has caused a reduction in the size of extant populations of the listed plants. The Department is re-establishing appropriate grazing practices on some Department-owned lands to reduce thatch build-up and nonnative competitors to the three listed plants (e.g., Todd Road Unit Ecological Preserve). However, reintroduction of grazing may not return a site to its former condition because nonnative plants may continue to occupy the once-vacant niches. For example, harding grass (*Phalaris aquatica*), a robust, invasive perennial grass, can be present in a grazed field, and not be obvious. If grazing is removed, however, the suppressed harding grass can become vigorous and dominate the entire field within a year or two and grazing will not remove this species once it is established (G. Cooley, in litt. 2014). We recognize that there is disagreement among biologists as to the extent of the threat of inappropriate grazing on the three species. As the final rule concluded, we believe that although the effect of well-managed livestock grazing may be beneficial to vernal pool ecosystem. (USFWS, 2016)

Stressor: Loss of Genetic Diversity / Inappropriate Mixing of Populations(USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: An additional potential threat to these three plants is the disruption of normal gene flow due to population restoration efforts that may mix populations, which may cause unanticipated adverse effects such as disruption of locally adapted gene complexes and outbreeding depression (when offspring from individuals from different populations have lower health/fitness than progeny from individuals from the same population). Several sites are proposed as Preserves in the Santa Rosa Plain and include proposals to seed/inoculate created or restored vernal pools. Seed from a limited number of donor occurrences has already been used for several years to inoculate multiple created or restored sites, creating a risk of overrepresentation of a small gene pool (swamping). The threat level of this activity is unknown; however, the 2007 Programmatic Biological Opinion (Service 2007) includes measures to reduce this potential threat as well as the requirement to obtain a collection permit from the Department. (USFWS, 2016)

Stressor: Climate change (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: Since the 1950s, the Northern Hemisphere has experienced warmer air temperatures and decreased snowfall (Ackerly et al. 2010, IPCC 2013). By the end of the 21st century, climate change is predicted to result in more intense precipitation events in the form of rain, increased summer continental drying, extreme weather events, and increased wildfire (Ackerly et al. 2010, IPCC 2013). However, current climate change predictions for terrestrial areas in the Northern

Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2013). Climate simulations have shown that California temperatures are likely to increase by 2.7 degrees Fahrenheit (1.5 degrees Celsius) to 8.1 degrees Fahrenheit (4.5 degrees Celsius) depending on the emissions scenario (Cayan et al. 2008). The predicted impacts on California's ecosystems projected with a high certainty include (1) higher sea level and (2) decreased suitable habitat for many terrestrial species as climate change intensifies human impacts [for example isolated patches of vernal pools can be so poorly connected with other patches that migrations required by climate change may be difficult or impossible without human intervention (Field et al. 1999)]. Climate change threatens to increase the loss of pollinators if the abundance of flowers preferred by pollinators decreases. Pollinator emergence times may also be altered by a warming climate. If this occurs, the synchrony of bloom periods and pollinator emergence could be disrupted. The loss of pollinators would further reduce the amount of seed produced by the listed plants because of the plants' limited ability to self-pollinate. Although there currently are no data available regarding changes in plant bloom periods or emergence dates of pollinators in the Santa Rosa Plain in response to climate change, Forister and Shapiro (2003) found that over a period of 31 years, warmer and drier winter conditions were associated with earlier butterfly appearance in the Central Valley of California. Although the loss of seed produced in a single year would not likely lead to the extirpation of the species, the continued reduction of the seed crop or dependence on self-pollination would reduce the seedbank, genetic variation, and the potential for population expansion. Monitoring of vernal pool ecosystems to determine effects from climate change is necessary to determine what adaptive land management practices would be the most appropriate to ensure the sustainability of vernal pool species (Pyke and Marty 2005), including *B. bakeri*, *L. burkei*, and *L. vinculans*. (USFWS 2016)

Stressor: Extirpation due to Stochastic Events, Isolated Occurrences, and Small Size of Occurrences (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: Chance events constitute a serious threat to *Blennosperma bakeri*. Because the known occurrences of *B. bakeri* are limited in number and in range, the species are vulnerable to stochastic (random) events—natural but damaging environmental perturbations and catastrophes such as droughts, storm damage, disease outbreaks, and fires, from which large wide-ranging populations can generally recover, but may lead to extirpation of small isolated populations (Gilpin and Soule 1986). The majority of the remaining habitat associated with the three species is vernal pools and swales in the Santa Rosa Plain. The nature of the vernal pool and swale habitat associated with the three plants may also increase the effects of drought. Vernal pools and swales are inundated only briefly and may not fill during dry years. As a result, we consider stochastic events to be of significant concern for these species. Isolated, small occurrences may also be at risk from a decrease in reproductive rate resulting from decreasing population density. The correlation of reproductive rate with population density, called the Allee effect, may be the result of either increased density or quality of compatible mates, or increased pollination, or both (Stephens et al. 1999). In small populations, if either the plants or their pollinators decline, consequences on the reproductive output of the other may result in an extinction vortex in which each generation is more likely to go extinct (Gilpin and Soule 1986, Soule and Mills 1998). (USFWS, 2016)

Stressor: Inadequacy of Existing Regulatory Mechanisms (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: The Service found that many existing regulatory mechanisms were not sufficient to protect plants, including section 404 of the Clean Water Act, the protections of the California Endangered Species Act, and the California Environmental Quality Act. The 1991 final rule also found that listing the plants under the Federal Endangered Species Act would provide better protection by requiring the Army Corps of Engineers (and other Federal agencies) to consult with the Service prior to final determinations on a proposed activity. (USFWS, 2016)

Stressor: Non-native invasive species (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: creating a drier habitat and facilitating the invasion of non-native upland species, may permanently change the plant community and the non-native plants may outcompete the listed species (Bauder 2000, Marty 2005, competition discussed further below). With insufficient water, the distribution of plant species that are normally found higher on the edge of the vernal pools may shift downward along the moisture gradient in response to the introduction of invasive plants that now flourish at pool edges. Non-native grasses maintain dominance at pool edges, sequestering light and soil moisture, promoting thatch build-up, and shortening inundation periods. Species strongly associated with vernal pools may disappear from shallow pools as a result of invasion by upland non-native plants. In addition, the invasive species can further alter the hydrology of the site by reducing the inundation period (Marty 2005). Reduction in inundation period is thought to be due to increased evapo-transpiration associated with dense cover of nonnative plants at the vernal pools (Marty 2005). Once non-native, invasive plants are introduced to vernal pools, competition with native species can come from several interactions including root competition (roots of one species are more efficient at absorbing moisture and nutrients from the soil) and pollination success (one species will set more seed and produce more plants). Plant size can also confer superiority when competing with smaller plants. A larger plant can shade smaller or shorter plants and seedlings, depriving them of adequate sunlight which is necessary for plant and seedling growth and survival, and in some cases necessary for seed germination (Barbour et al. 1987). (USFWS, 2016)

Recovery

Reclassification Criteria:

A/1: Eighty percent of extant, native occurrences, not protected as of December 2014, within each core area (Windsor Core Area, Alton Lane Core Area, and *Blennosperma bakeri* Southern Core Area) are permanently protected to maintain the current geographic, elevational, and ecological distribution of the species. Priority should be given to preserve isolated and/or genetically unique occurrences. (USFWS, 2016)

A/2: The following additional habitat is needed in order to downlist *B. bakeri*. New preserves protect a minimum of 50 ac in the Windsor Core Area, a minimum of 500 ac in the Alton Lane Core Area, and a minimum of 300 ac in the *Blennosperma bakeri* Southern Core Area. These preserves consist of occupied habitat that is not currently protected. The ecological integrity

(e.g., water quality, hydrology, uplands conditions) of these areas is not threatened by adverse habitat modification. Buffers between the protected habitat and incompatible land uses must be sufficient to ensure that there are no significant adverse effects to *Blennosperma bakeri*, such as changes in hydrology, or contamination by pesticides or herbicides, currently and into the foreseeable future. (USFWS, 2016)

A/3: New preserves (comprised of restored or created habitat) must be 10 ac or greater; however, preserves with native occurrences may be less than 10 ac. The preserves should be as near to new or existing preserves as possible. (USFWS, 2016)

A/4: The total new preserve acreage in core area includes no less than 175 ac of vernal pools and swales in the Alton Lane Core Area, no less than 105 ac in the *Blennosperma bakeri* Southern Core Area, and no less than 18 ac in the Windsor Core Area. However, new preserves are no more than 35 percent wetland which is based on general wetland to upland percentages. (USFWS, 2016)

A/5: Service-approved conservation and management plans that protect vernal pool habitat and upland habitat and address effects of invasive plants are developed and are being effectively implemented. (USFWS, 2016)

A/6: Service shall work with Mosquito Abatement Districts so that their practices in the core and management areas are implemented to avoid impacts to the species. (USFWS, 2016)

E/1: Native occurrences, extant as of December 2014, in (a) the Windsor Core Area, and (b) the *Blennosperma bakeri* Southern Core Area are replicated at 1:3 (quadrupled in numbers of occurrences) in permanently protected sites. Extant native occurrences in the Alton Lane Core Area are replicated at 1:2 (tripled) in permanently protected appropriate sites²⁴. Replication is accomplished by collecting seed or inoculum from a natural occurrence and planting it at additional sites. For example: collecting seed or inoculum at one site and planting it at two additional sites increases the original single occurrence to 3 occurrences (1:2); planting it at three additional sites increases the original occurrence to 4 occurrences (1:3). (USFWS, 2016)

E/2: The preserves noted in Factor A are occupied by *Blennosperma bakeri* seeds at a density of 2,500 seeds per square meter averaged over whole vernal pools and swales when measured on a 25-year moving average which includes at least one above average and one average rainfall year, and a multi-year drought. A multi-year drought is defined as a period of 3 or more years of below average local rainfall. (USFWS, 2016)

E/3: Service-approved conservation and management plans that protect vernal pool habitat and address the effects of small occurrence size, and climate change, among other threats, are developed and are being effectively implemented. (USFWS, 2016)

Delisting Criteria:

A/1: At least 90 percent of all known native occurrences of *Blennosperma bakeri* that are extant as of December 2014, have been fully protected in perpetuity. (USFWS, 2016)

A/2: 100 ac of habitat containing *Blennosperma bakeri* is preserved and appropriately managed in the Sonoma Valley Management Area. (USFWS, 2016)

E/1: In addition to replication noted in E/1 of the downlisting criteria for *Blennosperma bakeri*, all occurrences in management areas have been replicated at 1:2 at appropriate locations. Bouverie Preserve, east of the Town of Glen Ellen, may be considered as part of the Sonoma Valley Regional Park Management Area and replicated at 1:2 if *Blennosperma bakeri* is still found there. This occurrence, if not already lost, could provide important genetic diversity and thus be valuable for the recovery of the species. The occurrences in the Sonoma Valley Management Area should be replicated at 1:3. (USFWS, 2016)

E/2: All replicate occurrences from E/1 have achieved the same rates of seed density (2,500 seeds per square meter), as the core area occurrences. (USFWS, 2016)

E/3: All genetically unique and isolated unprotected sites in management areas are permanently protected in situ including: occurrences in Sonoma Valley Regional Park and the Wood Road area in the northern portion of the Alton Lane core area. Identification of some genetically unique occurrences is not yet known but will be determined during research listed in Table 6 of the Recovery Plan. (USFWS, 2016)

Recovery Actions:

- 1. Protect extant occurrences and potential habitat for *Blennosperma bakeri*. Natural areas that are known to contain species covered in this recovery plan should be protected in perpetuity through land acquisition, conservation easements, or other means. Protection of these areas will need to be followed by identification of threats and application of appropriate and adaptive management to ensure abatement of these threats. In addition to areas that currently support the species, two other types of natural areas also need to be protected or secured: areas where the endangered plants have been found in the past but not been seen recently, and that retain habitat that can be readily restored so that plants can be reintroduced successfully; and areas where the plants have not been found but are appropriate for vernal pool creation, and subsequent introduction of the endangered plants. (USFWS, 2016)
- 2. Develop a central database for survey data from all natural and created occurrences of *Blennosperma bakeri* including information on protection status. Data should include numbers of plants; area occupied by the species; presence of invasive species; site condition; land ownership; level of management; disturbance; whether the site is natural, restored, or created; and degree of genetic uniqueness. If the site has been seeded, the origin of the seed should be identified by name and location of parcel where seed was collected, location of specific pools where seed was collected, and date of seed collection. Any observations of pollinators, such as species or type of pollinator, should also be recorded. This information will serve as the current baseline for evaluating progress of the Factor A and Factor E comparative downlisting and delisting recovery criteria for each of the three plant species. This database should be updated regularly and should be available to all management agencies (USFWS, 2016). In addition, the database should track the location of source seed for sites with created occurrences (USFWS, 2019).
- 3. Collect and store seed from all occurrences of *Blennosperma bakeri*. Seed collections for each plant taxon should be representative of both population- and species-level genetic diversity; seeds should be collected from multiple plants at each occurrence. Seed collection guidelines published by the Center for Plant Conservation (1991) should be followed. Seed collection should be conducted with caution to ensure that donor populations are not

adversely affected by the collection. No more than 5 percent of the reproductive output should be removed from donor populations. Store seeds at two storage facilities certified by the Center for Plant Conservation. Seeds should be collected every 5 years to ensure that seeds in storage are viable. Permits will be required for collecting federally-listed plant seed on federal lands. (USFWS, 2016)

- 4. Survey historical locations and other potential habitat (not previously surveyed) where *Blennosperma bakeri* may occur. (USFWS, 2016)
- 5. Conduct research necessary to develop a population viability analysis for *Blennosperma bakeri*. Table 2 of the Recovery Plan lists research tasks needed for the development of a population viability analysis for all three species in the Recovery Plan. All research tasks need to be performed for each of the three species. To maximize efficiency, it may be possible to study the effects of an experimental factor on all three species in the Recovery Plan via the same experiment. (USFWS, 2016)
- 6. Conduct necessary biological research on *Limnanthes vinculans* and use results to guide recovery efforts. Table 6 of the Recovery Plan the needed research tasks for the recovery of *Blennosperma bakeri*, *Lasthenia burkei*, and *Limnanthes vinculans*. All research tasks need to be performed for each of the three species. To maximize efficiency, it may be possible to study the effects of an experimental factor on all three species via the same experiment. (USFWS, 2016)
- 7. Habitat management for *Blennosperma bakeri*. Develop adaptive management plans and implement appropriate management actions for all protected sites. Work with local agricultural commissions to track conversion of agricultural uses to vineyards or other non-suitable agricultural uses. Decrease acreage of vernal pool habitat within priority preservation and restoration areas that are subjected to altered hydrologic regimes through irrigation practices. Develop treatment protocol with mosquito abatement district to avoid impacts to listed species and vernal pool habitat during treatment. (USFWS, 2016)
- 8. Restore or create vernal wetlands, followed by reintroduction of the species per a restoration techniques white paper and a Reintroduction and Genetic Management Plan. As noted in the Factor A discussion, much of the habitat and occurrences of the three listed plants has been destroyed or fragmented by urban development and conversion to agricultural use. Restoration or creation of habitat, when appropriate, will be necessary to maintain the numbers of plants and occurrences at levels sufficient for survival of the species. Restoration and creation of vernal pool habitat has been conducted for many years in the Santa Rosa Plain for the three plants. To better understand these processes and their rates of success, a white paper and a Reintroduction and Genetic Management Plan should be developed. (USFWS, 2016)
- 9. Monitor all protected occurrences. Monitoring plans should be developed and implemented for all protected natural and replicated occurrences. Protected occurrences should be monitored annually for plant density, area occupied by the listed species, site condition, changes in hydrology, application of recycled water and wastewater, effects of grazing, invasive species, vandalism, and whether management is appropriate for the listed species' needs. The responsible party for monitoring should also keep an ongoing record of management activities and precipitation on the site, so that changes in rare plant populations can be related to changes in management activities. Monitoring efforts for co-occurring species (e.g. *Blennosperma bakeri* and *Limnanthes vinculans* at Wright Mitigation Bank) should be coordinated to increase efficiency and reduce costs. (USFWS, 2016)

- 10. Engage and educate the public about *Blennosperma bakeri* recovery. Public education and outreach is important to inform residents and land managers in the Santa Rosa Plain and other areas that support habitat for the species about the significance of the plants and the importance of management and protection of habitat for their persistence. Education and outreach activities should include: (1) develop a public outreach plan, (2) outreach to enhance public understanding of vernal wetlands in general and of imperiled vernal wetland species in particular, (3) information on regulatory responsibilities with regard to endangered species, (4) programs to encourage local interest and involvement in site stewardship, and (5) programs including conservation easements and incentive programs that are available to landowners who may have the vernal pool species on their land. (USFWS, 2016)
- 13. Agency coordination. Partner with California Department of Fish and Wildlife, Army Corps of Engineers, Regional Water Quality Control Board, Sonoma County, Marin/Sonoma Mosquito and Vector Control District, and Cities of Santa Rosa, Cotati, Rohnert Park, and Windsor to ensure resource management practices are aligned with species conservation needs. Resource management practices to be addressed include: irrigation of vernal pool habitat with recycled water and wastewater within priority preservation and restoration areas; protection of habitat buffers; stream ordinances, grading ordinances, and water quality regulations; and vineyard conversion or other agricultural conversion of areas adjacent to vernal pool habitat that contribute to hydrologic regime and/or provide upland habitat for sustaining the Sonoma County California tiger salamander. Provide legal assurances to willing landowners who implement projects that provide a net conservation benefit. (USFWS, 2016)
- Recommendation for future action: In response to the recently discovered range expansion of Sonoma sunshine, the Service recommends surveying vernal pools in Mendocino County near the recent observation of Sonoma sunshine to search for additional occurrences. (USFWS, 2019)

SPECIES ACCOUNT: *Boltonia decurrens* (Decurrent false aster)

Species Taxonomic and Listing Information

Listing Status: Threatened; 11/14/1988; Great Lakes-Big Rivers Region (R3) (USFWS, 2016)

Physical Description

A robust, short-lived perennial herb, up to 2 m tall, that produces numerous flower heads with white or pale violet ray flowers surrounding a yellow central disk (NatureServe, 2015).

Taxonomy

Formerly classified as *Boltonia asteroides* var. *decurrens* or *B. latisquama* var. *decurrens*; now recognized as a distinct species (*B. decurrens*) by Flora of North America (2006) and Kartesz (1994), the U.S. Fish and Wildlife Service, and the Illinois and Missouri Heritage Programs (NatureServe, 2015).

Historical Range

Historical collection records reveal that *Boltonia decurrens* once occurred in almost contiguous populations along a 400 km stretch between LaSalle, Illinois and St. Louis, Missouri within the Illinois and Mississippi River floodplain. A disjunct population, reported in 1976, but not found since, is known from Cape Girardeau, MO, about 195 km down the Mississippi River from St. Louis (Schwegman and Nyboer, 1985) (NatureServe, 2015).

Current Range

The species is currently limited to disjunct populations from Woodford County, Illinois to Madison County, Illinois. In some years, ephemeral populations occur in St. Charles County, Missouri, in the area of confluence of the Mississippi and Illinois Rivers (NatureServe, 2015).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Asexual: vegetative, sexual: self-pollination, cross-pollination (NatureServe, 2015)

Lifespan

Adult: 1 - 2+ years (USFWS, 2012)

Breeding Season

Adult: August - October (NatureServe, 2015)

Key Resources Needed for Breeding

Adult: Unshaded soil surface (NatureServe, 2015)

Reproduction Narrative

Adult: Vegetative reproduction occurs through shoots formed from a basal rosette (Smith and Keevin 1998). The species is primarily outcrossing, but some selfing occurs (Smith, 1995). Seed production is prolific with an average of ca. 50,000 seeds produced per plant (Smith & Keevin 1998; Smith, 1990). Seedling survival in the field is < 1%. However, under optimal conditions, the average plant produces 40,000 seedlings but the rate of seedling survival is low (Smith & Keevin 1998). *Boltonia decurrens* blooms from August through October throughout its range (Schwegman and Nyboer, 1985). Germination and seedling establishment do not occur where the soil surface is shaded, such as in places where natural succession has been uninterrupted for a period of 3 - 5 years. Seed germination is also inhibited by silt deposition (NatureServe, 2015). It is considered a perennial plant but also exhibits annual and biennial lifecycles (USFWS, 2012).

Habitat Type

Adult: Riparian, wetland (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forested wetland, herbaceous wetland (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Disturbance regime, preferably flooding (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Successional vegetation (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Clumped (USFWS, 1990)

Environmental Specificity

Adult: Narrow (inferred from NatureServe, 2015)

Tolerance Ranges/Thresholds

Adult: Moderate (inferred from NatureServe, 2015)

Habitat Narrative

Adult: It colonizes periodically disturbed riverine moist soil habitats (Smith et al. 2005). In general, sites where the species is successful in reproducing sexually and maintaining a self-sustaining population are characterized by moist, sandy soil and regular disturbance, preferably periodic flooding, which maintains open areas with high light levels. Analysis of 19th-century habitat data taken from herbarium sheets indicates that natural habitat was the shores of lakes and the banks of streams, including the Illinois River. In these habitats, regular flooding prevented succession, allowing sunlight to reach the seedlings. *Boltonia decurrens* is still found in these occasional natural habitats, but it is now primarily restricted to disturbed lowland areas, where it appears to be dependent on human activities (mowing, cultivation) for survival. Although prolonged flooding by extremely turbid water can damage a population (US Fish and Wildlife Service, 1990), the species is extraordinarily flood tolerant (Stoecker, Smith and Melton, 1995) and is known to survive several months of complete inundation by relatively clear groundwater (Smith, 1990). The palustrine habitat is characterized as forested wetland and herbaceous wetland (NatureServe, 2015). As many as 11 plants have been observed to grow

from a single stem of the previous year, giving a 2-year-old wild population a definite clumped appearance (USFWS, 1990).

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Achenes float and are often dispersed by flowing water (Baskin and Baskin 2002). (NatureServe, 2015).

Population Information and Trends

Population Trends:

Unknown, periodic expansion and contraction (USFWS, 2012)

Species Trends:

10 - 30% decline (NatureServe, 2015)

Resiliency:

Low (inferred from NatureServe, 2015; see current range/distribution)

Representation:

High (inferred from NatureServe, 2015)

Redundancy:

High (inferred from USFWS, 2012)

Number of Populations:

43 (USFWS, 2012)

Population Size:

1000 - 10,000 individuals (NatureServe, 2015)

Population Narrative:

Like the numbers of populations, numbers of individuals of *B. decurrens* also fluctuate greatly from year to year. Larger stands sometimes have several thousand plants in good years, occasionally exceeding 10,000. Because of the vulnerability of this species to changes in flooding regime, population number is expected to continue to fluctuate in upcoming years. The short term population trend has been relatively stable to a < 30% decline. Preliminary isozyme data developed by Thomas Ranker (University of Colorado, Boulder) from seeds collected from three populations in Illinois in 1994 indicate that there is a high level of genetic diversity (Smith, 1995). This rare species is much more variable, by all the measures examined, than most rare or geographically-restricted plant species, and is even slightly more variable than the average plant species (NatureServe, 2015). Approximately 43 populations have been discovered and monitored intermittently from 1984 to present. Due to the intermittent nature of the available data, long-term trends are not readily apparent but appear to include a periodical expansion and contraction of populations (USFWS, 2012).

Threats and Stressors

Stressor: Habitat degradation (NatureServe, 2015 and USFWS, 1990)

Exposure:

Response:

Consequence:

Narrative: *Boltonia decurrens* is threatened primarily by anthropogenic disturbance of natural habitat. Principal threats include flood-control measures; agricultural use of marginal river-bottom land; increased siltation of floodwater, which decreases light availability and prevents germination and seedling establishment; herbicide use for weed control; and marina construction (NatureServe, 2015). *Boltonia decurrens* populations may also be vulnerable to destruction by discing and herbicide use in low-lying marginal lands for crop weed control. Nearly all stands are in habitats kept open by occasional cropping (USFWS, 1990).

Stressor: Hybridization (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Preliminary allozyme research has been conducted on the potential hybridization of *B. decurrens* and a related species in the genus, *B. asteroides*. Hybridization could pose a threat to the species through decreased fertility, genetic swamping, and ecological competition from hybrid individuals (DeWoody 2011). DeWoody et.al. (2011) tested for hybridization in sympatric populations using allozyme genetic marker data. The results revealed a very low rate of hybridization and introgression, indicating that cross-pollination and hybridization may not pose an immediate threat to the species. However, higher resolution genetic testing has yet to be performed, and therefore the level of threat posed by hybridization is currently indeterminable (USFWS, 2012).

Stressor: Prolonged flooding (USFWS, 1990)

Exposure:

Response:

Consequence:

Narrative: Prolonged flooding during the growing season appears to be a limiting factor. A flood in 1981 inundated most of the unvegetated flood plain of the Illinois River with turbid flood water for an extended period during the summer. Shrubs such as *Cephalanthus occidentalis* were killed by the prolonged total inundation in some areas, and herbs were buried under heavy deposits of silt. Despite intensive searches, no *B. decurrens* was found for 2 subsequent seasons along the Illinois River. Such conditions severely limit natural reproduction and survival by *B. decurrens* (USFWS, 1990).

Recovery

Reclassification Criteria:

Not available

Delisting Criteria:

1. A basic research program to determine the requirements of a naturally reproducing population must be completed (USFWS, 2012).

2. Twelve geographically distinct self-sustaining natural or established populations of the species must be protected through purchase in fee, easement, or by cooperative management agreements (USFWS, 2012).

3. Populations must be monitored for a period of five years to determine if they are self-sustaining. Self-sustaining is defined for recovery purposes as a population which is found to be stable or expanding during the five-year monitoring period (USFWS, 2013).

Recovery Actions:

- Survey suitable habitat for additional populations (USFWS, 1990).
- Protect existing and established populations (USFWS, 1990).
- Establish new populations (USFWS, 1990).
- Conduct research on the biology of the species (USFWS, 1990).
- Monitor natural and established populations (USFWS, 1990).
- Develop and maintain public support (brochure/display) (USFWS, 1990).

Conservation Measures and Best Management Practices:

- Continue to monitor known *B. decurrens* sites and search for new populations annually, collecting GPS location and census data. Include survey efforts for *B. decurrens* in suitable habitat at the confluence of the Illinois River and Mississippi River to determine the extent of the species' southern range (USFWS, 2012).
- Finalize the draft cooperative management agreement between the ILDNR and the Service (USFWS, 2012).
- Establish a consensus among the workgroup regarding the core sub-populations that are important for the survival of the species during times of adverse hydrologic conditions. Also, normal, expected patterns of expansion and contraction of populations over time should be identified to facilitate the definition of population stability in the context of recovery (USFWS, 2012).
- Based on the results of the genetic primer research by Drs. Romano, explore genetic relationships between sub-populations and refine the metapopulation model for the species. Specifically, dispersal patterns and important source populations could be identified through microsatellite research in combination with spatial analysis (USFWS, 2012).
- Explore the phenomenon of hybridization between *B. decurrens* and *B. asteroides* using microsatellite genetic markers. Research should include a confirmation of hybridization between the two species and an analysis of the extent of hybridization in the population (USFWS, 2012).

SPECIES ACCOUNT: *Bonamia grandiflora* (Florida bonamia)

Species Taxonomic and Listing Information

Listing Status: Threatened; 12/2/1987; Southeast Region (R4)

Physical Description

A perennial vine with appressed hairs and long prostrate stems a meter or more in length. It has a long, relatively slender tap root. The leathery sessile or subsessile leaves are up to 4 cm in length and ovate in shape. The flowers are solitary and sessile in the leaf axils. The funnel-shaped corolla is 7 to 10 cm long and 7 to 8 cm across. It has a deep blue or bluish-purple color with a white throat. The flowers open in the morning and are wilted by early afternoon (G. Romano, University of Florida, personal communication 1996). The fruits are capsules, normally containing four seeds. The seeds are smoothish, pale brown or greenish-brown, 5 to 8 mm long, and oblong (G. Romano, University of Florida, personal communication 1995). The outer face is convex, and the inner two faces are flat, forming an angle (Wunderlin et al. 1980). *B. grandiflora* is the only morning glory vine found in scrub areas with a large blue flower (Wunderlin et al. 1980), but could be confused with *Stylisma villosa*. (USFWS, 1999)

Taxonomy

Bonamia grandiflora was originally named by Asa Gray in 1880 as *Breweria grandiflora*. In 1897, Hans Hallier transferred it to the genus *Bonamia*. There have been no other taxonomic treatments of the species since then (Myint and Ward 1968). (USFWS, 1999)

Historical Range

Florida bonamia is found in herbaria with collection locations in Volusia and Marion counties south through Lake, Orange, Polk, Highlands, Hardee, and west to Hillsborough, Manatee, and Sarasota counties (Institute for Systematic Botany 2006). Of these records, three are historical (Sarasota County in 1878, Manatee County in 1916, and Volusia County in 1900) and no recent records exist. (USFWS, 2017)

Current Range

The South Florida multispecies Recovery Plan (1999) indicated that Florida bonamia was found in Charlotte, Hardee, Highlands, Hillsborough, Lake, Manatee, Marion, Orange, Osceola, and Polk counties in Florida. (USFWS, 2017)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual, asexual (USFWS, 1999)

Lifespan

Adult: 3 or more years (USFWS, 1999)

Dependency on Other Individuals or Species

Adult: Insect pollinators (USFWS, 1999)

Key Resources Needed for Breeding

Adult: Fire (NatureServe, 2015)

Other Reproductive Information

Adult: Seedling survival rates are not known but are currently being investigated (G. Romano, University of Florida, personal communication 1996). Due to the nature of *Bonamia*'s growth, identifying seedlings from older individuals' stems that are actually connected to other stems below-ground can be difficult. However, it is possible to distinguish these two life phases. Hartnett and Richardson (1989) excavated several plants and found that the clumps of prostrate stems seen at the surface are all connected to a "large central and somewhat woody rootstock." They had no difficulty distinguishing such well-established older individuals from young single-stem plants that had grown from seed. According to Hartnett and Richardson (1989), fire stimulates seed production and germination as well as regrowth from clonal stems. The first season after a fire, clonal stem production is the greatest and then declines. However, seed production is greatest during the second season after a fire. The lag is probably due to the increased energy needed for regrowth following fire; seed production is postponed to conserve energy. New seed production replaces the seed banks that are often destroyed by fire. (USFWS, 1999)

Reproduction Narrative

Adult: *Bonamia grandiflora* grows for 3 or more years (50 FR 42068, Wunderlin et al. 1980), flowering from spring to summer (Small 1933). It has a mixed mating system; it is highly self-compatible, it can self-pollinate, and it can produce seeds without fertilization (G. Romano, University of Florida, personal communication 1998). Pollinators are essential, however, to ensure substantial seed production by self- as well as cross-fertilization. *Bonamia grandiflora* shows some inbreeding depression in selfed fruits and seeds but it does not appear to be enough to hinder the present populations (G. Romano, University of Florida, personal communication 1998). The seeds of *Bonamia* become dormant, but may not require dormancy to germinate, particularly if the seeds are planted immediately. Hartnett and Richardson (1989) observed that populations of this species have large seed banks of dormant seeds, mostly within 1 cm of the surface, distributed rather homogeneously, with no relation to the distribution of mature plants. The seedlings germinate throughout the summer until September. The necessity of fire for germination has not been studied; however, germination occurs on sites with sparse vegetation that have not burned recently (G. Romano, University of Florida, personal communication 1996). (USFWS, 1999)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Shrubland/chaparral (NatureServe, 2015)

Environmental Specificity

Adult: Moderate (inferred from NatureServe, 2015)

Habitat Narrative

Adult: *Bonamia grandiflora* is a scrub endemic of central Florida. All of its known populations occur within or near scrub or on the edge of scrub habitat in the white sands associated with the ancient Pleistocene dune systems of the central ridge system (Ward 1979). These sands are of the St. Lucie-Paola complex, highly porous, acidic (4.5 to 6.0) and containing few nutrients (Wunderlin et al. 1980). This substrate is associated with a sand pine scrub vegetation consisting of evergreen scrub oak (*Quercus myrtifolia* and *Q. germinata*) and sand pine (*Pinus clausa*) with openings between the trees and shrubs occupied by lichens and herbs. The openings are cleared by infrequent fires or by mechanical disturbance. *Bonamia grandiflora* is also known to live in disturbed areas near roadways and clearings caused by logging operations (50 FR 42068). This species is not found on altered soils such as the clay applied to logging roads (Miller 1989). As the scrub community reaches maturity, encroachment and shading from overstory pines and oaks cause the decline of this species as well as other associated endemics (Wunderlin et al. 1980). It seems that this species prefers an open canopy in full sunlight in order to avoid competition from the surrounding shrubs. For example, in Ocala NF, the *Bonamia* grows in a variety of growth stages of sand pine, but flowers profusely only in the open, sunny conditions of regeneration stands, and sparsely if at all in older stands. (USFWS, 1999)

Dispersal/Migration**Dependency on Other Individuals or Species for Dispersal**

Adult: Unknown

Dispersal/Migration Narrative

Adult: Dispersal occurs via biotic and abiotic factors - specific factors are unknown.

Population Information and Trends**Population Trends:**

Declining (NatureServe, 2015)

Species Trends:

Declining (USFWS, 2017)

Number of Populations:

66 (estimated) (USFWS, 2017)

Population Size:

1000 - 10,000 individuals (NatureServe, 2015)

Additional Population-level Information:

Turner et al.'s (2006) assessment included locality records over the past 20 years and more recent observations and it is not evident from this database whether Florida bonamia is still found at each of the 66 locations. Therefore, without a comprehensive range-wide survey it is not possible to evaluate the spatial distribution and trends in spatial distribution of this species. Nonetheless, it is likely that some of the historic locality records on private lands have been lost

due to habitat degradation (fire exclusion) and destruction. As a result, since its listing, the distribution of Florida bonamia has likely become more fragmented. (USFWS, 2017)

Population Narrative:

The status of Florida bonamia is largely unknown because repeated surveys have not been conducted at most known populations. However, available monitoring suggests that some populations may be in decline and others may be increasing, but this may be reflective of Florida bonamia's typical boom and subsequent decline following fire. Use of periodic prescribed fire appears to be essential in maintaining suitable habitat. Sixty-six locality records existed for Florida bonamia in 2006, but the number of extant populations is not known because recent range wide surveys have not been conducted. Twenty-five locality records occur on public lands. (USFWS, 2017)

Threats and Stressors

Stressor: Fire Suppression (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: The most pervasive threat to Florida bonamia on public land is habitat degradation due to fire suppression, although off-road vehicle use on the ONF is likely to result in adverse impacts. Florida bonamia on private lands are also threatened long-term with fire suppression, but habitat destruction is a more immediate concern in many locations. Recent range wide surveys have not been conducted for this species so evaluating threats due to fire suppression and habitat destruction is problematic because in many instances we do not know if previously identified populations still exist. Nonetheless, most land managing agencies in Florida are not able to use prescribed fire at the rates, frequency, and/or intensity needed to restore and maintain most of Florida's fire-adapted ecosystems (R. Mulholland, Florida Department of Environmental Protection, personal communication, 2007; Service 2006). Consequently, the difficulties land managing agencies currently face in implementing prescribed fires probably have resulted in the degradation of Florida bonamia habitat in some areas. Except for several privately owned conservation parcels, most other private landowners are unlikely to use habitat management techniques such as prescribed fire to maintain or enhance Florida bonamia habitat. At present, there are no incentives available that would encourage private landowners to undertake prescribed fire, especially for those who own relatively small parcels embedded in urban matrices. As a result, we believe that many locality records for Florida bonamia on nonconservation parcels in private ownership are threatened with habitat modification due to fire suppression. (USFWS, 2017)

Stressor: Urban Development (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Florida bonamia that occur on non-conservation private lands also are vulnerable to destruction due to urban development, such as construction of roads; installation of utilities and other infrastructure; and residential, commercial, and industrial construction. Florida bonamia on each private parcel is vulnerable to this threat at any time, however, we are not aware of any imminent loss of Florida bonamia due to development. (USFWS, 2017)

Stressor: Overutilization for commercial, recreational, scientific, or educational purposes (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Overutilization is not currently thought to be a significant risk factor to Florida bonamia; however, TNC reported two occasions of unauthorized plant removal on INC property since 1991 (TNC 2006). (USFWS, 2017)

Stressor: Disease or predation (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Florida bonamia may be affected by fungus, but no detailed investigations have been undertaken (Romano 1999). Insect herbivory has been observed, but it is not thought to be a significant risk to Florida bonamia (Romano 1999). (USFWS, 2017)

Stressor: Disease or predation (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Florida bonamia may be affected by fungus, but no detailed investigations have been undertaken (Romano 1999). Insect herbivory has been observed, but it is not thought to be a significant risk to Florida bonamia (Romano 1999). (USFWS, 2017)

Stressor: Inadequacy of existing regulatory mechanisms: Florida (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Existing regulatory mechanisms appear adequate to protect Florida bonamia on State and federally owned lands. Furthermore, we believe Florida bonamia on private conservation parcels are adequately protected because The Nature Conservancy would not authorize removal or destruction of Florida bonamia except for scientific or educational purposes. Even then, we anticipate that TNC would seek research permits from the Service to evaluate potential impacts resulting from proposed research or educational projects involving Florida bonamia. On private properties, Federal or State laws provide little protection for Florida bonamia. Since the majority of extant Florida bonamia populations occur on unprotected private lands, we conclude that existing regulatory mechanisms are inadequate to protect this species. e. Other natural or manmade factors affecting its continued existence: The 1999 South Florida Multi-species Recovery Plan (Service 1999) indicated that competition with non-native vegetation (e.g., cogon grass) may have been a management concern at ONF. Although ONF has an exotic vegetation management program in place, this threat is not entirely controlled and it is possible that unknown bonamia populations within the ONF may be affected by cogon grass or other exotic vegetation. We suspect that there are other locations containing Florida bonamia that also contain exotic vegetation, but we did not find current literature indicating this to be a significant management problem. (USFWS, 2017)

Recovery**Reclassification Criteria:**

Not applicable.

Delisting Criteria:

1. The species is secure in Ocala National Forest and low-intensity monitoring must continue after delisting (USFWS, 2008).
2. Secure and monitor at least three sites in Highlands county; three sites in Polk county; and at least two sites in other counties (USFWS, 2008).
3. Provide at least five years of demographic monitoring at each of the sites identified in numbers 1 and 2 (USFWS, 2008).

In South Florida: Delisting can be achieved when: (1) sites, within the historic range of *B. grandiflora*, are adequately protected from habitat loss, degradation, and fragmentation; (2) when these sites are managed to maintain the seral stage of xeric oak scrub communities to support *B. grandiflora*; and (3) when monitoring programs demonstrate that these sites support the appropriate numbers of self-sustaining populations, and those populations are stable throughout the historic range of the species. (USFWS, 1999)

Recovery Actions:

- Protect habitat through purchase and other means (including the Habitat Conservation Plan process for threatened animals in the Florida scrub habitat) (USFWS, 1996).
- Manage protected habitats (USFWS, 1996).
- Assess progress and plan post-recovery monitoring (USFWS, 1996).
- S1. Determine current distribution of *B. grandiflora*. Some portions of *B. grandiflora*'s range have been well surveyed (Ocala NF and the southern Lake Wales Ridge), yet a distribution has not been ascertained for this species. Lack of survey knowledge in much of its range makes defining distribution difficult. (USFWS, 1999)
- S2. Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or urban development. The remaining habitat is fragmented into small parcels and in many cases, isolated. For this reason, existing populations are in need of protection from a variety of threats. (USFWS, 1999)
- S3. Conduct research on life history characteristics of *B. grandiflora*. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species more specific biological information is needed.
- S4. Monitor existing populations of *B. grandiflora*. Develop monitoring protocol to assess population trends for *B. grandiflora*. Develop a quantitative description of the population structure of *B. grandiflora*. (USFWS, 1999)
- S5. Provide public information about *B. grandiflora*. It is important for the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and private landowners be appropriately informed about this species. Public outreach efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and

endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of *B. grandiflora* and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999) (USFWS, 1999)

- Habitat-level Recovery Actions: Prevent degradation of existing habitat. Restore areas to suitable habitat. Conduct habitat-level research projects. Monitor habitat/ecological processes. Provide public information about scrub and its unique biota. (USFWS, 1999)
- Recommendation for Future Action from 2017 5-Year Review: Revise the recovery criteria to establish measureable goals for demographic monitoring, including but not limited to: the number of populations that should be monitored, the demographic parameters that should be measured, and the demographic performance levels/rates that should be met. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: A range wide survey should be conducted to determine the size and location of extant Florida bonamia populations and assessment of historic locality records. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: Demographic monitoring of Florida bonamia populations should be initiated on public lands. Level 2 monitoring (Menges and Gordon 1996) includes sufficient detail to evaluate trends in population status over time. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: Management activities should be implemented on public lands that contain Florida bonamia, including prescribed fire at return intervals and intensities necessary to restore and/or maintain the various xeric vegetative communities that support this species. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: An assessment of mechanical vegetation management (e.g., roller chopping, mowing, gyro-tracking, logging, and chain-saw felling) is needed to evaluate the response of Florida bonamia to various management alternatives. These data should be collected concurrently with level 2 monitoring. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: Future land acquisition or other conservation measures should be taken to protect large Florida bonamia populations on unprotected lands. Protection should target bonamia populations that are sufficiently large, or could be large if adequately managed, as to be self-sustaining and viable long-term. (USFWS, 2017)
- Recommendation for Future Action from 2017 5-Year Review: Given the relatively large number of unprotected Florida bonamia populations, efforts should be explored to encourage private landowners to conserve and manage property known to contain this species.

SPECIES ACCOUNT: *Bonamia menziesii* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 11/10/1994; Pacific Region (R1) (USFWS, 2016)

Physical Description

A vine with twining branches up to 10 m (33 ft) long that are fuzzy when young. The leathery, oblong to oval leaves measure 3 to 9 cm (1.2 to 3.5 in) in length and 1 to 4-cm (0.4 to 1.6 in) in width. The upper leaf surface is usually hairless or covered with sparse hairs and the lower surface is covered with tomentose. The white to greenish funnel-shaped flowers are produced singly or in clusters of three on stalks with tiny bracts (modified leaves) at the base of each stalk. Stamens usually have glandular hairs at their bases. The flower has two styles, which are separate or partly fused. The fruits are tan or yellowish brown and contain one or two oval seeds imbedded in black pulp. This species is the only member of the genus that is endemic to the Hawaiian Islands and differs from other genera in the family by its two styles, longer stems and petioles, and rounder leaves (Wagner et al 1999; Austin 1990) (USFWS, 2016).

Taxonomy

A member of the Convolvulaceae (morning-glory) family (USFWS, 2016).

Historical Range

Historically, *Bonamia menziesii* was known from scattered locations on Kauai, the Koolau and Waianae Mountains of Oahu, several locations on Molokai, one location on west Maui, and eastern Hawaii (USFWS, 2016).

Current Range

Currently, this species is extant on Kauai, Oahu, Lanai, Maui, and Hawaii. *Bonamia menziesii* is known from many occurrences on these five islands with the largest number of extant individuals located on Kauai comprising several thousand individuals (USFWS, 2016).

Critical Habitat Designated

Yes; 2/27/2003.

Legal Description

On March 18, 2003 (Revised March 30, 2016), the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Bonamia menziesii* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes nine detailed critical habitat units (CHUs), in Maui County, Hawaii (81 FR 17790-18110).

On September 18, 2012, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Bonamia menziesii* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes 20 critical habitat units (CHUs), which encompass approximately 9,747 acres in Honolulu County, Hawaii (77 FR 57648-57862).

On July 2, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, for *Bonamia menziesii* (68 FR 39623 - 39722).

On February 27, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Bonamia menziesii* under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes two critical habitat units (CHUs), in Hawaii (68 FR 9116-9479).

Critical Habitat Designation

The critical habitat designation for *Bonamia menziesii* includes nine CHUs in Maui County, Hawaii with detailed unit information. There are also an unknown number of units on Lanai that contain this species (number of units is unknown because detailed unit descriptions for Lanai are not available) (81 FR 17790-18110).

Molokai—Lowland Dry—Unit 1 consists of 24 ac (10 ha) of privately owned land, in a small gulch northwest of Mahana, in west-central Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). Although Molokai—Lowland Dry—Unit 1 is not known to be occupied by *Bonamia menziesii*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Hibiscus brackenridgei*, *Kokia cookei*, or *Sesbania tomentosa*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Lowland Dry—Unit 2 consists of 589 ac (238 ha) of State land at Kamiloloa on the southern slopes of Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). Although Molokai—Lowland Dry—Unit 2 is not known to be occupied by *Bonamia menziesii*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Hibiscus brackenridgei*, *Kokia cookei*, or *Sesbania tomentosa*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Lowland Mesic—Unit 1 (and) *Palmeria dolei*—Unit 37—Lowland Mesic (and) *Pseudonestor xanthophrys*—Unit 37—Lowland Mesic This area consists of 3,489 ac (1,412 ha) of State land, and 5,281 ac (2,137 ha) of privately owned land, from Waianui Gulch to Mapulehu, in central Molokai. These units are occupied by the plants *Alectryon macrococcus*, *Ctenitis squamigera*, *Cyanea dunbariae*, *C. mannii*, *C. profuga*, *Cyperus fauriei*, *Cyrtandra filipes*, *Gouania hillebrandii*, *Labordia triflora*, *Neraudia sericea*, *Santalum haleakalae* var. *lanaiense*, *Schiedea lydgatei*, *S. sarmentosa*, *Silene alexandri*, *S. lanceolata*, *Spermolepis hawaiiensis*, and *Zanthoxylum hawaiiense*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Lowland Mesic—Unit 1 is not known to be occupied by *Asplenium dielerectum*, *Bonamia menziesii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea procera*, *C. solanacea*, *Diplazium molokaiense*, *Festuca molokaiensis*, *Flueggea neowawraea*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Melicope mucronulata*, *M. munroi*, *M. reflexa*, *Phyllostegia haliakalae*, *P. mannii*, *P. pilosa*, *Sesbania tomentosa*, *Stenogyne bifida*, or *Vigna o-wahuensis*, or the forest birds, the akohekohe (*Palmeria*

dolei) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 2 consists of 1,851 ac (749 ha) of State land at Keokea on the southern slopes of east Maui. This unit is occupied by the plants *Bonamia menziesii*, *Canavalia pubescens*, and *Hibiscus brackenridgei*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 2 is not known to be occupied by *Alectryon macrococcus*, *Bidens micrantha* ssp. *kalealaha*, *Cenchrus agrimonioides*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Flueggea neowawraea*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Solanum incompletum*, *Spermolepis hawaiiensis*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 3 consists of 188 ac (76 ha) of privately owned land, at Keauhou on the southern slopes of east Maui. This unit is occupied by the plant *Canavalia pubescens*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 3 is not known to be occupied by *Bidens micrantha* ssp. *kalealaha*, *Bonamia menziesii*, *Cenchrus agrimonioides*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Flueggea neowawraea*, *Hibiscus brackenridgei*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Solanum incompletum*, *Spermolepis hawaiiensis*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 4 consists of 1,266 ac (512 ha) of State land (including the Department of Land and Natural Resources) at Ahihi-Kinau Natural Area Reserve on the southern slopes of east Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). Although Maui—Lowland Dry—Unit 4 is not currently occupied by *Bidens micrantha* ssp. *kalealaha*, *Bonamia menziesii*, *Canavalia pubescens*, *Cenchrus agrimonioides*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Flueggea neowawraea*, *Hibiscus brackenridgei*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*,

Nototrichium humile, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Solanum incompletum*, *Spermolepis hawaiiensis*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Dry Cliff—Unit 5 (and) *Palmeria dolei*—Unit 29—Dry Cliff (and) *Pseudonestor xanthophrys*—Unit 29— Dry Cliff This area consists of 1,298 ac (525 ha) of State land, from Helu and across Olowalu to Ukumehame Gulch, on west Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 5). They are occupied by the plant *Tetramolopium capillare*, and contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Dry Cliff—Unit 5 is not currently occupied by the plants *Bonamia menziesii*, *Diplazium molokaiense*, *Hesperomannia arbuscula*, *Isodendron pyrifolium*, *Kadua laxiflora*, or *Neraudia sericea*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Dry Cliff—Unit 6 consists of 279 ac (113 ha) of State land along the east wall of Ukumehame Gulch on west Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 5). Although Maui—Dry Cliff— Unit 6 is not currently occupied by the plants *Bonamia menziesii*, *Diplazium molokaiense*, *Hesperomannia arbuscula*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Neraudia sericea*, or *Tetramolopium capillare*, we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 8 consists of 337 ac (137 ha) of State land along Kahakuloa ridge on the north side of west Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). Although Maui—Wet Cliff— Unit 8 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. conjuncta*, *Bonamia menziesii*, *Ctenitis squamigera*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Tetramolopium capillare*, we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their

small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

The critical habitat designation for *Bonamia menziesii* includes 20 CHUs in Honolulu County, Hawaii. The designated critical habitats include: Oahu - Lowland Dry - Unit 1, 2, 8, 9, 10, 11; Oahu--Lowland Mesic - Unit 1, 2, 3, 4, 5, 6, 7; Oahu - Dry cliff--Unit 1, 2, 3, 4, 6, 7a, 8 (77 FR 57648-57862).

Oahu—Lowland Dry—Unit 1 consists of 49 ac (20 ha) of State land and 53 ac (22 ha) of privately owned land in the Waianae Mountains, extending from Haili Gulch to Kawaipahai. This unit is occupied by the plants *Bidens amplexans*, *Hibiscus brackenridgei*, *Nototrichium humile*, and *Schiedea kealiae*, and includes the dry forest and shrubland, the moisture regime, and canopy, subcanopy and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 4). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Lowland Dry—Unit 1 is not known to be occupied by the plants *Achyranthes splendens* var. *rotundata*, *Bonamia menziesii*, *Chamaesyce celastroides* var. *kaenana*, *Euphorbia haeleeleana*, *Gouania meyenii*, *G. vitifolia*, *Isodendron pyriformis*, *Melanthera tenuifolia*, *Neraudia angulata*, *Pleomele forbesii*, *Schiedea hookeri*, or *Spermolepis hawaiiensis*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Lowland Mesic—Unit 1 consists of 3,565 ac (1,443 ha) of State land, 583 ac (236 ha) of City and County of Honolulu land, 22 ac (9 ha) of Federal land, and 277 ac (112 ha) of privately owned land in the lowland mesic ecosystem in the Waianae Mountains, encompassing a large area including the north slopes of Mt. Kaala, from the Pahole NAR to the Kaala NAR, and south to the Waianae Kai Forest Reserve (FR). This unit is occupied by the plants *Abutilon sandwicense*, *Alectryon macrococcus*, *Bonamia menziesii*, *Cenchrus agrimonoides*, *Chamaesyce herbstii*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Cyanea acuminata*, *C. calycina*, *C. grimesiana* ssp. *grimesiana*, *C. grimesiana* ssp. *obatae*, *C. longiflora*, *C. superba*, *Cyrtandra dentata*, *Delissea subcordata*, *Diellia falcata*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Euphorbia haeleeleana*, *Flueggea neowawraea*, *Hesperomannia arborescens*, *H. arbuscula*, *Hibiscus brackenridgei*, *Isodendron laurifolium*, *I. longifolium*, *Kadua degeneri*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *M. pallida*, *Neraudia angulata*, *Nototrichium humile*, *Phyllostegia kaalaensis*, *Platydesma cornuta* var. *decurrens*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Schiedea hookeri*, *S. kaalae*, *S. nuttallii*, *S. obovata*, and *Viola chamissoniana* ssp. *chamissoniana*, and includes the mesic forest and shrubland, the moisture regime, and canopy, subcanopy and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 4). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Lowland Mesic—Unit 1 is not known to be occupied by the plants *Chamaesyce celastroides* var. *kaenana*, *Cyanea pinnatifida*, *Cyperus pennatifolius*, *Diellia unisora*, *Diplazium molokaiense*, *Eugenia koolauensis*, *Gardenia mannii*, *Gouania meyenii*, *G. vitifolia*, *Kadua coriacea*, *K. parvula*, *Labordia cyrtandrae*, *Melicope saint-johnii*, *Phyllostegia hirsuta*, *P. mollis*, *P. parviflora*, *Plantago princeps*, *Sanicula maritima*, *Silene perlmannii*, *Solanum*

sandwicense, *Stenogyne kanehoana*, *Tetramolopium lepidotum* ssp. *lepidotum*, or *Urera kaalae*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 1 consists of 49 ac (20 ha) in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the rim of Makua Valley. This unit is on State land within the Pahole Natural Area Reserve, and includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). This unit is occupied by the plants *Alectryon macrococcus*, *Cenchrus agrimonoides*, *Chamaesyce herbstii*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Kadua degeneri*, *Plantago princeps* var. *princeps*, and *Schiedea obovata*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 1 is not currently occupied by *Abutilon sandwicense*, *Achyranthes splendens* var. *rotundata*, *Bonamia menziesii*, *Chamaesyce kuwaleana*, *Diellia falcata*, *D. unisora*, *Dubautia herbertobatae*, *Eragrostis fosbergii*, *Flueggea neowawraea*, *Gouania meyenii*, *G. vitifolia*, *Isodendron laurifolium*, *I. pyriform*, *Kadua parvula*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *M. saint-johnii*, *Neraudia angulata*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Platydesma cornuta* var. *decurrens*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Sanicula mariversa*, *Schiedea hookeri*, *S. trinervis*, *Silene lanceolata*, *S. perlmannii*, *Spermolepis hawaiiensis*, *Tetramolopium filiforme*, *T. lepidotum* ssp. *lepidotum*, or *Viola chamissoniana* ssp. *chamissoniana*, we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Lowland Dry—Unit 2 consists of 29 ac (12 ha) in the lowland dry ecosystem in the Waianae Mountains, on Federal land within Kaena Point State Park. This unit is occupied by the plants *Bonamia menziesii*, *Melanthera tenuifolia*, *Nototrichium humile*, and *Pleomele forbesii*, and includes the dry forest and shrubland, the moisture regime, and canopy, subcanopy and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 4). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Lowland Dry—Unit 2 is not known to be occupied by the plants *Achyranthes splendens* var. *rotundata*, *Bidens amplexans*, *Chamaesyce celastroides* var. *kaenana*, *Euphorbia haeleeleana*, *Gouania meyenii*, *G. vitifolia*, *Hibiscus brackenridgei*, *Isodendron pyriform*, *Neraudia angulata*, *Schiedea hookeri*, *S. kealiae*, or *Spermolepis hawaiiensis*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Lowland Mesic—Unit 2 consists of 1,063 ac (430 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Puuhapapa south to Puukaua. This area was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit is occupied by the plants *Abutilon sandwicense*, *Alectryon macrococcus*, *Cenchrus agrimonoides*, *Chamaesyce herbstii*, *Cyanea calycina*, *C. grimesiana* ssp. *obatae*, *Delissea subcordata*, *Diellia falcata*, *Gardenia mannii*, *Phyllostegia hirsuta*, *P. kaalaensis*, *P. mollis*, *Platydesma cornuta* var. *decurrens*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Schiedea hookeri*, *S. kaalae*, *Solanum sandwicense*, *Stenogyne kanehoana*, and *Urera kaalae*, and includes the mesic forest and shrubland, the moisture regime, and canopy, subcanopy and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 4). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Lowland Mesic—Unit 2 is not known to be occupied by the plants *Bonamia menziesii*, *Chamaesyce celastroides* var. *kaenana*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Cyanea acuminata*, *C. grimesiana* ssp. *grimesiana*, *C. longiflora*, *C. pinnatifida*, *C. superba*, *Cyperus pennatifolius*, *Cyrtandra dentata*, *Diellia unisora*, *Diplazium molokaiense*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Eugenia koolauensis*, *Euphorbia haeleeleana*, *Flueggea neowawraea*, *Gouania meyenii*, *G. vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Hibiscus brackenridgei*, *Isodendron laurifolium*, *I. longifolium*, *Kadua coriacea*, *K. degeneri*, *K. parvula*, *Labordia cyrtandrae*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *M. pallida*, *M. saint-johnii*, *Neraudia angulata*, *Nototrichium humile*, *Phyllostegia parviflora*, *Plantago princeps*, *Sanicula mariversa*, *Schiedea nuttallii*, *S. obovata*, *Silene perlmanii*, *Tetramolopium lepidotum* ssp. *lepidotum*, or *Viola chamissoniana* ssp. *chamissoniana*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 2 consists of 320 ac (130 ha) of State land and 91 ac (37 ha) of City and County of Honolulu land in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the ridge from Keaau to Ohikilolo. This unit is almost entirely within the Makua Keaau Forest Reserve, and includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). Dry Cliff—Unit 2 is occupied by the plants *Abutilon sandwicense*, *Alectryon macrococcus*, *Dubautia herbstobatae*, *Gouania vitifolia*, *Kadua parvula*, *Lepidium arbuscula*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *Nototrichium humile*, *Peucedanum sandwicense*, *Platydesma cornuta* var. *decurrens*, *Pleomele forbesii*, *Sanicula mariversa*, *Schiedea hookeri*, *Tetramolopium filiforme*, and *Viola chamissoniana* ssp. *chamissoniana*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 2 is not currently occupied by *Achyranthes splendens* var. *rotundata*, *Bonamia menziesii*, *Cenchrus agrimonoides*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *D. unisora*, *Eragrostis fosbergii*, *Flueggea neowawraea*, *Gouania meyenii*, *Isodendron laurifolium*, *I. pyriforme*, *Kadua degeneri*, *Korthalsella degeneri*, *Lipochaeta lobata* var. *leptophylla*, *Melicope saint-johnii*, *Neraudia angulata*, *Phyllostegia kaalaensis*, *Plantago princeps*, *Pteralyxia macrocarpa*, *Schiedea obovata*, *S. trinervis*, *Silene lanceolata*, *S. perlmanii*, *Spermolepis hawaiiensis*, or *Tetramolopium lepidotum*

ssp. *lepidotum*, we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Lowland Mesic—Unit 3 consists of 353 ac (143 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Pohakea Pass to Kaiakuakai Gulch. This area was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit is occupied by the plants *Alectryon macrococcus*, *Cenchrus agrimonioides*, *Delissea subcordata*, *Diellia falcata*, *D. unisora*, *Hesperomannia arbuscula*, *Melicope saint-johnii*, *Phyllostegia mollis*, *P. parviflora*, *Plantago princeps*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Schiedea kaalae*, *Silene perlmanii*, and *Urera kaalae*, and includes the mesic forest and shrubland, the moisture regime, and canopy, subcanopy and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Lowland Mesic—Unit 3 is not known to be occupied by the plants *Abutilon sandwicense*, *Bonamia menziesii*, *Chamaesyce celastroides* var. *kaenana*, *C. herbstii*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Cyanea acuminata*, *C. calycina*, *C. grimesiana* ssp. *grimesiana*, *C. grimesiana* ssp. *obatae*, *C. longiflora*, *C. pinnatifida*, *C. superba*, *Cyperus pennatifolius*, *Cyrtandra dentata*, *Diplazium molokaiense*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Eugenia koolauensis*, *Euphorbia haeleeleana*, *Flueggea neowawraea*, *Gardenia mannii*, *Gouania meyenii*, *G. vitifolia*, *Hesperomannia arborescens*, *Hibiscus brackenridgei*, *Isodendron laurifolium*, *I. longifolium*, *Kadua coriacea*, *K. degeneri*, *K. parvula*, *Labordia cyrtandrae*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *M. pallida*, *Neraudia angulata*, *Nototrichium humile*, *Phyllostegia hirsuta*, *P. kaalaensis*, *Platydesma cornuta* var. *decurrens*, *Sanicula mariversa*, *Schiedea hookeri*, *S. nuttallii*, *S. obovata*, *Solanum sandwicense*, *Stenogyne kanehoana*, *Tetramolopium lepidotum* ssp. *lepidotum*, or *Viola chamissoniana* ssp. *chamissoniana*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 3 consists of 349 ac (141 ha) of City and County of Honolulu land and 101 ac (41 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the eastern rim of Makaha Valley along Kamaileunu Ridge. This unit is partially within the Waianae Kai Forest Reserve, and includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). This unit is occupied by the plants *Abutilon sandwicense*, *Alectryon macrococcus*, *Bonamia menziesii*, *Diellia falcata*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Flueggea neowawraea*, *Gouania meyenii*, *Isodendron laurifolium*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *Neraudia angulata*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Schiedea hookeri*, *Silene lanceolata*, *Tetramolopium filiforme*, and *Viola chamissoniana* ssp. *chamissoniana*. This unit also contains unoccupied habitat that is essential to the conservation of

these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 3 is not currently occupied by *Achyranthes splendens* var. *rotundata*, *Cenchrus agrimonoides*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia unisora*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua degeneri*, *K. parvula*, *Melicope saint-johnii*, *Plantago princeps*, *Platydesma cornuta* var. *decurrens*, *Sanicula maritima*, *Schiedea obovata*, *S. trinervis*, *Silene perlmannii*, *Spermolepis hawaiiensis*, or *Tetramolopium lepidotum* ssp. *lepidotum*, we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Lowland Mesic—Unit 4 consists of 20 ac (8 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, between the Waipilopilo and Hanaimoa gulches, on State-owned land within the Hauula Forest Reserve. This unit includes the lowland mesic forest and shrubland, the moisture regime, and canopy, subcanopy and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 4). Although Oahu—Lowland Mesic—Unit 4 is not known to be occupied by the plants *Alectryon macrococcus*, *Bonamia menziesii*, *Chamaesyce celastroides* var. *kaenana*, *Ctenitis squamigera*, *Cyanea acuminata*, *C. calycina*, *C. crispa*, *C. grimesiana* ssp. *grimesiana*, *C. lanceolata*, *C. longiflora*, *C. truncata*, *Cyrtandra dentata*, *C. polyantha*, *Delissea subcordata*, *Diellia erecta*, *D. falcata*, *Eugenia koolauensis*, *Gardenia mannii*, *Hesperomannia arborescens*, *Isodendron laurifolium*, *I. longifolium*, *Kadua coriacea*, *Labordia cyrtandrae*, *Lobelia monostachya*, *Melicope lydgatei*, *M. saint-johnii*, *Phyllostegia hirsuta*, *P. mollis*, *P. parviflora*, *Plantago princeps*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Schiedea kaalae*, *S. nuttallii*, *Solanum sandwicense*, *Tetraplasandra gymnocarpa*, or *T. lydgatei*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 4 consists of 24 ac (10 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along Kauaopuu ridge, which divides Waianae Kai and Lualualei valleys. This unit is partially within the Waianae Kai Forest Reserve, and includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). This unit is occupied by the plants *Alectryon macrococcus*, *Chamaesyce kuwaleana*, and *Spermolepis hawaiiensis*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 4 is not currently occupied by *Abutilon sandwicense*, *Achyranthes splendens* var. *rotundata*, *Bonamia menziesii*, *Cenchrus agrimonoides*, *Chamaesyce herbstii*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *D. unisora*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Flueggea neowawraea*, *Gouania meyenii*, *G. vitifolia*, *Isodendron laurifolium*, *I. pyriformis*, *Kadua degeneri*, *K. parvula*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *M. saintjohnii*, *Neraudia angulata*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia*

kaalaensis, *Plantago princeps*, *Platydesma cornuta* var. *decurrans*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Sanicula mariversa*, *Schiedea hookeri*, *S. obovata*, *S. trinervis*, *Silene lanceolata*, *S. perlmannii*, *Tetramolopium filiforme*, *T. lepidotum* ssp. *lepidotum*, or *Viola chamissoniana* ssp. *chamissoniana*, we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Lowland Dry—Unit 8 consists of 96 ac (40 ha) of privately owned land and 3 ac (1 ha) of State land as part of the old railroad right-of-way in the lowland dry ecosystem, at the Kalaeloa Barber's Point Harbor area. The area was occupied by *Chamaesyce skottsbergii* var. *skottsbergii* at the time the species was listed (see 47 FR 36846, August 24, 1982), although it is not currently known to be occupied by *C. skottsbergii* var. *skottsbergii*. The species was last observed on this site in 1989. However, even though the site is degraded, during two recent field surveys (November 2011 and June 2012), we verified that the area being designated contains the physical and biological features of the lowland dry ecosystem and the coral outcrop substrate that is essential for the conservation of *C. skottsbergii* var. *skottsbergii* (see Tables 4 and 5). Based on the field visits, the boundaries of the unit were revised to remove areas that were modified by construction and excavation activities, and do not contain essential features. This resulted in the reduction of the unit from the 292 ac (118 ha) that were originally proposed to the 99 ac (40 ha) that are included in this final rule. These physical and biological features are essential to the conservation of the species in this location because the conservation of the species requires reestablishment of populations of this species in areas where it once occurred. Based on our evaluation of the conservation needs for *Chamaesyce skottsbergii* var. *skottsbergii*, a plant requiring another individual for pollination (obligate-outcrosser) and living 10 years or less (short-lived perennial), we will need 7 to 8 populations containing a total of 10,000 mature individuals with at least 1,000 mature individuals per population in order to recover the species. The numbers of individuals and numbers of populations calculated for the 4 Lowland Dry units for akoko was based on our analysis (white paper) "Recovery Needs and Strategy for Akoko", June 20, 2012. This analysis incorporated data from the Recovery Plan for *C. skottsbergii* var. *skottsbergii* and *Achyranthes splendens* var. *rotundata* (1993), surveys/species reports from 1979, 1981, 1984, and 2012, the Revised Recovery Objective Guidelines as determined by the Hawaii and Pacific Plants Recovery Coordinating Committee (HPPRCC) 2011, and plant genetics information from Guerrant et al. (2004, pp. 419–441) and Neel and Cummings (2003). Currently, *Chamaesyce skottsbergii* var. *skottsbergii* is found in 2 occurrences in the lowland dry ecosystem on the Ewa Plain in southwestern Oahu, totaling approximately 200 wild individuals and 600 outplanted individuals (Guinther and Withrow 2008, pp. 6, 9–10; Whistler 2008, pp. 7–9; U.S. Navy et al. 2012, pp. 19–20). In our review of areas on the Ewa Plain where the features essential to the conservation of this species are still present, we were only able to find four sites that still had the essential features; were not already modified by construction, development, or excavation activities; were large enough to provide habitat for at least one self-sustaining population; and provided adequate distribution across the historical range of the species. To the extent that portions of this unit may not have been occupied at the time of listing, they are essential to the conservation of the species because, as discussed above, conservation of this species will require establishment of additional populations and this is one of the few suitable locations. Oahu—Lowland Dry—Unit 8 is one of four locations included in this final critical habitat designation that is essential to the conservation of *Chamaesyce skottsbergii* var.

skottsbergii. It was previously occupied by the species and still contains the features essential to its conservation, such as the unique coral outcrop substrate. Oahu—Lowland Dry—Unit 8 may be able to provide for two separate populations of *C. skottsbergii* var. *skottsbergii*. A designation limited to areas presently occupied by the species would be inadequate to ensure the conservation of the species because the one occupied unit (only Oahu—Lowland Dry—Unit 11, see below, is occupied by wild individuals; Oahu—Lowland Dry—Unit 9 contains outplanted, propagated individuals) would not provide enough area to support 7 to 8 populations needed for recovery, as determined in the “Recovery Needs and Strategy for *Chamaesyce skottsbergii* var. *skottsbergii* (Ewa Plains akoko)” (Service 2012, entire). There are no other geographic areas that are both undeveloped and contain the species-specific PCE of coral outcrop substrate. Oahu—Lowland Dry—Unit 8 is not known to be occupied by *Bidens amplexans*, one of the plants being listed in this rule as endangered. However, we have determined the lands within this unit are essential for the conservation of this lowland dry species, because they provide the habitat necessary for the reestablishment of wild populations within the historical ranges of the species (see Table 4). Due to their small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery. Additionally, Oahu—Lowland Dry—Unit 8 was not occupied by the endangered plants *Achyranthes splendens* var. *rotundata*, *Bonamia menziesii*, *Chamaesyce celastroides* var. *kaenana*, *Euphorbia haelealeana*, *Gouania meyenii*, *G. vitifolia*, *Hibiscus brackenridgei*, *Isodendron pyriformis*, *Melanthera tenuifolia*, *Neraudia angulata*, *Nototrichium humile*, *Schiedea hookeri*, *S. kealiae*, or *Spermolepis hawaiiensis* (see 51 FR 10518, March 26, 1986, and 68 FR 35950, June 17, 2003, for previous Federal actions), at the time they were listed, and is not currently known to be occupied by these 14 species. However, we have determined the lands within this unit are essential for the conservation of these lowland dry species, because they provide the habitat necessary for the reestablishment of wild populations within the historical ranges of the species (see Table 4). Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Lowland Mesic—Unit 5 consists of 29 ac (12 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, in Maakua Gulch and ridge; is State-owned; and within the Hauula FR. This unit includes the mesic forest and shrubland, the moisture regime, and canopy, subcanopy and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 4). Although Oahu—Lowland Mesic—Unit 5 is not known to be occupied by the plants *Alectryon macrococcus*, *Bonamia menziesii*, *Chamaesyce celastroides* var. *kaenana*, *Ctenitis squamigera*, *Cyanea acuminata*, *C. calycina*, *C. crispa*, *C. grimesiana* ssp. *grimesiana*, *C. lanceolata*, *C. longiflora*, *C. truncata*, *Cyrtandra dentata*, *C. polyantha*, *Delissea subcordata*, *Diellia erecta*, *D. falcata*, *Eugenia koolauensis*, *Gardenia mannii*, *Hesperomannia arborescens*, *Isodendron laurifolium*, *I. longifolium*, *Kadua coriacea*, *Labordia cyrtandrae*, *Lobelia monostachya*, *Melicope lydgatei*, *M. saint-johnii*, *Phyllostegia hirsuta*, *P. mollis*, *P. parviflora*, *Plantago princeps*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Schiedea kaalae*, *S. nuttallii*, *Solanum sandwicense*, *Tetraplasandra gymnocarpa*, or *T. lydgatei*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 6 consists of 149 ac (60 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Lualualei Valley from Puukanehoa to Puukaua. This area was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). The unit is occupied by the plants *Cenchrus agrimonoides*, *Diellia unisora*, *Flueggea neowawraea*, *Lepidium arbuscula*, *Lobelia niihauensis*, *Melicope saintjohnii*, *Neraudia angulata*, *Plantago princeps*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, and *Tetramolopium lepidotum* ssp. *lepidotum*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 6 is not currently occupied by *Abutilon sandwicense*, *Achyranthes splendens* var. *rotundata*, *Alectryon macrococcus*, *Bonamia menziesii*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Gouania meyenii*, *G. vitifolia*, *Isodendron laurifolium*, *I. pyrifolium*, *Kadua degeneri*, *K. parvula*, *Korthalsella degeneri*, *Lipochaeta lobata* var. *leptophylla*, *Melanthera tenuifolia*, *Melicope makahae*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Platydesma cornuta* var. *decurrens*, *Sanicula mariversa*, *Schiedea hookeri*, *S. obovata*, *S. trinervis*, *Silene lanceolata*, *S. perlmanii*, *Spermolepis hawaiiensis*, *Tetramolopium filiforme*, or *Viola chamissoniana* ssp. *chamissoniana*, we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Lowland Dry—Unit 9 consists of 17 ac (7 ha) of City and County land, 3 ac (1 ha) of privately owned land, 1 ac (0.5 ha) of State land, and 16 ac (6 ha) of Federal (Pearl Harbor NWR) land in the lowland dry ecosystem at Kalaehoa. This unit was not occupied by *Chamaesyce skottsbergii* var. *skottsbergii* at the time the species was listed (see 47 FR 36846, August 24, 1982). As noted in the description of Oahu—Lowland Dry—Unit 8 above, we have determined that for *C. skottsbergii* var. *skottsbergii*, a plant requiring another individual for pollination (obligate-outcrosser) and living 10 years or less (short-lived perennial), we will need 7 to 8 populations containing at least a total of 10,000 mature individuals with at least 1,000 mature individuals per population in order to recover the species (HPPRCC 2011; Guerrant et al. 2004, pp. 419–441; Neel and Cummings 2003). Oahu—Lowland Dry—Unit 9 is one of the four locations included in this final critical habitat designation that is essential to the conservation of *C. skottsbergii* var. *skottsbergii*; please see discussion of the importance of these areas on the Ewa Plain, above, in the description of Oahu—Lowland Dry—Unit 8. This unit is currently occupied by recently outplanted individuals of *Chamaesyce skottsbergii* var. *skottsbergii*, and includes the dry forest and shrubland, the moisture regime, and canopy, subcanopy and understory native plant species identified as physical or biological features in the lowland dry ecosystem, and the unique PCEs for the species *C. skottsbergii* var. *skottsbergii* (see Tables 4 and 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing populations. Oahu—Lowland Dry—Unit 9 may be able to provide for one separate population of *C. skottsbergii* var. *skottsbergii*. Oahu—Lowland Dry—Unit 9 is not known to be occupied by another plant being listed as endangered in this rule, *Bidens amplexans*. We have determined this area to be essential for the conservation and recovery of both of these lowland dry species because it provides the habitat necessary for the

reestablishment of wild populations within the historical ranges of the species (see Table 4). Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery. A designation limited to areas presently occupied by the species would be inadequate because the one occupied unit (only Oahu—Lowland Dry—Unit 11, see below, is occupied by wild individuals; Oahu—Lowland Dry—Unit 9 contains outplanted, propagated individuals) would not provide enough area to support 7 to 8 populations needed for recovery, as determined in the “Recovery Needs and Strategy for *Chamaesyce skottsbergii* var. *skottsbergii* (Ewa Plains akoko)” (Service 2012, entire). There are no other geographic areas that are both undeveloped and contain the species-specific PCE of coral outcrop substrate. Additionally, Oahu—Lowland Dry—Unit 9 was not occupied by the endangered plants *Achyranthes splendens* var. *rotundata*, *Bonamia menziesii*, *Chamaesyce celastroides* var. *kaenana*, *Euphorbia haeleeleana*, *Gouania meyenii*, *G. vitifolia*, *Hibiscus brackenridgei*, *Isodendron pyriformis*, *Melanthera tenuifolia*, *Neraudia angulata*, *Nototrichium humile*, *Schiedea hookeri*, *S. kealiae*, or *Spermolepis hawaiiensis* (see 51 FR 10518, March 26, 1986 and 68 FR 35950, June 17, 2003), at the time they were listed, and is not currently known to be occupied by these 14 species. We have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species (see Table 4). Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery. Oahu—Lowland Dry—Unit 10 consists of 43 ac (17 ha) of State land (DHHL) in the lowland dry ecosystem at Kalaeloa. This unit was not occupied by *Chamaesyce skottsbergii* var. *skottsbergii* at the time the species was listed (see 47 FR 36846, August 24, 1982); however, *C. skottsbergii* var. *skottsbergii* was observed in the area in 1998, but has not been re-observed since that time. As noted in the description of Oahu—Lowland Dry—Unit 8, above, we have determined that *C. skottsbergii* var. *skottsbergii*, a plant requiring another individual for pollination (obligate outcrosser) and living 10 years or less (short-lived perennial), we will need 7 to 8 populations containing a total of 10,000 mature individuals with at least 1,000 mature individuals per population in order to recover the species (HPPRCC 2011; Guerrant et al. 2004, pp. 419–441; Neel and Cummings 2003). Oahu—Lowland Dry—Unit 10 is one of the four locations included in this final critical habitat designation that is essential to the conservation of *C. skottsbergii* var. *skottsbergii*; please see discussion of the importance of these areas on the Ewa Plain, above, in the description of Oahu—Lowland Dry—Unit 8. This unit was previously occupied by *Chamaesyce skottsbergii* var. *skottsbergii* and still contains the features essential to its conservation, such as the unique coral outcrop substrate (see Tables 4 and 5). In the future, Oahu—Lowland Dry—Unit 10 may be able to provide for one separate population of *C. skottsbergii* var. *skottsbergii*. A designation limited to areas presently occupied by the species would be inadequate to ensure the conservation of the species, because the one occupied unit (Oahu—Lowland Dry—Unit 11) would not provide enough area to support 7 to 8 populations needed for recovery, as determined in the “Recovery Needs and Strategy for *Chamaesyce skottsbergii* var. *skottsbergii* (Ewa Plains akoko)” (Service 2012, entire). There are no other geographic areas that are both undeveloped and contain the species-specific PCE of coral outcrop substrate.

Oahu—Lowland Mesic—Unit 6 (and) Oceanic Hawaiian Damselfly—Unit 1—Lowland Mesic This area consists of 12 ac (5 ha) State land and 235 ac (95 ha) of privately owned land in the lowland mesic ecosystem on the windward side of the Koolau Mountains, inland of Kaaawa Point, and is partially within Ahupuaa O Kahana State Park. This area is occupied by the plants *Cyanea*

acuminata, *C. crispa*, *C. truncata*, *Gardenia mannii*, *Pteralyxia macrocarpa*, and *Schiedea kaalae*; and the invertebrate, the oceanic Hawaiian damselfly. This area includes the lowland mesic forest and shrubland, the moisture regime, and canopy, subcanopy and understory native plant species identified as physical or biological features in the lowland mesic ecosystem, as well as unique PCEs for the damselfly (see Tables 4 and 5). Because the streams and upland foraging and cover areas required by the oceanic Hawaiian damselfly are dispersed in the lowland mesic ecosystem, the lowland mesic ecosystem's physical or biological features are essential to the damselfly because they provide for the proper ecological functioning of this ecosystem. This area also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although this area is not known to be occupied by the plants *Alectryon macrococcus*, *Bonamia menziesii*, *Chamaesyce celastroides* var. *kaenana*, *Ctenitis squamigera*, *Cyanea calycina*, *C. grimesiana* ssp. *grimesiana*, *C. lanceolata*, *C. longiflora*, *Cyrtandra dentata*, *C. polyantha*, *Delissea subcordata*, *Diellia erecta*, *D. falcata*, *Eugenia koolauensis*, *Hesperomannia arborescens*, *Isodendron laurifolium*, *I. longifolium*, *Kadua coriacea*, *Labordia cyrtandrae*, *Lobelia monostachya*, *Melicope lydgatei*, *M. saint-johnii*, *Phyllostegia hirsuta*, *P. mollis*, *P. parviflora*, *Plantago princeps*, *Pleomele forbesii*, *Schiedea nuttallii*, *Solanum sandwicense*, *Tetraplasandra gymnocarpa*, or *T. lydgatei*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 7a consists of 68 ac (27 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley to Pohakea. This area was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4), and is occupied by the plants *Flueggea neowawraea*, *Kadua parvula*, *Melicope saint-johnii*, *Plantago princeps*, *Platydesma cornuta* var. *decurrens*, *Pleomele forbesii*, *Silene perlmannii*, and *Viola chamissoniana* ssp. *chamissoniana*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 7a is not currently occupied by *Abutilon sandwicense*, *Achyranthes splendens* var. *rotundata*, *Alectryon macrococcus*, *Bonamia menziesii*, *Cenchrus agrimonioides*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *D. unisora*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Gouania meyenii*, *G. vitifolia*, *Isodendron laurifolium*, *I. pyriformis*, *Kadua degeneri*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *Neraudia angulata*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Pteralyxia macrocarpa*, *Sanicula mariversa*, *Schiedea hookeri*, *S. obovata*, *S. trinervis*, *Silene lanceolata*, *Spermolepis hawaiiensis*, *Tetramolopium filiforme*, or *T. lepidotum* ssp. *lepidotum*, we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery. Oahu—Dry Cliff—Unit 7b consists of 38 ac (16 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the

rim of Lualualei Valley at Palikea. This area was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). Although Oahu—Dry Cliff—Unit 7b is not currently occupied by *Abutilon sandwicense*, *Achyranthes splendens* var. *rotundata*, *Alectryon macrococcus*, *Bonamia menziesii*, *Cenchrus agrimonoides*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *D. unisora*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Flueggea neowawraea*, *Gouania meyenii*, *G. vitifolia*, *Isodendrion laurifolium*, *I. pyriformis*, *Kadua degeneri*, *K. parvula*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Lobelia niihauensis*, *Melanthera tenuifolia*, *Melicope makahae*, *M. saintjohnii*, *Neraudia angulata*, *Nototrichium humile*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Plantago princeps*, *Platydesma cornuta* var. *decurrens*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, *Sanicula mariversa*, *Schiedea hookeri*, *S. obovata*, *S. trinervis*, *Silene lanceolata*, *S. perlmanii*, *Spermolepis hawaiiensis*, *Tetramolopium filiforme*, *T. lepidotum* ssp. *lepidotum*, or *Viola chamissoniana* ssp. *chamissoniana*, we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Lowland Dry—Unit 10 (43 acres) is not known to be occupied by another plant being listed as endangered in this rule, *Bidens amplexans*. However, we have determined this area to be essential for the conservation and recovery of this lowland dry species, because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species (see Table 4). Due to its small numbers of individuals or low population sizes, this species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery. Additionally, Oahu—Lowland Dry—Unit 10 was not occupied by the endangered plants *Achyranthes splendens* var. *rotundata*, *Bonamia menziesii*, *Chamaesyce celastroides* var. *kaenana*, *Euphorbia haeleeleana*, *Gouania meyenii*, *G. vitifolia*, *Hibiscus brackenridgei*, *Isodendrion pyriformis*, *Melanthera tenuifolia*, *Neraudia angulata*, *Nototrichium humile*, *Schiedea hookeri*, *S. kealiae*, or *Spermolepis hawaiiensis* (see 51 FR 10518, March 26, 1986, and 68 FR 35950, June 17, 2003), at the time they were listed, and is not currently known to be occupied by these 14 species. We have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species (see Table 4). Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery. We are aware of the planned development of the Kalaeloa Solar One and Two alternative energy facilities (DHHL 2011, in litt.) on lands within, and adjacent to, this unit. The facilities, which are independently owned and operated, are being developed for the purpose of reducing Oahu's dependence on fossil-fuel for power generation. The January 2011 Draft Environmental Assessment prepared for this project states that no Federal funding or Federal authorizations will be required to develop this facility. We are also unaware of any Federal nexus for this project. Accordingly, since a critical habitat designation only triggers a consultation under section 7(a)(2) of the Act for activities that have a Federal nexus, the designation of this unit as critical habitat is not anticipated to have an impact on this project as proposed.

Oahu—Lowland Mesic—Unit 7 consists of 681 ac (276 ha) of State land, 129 ac (52 ha) of City and County of Honolulu land, and 852 ac (345 ha) of privately-owned land in the lowland mesic ecosystem on the leeward side of the Koolau Mountains, on Waialae Nui ridge. This unit is occupied by the plants *Bonamia menziesii*, *Cyanea acuminata*, *C. grimesiana* ssp. *grimesiana*, *C. lanceolata*, *Cyrtandra polyantha*, *Diellia erecta*, *Lobelia monostachya*, *Pleomele forbesii*, *Pteralyxia macrocarpa*, and *Tetraplasandra lydgatei*, and includes the mesic forest and shrubland, the moisture regime, and canopy, subcanopy and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 4). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Lowland Mesic—Unit 7 is not known to be occupied by the plants *Alectryon macrococcus*, *Chamaesyce celastroides* var. *kaenana*, *Ctenitis squamigera*, *Cyanea calycina*, *C. crispa*, *C. longiflora*, *C. truncata*, *Cyrtandra dentata*, *Delissea subcordata*, *Diellia falcata*, *Eugenia koolauensis*, *Gardenia mannii*, *Hesperomannia arborescens*, *Isodendron laurifolium*, *I. longifolium*, *Kadua coriacea*, *Labordia cyrtandrae*, *Melicope lydgatei*, *M. saint-johnii*, *Phyllostegia hirsuta*, *P. mollis*, *P. parviflora*, *Plantago princeps*, *Schiedea kaalae*, *S. nuttallii*, *Solanum sandwicense*, or *Tetraplasandra gymnocarpa*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Dry Cliff—Unit 8 consists of 259 ac (105 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Nanakuli Valley from Palehua to Puumanawanua, and partially within the Nanakuli Forest Reserve. A small portion of this area was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. This unit includes the shrubland, the moisture regime, and subcanopy and understory native plant species identified as physical or biological features in the dry cliff ecosystem (see Table 4). This unit is occupied by the plants *Abutilon sandwicense*, *Bonamia menziesii*, *Flueggea neowawraea*, *Lobelia niihauensis*, *Neraudia angulata*, *Nototrichium humile*, and *Pleomele forbesii*. This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Oahu—Dry Cliff—Unit 8 is not currently occupied by *Achyranthes splendens* var. *rotundata*, *Alectryon macrococcus*, *Cenchrus agrimonioides*, *Chamaesyce herbstii*, *C. kuwaleana*, *Cyanea grimesiana* ssp. *obatae*, *Cyrtandra dentata*, *Diellia falcata*, *D. unisora*, *Dubautia herbstobatae*, *Eragrostis fosbergii*, *Gouania meyenii*, *G. vitifolia*, *Isodendron laurifolium*, *I. pyrifolium*, *Kadua degeneri*, *K. parvula*, *Korthalsella degeneri*, *Lepidium arbuscula*, *Lipochaeta lobata* var. *leptophylla*, *Melanthera tenuifolia*, *Melicope makahae*, *M. saint-johnii*, *Peucedanum sandwicense*, *Phyllostegia kaalaensis*, *Plantago princeps*, *Platydesma cornuta* var. *decurrens*, *Pteralyxia macrocarpa*, *Sanicula mariversa*, *Schiedea hookeri*, *S. obovata*, *S. trinervis*, *Silene lanceolata*, *S. perlmanii*, *Spermolepis hawaiiensis*, *Tetramolopium filiforme*, *T. lepidotum* ssp. *lepidotum*, or *Viola chamissoniana* ssp. *chamissoniana*, we have determined this area to be essential for the conservation and recovery of these dry cliff species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Oahu—Lowland Dry—Unit 11 consists of 166 ac (67 ha) of federal land (U.S. Navy) in the lowland dry ecosystem at Kalaeloa. The area was occupied by *Chamaesyce skottsbergii* var. *skottsbergii* at the time the species was listed (47 FR 36846, August 24, 1982), and is currently occupied by *C. skottsbergii* var. *skottsbergii*. As noted in the description of Oahu—Lowland Dry—Unit 8, above, we have determined that for *C. skottsbergii* var. *skottsbergii*, a plant requiring another individual for pollination (obligate-outcrosser) and living 10 years or less (short-lived perennial), we will need 7 to 8 populations containing a total of 10,000 mature individuals with at least 1,000 mature individuals per population in order to recover the species (HPPRCC 2011; Guerrant et al. 2004, pp. 419- 441; Neel and Cummings 2003). Oahu— Lowland Dry—Unit 11 is one of the four locations included in this final critical habitat designation that is essential to the conservation of *C. skottsbergii* var. *skottsbergii*; please see discussion of the importance of these areas on the Ewa Plain, above, in the description of Oahu—Lowland Dry—Unit 8. Oahu—Lowland Dry—Unit 11 includes the dry forest and shrubland, the moisture regime, and canopy, subcanopy and understory native plant species identified as physical or biological features in the lowland dry ecosystem, as well as unique PCEs for *Chamaesyce skottsbergii* var. *skottsbergii* (see Tables 4 and 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the habitat necessary for the expansion of the existing wild populations. A designation limited to areas presently occupied by the species would be inadequate to ensure the conservation of the species because this occupied unit (only Oahu—Lowland Dry—Unit 11 is occupied by wild individuals; Oahu— Lowland Dry—Unit 9 (see above) contains outplanted, propagated individuals, not wild plants) would not provide enough area to support 7 to 8 populations needed for recovery, as determined in the “Recovery Needs and Strategy for *Chamaesyce skottsbergii* var. *skottsbergii* (Ewa Plains akoko)” (Service 2012, entire). There are no other geographic areas that are both undeveloped and contain the species-specific PCE of coral outcrop substrate. In the future, Lowland Dry—Unit 11 may be able to provide for three or four separate populations of *C. skottsbergii* var. *skottsbergii*. Oahu—Lowland Dry—Unit 11 is not known to be occupied by another plant being listed as endangered in this rule, *Bidens amplexans*. However, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species (see Table 4). Due to its small numbers of individuals or low population sizes, this species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery. Additionally, Lowland Dry—Unit 11 was not occupied by the endangered plants *Achyranthes splendens* var. *rotundata*, *Bonamia menziesii*, *Chamaesyce celastroides* var. *kaenana*, *Euphorbia haelealeana*, *Gouania meyenii*, *G. vitifolia*, *Hibiscus brackenridgei*, *Isodendron pyriformis*, *Melanthera tenuifolia*, *Neraudia angulata*, *Nototrichium humile*, *Schiedea hookeri*, *S. kealiae*, or *Spermolepis hawaiiensis* (see 51 FR 10518, March 26, 1986, and 68 FR 35950, June 17, 2003) at the time they were listed, and is not currently known to be occupied by these 14 species. We have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species (see Table 4). Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery. We are aware and supportive of the efforts underway by State and the Navy, in coordination with the Service, to develop a long-term preservation or conservation plan for *Chamaesyce skottsbergii* var. *skottsbergii* within this unit. These include the development of a State of Hawaii Habitat Conservation Plan and the conditional transfer of some of the Navy lands within this unit to the Hawaii Community Development Authority (HCDA). The State of Hawaii

Endangered Species Act already prohibits the take of individual listed plants by the State or any other nonFederal entity, without State review and authorization. If the lands are transferred by the Navy, the deed will require Grantees and successors to enter into a legally binding conservation and management plan approved by the Hawaii Department of Land and Natural Resources, to ensure protection of *C. skottsbergii* var. *skottsbergii* before conveying the property (U.S. Navy 2011, in litt.), based on the species being State and federally listed. The purpose of this agreement is to ensure the use or development of the transferred property does not adversely affect *C. skottsbergii* var. *skottsbergii*, as long as the species remains listed under the Act. If the Navy lands are transferred to HCDA, a portion of the lands may be used to develop a photovoltaic alternative energy project (HCDA 2012, in litt.; HDOFAW 2012, in litt.). The HCDA plans to use a portion of the revenue generated by commercial use of HCDA property to fund the conservation actions required under a conservation management plan (U.S. Navy 2011, in litt.). The Service is committed to working with the Navy and HCDA in the development of this conservation plan, to ensure it will provide for the long-term conservation of the plant and its habitat. Because of this close coordination, and because the deed restriction stipulates that *C. skottsbergii* var. *skottsbergii* will not be adversely affected, we believe the development of the photovoltaic alternative energy project, as proposed, will not be impacted by the designation of critical habitat in this unit, and it is our intent to work with our partners to facilitate this project.

The critical habitat designation for *Bonamia menziesii* includes one unit totaling 402 acres on the island of Hawaii. The critical habitat unit is Hawaii 10—*Bonamia menziesii*—a.

Hawaii 10—*Bonamia menziesii*—a [163 ha (402 ac)]: This unit contains no named natural features and lies completely within the Kiholo watershed just above the highway. This unit, in combination with Kamehameha Schools land adjacent to the unit, provides habitat for 1 population of 300 mature, reproducing individuals of *B. menziesii* and is currently unoccupied (although the adjacent, excluded Kamehameha Schools land is occupied by 6 to 8 individuals). This unit is essential to the conservation of *B. menziesii* because it is adjacent to excluded land that supports an extant colony of this species and includes habitat that is important for the expansion of that population.

The critical habitat designation for *Bonamia menziesii* includes two CHUs in Kauai County, Hawaii (68 FR 9116-9479).

Kauai 10—*Bonamia menziesii*—a: This unit is critical habitat for *Bonamia menziesii* and is 420 ha (1,038 ac) on State (Lihue-Koloa Forest Reserve) and private land. This unit contains Kahili Summit and portions of Kanaele Swamp. This unit provides habitat for one population of 300 mature, reproducing individuals of the short-lived perennial *Bonamia menziesii* and is currently occupied with 25 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered non-viable. It provides habitat for the westernmost range of the species and wet habitat that is unique to the Kauai populations. The habitat features contained in this unit that are essential for this species include, but are not limited to, dry, mesic, or wet *Metrosideros polymorpha*-*Cheirodendron*-*Dicranopteris* forest. This unit provides for one population within this multi-island species' historical range on Kauai that is some distance away from the other critical habitat for this species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophic event.

Kauai 11—*Bonamia menziesii*—b: This unit is critical habitat for *Bonamia menziesii* and is 93 ha (229 ac) on State land (Alakai Wilderness Preserve) and contains a portion of Koaie Stream and Kipalau Valley. This unit provides habitat for one population of 300 mature, reproducing individuals of the short-lived perennial *Bonamia menziesii* and is currently occupied with one plant. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered non-viable. It provides habitat for the westernmost range of the species and wet habitat that is unique to the Kauai populations. The habitat features contained in this unit that are essential for this species include, but are not limited to, dry, mesic, or wet *Metrosideros polymorpha*-*Cheirodendron*-*Dicranopteris* forest. This unit provides for one population within this multi-island species' historical range on Kauai that is some distance away from the other critical habitat for this species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophic event.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Bonamia menziesii* critical habitat consists of four components. Lowland dry (east Maui), Lowland mesic (Lanai and Molokai), Dry cliff (west Maui) and Wet cliff (west Maui) (81 FR 17790-18110):

Ecosystem: Lowland Dry. Elevation: <3,300 ft (<1,000 m). Annual precipitation: <50 in (<130 cm). Substrate: Weathered silty loams to stony clay, rocky ledges, littleweathered lava. Canopy: *Diospyros*, *Myoporum*, *Pleomele*, *Santalum*. Subcanopy: *Chamaesyce*, *Dodonaea*, *Leptecophylla*, *Osteomeles*, *Psydrax*, *Scaevola*, *Wikstroemia*. Understory: *Alyxia*, *Artemisia*, *Bidens*, *Chenopodium*, *Nephrolepis*, *Peperomia*, *Sicyos*.

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<914 m). Annual precipitation: 50–75 in (127–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. Subcanopy: *Dodonaea*, *Freyinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Ecosystem: Dry Cliff. Elevation: unrestricted. Annual precipitation: < 75 in (<190 cm). Substrate: >65 degree slope, rocky talus. Canopy: None. Subcanopy: *Antidesma*, *Chamaesyce*, *Diospyros*, *Dodonaea*. Understory: *Bidens*, *Eragrostis*, *Melanthera*, *Schiedea*.

Ecosystem: Wet Cliff. Elevation: unrestricted. Annual precipitation: >75 in (>190 cm). Substrate: >65 degree slope, shallow soils, weathered lava. Canopy: None. Subcanopy: *Broussaisia*, *Cheirodendron*, *Leptecophylla*, *Metrosideros*. Understory: *Bryophytes*, *Ferns*, *Coprosma*, *Dubautia*, *Kadua*, *Peperomia*.

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Bonamia menziesii* critical habitat consists of three components (Lowland dry, Lowland mesic and Dry cliff). Species occurs within the indicated ecosystem in the Waianae Mountain caldera complex (Lowland dry, Lowland mesic and Dry cliff). Species occurs within indicated ecosystem in the Koolau Mountain caldera complex (Lowland mesic) (77 FR 57648-57862):

Ecosystem: Lowland Dry. Elevation: <3,300 ft (<1,000 m). Annual precipitation: <50 in (<130 cm). Substrate: Weathered silty loams to stony clay, rocky ledges, little weathered lava. Canopy: Diospyros, Myoporum, Pleomele, Santalum, Sapindes. Subcanopy: Chamaesyce, Dodonaea, Leptecophylla, Osteomeles, Psydrax, Scaevola, Wikstroemia. Understory: Alyxia, Artemisia, Bidens, Chenopodium, Nephrolepis, Peperomia, Plumbago, Sicyos, Sida, Waltheria.

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<914 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: Acacia, Diospyros, Metrosideros, Myrsine, Pouteria, Santalum. Subcanopy: Dodonaea, Freycinetia, Leptecophylla, Melanthera, Osteomeles, Pleomele, Psydrax. Understory: Carex, Dicranopteris, Diplazium, Elaphoglossum, Peperomia.

Ecosystem: Dry Cliff. Elevation: unrestricted. Annual precipitation: < 75 in (<190 cm). Substrate: >65 degree slope, rocky talus. Canopy: None. Subcanopy: Antidesma, Chamaesyce, Diospyros, Dodonaea. Understory: Bidens, Eragrostis, Melanthera, Schiedea.

The habitat features contained in this unit that are essential for this species include, but are not limited to, dry forest.

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Bonamia menziesii* critical habitat consists of two components (68 FR 9116-9479):

(i) Dry, mesic, or wet *Metrosideros polymorpha*-*Cheirodendron*-*Dicranopteris* forest and containing one or more of the following native plant species: *Antidesma platyphyllum*, *Alphitonia ponderosa*, *Acacia koa*, *Cyanea* spp., *Cyrtandra pickeringii*, *Cyrtandra limahuliensis*, *Dianella sandwicensis*, *Diospyros sandwicensis*, *Dodonaea viscosa*, *Dubautia knudsenii*, *Hedyotis terminalis*, *Isodendron longifolium*, *Labordia hirtella*, *Melicope anisata*, *Melicope barbiger*, *Myoporum sandwicense*, *Nestegis sandwicensis*, *Pisonia* spp., *Pittosporum* spp., *Pouteria sandwicensis*, *Psychotria mariniana*, *Psychotria hexandra*, *Psydrax odorata*, *Sapindus oahuensis*, *Scaevola procera*, or *Syzygium sandwicensis*; and

(ii) Elevations between 566 and 1,127 m (1,858 and 3,695 ft).

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia*

var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to

reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contains the physical or biological features essential to the conservation of the species that may require special management considerations or protection. It is recognized that activities in and adjacent to areas designated as critical habitat may affect one or more of the PCEs found in these areas. Special management is needed throughout each of the designated critical habitat units. The following discussion of special management needs is applicable to each of the 47 Kauai species for which we are designating critical habitat. These 47 Kauai species include 41 species that are currently found in the wild, and 6 species that are not currently extant in the wild. For each of the 41 Kauai species found in the wild, we have determined that the features essential to their conservation are primarily dependent on maintaining the successful functioning of the ecosystem(s) in which they occur (Tables 3 and 4). In some cases, additional species-specific primary constituent elements have also been identified (Table 4). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical and biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, predation by nonnative species, competition with nonnative species, hurricanes, landslides, flooding, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by feral ungulates (pigs, goats, and black-tailed deer). Feral ungulates also impact the habitat through predation and trampling. The State of Hawaii provides game mammal (feral pigs and goats, and black-tailed deer) hunting opportunities on one or more State-designated public hunting areas on the islands of Kauai, Oahu, Maui, Molokai, Lanai, and Hawaii (Hawaii Administrative Rules 13-123; DLNR 2009a). Management of game animals by the State ranges from providing maximal sustained public hunting opportunities and benefits (e.g., “sustained yield”) in some areas to game animal removal by State staff, or their designees, in other areas (DLNR 2009b). Public hunting areas are not fenced, and game mammals have unrestricted access to most areas across the landscape, regardless of the underlying land use designation. While fences are sometimes built to provide protection from game mammals to the natural resources within the fenced area, the current number and locations of fences are not sufficient to prevent habitat destruction and degradation. Without special management, the features that are

essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new alien plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds.

Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species will help to address the threat presented by fire to three critical habitat areas in particular (Kauai—Lowland Mesic— Section 1, Kauai—Montane Mesic— Section 2, and Kauai—Dry Cliff— Section 1; see Table 5 for corresponding CFR unit numbers). This threat is primarily due to the presence of nonnative species, such as the grasses *Andropogon* sp. and *Setaria* sp., which increase the fuel load and quickly regenerate after a fire. These species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64– 66; Brooks et al. 2004, p. 680). In addition, five sections (Kauai—Dry Cliff—Section 1, Kauai—Dry Cliff— Section 2, Kauai—Wet Cliff—Section 1, Kauai—Wet Cliff—Section 2, and Kauai—Wet Cliff—Section 3; see Table 5 for corresponding CFR unit numbers) may require special management to reduce the threat of landslides and flooding, which threaten to further degrade the habitat conditions and have the potential to eliminate some species in their entirety (e.g., *Schiedea attenuata*). In summary, we find that each of the areas we are designating as critical habitat contains features essential to the conservation of the species that may require special management considerations or protection to ensure the conservation of the 47 Kauai species. These special management considerations and protections are required to preserve and maintain the essential features provided to these species by the ecosystems upon which they depend. A more detailed discussion of each of these threats is presented above, under the Summary of Factors Affecting the Species section.

The following management actions are important in providing a conservation benefit to the species: feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access

The Service publishes this final rule acknowledging that they have incomplete information regarding many of the primary biological and physical requirements for these species. However, both the Act and the relevant court orders require the Service to proceed with designation at this time based on the best information available. As new information accrues, the Service may consider reevaluating the boundaries of areas that warrant critical habitat designation.

Existing manmade features and structures within the boundaries of the mapped areas, such as buildings; roads; aqueducts and other water system features, including but not limited to pumping stations, irrigation ditches, pipelines, siphons, tunnels, water tanks, gaging stations, intakes, reservoirs, diversions, flumes, and wells; existing trails; campgrounds and their immediate surrounding landscaped area; scenic lookouts; remote helicopter landing sites;

existing fences; telecommunications equipment towers and associated structures and equipment; electrical power transmission lines and distribution, and communication facilities and regularly maintained associated rights-of-way and access ways; radars, telemetry antennas; missile launch sites; arboreta and gardens; heiau (indigenous places of worship or shrines), and other archaeological sites; airports; other paved areas; and lawns and other rural residential landscaped areas do not contain one or more of the primary constituent elements described for each species and therefore are not included in the critical habitat designations.

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Sexual (NatureServe, 2015)

Reproduction Narrative

Adult: Reproduction is sexual (NatureServe, 2015).

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Dry to mesic forest, rarely in wet forest (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Occurs at 490 - 2,050 ft. elevation (USFWS, 2016)

Habitat Narrative

Adult: Inhabits dry to mesic forest, rarely in wet forest (NatureServe, 2015). *Bonamia menziesii* is found on steep slopes as well as on level ground in dry to mesic forest and sometimes in wet forest, between the elevations of 150 and 625 m (490 and 2,050 ft) (USFWS, 2016).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Not available

Species Trends:

Oahu: declining; Kauai: unknown (USFWS, 2016)

Resiliency:

Low to moderate (inferred from USFWS, 2016)

Redundancy:

Moderate to high (inferred from USFWS, 2016)

Number of Populations:

Kauai: 12+; Oahu: 12; Lanai: 3; Maui: 4 - 6; Hawaii: 1 (USFWS, 2016)

Population Size:

Kauai: > 1,000; Oahu: < 60; Lanai: ~11; Maui: 10 - 15; Hawaii: 3+ (USFWS, 2016)

Population Narrative:

Total estimate probably fewer than 1000 plants. Twenty-five current (between 1982 and 1997), sixteen historical occurrences and two with status unknown (NatureServe, 2015). At least a dozen occurrences are known from Kalalau, upper Waioli Valley, scattered across the north coast from Limahuli, Hanakapiai to Milolii, Kawaiula Valley, Hipalau Valley, Paaiki Valley, Mount Kahili, and Hono O Na Pali Natural Area Reserve on State and private land, and Wahiawa drainage on private land totaling more than 1,000 individuals. There are 12 occurrences on Oahu that total fewer than 60 plants located both the Waianae and the Koolau Mountains (U.S. Army Garrison 1999a). On Lanai, *B. menziesii* is known from three scattered occurrences: about six individuals at Kaa, two individuals on Puhielele Ridge, and four individuals at Paomai, on private land. On Maui, one occurrence of a single individual is known from private land on the western slopes of West Maui, and three to five occurrences with nine to 14 individuals are located on private and State land on East Maui. On the island of Hawaii, a single occurrence of at least three individuals is located at Kaupulehu on private land (Hawaii Natural Heritage Program 1995; Lorence and Flynn 1991; S. Perlman and K. Wood, pers. comm. 1997). Recent survey data from the island of Oahu suggests the number of individuals and occurrences is decreasing on the island. Even though there are thought to be several thousand individuals on the island of Kauai, these populations are not managed or monitored so their status is unknown (USFWS, 2016).

Threats and Stressors

Stressor: Nonnative species (NatureServe, 2015; USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: Threats are from non-native weed invasion, feral pigs and goats, black-Tailed Deer, and cattle (NatureServe, 2015). An alien beetle (*Physomerus grossipes*), which has recently become established on Oahu, is potentially a significant threat to *B. menziesii* (D. Orr, pers. comm. 1999) (USFWS, 2016).

Stressor: Fire (NatureServe, 2015)

Exposure:

Response:

Consequence:

Narrative: There is a risk of losing a significant proportion of this species from the island of Oahu since 10 individuals of *B. menziesii* are located in the high fire risk zone (USFWS, 2016).

Recovery

Conservation Measures and Best Management Practices:

- Surveys should be conducted to identify and assess the effects of the alien beetle on this species (USFW, 2016).
- The *Bonamia menziesii* plant on the Navy's Lualualei Naval Reservation has been fenced for protection from cattle. A program of alien plant removal within the enclosure is ongoing (J. Moribe, pers. comm. 1997). Most of the *B. menziesii* at Kanepuu Preserve on Lanai are found within fenced enclosures. In addition, the Nature Conservancy of Hawaii has implemented a fuel reduction treatment strategy for the Kanepuu Preserve on Lanai that includes mowing, at least yearly, portions of the seven distinct fenced units (C. Cory, pers. comm. 1999). The Kanepuu Preserve fire protection plan is updated each year and incorporates the participation of local, State, and private agencies (A. Remec, pers. comm. 1999). It is expected that these actions may enhance conservation of the *B. menziesii* plants found there (USFWS, 2016).
- *Bonamia menziesii* has been successfully propagated at the Lyon Arboretum's micropropagation laboratories, at the Waimea Arboretum, and the National Tropical Botanical Garden (Koob 1996; M. Chapin, pers. comm. 1997; G. Koob pers. comm. 1997; D. Orr, pers. comm. 1997). Currently, approximately 25 individuals exist in cultivation (Koob 1996; M. Chapin, pers. comm. 1997; D. Orr, pers. comm. 1997). Reintroduction of cultivated individuals to the wild has not been attempted (USFWS, 2016).

SPECIES ACCOUNT: *Brickellia mosieri* (Florida brickell-bush)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/6/2014; Southeast Region (R4) (USFWS, 2015)

Physical Description

Brickellia mosieri is a perennial herb. Mature plants are 0.3–1.1 meters (m) (1.0–3.5 feet (ft)) tall, slender, erect, and branching (Chafin 2000, page numbers not applicable). Leaves are 1–3 centimeters (cm) (0.4–1.2 inches (in)) long, alternate, narrow, linear, thick, usually spreading or curved downward, entire or slightly toothed, and resin dotted. The flower heads are in loose, open clusters at the ends of branches. Disk flowers are white in small, dense heads surrounded by hairy, slightly ribbed bracts; there are no ray flowers, although long-style branches (white, sometimes brown) may appear to be rays. (USFWS, 2013)

Taxonomy

Brickellia mosieri (Family: Asteraceae) was first described by Small in 1933 as *Kuhnia mosieri*. In 1970, Long called the species *Kuhnia eupatorioides* var. *floridana*, reducing it to a variety of a more widespread species occurring in the eastern United States. In 1971, Shinnars included all members of the genus *Kuhnia* in *Brickellia* and restored the plant to species status, calling it *Brickellia mosieri* (USFWS, 2013). Kartesz (1999) lists *B. mosieri* as a synonym of *Brickellia eupatorioides* var. *floridana*. (NatureServe, 2015).

Historical Range

Brickellia mosieri is endemic to the pine rocklands of the Miami Rock Ridge in Miami-Dade County. It was historically known from central and southern Miami-Dade County from approximately Coconut Grove to Florida City, a range of approximately 45.0 km (28.0 mi), along the Miami Rock Ridge. (USFWS, 2014)

Current Range

Brickellia mosieri is currently distributed from central and southern Miami-Dade County from SW 120 St. to Florida City, suggesting its historical range has contracted at least 13.6 km (8.5 mi), or more than 30 percent. (USFWS, 2014)

Critical Habitat Designated

Yes; 9/16/2015.

Legal Description

On August 17, 2015, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective September 16, 2015) for *Brickellia mosieri* (Florida brickell-bush) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six critical habitat units (CHUs), in Florida (80 FR 49846-49886).

Critical Habitat Designation

The critical habitat designation for *Brickellia mosieri* includes six CHUs (40 sub-units) in Miami-Dade County, Florida. This species critical habitat encompasses approximately 2,624 acres (ac) (1,062 hectares (ha)). Brief descriptions are presented below. Maps depicting the CH units are available in the Final Rule. (80 FR 49846-49886).

Unit BM1: Trinity Pineland and Surrounding Areas, Miami-Dade County, Florida: Unit BM1 consists of 18 ha (43 ac) in Miami-Dade County. Within Unit BM1, there are two subunits—BM1A (Countyowned) and BM1B (combination of State, County, and privately owned lands). The unit is comprised of State lands within Trinity Pineland County Park (4 ha (10 ac)); County lands primarily within A. D. “Doug” Barnes Park (6 ha (14 ac)); and parcels in private ownership (8 ha (19 ac)). This unit is bordered on the north by SW 24 Street, on the south by the Snapper Creek Expressway (State Road (SR) 878), on the east by SW 67 Avenue, and on the west by SW 87 Avenue.

Unit BM2: Nixon Smiley Pineland Preserve and Surrounding Areas, Miami-Dade County, Florida: Unit BM2 consists of approximately 108 ha (267 ac) of habitat in MiamiDade County. Within Unit BM2, there are seven subunits (BM2A–BM2G) comprising primarily conservation lands and including four larger areas plus three smaller areas. The unit is comprised of State lands within Camp Matecumbe, Tamiami Pineland Complex Addition, and Rockdale Pineland (49 ha (121 ac)); County/local lands primarily within Nixon Smiley Pineland Preserve, Tamiami #8 (Nixon Smiley Addition) Pineland, Pine Shore Pineland Preserve, Ron Ehman Park, and Rockdale Pineland Addition (59 ha (146 ac)); and small portions of parcels in private or other ownership (less than 1 ha (less than 1 ac)). This unit is bordered on the north by SW 104 Street, on the south by SW 152 Street (Coral Reef Drive), on the east by U.S. 1 (South Dixie Highway), and on the west by SW 177 Avenue (Krome Avenue).

Unit BM3: USDA Subtropical Horticultural Research Station and Surrounding Areas, Miami-Dade County, Florida: Unit BM3 consists of approximately 127 ha (315 ac) of habitat in MiamiDade County. Within Unit BM3, there are eight subunits (BM3A–BM3H), including two larger areas (U.S. Department of Agriculture (USDA) Subtropical Horticultural Research Station, and Deering Estate at Cutler) plus six smaller areas surrounding these. The unit is comprised of Federal lands within the USDA Subtropical Horticultural Research Station (59 ha (145 ac)); State lands within the R. Hardy Matheson Preserve, Ludlam Pineland, Deering Estate at Cutler, and Deering Estate South Addition (45 ha (112 ac)); County/local lands within Coral Reef Park, Ned Glenn Nature Preserve, and Bill Sadowski Park (15 ha (38 ac)); and parcels in private ownership (8 ha (19 ac)). This unit is bordered on the north by SW 112 Street, on the south by the intersection of Old Cutler Road and Franjo Road (County Road (CR) 977), on the east by the Atlantic Ocean, and on the west by U.S. 1 (South Dixie Highway).

Unit BM4: Richmond Pinelands and Surrounding Areas, Miami-Dade County, Florida: Unit BM4 consists of approximately 395 ha (975 ac) in Miami-Dade County. Within Unit BM4, there are eight subunits (BM4A–BM4H), most within the Richmond Pinelands complex (made up of Federal and County-owned lands, as well as land owned by the University of Miami). The unit is comprised of Federal lands owned by the USCG (Homeland Security), U.S. Army Corps of Engineers (ACOE; Department of Defense), U.S. Prison Bureau (Department of Justice), and the U.S. Department of Commerce/National Oceanic and Atmospheric Administration (NOAA) (75 ha (185 ac)); County/local lands within and adjacent to Larry and Penny Thompson Park, Martinez Pineland, Zoo Miami, and Eachus Pineland (239 ha (590 ac)); and parcels in private or other ownership (81 ha (200 ac)). This unit is bordered on the north by SW 152 Street (Coral Reef Drive), on the south by SW 200 St (Quail Drive/SR 994), on the east by U.S. 1 (South Dixie Highway), and on the west by SW 177 Avenue (Krome Avenue).

Unit BM5: Quail Roost Pineland and Surrounding Areas, Miami-Dade County, Florida: Unit BM5 consists of approximately 96 ha (238 ac) in Miami-Dade County. Within Unit BM5, there are 11 subunits (BM5A–BM5K), including 4 larger areas plus 7 smaller areas surrounding these. The unit is comprised of State lands within Quail Roost Pineland, Goulds Pineland and Addition, and Silver Palm Groves Pineland (39 ha (97 ac)); County/ local lands including Black Creek Forest, Rock Pit #46, and lands owned by the School Board of Miami-Dade County (15 ha (37 ac)); and parcels in private ownership (42 ha (104 ac)), including Porter-Russell Pineland owned by the Tropical Audubon Society. This unit is bordered on the north by SW 200 St (Quail Drive/SR 994), on the south by SW 248 Street, on the east by the Florida Turnpike, and on the west by SW 194 Avenue.

Unit BM6: Camp Owaissa Bauer and Surrounding Areas, Miami-Dade County, Florida: Unit BM6 consists of approximately 112 ha (276 ac) of habitat in MiamiDade County. Within Unit BM6, there are 12 subunits (BM6A–BM6L), composed of 1 larger area (Camp Owaissa Bauer and its addition) and 11 smaller areas to the south. The unit is comprised of State lands within Owaissa Bauer Pineland Addition, Ingram Pineland, West Biscayne Pineland, and Fuchs Hammock Addition (20 ha (50 ac)); County/local lands including Camp Owaissa Bauer, Pine Island Lake Park, Seminole Wayside Park, and Northrop Pineland (63 ha (156 ac)); and parcels in private ownership (28 ha (70 ac)), including the private conservation area, Pine Ridge Sanctuary. This unit is bordered on the north by SW 248 Street, on the south by SW 312 Street, on the east by SW 112 Avenue, and on the west by SW 217 Avenue.

Unit BM7: Navy Wells Pineland Preserve and Surrounding Areas, Miami-Dade County, Florida: Unit BM7 consists of approximately 206 ha (510 ac) of habitat in MiamiDade County. Within Unit BM7, there are eight subunits (BM7A–BM7H), including one larger area (Navy Wells Pineland Preserve) and seven smaller outlying areas. The unit is comprised of State lands within Palm Drive Pineland, Navy Wells Pineland #39, Navy Wells Pineland Preserve (portion), and Florida City Pineland (53 ha (132 ac)); County/ local lands including primarily Sunny Palms Pineland and Navy Wells Pineland Preserve (portion) (125 ha (309 ac)); and parcels in private ownership (28 ha (68 ac)). This unit is bordered on the north by SW 320 Street, on the south by SW 368 Street, on the east by U.S. 1 (South Dixie Highway), and on the west by SW 217 Avenue.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Brickellia mosieri* critical habitat consists of three components (80 FR 49846-49886):

(i) Areas of pine rockland habitat that contain: (A) Open canopy, semi-open subcanopy, and understory; (B) Substrate of oolitic limestone rock; and (C) A plant community of predominately native vegetation that may include, but is not limited to: (1) Canopy vegetation dominated by *Pinus elliottii* var. *densa* (South Florida slash pine); (2) Subcanopy vegetation that may include, but is not limited to, *Serenoa repens* (saw palmetto), *Sabal palmetto* (cabbage palm), *Coccothrinax argentata* (silver palm), *Myrica cerifera* (wax myrtle), *Myrsine floridana* (myrsine), *Metopium toxiferum* (poisonwood), *Byrsonima lucida* (locustberry), *Tetrazygia bicolor* (tetrazygia), *Guettarda scabra* (rough velvetseed), *Ardisia escallonioides* (marlberry), *Psidium longipes* (mangroveberry), *Sideroxylon salicifolium* (willow bustic), and *Rhus copallinum* (winged sumac); (3) Short-statured shrubs that may include, but are not limited to, *Quercus pumila* (running oak), *Randia aculeata* (white indigoberry), *Crossopetalum ilicifolium* (Christmas berry), *Morinda royoc* (redgal), and *Chiococca alba* (snowberry); and (4) Understory vegetation that may

include, but is not limited to: *Andropogon* spp.; *Schizachyrium gracile*, *S. rhizomatum*, and *S. sanguineum* (bluestems); *Aristida purpurascens* (arrowfeather threeawn); *Sorghastrum secundum* (lopsided Indiangrass); *Muhlenbergia capillaris* (hairawn muhly); *Rhynchospora floridensis* (Florida white-top sedge); *Tragia saxicola* (pineland noseburn); *Echites umbellata* (devil's potato); *Croton linearis* (pineland croton); *Chamaesyce* spp. (sandmats); *Chamaecrista deeringiana* (partridge pea); *Zamia integrifolia* (coontie); and *Anemia adiantifolia* (maidenhair pineland fern).

(ii) A disturbance regime that naturally or artificially duplicates natural ecological processes (e.g., fire, hurricanes, or other weather events) and that maintains the pine rockland habitat described in paragraph (2)(i) of this entry.

(iii) Habitats that are connected and of sufficient area to sustain viable populations of *Brickellia mosieri* in the pine rockland habitat described in paragraph (2)(i) of this entry.

Special Management Considerations or Protections

When designating critical habitat, the Service assesses whether the specific areas within the geographic area occupied by the species at the time of listing contain features which are essential to the conservation of the species and which may require special management considerations or protection. The features essential to the conservation of *Brickellia mosieri* and may require special management considerations or protection to reduce threats related to habitat loss, fragmentation, and modification primarily due to development; inadequate fire management; nonnative, invasive plants; and sea level rise. Destruction of the pinelands for economic development has reduced pine rockland habitat on the Miami Rock Ridge outside of ENP by over 98 percent, and remaining habitat in this area is highly fragmented. *Brickellia mosieri* occurs on a mix of private and publicly owned lands, only some of which are managed for conservation. Populations of the plants that occur on private land or non-conservation public land are vulnerable to habitat loss, while populations on conservation lands are vulnerable to the effects of habitat degradation if natural disturbance regimes are disrupted (e.g., through inadequate fire management). Prolonged lack of fire in pine rockland typically results in succession to rockland hammock, and displacement of native species by invasive, nonnative plants often occurs. Further development and degradation of pine rocklands increase fragmentation and decrease the conservation value of the remaining functioning pine rockland habitat. In addition, pine rocklands are expected to be further degraded and fragmented due to anticipated sea level rise, which would fully or partially inundate some pine rocklands along the coast and in the southern portion of Miami-Dade County (near Navy Wells Pineland Preserve), and cause increases in the salinity of the water table and soils resulting in vegetation shifts in additional pine rocklands across the Miami Rock Ridge. Many existing pine rockland fragments are also projected to be developed for housing as the human population grows and adjusts to changing sea levels. Special management considerations and protections that will address these threats include increased coordination and conservation of these plants and their habitat on Federal lands, and improved habitat restoration and management efforts (including fire management and nonnative plant treatments) of high-priority and high-elevation sites. (USFWS, 2013)

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (USFWS, 2014)

Breeding Season

Adult: August - October (USFWS, 2014)

Key Resources Needed for Breeding

Adult: Fire (USFWS, 2014)

Reproduction Narrative

Adult: Pollination occurs via insects and abiotic factors (EPA, 2016). Reproduction is sexual (Bradley and Gann 1999, p. 12). Flowering takes place primarily in the fall (August–October) (Bradley and Gann 1999, p. 12). Off-season flowering is usually the result of fire, and *B. mosieri* will flower within 1 to 2 months following a fire, regardless of the time of year (Possley 2013 pers. comm.) (USFWS, 2014).

Habitat Type

Adult: Terrestrial (EPA, 2016).

Habitat Vegetation or Surface Water Classification

Adult: Pine rockland (EPA, 2016)

Dependencies on Specific Environmental Elements

Adult: Periodic fire (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Scattered (USFWS, 2014)

Environmental Specificity

Adult: Very narrow

Habitat Narrative

Adult: Grows exclusively in pine rockland (EPA, 2016). Pine rockland is characterized by an open canopy of South Florida slash pine (*Pinus elliottii* var. *densa*). Subcanopy development is rare in well-maintained pine rocklands, with only occasional hardwoods, such as *Lysiloma latisiliquum* (wild tamarind) and *Quercus virginiana* (live oak) growing to tree size in Miami Rock Ridge pinelands (Snyder et al. 1990, p. 253). The shrub/ understory layer is a diverse mix of species including both temperate and tropical shrubs and palms. The pine rocklands where *Brickellia mosieri* occurs are characterized by an open shrub canopy of *Serenoa repens* (saw palmetto), *Myrica cerifera* (wax myrtle), *Metopium toxiferum* (poisonwood), and *Sideroxylon salicifolium* (willow bustic) as well as species with more restricted distribution within pine rocklands including *Sideroxylon reclinatum* ssp. *austrofloridense* (Everglades bully), *Callicarpa americana* (beauty berry), *Dodonaea angustifolia* (varnish leaf), and *Ilex cassine* (dahoon holly) (Snyder et al. 1990, p. 254; Bradley and Gann 1999, p. 12). Populations are typically sparse and contain a low density of plants even in well-maintained pine rockland habitat (Bradley and Gann 1999, p. 12) (USFWS, 2014). The environmental specificity of this species is very narrow, as it is known

only from pine rockland habitat in southern Florida, requiring fire to maintain the openings in which the plant occurs (NatureServe, 2015).

Dispersal/Migration

Dependency on Other Individuals or Species for Dispersal

Adult: Unknown (EPA, 2016)

Dispersal/Migration Narrative

Adult: Fruit dispersal occurs via unknown abiotic and biotic mechanisms (EPA, 2016). Wind is one likely dispersal vector (Gann 2013b, pers. comm.) (USFWS, 2014).

Population Information and Trends

Population Trends:

50% decline (USFWS, 2013)

Species Trends:

50 - 70% decline (NatureServe, 2015)

Number of Populations:

Unknown, presumed 17+ (USFWS, 2013)

Population Size:

2,150 - 3,700 (USFWS, 2013)

Population Narrative:

At least 9 known populations on private lands have been extirpated, plus at least 6 of 18 undated occurrences reported by Alan Herndon. Based on current estimates, the total population of *B. mosieri* has apparently declined by approximately 50 percent since 1999. The number of extant occurrences of this species is somewhat uncertain due to the lack of complete and recent survey information, however populations of *B. mosieri* are believed to occur on at least 17 (extant or presumed extant) sites. Based on the 17 populations considered to be extant, the current total population estimate is between 515 and 4,935 plants, although the actual number of individuals is probably closer to between 2,150 and 3,700. The current range of *Brickellia mosieri* spans a narrow band approximately 30.1 km (18.7 mi) wide and 26.9 km (16.7 mi) in length (USFWS, 2013). Even conservation areas are suffering due to lack of fire and exotic species invasion, and the short-term trend for this species is a 50 - 70 % decline (NatureServe, 2015).

Threats and Stressors

Stressor: Habitat destruction and modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: The pine rockland community of south Florida, to which the species endemic, is critically imperiled globally (FNAI 2012, p. 27). Since the 1800s, residential and commercial

development and agriculture have drastically reduced the habitat for these plants throughout pine rocklands in south Florida. Habitat loss continues to occur in its range, and most remaining suitable habitat has been negatively altered by human activity. Another human-related factor that can modify public and private lands alike is the potential for high levels of nutrients from agricultural and urban areas to enter into pine rockland systems. Such chemical alteration of pine rockland soil, which has naturally low amounts of phosphorus and nitrogen, can result in changes to vegetation composition and structure, at the expense of pine rockland endemics such as *Brickellia mosieri*. Effects of fragmentation on pollinators may include changes to the pollinator community as a result of limitation of pollinator-required resources (e.g., reduced availability of rendezvous plants, nesting and roosting sites, and nectar/pollen); these changes may include changes to pollinator community composition, species abundance and diversity, and pollinator behavior (Rathcke and Jules 1993, pp. 273–275; Kremen and Ricketts 2000, p. 1227; Harris and Johnson 2004, pp. 30–33). As a result, plants in fragmented habitats may experience lower visitation rates, which in turn may result in reduced seed production of the pollinated plant (which may lead to reduced seedling recruitment), reduced pollen dispersal, increased inbreeding, reduced genetic variability, and ultimately reduced population viability (Rathcke and Jules 1993, p. 275; Goverde et al. 2002, pp. 297–298; Harris and Johnson 2004, pp. 33–34). Exclusion of fire for approximately 25 years will likely result in gradual hammock development over that time period, leaving a system that is very fire resistant if additional pre-fire management (e.g., mechanical hardwood removal) is not undertaken. Now, natural fires are unlikely to occur or are likely to be suppressed in the remaining, highly fragmented pine rockland habitat. The suppression of natural fires has reduced the size of the areas that burn, and habitat fragmentation has prevented fire from moving across the landscape in a natural way. Without fire, successional climax from pine rockland to rockland hammock is rapid, and displacement of native species by invasive nonnative plants often occurs. Understory plants such as *Brickellia mosieri* are shaded out by hardwoods and nonnatives alike (USFWS, 2013).

Stressor: Nonnative plants (USFWS, 2014)

Exposure:

Response:

Consequence:

Narrative: Nonnative plants have significantly affected pine rocklands, and threaten all occurrences of *Brickellia mosieri* to some degree (Bradley and Gann 1999, pp. 15, 72; Bradley and Gann 2005, page numbers not applicable; Bradley 2007, pers. comm.; Bradley and van der Heiden 2013, pp. 12–16). As a result of human activities, at least 277 taxa of nonnative plants have invaded pine rocklands throughout south Florida (Service 1999, p. 3–175). Nonnative invasive plants compete with native plants for space, light, water, and nutrients, and make habitat conditions unsuitable for *Brickellia mosieri* which responds positively to open conditions (USFWS, 2014).

Stressor: Small isolated populations (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Only small and fragmented occurrences of this plant remains. The current range spans such a small area that all populations could be affected by a single event (e.g., hurricane). Although robust population viability analyses (including minimum viable population calculations)

have not been conducted for these plants, indications are that most existing populations for this plant are at best marginal (USFWS, 2013).

Stressor: Climate change (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Drier conditions and increased variability in precipitation associated with climate change are expected to hamper successful regeneration of forests and cause shifts in vegetation types through time (Wear and Greis 2012, p. 39). Although it has not been well studied, existing pine rocklands have probably been affected by reductions in the mean water table. Climate changes are also forecasted to extend fire seasons and the frequency of large fire events throughout the Coastal Plain (Wear and Greis 2012, p. 43). While restoring fire to pine rocklands is essential to the long-term viability of *Brickellia mosieri* populations, increases in the scale, frequency, or severity of wildfires could have negative effects on this species considering its general vulnerability due to small population size, restricted range, few colonies, and relative isolation (USFWS, 2013).

Recovery

Reclassification Criteria:

Not available - this species does not have a recovery plan.

Delisting Criteria:

Not available - this species does not have a recovery plan.

Recovery Actions:

- Not available - this species does not have a recovery plan.

Conservation Measures and Best Management Practices:

- Not available - this species does not have a recovery plan.

SPECIES ACCOUNT: *Brighamia insignis* (Olulu)

Species Taxonomic and Listing Information

Listing Status: Endangered; 02/25/1994; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Brighamia insignis, a member of the bellflower family (Campanulaceae), is an unbranched plant 1 to 5 m (3 to 16 ft) tall with a succulent stem that is bulbous at the bottom and tapers toward the top. The fleshy leaves, which measure 12 to 20 cm (5 to 8 in) long and 6.5 to 11 cm (2.5 to 4.5 in) wide, are arranged in a compact rosette at the apex of the stem. Fragrant yellow flowers are clustered in groups of three to eight in the leaf axils (the point between the leaf and the stem), with each flower on a stalk 1 to 3 cm (0.4 to 1.2 in) long. The hypanthium (basal portion of the flower) has 10 ribs and is topped with 5 oval or loosely triangular calyx lobes (partially fused sepals) 0.5 to 1 mm (0.02 to 0.04 in) long. The yellow petals are fused into a tube 7 to 14 cm (2.8 to 5.5 in) long and 3 to 4 mm (0.1 to 0.2 in) wide, which flares into five elliptic lobes. The fruit is a capsule 13 to 19 mm (0.5 to 0.7 in) long which contains numerous seeds. (USFWS, 1998)

Taxonomy

Asa Gray (in Mann 1868) described *Brighamia insignis* based upon alcohol-preserved flowers and fruits collected by William Tufts Brigham on Molokai and a dried specimen collected on Kauai or Niihau by Ezechiel Jules Remy. Brigham's bottled material, since lost, would today be considered to be *Brighamia rockii*. Other published names that Thomas C. Lammers (1989), in the currently accepted treatment of the genus, considers to be synonymous with *B. insignis* include *B. insignis* f. *citrina* (Forbes 1917a), *B. citrina* (St. John 1958), and *B. citrina* var. *napahiensis* (St. John 1969b). (USFWS, 1998)

Historical Range

Historically, *B. insignis* was known from the headland between Hoolulu and Waiahuakua Valleys along the Na Pali Coast on the island of Kauai, and from Kaali Spring on the island of Niihau (HHP 1994). (USFWS, 1998)

Current Range

Range includes Na Pali and Hapuu areas of Kauai, current reports on Niihau but no specimens collected. (NatureServe, 2015)

Critical Habitat Designated

Yes; 2/27/2003.

Legal Description

On February 27, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Brighamia insignis* on the islands of Kauai and Niihau, Hawaii (68 FR 9116 - 9479).

Critical Habitat Designation

The critical habitat designation for *Brighamia insignis* includes three units totaling 5,047 acres on the island of Kauai and one unit totaling 52,549 acres on the island of Niihau. The units are Kauai

6—*Brighamia insignis*—a, Kauai 7—*Brighamia insignis*—b, Kauai 11—*Brighamia insignis*—c, and Niihau 1—*Brighamia insignis*—a.

Kauai 6—*Brighamia insignis*—a: This unit is critical habitat for *Brighamia insignis* and is 63 ha (156 ac) on private land and contains a portion of Keopaweo Summit on the north side of Mount Haupu. This unit provides habitat for one population of 300 mature, reproducing individuals of the short-lived perennial *Brighamia insignis* and is currently occupied with one plant. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered non-viable. The habitat features contained in this unit that are essential for this species include, but are not limited to, rocky ledges with little soil or steep sea cliffs in lowland dry grasslands or shrublands with annual rainfall that is usually less than 170 cm (65 in). This unit provides for one population within this multi-island species' historical range on Kauai that is some distance away from the other critical habitat for this species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophic event.

Kauai 7—*Brighamia insignis*—b: This unit is critical habitat for *Brighamia insignis* and is 340 ha (843 ac) on private land. This unit contains the Haupu and Naluakeina Summits and Queen Victoria's Profile. This unit provides habitat for one population of 300 mature, reproducing individuals of the short-lived perennial *Brighamia insignis* and is currently occupied with one plant. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered non-viable. The habitat features contained in this unit that are essential for this species include, but are not limited to, rocky ledges with little soil or steep sea cliffs in lowland dry grasslands or shrublands with annual rainfall that is usually less than 170 cm (65 in). This unit provides for one population within this multi-island species' historical range on Kauai that is some distance away from the other critical habitat for this species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophic event.

Kauai 11—*Brighamia insignis*—c: This unit is critical habitat for *Brighamia insignis* and is 1,639 ha (4,051 ac) on State land (Hono o Na Pali NAR, Puu Ka Pele Forest Reserve, and Milolii, Nualolo Kai, and Na Pali Coast State Parks). This unit contains Alapii, Mukuaiki, and Puanaiea Points; Awaawapuhi, Honopu, Kalalau, Kawaiula, Makaha, Milolii, Nualolo, Paaiki, and Poopooiki Valleys; Hanakoa, Hoolulu, Kalalau, and Waiahuakua Streams; Kalalau Beach and Trail; Kanakou Summit and Nakeikionaiwi Pillar. The habitat features contained in this unit that are essential for this species include, but are not limited to, rocky ledges with little soil or steep sea cliffs in lowland dry grasslands or shrublands with annual rainfall that is usually less than 170 cm (65 in). This unit provides habitat for seven populations of 300 mature, reproducing individuals of the short-lived perennial *Brighamia insignis* and is currently occupied with between 40 and 60 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered non-viable. This unit provides for seven populations within this multi-island species' historical range on Kauai that are some distance away from the other critical habitat for this species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophic event.

Niihau 1—*Brighamia insignis*—a: This unit is critical habitat for *Brighamia insignis* and is 144 ha (357 ac) on private land. This unit contains Puu Alala and Mokouia Valley. The habitat features contained in this unit that are essential for this species include, but are not limited to, rocky ledges with little soil or steep sea cliffs in lowland dry grasslands or shrublands with annual rainfall that is usually less than 170 cm (65 in). This unit provides habitat for one population of 300 mature, reproducing individuals of the short-lived perennial *Brighamia insignis* and is currently occupied with at least one plant. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered non-viable. This unit provides for one population within this multi-island species' historical range on Niihau that is some distance away from the other critical habitat for this species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophic event.

Primary Constituent Elements/Physical or Biological Features

Within these units, the currently known primary constituent elements of critical habitat include, but are not limited to, the habitat components provided by:

(i) Rocky ledges with little soil or steep sea cliffs in lowland dry grasslands or shrublands with annual rainfall that is usually less than 170 cm (65 in) and containing one or more of the following native plant species: *Artemisia australis*, *Chamaesyce celastroides*, *Eragrostis variabilis*, *Heteropogon contortus*, *Hibiscus kokio*, *Hibiscus kokio* ssp. *saintjohnianus*, *Lepidium serra*, *Lipochaeta succulenta*, *Munroidendron racemosum*, or *Sida fallax*; and

(ii) Elevations between 0 and 748 m (0 and 2,453 ft).

Special Management Considerations or Protections

The following management actions are important: feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas deemed essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas deemed essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (outcrossing) and asexual (vegetative) (USFWS, 1998)

Dependency on Other Individuals or Species

Adult: Pollination by sphingid moths is likely (David Lorence, NTBG, personal communication 1994). (USFWS, 1998)

Reproduction Narrative

Adult: Pollination by sphingid moths is likely (David Lorence, NTBG, personal communication 1994). Pollination failure is common, and may be due to a lack of pollinators or a reduction in genetic variability due to the few remaining individuals. The flower structure appears to favor outcrossing. Some vegetative cloning has been observed and flower and leaf size appear to be dependent on moisture availability (Takeuchi 1982, USFWS 1994a). (USFWS, 1998)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Cliff, savanna (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Moist, or rarely dry habitats (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations from sea level to 400 meters (USFWS, 1998)

Environmental Specificity

Adult: Medium, with some key requirements (USFWS, 1998)

Habitat Narrative

Adult: This species is found in moist, or rarely dry habitats. Usually on steep cliffs, sparsely vegetated with native shrubs and grasses. *Brigharnia insignis* grows from sea level to 400 meters (1,300 feet) on rocky ledges with little soil or steep sea cliffs in lowland dry grassland and shrubland. This habitat has annual rainfall that is usually less than 170 centimeters (65 inches). Associated native plant taxa include *Canthiurn odoratum* (alahee), *Charnaesyce celastroides* (akoko), *Eragrostis variabilis* (kawelu), and *Heteropogon contortus* (pili grass) (USFWS 1994a). (USFWS, 1998; NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Seeds of this species are undoubtedly dispersed by gravity. Although they may be blown for short distances, they are not obviously adapted for wind dispersal, being ovoid to ellipsoid, smooth, and lacking any sort of wing or outgrowth (David Lorence, NTBG, personal communication 1994). (USFWS, 1998)

Population Information and Trends**Population Trends:**

Declining (USFWS, 2008)

Resiliency:

Very low (inferred from USFWS, 2008)

Representation:

Very low (inferred from USFWS, 2008)

Redundancy:

Very low (inferred from USFWS, 2008)

Number of Populations:

1 (USFWS, 2008)

Population Size:

0 (USFWS, 2017)

Population Narrative:

Brighamia insignis occurs on a steep cliff face and the only known wild individual was last observed in 2012 via helicopter (PEPP 2014; Walsh 2016; Walsh 2017, in litt.). (USFWS, 2017); This species has declined to only one naturally occurring wild individual, and the distribution has declined from four populations on two mountain ranges to only one on the Na Pali Coast. Three additional plants have been outplanted by Hawaii Division of Forestry and Wildlife (National Tropical Botanical Garden 2006a). Probably less than 100 plants. (USFWS, 2008; NatureServe, 2015);

Threats and Stressors

Stressor: Habitat degradation by animals (USFWS, 1998)

Exposure:

Response:

Consequence:

Narrative: The major threats to Brighamia insignis are predation and habitat degradation by feral goats and pigs. Other threats that affect B. insignis include: slugs and rats that eat seeds and leaves, carmine spider mites, and feral goats that are known to defoliate B. insignis. (USFWS, 2008)

Stressor: Small population size (USFWS, 1998)

Exposure:

Response:

Consequence:

Narrative: Brighamia insignis is threatened by stochastic extinction due to the small number of individuals and their restricted distribution. Small numbers may result in reduced reproductive vigor, and stochastic environmental disturbances, such as rock slides, are frequent in their cliff habitat (USFWS 1994a). Species like B. insignis that are very low in number and endemic to small portions of an island are inherently more vulnerable to extinction than widespread species because of the higher risks posed by genetic bottlenecks, random demographic fluctuations and localized catastrophes such as hurricanes. (USFWS, 1998; USFWS, 2008)

Stressor: Invasive plants (USFWS, 1998)

Exposure:

Response:

Consequence:

Narrative: Habitat degradation and competition from invasive plants such as Melinis minutiflora (molasses grass), Setaria gracilis (yellow foxtail), Sporobolus africanus (smutgrass),

lantana, *Psidium cattleianum* (strawberry guava), *Psidium guajava* (common guava), *Kahanchoe pinnata* (air plant), *Ageratum conyzoides* (maile hohono) and *Stachytarpheta* (NCN)) are threats to *B. insignis*. (USFWS, 1998)

Stressor: Fungal disease (USFWS, 1998)

Exposure:

Response:

Consequence:

Narrative: An unidentified fungal disease affected a number of cultivated *B. insignis*, causing a softening and collapse of the main stem tissue from the base (Factor C) (S. Perlman, National Tropical Botanical Garden, pers. comm. 2006). (USFWS, 2008)

Stressor: Pollination (USFWS, 2008)

Exposure:

Response:

Consequence:

Narrative: Pollination has been a problem for this species; it is presumed that the natural pollinator is a Sphingidae moth that now is either extinct or in extremely low numbers, which directly affects the amount of seed production for this species (Perlman 2006; K. Wood, pers. comm. 2006). (USFWS, 2008)

Stressor: Over-collection (USFWS, 2008)

Exposure:

Response:

Consequence:

Narrative: Some of the extirpated populations on the Na Pali Coast occurred near trails, which exposed the plants to overcollection and an increased likelihood of rock slides and invasive species introductions caused by hikers (Factor B) (USFWS 1995). (USFWS, 2008)

Stressor: Climate change loss or degradation of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Brighamia insignis* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.867 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2017)

Recovery

Reclassification Criteria:

1. A total of five to seven populations of each taxon should be documented on Maui and at least one other island where they now occur or occurred historically. (USFWS, 1998)

2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1998)

3. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered. (USFWS, 1998)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Maui and at least one other island where they now occur or occurred historically. (USFWS, 1998)

2. Each population must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1998)

3. Each population should persist at this level for a minimum of five consecutive years. (USFWS, 1998)

Recovery Actions:

- In order to prevent this taxon from going extinct, propagation efforts and the maintenance of adequate genetic stock ex situ should be undertaken immediately. (USFWS, 1998)
- It also crucial to protect the remaining wild individuals from goats and alien weed threats. (USFWS, 1998)
- Protect current populations, control threats and monitor. (USFWS, 1998)
- Expand current populations. (USFWS, 1998)
- Conduct research essential to conservation of the species. (USFWS, 1998)
- Establish new populations as needed to reach recovery objectives. (USFWS, 1998)
- Validate and revise recovery objectives. (USFWS, 1998)
- Devise and implement a public education program. (USFWS, 1998)
- Surveys and inventories—Survey for additional populations of *Brighamia insignis* in areas of potentially suitable habitat. (USFWS, 2017)
- Ungulate monitoring and control—Determine management needs of the immediate area of the one remaining wild individual and implement them to prevent extinction in the wild. (USFWS, 2017)
- Captive propagation for genetic storage and reintroduction—Continue to conduct research on outcrossing success, and collect seeds from living collections and handpollinations for adequate genetic representation. (USFWS, 2017)
- Reintroduction and translocation—Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. (USFWS, 2017)
- Predator and herbivore monitoring and control—Implement effective control methods for rodents at the last known location. (USFWS, 2017)
- Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from landslides. (USFWS, 2017)

- Genetic research—Review the complete living collections to determine origin of progeny, as plants with genetic representation from the Waiahuakua Valley population would provide the best source to increase genetic diversity within the species, based on the existing genetic studies. (USFWS, 2017)
- Population biology research—Conduct a more detailed genetic study of propagules from the wild individual and those in cultivation to determine genetic diversity between populations and individuals to assist in determination of suitable material to use in hand-pollination. (USFWS, 2017)

Conservation Measures and Best Management Practices:

- Determine management needs of the immediate area of the one remaining naturally occurring wild individual and implement them to prevent complete extinction in the wild. (USFWS, 2008)
- Increase the number of individuals in cultivation and genetic storage through controlled breeding. (USFWS, 2008)
- Reintroduce populations in areas of suitable habitat that can be protected from goats and other ungulates, rats, and human disturbance. (USFWS, 2008)
- Review the complete living collections to determine where progeny derived from crosses with the Waiahuakua Valley population still exist, as these plants would provide the best source to increase the genetic diversity within the species, based on the existing genetics work. (USFWS, 2008)
- Conduct a more detailed genetic study of the individuals in the wild and in cultivation to determine micro-level distinctions between populations and individuals, to assist in determining suitable material to use of hand pollinated crosses. (USFWS, 2008)

SPECIES ACCOUNT: *Brighamia rockii* (Pua `ala)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/08/1992; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Brighamia rockii, a member of the bellflower family (Campanulaceae), grows as an unbranched plant 1 to 5 m (3.3 to 16 ft) tall with a thickened, succulent stem that tapers from the base. The fleshy, oval leaves are widest at their tips and are arranged in a rosette at the top of the plant. They measure 6 to 22 cm (2.4 to 8.7 in) long and 5 to 15 cm (2 to 6 in) wide. The fragrant flowers are clustered in groups of three to eight in the leaf axils. Each flower cluster is on a stalk 3.5 to 7.5 cm (1.4 to 3.0 in) long, and each flower is on a stalk 6 to 12 mm (0.2 to 0.5 in) long. The green basal portion of the flower (hypanthium) has 10 ribs and is topped by 5 calyx lobes 2.5 to 8 mm (0.01 to 0.3 in) long. The petals are fused into a green to yellowish green tube 8 to 13 cm (3.1 to 5.1 in) long and 0.2 to 0.4 cm (0.1 to 0.2 in) wide that flares into five white, elliptic lobes 1.7 to 3.7 cm (0.7 to 1.5 in) long and 0.8 to 1.3 cm (0.3 to 0.5 in) wide. The fruit is a capsule 13 to 20 mm (0.5 to 0.8 in) long, 7 to 10 mm (0.3 to 0.4 in) wide, and 3 to 4 mm (0.1 to 0.2 in) thick containing numerous seeds about 1.1 to 1.2 mm (0.05 in) long. This species is a member of a unique endemic Hawaiian genus with only one other species, found on Kauai, from which it differs by the color of its petals, its longer calyx (fused sepals) lobes, and its shorter flower stalks (USFWS 1992). (USFWS, 1996)

Taxonomy

Genus endemic to hawaiian islands, species endemic to molokai. (NatureServe, 2015)

Historical Range

This long-lived perennial unbranched plant is endangered and occurred historically on the islands of Molokai, Maui, and Lanai. (USFWS, 2014)

Current Range

It is currently only found on Molokai. (USFWS, 2014)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Brighamia rockii* (Pua `ala) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes 18 detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Brighamia rockii* includes 18 CHUs in Maui County, Hawaii with detailed unit information. There are also an unknown number of units on Lanai that contain this species (number of units is unknown because detailed unit descriptions for Lanai are not available) (81 FR 17790-18110).

Maui—Coastal—Unit 1 consists of 2 ac (1 ha) on Keopuka Rock on the northern coast of east Maui. This unit is State-owned, and is classified as a State Seabird Sanctuary. It is occupied by the plant *Peucedanum sandwicense* and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Coastal—Unit 1 is not known to be occupied by *Brighamia rockii*, *Cyperus pennatiformis*, *Ischaemum byrone*, or *Vigna o-wahuensis*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Coastal—Unit 2 consists of 16 ac (6 ha) of State land, and 9 ac (4 ha) of privately owned land, from Wahinepee Stream to Moiki Point on the northern coast of east Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). Although Maui—Coastal—Unit 2 is not currently occupied by *Brighamia rockii*, *Cyperus pennatiformis*, *Ischaemum byrone*, *Peucedanum sandwicense*, or *Vigna o-wahuensis*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the physical or biological features necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, these species require suitable habitat and space for expansion or reintroduction to achieve population levels that could achieve recovery.

Molokai—Coastal—Unit 2 consists of 263 ac (106 ha) of State land, and 710 ac (287 ha) of privately owned land, from Ilio Point to Kaa Gulch, along the northwestern coast of Molokai. This unit is occupied by the plant *Marsilea villosa* and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 2 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Coastal—Unit 3 consists of 10 ac (4 ha) of privately owned land at Pauwalu Point on the northern coast of east Maui. This unit is occupied by the plant *Ischaemum byrone* and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations.

Although Maui—Coastal— Unit 3 is not known to be occupied by *Brighamia rockii*, *Cyperus pennatiformis*, *Peucedanum sandwicense*, or *Vigna o-wahuensis*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Coastal—Unit 4 consists of 40 ac (16 ha) of State land, and 35 ac (14 ha) of privately owned land, from Papiha Point to Honolulu Nui Bay on the northeastern coast of east Maui. This unit is occupied by the plant *Cyperus pennatiformis* and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Coastal—Unit 4 is not known to be occupied by *Brighamia rockii*, *Ischaemum byrnone*, *Peucedanum sandwicense*, or *Vigna owahuensis*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Coastal—Unit 5 consists of 26 ac (11 ha) of State land from Keakulikuli Point to Pailoa Bay on the northeastern coast of east Maui. This unit is occupied by the plant *Ischaemum byrnone* and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Coastal—Unit 5 is not known to be occupied by *Brighamia rockii*, *Cyperus pennatiformis*, *Peucedanum sandwicense*, or *Vigna o-wahuensis*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 5 consists of 1 ac (0.5 ha) on Huelo islet on the northern coast of Molokai. This area is State-owned, and is classified as a State Seabird Sanctuary. This unit is occupied by the plants *Brighamia rockii*, *Peucedanum sandwicense*, and *Pittosporum halophilum*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 5 is not known to be occupied by *Bidens wiebkii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrnone*, *Marsilea villosa*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low

population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Coastal—Unit 6 consists of 356 ac (144 ha) of State land at Kamanamana on the southern coast of East Maui. This unit is occupied by the plant *Vigna owahuensis* and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Coastal—Unit 6 is not known to be occupied by *Brighamia rockii*, *Cyperus pennatiformis*, *Ischaemum byrone*, or *Peucedanum sandwicense*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 6 consists of 190 ac (77 ha) of State land, and 1,685 ac (682 ha) of privately owned land, from Kaholaiki Bay to Halawa Bay, on the northeastern coast of Molokai. This unit is occupied by the plants *Bidens wiebkei*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, and *Ischaemum byrone*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 6 is not known to be occupied by *Brighamia rockii*, *Hibiscus brackenridgei*, *Marsilea villosa*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Coastal—Unit 7 consists of 30 ac (12 ha) of State land, and 15 ac (6 ha) of privately owned land, from Kailio Point to Waiuha Bay, on the southern coast of east Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). Although Maui—Coastal—Unit 7 is not currently occupied by *Brighamia rockii*, *Cyperus pennatiformis*, *Ischaemum byrone*, *Peucedanum sandwicense*, or *Vigna owahuensis*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 7 consists of 49 ac (20 ha) of privately owned land from Alanuihipaka Ridge to Kalanikaula, on the northeastern coast of Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). Although

Molokai—Coastal—Unit 7 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrnone*, *Marsilea villosa*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Coastal—Unit 8 consists of 493 ac (199 ha) of State land from Kiakeana Point to Manawainui on the southern coast of east Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). Although Maui—Coastal—Unit 8 is not currently occupied by *Brighamia rockii*, *Cyperus pennatifolius*, *Ischaemum byrnone*, *Peucedanum sandwicense*, or *Vigna owahuensis*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Coastal—Unit 9 consists of 170 ac (69 ha) of State land and 0.3 ac (0.1 ha) of privately owned land, from Poelua Bay to Mokolea Point on the northwestern coast of west Maui. This unit is occupied by the plants *Schenkia sebaeoides* and *Sesbania tomentosa*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Coastal—Unit 9 is not known to be occupied by *Brighamia rockii*, we have determined this area to be essential for the conservation and recovery of this coastal species because it provides the PCEs necessary for the reestablishment of wild populations within its historical range. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could approach recovery.

Maui—Coastal—Unit 10 consists of 147 ac (60 ha) of State land and 26 ac (10 ha) of privately owned land, from Kahakuloa Head to Waihee Point on the northeastern coast of west Maui. This unit is occupied by the plant *Schenkia sebaeoides*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Coastal—Unit 10 is not known to be occupied by *Brighamia rockii* or *Sesbania tomentosa*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within its historical range. Due to the small numbers of individuals or low population sizes, this species requires suitable habitat and space for expansion or reintroduction to achieve population levels that could approach recovery.

Maui—Coastal—Unit 11 consists of 6 ac (3 ha) of State land on Mokeehia Island on the northeastern coast of west Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). Although Maui—Coastal—Unit 11 is not currently occupied by *Brighamia rockii*, *Schenkia sebaeoides*, or *Sesbania tomentosa*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Wet Cliff—Unit 1 (and) *Palmeria dolei*—Unit 43—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 43—Wet Cliff This area consists of 1,395 ac (565 ha) of State land, and 212 ac (86 ha) of privately owned land, and encircles the plateau between Pelekunu and Wailau valleys, in north-central Molokai. These units are occupied by the plants *Brighamia rockii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea munroi*, and *Hibiscus arnottianus* ssp. *immaculatus*, and include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Wet Cliff—Unit 1 is not known to be occupied by *Cyanea grimesiana* ssp. *grimesiana*, *Hesperomannia arborescens*, *Phyllostegia hispida*, *Pteris lidgatei*, or *Stenogyne bifida*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Wet Cliff—Unit 2 (and) *Palmeria dolei*—Unit 44—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 44—Wet Cliff This area consists of 462 ac (187 ha) of State land, and 806 ac (326 ha) of privately owned land (partly within The Nature Conservancy's Pelekunu Preserve), along the rim of Pelekunu Valley from Kipapa Ridge to Mapulehu, in central Molokai. These units are occupied by the plants *Clermontia oblongifolia* ssp. *brevipes* and *Phyllostegia hispida*, and include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Wet Cliff—Unit 2 is not known to be occupied by *Brighamia rockii*, *Canavalia molokaiensis*, *Cyanea grimesiana* ssp. *grimesiana*, *C. munroi*, *Hesperomannia arborescens*, *Hibiscus arnottianus* ssp. *immaculatus*, *Pteris lidgatei*, or *Stenogyne bifida*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Wet Cliff—Unit 3 consists of 1,137 ac (460 ha) of State land, and 225 ac (91 ha) of privately owned land, along the rim of Wailau Valley from Mapulehu to Kahiwa Gulch, in eastern Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). Although Molokai—Wet Cliff—Unit 3 is not known to be occupied by *Brighamia rockii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea grimesiana* ssp. *grimesiana*, *C. munroi*, *Hesperomannia arborescens*, *Hibiscus arnottianus* ssp. *immaculatus*, *Phyllostegia hispida*, *Pteris lidgatei*, or *Stenogyne bifida*, we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Brighamia rockii* critical habitat consists of three components. Coastal (east Maui, west Maui and Molokai), Dry cliff (Lanai) and Wet cliff (Molokai) (81 FR 17790-18110):

Ecosystem: Coastal. Elevation: <980 ft (<300 m). Annual precipitation: <20 in (<50 cm). Substrate: Well-drained, calcareous, talus slopes; dunes; weathered clay soils; ephemeral pools; mudflats. Canopy: *Hibiscus*, *Myoporum*, *Santalum*, *Scaevola*. Subcanopy: *Gossypium*, *Sida*, *Vitex*. Understory: *Eragrostis*, *Jacquemontia*, *Lyceum*, *Nama*, *Sesuvium*, *Sporobolus*, *Vigna*.

Ecosystem: Dry Cliff. Elevation: unrestricted. Annual precipitation: <75 in (<190 cm). Substrate: >65 degree slope, rocky talus. Canopy: None. Subcanopy: *Antidesma*, *Chamaesyce*, *Diospyros*, *Dodonaea*. Understory: *Bidens*, *Eragrostis*, *Melanthera*, *Schiedea*.

Ecosystem: Wet Cliff. Elevation: unrestricted. Annual precipitation: >75 in (>190 cm). Substrate: >65 degree slope, shallow soils, weathered lava. Canopy: None. Subcanopy: *Broussaisia*, *Cheirodendron*, *Leptecophylla*, *Metrosideros*. Understory: *Bryophytes*, *Ferns*, *Coprosma*, *Dubautia*, *Kadua*, *Peperomia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight

plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; MauiWet

Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History

Food/Nutrient Resources

Breeding Season

Adult: August but may occur during other months (USFWS, 1996)

Reproduction Narrative

Adult: Recent observations of *Brighamia* by Geminill et al. (In Prep.) has provided the following information: the reproductive system is protandrous, meaning there is a temporal separation between the production of male and female gametes, in this case a separation of several days; only 5 percent of the flowers produce pollen; very few fruits are produced per inflorescence; there are 20-60 seeds per capsule; and plants in cultivation have flowers at an age of 9 months. This species was observed in flower during August 1987 (HHP 1994a). (USFWS, 1996)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Cliff, forest- hardwood, forest/woodland, shrubland/chaparral (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations from sea level to 470 meters (USFWS, 1996)

Environmental Specificity

Adult: Medium, with some key requirements (USFWS, 1996)

Habitat Narrative

Adult: This species is found on ledges on exposed steep moist coastal cliffs, with native grasses, shrubs and trees. The plants are found in rock crevices on steep sea cliffs, often within the spray zone, in Coastal Dry to Mesic Forests or Shrublands at an elevational zone from sea level to 470 meters (1,540 feet) with such associated species as ohia, *Canthium odoratum* (alahee),

Diospyros sandwicensis (lama), *Osteomeles anthyllidifolia* (ulei), and *Scaevola* (naupaka) (USFWS 1992). (USFWS, 1996; NatureServe, 2015)

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Not available.

Population Information and Trends

Population Trends:

Not available.

Resiliency:

Very low (USFWS, 2014)

Redundancy:

Very low (USFWS, 2014)

Number of Populations:

3 (1 wild population and 2 outplanted populations; USFWS, 2018)

Population Size:

~205 individuals (45 in the wild population and ~160 in the outplanted populations; USFWS, 2018)

Population Narrative:

The previous 5-year review in 2014 reported three populations totaling 34 individuals on Molokai. Currently, there is one wild population at Waiehu totaling 45 individuals. The large majority of plants, however, are inaccessible. There are also two outplanted populations, one with seven individuals and another with 42 (PEPP 2017). (USFWS, 2018)

Threats and Stressors

Stressor: Climate change (USFWS, 2014)

Exposure:

Response:

Consequence:

Narrative: Climate change destruction or degradation of habitat – Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Brighamia rockii* is highly vulnerable to the impacts of climate change. Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2014); The assessment by Fortini et al. (2013) concluded that *Brighamia rockii* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.838 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). (USFWS, 2018)

Stressor: Habitat damage from animals (USFWS, 1996)

Exposure:

Response:

Consequence:

Narrative: Habitat damage (and possibly predation) by deer and goats poses a serious threat to *Brighamia rockii*. (USFWS, 1996)

Stressor: Non-native plant species (USFWS, 1996)

Exposure:

Response:

Consequence:

Narrative: Competition with alien plants is also a threat. (USFWS, 1996)

Stressor: Low reproductive rates (USFWS, 1996)

Exposure:

Response:

Consequence:

Narrative: Recent observations suggest that low reproductive rates in wild populations could be due to a combination of factors including low production of pollen, low establishment of seedlings and a lack of pollinators (Gemmill et al. In Prep.). (USFWS, 1996)

Recovery

Reclassification Criteria:

1. A total of five to seven populations of each taxon should be documented on Molokai and at least one other island where they now occur or occurred historically. (USFWS, 1996)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1996)
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered. (USFWS, 1996)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Molokai and at least 1 other island where they now occur or occurred historically. (USFWS, 1996)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1996)
3. Each population should persist at this level for a minimum of 5 consecutive years. (USFWS, 1996)

Recovery Actions:

- Implementation of immediate recovery actions needed to keep “on-the-brink” species (those that number fewer than 100 individuals in the wild) from going extinct. These actions include propagation and maintenance of genetic stock ex situ, and protection of remaining wild individuals from threats. (USFWS, 1996)
- Delineation of management units to conserve not only these taxa, but their habitats as well. These units should be managed to preserve as many native species (flora and fauna) as possible, through threat-control and forest-restoration programs. (USFWS, 1996)
- Augmentation of small populations and re-establishment of new populations within the historical range of the species. (USFWS, 1996)
- A research program is also recommended to study the growth and reproductive viability of each taxon, determine the parameters of viable populations of each taxon, study the reproductive strategy and pollinators of each taxon, and study possible pests and diseases. (USFWS, 1996)
- Surveys and inventories—Survey for additional populations of *Brighamia rockii* in areas of potentially suitable habitat. (USFWS, 2018)
- Ungulate monitoring and control—Construct and maintain fenced exclosures to protect individuals from the negative impacts of feral ungulates. Protect all occurrences against browsing and habitat disturbances from feral ungulates. (USFWS, 2018)
- Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations. Control invasive nonnative species that compete with the species around all populations. (USFWS, 2018)
- Captive propagation for genetic storage and reintroduction—Evaluate genetic resources currently in storage to determine the need to place additional genetic resources in long-term storage due to this species’ high vulnerability to climate change. Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. (USFWS, 2018)
- Climate change adaptation strategy—Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change. (USFWS, 2018)
- Predator and herbivore monitoring and control—Implement effective control methods for rodents and slugs within the vicinity of all known *Brighamia rockii* populations. (USFWS, 2018)
- Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from low numbers. (USFWS, 2018)

Conservation Measures and Best Management Practices:

- Survey geographical and historical range for a current assessment of the species’ status. (USFWS, 2014)
- Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. Evaluate genetic resources currently in storage to determine the need to place additional genetic resources in long-term storage due to this species’ high vulnerability to climate change. (USFWS, 2014)
- Fence remaining populations to protect them from the impacts of feral ungulates. (USFWS, 2014)
- Eradicate invasive introduced plant species within ungulate exclosures and maintain the exclosures free of invasive introduced plants. (USFWS, 2014)

- Control slugs and rodents within the vicinity of all known *Brighamia rockii* populations. (USFWS, 2014)
- Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change. (USFWS, 2014)
- Continue monitoring wild and outplanted individuals. (USFWS, 2014)
- Initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2014)

SPECIES ACCOUNT: *Buxus vahlii* (Vahl's boxwood)

Species Taxonomic and Listing Information

Listing Status: Endangered; 8/13/1985; Southeast Region (R4) (USFWS, 2015)

Physical Description

An evergreen shrub or small tree reaching 16 feet in height, with a stem diameter of 5 inches. The leaves are simple, opposite, and oblong to obovate (USFWS, 1987).

Taxonomy

A member of the boxwood family (Buxaceae). The type material was originally identified as *Crantzia laevigata* (USFWS, 1987).

Historical Range

Historical records of the species include only two locations within the karst region in Puerto Rico (USFWS, 1987).

Current Range

Vahl's boxwood is endemic to the islands of Puerto Rico and St. Croix, US Virgin Islands (USFWS, 2013).

Critical Habitat Designated

Yes;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (inferred from EPA, 2016), asexual (USFWS, 1987)

Breeding Season

Adult: December - April (EPA, 2016)

Key Resources Needed for Breeding

Adult: Unknown - possibly wind or insects (EPA, 2016)

Reproduction Narrative

Adult: Flowering occurs from December to April and fruiting occurs in July. Pollination occurs possibly via wind or insects (EPA, 2016) and reproductive biology consists of capsules with tiny seeds that depend on mechanical dispersal (USFWS, 2019). Floral morphology suggests self-pollination is possible (USFWS, 1987).

Habitat Type

Adult: Terrestrial (EPA, 2016)

Habitat Vegetation or Surface Water Classification

Adult: Subtropical dry forest, subtropical moist forest (EPA, 2016)

Geographic or Habitat Restraints or Barriers

Adult: 33 - 984 ft. elevation (EPA, 2016)

Environmental Specificity

Adult: Moderate (inferred from EPA, 2016)

Habitat Narrative

Adult: Occurs in the subtropical dry forest life zone and to a lesser extent in the subtropical moist forest life zone; within semi-evergreen forests of the subtropical moist forest zone in limestone hills of the Karst region. Karst region is characterized by undulating topography of relatively low relief, but with steep rounded hills, caves, sinkholes, and subterranean streams. At Hato Tejas site, forest has two canopy layers, an open understory, and sparse groundcover. Much of upper canopy is deciduous and lower canopy is evergreen; heavily shaded. The other site is Punta Higuero and it is largely deforested and occupied by coastal forest tree species as well as salt tolerant shrub and herbaceous species. More open habitat and exposure to salt spray and wind. Both populations are currently restricted to ravines. Soils usually derived from limestone and poorly developed and excessively drained, although volcanic alluvium has been incorporated into the bottomland soils. Occurs at elevations around 33 to 984 ft. (EPA, 2016).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Seed dispersal occurs via explosion (EPA, 2016).

Population Information and Trends**Population Trends:**

Increasing (USFWS, 2019)

Redundancy:

Moderate (inferred from USFWS, 2013)

Number of Populations:

10 (USFWS, 2019)

Population Size:

5,400 (USFWS, 2019)

Population Narrative:

The species status is overall increasing. Currently overall, the Service knows of ten populations with over 5,400 individuals estimated, including 100 trees identified on a new site in March, 2018. This reflects an increase since the time of listing and a 20% overall increase since 2013 (USFWS, 2013; 2019).

Threats and Stressors

Stressor: Habitat destruction and modification (USFWS, 2013; 2019)

Exposure:

Response:

Consequence:

Narrative: The Rincón population is located on land owned by PREPA (a public corporation) adjacent to the long defunct BONUS nuclear reactor. However, there is no evidence that PREPA manages the area in any way. There is no fence or other access limitations. Breckon and Kolterman (1993) documented damage to this area and to plants of *B. vahlii* due to the apparent incursion of undocumented aliens and to presumably anthropogenic fires. In the case of Rincón, the boundaries of the property are not clearly defined and it is not possible to determine if part of the population lies within private land. The properties adjacent to this population have a great potential for urban and tourism development, which could result in further encroachment of the population and the modification of suitable habitat for the expansion of the population. For the Peñuelas-Ponce area the greatest threat is urban development (quarries, landfills, telecommunication towers, and residential housing and tourist development projects). All the populations within this area lie within private lands with no protection; the same applies to two of the St. Croix populations, as evidenced from the access road constructed through the center of the population. The native forest that harbors one of the populations at Ponce has been severely fragmented for housing lots (Omar Monsegur, Service, pers. obs. 2011). Furthermore, the general area that harbors suitable habitat for the species between Ponce and Peñuelas has been proposed for the construction of several infrastructure projects (Gasoducto del Sur and Vía Verde Gas Pipeline). In fact, one of the populations at Peñuelas lies within the boundaries of a rock quarry (Cantera Valdivieso; José Sustache, PRDNER, per. comm. 2011). Evidence of recent fires in the habitat and adjacent to known populations have been observed recently at Ponce (Omar A. Monsegur, Service, pers. obs. 2011) (USFWS, 2013; 2019).

Stressor: Other natural or manmade factors (USFWS, 2013; 2019)

Exposure:

Response:

Consequence:

Narrative: Vahl's boxwood may be further threatened by fires, hurricanes and climate change, although these are considered low and non-imminent threats to the species. Climate change is predicted to increase the frequency and strength of tropical storms, which could possibly impact the Rincón and Sandy Point "St. Croix" populations. The cumulative effect of coastal erosion due to severe hurricanes, plus the habitat modifications for urban and tourism development can further diminish the availability of suitable habitat, and therefore, limit the population expansion and colonization of new areas at Rincón and St. Croix. Hurricane Maria in 2017 devastated most habitats in Puerto Rico and St. Croix in 2017 and likely impacted this species. Human-induced fires may lead to destruction of the native vegetation seed bank and create favorable conditions for non-native plant species to out compete *Buxus vahlii*, particularly those populations occurring near forests where accidental or deliberate forest fires occur. In addition, the possibility of severe droughts may contribute to an increase in the quantity and frequency of fires on the Island. We have observed unusual shifts on dry and rainy seasons. In some cases these events have produced an overload of fuel (primary by exotic grasses) that when burned during the next dry season or drought produces severe damage to the native vegetation and seed bank (USFWS, 2013; 2019).

Stressor: Disease or predation (USFWS, 2019)

Exposure:**Response:****Consequence:**

Narrative: In 2013, the presence of the insect lobate lac scale *Paratachardina lobata*, was found in Bayamon and Rincon. Infestation in *Buxus vahlii* was more than 50% of the population. Although there is not enough evidence about the effect of this disease on the species, such pest may compromise the photosynthetic rate of the species and result in low reproductive output (reduced production of flowers and fruits).

Recovery**Reclassification Criteria:**

1. The two known populations at Hato Tejas (Bayamon) and Punta Higüero (Rincon) are placed under protective status (USFWS, 2013).
2. At least three new populations capable of self-perpetuation have been established within protected units of the Commonwealth Forest System in the karst region (e.g., Vega or Cambalache forests) (USFWS, 2013).

Delisting Criteria:

1. The five (5) existing population on private land (Rincon, Bayamon, Penuelas-Ponce, Aguadilla, and St Croix) show a stable or increasing trend, evidenced by natural recruitment and multiple age classes, and are protected via a conservation mechanism (USFWS, 2019).
2. Within the historic range and in protected suitable habitat, establish and manage four (4) additional population with a stable or increasing trend, evidenced by natural recruitment and multiple age classes (USFWS, 2019).
3. Threat reduction and management activities have been implemented to a degree that the species will remain viable into the foreseeable future (USFWS, 2019).

Recovery Actions:

- Prevent further habitat loss and population decline (USFWS, 1987).
- Continue to gather information on the distribution and abundance of *Buxus vahlii* in northern Puerto Rico (USFWS, 1987).
- Research (USFWS, 1987).
- Refine recovery goals (USFWS, 1987).
- Long-term protection and management of existing populations, including land acquisition, conservation easements, private landowner agreements and habitat restoration practices (USFWS, 2019).
- Establish four (4) new self-sustaining populations with genetics representation from each site within protected suitable habitat in Puerto Rico and USVI (USFWS, 2019).

Conservation Measures and Best Management Practices:

- The recovery of the species should focus on the protection of the known populations and its habitat. Conservation Agreements should be signed between the Service and private landowners to protect natural populations (USFWS, 2013).

- The land on which the Rincón population of *B. vahlii* occurs should be transferred from PREPA either to PRDNER or to the Puerto Rico Conservation Trust. Then, a management plan for the conservation of the species should be developed and implemented. The Service will start to advise PREPA on the benefits for the ecosystem and for the species by protecting this natural area (USFWS, 2013).
- The populations that are actively reproducing need to be identified and monitored to collect seed material for propagation purposes. A protocol to collect seed should be created and implemented to avoid altering the natural recruitment of the species (USFWS, 2013).
- The efforts by José R. Roman and Michael Morgan to germinate and to propagate the species need to be coordinated toward the recovery (ensuring that propagated material is used for the establishment and enhancement of populations) of the species (USFWS, 2013).
- The Bayamón, Peñuelas-Ponce, and St. Croix populations should be visited, and monitored on a regular basis; additional visits should be made after hurricanes, fires, or other major disturbances to determine their impacts on the populations (USFWS, 2013).
- The recovery plan should be revised to establish measurable criteria, including how many individuals constitute a self-sustainable population and how many populations would be needed to delist the species (USFWS, 2013).
- Studies should be conducted to determine the patterns of genetic variation within and among populations, in order to develop a plan to preserve the species germplasm (USFWS, 2013).
- Rincón has one of the most active “environmentalist” communities in Puerto Rico, which might well be recruited to assist in the species’ conservation. In fact, *B. vahlii* may well be the only endangered plant species with a major population located at Rincón, so it may be proposed as an iconic species for environmental education among school children and the general public at a local level (USFWS, 2013).

SPECIES ACCOUNT: *Callicarpa ampla* (Capa rosa)

Species Taxonomic and Listing Information

Listing Status: Endangered; Southeast Region (R4) (USFWS, 2015) 4/22/1992

Physical Description

An evergreen shrub or small tree reaching up to 15 meters (in) in height, with stout, tetragonal or subterete branches, and internodes of up to 6.5 centimeters (cm) long. Young branches are tetragonal, purplish-black in color, white scurfy, and glabrescent. The leaves are simple, opposite, decussate, and extipulate, dark shiny green above and pale green with white scurfy and raised veins and midveins below. The leaves are membranaceous or rarely subcoriaceous, measuring 8-35 cm long, and 3.5-8 cm wide; the leaf blade is elliptic to oblong, with an acute to acuminate apex, and with margins entire or slightly sinuate or dentate. The inflorescence is an axillary, corymbose cyme about 11 cm long. The cymes are densely whitish scurfy, with peduncles of 1-6.5 cm long. The flowers are actinomorphic and hermaphroditic. The species has a four-lobed, campanulate to subentire, lepidote or puberulent calyx which is 0.6-1.8 millimeters (mm) long and 1.3- 1.4 mm wide. The white four-lobed corolla is broadly tubular, measuring about 1.8 mm long and 1.7 mm wide. The four stamens of the flower measure 5.2 mm long, and are exerted and epipetalous at the base of the corolla. The four-lobed and four-celled ovary is subglobose, measuring about 1 mm in diameter. The fruit is a fleshy four-seeded drupe, about 6 mm in diameter. The fruit is whitish when young and becomes purple when ripe (Little et al. 1974). (USFWS, 1993)

Historical Range

Not Available

Current Range

Known from the lower montane forests of Puerto Rico (Ewel and Whitmore 1973) and one from St. Thomas, U.S. Virgin Islands (Vivaldi and Woodbury). (USFWS, 1993). As of 2019, predominantly restricted to El Yunque National Forest (EYNF) in northeastern Puerto Rico. (USFWS, 2019).

Critical Habitat Designated

Yes;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Unknown (USFWS, 2015)

Reproduction Narrative

Adult: Little is known about the reproductive biology of this species. Although adults in all populations of *Callicarpa ampla* were seen in either flower or fruit during February of 1991, seedlings have been seen in only one locality (Garcia and Laboy 1991). Fruits are present in

Holdridge herbarium specimen number 245, collected in September of 1940 (Vivaldi and Woodbury 1981a) (USFWS, 1993).

Habitat Type

Adult: Palo colorado forest (USFWS, 1993)

Habitat Vegetation or Surface Water Classification

Adult: Palo colorado forest (USFWS, 1993)

Tolerance Ranges/Thresholds

Adult: Low (inferred from USFWS, 1993)

Site Fidelity

Adult: High (inferred from USFWS, 1993)

Habitat Narrative

Adult: The Luquillo Mountains region is of volcanic origin and of a rough topography, with cliffs and rock exposures at high elevations. Six major rivers are born in the mountains and waterfalls are numerous. Nineteen soils belonging to four soil associations have been identified within the Caribbean National Forest (Silander et al. 1986), of which the Los Guineos-Guayabota-Rock land association constitutes the most extensive one (USDA 1977). This association contains acidic, shallow to deep, well drained to poorly drained steep soils. The Caribbean National Forest holds four vegetation types: tabonuco forest, palo colorado forest, palma de sierra forest, and dwarf or elfin forest. All the known localities of *Callicarpa ampla* and *Styrax portoricensis*, and some localities of *Ternstroemia luquillensis* and *Ternstroemia subsessilis* occur within the palo colorado vegetation type. Some localities of *Ternstroemia luquillensis* and *Ternstroemia subsessilis*, and all the localities of *Ilex sentenisi* occur in the dwarf forest vegetation type (USFWS, 1993). High ecological integrity and site fidelity as well as low tolerance ranges are inferred based on species specific habitat needs and low number of populations.

Dispersal/Migration**Motility/Mobility**

Adult: Low (Inferred from USFWS, 1993)

Dispersal

Adult: Low (Inferred from USFWS, 1993)

Dependency on Other Individuals or Species for Dispersal

Adult: Low/Slow (inferred from USFWS, 1993)

Population Information and Trends**Population Trends:**

Unknown (USFWS, 2015)

Species Trends:

Unknown (USFWS, 2015)

Resiliency:

Low (inferred from USFWS, 2015)

Representation:

Low (inferred from USFWS, 2015)

Redundancy:

Low (inferred from USFWS, 2015)

Number of Populations:

5 (USFWS, 2015)

Population Size:

~15 total individuals (USFWS< 2015)

Population Narrative:

Callicarpa ampla: When the recovery plan was approved in 1995, the number of individuals of this species was known to be approximately 14 distributed within five localities in the Palo Colorado Association Forest Type in the Luquillo Mountains (USFWS 1995). During the interagency assessment in 2011, a total of 15 individuals were identified in only two natural populations within El Yunque National Forest (Table 1). From two localities reported in the Recovery Plan in the Rio Blanco Ward, municipality of Naguabo, only one site with three individuals was located by USFS personnel in 2011 (Luis Rivera, USFS, 2011, pers. comm.). A previously reported site at Mameyes II Ward, municipality of Rio Grande, was not located, and in the Jimenez Ward, also in Rio Grande, only one of the two populations identified in the recovery plan was located. The Jimenez population consists of 12 individuals (27 stems). The site with three planted individuals at El Portal Visitor Center also was recorded by USFS during the assessment (Table 1). These individuals are the product of one air layer (asexual propagation) from the Rio Blanco Ward site in Naguabo (USFS 1985) that was not located in 2011 and two additional artificial air layers produced from the Jimenez Ward site near Sonadora Creek (Luis Rivera, USFS, 2011, pers. comm.). There is no long term monitoring of the natural populations, and the USFWS does not have accurate location for most of the historical populations of *C. ampla*. It is possible that some of the populations not found during the 2011 assessment may be extirpated (e.g., by landslides) (see factor D). The USFWS suspects that additional populations of these species may occur within the El Yunque National Forest, and probably in some remnants of native forest in the Carite and Guilarte Commonwealth Forests. However, if present we anticipate low number of individuals and little recruitment, similar to the originally known populations in El Yunque (USFWS, 2015).

Threats and Stressors

Stressor: Forest management (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: At the time of listing, forest management practices such as the establishment and maintenance of plantations, selective cutting, trails and roads construction and maintenance,

and shelter construction may have affected these trees. Furthermore, the proposed reconstruction and reopening of Road PR 191 was considered as a direct threat to some populations of these species. The destruction of the dwarf or elfin forests for the construction and/or expansion of communication facilities by the U.S. Navy and private entities were also considered a threat. Based on the available information, the core of the known populations of *L. sintenisii*, *S. portoricensis*, *C. ampla*, *T. subsessilis*, and *T. luquillensis* occur within the boundaries of El Yunque National Forest. Since the time of listing the USFWS has not documented any case of an individual of an endangered species being affected by forest management practices (management of plantations, trail maintenance or road construction). Moreover, the plans to reopen Road PR 191 have been abandoned due to the potential for further landslides that may compromise the project. Nonetheless, the USFS consults with the Service under Section 7 of the ESA when proposing actions within the forest to ensure that possible adverse effects to listed species are avoided or minimized before any such project is implemented. In addition, the USFS conduct environmental reviews documents under NEPA for all actions in the forest. These consultation mechanisms are effective tools to minimize possible effects of management activities on species and their habitats. Based on the above, we consider the present or threatened destruction, modification, or curtailment of the species habitat or range as low in magnitude and not imminent threat to these species (USFWS, 2015).

Stressor: Overutilization (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of individuals

Narrative: Despite the fact that plant collection in El Yunque National Forest is prohibited, when the five species were listed, collection was considered a threat due to the ornamental potential of these species. However, there is no evidence indicating that the species has been affected by these factors. Based on the above, we believe that overutilization for commercial, scientific or educational purposes is no longer a threat to these species (USFWS, 2015).

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: Since the currently known populations of these species are mostly restricted to El Yunque National Forest, and there are appropriate Commonwealth and Federal laws and regulations protecting these five species, we believe that the inadequacy of existing regulatory mechanisms should no longer be considered a threat to them. However, historical collections indicate that suitable habitat may extend to private properties adjacent to El Yunque. In fact, some of the known populations that occur within El Yunque National Forest are located just along the boundaries of the forest. Thus, it is important to note that enforcement on private lands continues to be a challenge as accidental damage or extirpation of individuals has occurred with other federally listed species due to lack of knowledge of the species by private land owners and law enforcement officers (USFWS, 2015).

Stressor: Hurricanes (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: Due to the low number of populations and individuals, hurricanes were identified as a threat to *I. sintenisii*, *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis* in the final rule. As endemic to the Caribbean, these tree species should be well adapted to tropical storms disturbance. However, the low number of populations and individuals pose a threat to the species by making them more susceptible to stochastic events such as hurricanes. In fact, it is not clear to what extent populations of these species may have been affected by Hurricane Hugo (which devastated El Yunque National Forest in 1989) or Hurricane Georges (in 1998). The heavy rains associated with tropical storms and hurricanes in the mountains of Puerto Rico often lead to landslides. Despite the low number of populations and individuals, the USFWS considers hurricanes, landslides and climate change as a moderate and non-imminent threat to these species (USFWS, 2015).

Stressor: Landslides (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: Natural landslides are common as part of the forest dynamics of El Yunque and it is expected that the frequency of this disturbance increases as a result of severe extreme rain events or droughts. Given the steep slopes on which most of these species grow, massive landslides may extirpate entire populations. The USFWS is aware that an area of road PR 191 that formerly connected the municipalities of Río Grande and Naguabo, and that run across the forest has historically been affected by landslides. This area was the site of some populations that were not located by the interagency group in 2011. Due to the severity of landslides, it was determined that it was not logistically and economically feasible to repair this road. Based on the 2011 surveys, *I. sintenisii* seems to be the only species that is not imminently threatened by hurricanes and landslides. The prime habitat for *I. sintenisii* is associated with dwarf forest vegetation. Due to the low agricultural value and inaccessibility of this habitat, this vegetation was not cleared during the peak of the deforestation of the island, and thus some of the highest parts of El Yunque remain as pristine forest. This explains the relative abundance of the species along the summits of Pico El Yunque and Pico del Este. Despite the low number of populations and individuals, the USFWS considers hurricanes, landslides and climate change as a moderate and non-imminent threat to these species (USFWS, 2015).

Stressor: Climate change (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of habitat/Loss of individuals

Narrative: This species may be further threatened by climate change, which is predicted to increase the frequency and strength of tropical storms and can cause severe droughts (Hopkinson et al. 2008). Vulnerability to climate change impacts is a function of sensitivity to those changes (e.g., changes rain regime and moisture availability), exposure to those changes, and adaptive capacity (Glick et al. 2011). Despite the relative abundance and apparently stability of the populations of *I. sintenisii*, its habitat is considered rare in Puerto Rico. These areas (dwarf forest vegetation) are ecological islands that harbor unique vegetation and environmental conditions. Shifts of vegetation communities are expected as temperatures and moisture regimes are altered by climate change. Under this scenario populations of *I. sintenisii* as well as *S. portoricensis*, *C. ampla*, *T. subsessilis*, and *T. luquillensis* may be displaced or outcompeted by native or exotic species with wider environmental plasticity. Despite the low number of

populations and individuals, the USFWS considers hurricanes, landslides and climate change as a moderate and non-imminent threat to these species (USFWS, 2015).

Stressor: Genetic variation (USFWS, 2015)

Exposure:

Response:

Consequence: Loss of viability

Narrative: Along with a decreasing population size, negative impacts of habitat fragmentation may result in erosion of genetic variation through the loss of alleles by random genetic drift (Honney and Jacquemyn 2007) and may also limit the ability of a species to respond to a changing environment (Booy et al. 2000). Given the extremely small population size and lack of connectivity between populations of *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis* in Puerto Rico, it is highly likely that their genetic variability is extremely low. Based on the above, we consider the lack of genetic variation a high and imminent threat to *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis*. Overall, we consider hurricanes, landslides, climate change and genetic variation as threats to *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis*. Due to the small number of populations, the USFWS considers the above mentioned threats as high in magnitude and imminent for those species. In the case of *I. sintenisii*, the species is at least stable and probably improving, thus we consider the above mentioned threats as low and non-imminent (USFWS, 2015).

Recovery

Reclassification Criteria:

An agreement between the Fish and Wildlife Service and the USDA Forest Service concerning the protection of *Callicarpa ampla*, *Ilex sintenisii*, *Styrax portoricensis*, *Ternstroemia luquillensis*, and *Ternstroemia subsessilis* within the Caribbean. National Forest property has been prepared and implemented (USFWS, 1993).

An agreement between the Fish and Wildlife Service and the Department of Natural and Environmental Resources (DNER) concerning the protection of the three species in Commonwealth forests has been prepared and implemented, if the species is found within DNER properties (USFWS, 1993).

New populations (the number of which should be determined following the appropriate studies) capable of self perpetuation have been established within protected areas (USFWS, 1993).

Delisting Criteria:

1. Existing natural populations exhibit a stable or increasing trend, evidenced by natural recruitment, and multiple age classes (addresses Factors E). (USFWS, 2019).
2. Establish or discover four (4) additional populations each of *Callicarpa ampla* within the current range at EYNF that exhibit a stable or increasing trend, evidenced by natural recruitment, and multiple age classes (addresses Factors A and E). (USFWS, 2019).
3. Establish or discover two (2) new populations of *Callicarpa ampla* outside the current range but within the historical range (e.g., Carite, Guilarte or Toro Negro Commonwealth Forests) that

exhibit a stable or increasing trend, evidenced by natural recruitment, and multiple age classes (addresses Factors A and E). (USFWS, 2019).

4. Threats have been addressed and/or managed to the extent that the species will remain viable into the foreseeable future (addresses Factor A and E). (USFWS, 2019).

Recovery Actions:

- Criterion 1 has been partially met. There is no formal agreement between the USFS and the USFWS for the implementation of a management plan to protect these five species. However, the El Yunque National Forest is managed by the USFS for conservation, and has an approved “Revised Land and Resource Management Plan” (1997), which is currently under revision. Moreover, Federal agencies are mandated to carry out programs for the conservation of endangered species under Section 7 of the Endangered Species Act (ESA) to ensure that any action authorized, funded or carried out by a Federal agency is not likely to jeopardize the continued existence of a federally listed species. Thus, the USFS continually consults with the USFWS to avoid and minimize impacts to listed species and their habitat at El Yunque National Forest. In addition, on July 26, 2005, the U.S. Congress enacted the Caribbean National Forest Act to designate approximately 10,000 acres of land in the El Yunque National Forest as wilderness and as a component of the National Wilderness Preservation System in accordance with the Wilderness Act (16 U.S.C. 1131 et seq.). This Act prohibits certain activities (e.g., timber harvest) within wilderness designated areas, although it does not preclude the installation and maintenance of facilities (e.g., data collection and remote transmission facilities) essential to the scientific and conservation purposes of the Forest Service. Therefore, the majority of the habitat upon which these species depend upon is essentially protected (USFWS, 2015).
- Criterion 2 has been partially met. Although there is no specific agreement between USFWS and the PRDNER concerning the protection of these three species in Commonwealth forests, there is an agreement between the two agencies under Section 6 of the Endangered Species Act, in which the PRDNER carries out conservation activities for the benefit of threatened and endangered species. Furthermore, these five species are listed by the PRDNER as endangered, and thus are protected by regulations of the Commonwealth of Puerto Rico (See factor D.). Therefore, special consideration is taken when considering actions within areas that harbor suitable habitat for these species (USFWS, 2015).
- Criterion 3 has been initiated. The Puerto Rico Conservation Trust (PRCT) is successfully propagating *Styrax portoricensis*. The USFWS has utilized some of this material and begun planting this species (approximately 50 individuals) at El Yunque National Forest. In addition, the PRDNER began planting *Styrax portoricensis* (approximately 5 individuals) in the Carite Commonwealth Forest. Furthermore, the USFS has propagated *Callicarpa ampla* by air layering (cloning by promoting rooting of branches using hormones), and has planted about three individuals at El Portal in El Yunque National Forest. However, little information is available about the reproductive biology and the ecology of these species. Further research and monitoring of reintroduced individuals is required to determine the success of these actions. There is no information about the propagation of any of the remaining three species (*Ilex sintenisii*, *Ternstroemia luquillensis* and *Ternstroemia subsessilis*) (USFWS, 2015).
- New in 2019: 1. Establish long-term conservation mechanisms (e.g., land conservation easements and conservation agreements) for private lands outside/bordering EYNF since

- these lands share similar vegetation and habitat characteristics. This new action should be included within Recovery Task 11. (USFWS, 2019).
- New in 2019 2: A protocol for the propagation and reintroduction of all five species should be developed in collaboration with partners (e.g., University of Puerto Rico, KEW, Fairchild Tropical Botanic Garden, PRDNER, Para La Naturaleza and Natural Resources Conservation Service). The protocol should address the feasibility of seed banking these species, and if deemed necessary, seed material should be stored at the Millennium Seed Bank (KEW) and USDA National Laboratory for Genetic Resources Preservation in Ft. Collins. This new action should be included within Recovery Task 33. (USFWS, 2019).
 - 2019 3. Studies in the species' population genetics should be conducted to determined patterns of genetic diversity across the species natural distribution, and to provide baseline information for sound management of these species. This new action should be included within Recovery Task 3. (USFWS, 2019).

Conservation Measures and Best Management Practices:

- 1. The USFS should establish a long term monitoring program for the populations of listed plants at El Yunque National Forest to determine population trends for these species. The guidelines for these monitoring should be included as part of the El Yunque National Forest Management Plan (USFWS, 2015).
- 2. Develop a comprehensive survey and assessment of the population of *I. sintenisii*. This survey must be standardized to ensure that the habitat (dwarf forest) is efficiently surveyed (USFWS, 2015).
- 3. Molecular studies should be conducted to determine the relationships within the genus *Ilex* in Puerto Rico (USFWS, 2015).
- 4. The USFS, PRDNER and the USFWS should develop an intensive survey program to inventory areas within and outside El Yunque National Forest with potential habitat for these species. This program should include training to field biologists to allow personnel to recognize listed species in the field (USFWS, 2015).
- 5. The populations that are actively producing seeds need to be identified and monitored to collect seed material for recovery purposes. A protocol to collect seed should be developed and implemented to avoid altering the natural recruitment of the species (USFWS, 2015).
- 6. Enhancement of natural populations should be considered a priority, particularly for *S. portoricensis*, *C. ampla*, *T. subsessilis* and *T. luquillensis*. The development of adequate propagation techniques is essential for the recovery of these species (USFWS, 2015).
- 7. Studies should be conducted to determine the patterns of genetic variation within and among populations, in order to develop a plan to preserve the species genetic variability (USFWS, 2015).
- 8. The recovery plan should be revised to establish measurable delisting criteria, including how many individuals constitute a self-sustainable population and how many populations would be needed to delist the species (USFWS, 2015).

SPECIES ACCOUNT: *Callirhoe scabriuscula* (Texas poppy-mallow)

Species Taxonomic and Listing Information

Listing Status: Endangered; 2/12/1981; Southwest

Physical Description

A perennial herbaceous plant found in deep, loose, sandy soils near the Colorado River in west Texas. The fleshy taproots extend about 45 centimeters (cm) (18 inches (in)) deep before branching. During the winter, the plants form rosettes of 3 to 8 basal leaves that have 3 to 5 palmately-arranged lobes. Flower stalks emerge in the spring, reaching up to 45 cm (18 in) tall. The stems and leaves have a rough texture due to a covering of stellate pubescence (star-shaped hairs). Flowers have 5 reddish-purple petals, about 3.8 cm (1.5 in) long, arranged in the form of a cup, with dark maroon centers. This species is distinguished from others in the Genus by its linear involucellar bractlets, valvate calyx lobes that form an apiculate or acuminate point in bud (cover photograph), indehiscent mericarps, stiffly erect stems, and 6- to 8-rayed stellate hairs. (USFWS, 2019a)

Taxonomy

Robinson (1895–1897, p. 302) described *Callirhoe scabriuscula* as a new species in the Malvaceae (Mallow Family), based on a single specimen collected by Dr. Sutton Hayes. Robinson distinguished this from other species in the genus by its densely pubescent carpels with short beaks and involucl of 3 linear bractlets (figure 1.e.a). *Callirhoe leiocarpa* (tall poppymallow) and *C. involucrata* (winecup) occur near *C. scabriuscula*. These are distinguished by smaller flowers with white petal bases and the absence of stellate pubescence; additionally, *C. leiocarpa* is an annual species and lacks an involucl, and *C. involucrata* has a prostrate rather than erect habit. (USFWS, 2019a)

Historical Range

Historically known from Runnels County, Texas.

Current Range

In four counties in Texas: Runnels, Coke, Mitchell, and Scurry. (USFWS, 2019a)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Lifespan

Adult: short-lived perennial (USFWS, 2019a)

Breeding Season

Adult: Flowers from late April to mid-June (USFWS, 2019a).

Key Resources Needed for Breeding

Adult: Insects for pollination (USFWS, 1985).

Reproduction Narrative

Adult: Texas poppy-mallow flowers from late April until mid-June (Amos 1979, pp. 8–10; USFWS 1985, pp. 7–9). Flowers open 2 to 3 hours after sunrise and close before sunset. If pollinated, flowers close within 30 to 90 minutes. Un-pollinated flowers continue to open for 6 to 8 days. Anthers of individual flowers mature prior to stigmas (figure 1.d), releasing their pollen about 36 hours before stigmas emerge. Less than 1 percent of flowers from which insects were excluded produced seeds. Conversely, 85 percent of open-pollinated flowers produced seeds; therefore, Texas poppy-mallow is a predominantly out-crossing species. Plants produced an average of 41.4 fruits per plant per year, and fruits averaged 19 seeds each; thus, individuals produced an average of 878 seeds per year. Three species of bees, *Diadasia afflicta*, *Melissodes intorta*, and *M. tepanica*, forage for nectar and pollen in Texas poppy-mallow flowers and use the staminal column as a landing and take-off platform; the foraging behaviors of these bees indicates that they are likely to be effective pollinators. *D. afflicta* and *M. intorta* are oligolectic species that forage primarily within the genus *Callirhoe*. Seeds mature and dehisce from 10 to 18 days after flowering and fertilization. Flowering ceases by late June, as the weather becomes increasingly hot and dry, and the stems die by late July. New rosettes emerge from the taproots in late August and September. (USFWS, 2019a)

Habitat Type

Adult: Terrestrial (USFWS, 2019a)

Habitat Vegetation or Surface Water Classification

Adult: Grasslands, shin oak shrublands, or open oak or mesquite woodlands (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Deep sandy soil blown from alluvial deposits along the Colorado River (USFWS, 2019a)

Habitat Narrative

Adult: Texas poppy-mallow occurs in deep, loose sands of the Tivoli and Brownfield Soil Series (USFWS 1985, pp. 3–4). These sands are carried by wind from alluvial formations in the Colorado River flood plain and deposited on the lee (north and east) side of the river (USDA Soil Conservation Service 1970, p. 26). The difference between Tivoli and Brownfield soils is that the former lacks a distinct B horizon, while the latter has a sandy clay subsoil at a depth of about 0.51–1.02 m (20–40 in). Dunes up to 9 m (30 ft) high and 61 m (200 ft) wide form to the lee of cultivated fields. These soils have very rapid rainfall infiltration rates, very little runoff, and low water holding capacity. Cruze (1991, pp. 12, 15) found 159 Texas poppy-mallow plants within an area of 225 m² (2,422 ft²) at the study site at EO3. About 80 percent of Texas poppy-mallow plants occurred on 1-m² (10.76 ft²) plots that had from 3 to 16 percent cover of forbs and grasses; 79 percent of plots were within this range of vegetative cover (p. 12). This demonstrates that occupied habitats have sparse vegetative cover. (USFWS, 2019a)

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Cruze (1991) investigated the soil seed reserve of the Runnels County population mentioned above (EO3). She recovered 325 seeds from 6,583 soil samples totaling 1.7 m³ (60.0

ft3) of soil (pp. 6, 9). Seed distribution was uneven, with 91 percent of recovered seeds in the uppermost 5 cm of the soil; 85 percent of seeds were found within 1 m (3.28 ft) in horizontal distance of an established individual (pp. 9–11), indicating that seeds have very limited dispersal. Seed viability, tested with tetrazolium chloride, was 16.3 percent (p. 12); on this basis, the author concluded that seed viability declines rapidly in the soil (p. 19). (USFWS, 2019a)

Population Information and Trends

Population Trends:

Not available.

Species Trends:

Not available.

Number of Populations:

10 (USFWS, 2019a)

Population Size:

Approximately 2800 individuals (USFWS, 2019a)

Minimum Viable Population Size:

1,300 mature, reproductive individuals (USFWS, 2019a)

Population Narrative:

The Texas Natural Heritage Program conducted extensive surveys for Texas poppy-mallow from 1987 through 1989 at 143 sites in 37 counties (Poole (1990). This project documented 9 new populations at 6 sites in Runnels, Coke, and Mitchell counties, totaling 2,817 individuals, and reported an additional population discovered in Coke County in 1990 by an environmental consultant (Poole 1990, pp. 1, 3). All populations were found in areas of intact native vegetation on deep, loose, sandy soils of the Tivoli and Brownfield Series near the Colorado River (note that Likes and Heatly are alternate names for the Tivoli and Brownfield soil map units, respectively). The species has now been documented in four counties—Runnels, Coke, Mitchell, and Scurry (Amos 2008, 2019). The most recent censuses (TXNDD 2019) for all known EOs totals less than 3,000 individuals; however, we have no survey data more recent than 2001. All known populations of Texas poppy-mallow occur in Tivoli (Likes) and Brownfield (Heatly) fine sands (NRCS 2019c) in Runnels, Coke, Mitchells, and Scurry counties. Although we do not have geographic data for populations in Scurry County, Amos (2008, 2019) confirmed that at least one population extends from northern Mitchell County into southern Scurry County. The known populations span a linear distance of about 155 km (96 mi) from northwest to southeast. Within the counties mentioned, NRCS (2019c) classifies 16,987 ha (41,975 ac) as Tivoli (Likes) or Brownfield (Heatly) fine sands. (USFWS, 2019a)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 1981)

Exposure:

Response:

Consequence:

Narrative: Much of the natural habitat of *Callirhoe scabriuscula* has been disturbed. The present-range is limited to one Texas county, much of which is no longer suitable habitat for the plant. The actual area covered by the plant is very small. The range is dissected by a four-lane divided highway (Highway 67) and two frontage roads. All of the land on which the plants now occur is in private ownership. Cultivation, establishment of rural residences, and development of roads and a railway have reduced the range and the size of the populations. An imminent threat to all existing populations is commercial sand mining within the plant's habitat (USFWS, 1981).

Stressor: Overutilization (USFWS, 1981)

Exposure:

Response:

Consequence:

Narrative: If exact localities were published, the plant's conspicuous and showy blooms could cause it to be threatened by amateur gardeners wildflower enthusiasts, and commercial horticultural collecting. Since all the populations occur on privately owned land, taking of these attractive plants could not be prohibited (USFWS, 1981).

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2019a)

Exposure:

Response:

Consequence:

Narrative: The ESA does provide some legal protection for federally-listed plants on land under federal jurisdiction; however, the known populations of Texas poppy-mallow occur almost entirely on privately-owned land (as well as a small amount of state highway ROW). Federally-listed plants occurring on private lands have limited protection under the ESA, unless they are protected by state laws; the State of Texas also provides very little protection to listed plant species on private lands. It is reasonable to assume that any undiscovered populations are also likely to be privately owned. Therefore, none of the species' populations and habitats are subject to federal protection unless there is a federal nexus, such as provisions of the Clean Water Act, or a federally-funded project, for example, a new highway or water treatment plant. Chapter 88 of the Texas Parks and Wildlife Code lists plant species as state-threatened or endangered once they are federally listed with these statuses. The State of Texas listed Texas poppy-mallow as endangered on April 29, 1983. The State prohibits taking and/or possession for commercial sale of all or any part of an endangered, threatened, or protected plant from public land. Texas Parks and Wildlife Department requires permits for the commercial use of listed plants collected from private land. Scientific permits are required for collection of endangered plants or plant parts from public lands for scientific or educational purposes. In addition to state endangered species regulations, other state laws may apply. For example, state law prohibits the destruction or removal of any plant species from state lands without a Texas Parks and Wildlife Department permit. (USFWS, 2019a)

Stressor: Demographic and genetic consequences of small population sizes (USFWS, 2019a)

Exposure:

Response:

Consequence:

Narrative: Small populations are less able to recover from losses caused by random fluctuations in recruitment (demographic stochasticity) or variations in rainfall (environmental stochasticity) (Shaffer and Stein 2000, pp. 308-310). In addition to population size, it is likely that population

density also influences population viability, since successful sexual outcrossing—necessary to maintain genetic diversity in populations—requires genetically distinct individuals to be in sufficiently close proximity for cross-pollination to occur. Small, reproductively isolated populations are also susceptible to the loss of genetic diversity, to genetic drift, and to inbreeding depression. The combined demographic and genetic consequences of small population sizes may reduce population recruitment, leading to an extinction vortex of even smaller populations, greater isolation, decreasing genetic diversity, and loss of viability. These factors may already have contributed to the restriction of Texas poppy-mallow to its current state of extreme endemism in the Tivoli (Likes) and Brownfield (Heatly) sands along the Colorado River of Texas. (USFWS, 2019a)

Recovery

Reclassification Criteria:

1. Texas poppy-mallow is documented in 10 or more protected, viable populations, with at least 3 viable populations in each of 3 recovery units. Populations and metapopulations are delineated by unpopulated gaps of at least 1 km (0.6 mi). However, viable populations that expand and merge with other populations may be counted as separate populations for the specific purpose of meeting this criterion. (USFWS, 2019b)
2. Viable populations have 1,600 or more mature individuals. Mature individuals have flowered at least once or are judged capable of flowering. Population surveys should be conducted during the peak of flowering and fruiting, from April through June. (USFWS, 2019b)
3. Protected populations occur on lands that are legally protected and managed to conserve the Region's native flora and fauna, including Texas poppy-mallow, its habitats, and its pollinators. Examples include, but are not limited to, conservation easements on private lands, lands owned and managed for conservation by non-profit organizations, publicly-owned land managed for conservation purposes, and legally binding long-term management agreements with private landowners. (USFWS, 2019b)

Delisting Criteria:

1. Periodic monitoring indicates that the downlisting criteria have been met, and that demographic trends have subsequently remained stable or have increased over a period of 25 years. Ideally, monitoring (censuses) of each protected population should be conducted during years of above-average April–May rainfall; trend detection should be based on the largest populations observed during each 5-year period. (USFWS, 2019b)

Recovery Actions:

- Manage presently known individuals and habitat for maintenance and expansion of existing wild populations.. A crucial step in recovery is to protect existing populations and the habitat upon which they depend. All populations are threatened by expansion of commercial sand mining and development. The land presently inhabited by the Texas poppy-mallow is under private ownership. The Endangered Species Act is most effective in protecting populations on Federal lands. Immediate protection of the habitat and cooperation with landowners is essential to recovery of the species. (USFWS, 1985)

- Sustain healthy populations in their natural habitat at existing sites. In order to develop management plans for sustaining healthy populations, it may be necessary to learn more about the Texas poppy-mallow. (USFWS, 1985)
- Search potential habitat for additional populations. Other windblown sand deposits similar to the habitat presently occupied by Texas poppy—mallow exist on the upper Colorado River between Ballinger and Colorado City (a distance of about 80 miles). These areas need to be thoroughly searched for new populations. Additionally, deep sands are extensive in Jones, Haskell, Knox, Foard, Hardeman, and adjacent counties north of the presently known populations. Suitable habitat may exist in some of these counties and they should also be searched for presence of the species structure. (USFWS, 1985)
- Establish additional populations within the historic range. If searches fail to locate enough new populations to ensure safety for the species, expanding present populations within the essential habitat and introducing the species into new areas within its historic range would diminish the risk of extinction. (USFWS, 1985)
- Develop public awareness, appreciation, and support for presentation of the Texas poppy-mallow. Education and cooperation of the public is a vital part of the recovery process. Enlist the support of public interest groups such as the Texas Organization for Endangered Species, The Nature Conservancy, and local garden clubs. The visibility of this support can be instrumental in shaping public opinion. Useful tools in this endeavor would include talks and slide presentations to local interest groups and articles on the Texas poppy-mallow in newspapers and nature magazines. (USFWS, 1985)
- Recommendation for Future Action (USFWS, 2019a): Revise the recovery plan and recovery criteria to incorporate updated guidance and specific, measurable recovery criteria (U.S. Fish and Wildlife Service 2017). Use the MVP level and population delimitation distances described in this review as components of recovery criteria that address resilience and redundancy. Adopt the provisional recovery units discussed in this review to develop recovery criteria that address the species' ecological and genetic representation.
- Recommendation for Future Action (USFWS, 2019a): Promote awareness and conservation of Texas poppy-mallow in Runnels, Coke, Mitchell, and Scurry counties.
- Recommendation for Future Action (USFWS, 2019a): Seek permission to survey and monitor populations on private land.
- Recommendation for Future Action (USFWS, 2019a): Conduct up-to-date censuses of the accessible populations and revise the TXNDD EO records.
- Recommendation for Future Action (USFWS, 2019a): Work cooperatively with private landowners who are interested in conserving and managing the species on their lands. Consider voluntary measures to confer long-term protection for populations on private lands, such as conservation agreements and conservation easements.
- Recommendation for Future Action (USFWS, 2019a): Propagate the species, using seeds in the Lady Bird Johnson Wildflower Center seed bank, to establish seed production plots, renew the seed bank, and reintroduce populations in appropriate sites that can be protected.
- Recommendation for Future Action (USFWS, 2019a): Recommendation for Future Action (USFWS, 2019a): Obtain support for conservation actions from the Cooperative Endangered Species Conservation Fund (Section 6) or other grant sources.

Conservation Measures and Best Management Practices:

- Not available.

SPECIES ACCOUNT: *Calypttranthes thomasiana* (Thomas' Lidflower)

Species Taxonomic and Listing Information

Listing Status: Endangered; 2/18/1994; Southeast Region (R4) (USFWS, 2015)

Physical Description

An evergreen shrub or small tree that may reach 10 meters (30 feet) in height and 13 centimeters (5 inches) in diameter. Leaves are opposite, obovate to oblong, 2 to 4 centimeters long, blunt at the apex, and short pointed at the base. The leaves are coriaceous, with gland dots, shiny on the upper surface, and dull on the lower surface. The inflorescences are subaxillary and the cymes trichotomous. Flower-buds are obovoid, apiculate, and 3 millimeters long. Flowers have four small, spatulate petals. The fruit has not been described (Liogier 1994) (USFWS, 1997).

Taxonomy

It may be pointed out that the recovery plan for *Calypttranthes thomasiana* (USFWS, 1997) cites “no common name” but Thomas' Lidflower seems well established: Lidflower is the common name in English for other *Calypttranthes* species and Thomas is an appropriate geographical reference. This common name has been adopted by both the USDA PLANTS database and the IUCN Red List (USFWS, 2013).

Historical Range

At the time of listing, Thomas' Lidflower was reported from small populations from four islands: Vieques (PR), St. John and St. Thomas (USVI), and Virgin Gorda (BVI) (Clubbe et al. 2003) (USFWS, 2013).

Current Range

Currently, the species is known only from St. John and Virgin Gorda (USFWS, 2013). As of 2019: The known species occurrence is restricted to the USVI and BVI: St. John and St. Thomas (USVI), and Virgin Gorda and Tortola (BVI) (USFWS 2013). The species is estimated to be between 1,000 and 2,000 mature individuals and all sub-populations are suspected of having less than 1,000 mature individuals (IUCN 2018). In St John, the species is located within the Virgin Islands National Park managed by the U.S. National Park Service. (USFWS, 2019). In St. Thomas, the species was rediscovered by local plant experts and occurs at possibly two locations with an estimated population of 30 to 45 individuals between the two sites (IUCN 2018). (USFWS, 2019b).

Critical Habitat Designated

Yes;

Life History

Food/Nutrient Resources

Dependency on Other Individuals or Species

Adult: Unknown - possibly insects (EPA, 2016)

Reproduction Narrative

Adult: Insects are potential pollinators (EPA, 2016).

Habitat Type

Adult: Terrestrial (EPA, 2016)

Habitat Vegetation or Surface Water Classification

Adult: Subtropical moist forest (EPA, 2016)

Geographic or Habitat Restraints or Barriers

Adult: 984 - 1312 ft. elevation (EPA, 2016)

Environmental Specificity

Adult: Narrow (inferred from EPA, 2016)

Habitat Narrative

Adult: Occurs primarily within the subtropical moist forest life zone, perhaps extending into the subtropical dry forest zone. It has been reported to exist in the moist forest type at the Gorda Peak National Park in Virgin Gorda. In St. John, the species is found in the moist forest life zone but on the windward side of the Bordeaux Mountain where the effects of the wind make it a drier forest type. Rainfall ranges from 600 to 1,100 mm (24-44 in.) per year in the subtropical dry forest and from 1,100 to 2,200 mm (44-88 in.) per year in the subtropical moist forest. Soils are volcanic in origin and dominated by Cramer clay loam (St. John). Soils classified as Pandura-Very Stony Land Complex and is characterized by shallow, well-drained soils that are moderately permeable and acidic (Monte Pirata). Occurs between 984 and 1312 ft. elevation (EPA, 2016).

Dispersal/Migration**Dependency on Other Individuals or Species for Dispersal**

Adult: Bats (EPA, 2016)

Dispersal/Migration Narrative

Adult: Bats have been observed feeding on the fruits. Fruit dispersal also potentially occurs via abiotic factors (EPA, 2016).

Population Information and Trends**Population Trends:**

Decreasing (USFWS, 2013)

Species Trends:

Unknown (USFWS, 2013)

Resiliency:

Very low (inferred from USFWS, 2013)

Representation:

Low (inferred from USFWS, 2013)

Redundancy:

Very low (inferred from USFWS, 2013)

Number of Populations:

2 (USFWS, 2013)

Population Size:

59 (USFWS, 2013). At present time, between 1,000 and 2,000 mature individuals are known to occur in four sites: St Thomas, St. John, Virgin Gorda and Tortola (IUCN 2018). (USFWS, 2019).

Population Narrative:

The species status is unknown; the populations of Thomas' Lidflower have been poorly monitored and no information on population trends and demographic features are currently available. New information on the Thomas' Lidflower indicates that the species' population has decreased since the time of listing in 1994. Clubbe et al. (2003) cited that work in the BVI has documented a single locality on Virgin Gorda that comprises two subpopulations, one with 34 and another with 25 mature individuals, making a total population size for Virgin Gorda at 59 individuals within Gorda Peak National Park. With respect to the population from Vieques, recently, species' experts excluded the species from that island. Limited distribution suggests this species has low genetic variability (USFWS, 2013).

Threats and Stressors

Stressor: Exotic mammals (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Exotic mammals such as white-tailed deer (*Odocoileus virginianus*) and wild domestic mammal such as feral goats (*Capra aegagrus hircus*), pigs (*Sus scrofa*), and donkeys (*Equus asinus*) are found throughout the range of the Thomas' Lidflower on St. John and Virgin Gorda (Carlos Pacheco, USFWS, 2012, pers. obs.). Clubbe et al (2003) also mentioned loose cattle trampling through the Gorda Peak National Park may pose a threat to individuals in Virgin Gorda. It is expected that, due to their abundance, these exotic mammals are modifying the forest structure through overgrazing or altered seed dispersal mechanisms (Chakroff 2010). This may imply changes to microhabitat conditions that are necessary for seed germination and seedling recruitment of the specie (USFWS, 2013).

Stressor: Habitat destruction and modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: The Thomas' Lidflower population in Virgin Gorda lies within the Gorda Peak National Park. Clubbe et al (2003) cited that some developments are occurring close to the Park boundary that may negatively affect the species' habitat and could result in loss of mature individuals. The author also mentioned increase of visitation by hikers (locals and tourist) through the walking trails and human trampling through the Park to exploring new areas may result in losses of individuals in Virgin Gorda. Proctor (1992) stated that although Thomas' Lidflower had not been

found on St. Thomas since 1980, deforestation at the collection area for residential and tourist development may pose imminent threats to the survival of the species, if present (USFWS, 2013).

Stressor: Limited distribution (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Thomas' Lidflower is vulnerable to extinction due to its limited distribution and highly specialized ecological requirements. The low population number and restricted distribution (i.e., only 2 populations reported), coupled with habitat alteration or loss may also exacerbate its vulnerability to natural or anthropogenic events such as hurricanes, compromising the continued existence of this species (USFWS 1997). Given the extremely limited geographic distribution of Thomas' Lidflower, it is highly likely that its genetic variability is very low. This would result in a loss of alleles by random genetic drift, which would limit the species' ability to respond to changes in the environment (Honney and Jacquemyn, 2007) (USFWS, 2013).

Stressor: Invasive species (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: The most comprehensive forest inventory of the U.S. Virgin Islands indicate that three most common plant species are the invasive exotic plants, *Leucaena leucocephala*, *Tecoma stans* and *Megathyrsus maximus* (Chakaroff 2012). Any disturbance on vegetation along the road may create conditions favorable for the establishment of invasive species that may outcompete with native plants species changing vegetation structure. Invasive species (e.g. *Leucaena leucocephala* and *Megathyrsus maximus*) may spread and colonized the Thomas' Lidflower habitat, and it could alter fire regimes, microclimate, and nutrient cycling of the habitat that the species depend (USFWS, 2013).

Stressor: Climate change (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: As a species endemic to the Lesser Antillean, the Thomas' Lidflower should be adapted to hurricanes, but its occurrence at the highest elevations of St John and Virgin Gorda, where winds may be stronger, may place it at increased risk, especially as climate change is predicted to increase the frequency and strength of hurricanes. Hurricane winds often lead to tree defoliation, loss of small and large branches, and up-rooted resulting in damage to adjacent trees and understory plants when trees or branches fall, and ultraviolet damage to leaves of understory juveniles exposed to high light levels (Brokaw and Walker 1991). Additionally, high rainfall associated with tropical storms and hurricanes, sometimes about 24 inches (2 feet) of rain in a single storm event, can cause floods and interacting with topography and geologic substrate may induce mass wasting events, e.g. land, mud and debris slides (Lugo 2000). An expected effect of the climate change is the increase in intensity of hurricanes and tropical storm, followed by extended period of drought (IPCC 2012). This climate change may alter (modify) the surrounding vegetation around the populations of the Thomas' Lidflower. Hurricane effects followed by extended period of drought may result in changes in soil conditions and

microclimate and may allow other plants (native or non-native, herbaceous or woody) adapted to drier conditions to become established (Lugo 2000) (USFWS, 2013).

Recovery

Reclassification Criteria:

1. An agreement between the U.S. Fish and Wildlife Service and the U.S. Navy has been prepared and implemented for the protection of the known population on Vieques (USFWS, 2013). Criteria deemed obsolete in 2019. (USFWS, 2019).
2. An agreement between the U.S. Fish and Wildlife Service and the National Park Service has been prepared and implemented for the protection of the known population on St. John (USFWS, 2013).
3. New populations (the number of which should be determined following the appropriate studies) capable of self-perpetuation have been established in protected areas such as other areas on Vieques or St. John (USFWS, 2013).

Delisting Criteria:

1. The two (2) existing populations on the U.S. Virgin Islands, and two (2) existing populations on the British Virgin Islands show a stable or increasing trend, evidenced by natural recruitment and multiple age classes (addresses Factors A and E). (USFWS, 2019b).
2. Populations that exists on privately owned lands on St. Thomas are protected and managed through a conservation mechanisms (addresses Factor A). (USFWS, 2019b).
3. Establish two (2) new populations on lands protected by a conservation mechanism, and these populations show a stable or increasing trend, evidenced by natural recruitment and multiple age classes (addresses Factors A and E). (USFWS, 2019b).
4. Threat reduction and management activities have been implemented to a degree that the species will remain viable into the foreseeable future (addresses Factor C). (USFWS, 2019b).

Recovery Actions:

- Protect the existing population and its habitat through an agreement with the U.S. Navy and National Park Service (USFWS, 1997).
- Develop a management plan for the species in cooperation with these entities (USFWS, 1997). Refinement in 2019: The Service and the National Park Service should develop a plan with specific actions for the management and enhancement of existing populations within the Virgin Islands National Park. (USFWS, 2019, Recommended Action 7).
- Monitor known populations (USFWS, 1997). Refinement in 2019: The population should be monitored on a regular basis, and additional survey visits should be made after hurricanes, landslides, or other major disturbances. The known population at St. John should be monitored on a long term basis to determine the species' trends. (USFWS, 2019, recommended action #6).
- Enforce existing Commonwealth and Federal endangered species regulations (USFWS, 1997).

- Conduct research on the life history of the species and evaluate propagation techniques (USFWS, 1997). Refinement in 2019: Studies should be conducted on the species' phenology and reproductive biology. (USFWS, 2019, Recommended Action 3).
- Conduct propagation and enhance existing populations or establish new ones on protected lands (USFWS, 1997). Refinement in 2019: Propagation and reintroduction of the species should be conducted in order to strengthen the existing population. This action should be carefully evaluated by the Service taking into consideration if the species continues to be viable, existing threats to the species, genetic variations and if we can find ways to propagate without seeds. (USFWS, 2019, Recommended action 5).
- New in 2019: The status (distribution, abundance, possible threats) of Thomas' Lidflower in the U.S. and BVI should be ascertained. Mechanisms should be developed to share information on this and other Puerto Rican Bank species, and to coordinate conservation plans and activities. (USFWS, 2019, Recommended Action 1).
- New in 2019: Field surveys on Thomas' Lidflower should be conducted within historical sites and in non-traditional sites with suitable habitat to determine the existence of this species. (USFWS, 2019, Recommended action 2)
- New in 2019: Studies should be conducted to determine the patterns of genetic variation, in order to develop a plan to preserve the species' germplasm. (USFWS, 2019, Recommended Action 4).
- New in 2019: As new information becomes available, when individuals are documented, and the Service works further with partners like the National Park Service, the recovery plan should be revisited and possibly revised to establish measurable criteria, including how many individuals constitute a self-sustainable population and how many populations would be needed to delist the species. (USFWS, 2019, Recommended action 8).

Conservation Measures and Best Management Practices:

- The status (distribution, abundance, possible threats) of Thomas' Lidflower in the U.S. and BVI should be ascertained. Mechanisms should be developed to share information on this and other Puerto Rican Bank species, and to coordinate conservation plans and activities (USFWS, 2013).
- Field surveys on Thomas' Lidflower should be conducted within historical sites and in non-traditional sites with suitable habitat to determine the existence of this species (USFWS, 2013).
- Studies should be conducted on the species' phenology and reproductive biology (USFWS, 2013).
- Studies should be conducted to determine the patterns of genetic variation, in order to develop a plan to preserve the species' germplasm (USFWS, 2013).
- Propagation and reintroduction of the species should be conducted in order to strengthen the existing population. This action should be carefully evaluated by the Service taking into consideration if the species continues to be viable, existing threats to the species, genetic variations and if we can find ways to propagate without seeds (USFWS, 2013).
- The population should be monitored on a regular basis, and additional survey visits should be made after hurricanes, landslides, or other major disturbances. The known population at St. John should be monitored on a long term basis to determine the species' trends (USFWS, 2013).
- The Service and the National Park Service should develop a plan with specific actions for the management and enhancement of existing populations within the Virgin Islands National Park (USFWS, 2013).
- As new information becomes available, when individuals are documented, and the Service works further with partners like the National Park Service, the recovery plan should be revisited and possibly revised to establish measurable criteria, including how many individuals constitute a self-

sustainable population and how many populations would be needed to delist the species (USFWS, 2013).

SPECIES ACCOUNT: *Calyptridium pulchellum* (Mariposa pussypaws)

Species Taxonomic and Listing Information

Listing Status: Threatened; 10/14/1998; Pacific Southwest (R8) (USFWS, 2015)

Physical Description

An annual herb that forms a basal rosette of leaves and slender, spreading, leafy stems, 1-2 dm long. Loose inflorescences (generally 2+ per rosette), made up of head-like clusters of rose-colored flowers bloom in the spring and summer. (NatureServe, 2015)

Taxonomy

U.S. FWS uses the name *Calyptridium pulchellum*. (NatureServe, 2015). *Calyptridium pulchellum* is an annual member of the Portulacaceae (purslane family). (USFWS, 2007)

Historical Range

No evidence exists that the historical range of *Calyptridium pulchellum* was ever wider than the current range. (USFWS, 2007)

Current Range

Mariposa, Madera, and Fresno counties, California; all are within a 20 mile stretch. (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Breeding Season

Adult: Spring and summer. (Nature Serve, 2015)

Reproduction Narrative

Adult: Loose inflorescences (generally 2+ per rosette), made up of head-like clusters of rose-colored flowers bloom in the spring and summer. (Nature Serve, 2015)

Habitat Type

Adult: Terrestrial (USFWS, 2007)

Habitat Vegetation or Surface Water Classification

Adult: Granite domes and gravelly openings (J. Clines, Sierra National Forest, in litt. 1998; CNDDDB 2006). (USFWS, 2007)

Dependencies on Specific Environmental Elements

Adult: Sparsely-vegetated (J. Clines, Sierra National Forest, in litt. 1998; CNDDDB 2006) and sandy soils (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Sparsely vegetated areas, 400-1100 m elevations (USFWS, 2007)

Spatial Arrangements of the Population

Adult: Colonial (inferred from USFWS, 2007)

Dependency on Other Individuals or Species for Habitat

Adult: Calyptridium pulchellum typically grows in association with the rare species Lupinus citrinus. (USFWS, 2007)

Habitat Narrative

Adult: Calyptridium pulchellum is an annual member of the Portulacaceae (purslane family) that grows in sparsely-vegetated areas such as granite domes and gravelly openings within foothill woodland communities (J. Clines, Sierra National Forest, in litt. 1998; CNDDDB 2006). (NatureServe, 2015). Occurrences range in elevation from a low of 442 meters (1,450 feet) in Mariposa County to a high of 1,097 meters (3,600 feet) in Fresno County (D. Hamon, Sierra National Forest, in litt. 1980; CNDDDB 2006). Populations, individuals, or colonies located within one-fourth of a mile of each other generally constitute a single occurrence (CNDDDB 2006). Calyptridium pulchellum typically grows in association with the rare species Lupinus citrinus. (USFW, 2007). Calyptridium pulchellum co-occurs with L. citrinus var. citrinus (orange lupine) at five locations and with L. citrinus var. deflexus (Mariposa lupine) at two locations. Mimulus layneae (Layne's monkeyflower) is the second most common associate, occurring with C. pulchellum at four sites. (USFWS, 2007)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

5 unknown, 2 declining, and 1 fluctuating (CNDDDB 2006). (USFWS, 2007)

Species Trends:

5 unknown, 2 declining, and 1 fluctuating (CNDDDB 2006). (USFWS, 2007)

Resiliency:

Low (inferred from USFWS, 2007)

Redundancy:

Low (inferred from USFWS, 2007)

Number of Populations:

9 or 10 (USFWS, 2007)

Population Size:

1680-1690 individuals (NatureServe, 2015)

Population Narrative:

Approximately 1680-1690 plants; the bulk is found in two occurrences; 874 (may be divided into 2 subpopulations) and 701 plants (NatureServe, 2015). *Calyptridium pulchellum* is reported from 9 or 10 occurrences in Mariposa, Madera, and Fresno Counties, occurring within a range of approximately 64 kilometers (40 miles) (CNDDDB 2006). Seven occurrences in three central California counties (one may be extirpated). Currently, the population trends for occurrences that have been reported to the California Natural Diversity Database are: 5 unknown, 2 declining, and 1 fluctuating (CNDDDB 2006). (NatureServe, 2015; USFWS, 2007).

Threats and Stressors

Stressor: Human populations (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: The human populations of Madera and Mariposa Counties are expected to increase by 49 percent and 20 percent, respectively, between 2000 and 2020 (Hickey et al. 2005). The region of Madera County covered by the Coarsegold Area Plan (Madera County 2006), which provides the framework in which development will occur, contains about 60,000 acres and at least 4 of the occurrences of *C. pulchellum*. The habitat for this species located near Coarsegold, in Madera County, will likely continue to be fragmented due to increased infrastructure associated with the need for housing and services for this area, and the construction of a gaming casino and hotel on the Chukchansi Tribal Lands (Madera County 2006). Activities associated with residential development such as landscaping, dirt bike riding, or foot traffic are a threat at Element Occurrence 3 near Ahwahnee and Element Occurrences 4 (if extant) and 5 (if extant) in Madera County, all of which are in residential subdivisions (CNDDDB 2006).(USFWS, 2007)

Stressor: Competition (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Competition from nonnative plants and native live oak potentially threatens *Calyptridium pulchellum* at four sites. (USFWS, 2007)

Stressor: Small population size

Exposure:

Response:

Consequence:

Narrative: small population size increases the susceptibility of a population to extirpation from random demographic, environmental and/or genetic events (Shaffer 1981, 1987; Lande 1988; Primack 2006; Groom et al. 2006). The combination of few populations, small range, and restricted habitat still renders *Calyptridium pulchellum* highly susceptible to extirpation due to random events, such as flood, drought, disease, or other factors (Shaffer 1981, 1987; Groom et al. 2006).

Recovery

Recovery Actions:

- There is no recovery plan for this species.

Conservation Measures and Best Management Practices:

- Protect the extant occurrences of *Calyptridium pulchellum* through mechanisms such as conservation easements. (USFWS, 2007)
- Complete and publish the draft recovery plan, and approve a final recovery plan. (USFWS, 2007)
- Map the potential habitat for *Calyptridium pulchellum* using the indicators mentioned in II.C.1.d. and survey for additional populations. (USFWS, 2007)
- Monitor the status and trend of *Calyptridium pulchellum* in order to estimate current population sizes, the number and distribution of populations, and whether the species is stable, increasing, or declining. (USFWS, 2007)

SPECIES ACCOUNT: *Calystegia stebbinsii* (Stebbins' morning-glory)

Species Taxonomic and Listing Information

Listing Status: Endangered; 11/18/1996; Pacific Southwest (R8)

Physical Description

A leafy herbaceous perennial (persisting or living for several years with a period of growth each year) in the morning-glory family (Convolvulaceae). Its stems, which range up to 1 meter (3.3 feet) in length, generally lie flat on the ground. The leaves are palmately lobed (lobing radiating from a common point) with the two outermost lobes (major expansion or bulge) being divided again. The leaf lobes are narrow and lance-shaped. White flowers are on stalks 3 to 13 centimeters (1 to 5 inches) long and bear two leaf-like bracts. The fruit is a slender capsule. *Calystegia stebbinsii* flowers from May through June. *Calystegia occidentalis* (chaparral false bindweed) and *C. purpurata* ssp. *saxicola* (Pacific false bindweed) also occur on gabbro-derived soils in the Pine Hill area (Wilson 1986). *Calystegia stebbinsii* can be distinguished from other California morning-glories by its distinctively shaped leaves, each having 7 to 9 narrow lance-shaped lobes. (USFWS, 2002)

Taxonomy

Brummitt (1974) described *Calystegia stebbinsii* (Stebbins' morning-glory) from the type collection made by G. Ledyard Stebbins in 1970, 17 kilometers (10 miles) west of Placerville in El Dorado County, California. (USFWS, 2002)

Historical Range

In western El Dorado County that includes the Pine Hill formation (northern and southern portions). (USFWS, 2002)

Current Range

On the Pine Hill formation in western El Dorado County, California; a few known isolated occurrences in El Dorado, Nevada and/or Tuolumne Counties. (USFWS, 2019)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Lifespan

Adult: Lives for several years (USFWS, 2002).

Breeding Season

Adult: May through June (USFWS, 2002)

Key Resources Needed for Breeding

Adult: Insect pollinators; disturbance (USFWS, 2002)

Reproduction Narrative

Adult: The fruit is a slender capsule. *Calystegia stebbinsii* appears to emerge from a dormant seed bank or rootstock after disturbance. The plants grow and begin to flower in the year following germination or re-emergence. While an above-ground shoot may appear in the same spot for only several years, other portions of this plant's extensive root system might survive much longer (L. Eng in litt. 1999). Pollination studies showed that animal vectors were needed for successful seed set. Observations showed that *Calystegia stebbinsii* is only pollinated by insects. Eighty percent of all visits were made by Hymenoptera, the Halictidae (solitary bees) and Apidae (honey bees) being the most important families (Nosal 1997). Seed production ranged from an average of 20.6 seeds per square meter (1.9 seeds per square foot) at Grass Valley to 380 seeds per square meter (35.3 seeds per square foot) at Salmon Falls. (USFWS, 2002)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Barrens, Shrubland/ chaparral (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Seeds require heat or scarification for germination. (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Well-burned areas; shade intolerant (USFWS, 2002)

Spatial Arrangements of the Population

Adult: Discontinuously scattered (USFWS, 2002)

Environmental Specificity

Adult: Narrow/specialist (inferred from USFWS, 2002)

Habitat Narrative

Adult: *Calystegia stebbinsii* prefers mixed chaparral communities on gabbro-derived and serpentine-derived soils (NatureServe, 2015). Most occurrences of *C. stebbinsii* are discontinuously scattered within two population centers in the northern and southern portions of the Pine Hill formation. *Calystegia stebbinsii* produce fire adapted: seeds need heat or scarification for germination; plants grow well in burned-over areas, but are eliminated when surrounding chaparral grows tall enough to shade them. (NatureServe, 2015). *Calystegia stebbinsii* seems to be shade intolerant and does not occur beneath a closed canopy of vegetation (Baad and Hanna 1987). (USFWS, 2002)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends

Population Trends:

Unknown (USFWS, 2019)

Number of Populations:

3 known extant; 8 presumed extant; 3 possibly extirpated; 1 extirpated. (USFWS, 2019)

Population Size:

Greater than 9800 individuals (USFWS, 2019)

Population Narrative:

At the time of listing Stebbins' morning-glory occurred primarily on the Pine Hill formation an area of approximately 10,400 hectares (ha) (25,700 acres (ac)), in western El Dorado County, California, ranging in elevation from 138 to 628 m (453 to 2,060 ft). In addition, Stebbins' morning-glory had "a few known isolated occurrences in El Dorado, Nevada and/or Tuolumne Counties" (Service 1996). Today, the species continue to occur primarily at the Pine Hill Preserve, but Stebbins' morning-glory has a few known occurrences in Nevada County near Grass Valley. (USFWS, 2019)

Threats and Stressors

Stressor: Habitat destruction and modification (USFWS, 2002)

Exposure:

Response:

Consequence:

Narrative: Historically, gold rush activities and clearing for agriculture reduced and fragmented habitat in western El Dorado County. More recently, vegetation on the Pine Hill formation has changed significantly due to commercial and residential development, road construction, and fragmentation. Commercial or residential developments have partially or completely destroyed occurrences of the species (California Natural Diversity Data Base 1998; California Department of Fish and Game 1990a, 1990b; G. Clark in litt. 1993). Proposed residential or commercial development within the Pine Hill formation threatens most of the remaining sites within the Pine Hill formation and adjacent serpentine in western El Dorado County, and either directly or indirectly will adversely affect most of the range of this species. Additionally, habitat fragments may be too small to support viable populations of animals serving as pollinators or seed dispersal agents for the species. Edge effects, which occur at the interfaces of any two or more habitat types, typically increase with habitat fragmentation and are more pronounced for natural communities bordered by human disturbances. (USFWS, 2002)

Stressor: Other species-specific threats (USFWS, 2002)

Exposure:

Response:

Consequence:

Narrative: *Calystegia stebbinsii* is threatened by altered periodicity of fire (either too frequent or fire suppression), competition with invasive alien vegetation, herbicide spraying, and unauthorized dumping. There is an increased risk of extinction due to environmental, demographic, or genetic random events due to habitat fragmentation (USFWS, 2002).

Stressor: Alteration of the natural fire regime (USFWS, 2019)

Exposure:**Response:****Consequence:**

Narrative: The primary overall threat is encroachment of native vegetation due to succession, even on lands in conservation ownership, in the absence of the natural fire regime. The long fire return interval due to fire suppression is preventing the formation of necessary clearings for Stebbins' morning-glory establishment and possibly the scarification of seeds needed for germination. (USFWS, 2019)

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2019)

Exposure:**Response:****Consequence:**

Narrative: The State's authority to conserve rare wildlife and plants is comprised of four major pieces of legislation: the California Endangered Species Act, the Native Plant Protection Act, the California Environmental Quality Act, and the Natural Community Conservation Planning Act. The State may authorize permits for scientific, educational, or management purposes, and to allow take that is incidental to otherwise lawful activities. Landowners are exempt from the prohibition for plants to be taken in the process of habitat modification. Protection of listed species through California Environmental Quality Act is dependent upon the discretion of the lead agency involved. The National Environmental Policy Act (NEPA) does not require that adverse impacts be fully mitigated, only that impacts be assessed and the analysis disclosed to the public. More details about existing protections are provided in the 2019 5-Year Review. (USFWS, 2019)

Recovery**Reclassification Criteria:**

1. Secure and protect specified recovery areas from incompatible uses: (a) Cameron Park preserve north of Highway 50; (b) Cameron Park preserve south of Highway 50; (c) Salmon Falls/Martel Creek preserve; (d) occurrences in Nevada County; along with sufficient adjacent unoccupied habitat for fire management and a 150-meter (500-foot) buffer. (USFWS, 2002)
2. Management plan approved and implemented for recovery areas, including survival and recovery of the species as the objective for all populations recommended for protection and any adjacent areas identified as necessary for continued survival and recovery. (USFWS, 2002)
3. Monitoring in all recommended preserves shows: (a) Populations stable or increasing over one fire cycle (about 30 years) (subject to modification depending on results of fire management studies). (b) Habitat monitoring shows a mosaic of multiage -class stands and habitat fragmentation has not appreciably increased (less than 5 percent) within any preserve over current (2000) conditions. (c) Spatially and temporally, the establishment of occurrences must be greater than the extirpation of occurrences. (USFWS, 2002)
4. Other actions: (a) Ameliorate or eliminate threats; (b) Fire management studies; (c) Research on genetics of Nevada County population; (d) Seeds of disjunct populations stored in at least two Center for Plant Conservation certified facilities; (e) Research on propagation techniques if repatriation, enhancement, or restoration are determined to be necessary (f) Maintain metapopulation dynamics of at least 2 very large, 7 medium, and 4 small occurrences

throughout the northern and southern portions of the Pine Hill formation; and of at least 1 medium and 5 small occurrences near Grass Valley in Nevada County. (USFWS, 2002)

Delisting Criteria:

1. Management plan approved and implemented for recovery areas, including survival and recovery of the species as the objective: For all occurrences and any adjacent areas identified as necessary for continued survival and recovery. (USFWS, 2002)
2. Monitoring in all recommended preserves shows: (d) No population decline after downlisting during two additional fire cycles (about 60 years); if declining, determine cause and reverse trend. (e) Habitat monitoring continues to show a mosaic of multi-age class stands and habitat fragmentation has not appreciably increased (less than 5 percent) within any preserves over current (2000) conditions. (f) Spatially and temporally, the establishment of occurrences must continue to be greater than the extirpation of occurrences. (USFWS, 2002)
3. Other actions: (g) Ameliorate or eliminate threats. (USFWS, 2002)

Recovery Actions:

- 1. Develop and implement a cooperative program and participation plan. A cooperative program is needed to coordinate local public and private land use planning with State and Federal land use and recovery planning for gabbro species. A cooperative program needs to be developed focusing on western El Dorado County. A participation plan produced from this program will increase the chances of recovery for listed species. (USFWS, 2002)
- 2. Protect and secure existing populations. Natural lands that contain this species need to be protected in perpetuity. Protection of these lands includes identification and minimization of threats in perpetuity and application of appropriate and adaptive management (see Task 3) to ensure species survival and recovery. Natural lands that need protection can be categorized into two types: (1) blocks of land that contain occupied or potential habitat for two or more this species and (2) blocks of land that contain occupied or potential habitat for one this species. All potential preserve areas should be evaluated based on current mapping information and ground-truthed prior to purchase to confirm their value for recovery. (USFWS, 2002)
- 3. Manage Habitat Managing habitat is essential to the recovery of the listed species. Habitat management includes preparation and implementation of management plans for all areas inhabited by special status species being proposed for preservation, and periodic monitoring of populations in each of these areas. Within western El Dorado County, a multi-constituent committee should be formed to oversee the management of preserves located on the Pine Hill formation. The preserve management committee should include, at a minimum, representatives from the California Department of Fish and Game, U.S. Fish and Wildlife Service, Bureau of Land Management, El Dorado County, California Department of Forestry and Fire Protection, California Native Plant Society, American River Conservancy, and a private landowner representative. (USFWS, 2002)
- 4. Survey historical locations and other potential habitat where this species may occur. Recovery of listed species may often require relocating historic populations or locating new populations of these species. Historical locations should be surveyed to determine whether suitable habitat remains, the species persists at the sites, and/or the sites may be suitable for repatriation. Suitability of historical locations for repatriation would depend upon: (1) whether potential habitat exists, (2) the presence and magnitude of threats, and (3)

- whether the sites can be secured and managed for the long-term protection of the species. Surveys should also include other potential gabbro or serpentine habitat to determine whether undiscovered populations may exist. If new populations are discovered, they need to be protected and managed as discussed above. During the surveys, potential introduction sites should also be identified. (USFWS, 2002)
- 5. Conduct necessary biological research and use results to guide recovery/conservation efforts. - Develop propagation techniques for listed plant species for which enhancement, repatriation, or introductions would be appropriate. Geographic area research is outlined in the Recovery Plan. Species-specific research is described as follows: Habitat Survey Research: Nevada County on gabbro and serpentine soils. Reproduction and Demography Research: Including determining limiting life stages, seed production, and survival in soil to determine appropriate fire return period. Genetics research. Other Research Needs: Propagation techniques; fire management techniques; metapopulation analysis; determine efficacy of other types of disturbance regimes for species and habitat management; feasibility of habitat restoration/ enhancement. Management Actions Needed: Burning; general surveys; baseline monitoring; monitoring for trends of populations, success of management actions, and threats at all populations identified for protection; monitoring for habitat fragmentation, major shifts in vegetation type, and tracking of occurrence establishment, and extirpation; seed banking for disjunct populations. (USFWS, 2002)
 - 6. Undertake artificial enhancement, repatriation, or introduction efforts where necessary. Where it is deemed necessary, artificial enhancement, repatriation, or introduction efforts for sensitive plants should be undertaken. Prior to repatriation or introduction of sensitive plants, genetics studies are needed (see Task 5) to ensure that new populations will not disrupt unique local gene complexes. Plant repatriation or introduction efforts should be undertaken using collected seeds or plant propagules. (USFWS, 2002)
 - 7. Determine possible prescribed burning management strategies and incorporate the strategies into the management plans (Priority 1). Possible prescribed burning management strategies need to be evaluated, peer reviewed, and incorporated into management plans. (USFWS, 2002)
 - 8. Perform metapopulation-type analyses for this species (Priority 2). The results of a metapopulation-type analysis may be useful in clarifying uncertainties, data needs, and research, management priorities, and delisting criteria. Metapopulation-type analyses should be based on the results of monitoring and research. (USFWS, 2002)

Conservation Measures and Best Management Practices:

- Preserves must include sufficient habitat to allow for expansion or shifts in occupied habitat.
- In addition to securing and protecting habitat, maintenance of the metapopulation dynamics will be important for survival and recovery.
- Unless the metapopulation analysis shows otherwise, at least two very large occurrences each greater than 128 hectares (315 acres); seven medium occurrences each between 4 and 40 hectares (10 and 100 acres); and four small occurrences each smaller than 4 hectares (10 acres), are to be maintained at any given time throughout the northern and southern portions of the Pine Hill formation. In addition at least one medium and five small occurrences are to be maintained at any given time at the metapopulation near Grass Valley in Nevada County.
- In addition to securing and protecting habitat, directed surveys for *Calystegia stebbinsii* should be conducted on gabbro and serpentine soils in Nevada County. If plants (or additional populations) are

discovered in Nevada County, they should be secured through land acquisition, conservation easements, or other means. (USFWS, 2002)

- In addition, unoccupied habitat that might provide space for expansion of the populations and habitat for pollinators and seed dispersers must be protected along with sufficient adjacent unoccupied habitat for fire management, and a 150-meter (500-foot) buffer for fire safety. (USFWS, 2002)
- Dedicate more resources toward the investigation of best management approaches for the Pine Hill listed plant species, even at the cost of a temporary hiatus in land acquisition efforts. Investigation should be made into fire-related and non-fire related methods of disturbance to maintain listed plant species habitat. (USFWS, 2019)
- Once the best management strategy (in terms of technique, frequency, timing, and intensity) is determined at each site, implement these management practices to achieve and maintain a habitat mosaic that enables the attainment of recovery criteria for the species. (USFWS, 2019)

SPECIES ACCOUNT: *Camissonia benitensis* (San Benito evening-primrose)

Species Taxonomic and Listing Information

Listing Status: Threatened; 2/12/1985; Pacific Southwest (R8) (USFWS, 2015); Proposed Delisting

Physical Description

A small, yellow-flowered, annual herb in the evening-primrose family (Onagraceae) (USFWS, 2009)

Taxonomy

Recognized as distinct by Peter Raven (1969) and J. Griffin (1984). Similar to non-serpentine *C. contorta* but differs in chromosome number, pollen morphology, leaf shape and pubescence. (NatureServe, 2015)

Historical Range

See current range/distribution.

Current Range

Local endemic to serpentine alluvial terraces in the Clear Creek and San Carlos Creek drainages, California. (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Self-fertilization (USFWS, 2009)

Lifespan

Adult: 1 year (annual) (USFWS, 2009)

Breeding Season

Adult: Mid-spring (USFWS, 2009)

Reproduction Narrative

Adult: *Camissonia benitensis* is autogamous (self-pollinating), and therefore does not require insects or other abiotic mechanisms for pollination. Germination occurs from February to March, flowering in mid-spring, and seed pods mature by early summer. An individual plant typically produces one capsule containing approximately 90-100 seeds. Maintaining a seedbank in the soil is an important survival mechanism for many short-lived annual species in years of poor conditions (Baskin and Baskin 1978). (USFWS, 2009)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Barrens, Forest/Woodland, Shrubland/chaparral, Woodland - Mixed (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Low rainfall; hot summers; elevations above 1,372 m (4,500 feet). (USFWS, 2009)

Spatial Arrangements of the Population

Adult: Colonial (inferred from USFWS, 2009)

Tolerance Ranges/Thresholds

Adult: Moderate (inferred from USFWS, 2009)

Habitat Narrative

Adult: All of the known occurrences of *Camissonia benitensis* are on serpentine alluvial flats, terraces, and debris flows (alluvial outwash) terraces and deposits near San Benito Mountain in San Benito County, California, and in western Fresno County, California. Physical characteristics desired for *C. benitensis* include alluvial terraces or areas adjacent to slopes (alluvial outwash) below an elevation of approximately 1,372 meters (4,500 feet). The habitat is flat to gently sloping (less than 3 degrees), on residual serpentine or serpentine alluvium, subject to frost heaving, and with minimal cover of surface gravel. Biotic characteristics include an association of annual plants, and no more than 25 percent of the terrace covered with chaparral. The habitat should be relatively stable with little soil erosion caused by natural processes (e.g., mass wasting), historical uses (e.g., mining activities), and current uses (e.g., recreational activities). The extent of stable habitat needs to include not only the current area occupied by *Camissonia benitensis*, but also sufficient surrounding habitat for maintaining stable soil and hydrologic processes, and for ensuring the species' ability to migrate within potentially suitable habitat at a site. A study of associated species identified six annual herbs that together are indicators for suitable habitat: *Cryptantha micromeres* (popcorn flower), *Erodium cicutarium* (filaree), *Eschscholzia californica* (California poppy), *Malacothrix floccifera* (wooly malacothrix), *Lotus subpinnatus* (deerweed), and *Vulpia microstachys* (Nuttall's fescue) (USFWS, 2006). The only non-native species is *Erodium cicutarium* (Taylor 1990 (USFWS, 2006). Low annual rainfall and hot summer temperatures limit the growing season for plants. (USFWS, 2009; USFWS, 2006)

Dispersal/Migration**Motility/Mobility**

Adult: High (inferred from USFWS, 2009)

Dispersal

Adult: Moderate (inferred from USFWS, 2009)

Dispersal/Migration Narrative

Adult: *Camissonia benitensis* may utilize both short-distance and long-distance seed dispersal mechanisms. The short stature of the plants when in fruit (5 to 10 centimeters or 2 to 4 inches) facilitates short-distance seed dispersal.. The distribution of occurrences over a large geographic

area in a number of watersheds are evidence of long-distance seed dispersal (Service 2006). (USFWS, 2009)

Population Information and Trends

Population Trends:

Slight increase

Resiliency:

Low (NatureServe, 2015)

Representation:

Low (inferred from USFWS, 2009)

Redundancy:

Low (inferred from USFWS, 2009)

Number of Populations:

69 (USFWS, 2009)

Population Size:

2500 - 10,000 individuals (NatureServe, 2015)

Minimum Viable Population Size:

100,000 to 1,000,000 (USFWS, 2009)

Population Narrative:

The known distribution of *Camissonia benitensis* comprises a total of 69 known populations, as summarized in Table 2 (R. O'Dell, Bureau, pers. comm. 2009d). Population numbers of *Camissonia benitensis* fluctuate from year to year, exhibiting a repetitive "boom-bust" population cycle occurring approximately every 2-3 years as described by O'Dell (2009b). In 1988, a record high number of 165,168 individuals of *Camissonia benitensis* were recorded. When population numbers from all sites were considered from 1983 to 2007, O'Dell (2009b) demonstrated that removal of this statistical outlier indicates that the population trend has slightly increased over time. Annual counts of *Camissonia benitensis* between 1983 and 2009 (a span of 26 years) reveal: of these years contained numbers above 1,000 individuals; 8 of the 20 years contained numbers over 10,000 individuals; and 1 of the 20 years contained numbers above 100,000 as illustrated in Table 3 (O'Dell, pers. comm. 2009b). For a long-lived perennial species, a population size of 1,000 individuals may be sufficient, but annual species may require larger populations (at least 100,000 to 1 million in climatically favorable years) to survive natural events that can eliminate occurrences and suitable habitat (Thomas 1990). (USFWS, 2009)

Threats and Stressors

Stressor: Off-highway Vehicle Recreation

Exposure:

Response:

Consequence:

Narrative: OHV use has been a substantial threat to *Camissonia benitensis* and its habitat (Bureau 1970, 1981, 1982, 1984, 1986, 1993, 1995, 2005a, and 2005c; Losos et al. 1993; Taylor 1990, 1991, 1993, and 1995). The CCMA attracts OHV recreationists in large numbers because its serpentine areas offer open slopes (barrens) for riding (Bureau 2005c), and visitor use in the CCMA has increased over the past decade. The silt-clay crust that forms on serpentine soils protects open, undisturbed slopes from erosion. When the crust is disturbed, sheet erosion, rilling, and gullying occur (Kruckeberg 1984). OHV recreation at the CCMA has caused disturbance of soil integrity, soil loss, compaction of soil, and destruction of plants (Bureau 2005c). In addition, recreation (e.g., camping, vehicle traffic, and OHV use) has disturbed alluvial terraces in Clear Creek Canyon (Bureau 2005c, Bureau 2006a). (USFWS, 2009)

Stressor: Soil Loss and Elevated Erosion Rates

Exposure:

Response:

Consequence:

Narrative: Erosion on both barren and vegetated slopes causes soil loss and other physical and chemical changes. These changes negatively affect the soil's texture, composition, and chemistry. They also can reduce the soil's water infiltration capacity and productivity, which in turn affects the ability of plants to grow in these soils. Riparian habitats (and the streamside terraces upon which *Camissonia benitensis* occurs) can be adversely affected by accelerated sediment deposition from wet-season use of the road system in the CCMA. (USFWS, 2009)

Stressor: Facilities Construction and Maintenance

Exposure:

Response:

Consequence:

Narrative: The Bureau established an administrative site in 1988 that lies to the north of the CCMA. Its purpose is to support ranger and law enforcement services and to facilitate asbestos (chrysotile) decontamination. The Bureau inadvertently constructed a residence within a *Camissonia benitensis* suboccurrence (suboccurrence 19110) at the administrative site, resulting in the direct loss of plants and habitat. (USFWS, 2009)

Stressor: Mining Activities

Exposure:

Response:

Consequence:

Narrative: Mining activity in the CCMA has decreased since the early 1900s, and the last commercial mining operation ceased its activities in 2002. Residual soil erosion problems from historic mines and their access roads may affect certain occurrences of *Camissonia benitensis*. The primary mining activity in the CCMA now consists of rock hounding for gems and minerals. In 1994, the Bureau estimated that 5 percent of the visitor use was comprised of rock hounders. The Service believes the impact of this activity on *Camissonia benitensis* and its habitat is minimal. (USFWS, 2009)

Stressor: Succession to Woody Shrub Community

Exposure:

Response:

Consequence:

Narrative: Several non-native plant species, including *Centaurea solstitialis* (yellow star-thistle) and *Taeniatherum caput-medusae* (medusahead) have been found in the Clear Creek watershed. Once established, these weeds are difficult to eradicate and therefore pose a potential threat to *Camissonia benitensis* habitat in certain areas. *Centaurea solstitialis* and non-native annual grasses occur on the Franciscan soils throughout the Clear Creek watershed where several *Camissonia benitensis* suboccurrences occur at the interfaces between Franciscan and serpentine soils (J.A. Delgado, pers. comm. 2002). Feral pigs (*Sus scrofa*) are also present in the Clear Creek watershed. As pigs root for bulbs and tubers, they churn the soil. Churning of the soil not only disrupts the existing native vegetation, but also facilitates establishment of non-native plant species. In spring 2002, feral pig damage was extensive throughout Clear Creek Canyon on partially vegetated alluvial terraces. Pigs affected several *Camissonia benitensis* suboccurrences after germination had occurred. (USFWS, 2009)

Stressor: Succession to Woody Shrub Community

Exposure:

Response:

Consequence:

Narrative: Woody plants have been encroaching on a number of alluvial terraces and may be reducing the amount of habitat available for *Camissonia benitensis* (Taylor 1990). Taylor (1990) speculated that seed of *Camissonia benitensis* is not likely to remain viable through an entire cycle of woody vegetation encroachment into occupied habitat. (USFWS, 2009)

Stressor: Stochastic Events

Exposure:

Response:

Consequence:

Narrative: Randomly-occurring events, such as prolonged drought, wildfire, flooding, and catastrophic erosion and sedimentation, have the potential to affect the continued existence of this species, but to an unknown extent. (USFWS, 2009)

Recovery

Reclassification Criteria:

1. Habitat condition within currently occupied or suitable habitat shows a substantial decline. (USFWS, 2006)
2. Population sizes decline over a 20-year period that includes multiple rainfall cycles (successive periods of drought and wet years). (USFWS, 2006)
3. The Bureau is unable to effect sufficient compliance with OHV restrictions in *Camissonia benitensis* habitat within the Clear Creek Management Area as the amended CCMA Management Plan is implemented. (USFWS, 2006)

Delisting Criteria:

1. Research has been completed and delisting criteria 2 through 4 have been refined as appropriate based on research findings. Factors that should be studied include: (a) Potential for restoration of serpentine terrace habitat and natural rate of habitat replacement (excluding human-caused activities); (b) Ecology of *Camissonia benitensis* seed banks; and (c) Population

viability modeling and estimation of habitat area and population levels necessary for dispersal, seed bank viability, and long-term persistence of the species. (USFWS, 2006)

2. Known occurrences and sufficient additional suitable habitat, within each watershed unit throughout its range, are protected from direct effects from OHV use and other recreational activities. Appropriate levels of compliance with use regulations by recreationists have prevented adverse impacts to *Camissonia benitensis* suboccurrences and habitat. (USFWS, 2006)

3. Currently occupied and suitable habitat for the species has been restored and maintained over an appropriate period of time, as informed by monitoring and research. Given current knowledge, we expect that the “appropriate period of time” will be no less than 20 years. Because the number of individuals in a suboccurrence fluctuates widely from year to year, more emphasis should be placed on maintaining the habitat that supports known suboccurrences. Disturbance and erosion rates should not be substantially elevated above natural levels, and *Camissonia benitensis* should persist in suitable habitat. (USFWS, 2006)

4. Population sizes have been maintained over a 20-year period during a normal rainfall cycle (i.e., includes periods of drought and wet years). (USFWS, 2006)

Recovery Actions:

- Protect known occurrences and suitable habitat for *Camissonia benitensis* throughout its range in the CCMA. Close use areas that occur in proximity to *Camissonia benitensis* and special status species habitats on Bureau lands. Maintain a weed control program for the CCMA. The Bureau has established a weed control program to ensure that highly invasive species, such as yellow star-thistle and medusahead, do not continue to spread in the CCMA. Ensure protection of *Camissonia benitensis* on non-Bureau lands by establishing private landowner contacts. Protecting the four known occurrences on private lands, and others as yet undiscovered, is important for the continued persistence of this species. (USFWS, 2006)
- Reduce soil erosion and stream sedimentation above natural levels in watersheds that support habitat for *Camissonia benitensis* in the Clear Creek Management Area. Establish an interagency technical team to assist in the development of a watershed management, protection, and restoration strategy, including soil erosion standards. Continue to identify and prioritize sites for restoration of *Camissonia benitensis* habitat. Continue to monitor effectiveness of habitat management. Use aerial and ground photography to monitor landscape scale changes over time. Compare photography to determine habitat conditions as related to user compliance. Monitor soil loss, erosion, and sediment loading conditions in the five watersheds in the CCMA. (USFWS, 2006)
- Continue improvement and implementation of the management and monitoring plan for *Camissonia benitensis*. Use technical specialists to provide review and assistance in development and implementation of the monitoring and research programs. Continue monitoring *Camissonia benitensis* occurrences. Conduct additional research on the ecology and life history of *Camissonia benitensis*. Search for new occurrences on alluvial outwash habitat. Revise management based on monitoring and research results. (USFWS, 2006)
- Establish an ex situ seed collection. (USFWS, 2006)
- Develop and implement a public awareness program for conserving *Camissonia benitensis* and its habitat. Install and maintain interpretive and informational signs near occurrences of

Camissonia benitensis, and implement other interpretive activities. Continue to work with OHV and other user groups to conserve the Clear Creek Management Area and other habitat. (USFWS, 2006)

Conservation Measures and Best Management Practices:

- The Service, the Bureau, and the County of San Benito (County) should coordinate to reroute Clear Creek Road out of Clear Creek Canyon. Even if the Bureau's efforts to reduce the adverse effects of authorized OHV use and eliminate unauthorized OHV use are fully successful, the presence of staging areas and Clear Creek Road will likely result in sediment movement into Clear Creek that would exceed natural levels. (USFWS, 2009)
- The Service should work with the Bureau to develop and implement an active program to determine the type of vegetation management that would promote the conservation of Camissonia benitensis. These measures could include reducing the amount of non-native weeds at various times of the year through mechanical or other means. (USFWS, 2009)
- The Service should work with the Bureau to develop and implement methods to monitor the abundance and other characteristics of the seed bank of Camissonia benitensis occurrences at the CCMA. Information from seed bank studies could be used along with information on the life history of this species and the requirements for suitable habitat to develop population models. Population modeling could allow us to compare the risk of extinction under natural rates of habitat replacement (terrace erosion and formation) with the risk of extinction under a range of rates of soil loss resulting from different scenarios of habitat management. This information would assist us and the Bureau in making and adjusting management decisions that will promote the long-term conservation of Camissonia benitensis. (USFWS, 2009)
- The Service, the Bureau, and the County should coordinate to develop and implement a program for applying dust suppressant to heavily-used routes which are under County jurisdiction. Under some conditions, encroachment by woody vegetation onto terraces that are otherwise suitable for Camissonia benitensis may reduce its ability to persist or preclude its establishment. If dust can be effectively suppressed, thereby reducing the hazards of asbestos contamination to firefighters, the Bureau may be more able to use prescribed fire as a management tool to maintain terraces in a condition that could potentially support Camissonia benitensis. (USFWS, 2009)

SPECIES ACCOUNT: *Campanula robinsiae* (Brooksville bellflower)

Species Taxonomic and Listing Information

Listing Status: Endangered; 8/28/1989; Southeast Region (R4)

Physical Description

Campanula robinsiae is an annual herb, with stems 1-15 cm (0.5-6 in.) tall, very slender, simple or branched, faintly winged or 4-angled. The stems are glabrous except for a few trichomes in the angles (Morn 1987). The plant may be submerged for part of its life, which may affect its growth. Some stems root at the nodes (Morn 1987). The leaves are alternate, the blades varying in size and shape on different parts of the plant and from plant to plant (Morn 1987). Open flowers are solitary, 3-10 mm long, bell-shaped, "deep purple" (Morn 1987). Steven Leonard (under contract to The Nature Conservancy; report at Florida Natural Areas Inventory) discovered in 1983 that the plant has cleistogamous (closed, self-pollinating) flowers, which are quite small. This is the only North American *Campanula* with cleistogamous flowers (Morn 1987). The fruit is a subglobose capsule about 2 mm in diameter (Wunderlin et al. 1980a). The seeds are about 1 mm long, the smallest of any North American member of the genus (Shetler and Morn 1986; description adapted from Wunderlin et al. [1980a] and other sources as noted). Leonard observed only cleistogamous flowers on February 8 and 11, 1983, and did not see a chasmogamous flower until February 23 (letters from Leonard to Morn in Morn 1987). Flowering specimens have also been collected March 11, 1983; April 13, 1983; and April 26, 1958. Seed production proceeds while flowering continues. *Campanula robinsiae* may be confused with *Campanula floridana*, but the latter species has very different seeds and leaves that are "much firmer than those of *C. robinsiae*" (Morn 1987). (USFWS, 1993)

Taxonomy

Small (1926) formally published the species, but later (Small 1933) transferred the species to his new genus *Rotantha*, along with *Campanula floridana*, based on the shared character of their rotate corollas' (Small 1933). Later workers (Shetler 1963, Wunderlin et al. 1980a) determined that these two species are not closely related, so *Rotantha* is an artificial genus; the two species are retained in *Campanula* (USFWS, 1993).

Historical Range

All historically known sites of *C. robinsiae* occurred within approximately 2-3 square miles centered on Chinsegut Hill, which is located 5 miles north of Brooksville, in Hernando County, Florida. (USFWS, 2019)

Current Range

Hernando and Hillsborough Counties, Florida. (USFWS, 2019)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (inferred from EPA, 2016); asexual (EPA, 2016)

Dependency on Other Individuals or Species

Adult: Insect and bird pollinators (EPA, 2016)

Breeding Season

Adult: March - April (EPA, 2016)

Key Resources Needed for Breeding

Adult: Insect and bird pollinators (EPA, 2016); rainfall (USFWS, 2010)

Reproduction Narrative

Adult: Flowering specimens have been collected March-April. Capable of self-pollination. Insects and birds are also potential pollinators. Seeds germinate in winter or spring. Seed production occurs while flowering continues (EPA, 2016). It was determined that water levels from rainfall rather than time of year may be a critical factor controlling germination (Williams 1998) (USFWS, 2010).

Habitat Type

Adult: Palustrine, terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Herbaceous wetland, forest (NatureServe, 2015)

Environmental Specificity

Adult: Moderate (inferred from NatureServe, 2015)

Habitat Narrative

Adult: *Campanula robinsiae* was originally found in a seepage area on the north facing slope of Chinsegut Hill surrounded by pasture used for animal husbandry. It has since been found within an oak/palm hydric hammock along the edge of an elongated maidencane (*Panicum hemitomom*) marsh at Burns Prairie (Laundry 1996). Typically this species is found along the margins of ponds and marshes with fluctuating water levels and moist seepage areas, both surrounded by pastures. *C. robinsiae* is associated with other wetland plants, such as mosquito fern (*Azolla carolinaiana*), hair sedge (*Bulbostylis* spp.), coinwort (*Centella asiatica*), button snakeroot (*Eryngium* spp.), pennywort (*Hydrocotyle* spp.), rush (*Juncus* spp.), pimpernel (*Anagallis minima*), pearlwort (*Sagina decumbens*), and maidencane (*Panicum hemitomom*). (USFWS, 2019)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Fruit dispersal potential occurs via abiotic factors and birds and mammals (EPA, 2016).

Population Information and Trends**Population Trends:**

Not available

Species Trends:

Stable (USFWS, 2019)

Number of Populations:

6 (USFWS, 2019)

Population Size:

~8600 individuals (USFWS, 2019)

Population Narrative:

Although there are six extant populations (Burns Prairie, Croom- Bell Heaven, Croom- Power Line Road, and Hillsborough River State Park #1, #2, and #4) (Fig. 1), all on public land along wet prairies, pond margins, or seepage areas. There is one more population than when the last 5-Year Review was conducted in 2010. Three populations have been discovered and two are now considered historic due to habitat degradation and development. Populations are determined based on whether there was a hydrological connection and are considered extant if plants were found within the past 6 years. Most populations have been monitored yearly by Bok Tower Botanical Garden (BTG) since 2001. The species is only found in Hernando and Hillsborough Counties. The oldest remaining population in Hernando County is Burns Prairie, which was discovered in 1983. Most of the Burns Prairie population occurs on land owned by Florida Agricultural and Mechanical University (FAMU) and the southern extent is owned by the Florida Fish and Wildlife Conservation Commission (FWC). Less than 3 miles from Burns Prairie are two other populations that have not had plants in several years due to habitat degradation (Chinsegut Hill) and development (Young). In 2015, several plants were found in the Croom Tract of Withlacoochee State Park (WSF) in Hernando County along a power line road (Croom- Power Line Road). A year later, another population was found along a pond margin a tenth of a mile away (Croom- Bell Heaven) (Peterson, BTG pers. comm. 2018b). These populations are located approximately 5 miles southeast of the other Hernando County sites. Approximately 40 miles south of all other known sites are four populations within Hillsborough River State Park (HRSP #1-4). The HRSP populations were found starting in 2006 along pond margins and wetlands within HRSP, all within approximately 0.4 miles of each other. Surveyors have not found plants in one of the populations since 2009. These populations are much lower in elevation than the Hernando County sites. From 2016- 2018 three populations consistently had more than three hundred plants: Burns Prairie, Croom-Bell Heaven, and HRSP #2. Minimal to no habitat management is taking place for any of the populations. Without regular management, it is possible that the species will disappear from these sites. (USFWS, 2019)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2019)

Exposure:

Response:

Consequence:

Narrative: This species is threatened by habitat destruction and degradation on its six extant sites due to the lack of habitat management and development of the land surrounding protected sites. Previously, conversion of existing sites to residential and agriculture was determined to be

the primary threat and resulted in the need to list the species (USFWS 1994). Since all six known extant populations now occur on public land, the threat of conversion of known sites to residential land use has been significantly reduced. The lack of habitat management has resulted in the disappearance of the Chinsegut Hill and Young populations and may be affecting other populations, such as the introduction and Burns Prairie. At Chinsegut Hill and the Young site, *C. robinsiae* was likely outcompeted by dense vegetation due to lack of disturbance, which was previously created by mowing or trampling by cattle. In addition, at Chinsegut Hill, the death of an oak tree that provided shade to *C. robinsiae* likely affected moisture levels (Service 2010). It is important to consider overstory composition when managing habitat. The introduction at the Blackwater Creek Preserve failed due to lack of habitat management that would have allowed cattle to graze the site. In 2012, Burns Prairie lost its grazing cattle and the only management that has taken place is that overgrown competing vegetation was removed in 2015 (Peterson, BTG pers. comm. 2019a). It is possible that this population will disappear if grazing or other habitat management is not continued. More research is needed to determine which methods are effective at managing habitat. Development of the land surrounding protected lands may alter hydrology by increasing runoff to *C. robinsiae* sites. This runoff may also contain fertilizers and herbicides that may affect growth and germination of the plants. *C. robinsiae* occurs in the Central Region of Florida, which is projected to experience the greatest population growth in the state in the near future. By 2070, the percentage of developed land is expected to double from 25% in 2010 to almost 50% (Carr and Zwick 2016). Due to modeling efforts (Lewis 2010, 2011), unknown populations and suitable habitat for introductions likely exist on private land and may be at risk to development. It is likely that agricultural lands will be converted to residential land uses in the near future (Carr and Zwick 2016). This conversion may negatively affect *C. robinsiae* habitat because cattle may benefit the species by providing the disturbance necessary to reduce competition from other plants. (USFWS, 2019)

Recovery

Reclassification Criteria:

Not developed

Delisting Criteria:

Not developed - Plausible criteria for recovery might include securing at least 10 viable and self-sustaining populations of Brooksville bellflower in pond margin habitats, consisting of approximately 10,000 individuals during prolific years (USFWS, 1993).

Recovery Actions:

- Develop management and protection criteria for populations on current managed areas (includes collection of biological/systematic data and control of exotic plants) (USFWS, 1993).
- Acquire additional habitat, or protect habitat through conservation easements and/or regulation. Sufficient information is available to proceed immediately (USFWS, 1993).
- Conduct additional surveys for new populations of the species (USFWS, 1993).
- Augment existing cultivated populations, including establishment of a germ plasm bank (USFWS, 1993).
- Develop plans for possible (re)introduction of plants into suitable habitats (includes 10-year monitoring of existing and/or reintroduced populations) (USFWS, 1993).

- Enforce protective legislation (USFWS, 1993).

Conservation Measures and Best Management Practices:

- Revise the current recovery plan to include updated objective and measurable recovery criteria for reclassifying this species to threatened status and delisting that are related to reducing the threats identified in the recovery plan, as well as updated information on the species distribution and biology (USFWS, 2010).
- Support further research on: a. Effects of cattle grazing on this species. b. Life history needs. c. Microhabitat requirements of this species. d. Effect of severe changes in temperatures (freezing) on germination. e. Drought and fluctuating water levels and their effect on germination. f. Transplant experiments, long-term seed viability trials, and optimizing germination protocols (USFWS, 2010).
- Continue working with public land managers to increase management efforts to benefit *C. robinsiae*. No management plans have been developed for this species but are necessary. Minimal management has been taking place at some sites. Once disturbance has been removed from some sites, populations have disappeared. Burns Prairie especially needs additional management because competing vegetation has taken over since grazing cattle were removed from the site. (USFWS, 2019)
- Continue conducting surveys at known sites of occurrence and expand surveys to other suitable areas in Hillsborough and Hernando Counties. This information is necessary to determine where plants currently exist and to prioritize recovery actions such as reintroductions at suitable sites. BTG has continued conducting surveys at known sites of occurrence. This work has been made possible through annual grants from the State of Florida, Department of Agriculture and Consumer Services, Division of Plant Industry, which funds the basic operations of BTG's Rare Plant Conservation Program. Surveys have been expanded to other sites determined by a GIS model to have suitable habitat. However, due to either flood or drought conditions during the survey periods, no plants were found. One introduction took place in 2013, but no plants were found the following year due to overgrowth of competing vegetation. No plants have been found at the introduction site since. Habitat management is necessary to control competing vegetation. (USFWS, 2019)

SPECIES ACCOUNT: *Canavalia molokaiensis* (`Awikiwiki)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/08/1992; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Canavalia molokaiensis, a member of the pea family (Fabaceae), is a perennial climbing herb with twining branches. Each leaf is made up of three lance-shaped or sometimes oval leaflets, which usually measure 3.5 to 8 cm (1.4 to 3 in) long and 1.3 to 5.4 cm (0.5 to 2.1 in) wide. Four to 15 flowers are arranged along a stalk 3 to 9 cm (1.2 to 3.5 in) long. The calyx (fused sepals), which is 20 to 28 mm (0.8 to 1.1 in) long, comprises a larger upper lip with two lobes and a smaller lower lip with three lobes. The five rose-purple petals vary from 36 to 47 mm (1.4 to 1.9 in) in length. The flattened pods, 12 to 16 cm (4.7 to 6.3 in) long and 2.3 to 3.5 cm (0.9 to 1.4 in) wide, enclose flattened, dark reddish-brown, oblong-elliptic seeds, which are 17 to 22 mm (0.7 to 0.9 in) long and about 12 to 14 mm (0.5 in) wide. (USFWS, 1996)

Taxonomy

Fosberg (1966) reduced several Hawaiian species of the genus to varieties, resulting in the name *C. galeata* var. *molokaiensis* for this taxon. In his revision of the Hawaiian taxa of the genus, St. John (1970) accepted *C. molokaiensis* and published two additional names, *C. peninsularis* and *C. stenophylla*, for Molokai plants. In the current treatment (Wagner and Herbst 1990), however, only *C. molokaiensis* is recognized. (USFWS, 1996)

Historical Range

Historically, *Canavalia molokaiensis* was known from East Molokai, at Kalaupapa, Pelekunu, and farther south in Kahuaawi Gulch and the region of Manawai (USFWS 1992). (USFWS, 1996)

Current Range

Known from Kalaupapa to Waialeia, Kaunakakai, and Kamakou in Molokai (USFWS 1992). (USFWS, 1996)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Canavalia molokaiensis* (`Awikiwiki) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Canavalia molokaiensis* includes six CHUs in Maui County, Hawaii (81 FR 17790-18110).

Molokai—Coastal—Unit 1 consists of 70 ac (28 ha) of privately owned land, and 54 ac (22 ha) of federally owned land (U.S. Coast Guard) at Laau Point, from Kahaiaawa to Keawakalani, along the western coast of Molokai. This unit is occupied by the plant *Marsilea villosa*, and includes the

mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 1 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 3 consists of 794 ac (321 ha) of State land, and 3 ac (1 ha) of federally owned land (Kalaupapa National Historical Park), from Kahu Point to Wainene, along the north-central coast of Molokai. This unit is occupied by the plants *Pittosporum halophilum*, *Schenkia sebaeoides*, and *Tetramolopium rockii*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 3 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Marsilea villosa*, *Peucedanum sandwicense*, or *Sesbania tomentosa*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 4 consists of 10 ac (4 ha) on Mokapu Island on the northern coast of Molokai. This area is State-owned, and is classified as a State Seabird Sanctuary. This unit is occupied by the plants *Peucedanum sandwicense* and *Pittosporum halophilum*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 4 is not known to be occupied by *Bidens wiebkei*, *Brighamia rockii*, *Canavalia molokaiensis*, *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *Ischaemum byrone*, *Marsilea villosa*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Coastal—Unit 6 consists of 190 ac (77 ha) of State land, and 1,685 ac (682 ha) of privately owned land, from Kaholaiki Bay to Halawa Bay, on the northeastern coast of Molokai. This unit is occupied by the plants *Bidens wiebkei*, *Canavalia molokaiensis*, *Hibiscus arnottianus*

ssp. *immaculatus*, and *Ischaemum byrone*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the coastal ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Coastal—Unit 6 is not known to be occupied by *Brighamia rockii*, *Hibiscus brackenridgei*, *Marsilea villosa*, *Peucedanum sandwicense*, *Pittosporum halophilum*, *Schenkia sebaeoides*, *Sesbania tomentosa*, or *Tetramolopium rockii*, we have determined this area to be essential for the conservation and recovery of these coastal species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Wet Cliff—Unit 2 (and) *Palmeria dolei*—Unit 44—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 44—Wet Cliff This area consists of 462 ac (187 ha) of State land, and 806 ac (326 ha) of privately owned land (partly within The Nature Conservancy's Pelekunu Preserve), along the rim of Pelekunu Valley from Kipapa Ridge to Mapulehu, in central Molokai. These units are occupied by the plants *Clermontia oblongifolia* ssp. *brevipes* and *Phyllostegia hispida*, and include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Wet Cliff—Unit 2 is not known to be occupied by *Brighamia rockii*, *Canavalia molokaiensis*, *Cyanea grimesiana* ssp. *grimesiana*, *C. munroi*, *Hesperomannia arborescens*, *Hibiscus arnottianus* ssp. *immaculatus*, *Pteris lidgatei*, or *Stenogyne bifida*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Wet Cliff—Unit 3 consists of 1,137 ac (460 ha) of State land, and 225 ac (91 ha) of privately owned land, along the rim of Wailau Valley from Mapulehu to Kahiwa Gulch, in eastern Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). Although Molokai—Wet Cliff—Unit 3 is not known to be occupied by *Brighamia rockii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea grimesiana* ssp. *grimesiana*, *C. munroi*, *Hesperomannia arborescens*, *Hibiscus arnottianus* ssp. *immaculatus*, *Phyllostegia hispida*, *Pteris lidgatei*, or *Stenogyne bifida*, we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Canavalia molokaiensis* critical habitat consists of four components. Coastal (Molokai), Lowland mesic (Molokai), Lowland wet (Molokai) and Wet cliff (Molokai) (81 FR 17790-18110):

Ecosystem: Coastal. Elevation: <980 ft (<300 m). Annual precipitation: <20 in (<50 cm). Substrate: Well-drained, calcareous, talus slopes; dunes; weathered clay soils; ephemeral pools; mudflats. Canopy: Hibiscus, Myoporum, Santalum, Scaevola. Subcanopy: Gossypium, Sida, Vitex. Understory: Eragrostis, Jacquemontia, Lyceum, Nama, Sesuvium, Sporobolus, Vigna.

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: Acacia, Diospyros, Metrosideros, Myrsine, Pouteria, Santalum. Subcanopy: Dodonaea, Freycinetia, Leptecophylla, Melanthera, Osteomeles, Pleomele, Psydrax. Understory: Carex, Dicranopteris, Diplazium, Elaphoglossum, Peperomia.

Ecosystem: Lowland Wet. Elevation: <3,330 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: Antidesma, Metrosideros, Myrsine, Pisonia, Psychotria. Subcanopy: Cibotium, Claoxylon, Kadua, Melicope. Understory: Alyxia, Cyrtandra, Dicranopteris, Diplazium, Machaerina, Microlepidia.

Ecosystem: Wet Cliff. Elevation: unrestricted. Annual precipitation: >75 in (>190 cm). Substrate: >65 degree slope, shallow soils, weathered lava. Canopy: None. Subcanopy: Broussaisia, Cheirodendron, Leptecophylla, Metrosideros. Understory: Bryophytes, Ferns, Coprosma, Dubautia, Kadua, Peperomia.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be

currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium*

molokaiense, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: This species has been observed in flower during May 1982 (HHP 1990b) and December 1989 (HHP 1990c). Fruits and flowers were observed in March 1989 (HHP 1990d). (USFWS, 1996)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland, shrubland/chaparral (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 850 to 930 meters (2,790 to 3,050 feet) (USFWS, 1996)

Habitat Narrative

Adult: *Canavalia molokaiensis* is found in moist shrublands and forests on gulch slopes and in gulch bottoms. This species typically grows in exposed dry sites on steep slopes in mesic shrublands and forests at 850 to 930 meters (2,790 to 3,050 feet) elevation (USFWS 1992). Associated plant species include ohia, *Chamaesyce* (akoko), *Dodonaea viscosa* (aalii), *Styphelia tameiameia* (pukiawe), and *Wikstroemia* (akia) (USFWS 1992). (USFWS, 1996; NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

Low (inferred from NatureServe, 2015)

Redundancy:

Low (inferred from NatureServe, 2015)

Number of Populations:

6 (3 populations on Moloka'i and three that have not been visited within the last 10 years; USFWS, 2018)

Population Size:

18-33 (wild populations; USFWS, 2018)

Population Narrative:

In 2011, there were 10 populations of *Canavalia molokaiensis* totaling approximately 175 individuals on Moloka'i. Currently, there are three populations of 5 to 10 individuals each at Kalaupapa, Kūpā'ia, and Pua'ahala (Bakutis 2018, in litt.), and three individuals observed at Kua Gulch in 2013 (PEPP 2013). There are no new reports on the current status of other populations at Mokomoko Gulch (3 to 6 individuals) and Wai'ale'ia stream (10 individuals) since 2009 (Tangalin 2009, in litt.), or for two individuals at Wailau since 2005. (USFWS, 2018)

Threats and Stressors

Stressor: Habitat degradation from animals (USFWS, 1996; USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Feral ungulates, particularly goats and pigs, degrade the habitat of *Canavalia molokaiensis* extensively and pose an immediate threat to this species. Predation on a related species of *Canavalia* suggests that goats may possibly consume this species. At Mokomoko, Kua, and Waiehu, deer (*Axis axis*), goats (*Capra hircus*), and pigs (*Sus scrofa*) are very abundant, which contributes to habitat degradation and landslides. (USFWS, 1996; USFWS, 2011)

Stressor: Non-native plant species (USFWS, 1996; USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Competition with the alien plant, molasses grass, is also an immediate threat. Invasive introduced plant species that compete with natives and degrade *C. molokaiensis* habitat include *Ageratina adenophora* (sticky snake root), *Buddleia asiatica* (dog tail), *Clidemia hirta* (Koster's curse), *Cordyline fruticosa* (ti), *Bryophyllum pinnatum* (airplant), *Lantana camara* (lantana), *Melinis minutiflora* (molasses grass), *Psidium cattleianum* (strawberry guava), *Rubus rosifolius* (thimbleberry), and *Schinus terebinthifolius* (Christmasberry) (Hawaii Biodiversity and Mapping Program 2009; Perlman 2009; Tangalin 2009; Wood 2009). At Mokomoko, *Erigeron karvinskianus* (daisy fleabane), which blankets and outcompetes seedlings, is especially dense (Tangalin 2009). At Kupaia, the threats are introduced invasive plants including *Pinus* sp. (pine), *Melinis minutiflora*, *Casuarina* sp. (ironwood), and *Psidium cattleianum*. (USFWS, 1996; USFWS, 2011)

Stressor: Climate change (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Climate change may also pose a threat to this species. However, current climate change analyses in the Pacific Islands lack sufficient spatial resolution to make predictions on impacts to this species. The Pacific Islands Climate Change Cooperative (PICCC) has currently funded climate modeling that will help resolve these spatial limitations. The Service anticipates high spatial resolution climate outputs by 2013. (USFWS, 2011); The assessment by Fortini et al. (2013) concluded that *Canavalia molokaiensis* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.761 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). (USFWS, 2018)

Recovery

Reclassification Criteria:

1. A total of five to seven populations of each taxon should be documented on Molokai and at least one other island where they now occur or occurred historically. (USFWS, 1996)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1996)
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered. (USFWS, 1996)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Molokai and at least 1 other island where they now occur or occurred historically. (USFWS, 1996)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1996)
3. Each population should persist at this level for a minimum of 5 consecutive years. (USFWS, 1996)

Recovery Actions:

- The highest priority for the recovery of the Molokai plant cluster taxa is the implementation of immediate recovery actions needed to keep “on-the-brink” species from going extinct. These actions include propagation and maintenance of genetic stock ex situ, and protection of remaining wild individuals from threats. (USFWS, 1996)
- Secondly, the plan proposes the delineation of management units to conserve not only these taxa, but their habitats as well. These units should be managed to preserve as many native species (flora and fauna) as possible, through threat-control and forest-restoration programs. (USFWS, 1996)
- The next step in the recovery of these species is augmentation of small populations and re-establishment of new populations within the historical range of the species. This includes selection of areas for augmentation and reestablishment, determination of the best methods for ex situ propagation and transplanting, selection of the best genetic stock for

- each area, propagation of suitable stock, preparation of sites for seeding and/or transplanting, and monitoring and maintenance of new individuals and populations as they are established. (USFWS, 1996)
- A research program is also recommended to study the growth and reproductive viability of each taxon, determine the parameters of viable populations of each taxon, study the reproductive strategy and pollinators of each taxon, and study possible pests and diseases. (USFWS, 1996)
 - Surveys and inventories—Survey for additional populations of *Canavalia molokaiensis* in areas of potentially suitable habitat. (USFWS, 2018)
 - Ungulate monitoring and control—Construct and maintain fenced exclosures to protect individuals from the negative impacts of feral ungulates. Protect all occurrences against browsing and habitat disturbances from feral ungulates. (USFWS, 2018)
 - Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations. Control invasive nonnative species that compete with the species around all populations. (USFWS, 2018)
 - Captive propagation for genetic storage and reintroduction—Continue propagation efforts for maintenance of genetic stock. (USFWS, 2018)
 - Reintroduction and translocation—Continue to reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. (USFWS, 2018)
 - Climate change adaptation strategy—Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of this species. (USFWS, 2018)
 - Alliance and partnership development—Work with the Hawai'i Division of Forestry and Wildlife and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species. (USFWS, 2018)

Conservation Measures and Best Management Practices:

- Continue protection from feral ungulates. (USFWS, 2011)
- Continue removal of invasive introduced plant species. (USFWS, 2011)
- Collect propagules for propagation and genetic storage. (USFWS, 2011)
- Propagate for reintroduction to augment existing populations. (USFWS, 2011)
- Establish additional populations within protected habitat. (USFWS, 2011)
- Work with Hawaii Division of Forestry and Wildlife and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species. (USFWS, 2011)
- Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species. (USFWS, 2011)

Species Taxonomic and Listing Information

Listing Status: Endangered; 05/13/2010; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Canavalia napaliensis is a perennial climbing plant in the pea family (Fabaceae) having elliptical, papery leaflets 6 to 13 centimeters (cm) (2.4 to 5.0 inches (in)) long and 3.5 to 7.5 cm (1.4 to 3.0 in) wide. The upper surfaces of the leaves are sparsely pubescent, and the lower surfaces are densely pubescent. Flowers number 7.6 to 40.6 cm (3 to 16 in), pseudoracemes (multiple flowers in each bracket axil) are 1.9 cm (0.8 in) long, with dark purple corollas that are white spotted at the base. The flowers are 36 to 39 millimeters (mm) (1.4 to 1.5 in) long with wing petals 37 to 45 mm (1.5 to 2.0 in) long. The fruit pods are compressed, 14 to 20 cm (5.5 to 8.0 in) long by 3.0 to 3.8 cm (1.0 to 1.5 in) wide and densely silky pubescent. The seeds are reddish brown, oblong-elliptic, strongly compressed, 20 to 24 mm (0.8 to 1.0 in) long, and 14 to 16 mm (0.55 to 0.63 in) wide (Wagner and Herbst 1999). (USFWS, 2017)

Taxonomy

Genus found throughout tropical & subtropical Asia, Africa & America. Species endemic to Northwest Kauai. Wagner et al. have synonymized *C. makahaensis* & *C. nualoloensis* with this species. (NatureServe, 2015)

Historical Range

Canavalia napaliensis was historically known from 12 locations along the northwestern coast of Kauai, extending westward from Haena to Makaha Ridge (HBMP 2010). (USFWS, 2017)

Current Range

At the time of listing, five populations totaling between 106 and 206 individuals were reported from Haena to Kalalau Valley (Perlman 2007; HBMP 2007). Currently, this species is restricted to a small section of the Na Pali coast in eight populations totaling approximately 900 individuals. (USFWS, 2017)

Critical Habitat Designated

Yes; 4/13/2010.

Legal Description

On April 13, 2010, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Canavalia napaliensis* (`Awikiwiki) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes five critical habitat units (CHUs), in Hawaii (75 FR 18960-19165).

Critical Habitat Designation

The critical habitat designation for *Canavalia napaliensis* includes five CHUs in Kauai County, Hawaii (75 FR 18960-19165).

Kauai—Lowland Mesic—Section 1: Lowland Mesic—Section 1 consists of 2,006 ac (812 ha) in the lowland mesic ecosystem, including mesic forest extending from Awaawapuhi Trail south to

Makaha Ridge, in the Na Pali Kona Forest Reserve and the Kuia NAR (Figure 1-A). The entire section is State-owned and within previously designated critical habitat; it falls within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 66a. This section is occupied by the plants *Doryopteris angelica*, *Labordia helleri*, *Platydesma rostrata* and *Psychotria hobbdi*, and includes mesic forest, the moisture regime, and canopy, subcanopy, and understory native plant species identified as PCEs in the lowland mesic ecosystem (Table 3). This section also contains unoccupied habitat that is essential to the conservation of these four species by providing the physical and biological features necessary for the expansion of the existing wild populations. Although Lowland Mesic–Section 1 is not known to be occupied by the species *Canavalia napaliensis*, *Chamaesyce eleanoriae*, *Chamaesyce remyi* var. *remyi*, *Charpentiera densiflora*, *Dubautia kenwoodii*, *Pittosporum napaliense*, and *Tetraplasandra bisattenuata*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

"Kauai—Lowland Mesic—Section 2: Lowland Mesic—Section 2 consists of 379 ac (154 ha) in the lowland mesic ecosystem, including mesic forest extending from Keanapuka to Kahuamaa Flat along the rim and cliffs of the Kalalau Valley, in the Na Pali Coast State Park (Figure 1-A, above). The entire section is State-owned and within previously designated critical habitat; it falls within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 66a. This section is occupied by the plants *Canavalia napaliensis*, *Chamaesyce eleanoriae*, *C. remyi* var. *remyi*, *Charpentiera densiflora*, *Pittosporum napaliense*, and *Psychotria hobbdi*, and includes mesic forest, the moisture regime, and canopy, subcanopy, and understory native plant species identified as PCEs in the lowland mesic ecosystem (Table 3). This section also contains unoccupied habitat that is essential to the conservation of these six species by providing the physical and biological features necessary for the expansion of the existing wild populations. Although Lowland Mesic–Section 2 is not known to be occupied by the species *Doryopteris angelica*, *Dubautia kenwoodii*, *Labordia helleri*, *Platydesma rostrata*, and *Tetraplasandra bisattenuata*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historical range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery. "

"Kauai—Lowland Mesic—Section 3: Lowland Mesic—Section 3 consists of 124 ac (50 ha) in the lowland mesic ecosystem, including mesic forest extending from Manono Ridge, Pohakuao Valley, to Kanakuu, within the Na Pali Coast State Park (Figure 1-A, above). The entire section is State-owned and within previously designated critical habitat; it falls within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 66a. This section is occupied by the plants *Canavalia napaliensis*, *Chamaesyce eleanoriae*, and *Charpentiera densiflora*, and includes mesic forest, the moisture regime, and canopy, subcanopy, and understory native plant species identified as PCEs in the lowland mesic ecosystem (Table 3). This section also contains unoccupied habitat that is essential to the conservation of these three species by providing the physical and biological features necessary for the expansion of the existing wild populations. Although Lowland Mesic–Section 3 is not known to be occupied by the species *Chamaesyce remyi* var. *remyi*, *Doryopteris angelica*, *Dubautia kenwoodii*, *Labordia helleri*, *Pittosporum napaliense*, *Platydesma rostrata*,

Psychotria hobbdi, and *Tetraplasandra bisattenuata*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery. "

"Kauai—Lowland Mesic—Section 4: Lowland Mesic—Section 4 consists of 81 ac (33 ha) in the lowland mesic ecosystem, including mesic forest at the head of the Hanakapiai Valley, in the Na Pali Coast State Park (Figure 1-A, above). The entire section is State owned and within previously designated critical habitat; it falls within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 66a. This section is occupied by the plant *Charpentieradensiflora* and includes mesic forest, the moisture regime, and canopy, subcanopy, and understory native plant species identified as PCEs in the lowland mesic ecosystem (Table 3). This section also contains unoccupied habitat that is essential to the conservation of this species by providing the physical and biological features necessary for the expansion of the existing wild population. Although Lowland Mesic—Section 4 is not known to be occupied by the species *Canavalia napaliensis*, *Chamaesyce eleanoriae*, *Chamaesyce remyi* var. *remyi*, *Doryopteris angelica*, *Dubautia kenwoodii*, *Labordia helleri*, *Pittosporum napaliense*, *Platydesmarostrata*, *Psychotria hobbdi*, and *Tetraplasandra bisattenuata*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery."

"Kauai—Lowland Mesic—Section 5: Lowland Mesic—Section 5 consists of 37 ac (15 ha) in the lowland mesic ecosystem, including mesic forest on the slopes of Mt. Haupū, on privately owned land (Figure 1-B). The entire section is within previously designated critical habitat, and falls within Critical Habitat Unit 7 of 50 CFR 17.99(a)(1), Map 23a. This section is occupied by the plants *Chamaesyce remyi* var. *remyi* and *Tetraplasandra bisattenuata*, and includes mesic forest and shrubland, the moisture regime, and subcanopy and understory native plant species identified as PCEs in the lowland mesic ecosystem (Table 3). This section also contains unoccupied habitat that is essential to the conservation of these two species by providing the physical and biological features necessary for the expansion of the existing wild populations. Although Lowland Mesic—Section 5 is not known to be occupied by the species *Canavalia napaliensis*, *Chamaesyce eleanoriae*, *Charpentieradensiflora*, *Doryopteris angelica*, *Dubautia kenwoodii*, *Labordia helleri*, *Pittosporum napaliense*, *Platydesmarostrata*, and *Psychotria hobbdi*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery. "

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Canavalia napaliensis* critical habitat consists of one component (Lowland mesic) (75 FR 18960-19165):

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<914 m). Annual precipitation: 50–75 in (127–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: Acacia, Diospyros, Metrosideros, Myrsine, Pouteria, Santalum. Subcanopy: Dodonaea, Freycinetia, Leptecophylla, Melanthera, Osteomeles, Pleomele, Psydrax. Understory: Carex, Dicranopteris, Diplazium, Elaphoglossum, Peperomia.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contains the physical or biological features essential to the conservation of the species that may require special management considerations or protection. It is recognized that activities in and adjacent to areas designated as critical habitat may affect one or more of the PCEs found in these areas. Special management is needed throughout each of the designated critical habitat units. The following discussion of special management needs is applicable to each of the 47 Kauai species for which we are designating critical habitat. These 47 Kauai species include 41 species that are currently found in the wild, and 6 species that are not currently extant in the wild. For each of the 41 Kauai species found in the wild, we have determined that the features essential to their conservation are primarily dependent on maintaining the successful functioning of the ecosystem(s) in which they occur (Tables 3 and 4). In some cases, additional species-specific primary constituent elements have also been identified (Table 4). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical and biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, predation by nonnative species, competition with nonnative species, hurricanes, landslides, flooding, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by feral ungulates (pigs, goats, and black-tailed deer). Feral ungulates also impact the habitat through predation and trampling. The State of Hawaii provides game mammal (feral pigs and goats, and black-tailed deer) hunting opportunities on one or more State-designated public hunting areas on the islands of Kauai, Oahu, Maui, Molokai, Lanai, and Hawaii (Hawaii Administrative Rules 13-123; DLNR 2009a). Management of game animals by the State ranges from providing maximal sustained public hunting opportunities and benefits (e.g., “sustained yield”) in some areas to game animal removal by State staff, or their designees, in other areas (DLNR 2009b). Public hunting areas are not fenced, and game mammals have unrestricted access to most areas across the landscape, regardless of the underlying land use designation. While fences are sometimes built to provide protection from game mammals to the natural resources within the fenced area, the current number and locations of fences are not sufficient to prevent habitat destruction and degradation. Without special management, the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new alien plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species will help to

address the threat presented by fire to three critical habitat areas in particular (Kauai—Lowland Mesic— Section 1, Kauai—Montane Mesic— Section 2, and Kauai—Dry Cliff— Section 1; see Table 5 for corresponding CFR unit numbers). This threat is primarily due to the presence of nonnative species, such as the grasses *Andropogon* sp. and *Setaria* sp., which increase the fuel load and quickly regenerate after a fire. These species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D’Antonio and Vitousek 1992, pp. 64– 66; Brooks et al. 2004, p. 680). In addition, five sections (Kauai—Dry Cliff—Section 1, Kauai—Dry Cliff— Section 2, Kauai—Wet Cliff—Section 1, Kauai—Wet Cliff—Section 2, and Kauai—Wet Cliff—Section 3; see Table 5 for corresponding CFR unit numbers) may require special management to reduce the threat of landslides and flooding, which threaten to further degrade the habitat conditions and have the potential to eliminate some species in their entirety (e.g., *Schiedea attenuata*). In summary, we find that each of the areas we are designating as critical habitat contains features essential to the conservation of the species that may require special management considerations or protection to ensure the conservation of the 47 Kauai species. These special management considerations and protections are required to preserve and maintain the essential features provided to these species by the ecosystems upon which they depend. A more detailed discussion of each of these threats is presented above, under the Summary of Factors Affecting the Species section.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Not available.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland, shrubland/chaparral (NatureServe, 2015)

Environmental Specificity

Adult: Unknown (NatureServe, 2015)

Habitat Narrative

Adult: *Canavalia napaliensis* occurs in open, dry sites and coastal strand, diverse lowland dryland-mesic forest to mixed mesophytic forest on talus slopes, and in shrubby, grassy gulch bottoms, at elevations between 6 to 695 meters (20 to 2,280 feet). Associated native species are: *Antidesma platyphyllum* (hame), *Chrysodracon aurea* (hala pepe), *Diospyros sandwicensis* (lama), *Dodonaea viscosa* (aalii), *Metrosideros* spp. (ohia), *Polyscias kawaiensis* (oheohe), *Pisonia* spp. (papala kepau), *Pittosporum kauaiense* (hoawa), *Planchonella sandwicensis* (alaa), *Psychotria mariniana* (kopiko), *Vitex rotundifolia* (beach vitex), and *Wikstroemia furcata* (akia) (Wagner and Herbst 1999; HBMP 2010; NTBG 2010, 2011, 2012, 2013, 2014). (USFWS, 2017)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends

Population Trends:

Long-term trends are unknown, but short-term trends indicate a relatively stable population (NatureServe, 2015)

Resiliency:

Low (inferred from NatureServe, 2015)

Redundancy:

Low (inferred from NatureServe, 2015)

Number of Populations:

8 (USFWS, 2017)

Population Size:

~900 individuals [Na Pali (500 individuals), Makaha (100 individuals), Hikimoe (100 individuals), Haeleele (100 individuals) and four other scattered smaller populations totaling approximately 100 individuals; USFWS, 2017]

Population Narrative:

Long-term trends are unknown, but short-term trends indicate a relatively stable population. The original range of this species was probably much larger (Russell 2002). The number of plants remaining is probably under a thousand. Total number of environmental occurrences are 12, of those five are known extant occurrences found only on Kauai. Observation records range from 1986-2007 (HBMP 2007). (NatureServe, 2015); *Canavalia napaliensis* was historically known from 12 locations along the northwestern coast of Kauai, extending westward from Haena to Makaha Ridge (HBMP 2010). At the time of listing, five populations totaling between 106 and 206 individuals were reported from Haena to Kalalau Valley (Perlman 2007; HBMP 2007). Currently, this species is restricted to a small section of the Na Pali coast in eight populations totaling approximately 900 individuals. The populations include: Na Pali (500 individuals), Makaha (100 individuals), Hikimoe (100 individuals), Haeleele (100 individuals) and four other scattered smaller populations totaling approximately 100 individuals (Wood 2016, in litt.). Numbers have likely increased resulting from continued surveys of the area. (USFWS, 2017)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from non-native plants, goats, fire, hurricanes, and climate change. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct

consumption of native vegetation; soil disturbance; dispersal of alien plant seeds, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Fire can destroy dormant seeds and plants, even in steep in inaccessible areas. Successive fires can remove habitat for native species by altering microclimate conditions favorable to alien plants.

Stressor: Predation and herbivory (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species present an immediate and significant threat to *Canavalia napaliensis* throughout its range due to documented browsing and trampling by pigs, goats, and deer and documented mechanical damage by rats and the black twig borer (*Xylosandrus compactus*) (USFWS, 2010).; Herbivory by rats has been noted as a threat to *Canavalia napaliensis* (HBMP 2010). Rats eat virtually every part of plants and at every stage: fleshy fruits, seeds, flowers, stems, leaves, shoot, seedlings, and roots (Russell 1980; Cuddihy and Stone 1990). The effects on plants range from reduced vigor and decreased reproduction to mortality of individuals and complete lack of recruitment. (USFWS, 2017)

Stressor: Ungulate modification and degradation of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Feral pigs (*Sus scrofa*), goats (*Capra hircus*), and black-tailed deer (*Odocoileus hemionus*) (Corn et al. 1978; HBMP 2010; NTBG 2010) modify and destroy habitat by disturbing and destroying vegetative cover, trampling plants and seedlings, reducing or eliminating plant regeneration by damaging seeds and seedlings, and increasing erosion by creating large areas of bare soil. (USFWS, 2017)

Stressor: Established ecosystem-altering invasive plant modification and degradation of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Invasive introduced plant species modify habitats occupied by native plant species by changing the availability of light, altering soil-water regimes, modifying nutrient cycling, and changing the fire characteristics of the native plant community. Invasive introduced plants impacting *Canavalia napaliensis* are *Adiantum hispidulum* (rough maidenhair fern), *Ageratum conyzoides* (maile honohono), *Andropogon glomeratus* (bushy beardgrass), *A. virginicus* (broomsedge), *Blechnum appendiculatum* (no common name (NCN)), *Clidemia hirta* (Koster's curse), *Cyperus meyenianus* (NCN), *Elephantopus mollis* (elephant's foot), *Erigeron karvinskianus* (daisy fleabane), *Hedychium gardnerianum* (kahili ginger), *Kalanchoe pinnata* (air plant), *Lantana camara* (lantana), *Melia azedarach* (chinaberry), *Melinis minutiflora* (molasses grass), *Oplismenus hirtellus* (basketgrass), *Plantago lanceolata* (narrow-leaved plantain), *Pluchea carolinensis* (sourbush), *Psidium guajava* (common guava), *Rubus rosifolius* (thimbleberry), *Setaria gracilis*

(yellow foxtail), and *Vulpia bromoides* (brome fescue) (Corn et al. 1978; HBMP 2010; NTBG 2010, 2011, 2012, 2013, 2014). (USFWS, 2017)

Stressor: Landslides and flooding destruction or degradation of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Landslides, including tree falls and erosion associated with them, can have a significant effect on small populations of *Canavalia napaliensis* (NTBG 2011, 2013; HBMP 2010). Landslides and erosion due to natural weathering destabilize substrates, damage and destroy individual plants, and alter hydrological patterns (Stearns 1985). (USFWS, 2017)

Stressor: Fire destruction or degradation of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: *Canavalia napaliensis* occurs in mesic and mesophytic forest areas that are more susceptible to fires (NTBG 2014). Fire kills most native trees and shrubs, and alters the native ecosystem, leading to invasion by nonnative grasses that contribute to the grass/fire cycle (D'Antonio and Vitousek 1992). (USFWS, 2017)

Stressor: Hurricanes (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: In November 1982, Hurricane Iwa struck the Hawaiian Islands, with wind gusts exceeding 100 miles per hour (mph) (161 kilometers per hour (kph)), causing extensive damage, especially on the islands of Niihau, Kauai, and Oahu (Businger 1998). In September 1992, Hurricane Iniki, a category 4 hurricane with maximum sustained wind speeds recorded at 140 mph (225 kph), passed directly over the island of Kauai. Many forest trees were destroyed (Perlman 1992), which opened the canopy and facilitated the invasion of nonnative plants (Kitayama and Mueller-Dombois 1995). A destructive hurricane holds the potential of driving a localized endemic species to extinction in a single event. Hurricanes pose an ongoing and ever-present threat because they can happen at any time, although their occurrence is not predictable. Tropical cyclone frequency and intensity are projected to change as a result of climate change over the next 100 to 200 years (Vecchi and Soden, 2007; Emanuel et al. 2008; Yu et al. 2010). In the central Pacific, modeling projects an increase of up to two additional tropical cyclones per year in the main Hawaiian Islands by 2100 (Murakami et al. 2013). (USFWS, 2017)

Stressor: Climate change loss or degradation of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. This assessment concluded that *Canavalia napaliensis* is highly vulnerable to the impacts of climate change, with a vulnerability

score of 0.711 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2017)

Stressor: Black twig borer herbivory (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Infestation by and damage or death caused by the black twig borer (*Xylosandrus compactus*) is a threat to *Canavalia napaliensis* (HBMP 2010). This insect pest burrows into branches, introduces a pathogenic fungus as a food source for its larvae, and lays its eggs (Davis 1970). In Hawaii, the black twig borer has many host plants, disperses easily, and is probably present at most elevations up to 762 meters (2,500 feet). (USFWS, 2017)

Stressor: Lack of adequate hunting regulations (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Nonnative feral ungulates pose a major ongoing threat to native species through destruction and modification of habitat, and by direct herbivory or predation. Management of game animals by the State ranges from providing maximal sustained public hunting opportunities and benefits (i.e., sustained yield) in some areas, with one animal allowed per day; to other areas with as few as one animal allowed per year (DLNR 2010). All of the populations occur in State hunting areas. None of these populations are within fenced exclosures. Game mammals have unrestricted access to most areas across the landscape, regardless of underlying land use designation; therefore, any unfenced populations are at risk (DLNR 2010). (USFWS, 2017)

Stressor: Lack of adequate biosecurity legislation (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Introduction of invasive nonnative plant species to the State of Hawaii and destruction of habitat and competition by nonnative plants are threats to *Canavalia napaliensis*. The U.S. Department of Agriculture, Animal and Plant Health Inspection Service, Plant Protection and Quarantine, is authorized to prevent the introduction or dissemination of animal and plant pests on all ships, aircraft, and their cargo and baggage arriving in the U.S. and its territories; however, pest species continue to enter the State. In addition, Federal import regulations do not address many species that could be pests in Hawaii (CGAPS 2009; Ikuma et al. 2002). (USFWS, 2017)

Stressor: Invasive species (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Established invasive plant species competition—Plant species including *Aleurites moluccana* (candlenut, kukui), *Cyclosorus dentatus* (downy wood fern), *Cordyline fruticosa* (ti), *Kalanchoe pinnata* (air plant), *Pluchea* spp. (marsh fleabane), and *Syzygium cumini* (Java plum) compete with *Canavalia napaliensis* for water, light, and nutrients (HBMP 2010; NTBG 2014). (USFWS, 2017)

Stressor: Stochastic events - Tsunami mortality and reduced viability (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Populations of *Canavalia napaliensis* near the shoreline are at very high risk of tsunamis. Even if plants survive the initial waves, salt water inundation can kill any salt-intolerant plants (USFWS 2011; Starr and Starr 2011, in. litt.). (USFWS, 2017)

Stressor: Stochastic events - reduced viability due to low numbers (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Small, isolated populations often exhibit reduced levels of genetic variability, which diminishes the species' capacity to adapt and respond to environmental changes, thereby lessening the probability of long-term persistence (Barrett and Kohn 1991; Newman and Pilson 1997; HBMP 2010). The problems associated with small population size and vulnerability to random demographic fluctuations or natural catastrophes are further magnified by synergistic interactions with other threats, such as anthropogenic impacts like habitat loss from human development or predation by nonnative species. Very small plant populations may experience reduced reproductive vigor due to ineffective pollination or inbreeding depression. (USFWS, 2017)

Recovery

Reclassification Criteria:

Reclassification criteria are not available.

Delisting Criteria:

Delisting criteria are not available.

Recovery Actions:

- Assess the distribution, current status, and potential future distribution of existing ecosystems and determine the most important sites for ecosystem management. Make use of landscape modeling, spatial analysis, remote sensing technology, and existing survey data to better understand species distributions and priority ecosystem areas for targeting future surveys. (USFWS, 2010)
- Initiate control of ecosystem-modifying threats, such as ungulates and invasive introduced plant species, as soon as possible within the highest priority management units. (USFWS, 2010)
- Stabilize and protect remaining extant populations of the 45 plants and 2 bird species. Conduct systematic, island-wide surveys for additional populations. Make use of landscape modeling, spatial analysis, remote sensing technology, and existing survey data to better understand distributions and priority areas for targeting future surveys. (USFWS, 2010)
- Restore and maintain multiple viable populations of the 45 plants and 2 bird species by protecting, restoring, and maintaining existing habitats or areas with potential for restoration that are within their historical range. (USFWS, 2010)
- Conduct research on control methods for introduced slugs and avian malaria. (USFWS, 2010)

- Develop an augmentation plan to collect and propagate seed from the 45 plant species that can later be utilized for population restoration, augmentation, and reintroduction. (USFWS, 2010)
- Identify threats and prioritize which ones to address first for the two birds. (USFWS, 2010)
- Determine if a captive propagation program for the two birds is necessary; if so, develop a captive propagation program. (USFWS, 2010)
- Prevent the influx of new pests and invasive species into recovery areas. Increase the efforts of the Kauai Invasive Species Committee and improve border security. (USFWS, 2010)
- Prioritize research studies that will provide information and tools aiding in the mitigation of known threats and limiting factors of the species and ecosystems. (USFWS, 2010)
- Increase outreach effort and coordination with State agencies and private landowners regarding ecosystem conservation. Promote opportunities to assist in the recovery of these species through Habitat Conservation Plans, Safe Harbor Agreements, and through various conservation partnerships funded by State and Federal agencies and private organizations. (USFWS, 2010)
- Surveys and inventories—Survey for populations of *Canavalia napaliensis* in areas of suitable habitat. (USFWS, 2017)
- Ungulate monitoring and control—Construct protective fences around all known populations and protect all occurrences against browsing and disturbances from feral ungulates. (USFWS, 2017)
- Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations. Control invasive nonnative plant species around all populations that compete with the species. (USFWS, 2017)
- Fire monitoring and control—Develop and implement a fire management plan for existing populations (USFWS, 2017).
- Predator and herbivore control—Implement rat control at current populations. (USFWS, 2017)
- Predator and herbivore control research—Develop and implement control methods for the black twig borer (*Xylosandrus compactus*). (USFWS, 2017)
- Captive propagation for genetic storage and reintroduction—Continue propagation efforts for maintenance of genetic stock. (USFWS, 2017)
- Reintroduction and translocation—Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. (USFWS, 2017)
- Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from land slides and storms. (USFWS, 2017)
- Based on the recovery criteria above, consider development of a recovery plan. (USFWS, 2017)

Conservation Measures and Best Management Practices:

- Conservation measures are not available.

SPECIES ACCOUNT: *Canavalia pubescens* (ʻAwikiwiki)

Species Taxonomic and Listing Information

Listing Status: Endangered; 06/27/2013; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

A twining perennial vine. Leaves with 3 leaflets, usually hairy. Flowers usually 8-20 in pseudoracemes 3-5 cm long. Corollas dark red to pink, rarely white(?). (NatureServe, 2015)

Taxonomy

Genus found throughout tropical and subtropical Asia, Africa and America. Species endemic to Hawaiian islands. Wagner et al. have listed the following as synonyms of this taxon: *C. forbesii*, *C. haleakalaensis*, *C. Munroi*, *C. galeata* var. *pubescens*. (NatureServe, 2015)

Historical Range

Recorded from the islands of Niihau, Kauai, Maui, and Lanai in the state of Hawaii. (NatureServe, 2015)

Current Range

Recorded from the islands of Niihau, Kauai, Maui, and Lanai in the state of Hawaii. Current records (1983-1998) from Maui and Lanai. (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Canavalia pubescens* (ʻAwikiwiki) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes three detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Canavalia pubescens* includes three CHUs in Maui County, Hawaii with detailed unit information. There are also an unknown number of units on Lanai that contain this species (number of units is unknown because detailed unit descriptions for Lanai are not available) (81 FR 17790-18110).

Maui—Lowland Dry—Unit 1 consists of 11,465 ac (4,640 ha) of State land, 2,069 ac (837 ha) of federally owned land, and 3 ac (1 ha) of privately owned land, from Kanaio to Kahualau Gulch on the southern slopes of east Maui. This unit is occupied by the plants *Bonamia menziesii*, *Cenchrus agrimonioides*, *Flueggea neowawraea*, *Melicope adscendens*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 1 is not known to be occupied by *Alectryon macrococcus*, *Bidens micrantha* ssp. *kalealaha*, *Canavalia*

pubescens, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Hibiscus brackenridgei*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Sesbania tomentosa*, *Solanum incompletum*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 3 consists of 188 ac (76 ha) of privately owned land, at Keauhou on the southern slopes of east Maui. This unit is occupied by the plant *Canavalia pubescens*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 3 is not known to be occupied by *Bidens micrantha* ssp. *kalealaha*, *Bonamia menziesii*, *Cenchrus agrimonioides*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Flueggea neowawraea*, *Hibiscus brackenridgei*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Solanum incompletum*, *Spermolepis hawaiiensis*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 4 consists of 1,266 ac (512 ha) of State land (including the Department of Land and Natural Resources) at Ahihi-Kinohiwa Natural Area Reserve on the southern slopes of east Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). Although Maui—Lowland Dry—Unit 4 is not currently occupied by *Bidens micrantha* ssp. *kalealaha*, *Bonamia menziesii*, *Canavalia pubescens*, *Cenchrus agrimonioides*, *Colubrina oppositifolia*, *Ctenitis squamigera*, *Flueggea neowawraea*, *Hibiscus brackenridgei*, *Melanthera kamolensis*, *Melicope mucronulata*, *Neraudia sericea*, *Nototrichium humile*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Solanum incompletum*, *Spermolepis hawaiiensis*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Canavalia pubescens* critical habitat consists of two components. Coastal (Lanai) and Lowland dry (east Maui) (81 FR 17790-18110):

Ecosystem: Coastal. Elevation: <980 ft (<300 m). Annual precipitation: <20 in (<50 cm). Substrate: Well-drained, calcareous, talus slopes; dunes; weathered clay soils; ephemeral pools; mudflats.

Canopy: Hibiscus, Myoporum, Santalum, Scaevola. Subcanopy: Gossypium, Sida, Vitex.
Understory: Eragrostis, Jacquemontia, Lyceum, Nama, Sesuvium, Sporobolus, Vigna.

Ecosystem: Lowland Dry. Elevation: <3,300 ft (<1,000 m). Annual precipitation: <50 in (<130 cm).
Substrate: Weathered silty loams to stony clay, rocky ledges, littleweathered lava. Canopy: Diospyros, Myoporum, Pleomele, Santalum. Subcanopy: Chamaesyce, Dodonaea, Leptecophylla, Osteomeles, Psydrax, Scaevola, Wikstroemia. Understory: Alyxia, Artemisia, Bidens, Chenopodium, Nephrolepis, Peperomia, Sicyos.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative

ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: Not available.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland, grassland/herbaceous, shrubland/chaparral
(NatureServe, 2015)

Environmental Specificity

Adult: Unknown (NatureServe, 2015)

Habitat Narrative

Adult: This species is found on dry grasslands, shrublands, and forests that are often at the coast or a short distance inland on rocky lands. On East Maui plants often occur on old lava flows.
(NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Long-term trends are unknown, whereas short-term trends indicate declines of 10-30%
(NatureServe, 2015)

Resiliency:

Low (inferred from NatureServe, 2015)

Redundancy:

Low (inferred from NatureServe, 2015)

Number of Populations:

7-10+ (NatureServe, 2015)

Population Size:

<200 plants (NatureServe, 2015)

Population Narrative:

Long-term population trends are unknown, whereas short-term trends indicate declines of 10-30%. The original range of this species was probably much larger (Russell 2002). Probably fewer than 200 plants. Estimated to have seven extant and 16 historical occurrences. USFWS estimates >10 populations. (NatureServe, 2015)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (pigs, goats, axis deer, and cattle), nonnative plants, fire, drought, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Fire can destroy dormant seeds and plants, even in steep and inaccessible areas. Successive fires can remove habitat for native species by altering microclimate conditions favorable to alien plants. Drought destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (pigs, goats, axis deer, and cattle) is considered an ongoing threat to *Canavalia pubescens* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

Recovery

Reclassification Criteria:

Not available.

Delisting Criteria:

Not available.

Recovery Actions:

- Not available.

Conservation Measures and Best Management Practices:

- Not available.

SPECIES ACCOUNT: *Cardamine micranthera* (Small-anthered bittercress)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/23/1989; Southeast Region (R4)

Physical Description

It is an erect slender perennial herb with fibrous roots and one (or rarely more) simple or branched stem(s) growing 2 to 4 decimeters tall. Basal leaves are 1 to 5 centimeters long (occasionally longer), 0.5 to 2.0 centimeters wide, crenate, with one (or rarely two) pairs of small lateral lobes or leaflets. The stem leaves are alternate and mostly unlobed, 1 to 1.5 centimeters long, crenate and cuneate. Flowering and fruiting occur in April and May. The flowers, subtended by leafy bracts, have four white petals, six stamens, and small, round anthers. The fruit is a silique, 0.8 to 1.2 centimeters long and approximately 1 millimeter in diameter, with a beak 1 to 1.2 millimeters long. The brown seeds are approximately 1 millimeter long. *Cardamine micranthera* can be distinguished from its most similar relative, *Cardamine rotundifolia*, by its much smaller, nearly orbicular (instead of oblong) anthers, smaller flowers, and more angulate and nonclasping leaves. In *Cardamine micranthera*, the anthers are about 0.5 millimeter long, and the petals are 1.2 to 2 millimeters wide. Stem leaves of *Cardamine micranthera* are typically broadly cuneate (rarely narrowly cuneate, oblique, or cordate) and never cordate-clasping. *Cardamine micranthera* is typically erect, or occasionally has decumbent stems, but these do not develop proliferating branches. *C. micranthera* has only one to two pairs of lateral leaflets (or none), with the terminal leaflet being nearly one-half the total length. *Cardamine micranthera* has pedicels 9 to 15 mm long and siliques 14 to 22 mm (pods only one and one-fourth to one and one-half times the length of the stalks). The beak of the fruit corresponds to the style in the flower and is that portion of the pod extending beyond the seed-bearing part. *Cardamine micranthera*'s beak is about 2 mm long and can be readily seen as a sharp, spindle-like tip on the pod (T. Wieboldt, personal communication, 1991). (USFWS, 1991)

Taxonomy

Cardamine micranthera was first described by R. C. Rollins (1940) from material collected in North Carolina in 1939. (USFWS, 1991)

Historical Range

Native to the Dan River drainage of the North Carolina and Virginia piedmont. Historically found in Stokes and Forsyth Counties (USFWS, 1991).

Current Range

Stokes County, North Carolina and Patrick County, Virginia. (USFWS, 2016)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (inferred from EPA, 2016)

Key Resources Needed for Breeding

Adult: Insect pollinators - possibly ants (EPA, 2016)

Reproduction Narrative

Adult: Produces flowers and fruits April to May. Insects are potential pollinators (EPA, 2016).
Ants have been observed visiting the flowers (USFWS, 1991).

Habitat Type

Adult: Palustrine, terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Riparian, forest (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Full to partial shade (NatureServe, 2015)

Environmental Specificity

Adult: Narrow (NatureServe, 2015)

Habitat Narrative

Adult: Seepages, wet rock crevices, streambanks, sandbars, and wet woods along small streams (Murdock and Weakley 1991). The environmental specificity of this specie is narrow; *C. micranthera* occupies moist soils of the upper Piedmont that are fully to partially shaded (Murdock and Weakley 1991). More specifically, it is typically found in wet, boggy soils of deciduous woodlands and moist to wet soils along the edge of small to intermediate sized streams (NCA 1996). Within the stream bed plants also inhabit sand and gravel bars and wet rock crevices (Murdock and Weakley 1991) (NatureServe, 2015). Occurs on soils of the Rion, Pacolet, and Wateree series, where slopes are 25 to 60 percent (EPA, 2016).

Dispersal/Migration**Dependency on Other Individuals or Species for Dispersal**

Adult: Unknown (EPA, 2016)

Dispersal/Migration Narrative

Adult: Seed dispersal occurs via water but other means are possible (EPA, 2016).

Population Information and Trends**Population Trends:**

Unknown (NatureServe, 2015)

Species Trends:

Declining (NatureServe, 2015)

Number of Populations:

32 (USFWS, 2016)

Population Size:

Annual fluctuation; < 23,000 (USFWS, 2016)

Population Narrative:

Little is known about the age of maturity and fecundity of this species; however the plant is a perennial and flowers and fruits annually. About 20 populations have excellent/good viability. Populations in North Carolina are believed to be in decline (NatureServe, 2015). Estimates of abundance for the 32 extant populations range from one plant to 8,000 - 10,000 plants. If the maximum estimates for each population are considered in aggregate, the global population contains fewer than 23,000 plants. However, population sizes are known to fluctuate widely from one year to the next (Boyer 1996) (USFWS, 2016).

Threats and Stressors

Stressor: Beaver dams (USFWS, 2002)

Exposure:

Response:

Consequence:

Narrative: Beaver dams have been observed to constitute a significant threat to *Cardamine micranthera* at some locations, with one knowledgeable observer regarding this as perhaps the most immediate threat to the species (Bridle 2009, pers. comm.). Bridle notes that beaver activity (especially in drought years) within main stream channels has flooded entire colonies of the species (USFWS, 2016).

Stressor: Habitat destruction and modification (USFWS, 2002)

Exposure:

Response:

Consequence:

Narrative: Habitat alteration remains the primary threat to *Cardamine micranthera*, with impoundment, channelization, conversion associated with agriculture or silviculture, flooding, and encroachment of exotic species as threats affecting the species. Cattle trampling and downstream beaver impoundments have also been noted as threatening *C. micranthera* habitat (USFWS, 2016).

Stressor: Inadequacy of regulatory mechanisms (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: State statutes primarily regulate collection and trade in listed species, and do not prohibit land owners from neglecting or otherwise impacting such species on their own properties or in conjunction with otherwise legal activities (USFWS, 2016).

Recovery

Reclassification Criteria:

Not defined (USFWS, 1991)

Delisting Criteria:

1. It has been documented that at least six populations are self-sustaining and that necessary management actions have been undertaken by the landowners or cooperating agencies to ensure their continued survival (USFWS, 1991).
2. All of the above populations and their habitat are protected from present and foreseeable human-related and natural threats that may interfere with the survival of any of the populations (USFWS, 1991).

Recovery Actions:

- Protect existing populations and essential habitat. Only nine populations of small-anthered bittercress are currently known to exist, all in the piedmont of North Carolina and Virginia. Until more is known about the species' biology and specific habitat requirements, and about the measures necessary to protect occupied sites, all existing populations should be protected. The long-term survival of six populations is believed to be essential to the recovery of the species as a whole. (USFWS, 1991)
- Determine and implement management necessary for long-term reproduction, establishment, maintenance, and vigor. Protection of the species' habitat is the obvious first step in ensuring its long-term survival, but this alone may not be sufficient. Since very little is known about this species, information on its population biology and ecology is necessary before effective management guidelines can be formulated and implemented.
- Develop a cultivated source of plants and provide for long-term seed storage. There are presently no cultivated sources of this species. Techniques for seed storage, germination, and maintenance of cultivated specimens must be developed. (USFWS, 1991)
- Enforce laws protecting the species and/or its habitat. The Endangered Species Act prohibits taking of *Cardamine micranthera* from Federal lands without a permit and regulates trade. Section 7 of the Act provides additional protection of the habitat from impacts related to federally funded or authorized projects. In addition, the 1988 amendments to the Act prohibit (1) the malicious damage or destruction of listed plants on Federal lands and (2) the removal, cutting, digging, damaging or destroying of such plants in knowing violation of any State law or regulation, including State criminal trespass law. The State of North Carolina prohibits taking of the species without a permit and the landowner's written permission and regulates trade in the species (North Carolina General Statute 19-B, 202.12-202.19). The State of Virginia prohibits taking and trade of listed species without a permit (Code of Virginia 39:3.1-1020 to 31-030). Federal and State enforcement agents whose jurisdiction includes the known range of small-anthered bittercress should be made aware of the threats to the species and be able to identify specimens. (USFWS, 1991)
- Develop materials to inform the public about the status of the species and the recovery plan objectives. Public support for the conservation of small-anthered bittercress could play an important part in encouraging landowner assistance and conservation efforts. Information materials should not identify the plant's locations so as not to increase the threat of taking or vandalism. Annually assess success of recovery efforts for the species. Review of new information, evaluation of ongoing actions, and redirection, if necessary, is essential for assuring that full recovery is achieved as quickly and efficiently as possible. (USFWS, 1991)

- Recommendation for Future Action from 2016 5-Year Review: Continue to pursue follow-up information from stream restoration project on Snow Creek (involving a portion of one population of this species) from appropriate state, federal and private parties. (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: Communicate existing habitat protection priorities (VDCR 2007, Boyer 1996) to state agencies, local land trusts, and other conservation partners, to assess current and future options for protection. Encourage land protection strategies focused on headwater occurrences likely to serve as a seed source for recolonization of sites further downstream (Bridle 2009, pers. comm.). (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: Identify sites which have experienced recent disturbance, and evaluate the effects of ongoing and prior habitat disturbance upon the species. (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: Utilize information obtained from assessments of prior or ongoing habitat disturbance to devise and implement appropriate habitat management guidelines. (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: 5. Conduct site visits to determine if Boyer's (1996) long-term monitoring transects can be relocated and resurrected. If so, reinitiate monitoring efforts to learn more about the longevity and relative stability of populations of this short-lived species. If Boyer's (1996) monitoring transects cannot be resurrected, work to establish comparable monitoring (using Boyer's protocol or modifications thereof) at priority sites using standardized monitoring methods. (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: 6. Use monitoring data and other information to draft objective, measurable criteria for "self-sustaining" populations. (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: 7. Determine the status of genetic material held in botanical gardens and other institutions, and work to ensure that the species is adequately represented in long-term storage. (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: 8. Pursue development of habitat predictability models for this species, and iteratively refine and use these to search for new populations and guide land protection efforts. (USFWS, 1991)
- Recommendation for Future Action from 2016 5-Year Review: 9. Identify landowners, obtain permission to visit populations, and provide information to landowners about voluntary protection measures that may be implemented to protect the species (including best management practices, NHP Registry programs, conservation easements, and fee simple purchase by cooperating land protection agencies). (USFWS, 1991)

SPECIES ACCOUNT: *Castilleja affinis* ssp. *neglecta* (Tiburon paintbrush)

Species Taxonomic and Listing Information

Listing Status: Endangered; 3/6/1995; Pacific Southwest (R8)

Physical Description

Castilleja affinis ssp. *neglecta* (Figure II- 5) is a semi-woody perennial of the snapdragon family (Scrophulariaceae), with erect, branched stems 30 to 60 centimeters (1 to 2 feet) tall and a sparse covering of soft, spreading hairs (Munz and Keck 1959). The lance-shaped leaves are 20 to 40 millimeters (0.8 to 1.6 inches) long and have 0 to 5 lobes (Hickman 1993). The conspicuous floral bracts are yellowish and sometimes red-tipped; the flowers are yellow to red and 18 to 20 millimeters (0.7 to 0.8 inch) long. (USFWS, 1998)

Taxonomy

Transferred to varietal rank by Egger (2008). Treated as *Castilleja affinis* ssp. *neglecta* by Kartesz (1999 Synthesis), by The Jepson Manual (Hickman, 1993) and by the U.S. Fish and Wildlife Service. Originally named as a species (*Castilleja neglecta*), and treated at that level by Kartesz (1994). Kartesz notes (pers. comm. to Larry Morse, 25Nov99) that his treatment of this as a subspecies is based on a 1992 personal communication with Chuang. (NatureServe, 2015)

Historical Range

Never widespread; in 1998, locations were on the Tiburon Peninsula in Main County, one population in Napa County, and one population in Santa Clara County (USFWS, 1998)

Current Range

Known from Marin, Napa, Santa Clara counties in California (USFWS, 2012)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (inferred from USFWS, 2012)

Dependency on Other Individuals or Species

Adult: The yellow flowers of *Castilleja affinis* ssp. *neglecta* are pollinated by hummingbirds (County of Santa Clara et al. 2010). (USFWS, 2012)

Breeding Season

Adult: April to June (USFWS, 1998)

Key Resources Needed for Breeding

Adult: Low temperatures and leaching (USFWS, 1998)

Reproduction Narrative

Adult: *Castilleja affinis* ssp. *neglecta* is a root parasite on other angiosperm (flowering plant) species. *Castilleja affinis* ssp. *neglecta* is a perennial, flowering from April to June (Munz and Keck 1959). The yellow flowers of *Castilleja affinis* ssp. *neglecta* are pollinated by hummingbirds (County of Santa Clara et al. 2010). Seed germination occurs in January or February and seems to be induced by leaching and low temperatures (5 to 15 degrees Celsius or 45 to 59 degrees Fahrenheit) (Martin 1989). The mean number of inflorescences per plant was 2.3, the mean number of capsules per inflorescence was 8.8, and the mean number of seeds per capsule was 82.3. Based on these figures, seed production for 1 year was calculated to be 1,666 seeds per plant (Martin 1989). The plant dies back to its woody base after seed dispersal and new growth occurs after the first winter rain. Heckard (1968) observed evidence that polyploidy leads to patterns of variation that can lead to hybridization while plants maintain differences in their appearance. (USFWS, 1998; USFWS, 2012)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Serpentine grasslands (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Leaching and low temperatures (USFWS, 1998)

Geographic or Habitat Restraints or Barriers

Adult: Grows at elevations between 75 and 400 meters (USFWS, 2012)

Spatial Arrangements of the Population

Adult: Scattered colonies (USFWS, 2012)

Site Fidelity

Adult: High (inferred from USFWS, 2012)

Dependency on Other Individuals or Species for Habitat

Adult: The primary advantage of the parasitic attachment in *Castilleja* and related plants in the figwort family is reportedly an increased water and mineral supply. Though the parasitic relationship is not obligate (hemiparasitic), benefits to species of *Castilleja* from the parasitic habit are manifested in increased vigor with more branching, greater height, and earlier flowering (Heckard 1962). Heckard (1962) showed that a host plant is beneficial to *Castilleja affinis* ssp. *neglecta* and increases the species' chance for survival. (USFWS, 1998)

Habitat Narrative

Adult: Three scattered colonies of the occurrences of *Castilleja affinis* ssp. *neglecta* in Marin County occur on the Tiburon peninsula. *Castilleja affinis* ssp. *neglecta* occurs in serpentine bunchgrass communities typically on north to west facing slopes. *Castilleja affinis* ssp. *neglecta* grows on open, rocky, serpentine slopes within the serpentine grassland communities, between about 75 and 400 meters in elevation in Napa, Marin, and Santa Clara Counties (Service 1998, Safford et al. 2005, LSA 2007, CDFG 2010). Seed germination occurs in January or February and seems to be induced by leaching and low temperatures (5 to 15 degrees Celsius or 45 to 59

degrees Fahrenheit) (Martin 1989). *Castilleja affinis* ssp. *neglecta* parasitic attachment increases water and mineral supply. Though the parasitic relationship is not obligate (hemiparasitic), benefits to species of *Castilleja* from the parasitic habit are manifested in increased vigor with more branching, greater height, and earlier flowering (Heckard 1962). Heckard (1962) showed that a host plant is beneficial to *Castilleja affinis* ssp. *neglecta* and increases the species' chance for survival. (USFWS, 1998; USFWS, 2012)

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Seed dispersal occurs from June to October. (USFWS, 2012)

Additional Life History Information

Adult: Seed dispersal occurs from June to October. (USFWS, 2012)

Population Information and Trends

Number of Populations:

8 (USFWS, 2012)

Population Size:

Approximately 2,000 plants (USFWS, 2012)

Population Narrative:

The distribution of *C. affinis* ssp. *neglecta* has never been widespread. Seven occurrences are described: five in Marin County (three of which occur on the Tiburon Peninsula), one near American Canyon in Napa County, and one in Santa Clara County (Service 1998, CDFG 2010). The CNDDDB reports one additional occurrence in Santa Clara County (CDFG 2010) and one occurrence from Stinson Beach in Marin County that was last observed at 1965 with the exact location and number of plants listed as unknown (CDFG 2010). The range of *C. affinis* ssp. *neglecta* is approximately 50 kilometers (30 miles) from east to west, and 112 kilometers (70 miles) from north to south (Service 1995). (USFWS, 2012)

Threats and Stressors

Stressor: Residential Development (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: When *Castilleja affinis* ssp. *neglecta* was listed as endangered in 1995, residential development was identified as a primary threat to Marin County populations. It remains a significant threat today. At the time of listing, the St. Hilary's church occurrence on the Tiburon peninsula was threatened by a proposed residential development. A portion of the land supporting this population was purchased by the Marin County Open Space District and Town of Tiburon in 1997 as an open space preserve (the Old St. Hilary's Open Space Preserve), however, a portion of the population remains on private land where residential development has been proposed on multiple occasions. Residential development on the Middle Ridge adjacent to

Tiburon paintbrush habitat is anticipated to occur in the near future (S. Anderson personal communication 2009). (USFWS, 2012)

Stressor: Mining/Landfill (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Both Santa Clara County occurrences of *Castilleja affinis* ssp. *neglecta* occur on private land associated with the Kirby Canyon Landfill. However, both are located in areas currently managed as mitigation sites for landfill impacts. Both occurrences are monitored and managed by the Kirby Canyon Butterfly Trust, but neither site is permanently protected (County of Santa Clara et al. 2010). At the time of listing, the Napa County occurrence was threatened by the potential expansion of the American Canyon Quarry. In 1999 private landowners donated land supporting 5 to 10 percent of the *Castilleja affinis* ssp. *neglecta* occurrence to the City of American Canyon in order to create the Newell Preserve; the Land Trust of Napa County holds a conservation easement on the preserve land (Napa County Land Trust website). Currently, there are no active plans for quarry expansion on the land that supports the majority of this occurrence and quarry reclamation which was initiated in 2007 is not anticipated to affect this occurrence (D. Barrella personal communication 2011). However, the quarry property is in an area zoned for agriculture and low density residential and could potentially be developed in the future. (USFWS, 2012)

Stressor: Recreation (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: At the time *Castilleja affinis* ssp. *neglecta* was listed, we cited pedestrian traffic associated with recreation activities as a Factor A threat for the Middle Ridge and Ring Mountain populations of *C. affinis* ssp. *neglecta* on the Tiburon peninsula. Currently, wayward trails continue to crisscross Ring Mountain Preserve resulting in a small reduction in available habitat. *C. affinis* ssp. *neglecta* is most likely to be negatively affected by hikers, cyclists, and equestrians if they stray from designated and social trails and trample plants or if new trails are established. *C. affinis* ssp. *neglecta* plants on the Middle Ridge of the Town of Tiburon faces threats from hikers and their dogs that trample plants and habitat despite posted signs warning sensitive plant habitat (E. Buxton personal communication 2009). (USFWS, 2012) Currently, visitors are only allowed to visit Newell Preserve in Napa County during docent-led tours. Therefore, trampling and habitat destruction from recreational hikers, dogs, cyclists, and equestrians is currently not a threat to this *Castilleja affinis* ssp. *neglecta* occurrence. However, a master plan is being developed for the preserve that will likely include allowing public access without docent supervision. (USFWS, 2012)

Stressor: Landslide/Erosion (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: At the time of listing, soil slumping was identified as a threat to the *Castilleja affinis* ssp. *neglecta* occurrence at Ring Mountain Preserve (Service 1995). The toe of the slope that supports the population was removed to accommodate residential development in Corte Madera

in the 1960s and soil from the slope slips onto the street below. Some Town of Tiburon Open space parcels are mapped as being prone to landslides and erosion occurs along some trails and watercourses on open space parcels, but neither appears to be a major threat to *C. affinis* ssp. *neglecta* at this time (LSA 2010). (USFWS, 2012)

Stressor: Grazing (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Cattle grazing was cited as a factor C threat to *Castilleja affinis* ssp. *neglecta* at the time of listing. Improper grazing may remain a potential threat to the species, however, grazing can also be used as a management tool to reduce biomass of non-native vegetation and may actually be beneficial to the species if managed appropriately (County of Santa Clara et al. 2010). (USFWS, 2012)

Stressor: Herbivory (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Mammal herbivory by mule deer (*Odocoileus hemionus*) and black-tailed jackrabbits (*Lepus californicus*) may pose a threat to *Castilleja affinis* ssp. *neglecta* on the Ring Mountain Preserve. Results from 2007 monitoring showed that approximately 25 percent of the inflorescence branches in the 53 plants evaluated were removed by herbivory (LSA 2007). However, side branches developed when tips of branches were removed, so this type of herbivory may not pose a substantial threat. Disturbance from feral pig (*Sus scrofa*) rooting poses a threat to the Paintbrush Hill occurrence in Santa Clara County (County of Santa Clara et al. 2010). Cameras placed at the Santa Clara occurrences have documented rabbits and deer in the area and sharp incisions on the plants suggest that rabbits may be eating some *C. affinis* ssp. *neglecta* flowers and fruit at this location (C. Niederer personal communication 2011). It is not known whether any diseases threaten the species. (USFWS, 2012)

Stressor: Non-native Invasive Plant Species (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Competition from non-native invasive plant species continues to pose a serious threat to *Castilleja affinis* ssp. *neglecta* on the Tiburon peninsula. At the Ring Mountain Preserve, the Marin County Open Space District has been working to eradicate or control non-native invasive species for several years. The Ring Mountain Preserve Sensitive Resource Monitoring Plan (LSA Associates, Inc. 2007) provides a list of non-native invasive species that currently occur on Ring Mountain and describes treatment recommendations. Similarly, the Town of Tiburon has an Open Space Resource Management Plan (LSA 2010) that addresses invasive species that affect the Middle Ridge occurrence of *C. affinis* ssp. *neglecta*. Bull thistle (*Cirsium vulgare*), French broom (*Genista monspessulana*), and wild oats (*Avena* spp.), are problematic on parcels supporting *C. affinis* ssp. *neglecta*. Weed abatement is an ongoing activity that will likely need to occur in perpetuity at these locations. (USFWS, 2012) Non-native invasive plant species occur to some extent in association with occurrences of *Castilleja affinis* ssp. *neglecta* outside the Tiburon peninsula as well. Point Reyes National Seashore is working to control an invasion of distaff

thistle (*Carthamus lanatus*) in the vicinity of the Nicasio Ridge occurrence of *C. affinis* ssp. *neglecta* within the GGNRA and hand removal of tocolote (*Centaurea melitensis*) is conducted on Nicasio Ridge once or twice a year as funding allows. At this time, however, these non-native species do not appear to pose a serious threat to the Nicasio Ridge *C. affinis* ssp. *neglecta* occurrence (M. Chasse personal communication 2011). Treatments for barbed goatgrass (*Aegilops triuncialis*) have taken place on the Kirby Canyon Butterfly Preserve that supports Paintbrush Hill occurrence of *C. affinis* ssp. *neglecta* in Santa Clara County (Niederer 2008) and a number of non-native species occur in low densities within the North Canyon occurrence in Santa Clara County (C. Niederer personal communication 2009). At these two locations, efforts to control non-native plant species are necessary to keep them in control, but at this 14 time cattle grazing and current efforts appear to have prevented severe encroachment of non-native species (C. Niederer personal communication 2009). (USFWS, 2012)

Stressor: Nitrogen Deposition (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Air pollution and the resultant deposition of reactive airborne nitrogen has become a significant threat to many native California plants, in particular to those that occur in nutrient poor soils such those in serpentine areas (Weiss 1999). Increased nitrogen deposition allows nutrient-poor serpentine soils to be invaded by non-native annual grasses that displace the native forbs (Weiss 1999). Nitrogen deposition is especially high near urban areas where combustion sources produce substantial concentrations of nitrogen oxides (Weiss 1999). All occurrences of *Castilleja affinis* ssp. *neglecta* occur within or adjacent to urban areas with elevated levels of nitrogen deposition with particularly high nitrogen deposition levels occurring in Santa Clara County near San Jose (Weiss 2006). (USFWS, 2012)

Stressor: Stochasticity (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: The limited number and small sizes of *Castilleja affinis* ssp. *neglecta* occurrences increase this species vulnerability to chance events such as fire, flood, drought, disease, and other natural and human-caused disasters (Brook et al. 2002). The occurrences of *C. affinis* ssp. *neglecta* on the Tiburon peninsula in particular are located in close proximity to dense, residential development placing them at risk of catastrophic events associated with human activity such as fire or vandalism. In addition, small populations are subject to inbreeding (mating between closely related individuals) resulting in a subsequent loss of genetic diversity (Spielman et al. 2004). Small populations are also more likely to experience extinction as a result of “stochastic” demographic fluctuations or other density-dependent effects (Avis 2004). (USFWS, 2012)

Stressor: Climate Change/Drought (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer

continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). However, climatic conditions for smaller sub-regions such as California remain uncertain (Pyke 2005). It is unknown at this time if climate change in California will result in a localized, relatively small cooling and drying trend, or a warmer trend with higher precipitation events (Pyke 2005). A modeling study completed by Loarie et al. (2008) provides an evaluation of potential trends to California's floristic communities under climate change scenarios. The models suggest that shifts in species ranges may break up local floras, resulting in new species combinations, with new patterns of competition and biotic interactions (Loarie et al. 2008). While it appears reasonable to assume that *Castilleja affinis* ssp. *neglecta* will be affected by climate change, we lack sufficient certainty regarding how and how soon climate change will affect the species. Because *C. affinis* ssp. *neglecta* is restricted to limited and patchily distributed serpentine soils, however, the species will likely have difficulty shifting its range to adjust to changing conditions. (USFWS, 2012)

Recovery

Reclassification Criteria:

1. Six (6) populations of *Castilleja affinis* ssp. *neglecta* are fully protected and managed with the primary intention of preserving the populations in perpetuity (USFWS, 1998)
2. Six (6) populations of *Castilleja affinis* ssp. *neglecta* are shown to be stable or increasing with evidence of recruitment over a minimum of 20 years that include the normal precipitation cycle (or longer if suggested by the results of demographic monitoring) (USFWS, 1998)
3. Seed collected from natural populations throughout the range of the species is stored at a minimum of two Center for Plant Conservation certified botanic gardens (USFWS, 1998)
4. Reliable seed germination and propagation techniques for the species are understood (USFWS, 1998)

Delisting Criteria:

1. Ten (10) populations throughout its range are shown to be fully protected and managed with the primary intention of preserving the populations in perpetuity. At least 2 of the 10 should occur in Santa Clara County. (USFWS, 1998)
2. Ten (10) populations of *Castilleja affinis* ssp. *neglecta* are shown to be stable or increasing with evidence of recruitment over a minimum of 20 years that include the normal precipitation cycle (or longer if suggested by the results of demographic monitoring) (USFWS, 1998)
3. Seed collected from natural populations throughout the range of the species is stored at a minimum of two Center for Plant Conservation certified botanic gardens (USFWS, 1998)
4. Reliable seed germination and propagation techniques for the species are understood (USFWS, 1998)

Recovery Actions:

- Protecting and managing the known populations. Protection and management of populations on public lands will involve working with Main Open Space District, the town of Tiburon, and the Golden Gate National Recreation Area to ensure the long-term survival of

the species on their lands. The populations, or portions of populations, occurring on private lands should be protected by land acquisition, conservation easements, or other mechanisms. Among populations on private land, protection of the only known population in Santa Clara County is a particularly high priority because it is geographically disjunct from other populations. In general, the largest possible block of serpentine habitat should be protected at each site. Protection should, at least, involve securing the populations themselves as well as a 150-meter (500-foot) buffer around each population, where possible, to reduce external influences and allow expansion of populations. In addition, other unoccupied habitat at the sites that might provide space for expansion of the populations and habitat for pollinators and seed dispersers must be protected.

Management plans emphasizing *Castilleja affinis* ssp. *neglecta* and other special status species in each location must be developed and implemented. The plans should include provisions for standardized monitoring of *Castilleja affinis* ssp. *neglecta* populations every other year to determine demographic trends. The plans should also include strategies to minimize known threats (e.g. foot traffic) at the sites as well as to identify new threats should they appear. Removal of nonnatives should be a high priority for management of sites on the Tiburon Peninsula such as those on Middle Ridge and in Main County Open Space near Old St. Hilary's Church. In addition, soil slumping at the Ring Mountain Preserve needs to be minimized. If new threats are identified or other new information becomes available, management plans need to be reevaluated and revised. For populations on public lands, any management plan developed should include an educational outreach program. (USFWS, 1998)

- Collection and banking of seed in Center for Plant Conservation certified botanic gardens. Seed banking guards against extinction of populations from chance catastrophic events and provides potential material for enhancement efforts in existing populations, repatriations, and/or introductions to new sites. In the absence of genetic data for *Castilleja affinis* ssp. *neglecta*, seed collection efforts should represent populations throughout the range of the species, including the Santa Clara County population that is at least 100 kilometers (62 miles) south of the other known populations (Elam in prep). Care should be taken to ensure that seed collection does not adversely affect the donor populations. (USFWS, 1998)
- Other potential serpentine habitat throughout the range of the species should be surveyed to determine if other populations exist. Santa Clara County, in particular, contains habitat that should be surveyed (e.g. to the south of the known occurrence and in Henry Coe State Park east of Anderson Reservoir) (California Department of Fish and Game 1997a). If new populations are discovered, they should be protected and managed as discussed above. During these surveys, potential introduction sites might also be identified. (USFWS, 1998)
- The effect of various vegetation management techniques (e.g. grazing, mowing, and burning) on *Castilleja affinis* ssp. *neglecta* needs to be evaluated, because (1) *Castilleja affinis* ssp. *neglecta* occurs approximately 100 to 250 meters (328 to 820 feet) from relatively good quality bay checkerspot butterfly habitat (N. McCarten, in litt., 1998) in Santa Clara County, and (2) bay checkerspot butterfly habitat benefits from vegetation management. Although cattle and deer grazing of *Castilleja affinis* ssp. *neglecta* has not been observed (N. McCarten, in litt., 1998), evaluation of these techniques will ensure that managers select management strategies that maintain bay checkerspot butterfly habitat while not adversely affecting *Castilleja affinis* ssp. *neglecta*. Research on the effects of grazing are also important in recovery efforts for *Castilleja affinis* ssp. *neglecta* because grazing is a concern at the Golden Gate National Recreation Area in Main County. In addition, because other *Castilleja* species appear to benefit from fire (R. Raiche. cited in

California Department of Fish and Game 1997b, small scale experimental burning (e.g. using burn boxes) may reveal another possible management strategy. Any experimental burning should initially be limited to a very small area (e.g. 1 square meter [10.8 square feet]). (USFWS, 1998)

- Other research needs include germination and propagation techniques, taxonomic, demographic, and genetic studies as well as mating system and pollination studies. Demographic studies should include field studies of *Castilleja affinis* ssp. *neglecta*'s hemiparasitic nature, the frequency of seed germination and seedling recruitment in nature, and identification of limiting life history stages. Martin (1989) observed no seedlings in the field during a 2-year study. Genetic studies should focus on whether, and to what extent, populations throughout the range of the species are genetically different from one another. These genetic data would be valuable guides as to which populations should be chosen as sources for enhancement of existing populations or introduction of new populations. (USFWS, 1998)

Conservation Measures and Best Management Practices:

- Control and eradicate non-native, invasive plant species: continue to control non-native plant species at Ring Mountain Preserve and Town of Tiburon Open Space parcels according to existing management plans. Amend the Town of Tiburon Open Space Management Plan to include the Old Saint Hilary's Church Open Space parcel. Develop and implement management plans for controlling non-native invasive plant species in the area supporting the two *Castilleja affinis* ssp. *neglecta* occurrences on GGNRA land in Marin County, on the Newell Preserve in Napa County, and for the mitigation lands supporting the two *C. affinis* ssp. *neglecta* occurrences in Santa Clara County. (USFWS, 2012)
- Locations that should be targeted for protection in cooperation with willing landowners: in Santa Clara County, establish a conservation easement on the 250 acre Bay checkerspot butterfly reserve that supports the Paintbrush Hill *C. affinis* ssp. *neglecta* occurrence and on the entire mitigation parcel that supports the North Canyon occurrence. In Napa County, pursue opportunities to acquire or incorporate land supporting *C. affinis* ssp. *neglecta* in the former quarry area into Newell Open Space Preserve. In Marin County, establish a conservation easement on all remaining undeveloped serpentine habitat in the Old St. Hilary's Church area as mitigation for any development that takes place on private parcels in this location. (USFWS, 2012)
- Monitoring: Continue to monitor *Castilleja affinis* ssp. *neglecta* on the Ring Mountain Preserve using the 24 established 1m² monitoring plots for three years using the same parameters as those used in 2007 thereafter, every two years as recommended by the 1998 Recovery Plan (Service 1998). Add a monitoring protocol for *Castilleja affinis* ssp. *neglecta* to the Town of Tiburon Open Space Management Plan. In Marin County on GGNRA land, continue monitoring *Castilleja affinis* ssp. *neglecta* at Nicasio Ridge and initiate monitoring at CNDDDB occurrence 6. Include monitoring of grazing effects at these locations. (USFWS, 2012)
- Seeds from *Castilleja affinis* ssp. *neglecta* should be collected from populations throughout the range and banked in Center for Plant Conservation certified gardens. (USFWS, 2012)
- Other serpentine habitats with the potential to support *Castilleja affinis* ssp. *neglecta* should be surveyed to determine whether undiscovered populations exist. New populations should be noted with the appropriate County, California Department of Fish and Game, the Service and the California Native Plant Society. (USFWS, 2012)

SPECIES ACCOUNT: *Castilleja campestris* ssp. *succulenta* (Fleshy owl's-clover)

Species Taxonomic and Listing Information

Listing Status: Threatened; 03/26/1997; Pacific Southwest (R8) (USFWS, 2015)

Physical Description

A hemiparasitic annual herb, mostly 5-25 cm tall, with fleshy, somewhat brittle leaves. Produces dense inflorescences of yellow to white flowers subtended by green bracts. (NatureServe, 2015)

Taxonomy

Both Kartesz and the Fed. Reg. agree on the nomenclature of this element and now recognize it as part of the genus *Castilleja* (as opposed to *Orthocarpus*). (NatureServe, 2015)

Historical Range

The historical distribution between 1937 and 1986 was reported from 33 occurrences (Hoover 1937, 1968, CNDDB 2005), all in the Southern Sierra Foothills Vernal Pool Region (Keeler-Wolf et al. 1998). Sixteen of those occurrences, including the type locality, were in eastern Merced County. Six occurrences each were in Fresno and Madera Counties and five others were in Stanislaus County (CNDDB 2003). (USFWS, 2011)

Current Range

Found primarily in vernal pools along the lower rolling foothill grasslands in the eastern San Joaquin Valley of the Southern Sierra Foothills Vernal Pool Region. (USFWS, 2011)

Critical Habitat Designated

Yes; 2/10/2006.

Legal Description

On August 6, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Castilleja campestris* ssp. *succulenta* (Fleshy owl's-clover) (and other vernal pool species) under the Endangered Species Act of 1973, as amended (Act) (68 FR 46684 - 46867). On August 11, 2005, the Service issued a Final Rule that excluded some lands addressed in the 2003 rule from the final designation for economic reasons (70 FR 46924 - 46999). On February 10, 2006, the Service issued administrative revisions to the Final Rule (71 FR 7118-7316). The critical habitat designation for *Castilleja campestris* ssp. *succulenta* includes six critical habitat units (CHUs) in California.

Critical Habitat Designation

The critical habitat designation for *Castilleja campestris* ssp. *succulenta* includes six CHUs (some with multiple parts) in Fresno, Madera, Mariposa, Merced, San Joaquin, Stanislaus, and Tuolumne Counties, California. This species critical habitat encompasses approximately 175,873 acres (68 FR 46684 - 46867; 70 FR 46924-46999; 71 FR 7118-7316).

Unit 1: Sacramento and San Joaquin Counties, California. From USGS 1:24,000 scale quadrangles Clay and Lockeford.

Unit 2: Tuolumne and Stanislaus Counties, California. From USGS 1:24,000 scale quadrangles Keystone, La Grange, Cooperstown and Paulsell.

Unit 3: Mariposa and Merced Counties, California. (i) Unit 3A: Mariposa and Merced Counties, California. From USGS 1:24,000 scale quadrangles Merced Falls and Snelling.

Unit 3B: Mariposa and Merced Counties, California. From USGS 1:24,000 scale quadrangles Merced Falls, Snelling, Indian Gulch, Haystack Mountain, Yosemite Lake, Winton, Owen's Reservoir, Planada and Merced.

Unit 4: Madera and Merced Counties, California. (i) Unit 4A: Madera and Merced Counties, California. From USGS 1:24,000 scale quadrangle Raynor Creek.

Unit 4C: Madera and Fresno Counties, California. From USGS 1:24,000 scale quadrangles Millerton Lake West, Little Table Mountain, Daulton, Friant, Lanes Bridge and Gregg.

Unit 5: Fresno County, California. (i) Unit 5A: Fresno County, California. From USGS 1:24,000 scale quadrangles Friant and Round Mountain.

Unit 5B: Fresno County, California. From USGS 1:24,000 scale quadrangle Clovis.

Unit 6: Fresno County, California. (i) Unit 6A: Fresno County, California. From USGS 1:24,000 scale quadrangles Millerton Lake East and Academy.

Unit 6B: Madera County, California. From USGS 1:24,000 scale quadrangles North Fork and Millerton Lake East.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The primary constituent elements of critical habitat for *Castilleja campestris* ssp. *succulenta* (Fleshy owl's-clover) are the habitat components that provide:

(i) Topographic features characterized by isolated mound and intermound complex within a matrix of surrounding uplands that result in continuously, or intermittently, flowing surface water in the depressional features including swales connecting the pools described in paragraph (c)(8)(ii) of this section, providing for dispersal and promoting hydroperiods of adequate length in the pools; and

(ii) Depressional features including isolated vernal pools with underlying restrictive soil layers that become inundated during winter rains and that continuously hold water or whose soils are saturated for a period long enough to promote germination, flowering, and seed production of predominantly annual native wetland species and typically exclude both native and nonnative upland plant species in all but the driest years. As these features are inundated on a seasonal basis, they do not promote the development of obligate wetland vegetation habitats typical of permanently flooded emergent wetlands.

Special Management Considerations or Protections

Existing manmade features and structures, such as buildings, roads, railroads, airports, runways, other paved areas, lawns, and other urban landscaped areas do not contain one or more of the primary constituent elements. Federal actions limited to those areas, therefore, would not trigger a consultation under section 7 of the Act unless they may affect the species and/or primary constituent elements in adjacent critical habitat.

Life History**Food/Nutrient Resources****Lifespan**

Adult: 1 year (annuals) (USFWS, 2011)

Breeding Season

Adult: April and May (USFWS, 2011)

Reproduction Narrative

Adult: *Castilleja campestris* ssp. *succulenta* is an annual plant. Seeds of the *C. campestris* ssp. *succulenta* do not require the presence of a host to germinate, as they form root connections only after reaching a seedling stage.

Habitat Type

Adult: Vernal pools (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Small, seasonal pools. (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Occur at elevations of 24 m (80 feet) to 700 m (2,300 feet). (USFWS, 2011)

Spatial Arrangements of the Population

Adult: Widely scattered (USFWS, 2011)

Habitat Narrative

Adult: *Castilleja campestris* ssp. *succulenta* is found primarily in vernal pools, and only in the lower rolling foothill areas of the eastern San Joaquin Valley in the Southern Sierra Foothills Vernal Pool Region (Service Recovery Plan 2005). Soil textures at those sites range from extremely stony loam to loamy clay. At the U.C. Merced site and the surrounding community planning area, 81.4% of the individual pools where this taxon was found were on Redding gravelly loam, 9.5% were on Corning gravelly sandy loam, 6.4% were on Corning gravelly loam, 1.7% were on Keyes gravelly loam, 0.7% was on Keyes gravelly clay loam, and 0.3% was on Pentz loam (EIP Associates 1999). Self-pollinating species of *Castilleja* typically occur as widely scattered individuals, rather than dense colonies (Atsatt 1970). Populations of *Castilleja campestris* ssp. *succulenta* have been reported from elevations of 24.0 m (80 feet) at the San Joaquin County site to 700.0 m (2,300 feet) at Kennedy Table in Madera County (CNDDB 2003). (USFWS, 2011; NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Resiliency:**

Low (inferred from USFWS, 2011)

Representation:

Low (inferred from USFWS, 2011)

Redundancy:

Moderate (inferred from USFWS, 2011)

Number of Populations:

90 occurrences (USFWS, 2011)

Adaptability:

Low (inferred from USFWS, 2011)

Population Narrative:

At the time of the listing in 1997, there were 36 extant occurrences of *Castilleja campestris* ssp. *succulenta* and currently there are 90 presumed extant occurrences. The increase in occurrences is most likely a result of an increased number of surveys. Since the final listing rule, an additional threat to *Castilleja campestris* ssp. *succulenta* is that many of its populations are small in number. A small population size makes a population more vulnerable to extirpation from chance events. (USFWS, 2011)

Threats and Stressors

Stressor: Habitat degradation

Exposure:

Response:

Consequence:

Narrative: The 1997 final rule stated that nearly half of the extant *Castilleja campestris* ssp. *succulenta* occurrences are threatened by man-made activities such as urbanization, agricultural land conversion, discing, trampling due to overgrazing, mining, and a proposed road expansion project. The threats presented in the listing rule are still relevant. The habitat of this species has been reduced and fragmented throughout its range and vernal pools continue to be removed by the factors previously noted. Lands on the Central Valley floor are closer to existing cities and agricultural lands than the valley rim, which is steeper, less fertile and more removed from cities. As a result, valley floor vernal pools, along with open rangeland, have been and continue to be favored for urban and agricultural development. (USFWS, 2011)

Stressor: Stressor

Exposure:

Response:**Consequence:**

Narrative: According to a University of California, Berkeley study, the native plants unique to California are vulnerable to global climate change and that two-thirds of these endemics could suffer more than an 80% reduction in geographic range by the end of the century (U.C. Berkeley Press Release, June 2008). Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). It is unknown at this time if climate change in California specifically will result in a warmer trend with localized drying, higher precipitation events, or other effects. (USFWS, 2011)

Stressor: Small population size

Exposure:**Response:****Consequence:**

Narrative: Since the final listing rule, an additional threat to *Castilleja campestris* ssp. *succulenta* is that many of its populations are small in number. A small population size makes a population more vulnerable to extirpation from chance events as noted in the 2005 Recovery Plan. Among the 24 occurrences of *C. campestris* ssp. *succulenta* for which size estimates had been documented, ten consisted of fewer than 100 plants each at their peak size (J. Stebbins in litt. 2000b, CNDDDB 2003). According to the 2009 CNDDDB occurrences, 35 have population size estimates documented with approximately 16 occurrences with fewer than 100 plants and approximately 17 occurrences with more than 100 plants.

Stressor: Rainfall

Exposure:**Response:****Consequence:**

Narrative: This taxon is very cyclical and is somewhat scarce in normal or below normal rainfall years but large populations may be evident in wet years at the known sites (J. Stebbins, pers. comm. 2009). (USFWS, 2011)

Recovery**Reclassification Criteria:**

1. Habitat protection - Accomplish habitat protection that promotes vernal pool ecosystem function sufficient to contribute to population viability of the covered species. Suitable vernal pool habitat within each prioritized core area for the species is protected. Species occurrences distributed across the species geographic range and genetic range are protected. Protection of extreme edges of populations protects the genetic differences that occur there. Reintroductions must be carried out and meet success criteria established in the Recovery Plan. Additional occurrences identified through future site assessments, GIS and other analyses, and status surveys that are determined essential to the recovery are protected. Any newly found occurrences may count towards recovery goals if the occurrences are permanently protected as described in the Recovery Plan. Habitat protection results in protection of hydrology essential to vernal pool ecosystem function, and monitoring indicates that hydrology that contributes to population viability has been maintained through at least one multi-year period that includes

above average, average, and below average local rainfall as defined above, a multi-year drought, and a minimum of 5 years of post-drought monitoring. (USFWS, 2011)

2. Adaptive habitat management and monitoring: Habitat management and monitoring plans that ensure maintenance of vernal pool ecosystem function and population viability have been developed and implemented for all habitat protected. Mechanisms are in place to provide for long-term management and monitoring. Monitoring indicates ecosystem function has been maintained in the areas protected. Seed banking actions have been completed for species that would require it as insurance against risk of stochastic extirpations or that will require reintroductions or introductions to contribute to meeting recover criteria. (USFWS, 2011)

3. Status surveys, 5-year status reviews, and population monitoring show populations within each vernal pool region where the species occur are viable (e.g., evidence of reproduction and recruitment) and have been maintained (stable or increasing) for at least one multi-year period that includes above average, average, and below average local rainfall, a multi-year drought, and a minimum of 5 years of post-drought monitoring. Status surveys, status reviews, and habitat monitoring show that threats identified during and since the listing process have been ameliorated or eliminated. Site-specific threats identified through standardized site assessments and habitat management planning also must be ameliorated or eliminated. (USFWS, 2011)

4. Research actions necessary for recovery and conservation of the covered species have been identified (these are research actions that have not been specifically identified in the recovery actions but for which a process to develop them has been identified). Research actions (both specifically identified in the recovery actions and determined through the process) on species biology and ecology, habitat management and restoration, and methods to eliminate or ameliorate threats have been completed and incorporated into habitat protection, habitat management and monitoring, and species monitoring plans, and refinement of recovery criteria and actions. Research on genetic structure has been completed (for species where necessary – for reintroduction and introduction, seed banking) and results incorporated into habitat protection plans to ensure that within and among population genetic variation is fully represented by populations protected in the Habitat Protection section. Research necessary to determine appropriate parameters to measure population viability for each species has been completed. (USFWS, 2011)

5. Participation and outreach: recovery implementation team is established and functioning to oversee range-wide recovery efforts. Vernal pool regional working groups are established and functioning to oversee regional recovery efforts. Participation plans for each vernal pool region have been completed and implemented. Vernal pool regional working groups have developed and implemented outreach and incentive programs that develop partnerships. (USFWS, 2011)

Delisting Criteria:

Same as the reclassification criteria.

Recovery Actions:

- Conduct standardized vernal pool habitat site assessments for both the Southeastern Sacramento Valley and Southern Sierra Foothills vernal pool regions. (USFWS, 2011)
- Establish management and monitoring plans which include criteria for frequent surveys in order to capture the blooming period for this species. The *Castilleja campestris* ssp.

- succulenta population numbers vary widely from year to year depending on habitat conditions and rainfall (Vollmar 2002). Therefore, the Service should encourage bank owners and preserve managers to perform surveys on a frequent schedule in order to gather additional data which will increase knowledge. The additional information will be utilized for future 5-year reviews. (USFWS, 2011)
- The Vernal Pool Regional working group should formulate a plan to reach out and educate private landowners as to the value of federally-listed species on their lands, with a particular focus on plants. The Vernal Pool Regional group also should provide guidance to assist landowners on how to better manage their lands for the overall benefit of this species. (USFWS, 2011)
 - The Service should encourage collection of seeds and storage in approved seed banks from extant occurrences, in each core area, to aid in the establishment of a seed bank. (USFWS, 2011)
 - The Service should encourage County and local governments to consider developing Habitat Conservation Plans (HCPs) to include vernal pool species. Take of a federally listed invertebrate species would be permitted on private land, and any habitat acquisition to compensate for invertebrate species could include the *Castilleja campestris* ssp. *succulenta* if appropriate. Fresno County has been awarded Federal funds for the development of an HCP and additional funds may be available in the future for counties who apply for them. (USFWS, 2011)
 - Efforts to protect vernal pool species should include conservation efforts on a landscape scale (Vollmar 2002). Landscape Conservation Cooperatives provide Federal scientific and technical support for conservation on a landscape scale which is the entire range of an identified priority species. These cooperatives also have a role in helping partners identify common goals and priorities to target the right science for efficient and effective conservation. (USFWS, 2011)

Conservation Measures and Best Management Practices:

SPECIES ACCOUNT: *Castilleja cinerea* (Ash-grey paintbrush)

Species Taxonomic and Listing Information

Listing Status: Threatened; 10/14/1998; California/Nevada Region (R8)

Physical Description

A semi-parasitic perennial plant with several ascending to decumbent (reclining on the ground) grayish stems sprouting from the root-stem. These stems are 4-8 inches (in.) (10.2-20.3 centimeters (cm)) tall. The flower stalk is usually yellow-green (sometimes reddish-orange) with yellow hairs on the lower bracts. The calyx is almost equally divided into linear lobes; the corolla is yellowish (63 FR 49006). Ash-gray paintbrush is distinguished from other *Castilleja* in its range by short-haired stems and leaves, yellowish flowers, calyx lobes of equal length, and its perennial nature (63 FR 49006). (USFWS, 2008)

Taxonomy

At listing, ash-grey (Indian) paintbrush was considered to be in the Scrophulariaceae (figwort) family. Recent taxonomic studies have placed the genus *Castilleja* and other plant genera formerly in the Scrophulariaceae into the Orobanchaceae (broomrape) family (Olmstead et al. 2001). (USFWS, 2008)

Historical Range

See current range/distribution.

Current Range

Endemic to the San Bernardino Mountains, in San Bernardino County, California. (USFWS, 2013)

Critical Habitat Designated

Yes; 1/25/2008.

Legal Description

On December 26, 2007, the U.S. Fish and Wildlife Service (Service) designated critical habitat (effective January 25, 2008) for *Castilleja cinerea* (Ash-grey paintbrush) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes 24 critical habitat units (CHUs), in California (72 FR 73092-73178).

Critical Habitat Designation

The critical habitat designation for *Castilleja cinerea* includes 24 CHUs in San Bernardino County, California. approximately 1,769 ac (722 ha) of Federal, State, and private land are being designated as critical habitat (72 FR 73092-73178). Units are grouped by pebble plain complexes (e.g., Arrastre/Union Flat) as identified in the USFS's 2002 Management Guide. Detailed coordinates and maps are provided in the Final Rule. The 24 units contain a total of 1,769 ac (722 ha).

Units CACI 1 and CACI 2. Arrastre/Union Flat, San Bernardino County, California. CACI 1 contains 69 ac (28 ha); CACI 2 contains 229 ac (93 ha); the landowner is the U.S. Forest Service. CACI 1 is USFS Pebble Plain Number 100; CACI 2 is USFS Pebble Plain Number 87.

Units CACI 3 and CACI 4. Big Bear Lake, San Bernardino County. CACI 3 contains 21 ac (9 ha); CACI 4 contains 6 ac (2 ha); the landowner is the U.S. Forest Service. CACI 3 is USFS Pebble Plain Number 248; CACI 4 is USFS Pebble Plain Number 254.

Units CACI 5 and CACI 6. Broom Flat, San Bernardino County, California. CACI 5 contains 58 ac (23 ha); CACI 6 contains 326 ac (132 ha);. The CACI 5 landowner is the U.S. Forest Service; the CACI 6 landowners are the U.S. Forest Service (255 ac) and a private landowner (71 ac). CACI 5 is USFS Pebble Plain Number 311; CACI 6 is USFS Pebble Plain Numbers 285 and 309.

Units CACI 7, CACI 8, CACI 9. Fawnskin, San Bernardino County, California. CACI 7 contains 15 ac (6 ha); CACI 8 contains 24 ac (10 ha); CACI 9 contains 2 ac (1 ha). The landowner is the U.S. Forest Service. CACI 7 is USFS Pebble Plain Number 301; CACI 8 is USFS Pebble Plain Number 302; CACI 9 is USFS Pebble Plain "Juniper Point".

Units CACI 10, CACI 11, CACI 12, CACI 15, and CACI 16. Gold Mountain and North Baldwin Lake, San Bernardino County, California. CACI 10 contains 62 ac (25 ha); CACI 11 contains 43 ac (17 ha); CACI 12 contains 0.3 ac (0.1 ha); CACI 15 contains 320 ac (129 ha); CACI 16 contains 4 ac (2 ha). The landowner for CACI 10, CACI 11, CACI 12, and CACI 15 is the U.S. Forest Service. The landowner for CACI 16 is the California Department of Fish and Game. CACI 10 is USFS Pebble Plain Number 188; CACI 11 is USFS Pebble Plain Number 192; CACI 12 is USFS Pebble Plain "South Baldwin Meadow"; CACI 15 is USFS Pebble Plain Number 128; CACI 16 is USFS Pebble Plain Number 168.

Units CACI 13 and CACI 14. Holcomb Valley, San Bernardino County, California. CACI 13 contains 28 ac (11 ha); CACI 14 contains 44 ac (18 ha). The CACI 13 landowners are the U.S. Forest Service (22 ac) and a private landowner (6 ac); the CACI 14 landowner is the U.S. Forest Service. CACI 13 is USFS Pebble Plain Numbers 98 and 109; CACI 14 is USFS Pebble Plain Number 153.

Units CACI 17 and CACI 18. Sawmill, San Bernardino County, California. CACI 17 contains 36 ac (14 ha); CACI 18 contains 5 ac (2 ha). The CACI 17 landowners are the U.S. Forest Service (15 ac) and a private landowner (21 ac). The CACI 18 landowner is a private landowner. CACI 17 is USFS Pebble Plain Number 236; CACI 18 is USFS Pebble Plain Number 224.

Unit CACI 19. Snow Valley, San Bernardino County, California. CACI 19 contains 26 ac (10 ha); the landowner is the U.S. Forest Service. CACI 19 is USFS Pebble Plain Number 270.

Unit CACI 20: South Baldwin Ridge/Erwin Lake, San Bernardino County, California. CACI 20 contains 23 ac (9 ha); the landowner is the U.S. Forest Service. CACI 20 is USFS Pebble Plain Number 212.

Units CACI 21, CACI 22, CACI 23, and CACI 24. Sugarloaf Ridge, San Bernardino County, California. CACI 21 contains 127 ac (51 ha); CACI 22 contains 34 ac (14 ha); CACI 23 contains 76 ac (31 ha); CACI 24 contains 190 ac (77 ha). The landowner for these units is the U.S. Forest Service. CACI 21 is USFS Pebble Plain Number 294; CACI 22 is USFS Pebble Plain Number 289; CACI 23 is USFS Pebble Plain Number 286; CACI 24 is USFS Pebble Plain Number 293.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Castilleja cinerea* critical habitat are those habitat components that provide (72 FR 73092-73178):

- (i) Pebble plains in dry meadow-like openings, or non-pebble plain dry meadow margin areas, within upper montane coniferous forest, pinyonjuniper woodlands, or Great Basin sagebrush in the San Bernardino Mountains of San Bernardino County, California; at elevations between 5,900 to 9,800 ft (1,830 to 2,990 m) that provide space for individual and population growth, reproduction and dispersal.
- (ii) Seasonally wet clay, or sandy clay soils, generally containing quartzite pebbles, subject to natural hydrological processes that include water hydrating the soil and freezing in winter and drying in summer causing lifting and churning of included pebbles, or seasonally wet silt or saline clay soils in non-pebble plain dry meadow margin areas that provide space for individual and population growth, reproduction and dispersal, adequate water, air, minerals, and other nutritional or physiological requirements to the species.
- (iii) The presence of one or more of its known host species such as *Eriogonum kennedyi* var. *austromontanum*, *E. kennedyi* var. *kennedyi*, and *E. wrightii* var. *subscaposum* in pebble plain habitat and species such as *Artemisia tridentata*, *A. nova*, and *E. wrightii* var. *subscaposum* in pebble plain and non-pebble plain meadow margin habitat that provide some of the physiological requirements for this species.

Special Management Considerations or Protections

Critical habitat does not include manmade structures (such as buildings, aqueducts, airports, roads, and other paved areas) and the land on which they are located existing on the effective date of this rule and not containing one or more of the primary constituent elements.

Threats to listed pebble plains plants throughout their range include land development, off-highway vehicle (OHV) use off of designated routes, road maintenance activities, ground disturbance that affects surface hydrology, mining activities, recreational activities, and nonnative plant species (63 FR 49006; September 14, 1998). Pebble plain habitat is also threatened by vegetation and fuels management, hazard tree removal, and wildfire suppression activities (Eliason 2006). However, of the above threats, land development remains the primary cause of habitat loss on private lands; while on Federal lands, OHV use off of designated routes has historically been, and continues to be, the most significant threat to pebble plains habitat. Increasing residential populations adjacent to pebble plains habitat on private and Federal lands has also resulted in degradation of habitat, as dispersed recreation and unauthorized OHV use increases (Eliason 2006). Also, while forest system road use and maintenance, mining activities, and dispersed recreation continue to have adverse ongoing effects to pebble plain habitat and the species it supports, the magnitude and severity of effects caused by these activities are relatively small compared to the effects of unauthorized motorized vehicle use (Eliason 2006). The primary constituent elements for the listed pebble plains plants may require special management considerations or protection to minimize impacts associated with, (1) vehicle use and road maintenance; (2) recreational activities; and (3) the presence of nonnative species (63 FR 49006, September 14, 1998; USFS 2002, p. 17; USFS 2005, pp. 207, 249, 293).

Life History

Food/Nutrient Resources**Reproductive Strategy**

Adult: Sexual (outcrossing) (USFWS, 2013)

Breeding Season

Adult: June through August. (USFWS, 2013)

Reproduction Narrative

Adult: Castilleja cinerea flowers from June through August (California Native Plant Society [CNPS] 2012). O'Brien has determined that Castilleja cinerea is outcrossing; covered flowers produced no seeds (O'Brien 1979, p. 69). (USFWS, 2013)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Barrens, Forest - Conifer, Forest/Woodland, Shrubland/chaparral, meadows (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 1800 and 2800 m on mountain slopes. (USFWS, 2013)

Environmental Specificity

Adult: Narrow/specialist (NatureServe, 2015)

Dependency on Other Individuals or Species for Habitat

Adult: As a hemiparasitic plant, *C. cinerea* produces haustoria (modified structures on the plant's roots that penetrate the root tissues of a host plant) to obtain nutrients and water. Host plants include *Eriogonum kennedyi* var. *austromontanum*, *Eriogonum kennedyi* var. *kennedyi* (Kennedy's wild-buckwheat), *Eriogonum wrightii* var. *subscaposum* (short-stemmed bastardsage), *Artemisia tridentata* ssp. *tridentata* (big sagebrush), *Artemisia nova* (black sagebrush), and other *Artemisia* taxa (USFS 2005d, no page number). (USFWS, 2013)

Habitat Narrative

Adult: The primary habitat for *Castilleja cinerea* is pebble plains, so described because of the layer of orange quartzite pebbles that are pushed to the clay soil surface by frost heaving and thawing (Krantz 1983, p. 10). *Castilleja cinerea* is found in the San Bernardino Mountains at elevations between 1,800 and 3,300 meters (m) (5,905 to 10,827 feet (ft)) (Wetherwax et al. 2012, p. 960). Within the San Bernardino Mountains, *C. cinerea* occurs on various benches and on all mountain slope aspects including both south-facing and north-facing slopes (CNDDDB 2012; USFWS 2012). *Castilleja cinerea* occupies the meadow/forest ecotone (transitional area of vegetation between two different plant communities) of the San Bernardino Mountains and has been recorded in the following ecological communities: pebble plains, dry and wet forest meadows, mixed conifer forests, open pine forests, and pinyon-juniper woodlands (CNDDDB 2012). As a hemiparasitic plant, *C. cinerea* produces haustoria (modified structures on the plant's roots that penetrate the root tissues of a host plant) to obtain nutrients and water. Host

plants include *Eriogonum kennedyi* var. *austromontanum*, *Eriogonum kennedyi* var. *kennedyi* (Kennedy's wild-buckwheat), *Eriogonum wrightii* var. *subscaposum* (short-stemmed bastardsage), *Artemisia tridentata* ssp. *tridentata* (big sagebrush), *Artemisia nova* (black sagebrush), and other *Artemisia* taxa (USFS 2005d, no page number). (USFWS, 2013)

Dispersal/Migration

Motility/Mobility

Adult: Low (inferred from USFWS, 2013)

Dispersal/Migration Narrative

Adult: It is likely that seeds are shaken loose from the erect seed capsules and drop short distances from the parent plant, and then dispersed short distances by the wind as observed in *C. levisecta* (golden paintbrush), a prairie species from the Pacific Northwest (USFWS 2010, p. II-34). (USFWS, 2013)

Population Information and Trends

Population Trends:

Not available

Number of Populations:

47 occurrences (USFWS, 2013)

Population Narrative:

Low levels of gene transfer between obligate outcrossing populations within geographic areas (i.e., pebble plain complexes) that are subject to additional fragmentation. Of the 49 EOs described in the CNDDDB database for *C. cinerea* (CNDDDB 2012), we believe that two of these (EOs 42, 64), located just south of Big Bear Lake, are now extirpated (USFWS 2012).

Threats and Stressors

Stressor: Urban Development (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Much of the habitat of *Castilleja cinerea* historically found on private lands has been lost to residential and commercial development (USFS 2012c, p. 32). Urban development (primarily residences) and related recreational development on city, county or private lands within the Big Bear Lake and Baldwin Lake areas continue to represent an ongoing threat to *Castilleja cinerea* at seven of the pebble plain complexes. Threats and their effects on *C. cinerea* and other pebble plain and meadow plants were recently described in a biological assessment for ongoing activities within the SBNF (USFS 2012d, pp. 61–63, 76–78). (USFWS, 2013)

Stressor: Roads and Trails (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: In our final listing rule, we described impacts from this threat under the category of ORV activity, citing over 7 miles (mi) (11 kilometers (km)) of Forest Service roads and 10 mi (16 km) of unauthorized routes that directly impact pebble plain sites (USFWS 1998, p. 49013, citing Odell 1988, p. 4). Approximately 2.5 percent of the SBNF acreage consists of roads (USFS 2005e, Vol. 1, p. 114). The SBNF implements a Roads and Trails Management Program that incorporates roads, motorized trails, motorized interpretive trails, and non-motorized trails found within the SBNF (USFS 2012d, pp. 9–10). (USFWS, 2013)

Stressor: Road Construction, Use, and Maintenance (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Threats to *Castilleja cinerea* from roads and trails include both direct effects, such as habitat alteration, and indirect effects, including alteration of water flow and drainage patterns, sedimentation, deposition of particulates (dust), and effects related to wildfire (USFS 2012d, pp. 21–24). Roads, road construction, and road maintenance can also facilitate the introduction and establishment of nonnative plants by creating open, continually disturbed habitat as well as disrupt hydrological processes within pebble plains habitats. Nonnative plants can be transported along these road corridors by equipment and vehicles, and are often more easily established on exposed cut-and-fill slopes of roads than native plants (USFS 2005e, Vol. 1, p. 114). Open Forest Service roads present ongoing threats in the Baldwin Lake area (Sawmill pebble plain complex) and the Wildhorse Meadow area (Sugarloaf Ridge pebble plain complex) where *Castilleja cinerea* occurs, and the SBNF has installed fencing and signage to minimize impacts to the habitat, including effects related to crushing, uprooting, or burial of plants (USFS 2012d, pp. 77, 82). (USFWS, 2013)

Stressor: Recreational Use of Roads and Trails (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: The high frequency of ORV activity was described as the most significant and persistent threat in the final listing rule for *Castilleja cinerea* and other pebble plain plants and was reiterated as such in our 2008 5-year review (USFWS 1998, p. 49013; USFWS 2008, p. 5). Threats also result from the effects of non-motorized trails and mountain biking due to the proximity of *C. cinerea* and its habitat to urban areas (USFS 2012d, pp. 60–61). Associated with ORV activity is unauthorized collection of wood for fuel including removal of downed vegetation or trees. The SBNF has an active, personal use fuel-wood program in which the public can purchase permits for cutting wood from marked, downed logs in designated areas (USFS 2012d, p. 30). (USFWS, 2013)

Stressor: Alteration of Hydrology (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: The listing rule identified alteration of hydrological conditions as a threat to *Castilleja cinerea* habitat, noting that the majority of pebble plain complexes are directly impacted by vehicle routes that may lead to alterations in the surface hydrology (USFWS 1998, p. 49013). This threat is often the result of unauthorized ORV activities and direct and indirect impacts from

urbanization (USFS 2002, p. 25). Vehicle traffic within pebble plains habitats during the wet season is of particular concern because this activity creates deep ruts that change the hydrological patterns over the pebble plain (USFS 2002, p. 20). Alteration of hydrology can also result from land disturbance due to mining and fire suppression activities, which are discussed as separate threats to *C. cinerea* below. Our listing rule also highlighted activation or installation of wells within lower Holcomb Valley, Baldwin Lake (within the North Baldwin Lake complex) as a potential threat to pebble plains habitat through the alteration of hydrology in these areas (USFWS 1998, p. 49014). In an undisturbed condition, water generally flows evenly over the surface of pebble plains (Odell 1988, p. 19). However, disturbances to their surface can change hydrological patterns across these surfaces and can alter their soil composition through the erosion of clay sediments during rainfall events, leaving only large cobbles and pebbles (Neel and Chaney 1992, p. 1). These potential changes to soil morphology and composition can alter the vegetation structure and composition of the pebble plain, by creating favorable conditions for the invasion of both native and nonnative plant species that then out-compete *Castilleja cinerea* for space and resources, and further altering the soil composition by increasing the amount of organic debris (Derby 1979, pp. 72–73; USFS 2002, p. 15). (USFWS, 2013)

Stressor: Trampling of Habitat (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Moderate to heavy degradation of certain sites occupied by *Castilleja cinerea* from trampling by cattle has occurred in the past and some pebble plains and meadow complexes continue to be impacted by cattle, horses, and feral burros (USFWS 1998, p. 49016). However, we anticipated this threat would be reduced with the removal of feral burros from several pebble plain complexes under the provisions of the Big Bear Wild Burro Territory Management Plan (USFWS 1998, p. 49017). We also reported occasional trampling of *C. cinerea* from construction activities and trails near the Snow Valley Ski Area (USFWS 1998, p. 49016). (USFWS, 2013)

Stressor: Nonnative Plants (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: The Service identified exotic (nonnative) plants as a threat to *Castilleja cinerea* in the context of disturbances related to grazing, urban and rural development, and various recreational activities (USFWS 1998, p. 49017). These activities can threaten native plants by facilitating the establishment of nonnative species and resulting in the alteration of habitat through crowding or competition for resources (USFWS 1998, p. 49017). *Bromus tectorum* represents the primary species of concern for these pebble plain areas. This taxon, as well as *Erodium cicutarium* (filaree), represent very old invasions for the San Bernardino Mountains and are persistent threats within these complexes (Eliason 2012a, pers. comm.). More recent invasions of nonnative plant species within some of these pebble plain complexes include *Linaria dalmatica* (dalmatian toadflax), *Ranunculus testiculatus* (bur buttercup), and *Lepidium perfoliatum* (clasping pepperweed) (Eliason 2012a, pers. comm.). As with pebble plain habitat, ground disturbances by hikers, mountain bicyclists, and ORVs can create conditions favorable for the establishment and spread of nonnative plants into these areas. (USFWS, 2013)

Stressor: Mining (USFWS, 2013)

Exposure:**Response:****Consequence:**

Narrative: The Service indicated that mining activities had contributed to the decline of *Castilleja cinerea* due to effects from habitat destruction, degradation, and fragmentation of pebble plain habitats (USFWS 1998, p. 49013). We described mining as a secondary threat to habitat degradation (USFWS 1998, p. 49013). Mining claims on Forest Service lands were previously reported for five pebble plain complexes occupied by *Castilleja cinerea*: (1) Holcomb Valley (83 ac (33.6 ha)), (2) Fawnskin (24 ac (9.7 ha)), (3) Arrastre Flats (69 ac (28 ha)), (4) North Baldwin Lake (62 ac (25 ha)), and (5) Broom Flat (0.2 ac (0.08 ha)) (USFS 2002, pp. 42, 46, 48, 57, 65). These claims continue to represent a potential threat of ground disturbance for *C. cinerea*, specifically, gold prospecting activities or mining operations related to the ownership of mineral rights. (USFWS, 2013)

Stressor: Fire Suppression (USFWS, 2013)

Exposure:**Response:****Consequence:**

Narrative: Activities related to management of fire and fuels can also threaten *Castilleja cinerea* and its habitat. Though not recognized as a threat at the time of listing, fire suppression was known to impact one occurrence in 2008 when the previous status review was developed. However, fuelbreaks and vegetation treatment units are very rarely located in pebble plain habitat due to the scarcity of fuels (USFS 2005a, p. 255). Fire suppression activities typically include fire line construction; fire retardant and water drops; establishment of temporary fire camps, staging areas, parking sites, safety zones, and helipads; and post-fire rehabilitation (USFWS 2005, p. 27). Each of these activities can have negative impacts to *C. cinerea* and its habitat. (USFWS, 2013)

Stressor: Climate Change (USFWS, 2013)

Exposure:**Response:****Consequence:**

Narrative: Projected changes in April snow water equivalence across the Fawnskin, Holcomb Valley, and parts of Arrastre Flats pebble plains, under a low carbon emissions scenario (B1), indicate an 84 percent reduction in snow moisture; and a 92 percent reduction in snow moisture under a high emissions scenario (A2), between a baseline time period (1961 to 1990) and an end of century period (2070 to 2090). Similar reductions in snowpack are projected for the Bear Valley region and other parts of the SBNF. Projected changes in annual average in temperature for this region using the Cal-Adapt tool under the B1 scenario indicate a 3.9oF (2.1oC) increase in temperature, and 6.9oF (3.8oC) increase under the A2 scenario, between the baseline time period (1961 to 1990) and an end of century period (2070 to 2090). Although there is uncertainty in predictions of downscaled climate change models, these projected climate change effects could significantly alter the hydrology and vegetation that sustain and characterize pebble plain and other habitats occupied by *Castilleja cinerea*. (USFWS, 2013)

Recovery**Reclassification Criteria:**

Not applicable.

Delisting Criteria:

Not defined; a Recovery Plan is not available for this species.

Recovery Actions:

- Recommendation for Future Action from 2013 5-Year Review: Work with biologists at the SBNF to reduce impacts from recreational use of roads and trails through uncontrolled access to pebble plain habitat occupied by *Castilleja cinerea*. Prioritize protective measures being implemented (or planned) for controlling access to areas occupied by *Castilleja cinerea*. (USFWS, 2013)
- Recommendation for Future Action from 2013 5-Year Review: Reduce current and future impacts to *Castilleja cinerea* (and other federally listed pebble plain plants) from roads and trails through coordination with staff at SBNF. Identify and implement a priority strategy to identify roads and trails for decommissioning within pebble plain habitats. (USFWS, 2013)
- Recommendation for Future Action from 2013 5-Year Review: Conserve or preserve *Castilleja cinerea* occurrences on private lands. Continue to work with the State and local groups to purchase *C. cinerea* habitat from willing sellers, particularly within the Sawmill pebble plain complex. (USFWS, 2013)
- Recommendation for Future Action from 2013 5-Year Review: Develop a monitoring plan to provide early detection of downward trends in the populations of pebble plain plants, such as *Castilleja cinerea*, and quality of pebble plain and montane meadows habitats (adapted from USFS 2005b, p. 125). This monitoring plan should identify and prioritize surveys of plant populations, including abundance, and habitat conditions, in those areas most vulnerable to threats (e.g., pebble plain complexes with high levels of recreational activity) and should include remote sensing and mapping of unauthorized ORV trails. (USFWS, 2013)

SPECIES ACCOUNT: *Castilleja grisea* (San Clemente Island indian paintbrush)

Species Taxonomic and Listing Information

Listing Status: Threatened; 9/12/1977; California/Nevada Region (R8) (USFWS, 2015); Proposed Delisting

Physical Description

A perennial plant which is grayish in color and with short cobweb-like hairs throughout. The stem is woody and highly branched. The flowers are brownish-green. (NatureServe, 2015)

Taxonomy

Not available

Historical Range

Known range on coastal bluffs, slopes, canyons, escarpments and terraces across the southern two-thirds of the island (Helenurm et al. 2005, pp. 1221, 1226; Junak 2006, p. 47; USFWS 2007, p. 14) (USFWS, 2012)

Current Range

Endemic to San Clemente Island, CA. (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Bare rock/talus/scree, cliff, shrubland/chaparral (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Endemic to San Clemente Island (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Colonial (USFWS, 2012)

Habitat Narrative

Adult: *Castilleja grisea* is found in coastal scrub on steep canyon walls. The plants' presence in open habitat suggests that its restriction to cliffs and rocky habitats is an artifact of past goat predation or perhaps eradication by fire. (USFWS Endan. Pl. Sp. Status Report, Oct. 1979).

(NatureServe, 2015). One colony at the southern end of San Clemente Island has 500 to 600 plants located in a relatively flat open terrain. (USFWS, 2012; NatureServe, 2015)

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Not available

Population Information and Trends

Population Trends:

Declining. (NatureServe, 2015)

Resiliency:

Low (inferred from USFWS, 2012)

Representation:

Low (inferred from USFWS, 2012)

Redundancy:

Low (inferred from USFWS, 2012)

Number of Populations:

29 (USFWS, 2012)

Population Size:

10,000 - 100,000 individuals (NatureServe, 2015)

Population Narrative:

Populations of *Castilleja grisea* have been declining. (NatureServe, 2015). In late 1890s this species was reported to flourish on the island. By 1978 a frequent visitor to the island reported that he had seen only three plants, all on the canyon walls (Mohlenbrock, 1983). A 2011 estimate from the Navy reported 11,733 individuals recorded since 2006 (Munson 2011, pers. comm., cited by USFWS 2012). Since listing and the removal of feral goats and pigs on San Clemente Island, the distribution of *Castilleja grisea* has expanded from 19 to 29 occurrences. (NatureServe, 2015; USFWS, 2012)

Threats and Stressors

Stressor: Habitat degradation (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Currently, the habitat of *Castilleja grisea* is threatened by destruction and modification caused by land use, erosion, nonnative plants, fire, and fire management (USFWS 2012, pp. 29078–29128). To help ameliorate these threats, the Navy is applying erosion control measures and developing an erosion control plan, implementing a Fire Management Plan, and an island-wide nonnative species control program (USFWS 2008, pp. 1–237). Though increased impacts

associated with military training could impact habitat occupied by *C. grisea*, 16 of 29 occurrences fall outside of heavily impacted training areas where the most intensive habitat disturbances occur (USFWS 2012, pp. 29078–29128). (USFWS, 2012)

Stressor: Human development (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Threats associated with movement of troops and vehicles continue to impact *Castilleja grisea* at 17 of 29 occurrences on San Clemente Island. (USFWS, 2012)

Stressor: Fire (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Fire continues to impact *Castilleja grisea* at 17 of 29 occurrences on San Clemente Island. The Navy is implementing a Fire Management Plan and an Integrated Natural Resources Management Plan to help minimize these threats (USFWS 2008, pp. 1–237). (USFWS, 2012)

Stressor: Climate change (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Climate change may also influence *C. grisea*, though the magnitude of this threat effect is largely unknown (USFWS 2012, pp. 29078–29128). (USFWS, 2012)

Recovery

Reclassification Criteria:

Not available

Delisting Criteria:

Not available

Recovery Actions:

- Identify present adverse impacts to biological resources and strive to eliminate them. (USFWS, 2012)
- Protect known resources from further degradation by: (a) removal of feral herbivores, carnivores, and selected exotic plant species; (b) control of erosion in sensitive locations; (c) direct military operations and adverse recreational uses away from biologically sensitive areas. (USFWS, 2012)
- Restore habitats by revegetation of disturbed areas using native species. (USFWS, 2012)
- Identify areas of San Clemente Island where habitat restoration and population increase of certain addressed taxa may be achieved through a careful survey of the island and research on habitat requirements of each taxon. (USFWS, 2012)
- Delist or upgrade the listing status of those taxa that achieve vigorous, self-sustaining population levels as the result of habitat stabilization, restoration, and preventing or minimizing adverse human related impacts. (USFWS, 2012)

- Monitor effectiveness of recovery effort by undertaking baseline quantitative studies and subsequent follow-up work (USFWS 1984, pp. 106–107). (USFWS, 2012)

Conservation Measures and Best Management Practices:

- Develop a systematic survey protocol for *Castilleja grisea* on San Clemente Island. These surveys should include confirmation of existing locations at greater regularity to better determine accurate population status and trend for the species. Additionally, these protocols should include the standardization of information collected such as habitat conditions, habitat type, number of plants, date collected, etc. (USFWS, 2012)
- Conduct research to determine the host plant(s) of *Castilleja grisea* and degree of dependence on host plants. (USFWS, 2012)
- Conduct studies to establish the fire tolerance and preferred fire regime of *Castilleja grisea*. (USFWS, 2012)
- Work with the Navy to better estimate fire frequency in areas occupied by *Castilleja grisea* on San Clemente Island. (USFWS, 2012)

SPECIES ACCOUNT: *Castilleja levisecta* (Golden Paintbrush)

Species Taxonomic and Listing Information

Listing Status: Threatened; 7/11/1997; Pacific Region (R1); Proposed Delisting

Physical Description

Castilleja levisecta often has from 5 to 15 unbranched stems. The stems may be erect or spreading, in the latter case giving the appearance of being several plants, especially when in tall grass. Plants are up to 30 centimeters (12 inches) tall and are covered with soft, somewhat sticky hairs. The lower leaves are broader, with one to three pairs of short lateral lobes near the terminal third. The showy bracts are about the same width as the upper leaves, softly hairy and sticky, and are golden yellow. The bracts effectively hide the flowers. (USFWS, 2000)

Taxonomy

According to the Integrated Taxonomic Information System (2018), the genus *Castilleja* was formerly included within the Schrophulariaceae family, with current classification in the Orobanchaceae family. The taxonomic hierarchy for *C. levisecta* as determined by Flora of North America for the Integrated Taxonomic Information System is as follows: Kingdom: Plantae; Subkingdom: Viridiplantae; Infrakingdom: Streptophyta; Superdivision: Embryophyta; Division: Tracheophyta; Subdivision: Spermatophytina; Class: Magnoliopsida; Superorder: Asteranae; Order: Lamiales; Family: Orobanchaceae; Genus: *Castilleja* Mutis: ex L. f.; Species: *Castilleja levisecta* Greenm. (USFWS, 2019)

Historical Range

Historically, *C. levisecta* was reported from more than 30 sites in the Puget Trough of Washington and British Columbia, Canada, and as far south as the Willamette Valley of Oregon (Hitchcock et al., 1959, Sheehan and Sprague 1984, Gamon 1995; entire). (USFWS, 2019)

Current Range

C. levisecta occurs in the Puget Lowlands or Puget Trough Physiographic Province of Washington (as mapped by Franklin and Dyrness 1973) and lower Vancouver Island at elevations from sea level to about 100 meters (330 feet) above sea level. It has also been reestablished or introduced to a number of sites in Oregon since 2011. (USFWS, 2019)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Insect pollinated (USFWS, 2016)

Lifespan

Adult: 5-10 years (USFWS, 2016)

Dependency on Other Individuals or Species

Adult: Like most paintbrushes (Heckard 1962), this species is a hemi-parasite – its roots penetrate the roots of neighboring plant species and derive nutrients, carbohydrates, and other secondary compounds from these hosts (USFWS, 2016).

Breeding Season

Adult: Plants may flower as early as April with the major flush of flowering plants forming in May; with most flowering completed by July (USFWS, 2016).

Reproduction Narrative

Adult: *Castilleja levisecta* is a relatively short-lived perennial herb, with individual plants generally surviving 5 to 10 years (T. Thomas, USFWS, pers. comm. 2015). This species reproduces exclusively by seed; vegetative spread has never been reported. Plants may flower as early as April with the major flush of flowering plants forming in May; with most flowering completed by July. The fruit is a capsule, which matures in late summer, usually by August. The seed capsule generally dehisces by late summer, or early fall, distributing the abundant seed. Some capsules will persist into winter. By late summer the plants senesce, although some vegetative material may be present throughout the year, depending on the location. Like most paintbrushes (Heckard 1962), this species is a hemi-parasite – its roots penetrate the roots of neighboring plant species and derive nutrients, carbohydrates, and other secondary compounds from these hosts. The breeding system of *Castilleja levisecta* has not been thoroughly documented. Evans et al.(1984) reported that a species of bumblebee, *Bombus californicus*, was observed visiting *Castilleja levisecta*. Pollinator exclusion experiments showed that fruits can be produced in the absence of pollinator visitation, but fruit set was almost five times greater in unbagged inflorescences compared to inflorescences bagged to prevent visits from pollinators (Wentworth 1994). More recently, formal pollinator monitoring was conducted in 2011 to document all pollinators that visit *C. levisecta*. *Bombus* species (bumbees) were the most commonly observed pollinators (Bakker et al.2013); other types of pollinators included honey bees, solitary bees, flies, wasps, and a variety of butterflies (USFWS, 2016).

Habitat Type

Adult: Upland Prairie (USFWS, 2016)

Habitat Narrative

Adult: *Castilleja levisecta* occurs in upland prairies. Prairies may be generally flat in the glaciated portions of the species range; however, the species is also found on coastal bluffs in north Puget Sound, and on some grasslands characterized by mounded topography (T. Thomas, USFWS, pers. comm. 2015). The sites where *Castilleja levisecta* are found in the Willamette Valley, Oregon, are found on deeper, alluvial soils compared with the soil found at the Washington prairies within the species range. Low deciduous shrubs may be present as small to large thickets, although these shrub patches readily burn during prescribed fire events. With a fire return period of 2 to 5 years for prairies (Agee 1993, Hammond et al.2011), fire is thought to have historically played a key role in the maintenance of the upland prairie habitat occupied by this species by preventing the successional encroachment of woody shrubs and trees, and by creating bare soil areas to promote seed germination (T. Thomas, USFWS, pers. comm. 2015). In the absence of fire or other forms of management, most sites have been colonized by woody plants, primarily *Pseudotsuga menziesii*, and shrubs, including *Rosa nutkana* (wild rose), *Symphoricarpos albus* (snowberry) and *Cytisus scoparius*, an aggressive non-native, noxious

weed. The mainland population in Washington occurs in a gravelly, glacial outwash prairie (USFWS 2010). Most of the extant populations in Washington are on loamy sand or sandy loam soils derived from glacial origins. In the southern portion of its historic range in the Willamette Valley, populations occurred on clayey alluvial soils, in association with *Quercus garryana* (Oregon white oak) woodlands and savannah (Caplow 2004). Sites with a high abundance of native forbs and grasses have been determined to be the most suitable sites for reintroduction in Oregon (Lawrence and Kaye 2009), and likely this is the case throughout the species range (USFWS, 2016)

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Although seed dispersal has not been directly observed, the seeds are probably shaken from the seed capsules and fall a short distance from the parent plant. The seeds are minute, and light and could possibly be dispersed short distances by the wind; however, we observe little natural reproduction on sites that have not received management (T. Thomas, USFWS, pers. comm. 2015) (USFWS, 2016).

Population Information and Trends

Number of Populations:

48 (USFWS, 2019)

Population Size:

approximately 561,000 flowering plants across all known sites (USFWS, 2019)

Minimum Viable Population Size:

Greater than 100 flowering plants (USFWS, 2019; p. 27)

Additional Population-level Information:

Sites assigned a Low condition are found in the north and south areas of the species' range, though driving stressors vary by region. In the north part of the species range, sites are relatively small and some have inconsistent management, leading to a decline in number of plants through time. In the central part of the species' range, no currently extant sites are in low condition, though two sites have been excluded from recovery planning due to hybridization. There are several sites that exhibit low condition in Willamette Valley, though this includes recent outplantings that have low plant counts because they are just starting to produce flowering plants. (USFWS, 2019)

Population Narrative:

Per 2018 monitoring data and communications with various experts, there are 48 confirmed extant sites with patches of documented flowering *C. levisecta* that were monitored in 2018, 11 of which contained wild patches of the species (Figure 2). Two of these 48 sites (Hill Road in Ebey's Landing Reserve on Whidbey Island and Peach Cove in Clackamas County, Oregon) were observed to contain flowering plants in 2018, but a monitoring count was not obtained. These 48 populations are distributed thusly: • Washington: In Washington, there are 19 extant sites with flowering plants. Nine of these 19 extant sites have had, or currently have, only wild plants on site. Five of these 19 sites are located in the South Puget Sound prairie landscape in central

Washington. In northwestern Washington, six sites are in the San Juan Islands, seven sites currently exist on Whidbey Island, and one site is on the state mainland near Dungeness Bay (see Table 2 of USFWS, 2019). • Oregon: There have been 26 sites with successful outplantings in the Willamette Valley. There are no wild populations left extant in Oregon (see Table 3 of USFWS, 2019). • British Columbia, Canada: Three extant sites contain patches of *C. levisecta* in British Columbia. Two of these extant sites have had, or currently have, only wild plants on site. One is a recent outplanting (see Table 4 of USFWS, 2019). (USFWS, 2019)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Continued development in the Puget Trough and the Willamette Valley is increasing habitat fragmentation (Lawrence and Kaye 2006), and loss of native grasslands. This trend is anticipated to continue or increase with regional population growth. However, this threat has been somewhat mitigated for *Castilleja levisecta* through land acquisition, protection of suitable prairie lands, and active management as a priority. The purchase and conservation of land has increased the amount of potential habitat available for the species. (USFWS, 2007)

Stressor: Herbivory (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Herbivory by deer, rabbits, and voles has been observed, sometimes resulting in serious damage at two populations (Forbes Point and Naas Preserve). At each site deep thatch and dense shrub cover has produced vole and rabbit habitat, respectively. At both of these populations, there have been years when the entire population was browsed, which leads to complete loss of that year's natural seed reproduction. A fence was constructed to exclude rabbits and voles from approximately one-half of the population at Forbes Point and the decline of the *C. levisecta* population slowed, but herbivory continues outside of the quarter hectare (0.62 acres) fenced enclosure. At the Naas Preserve, most flowering plants in the native populations are caged to prevent herbivory and all plants that have been augmented into this population are fenced to keep out deer, rabbits and voles. A minor threat is present at most locations from herbivory by butterfly larvae and other insects but no serious damage has been observed. Microbial interactions are largely unknown. (USFWS, 2007)

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Outside of the protections afforded to the species through section 7 consultation for activities that are authorized, funded, or carried out by Federal agencies there is little additional protection given to the species through other means. The Endangered Species Act does not extend protection to listed plant species on private land. Although Washington State classifies plant species as endangered, threatened, or sensitive, the state does not provide protection to rare plants or the habitat upon which they depend. (USFWS, 2007)

Stressor: Fires and Erosion (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: An accidental fire occurred at the Ebey's Landing site during the growing season of 2002 and again during July 2007 when fireworks ignited the grass and forbs at this site. In each case the fire was extremely hot because the fuels on the site were abundant. Because the plant was flowering and no mature seed had formed for the year, the population was severely impacted by this event in both years that fire occurred. The fire intensity was hot enough to char the soil organic layers. Thus, the plants were killed by the fire, no seed was produced for the year, and the site was invaded by several species of invasive, nonnative plants. Up to one-half of the Castilleja plants were burned in each of these fires and the site has been dominated by nonnative species since the initial fire burned in 2002. Erosion at the same site has been a recurring problem and in 2004, a large section of the hillslope eroded from the site, carrying a large slab of soil and plants onto the beach and into the surf below. This erosion event removed an area of approximately 50 feet in width for the entire run of the slope. This type of random environmental event is not predictable in timing or in the amount of soil material that may be removed. However, because of the steepness of the slope at Ebey's Landing, erosion is expected to continue and this site may become extirpated at some time in the future. Between these two events (accidental fire and deep seated slope failure) this population has been reduced from several thousand flowering plants in 2000 to about 200 flowering plants in 2006, the last time a complete census of the site was made. (USFWS, 2007)

Recovery

Reclassification Criteria:

Not applicable.

Delisting Criteria:

Delisting will be considered when all of the following conditions have been met:

1. There are at least 20 stable populations distributed throughout the historic range of the species. To be deemed stable, a population must maintain a 5-year running average population size of at least 1,000 individuals. (USFWS, 2000)
2. At least 15 of these populations are located on protected sites. In order for a site to be deemed protected, it must be either owned and/or managed by a government agency or private conservation organization that identifies maintenance of the species as the primary management objective for the site, or the site must be protected by a permanent conservation easement or covenant that commits present and future landowners to the conservation of the species. (USFWS, 2000)
3. Genetic material, in the form of seeds adequately representing the geographic distribution or genetic diversity within the species, is stored in a facility approved by the Center for Plant Conservation. (USFWS, 2000)

4. Post-delisting monitoring of the condition of the species and the status of all individual populations is ready to begin. (USFWS, 2000)

5. Post-delisting procedures for the ecological management of habitats for all populations have been initiated. (USFWS, 2000)

Recovery Actions:

- 1. Maintain the current geographic distribution of the species through maintaining habitat integrity. Only 11 *Castilleja levisecta* populations are known to exist. A majority of these populations occur on small isolated fragments of remaining habitat and consist of relatively few individuals. Each of the 11 populations is subject to a number of current and potential threats, all of which compromise the integrity of the habitat. Since *C. levisecta* is adapted to specific habitat conditions, maintaining or restoring the integrity of the habitat is essential. (USFWS, 2000)
- 2. Identify and search potential habitat using standardized rare plant search methods developed by the U.S. Fish and Wildlife Service or other resource agencies. Although considerable inventory work has been undertaken for this species, the discovery in the last few years of previously unknown sites (two new occurrences and two new colonies within a previously known occurrence) suggests that other populations or colonies may yet be discovered. Comprehensive inventory is complicated because so much of the range of the species is privately owned, and because small remnant patches of habitat can be hidden from view from any point of public access. Although as yet undiscovered populations or colonies are likely to be small, they collectively have the potential to contribute substantially to the recovery effort. (USFWS, 2000)
- 3. Establish new populations of *Castilleja levisecta* within the historic range of the species. As noted above, the long term survival of *Castilleja levisecta* is likely to depend on the establishment of new populations. In order to accomplish this, a carefully prepared reintroduction plan is needed, along with research into the technical aspects of successfully growing the species. (USFWS, 2000)
- 4. Disseminate information about the species to appropriate audiences and landowners. Develop and conduct training programs to be provided to concerned agency personnel, as well as private landowners (Priority 3). Develop a brochure or fact sheet for public dissemination, and provide presentations as appropriate (Priority 3). Develop and disseminate species information to private landowners (Priority 3). (USFWS, 2000)
- 5. Promote State and county level legal protection for occurrences on non- Federal lands. Due to the limited number of known areas that harbor this species, and the limited number of known occurrences within those areas, it is important to secure the maximum legal protection available to all occurrences. (USFWS, 2000)
- 6. Establish a technical working group to periodically review the status of the species and assess the effectiveness of the management plans and other recovery tasks (Priority 3). Through periodic review, improvements to the overall recovery effort can be made, thereby accelerating recovery. (USFWS, 2000)
- 7. Collect seed adequately representing the genetic diversity within the species and store in a Center for Plant Conservation approved facility (Priority 3). The small number of known populations, area occupied, and the fact that many populations are few in number of individuals, make the species more vulnerable to random environmental and human-caused events. As a hedge against the loss of significant genetic material, seed representing the

diversity within the species should be collected and stored in a Center for Plant Conservation approved facility. The stored seed could also be used in efforts to establish new populations. (USFWS, 2000)

- Conservation measures to restore *Castilleja levisecta* (golden paintbrush) in the Willamette Valley: Some research has been conducted on the population biology, fire ecology, propagation and restoration of *Castilleja levisecta* (Dunwiddie et al. 2001, Gamon et al. 2001, Kaye 2001, Kaye and Lawrence 2003, Caplow 2004, Lawrence 2005). The results of these studies have been used to direct the management of the species at sites managed for upland prairies, and are critical to the future reintroduction and recovery of the species. A reintroduction plan has been prepared (Caplow 2004), as directed by the Golden Paintbrush Recovery Plan (U.S. Fish and Wildlife Service 2000b); reintroduction into likely historical habitat is the best hope for the species to recover in the prairies of Oregon and southwestern Washington. Recent research has considered the most appropriate seed sources and site characteristics for the reintroduction of *Castilleja levisecta* to the Willamette Valley (Lawrence 2005). The findings of this study are consistent with those recommended for the other prairie species addressed in this plan, in that the optimal sites for reintroduction were high quality prairies dominated by native perennial species with low abundance of non-native plant species. Furthermore, the study recommended against using genetic diversity, effective population size, or geographic distance in determining source material for reintroductions, instead suggesting that plant materials from Whidbey Island, Washington, had the greatest potential for successful reintroductions to the Willamette Valley (Lawrence 2005). Greenhouse trials and surveys of potential reintroduction sites in the Willamette Valley have recently been completed (Lawrence 2005). Seeds of this species have been banked at the Berry Botanic Garden in Portland, Oregon (Berry Botanic Garden 2005) and the University of Washington Botanic Garden. (USFWS, 2010)
- Recommendation for Future Action from 2007 5-Year Review: Upon completing this 5-year review of the status of *Castilleja levisecta* and its recovery plan, we recommend that surveyors monitoring the populations for *Castilleja levisecta* count only flowering plants. Counting vegetative individuals is difficult and impractical because small vegetative seedlings may be obscured by shrubs or tall grass and may not survive the growing season. To ensure monitoring is consistently applied across all ownerships and locations, the criterion used for monitoring the population should be modified to specify 1,000 flowering, rather than vegetative, plants as the threshold for a recovered population. (USFWS, 2007)
- Recommendation for Future Action from 2007 5-Year Review: Three items should be addressed when the Recovery Plan for *Castilleja levisecta* is revised: (1) modify how individual plants are counted during population monitoring by counting only flowering plants; (2) modify the number of populations that should be required to meet recovery based on our experience with restoring habitat and recovering *Castilleja levisecta*; and (3) reevaluate how we partition populations and determine if populations that are within close proximity to one another should be considered a single population using the current definition of "element occurrence". (USFWS, 2007)
- Recommendation for Future Action from 2007 5-Year Review: In addition to how we account for the number of plants in a population, we recommend that the number of populations that will be required to meet recovery of the species be reconsidered and modified. Currently, the Recovery Plan calls for at least 20 self-sustaining populations distributed throughout the species historic range. Because the species is reliant on regular management actions to sustain itself, it may be practical to focus on having fewer populations (for example, 15 protected populations) to meet the recovery needs of the

- species and to make sure these populations receive funding and regular management. It would still be required that a population would need to maintain a stable or positive trend for the number of plants in a population for a minimum of 5 years. (USFWS, 2007)
- Recommendation for Future Action from 2007 5-Year Review: It will be important to recognize the spatial relationship of populations. Closely situated populations should be counted as a single population and not be considered as separate populations. The standard definition for “element occurrence”, as it is used by the Washington Natural Heritage Program, is an area of land (or water) in which a species is, or was, present. Furthermore, the distance between occurrences of the element determines whether they are considered the same or separate occurrence. In addition to the distance criteria between populations, the pollination flight distance attributed to insects that are known to pollinate *Castilleja levisecta* and the availability of suitable habitat between two existing populations needs to be considered. The Recovery Plan should be revised to show our intent to apply the standard for element occurrence to *Castilleja levisecta*, which would combine some populations into single occurrences and would reduce the number of populations that we have currently, which would make each of the populations larger and more robust.

SPECIES ACCOUNT: *Castilleja mollis* (Soft-leaved paintbrush)

Species Taxonomic and Listing Information

Listing Status: Endangered; 07/31/1997; California/Nevada Region (R8) (USFWS, 2015)

Physical Description

A shrubby, hemiparasitic, perennial herb with soft-woolly, grayish-green foliage. The highly branched plants are somewhat prostrate, usually reaching only 3+ dm high. Inflorescences (April-August) have yellow bracts (the bracts much more conspicuous than the flowers). (NatureServe, 2015)

Taxonomy

This species was described by Pennell as *Castilleja mollis* in 1947, based on material collected on Santa Rosa Island in 1939 (Ingram 1990, Heckard et al. 1991). Hoover (1970) and Munz and Keck (1973) included plants of coastal sand dunes of San Luis Obispo County in the description of this taxon. (USFWS, 2000). Upon review and in agreement with available systematic and floristic literature and consultation with species experts, we intend to propose amending part 17, subchapter B of chapter I, title 50 of the Code of Federal Regulations to reflect the transfer of *Castilleja* taxa including *C. mollis* from the family Scrophulariaceae to the family Orobanchaceae. (USFWS, 2007)

Historical Range

See current range/distribution.

Current Range

Confined to the California Channel Islands, perhaps only Santa Rosa Island but possibly San Miguel Island as well. Not seen on San Miguel Island since 1938, despite recent surveys (CNPS 2001). (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (hybridization) NatureServe, 2015)

Breeding Season

Adult: April to August (NatureServe, 2015)

Other Reproductive Information

Adult: This plant occasionally hybridizes with *Castilleja affinis*. (NatureServe, 2015)

Reproduction Narrative

Adult: This plant occasionally hybridizes with *Castilleja affinis*. Inflorescences (April-August) have yellow bracts (the bracts much more conspicuous than the flowers). (NatureServe, 2015)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Sand/dune, Shrubland/chaparral (NatureServe, 2015)

Dependency on Other Individuals or Species for Habitat

Adult: Soft-leaved paintbrush is dependent on a host plant for water and dissolved resources. Some leaves have reduced chlorophyll and the plant compensates by parasitizing the roots of nearby vascular plants (Chuang and Heckard 1993). The most likely host is goldenbush (*Isocoma menziesii* var. *sedoides*) (E. Painter in litt. 1995, M. Wetherwax in litt. 1995). (USFWS, 2000)

Habitat Narrative

Adult: It is well established that *Castilleja mollis* requires the coastal scrub bluff community, which includes goldenbush, to establish and survive (USFWS, 2000). *Castilleja mollis* requires stabilized and partially stabilized coastal dunes (NatureServe, 2015). *Castilleja mollis* is dependent on a host plant for water and dissolved resources. Some leaves have reduced chlorophyll and the plant compensates by parasitizing the roots of nearby vascular plants (Chuang and Heckard 1993). The most likely host is goldenbush (*Isocoma menziesii* var. *sedoides*) (E. Painter in litt. 1995, M. Wetherwax in litt. 1995). (NatureServe, 2015; USFWS, 2000)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Decline of >10% (NatureServe, 2015)

Resiliency:

Very low (USFWS, 2007)

Representation:

Low (inferred from USFWS, 2007)

Redundancy:

Low (inferred from USFWS, 2007)

Population Growth Rate:

Slow decline (NatureServe, 2015)

Number of Populations:

2 (USFWS, 2007)

Population Size:

>1000 (NatureServe, 2015)

Population Narrative:

Population estimates are 1000 individuals in Jaw Gulch population and several thousand in Carrington Point population (USFWS 2000). There are only three occurrences at the California Natural Diversity Database for this species; one extant, two possibly extirpated. (NatureServe, 2015). Short term trends indicate a decline of approximately 10%. (NatureServe, 2015; USFWS, 2007)

Threats and Stressors

Stressor: Decline of plant host (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: We have information that indicates the direct dependency of *Castilleja mollis* on the coastal goldenbush scrub community (McEachern, pers. comm. 2006a). Before 1998, cattle grazing and ungulates rutting caused large gaps in the coastal goldenbush community. These gaps were then invaded by non-native grasses, inhibiting *Castilleja mollis* from making root connections with the goldenbush host plant. (USFWS, 2007)

Stressor: Non-native plants (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Competition with non-native plant taxa was also identified as a threat to *Castilleja mollis* in the final recovery plan (U.S. Fish and Wildlife Service 2000). *Castilleja mollis* is forced to compete with the invasive annual grasses for water and nutrients. This competition weakens the paintbrush, which may contribute to the failure of seedlings to make root connections with the goldenbush host plant (McEachern 2004a). (USFWS, 2007)

Stressor: Soil disturbance and trampling (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Although all cattle have been removed from Santa Rosa Island and deer numbers have decreased, elk numbers have increased since 2001 (see Figures 2 and 3). This is believed to be a continuing factor hindering *Castilleja mollis* recovery on the island (McEachern 2003). (USFWS, 2007)

Stressor: Habitat fragmentation (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Past habitat fragmentation that occurred as a result of grazing and trampling is still considered a major threat to the species. (USFWS, 2007)

Stressor: Predation (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: The listing rule also noted cattle herbivory as a problem for the species, but cattle were removed from Santa Rosa Island in 1998. Cattle removal and the reduction in the number of deer have, so far, not resulted in substantial improvements in *Castilleja mollis*. (USFWS, 2007)

Stressor: Soil disturbance and trampling (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Trends in the number of inflorescences and percent cover suggest that a large-scale event, such as weather, may also influence flowering and growth (McEachern, in litt. 2006b; McEachern, pers. comm. 2006c). (USFWS, 2007)

Stressor: Stochastic events (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Due to the small population size of this species, the listing rule noted that *Castilleja mollis* would be vulnerable to stochastic events (including variable weather patterns such as drought), reduced genetic integrity of the species, and depressed reproductive vigor (62 FR 40957). (USFWS, 2007)

Recovery

Reclassification Criteria:

1. Maintain the existing distribution with multiple colonies in each population on Santa Rosa Island. (USFWS, 2000)
2. Maintain stable or increasing population trends with evidence of natural recruitment for a period of 15 years that includes the normal precipitation cycle. (USFWS, 2000)
3. Damage from normative mammals significantly reduced. (USFWS, 2000)

Delisting Criteria:

1. Expansion of individuals into potential habitat within population boundaries. (USFWS, 2000)
2. No decline after downlisting for 10 years. (USFWS, 2000)

Recovery Actions:

- Provide protection and adaptive management of currently known (and in some cases historic) sites. (USFWS, 2007)

- Provide evidence that the populations at these sites are stable or increasing over a number of years, which is determined by the life history of the individual species. (USFWS, 2007)
- Support and intensify active control programs where herbivory or habitat alteration by alien animals exists. (USFWS, 2007)
- Develop and implement a plan to achieve the goals and standards of the Conservation Strategy. (USFWS, 2007)
- Seed is stored in Center for Plant Conservation cooperating facilities. (USFWS, 2007)
- Seed germination and propagation techniques are understood. (USFWS, 2007)
- Successful outplanting techniques are developed. (USFWS, 2007)
- Host plant and weed management plan are developed and implemented. (USFWS, 2007)
- Life history research is conducted that aids in the conservation and recovery of the species. (USFWS, 2007)
- Hybridization with *Castilleja affinis* is understood. (USFWS, 2007)
- If declining, determine the cause and reverse trend. (USFWS, 2007)

Conservation Measures and Best Management Practices:

- Because the removal of cattle and the reduction in deer have had a positive effect on seedling recruitment, the program to eliminate ungulates from the island by 2011 should continue as planned. (USFWS, 2007)
- During the time that the special use permits are in effect, if targeted hunting of deer and elk is no longer effective, the NPS should consider other actions to reduce the threats of these animals to the species. (USFWS, 2007)
- Based on the reports produced by the Scientific Panel, indeterminate threats, in addition to ungulate herbivory, scraping and general presence are contributing to the decline in the amount of inflorescence and percentage cover of *Castilleja mollis*. Therefore, other parameters that influence the species' ability to recover should be tracked at both locations where the species is found. In particular, the following monitoring actions are recommended: (a) monitor community species composition and cover to indicate whether the habitat is improving; (b) monitor rate of hybridization with *Castilleja affinis* to understand the level of threat this poses on recovering the species; (c) monitor damage to inflorescence, stems, and leaves caused by insects; (d) monitor the number of plants, or seedlings and juveniles within the populations; and (e) monitor the rate of erosion using soil depth/amount of litter. (USFWS, 2007)
- The following downlisting measures outlined in the recovery plan should be implemented: (1) seed storage in a Center for Plant Conservation facility, and (2) development and implementation of host plant and weed management actions. (USFWS, 2007)
- To secure several populations of *Castilleja mollis* containing a minimum of 2,000 plants each, efforts should focus on restoring coastal goldenbush scrub habitat so that there is reduced fragmentation within populations of *Castilleja mollis* on the island. (USFWS, 2007)

SPECIES ACCOUNT: *Catesbaea melanocarpa* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 3/17/1999; Southeast Region (R4) (USFWS, 2015)

Physical Description

A branching shrub that may reach approximately 9.8 feet (ft.) (3.0 meters (m)) in height. Spines are borne at every internode (space between nodes) and are from 0.39 to 0.78 inches (in) (1.00 to 2.00 centimeters (cm)) long. Leaves are small, from 0.19 to 1.0 in (5.00 to 25.00 millimeters (mm)) long, and 0.07 to 0.58 in (2.00 to 15.00 mm) wide, often opposite. The flowers are white, solitary or paired, and almost lacking a stalk in the axils (angle formed by a leaf or branch with the stem). The petals are united in the form of a funnel and measure from 0.31 to 0.39 in (8.00 to 10.00 mm) long. The fruit is black, spherical, and 0.19 to 0.23 in (5.00 to 6.00 mm) in diameter. The two-celled fruit contains five to seven seeds in each cell (Proctor 1991) (USFWS, 2005).

Taxonomy

Catesbaea melanocarpa, of the family Rubiaceae, belongs to a genus that consists of ten or more species of spiny shrubs confined to the Antilles, but some may extend into the Bahamas and the Florida Keys. Some authors have noted that *C. melanocarpa* may be a synonym or variant of *C. parviflora* and have recommended further review (Howard 1989, Proctor 1991). Dr. Frank Axelrod (personal communication (pers. comm.) 2004) of the University of Puerto Rico, however, does not believe that *Catesbaea melanocarpa* is a variety of *C. parviflora* (USFWS, 2005). *C. melanocarpa* is now being referred to by the English common name, Tropical Thorn Lily, by species experts (Morgan and Zimmerman, UVI, poster presentation, 2016). No common name in Spanish has been published. (USFWS, 2018).

Historical Range

Catesbaea melanocarpa was historically known from Puerto Rico, St. Croix in the U.S. Virgin Islands (USVI), Barbuda, Antigua, and Guadeloupe (Proctor 1991) (USFWS, 2011).

Current Range

Catesbaea melanocarpa is currently known from seven areas: the Guánica Commonwealth Forest in Puerto Rico, two privately owned localities in Puerto Rico (Peñones de Melones and Encarnación), one privately-owned locality in St. Croix in the U.S. Virgin Islands, Barbuda, Antigua, and Guadeloupe (USFWS, 2011).

Critical Habitat Designated

Yes; 8/28/2007.

Legal Description

On August 28, 2007, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Catesbaea melanocarpa* (No Common Name) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in the Virgin Islands (72 FR 49212-49228).

Critical Habitat Designation

The critical habitat designation for *Catesbaea melanocarpa* includes one CHU in St. Croix, Virgin Islands. This species critical habitat encompasses approximately 10 acres (ac) (4.3 hectares (ha)) (72 FR 49212-49228).

Halfpenny Bay, St. Croix, U.S. Virgin Islands. (i) General description: The Halfpenny Bay unit consists of approximately 10.5 ac (4.3 ha) on privately owned property located about 2.48 mi (4 km) south of Christiansted, St. Croix, U.S. Virgin Islands. The designated unit is located east of South Shore Road, approximately 342 m (1,122 ft) south of Road 62, approximately 600 m (1,968 ft) north of the Halfpenny Bay coast, and 70 m (230 ft) west of a local road to Halfpenny Bay. This unit encompasses the habitat features essential to the conservation of *Catesbaea melanocarpa* within Estate Granard, Christiansted, St. Croix, and does not contain any manmade structures.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Catesbaea melanocarpa* critical habitat consists of two components (72 FR 49212-49228):

(i) Single-layered canopy forest with little ground cover and open forest floor that supports patches of dry vegetation with grasses, and

(ii) Well to excessively drained limestone and serpentine-derived soils (including soils of the San Germa'n, Nipe, and Rosario series and Glynn and Hogensborg series).

Special Management Considerations or Protections

When designating critical habitat, we assess whether the areas determined to be occupied at the time of listing contain the PCEs that may require special management considerations or protection. As discussed in this section and in the unit description below, we find that all of the PCEs in Halfpenny Bay may require special management considerations or protection due to threats to the species or its habitat from periodic but intense grazing, human-induced fires, and potential development for a tourist project (USFWS 2005, p. 8). Such management considerations and protections include fencing off forest patches to exclude cattle, developing fire-breaks adjacent to existing roads and farm boundaries during dry season, and establishing conservation agreements with landowners to protect habitat within the property.

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (inferred from EPA, 2016)

Breeding Season

Adult: July (EPA, 2016)

Key Resources Needed for Breeding

Adult: Insect pollinators (EPA, 2016)

Reproduction Narrative

Adult: Flowering is observed in July and for several weeks onward. Green and mature fruit observed in July and for several weeks onward. Fruit is also observed in December. Insects are potential pollinators (EPA, 2016).

Habitat Type

Adult: Terrestrial (EPA, 2016)

Habitat Vegetation or Surface Water Classification

Adult: Subtropical dry forest (EPA, 2016)

Habitat Narrative

Adult: Occurs in the subtropical dry forest life zone, the driest life zone in Puerto Rico and U.S. Virgin Islands, this life zone receives a mean annual rainfall ranging from 24 to 40 inches (60 to 100 cm). In Puerto Rico, the vegetation is usually deciduous and forms a nearly continuous canopy with little groundcover. In St. Croix, the species is located on the dry coastal plain. Vegetation is made up of dry thicket scrub, dominated by grasses and patches of trees and shrubs. The site where species is found is an agricultural track that experiences periods of intense grazing. PCEs: 1) Single-layered canopy forest with little ground cover and open forest floor that supports patches of dry vegetation with grasses, and 2) well to excessively drained limestone and serpentine derived soils (including soils of the San German, Nipe, and Rosario series, and Glynn and Hogensborg series) (EPA, 2016).

Dispersal/Migration**Dependency on Other Individuals or Species for Dispersal**

Adult: Unknown (EPA, 2016)

Dispersal/Migration Narrative

Adult: Dispersal mechanisms are unknown (EPA, 2016)

Population Information and Trends**Population Trends:**

Not available

Species Trends:

Stable (USFWS, 2011)

Resiliency:

Low (inferred from USFWS, 2011)

Redundancy:

Low (inferred from USFWS, 2011)

Number of Populations:

4 (USFWS, 2011). The total number of known population locations decreased from four (3 in PR and 1 in USVI) to three (2 in PR and 1 in USVI) with only one individual making up one of the populations in Puerto Rico. (USFWS, 2018).

Population Size:

132 (USFWS, 2011). The total number of individuals has increased from approximately 132 individuals (125 adult plants and 7 wild seedlings) in 2011 to approximately 547 individuals in 2018. Of these, 12 were grown in the UVI greenhouse, and 116 are wild seedlings counted only once in 2013 at Ha'Penny (and carried over here as an estimate). Based on survey data, 406 were found in Ha'Penny, St. Croix, 12 were found in Guanica, Puerto Rico, 1 was found in Penuelas, Puerto Rico, and none were found in Punta Melones, Puerto Rico. In total, 522 individuals are known in the US Virgin Islands, and 13 in Puerto Rico. (USFWS, 2018).

Population Narrative:

The species status is stable; no evident increase or decline within these populations was observed in 2010. The species is currently present in four localities within Puerto Rico and the U.S. Virgin Islands. Based on the data currently available for the Service, the number of individuals is estimated at 132 plants (adults and seedlings) (USFWS, 2011).

Threats and Stressors

Stressor: Habitat destruction and modification (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Deforestation for residential and tourist development may pose imminent threats to the survival of the species. In Puerto Rico, a single individual was reported on a privately-owned land known as Peñones de Melones. This locality was threatened with a proposed high density residential/tourist development. Visits by Service biologist Carlos Pacheco suggest that individuals may no longer exist in Peñones de Melones as deforestation and fires associated with human activity continue within this area. In St. Croix, approximately 100 individuals are present in a privately-owned land. This population is subject to impacts from grazing activities. Also, the development of a golf course has been proposed for the site (USFWS, 2011). Additional disturbances are caused by fire, illegal off-road racing, cattle, and hurricanes. (USFWS, 2018).

Stressor: Limited distribution (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Limited distribution of the species was also identified as an important factor affecting the species. Catastrophic natural events, such as hurricanes, may dramatically affect forest species composition and structure, felling large trees and creating numerous canopy gaps (USFWS, 2011).

Recovery**Reclassification Criteria:**

1. The habitat known to support the two extant populations (St. Croix and Peñones de Melones) is enhanced and protected through landowner conservation agreements or easement (USFWS, 2011).

2. Extant populations are enhanced through the planting of additional propagated individuals to augment the number of adult individuals to at least 250 (USFWS, 2011).
3. At least one population within each of the following previously occupied habitat is found and/or established: Guánica Commonwealth Forest (PR), Susúa Commonwealth Forest (PR), Barbuda, Antigua, and Guadalupe (USFWS, 2011).
4. Research is conducted on key biological and genetic issues, including effective propagation techniques, and number of individuals within a population and number of populations needed for the establishment of self-sustaining populations and a viable overall population (USFWS, 2011).

Delisting Criteria:

1. A number of viable populations (to be determined following the appropriate studies) are protected by long term conservation strategies (USFWS, 2011).
2. viable populations (the number of which should be determined following the appropriate studies) are established in previously unoccupied but suitable habitat at Sandy Point National Wildlife Refuge (USVI), Cabo Rojo National Wildlife Refuge (PR), La Tinaja in Sierra Bermeja (Laguna Cartagena National Wildlife Refuge, PR), and any other identified suitable conservation area within the dry forest zone (USFWS, 2011).
3. The numbers of populations, their sizes, genetic makeup and distribution needed to ensure self-sustainability are determined and achieved (USFWS, 2011).

Recovery Actions:

- Protect existing populations (St. Croix and Cabo Rojo) from current and future threats and/or limiting factors through landowner agreements and other conservation mechanisms (USFWS, 2005).
- Determine the distribution and population status of *Catesbaea melanocarpa* throughout its present and historic range, including Barbuda, Antigua, and Guadalupe (USFWS, 2005).
Refinement in 2019: Conduct a full population assessment, including developing maps (GIS) with spatial information of the species for each area and information on recruitment. Historic data and observation records should be compiled into a single electronic database to inform a full population assessment. (USFWS, 2018).
- Evaluate techniques and develop a plant propagation program for *Catesbaea melanocarpa* (USFWS, 2005). Refinement in 2019: Establish a sound propagation protocol and subsequent plant production program; identify additional suitable habitat and develop partnerships to aid in the reintroduction of the species within its historic range in identified suitable habitat. (USFWS, 2018).
- Enhance existing populations and establish new self-sustaining populations (number of which should be determined by viability analysis) within protected areas by introducing additional individuals developed through propagation. Introduction sites may include, but are not limited to, the Guánica Commonwealth Forest, Susúa Commonwealth Forest, Sandy Point National Wildlife Refuge, and Cabo Rojo National Wildlife Refuge (USFWS, 2005).
- Conduct additional scientific research on *Catesbaea melanocarpa* (USFWS, 2005).

- Facilitate the recovery of *Catesbaea melanocarpa* through public awareness and education (USFWS, 2005).
- Provide technical assistance to Barbuda, Antigua, and Guadalupe for the development of conservation measures for the species (USFWS, 2005).
- Refine recovery criteria (USFWS, 2005).
- New in 2018: Further studies to confirm the presence or absence of *C. melanocarpa* at potential sites in Puerto Rico including an updated status on the population at the Guánica Commonwealth Forest. (USFWS, 2018).
- New in 2018: Identify Territorial and Commonwealth agencies able to monitor current populations and inform those agencies of the status and threats to the species. (USFWS, 2018).

Conservation Measures and Best Management Practices:

- Initiate propagation efforts and establish new populations in protected areas (USFWS, 2011).

SPECIES ACCOUNT: *Caulanthus californicus* (California jewelflower)

Species Taxonomic and Listing Information

Listing Status: Endangered; 07/19/1990; California/Nevada Region (R8) (USFWS, 2015)

Physical Description

Caulanthus californicus is a glabrous decumbent to erect often branched annual, with whitish petals and spherical seeds. Leaves are less than 11 millimeters (mm) (0.4 inch (in.)) in length and are shallowly cut to wavy-dentate and tapered. Calyx petals (outer whorl) are generally spreading, 4–10 mm (0.15–0.4 in.) in length, maroon, keeled, and darker in bud stage. Corolla petals (inner whorl) are 6–11 mm (0.2–0.4 in.) long and whitish, with wavy margins (Buck 1993). (USFWS, 2013)

Taxonomy

USFWS tracks as synonym 01 - *Caulanthus Californicus* (8/93). (NatureServe, 2015)

Historical Range

Originally in San Joaquin and adjacent valleys. Once fairly abundant in appropriate habitat in Fresno, Kern, King, Santa Barbara, San Luis Obispo and Tulare counties. (NatureServe, 2015)

Current Range

Appears to be currently extant in Fresno, Kings, Kern, and Santa Barbara Counties (CalFlora Occurrence Database website Feb. 2, 2000). Extirpated from Kings County, but present in San Luis Obispo County (CNPS Inventory, 2001). (NatureServe, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Dispersal/Migration

Population Information and Trends

Population Trends:

Decline (NatureServe, 2015)

Resiliency:

Low (inferred from USFWS, 2013)

Representation:

Low (inferred from USFWS, 2013)

Redundancy:

Low (inferred from USFWS, 2013)

Population Growth Rate:

Slowly declining (NatureServe, 2015)

Number of Populations:

34 (USFWS, 2013)

Population Narrative:

The long-term decline in population is primarily a result of loss of area and extent of occurrence (and resultant loss of population numbers; NatureServe, 2015). Additionally, the effects of soil nitrification, climate change, loss of pollinators, and loss in genetic diversity are emerging as new threats since the time of listing. (USFWS, 2013). Currently, the CNDDDB indicates that of the 34 occurrences listed as “presumed extant,” 26 occurrences have not been updated in 15 years. (USFWS, 2013)

Threats and Stressors

Stressor: Urbanization (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: At the time of listing the primary threats to *C. californicus* were the ongoing and threatened destruction and adverse modification of habitat due to agricultural land conversion and urbanization on the San Joaquin Valley floor (Service 1990). Non-urbanized or non-converted lands, which largely occurred in the neighboring foothills and valleys, were subject to livestock grazing, oil and gas exploration and development, off-road vehicle use, and mining (Service 1990). (USFWS, 2013)

Stressor: Agriculture (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: The CVP supplies water to more than 250 long-term water contractors in the Central Valley, Santa Clara Valley, and eastern San Francisco Bay Area. Agricultural conversions and related operations either directly or indirectly facilitated by the CVP include: conversion of native habitats to agricultural fields; conversion of land use to more water intensive purposes; disposal of agricultural drain water; application of pesticides; and other mowing and harvesting operations. Agricultural conversion and related operations have contributed to the loss and degradation of several habitat types, including grasslands and alkali scrub associated with declines of multiple listed species (Service 1998). (USFWS, 2013)

Stressor: Mining (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Mining presented a threat to *C. californicus* (Service 1990). On the Carrizo Plain National Monument (Monument), only valid leases, claims and other rights that existed as of the

date of the Proclamation, January 17, 2001, may see mineral development on federal lands within the Monument (BLM 2010). (USFWS, 2013)

Stressor: Oil and Gas Exploration and Development (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: At the time of listing, oil and gas exploration and development presented a threat to *C. californicus* (Service 1990). Adverse effects of oil and gas development on *C. californicus* include the loss of habitat, changes in habitat quality, destruction of individuals or populations and their seed bank, habitat fragmentation, and increased competition from nonnative plant species due to habitat degradation. (USFWS, 2013)

Stressor: Off-road Vehicle Use (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: At the time of listing, off-road vehicle use presented a threat to *C. californicus* (Service 1990). Off road vehicle use has been reported as a minor threat potentially affecting 7 occurrences on the Carrizo Plain National Monument where no off-road motorized or mechanized travel is legally permitted (BLM 2010). (USFWS, 2013)

Stressor: Solar Power Development (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: At the time of listing, solar power development did not present a threat to *C. californicus*. Solar power development projects pose potential threats to and may impact large amounts of habitat. These projects can destroy, fragment, or impact *C. californicus* habitat by: altering landscape topography, vegetation, and drainage patterns; and reducing habitat quality through interception of solar energy normally reaching the ground surface, affecting ambient air temperatures through habitat shading, and altering soil moisture regimes (Smith 1984; Smith et al. 1987 as cited in J.R. Single 2010). Moreover, recently proposed solar projects tend to be large contiguous blocks of disturbance in undeveloped habitat lands, ranging from hundreds to several thousand acres. (USFWS, 2013)

Stressor: Predation (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: At the time of listing, domestic livestock predation was thought to have extirpated colonies of *C. californicus* (Service 1990). On the Carrizo Plain, *C. californicus* is known to occur within and around the precincts or burrows of the endangered giant kangaroo rat (*Dipodomys ingens*). Giant kangaroo rats apparently seek out *C. californicus*, because stems of this species were clipped with equal frequency both on precincts (circular areas with a concentration of giant kangaroo rat burrows) and in interspaces of giant kangaroo rat burrows; however, directed research exploring interactions of plant and animal species in the community should be completed (Cypher 1994). (USFWS, 2013)

Stressor: Grazing (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Domestic livestock grazing has been used to reduce grass and forb competitors in endangered plant habitats; however, the use of domestic livestock grazing to benefit native plant species has had mixed results (Vesk and Westoby 2001; Floyd et al. 2003; Kimball and Schiffman 2003). Direct effects from cattle grazing are reported to be detrimental because cattle seek out and show preference for eating the plant (Service 1998). The habitat of *C. californicus* in Fresno County is grazed after the dispersal of its seeds in late spring and prior to the new growth of its basal rosettes in late winter. (USFWS, 2013)

Stressor: Competition from Nonnative Grasses (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: The southern San Joaquin Valley of California, as with much of western North America, has been invaded by nonnative plant species during the past 100 to 200 years. These include the following species: *Bromus rubens* (red brome), *Vulpia myuros* (mouse tail fescue), *Schismus arabicus* (Arabian grass), *Hordeum murinum* ssp. *glaucum* (known locally as foxtail and elsewhere as smooth barley), *Bromus diandrus* (ripgut brome), and *Bromus hordeaceus* (soft chess) (Biswell 1956; Germano et al. 2001). Individual invasive species could modify ecosystem properties (Gordon 1998). (USFWS, 2013)

Stressor: Competition from Nonnative Plant Species Due to Fire Retardant Application (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Another threat to California jewelflower is invasion and competition from nonnative plant species; this threat could be exacerbated by the application of fire retardant, which can act as a nutrient source for nonnative invasives. California jewelflower habitat includes slightly alkaline sandy loams; the low nitrogen levels of these soil conditions are unfavorable for nonnative, which in turn provides a competitive advantage to species, such as the jewelflower, which have adapted to the nutrient-poor environment. Nitrogen and phosphorus could be increased in the soil through the application of ammonium-based retardants. (USFWS, 2013)

Stressor: Nitrogen Deposition (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Nitrification of soil was not considered a threat at the time of listing *C. californicus*, but should currently be considered a threat. There is little information regarding *C. californicus* and soil nitrogen levels in which it occurs (B. Delgado, BLM pers. comm. 2011), however some adverse soil conditions (low nutrients, low water holding capacity) exert stress on plant species and can reduce competition, particularly for species that are not tolerant of the soil stress factors (R. O'Dell pers. comm. 2011). Human activities have increased nitrogen availability throughout

terrestrial systems (Suding et al. 2005). Three major producers of nitrogen emissions are transportation, agricultural production, and industrial activities including electricity production (Spiegel 2003). (USFWS, 2013)

Stressor: Pollinators (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: At the time of listing, the declines in the pollinators of all descriptions were not considered a threat to *C. californicus*. Since that time, the reduction to the population of the non-native honeybee (*Apis mellifera*), often referred to as colony collapse disorder, has been well documented. Native insects may pollinate the *C. californicus*, however a reduction in their abundance has been observed as well (United States 2007). (USFWS, 2013)

Stressor: Genetic Diversity (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Loss of genetic diversity was not considered a threat at the time of listing *C. californicus*. However, considering the reduction of the range of the *C. californicus* and fragmentation of habitat, lack of cross pollination between populations of the remaining localities may be a future threat. This may result in the loss of genetic diversity, which may reduce the adaptability of the plant to current and future environmental conditions and also increases the threat of inbreeding depression. Loss of genetic diversity and adaptability is likely to reduce the long-term survival of plant species (Huenneke 1991). (USFWS, 2013)

Stressor: Climate Change (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Climate change was not considered a threat to *C. californicus* at the time of listing; however, climate change is a potential threat to the species. Projected California temperature rise estimates range from an increase of 1.7° Celcius to 5.8° Celcius (3.0° Fahrenheit to 10.4° Fahrenheit) for years 2000 - 2100 (Cayan et al. 2006). Climate change has the potential to alter the timing and synchronicity of ecosystem processes. The interactions between flower production and insect availability for pollination may be altered (Field et al. 1999; Cayan et al. 2006). Changes in temperature and precipitation likely will alter the structure, composition, and productivity of vegetation communities and wildfire may become more frequent and intense (Lenihan et al. 2006). (USFWS, 2013)

Recovery

Reclassification Criteria:

1. Secure and protect specified recovery areas from incompatible uses on ninety-five percent of occupied habitat on public lands; 75 percent of population and occupied habitat in Santa Barbara Canyon. (USFWS, 2013)

2. Management Plan approved and implemented for recovery areas that include survival of the species as an objective for all protected areas identified as important to continued survival. (USFWS, 2013)

3. Population monitoring for specified recovery areas shows that the populations are stable or increasing through the normal precipitation cycle. (USFWS, 2013)

Delisting Criteria:

Delisting criteria is not available.

Recovery Actions:

- Surveys will be necessary to determine whether natural populations remain in all target areas. (USFWS, 1998)
- Unoccupied habitat within metapopulations also should be protected to facilitate movement of pollinators and seed dispersers. (USFWS, 1998)
- The top-priority action for recovery of California jewelflower is to protect the plants on private land in Santa Barbara Canyon. (USFWS, 1998)
- Buffer zones of 150 meters (500 feet) or more should be protected beyond the population margins to reduce external influences and to allow for population expansion. (USFWS, 1998)
- Additional tasks are required to achieve recovery goals. These tasks include developing management plans, surveying for additional populations, banking seed, conducting research, and modeling population demographics using matrix projection modeling. (USFWS, 1998)

Conservation Measures and Best Management Practices:

- Protection of extant populations and reintroductions as described in the 1998 Recovery Plan should be completed. Management on public lands should include provisions for suitable levels of sheep and cattle grazing. Protection of colonies on private lands or those to be re-established on private lands could result from partnering with landowners or offering conservation easements. (USFWS, 2013)
- Regular yearly surveys utilizing a standardized methodology should be conducted over the next five years at the Santa Barbara Canyon area in the Cuyama Valley in Santa Barbara County, at the Carrizo Plain National Monument in San Luis Obispo County, and at the Kreyenhagen Hills in Fresno County so that the determination of what constitutes a sustainable population can be defined and environmental variables affecting abundance, such as precipitation and temperature, can be monitored. (USFWS, 2013)
- Successful re-establishment of populations will require an adequate understanding of the biology of the species and a robust seed collection. Studies should be conducted that advance the understanding of the species' propagation requirements, knowledge of the physical and chemical elements of the soil required for successful re-establishment, the presence and role of mutualistic soil fungi, the species and role of pollinators, genetics, and seed dispersal mechanisms. Seeds should be collected from each of the three sites and banked at an appropriate depository. (USFWS, 2013)
- Threats such as loss and degradation of habitat should be eliminated, reduced, or ameliorated. The potential for habitat degradation due to nitrogen deposition and threats to pollinators from regional pesticide use should be analyzed and appropriate measures to ameliorate these threats should be implemented. (USFWS, 2013)

SPECIES ACCOUNT: *Ceanothus ferrisiae* (Coyote ceanothus)

Species Taxonomic and Listing Information

Listing Status: Endangered; 02/03/1995; California/Nevada Region (R8) (USFWS, 2015)

Physical Description

An evergreen shrub, 1-2 m tall. Leaves are < 3.2 cm long, rounded, tapering towards the base. The leaves are opposite and round with a dark green, hairless upper surface and a lighter green undersurface with minute hairs (Schmidt 1993). Leaf margins have short teeth or sometimes lack teeth; the leaf base is abruptly tapering or rounded. Small white flowers are borne in clusters 1.3 to 2.5 centimeters (0.5 to 1.0 inch) in length (McMinn 1933; Schmidt 1993). (NatureServe, 2015; USFWS, 2011)

Taxonomy

USFWS and CAHP tracks as synonym 01 - *Ceanthous ferrisiae* (9/93). (NatureServe, 2015)

Historical Range

See current range/distribution.

Current Range

Ceanothus ferrisiae are known from only three locations: Anderson Dam, Kirby Canyon, and Llagas Avenue north of Morgan Hill. All the locations are within 6 kilometers (4 miles) of each other in Santa Clara County (USFWS, 1998)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (inferred from USFWS, 2011)

Lifespan

Adult: 20 to 50 years (USFWS, 2011)

Breeding Season

Adult: January to March (USFWS, 2011)

Key Resources Needed for Breeding

Adult: Possibly fire; require multiple, large populations within close proximity to allow genetic migration to occur via pollination (USFWS, 2011)

Reproduction Narrative

Adult: *Ceanothus ferrisiae* is a perennial, flowering from January to May (Munz and Keck 1959). *Ceanothus* reach reproductive maturity after 5- 6 years. Will hybridize with other species or sub-

species in situations where only one plant exists or there is genetic incompatibility with surrounding plants of the same species. (USFWS, 2011). The role of fire in the ecology of this plant remains unclear. Fire appears to destroy all mature and older plants, and stimulate regeneration from soil seed banks. *C. ferrisae* require multiple, large populations within close proximity to allow genetic migration to occur via pollination. The average lifespan for this species is estimated to range from 20 to 50 years (Keeley 1975; T. Parker, pers. comm., 2010; D. Wilken, pers. comm., 2010). (USFWS, 2011)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Barrens, Shrubland/chaparral (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Possibly fire (USFWS, 2011)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations < 300 m (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Colonial (USFWS, 2011)

Environmental Specificity

Adult: Narrow/specialist (inferred from USFWS, 2011)

Dependency on Other Individuals or Species for Habitat

Adult: Rare species associated with *Ceanothus ferrisae* include the federally listed bay checkerspot butterfly (*Euphydryas editha bayensis*), Santa Clara Valley dudleya (*Dudleya setchellii*), and most beautiful jewelflower (*Streptanthus albidus* ssp. *peramoenus*) (Evens and San 2004). It is also associated with bigberry manzanita (*Arctostaphylos glauca*), California coffee berry (*Rhamnus californica*), California sagebrush (*Artemisia californica*), common yarrow (*Achillea millefolium*), foothill pine (*Pinus sabiniana*), leather oak (*Quercus durata*), and toyon (*Heteromeles arbutifolia*) (Corelli 1991; Evens and San 2004). Fire appears to destroy all mature and older plants, and stimulate regeneration from soil seed banks. (USFWS, 2011)

Habitat Narrative

Adult: *Ceanothus ferrisae* grows on arid slopes in mixed serpentine chaparral, valley, and foothill serpentine bunchgrass grasslands below 300 meters (about 1,000 feet) (Munz and Keck 1959; Hickman 1993). *C. ferrisae* is found in colonies at the Llagas Road location (CNDDDB, 2010). Rare species associated with *C. ferrisae* include the federally listed bay checkerspot butterfly (*Euphydryas editha bayensis*), Santa Clara Valley dudleya (*Dudleya setchellii*), and most beautiful jewelflower (*Streptanthus albidus* ssp. *peramoenus*) (Evens and San 2004). It is also associated with bigberry manzanita (*Arctostaphylos glauca*), California coffee berry (*Rhamnus californica*), California sagebrush (*Artemisia californica*), common yarrow (*Achillea millefolium*), foothill pine (*Pinus sabiniana*), leather oak (*Quercus durata*), and toyon (*Heteromeles arbutifolia*) (Corelli 1991; Evens and San 2004). (USFWS, 2011)

Dispersal/Migration**Dispersal/Migration Narrative**

Population Information and Trends**Population Trends:**

Declining (USFWS, 2011)

Resiliency:

Very low (inferred from USFWS, 2011)

Representation:

Low (inferred from USFWS, 2011)

Redundancy:

Low (inferred from USFWS, 2011)

Number of Populations:

4 (USFWS, 2011)

Population Size:

>100,000 (USFWS, 2011)

Minimum Viable Population Size:

5000 (USFWS, 2011)

Adaptability:

Low (inferred from USFWS, 2011)

Population Narrative:

Two of the four existing occurrences of *Ceanothus ferrisiae* have population sizes greater than 2,000 individuals (3,600 and > 100,000, respectively). Information available to the Service suggests a minimum population size of 5,000 may be necessary to maintain 95 percent fitness for plants (Reed 2005). A genetic Allee effect may be occurring as a result of limited availability of genetically suitable pollen mates in small populations of plants, thereby decreasing reproductive rates and increasing the risk of extinction (Berec et al. 2006; Wagenius et al. 2007). The survival and recovery of existing *C. ferrisiae* populations may be threatened by limited genetic diversity as a result of small or declining population size, habitat loss and fragmentation, and geographic isolation that may limit insect-mediated gene flow. (USFWS, 2011)

Threats and Stressors

Stressor: Habitat destruction (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Destruction and modification of habitat, and development on recreational and private lands continues to be a threat for *Ceanothus ferrisiae*. Construction of a commercial landfill at Kirby Canyon beginning in 1986 (prior to the listing of *C. ferrisiae* in 1995) may have resulted in the undocumented loss of thousands plants, as evidenced by the decline of this population from 5,000 in 1987 to about 100 individuals observed in 1992 (Freas, pers. comm. 1993; LSA Associates 1992). The remaining population is currently threatened by altered fire regime and lack of recruitment. Proximity to the commercial landfill and urban development may limit or prevent the use of fire for regeneration. The Llagas Road population exists on private land that is nearly surrounded by residential development. Future development could result in increased encroachment upon existing habitat necessary for expansion of the Llagas Road population to meet recovery goals. The proximity of urban development may limit or prevent the use of fire to regenerate this population as well. (USFWS, 2011)

Stressor: Cattle grazing (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Cattle have been grazing on the property for many years and may be negatively affecting the habitat and limiting recruitment for the Llagas Road population. The unprotected portion of the property where cattle grazing is permitted is nearly denuded of native chaparral vegetation with large areas of exposed soil and serpentine rocks evident (F. Gardipee pers. obs., 2010; T. Willsey, pers. obs., 2010; J. Hillman, pers. obs., 2010). The cattle have gained access into the existing conservation easement through broken fencing thereby allowing them to browse on inflorescences of young *C. ferrisiae* plants before seed production can occur (F. Gardipee pers. obs., 2010; T. Willsey, pers. obs., 2010; J. Hillman, pers. obs., 2010). Heavy browsing by cattle and wild ungulates was observed among young, reproductive-age, plants during the fall 2010 survey at all sites (F. Gardipee pers. obs., 2010; T. Willsey, pers. obs., 2010; J. Hillman pers. comm., 2010). (USFWS, 2011)

Stressor: Dam activities (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: The population located at Anderson Dam is threatened by loss and modification of habitat as a result of activities associated with the dam, actions to protect against damage from potential seismic activity, and un-regulated land management practices. Anderson Dam was constructed upon unstable materials and is positioned on a seismically active fault line (SCVHP 2010). (USFWS, 2011)

Stressor: Predation (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Several insect species have been noted to infest *Ceanothus* species in California and predation in the form of herbivory by native ungulates and seed consumption by small mammals, insects, and birds is common (Deveny and Fox 2006). The western tent caterpillar (*Malacosoma californicum*) is known to construct large web-like tents on the branches of *Ceanothus* species (USDA 2006). Larvae feed on the leaves within the tent, often defoliating entire branches (USDA

2006). The western tussock moth (*Orgyia vetusta*) has been reported on *Ceanothus* species (USDA 2006). Large masses of cocoons may be observed on branches in late spring. Western tussock moth larvae feed on leaves and young growth, sometimes causing substantial defoliation and branch dieback. The western sycamore borer (*Synanthedon resplendens*) may attack *Ceanothus* species (USDA 2006). Adults emerge in May through early August and lay eggs within cracks, depressions, and injured tissues in the bark of old or slow-growing plants (USDA 2006). After hatching, larvae tunnel into the inner bark, creating winding tunnels that extend over 100 square centimeters (about 15.5 square inches). The amount of Herbivory may retard plant growth, destroy plants, and often reduces seed production (Boyd 2003; Deveny and Fox 2006). Black-tailed deer (*Odocoileus hemionus columbianus*) are primary browsers of *C. ferrisiae* (Deveny and Fox 2006). Herds of black-tailed deer make their home in the Anderson Dam area. Evidence of browsing on fresh shoots, inflorescences, and leaves of young *C. ferrisiae* plants was observed among all populations surveyed in mid-July and fall 2010 (F. Gardipee, pers. obs., 2010; T. Willsey, pers. obs., 2010; J. Hillman, pers. obs., 2010). Damage caused by western sycamore borers is generally considered to be insignificant (USDA 2006). (USFWS, 2011)

Stressor: Genetic Allee effect (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: A genetic Allee effect may occur as a result of limited availability of genetically suitable pollen mates in small populations of plants, thereby decreasing reproductive rates and increasing the risk of extinction (Berec et al. 2006; Wagenius et al. 2007). Habitat loss and fragmentation, small population size, and genetic isolation may increase the risk of a genetic Allee effect for self-incompatible species, such as *Ceanothus ferrisiae*, and ultimately result in a subsequent loss of long-term population viability (Willi et al. 2005; Berec et al. 2006; Leimu et al. 2006; Honnay and Jacquemyn 2007; Wagenius et al. 2007; Pickup and Young 2008). The subdivision of this population has resulted in possible isolation and reduced connectivity, thus increasing the risk of genetic Allee effects and decreased population viability. (USFWS, 2011)

Stressor: Fire management (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: The proximity of *Ceanothus ferrisiae* to residential development may preclude or limit the use of fire that may be necessary for stand regeneration. Further research regarding the role of fire for *C. ferrisiae* is warranted to insure effective use of this management tool can be applied to benefit the long-term conservation of this species. (USFWS, 2011)

Stressor: Global climate change (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, altered fire regimes, and increased summer continental drying (Field et al. 1999; Cayan et al. 2005; IPCC 2007). However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain.

However, climate change may exacerbate the effects of altered fire regimes on population viability of *Ceanothus* species endemic to California (Lawson et al. 2010). (USFWS, 2011)

Recovery

Reclassification Criteria:

1. Protection and management of the four known occurrences of *Ceanothus ferrisiae* by working with Santa Clara County, the SCVWD, and private landowners to ensure long-term survival of the species on their lands. (USFWS, 2011)
2. Survey of other potential serpentine habitats to identify potential habitat. (USFWS, 2011)
3. Seed collection and research. Collection and banking of seed in Center for Plant Conservation certified botanic gardens is prudent to guard against extinction of the species from catastrophic events and to provide potential material for enhancement efforts in existing populations, repatriations, and/or introductions to new sites. All known populations should be represented in seed collections. Care should be taken to ensure that seed collection does not adversely affect the donor populations. (USFWS, 2011)
4. Research on demography, fire ecology, and effects of grazing. Important research questions include how grazing impacts the reproduction, recruitment, and survival of the species, and why so little recruitment is observed in natural populations. (USFWS, 2011)
5. Establishment of new populations to meet recovery goal of eight populations representing the entire historic range. *Ceanothus ferrisiae* should not be considered for delisting unless eight populations, consisting of at least, 2,000 individuals, within its historic range and representing its entire historic range. (USFWS, 2011)

Delisting Criteria:

Delisting criteria are not available.

Recovery Actions:

- Recovery actions are not available.

Conservation Measures and Best Management Practices:

- Habitat conservation to support the survival and recovery of *Ceanothus ferrisiae* should be accomplished through land acquisition and establishment of conservation easements where possible. Protection of *C. ferrisiae* populations on private lands through additional conservation easements and land purchases, and restoration of additional populations within the historic range should be prioritized to minimize the likelihood of extinction. (USFWS, 2011)
- Research that will inform management decisions, conservation planning, and restoration efforts for *Ceanothus ferrisiae* should be conducted. (USFWS, 2011)
- Establishment of additional *Ceanothus ferrisiae* populations where appropriate serpentine chaparral habitat has been identified in the proposed SCVHP. Restoration efforts should target habitat sites that can support a minimum population of at least 5,000 individuals. (USFWS, 2011)
- Enhancement and regeneration of existing populations of *Ceanothus ferrisiae* to achieve minimum populations of 5,000 plants through various strategies. For example, implementation of an optimal fire regime (determined through research) to stimulate seedling production from the soil seed bank

may prove to be a successful strategy to increase small population sizes. Fire applied to small areas over several years may yield large, sustainable populations, consisting of a mosaic of age classes and genotypes, which may be less vulnerable to stochastic events and senescence. Translocation efforts may prove successful as well. (USFWS, 2011)

SPECIES ACCOUNT: *Ceanothus ophiochilus* (Vail Lake ceanothus)

Species Taxonomic and Listing Information

Listing Status: Threatened; 10/13/1998; California/Nevada Region (R8) (USFWS, 2015)

Physical Description

A rounded shrub, usually 1.2-1.5 m (4-5 feet) tall. The flat, dull green leaves are opposite, with knob-like stipules, narrowly oblanceolate (broadest above the middle and tapering toward the base) to obovate (eggshaped) in shape, glabrous (smooth), with obscure veins and blades 3 to 7 mm long and 1 to 3 mm wide; fruits are 3 to 3.5 mm wide, and without horns (Wilken 2012, p. 1158). Flowers are pale blue, occasionally pink, in bloom from mid-February to March. (NatureServe, 2015)

Historical Range

See current range/distribution.

Current Range

Ceanothus ophiochilus is a narrow, edaphic endemic plant found only within 20 acres in Southwestern Riverside County, California (Fish and Wildlife Service 1998). (NatureServe, 2015)

Critical Habitat Designated

Yes; 9/27/2007.

Legal Description

On September 27, 2007, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Ceanothus ophiochilus* (Vail Lake ceanothus) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in California (72 FR 54984-55010).

Critical Habitat Designation

The critical habitat designation for *Ceanothus ophiochilus* includes one CHU (2 sub-units) in Riverside County, California. This species critical habitat encompasses approximately 283 acres (ac) (115 hectares (ha)) (72 FR 54984-55010).

Unit 1: Western Riverside County Unit 1 is located near Vail Lake in southern Riverside County, California. The area was occupied at the time of listing and contains all of the primary constituent elements essential to the conservation of the species that may require special management considerations or protection for *Ceanothus ophiochilus*. Below, we present a brief description of subunit 1B, reasons why it meets the definition of critical habitat for *C. ophiochilus*, and our rationale for our final designation of critical habitat. Subunit 1B, Agua Tibia Mountains, Riverside County, California Subunit 1B (Agua Tibia Mountains) consists of 203 ac (82 ha) of land which is managed by the USFS. Subunit 1B contains two of the three CNDDDB element occurrences (2 and 3) of *Ceanothus ophiochilus*, both known at the time of listing. The PCEs within this subunit may require special management considerations or protection to address the threats posed by short-interval fires, competing nonnative species, impacts to ridge tops (PCE 1) from grading associated with the creation of fuel breaks and impacts to the associated vegetation community (PCE 3) resulting from unnatural fire regimes. Subunit 1B is entirely within the Agua Tibia Wilderness of

the Cleveland National Forest. Recently the USFS completed the LMP for the Four Southern California National Forests. Implementation of the LMP was analyzed by the Service to address potential impacts to *Ceanothus ophiochilus*. This analysis found that impacts to *C. ophiochilus* would be minor or negligible upon implementation of appropriate minimization measures due to the low impact nature of activities planned (e.g., dispersed recreation, non-motorized trails) (Service 2005 p. 129–132). However, the LMP does not identify specific management measures to address the threat posed by short interval fires and by competing nonnative species (Keeley 2006, p. 367; Merriam et al. 2007, p. vi, v, 48, 61). Because the USFS does not have a management plan specific to *C. ophiochilus* that provides the same or better level of protection from adverse modification or destruction than that provided through a consultation under section 7 of the Act, we have determined that exclusion of these lands from the final designation of critical habitat pursuant to section 4(b)(2) of the Act is not appropriate for these Federal lands (please see “Exclusions under Section 4(b)(2) of the Act” for a detailed discussion). Therefore, we are designating the USFS lands containing features essential to the conservation of *C. ophiochilus* as critical habitat for this species.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Ceanothus ophiochilus* critical habitat consists of three components (72 FR 54984-55010):

- (i) Flat to gently sloping north to northeast facing ridge tops with slopes in the range of 0 to 40 percent slope that provide the appropriate solar exposure for seedling establishment and growth.
- (ii) Soils formed from metavolcanic and ultra-basic parent materials and deeply weathered gabbro or pyroxenitic outcrops that provide nutrients and space for growth and reproduction. Specifically in the areas that *Ceanothus ophiochilus* is found, the soils are: (A) Ramona, Cienaba, Las Posas, and Vista series in the Agua Tibia Wilderness; and (B) Cajalco series in the vicinity of Vail Lake.
- (iii) Chamise chaparral or mixed chamise-ceanothus-arctostaphylos chaparral at elevations of 2,000 feet to 3,000 feet (610 meters to 914 meters) that provide the appropriate canopy cover and elevation requirements for growth and reproduction.

Special Management Considerations or Protections

As stated in the final listing rule, threats to *Ceanothus ophiochilus* include habitat destruction, alteration, fragmentation, and degradation from urban development, as well as hybridization and fire at too frequent intervals to allow for sufficient seed bank replenishment in the soil (63 FR 54956, October 13, 1998). Threats to *Fremontodendron mexicanum* as cited in the final listing rule include altered fire regimes, indirect impacts from nearby urbanization, and increased competition from nonnative species (63 FR 54965, October 13, 1998). These threats could impact the PCEs determined to be essential for conservation of *C. ophiochilus* and *F. mexicanum*. Urban development near *Ceanothus ophiochilus* critical habitat units may alter the habitat characteristics required by the species. Land grading in and around occurrences of *C. ophiochilus* may affect the topography of the habitat and change the soil composition (PCEs 1 and 2) rendering the habitat unsuitable for species growth and reproduction. Urban development may also encourage invasion by nonnative plant species, changing the vegetation community and/or

directly impacting the vegetation community (PCE 3). In addition, urban development near this species may increase the frequency of fire. All identified private land is covered by the Western Riverside County MSHCP (MSHCP), and those lands have been excluded from the final designation (see “Relationship of Critical Habitat to Habitat Conservation Plan Lands—Exclusions Under Section 4(b)(2) of the Act” section for a detailed discussion). No urban development is expected to directly impact the occurrences of *C. ophiochilus* on land owned by the USFS. Therefore, we do not believe threats from urban development would require special management considerations or protection of the PCEs on designated critical habitat for this species. The management of both fire frequency and the placement of fuel breaks is important for the conservation of *Ceanothus ophiochilus*, and special management considerations or protection of the PCEs for *C. ophiochilus* may be required on USFS lands to address potential threats posed by fire management activities. In the past, fuel breaks have been placed on the ridgelines (PCE 1) in *C. ophiochilus* habitat and have caused soil disturbance (PCE 2). Studies of fuel breaks in the Cleveland National Forest near the critical habitat designation have demonstrated an increase in the density of competing nonnative species (Merriam et al. 2007, p. 48), and it has been hypothesized that fuel breaks promote the introduction and spread of nonnative plants (Merriam et al. 2007, p. vi). These nonnative invasive plants alter local fuel conditions and change fire behavior and frequency (Merriam et al. 2007, p. 61). *Ceanothus ophiochilus* is very sensitive to short-interval fires, which may extirpate the species from a site entirely (Keeley 2006, p. 367). Soil disturbance, caused by the creation of fuel breaks, has also led to increased hybridization between *Ceanothus ophiochilus* and *C. crassifolius*. However, the degree to which hybridization is impacting *C. ophiochilus* and its habitat is not yet known.

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Sexual (hybridization) (USFWS, 2013)

Breeding Season

Adult: Mid-February to March (NatureServe, 2015)

Key Resources Needed for Breeding

Adult: Fire (USFWS, 2013)

Reproduction Narrative

Adult: Flowers are pale blue, occasionally pink, in bloom from mid-February to March (NatureServe, 2015). Hybridization is common among *Ceanothus* species (Wilken 2012, p. 1153; Fross and Wilken 2006, pp. 132–133). *Ceanothus ophiochilus* generally requires a fire return interval between 10 to 20 years to adequately replenish the seed bank (Keeley and Davis 2007, p. 350). *Ceanothus ophiochilus* is an obligate seeder and therefore does not resprout following fire, but instead recovers through the germination of seeds stored in the soil (Boyd and Banks 1995, p. 28; Keeley 2006, p. 367). (USFWS, 2013)

Habitat Type

Adult: Terrestrial (NatureServe, 2013)

Habitat Vegetation or Surface Water Classification

Adult: Shrubland/chaparral

Dependencies on Specific Environmental Elements

Adult: Fire (USFWS, 2013)

Spatial Arrangements of the Population

Adult: Isolated patches (USFWS, 2013)

Environmental Specificity

Adult: Narrow/specialist (NatureServe, 2015)

Habitat Narrative

Adult: *Ceanothus ophiochilus* is restricted to isolated patches of gabbro and pyroxenite-rich outcrops (Vail Lake), or within a mix of gabbro and sedimentary deposits (Agua Tibia Wilderness) (Boyd and Banks 1995, p. 15). It is generally found within chamise chaparral habitats on ridge tops and north- to northeast-facing slopes (USFWS, 2013). *Ceanothus ophiochilus* generally requires a firereturn interval between 10 to 20 years to adequately replenish the seed bank (Keeley and Davis 2007, p. 350). (USFWS, 2013)

Dispersal/Migration**Motility/Mobility**

Adult: Low (USFWS, 2013)

Dispersal/Migration Narrative

Adult: Many plant species with refractory seeds (i.e., seeds that need a fire-related stimulus, alone or in conjunction with other conditions; Keeley 1991, p. 87) have propagules that are not specialized for widespread dispersal and therefore have a relatively short dispersal distance (Keeley 1991, p. 105). *Ceanothus* plants have capsules that eject seeds and studies on two Sierra Nevada *Ceanothus* species, *C. cuneatus* and *C. leucodermis*, found that most seeds fall beneath the canopy vegetation (Evans et al. 1987, p. 288); even on open sites, few seeds (less than 2 percent) reached a distance of 29.5 ft (9 m) (Evans et al., 1987, pp. 288–289). (USFWS, 2013)

Population Information and Trends**Population Trends:**

Number of Populations:

3 (USFWS, 2013)

Population Size:

~10,000

Population Narrative:

One population consists of about 3,000-5,000 individuals and occupies about 8 hectares; the remaining two populations comprise over 4,000 individuals in a 12 hectare area (Fish and Wildlife Service 1998). Known from only three occurrences near Vail Lake, California (Skinner 1997). (NatureServe, 2015).

Threats and Stressors

Stressor: Urban development (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: At the time of listing, the Service indicated that much of southwestern Riverside County was expected to become more urbanized based on development trends and planned developments on private lands in the Vail Lake area (USFWS 1998, p. 54961). In the 2008 5-year review, the Service reevaluated the proposed developments for this area and stated that the most recently proposed, large-scale development (Specific Plan No. 324) for this area had not been acted upon and the project was inactive (USFWS 2008, p. 8). However, the Service concluded that urban development in the Vail Lake area remained a significant threat to the Vail Lake occurrence of *Ceanothus ophiochilus* since no assurances of the conservation of this species have been made (USFWS 2008, p. 8). In summary, the Service believes that urban development represents a potential threat to *Ceanothus ophiochilus* at two of the three occurrences. (USFWS, 2013)

Stressor: Recreational activities (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Dispersed recreation (e.g., camping, hiking, mountain bike activity) is an occasional, ongoing use at the Agua Tibia Wilderness occurrences (USFS 2012b, p.41). The use of existing trails or the creation of new trails within the Agua Tibia Wilderness occurrences located on CNF lands represents a potential threat to *Ceanothus ophiochilus* primarily from soil compaction of habitat, although trampling of individual plants may also result from these activities. However, no designated USFS trails currently intersect with habitat occupied by *C. ophiochilus* (USFS 2012b, p. 41) and the recreational use, although allowed in or near the two Agua Tibia Wilderness occurrences within CNF by the public, is limited because access is controlled by adjacent private lands (USFS 2012b, pp. 40–41). (USFWS, 2013)

Stressor: Invasive non-native plants (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Invasive nonnative plants have been identified by the USFS as a threat to habitat quality for *Ceanothus ophiochilus*, particularly in those areas within the Agua Tibia Wilderness occurrences where recent wildland fire has exposed bare soils and created unclassified trails as a result of fire suppression activities (USFS 2005a, p. 259). Roads and road construction from grading of fuel breaks facilitate the introduction and establishment of invasive nonnative plants (discussed above) by creating open, continually disturbed habitat. Invasive nonnative plants can also be transported along these corridors by equipment and other vehicles, as well as recreational uses, and can become more readily established on exposed cut-and-fill slopes of roads than native plants (USFS 2005e, Volume 1, p. 114). Activities conducted by the USFS associated with the removal of invasive plants may have short-term adverse effects to *Ceanothus ophiochilus*. (USFWS, 2013)

Stressor: Wildland fire and fire Management (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: In the USFWS listing rule, the Service identified the change in fire cycle regimes (or fire frequency) as a threat to *Ceanothus ophiochilus* and other plants adapted to specific fire frequencies (USFWS 1998, p. 54964). Changes occurred from increased incidence of local accidental fires and less frequent natural fires resulting from human activity in fire prone areas (e.g., Vail Lake occurrence). The Service also highlighted fire management practices including grading of *C. ophiochilus* habitat for fire or implementation of fuel breaks as an important threat to this species for all three occurrences (Boyd 1991, pp. 2, 8; Boyd and Banks 1995, p. 16; USFWS 1998, p. 54961). Fire management and suppression activities including fire line construction, fire retardant and water drops, establishment of temporary fire camps, staging areas, parking sites, safety zones, helipads, and post-fire rehabilitation can affect *Ceanothus ophiochilus* habitat (USFWS 2005, p. 27). (USFWS, 2013)

Stressor: Hybridization and introgression (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: The Service identified hybridization and genetic introgression with *C. crassifolius* as a major threat to *C. ophiochilus* where the two species co-occur in our 2008 5-year review (USFWS 2008, p. 14). Without genetic evaluations and comprehensive surveys within the three occurrences, it is difficult to assess the nature and extent of hybrid individuals; thus, it is unclear if hybridization or introgression represents a current threat to *C. ophiochilus* at this time. Continued monitoring of disturbance to all three occurrences is needed in conjunction with additional genetic viability studies to better evaluate these two related threats to *C. ophiochilus*. (USFWS, 2013)

Stressor: Climate change (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Based on the best available information contained in model predictions for this general region of California, a change in temperature conditions resulting from climate change is considered a rangewide threat to *Ceanothus ophiochilus* due to predicted changes to its habitat.

Climate model predications also indicate a slight increase in fire risk to the geographical range of *C. ophiophilus*, which, when combined with anthropogenic facilitation, can produce a shortening of the fire return interval and affect its ability to recover and maintain its viability in the chaparral ecosystem. (USFWS, 2013)

Recovery

Reclassification Criteria:

Reclassification criteria are not available.

Delisting Criteria:

Delisting criteria are not available.

Recovery Actions:

- Recovery actions are not available.

Conservation Measures and Best Management Practices:

- Continue to work with the CNF to ensure that USFS guidelines and directives are being implemented for activities that might directly or indirectly impact *Ceanothus ophiophilus* habitat. This should include providing comment on biological assessments for proposed fire suppression activities and assistance in designing fuel breaks to protect populations of *C. ophiophilus*. (USFWS, 2013)
- Conserve or preserve *Ceanothus ophiophilus* occurrences on private lands, especially at Vail Lake. Pursue opportunities to purchase parcels through the Act's section 6 funding and other conservation partnership programs (i.e., Western Riverside County MSHCP) with willing sellers. (USFWS, 2013)
- Develop outreach or educational activities with the primary landowner adjacent to the Agua Tibia Wilderness–North occurrence to enlist their assistance in ensuring the survival and recovery of *Ceanothus ophiophilus*. (USFWS, 2013)
- Develop a monitoring plan for populations of *Ceanothus ophiophilus*, the quality of chamise chaparral habitats, and threats at the three *C. ophiophilus* occurrences. This monitoring plan should include surveys to detect abundance, habitat conditions, and potential threats to the taxon, particularly those related to the effects of fire and fire management activities. (USFWS, 2013)
- Determine the current level and pattern, extent, and impact of introgression of *Ceanothus ophiophilus* with *C. crassifolius* at all three occurrences. (USFWS, 2013)

SPECIES ACCOUNT: *Ceanothus roderickii* (Pine Hill ceanothus)

Species Taxonomic and Listing Information

Listing Status: Endangered; 11/18/1996; California/Nevada Region (R8)

Physical Description

A prostrate evergreen shrub of the buckthorn family (Rhamnaceae) that generally grows to 3 meters (9.8 feet) in diameter. The smooth gray-brown branches radiate from a central axis and root when they come into contact with the ground. Its leaves are semi-erect with entire (smooth-edged) margins. Small whitish flowers tinged with blue appear from May through June. Its fruit is an inconspicuously horned, globe-shaped capsule. *Ceanothus roderickii* can be differentiated from its congeners (other species of the same genus, other related species) by a combination of its blue-tinged flowers, prostrate habit, and inconspicuously horned fruit. (USFWS, 2002)

Taxonomy

Walter Knight (1968) described *Ceanothus roderickii* as *Ceanothus rodericki*, naming it after Wayne Roderick, who first recognized the horticultural value of this endemic shrub. Due to an orthographic change, the correct spelling is *Ceanothus roderickii*. Knight (1968) considered *C. roderickii* to be most closely related to *C. cuneatus* (buckbrush), which also grows throughout the area. *Ceanothus roderickii* is suggested to resemble the sprawling *C. fresnensis* (Fresno mat), which grows a considerable distance to the south at higher elevations; plants of the two species grown in a regional park flowered at different times (Knight 1968). (USFWS, 2002)

Historical Range

Endemic to western El Dorado County, California. (USFWS, 2002)

Current Range

On the Pine Hill formation in western El Dorado County, California.(USFWS, 2019)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Dependency on Other Individuals or Species

Adult: The pollination of *Ceanothus roderickii* is primarily by insects from the orders Diptera (flies and gnats) and Hymenoptera (bees and wasps). (USFWS, 2002)

Breeding Season

Adult: May to June (USFWS, 2002)

Key Resources Needed for Breeding

Adult: Fire/heat (USFWS, 2002)

Reproduction Narrative

Adult: Flower/fruit development in this species is negatively affected by canopy shading (James 1996). Unlike most chaparral shrub species, Pine Hill ceanothus will not resprout from a caudex (woody axis comprising the stem and root) after a fire, and therefore, depends on nearby plants connected via branch layering for survival or the seedbank for re-establishment (Boyd 2007). There is reason to believe that seeds can survive at least 80 years in the seedbank (Ayres 2011; Boyd 2007). Hot/cold stratification, but not necessarily fire (Boyd 2007), seems to be required for germination (James 1996; Boyd 2007). Because juvenile plants do not begin flowering until 5-6 years after fire, populations need a fire-free period of at least six years to replenish the seed bank (Marsh and Ayres 2002; Ayres 2011), otherwise populations may be permanently lost. (USFWS, 2019)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Barrens, Shrubland/chaparral (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Combination of heat and cold (USFWS, 2002)

Geographic or Habitat Restraints or Barriers

Adult: Shading limits flower production (USFWS, 2002)

Spatial Arrangements of the Population

Adult: Scattered (USFWS, 2002)

Habitat Narrative

Adult: Ceanothus roderickii is found in openings in chaparral communities on gabbro- or serpentinite- derived soils (NatureServe, 2015). Most occurrences are discontinuously scattered within two population centers in the northern and southern portions of the Pine Hill formation. The seeds treated with a combination of heat and cold have the best germination rate. Canopy shading was shown to negatively affect flower and fruit production in C. roderickii. (USFWS, 2002)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Unknown (USFWS, 2019)

Number of Populations:

2 known extant ; 7 presumed extant (USFWS, 2019)

Population Size:

Greater than 55,000 individuals (USFWS, 2019)

Population Narrative:

It is restricted to one localized area of approximately 10 occurrences discontinuously scattered in the Pine Hill formation in the north, central, and south areas (USFWS, 2019)

Threats and Stressors

Stressor: Habitat loss (USFWS, 2002)

Exposure:

Response:

Consequence:

Narrative: Proposed residential or commercial development within the Pine Hill formation threatens most of the remaining sites within the Pine Hill formation and adjacent serpentine in western El Dorado County, and either directly or indirectly will adversely affect most of the range. (USFWS, 2002)

Stressor: Habitat fragmentation (USFWS, 2002)

Exposure:

Response:

Consequence:

Narrative: The subsequent induced growth from water acquisitions would affect all six species on the Pine Hill formation and adjacent serpentine, either by further fragmenting the habitat or by directly destroying habitat. Habitat fragmentation and edge effects significantly affect gabbro plants. Habitat fragments are more susceptible to being burned in their entirety, with shorter than natural intervals between fires, relative to larger tracts of habitat. If an entire preserve burns more often than the natural fire frequency, the seed bank of certain chaparral shrub species may not be adequate to replace the population. Fragmentation splits habitat into smaller, more isolated units and has two primary effects. First, habitat fragmentation may alter the physical environment, changing the amount of incoming solar radiation, water, wind, or nutrients for the remnant vegetation (Saunders et al. 1991). Second, most of these fragmented natural areas are subject to influences from external factors (e.g., additional development, lawn and garden watering, herbicide drift, and off-road vehicular use) that disrupt natural ecosystem processes. (USFWS, 2002)

Stressor: Fire management (USFWS, 2002)

Exposure:

Response:

Consequence:

Narrative: Changes in fire frequency threaten *Ceanothus roderickii*. *C. roderickii* occur within a fire-adapted plant community, either within chaparral or on the ecotone between chaparral and woodland. Before the advent of fire suppression policies, chaparral stands may have burned at a frequency of roughly 3 to 5 times per 100 years (Boyd 1985). Longer than normal fire frequencies lead to the loss of some plant species from the chaparral plant community. (USFWS, 2002)

Stressor: Hydrologic changes (USFWS, 2002)

Exposure:

Response:**Consequence:**

Narrative: El Dorado Irrigation District, is attempting to get additional water from the South Fork of the American River through purchase of PG&E's Hydroelectric Project 184 and a storage contract with the Bureau of Reclamation utilizing Folsom Reservoir. This water is most likely to be used for developments in the extreme western part of El Dorado County, where the gabbro soil plants are found (A. Howard in litt. 1999). (USFWS, 2002)

Stressor: Development (USFWS, 2002)

Exposure:**Response:****Consequence:**

Narrative: Mitigation for development often is by small "set asides" (small natural areas within the development), which increase habitat fragmentation, are difficult to manage for fire, and are subject to edge effect problems. Land development and multiple ownership complicate the planning and implementation of controlled burns at the appropriate fire frequency necessary for maintenance of chaparral. (USFWS, 2002)

Stressor: Road widening and maintenance (USFWS, 2002)

Exposure:**Response:****Consequence:**

Narrative: Road widening occurs near development within El Dorado County threatens the habitat of *Ceanothus roderickii* at one site (California Natural Diversity Data Base 1994). (USFWS, 2002)

Stressor: Recreation (USFWS, 2002)

Exposure:**Response:****Consequence:**

Narrative: Off-road vehicle use has adversely affected the habitat of *Ceanothus roderickii* at three sites in the northern part of the Pine Hill formation. Several hills are scarred with off-road vehicle tracks. Erosion promoted by scarring adversely modifies the habitat. (USFWS, 2002)

Stressor: Invasive plants (USFWS, 2019)

Exposure:**Response:****Consequence:**

Narrative: Invasive plants continue to present a minor threat to gabbro plant species. Populations within the Pine Hill Preserve are not significantly threatened by invasive plants and any small infestations identified are largely reduced or eliminated by mechanical means (BLM 2008). (USFWS, 2019)

Recovery**Reclassification Criteria:**

1. Secure and protect specified recovery areas from incompatible uses: (a) Cameron Park preserve north of Highway 50; (b) Cameron Park preserve south of Highway 50; (c) Pine Hill

preserve; Salmon Falls/Martel Creek preserve; (d) sufficient adjacent unoccupied habitat for fire management and a 150- meter (500-foot) buffer. (USFWS, 2002)

2. Management plan approved and implemented for recovery areas, including survival and recovery of the species as the objective: For preserves and any adjacent occupied or unoccupied habitat identified as necessary for continued survival and recovery (USFWS, 2002).

3. Monitoring in all recommended preserves shows: (a) populations stable or increasing over one fire cycle (about 30 years), (b) habitat monitoring of recommended preserves shows a mosaic of multiage class stands and habitat fragmentation has not appreciably increased (less than 5 percent) within any preserves over current (2000) conditions, (c) spatially and temporally, the establishment of occurrences must be greater than the extirpation of occurrences. (USFWS, 2002)

4. Other actions: (a) Ameliorate or eliminate threats; (b) Fire management studies; (c) Research on propagation techniques if repatriation, enhancement, or restoration are determined to be necessary; (d) Maintain metapopulation dynamics of at least 2 very large, 2 large, 6 medium, and 7 small occurrences throughout the range of the species. (USFWS, 2002)

Delisting Criteria:

1. Management plan approved and implemented for recovery areas, including survival and recovery of the species as the objective: For all occurrences and any adjacent areas identified as necessary for continued survival and recovery. (USFWS, 2002)

2. Monitoring in all recommended preserves shows: (a) no decline after downlisting during two additional fire cycles (about 60 years); if declining, determine cause and reverse trend, (b) habitat monitoring of recommended preserves shows a mosaic of multiage class stands and habitat fragmentation has not appreciably increased (less than 5 percent) within any preserves over current (2000) conditions, (c) spatially and temporally, the establishment of occurrences must be at least 10 percent greater than the extirpation of occurrences. (USFWS, 2002)

3. Ameliorate or eliminate threats; research on propagation techniques if repatriation, enhancement, or restoration are determined to be necessary. (USFWS, 2002)

Recovery Actions:

- 1. Develop and implement a cooperative program and participation plan. A cooperative program is needed to coordinate local public and private land use planning with State and Federal land use and recovery planning for gabbro species. A cooperative program needs to be developed focusing on western El Dorado County. A participation plan produced from this program will increase the chances of recovery for listed species. (USFWS, 2002)
- 2. Protect and secure existing populations. Natural lands that contain this species need to be protected in perpetuity. Protection of these lands includes identification and minimization of threats in perpetuity and application of appropriate and adaptive management (see Task 3) to ensure species survival and recovery. Natural lands that need protection can be categorized into two types: (1) blocks of land that contain occupied or potential habitat for two or more this species and (2) blocks of land that contain occupied or potential habitat for one this species. All potential preserve areas should be evaluated based on current mapping

information and ground-truthed prior to purchase to confirm their value for recovery. (USFWS, 2002)

- 3. Manage Habitat Managing habitat is essential to the recovery of the listed species. Habitat management includes preparation and implementation of management plans for all areas inhabited by special status species being proposed for preservation, and periodic monitoring of populations in each of these areas. Within western El Dorado County, a multi-constituent committee should be formed to oversee the management of preserves located on the Pine Hill formation. The preserve management committee should include, at a minimum, representatives from the California Department of Fish and Game, U.S. Fish and Wildlife Service, Bureau of Land Management, El Dorado County, California Department of Forestry and Fire Protection, California Native Plant Society, American River Conservancy, and a private landowner representative. (USFWS, 2002)
- 4. Survey historical locations and other potential habitat where this species may occur. Recovery of listed species may often require relocating historic populations or locating new populations of these species. Historical locations should be surveyed to determine whether suitable habitat remains, the species persists at the sites, and/or the sites may be suitable for repatriation. Suitability of historical locations for repatriation would depend upon: (1) whether potential habitat exists, (2) the presence and magnitude of threats, and (3) whether the sites can be secured and managed for the long-term protection of the species. Surveys should also include other potential gabbro or serpentine habitat to determine whether undiscovered populations may exist. If new populations are discovered, they need to be protected and managed as discussed above. During the surveys, potential introduction sites should also be identified. (USFWS, 2002)
- 5. Conduct necessary biological research and use results to guide recovery/conservation efforts. - Develop propagation techniques for listed plant species for which enhancement, repatriation, or introductions would be appropriate. Geographic area research is outlined in the Recovery Plan. Species-specific research is described as follows: Reproduction and Demography Research: Including determining limiting life stages, seed production, and survival in soil to determine appropriate fire return period. Systematics research and genetic studies if repatriation is determined to be necessary. Other Research Needs: Propagation techniques; fire management techniques; metapopulation analysis; determine efficacy of other types of disturbance regimes for species and habitat management; feasibility of habitat restoration/ enhancement. Management Actions Needed: Burning; general surveys; baseline monitoring; monitoring for trends of populations, success of management actions, and threats at all populations identified for protection; monitoring for habitat fragmentation, major shifts in vegetation type, and tracking of occurrence establishment, and extirpation. (USFWS, 2002)
- 6. Undertake artificial enhancement, repatriation, or introduction efforts where necessary. Where it is deemed necessary, artificial enhancement, repatriation, or introduction efforts for sensitive plants should be undertaken. Prior to repatriation or introduction of sensitive plants, genetics studies are needed (see Task 5) to ensure that new populations will not disrupt unique local gene complexes. Plant repatriation or introduction efforts should be undertaken using collected seeds or plant propagules. (USFWS, 2002)
- 7. Determine possible prescribed burning management strategies and incorporate the strategies into the management plans (Priority 1). Possible prescribed burning management strategies need to be evaluated, peer reviewed, and incorporated into management plans. (USFWS, 2002)

- 8. Perform metapopulation-type analyses for this species (Priority 2). The results of a metapopulation-type analysis may be useful in clarifying uncertainties, data needs, and research, management priorities, and delisting criteria. Metapopulation-type analyses should be based on the results of monitoring and research. (USFWS, 2002)

Conservation Measures and Best Management Practices:

- Dedicate more resources toward the investigation of best management approaches for the Pine Hill listed plant species, even at the cost of a temporary hiatus in land acquisition efforts. Investigation should be made into fire-related and non-fire related methods of disturbance to maintain listed plant species habitat. (USFWS, 2019)
- Once the best management strategy (in terms of technique, frequency, timing, and intensity) is determined at each site, implement these management practices to achieve and maintain a habitat mosaic that enables the attainment of recovery criteria for the species. (USFWS, 2019)

SPECIES ACCOUNT: *Centaurium (= Zeltnera) namophilum* (Spring-loving centaury (= *Zeltnera namophila*))

Species Taxonomic and Listing Information

Listing Status: Threatened; 05/20/1985; California/Nevada Region (R8) (USFWS, 2015)

Physical Description

The species is an upright, annual herb that grows 17.5 in (45 cm) tall with many flowering branches bearing many flowers measuring approximately 0.3 to 0.5 in (7 to 12 mm) in diameter (Reveal, Broome and Beatley 1973). Flowers are deep rose-pink with a yellowish throat and five dark purple spots below where adjacent petals attach to the body of the flower (Reveal, Broome and Beatley 1973). (USFWS, 2009)

Taxonomy

As treated here (following Kartesz, 1994 checklist and 1999 Floristic Synthesis), *Centaurium exaltatum* and *C. namophilum* are considered distinct species. An alternative treatment maintains *C. namophilum* with two varieties (vars. *namophilum* and *nevadense*). According to Kartesz (pers. comm. to Larry Morse, 25Nov99), there are three significant references for this group: C. R. Broome's 1973 Ph.D. dissertation (Systematics of *Centaurium* (Gentianaceae) in Mexico and Central America, Duke Univ., Durham, N.C.); B.L. Turner's treatment in *Phytologia*, 1973; and Pringle's unpublished work for the Flora of North America (FNA). After review of these works, Kartesz concluded that these taxa are best recognized as separate species. However, some others (e.g., J.L. Reveal) disagree, and further taxonomic study is needed. Larry Morse, 23Dec99. (NatureServe, 2015)

Historical Range

Historically in the Death Valley region, California and Ash Meadows in Nye County, Nevada (NatureServe, 2015)

Current Range

Ash Meadows in Nye Co., Nevada (NatureServe, 2015)

Critical Habitat Designated

Yes; 5/20/1985.

Legal Description

On May 20, 1985, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Centaurium namophilum* (Spring-loving centaury) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes one critical habitat unit (CHU), in Nevada (50 FR 20777-20794).

Critical Habitat Designation

The critical habitat designation for *Centaurium namophilum* includes one CHU in Nye County, Nevada (50 FR 20777-20794).

Nevada, Nye County, Ash Meadows.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Centaureum nanophilum* critical habitat consists of one component (50 FR 20777-20794):

Known primary constituent elements include moist to wet clay soils along banks of streams or in seepage areas.

Life History**Food/Nutrient Resources****Lifespan**

Adult: 1 year (USFWS, 2009)

Breeding Season

Adult: July to September (USFWS, 2009)

Reproduction Narrative

Adult: The spring-loving centaury is an upright, annual herb. that flowers from July to September (Pavlik and Manning 1986). One plant can produce thousands of seeds. (USFWS, 2009)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Desert (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 2,070 and 2,320 feet (630 to 707 m) above mean sea level (USFWS, 2009)

Dependency on Other Individuals or Species for Habitat

Adult: The wet meadow ecosystem occupied by spring-loving centaury is typically dominated by saltgrass (*Distichlis spicata*) with scattered velvet ash (*Fraxinus velutina*) and screwbean mesquite trees (*Prosopis pubescens*). (USFWS, 2009)

Habitat Narrative

Adult: The spring-loving centaury grows between 2,070 to 2,320 feet (630 to 707 m) above sea level within the Mojave Desert Ecoregion. The species is adapted to clay soils of the Ash Meadows area, and water availability is a limiting factor to this species' distribution (Pavlik and Manning 1986). It typically grows in wet saltgrass meadows near springs and streams and occasionally in low uplands at seeps (Reveal, Broome and Beatley 1973). The wet meadow ecosystem occupied by spring-loving centaury is typically dominated by saltgrass (*Distichlis spicata*) with scattered velvet ash (*Fraxinus velutina*) and screwbean mesquite trees (*Prosopis pubescens*). (USFWS, 2009)

Dispersal/Migration**Motility/Mobility**

Adult: Likely to be low (inferred from USFWS, 2009)

Dispersal/Migration Narrative

Adult: Given the small size of spring-loving centaury seeds, seed may be dispersed by small animals, wind, and water. Most seeds probably remain near the plant that produced it. (USFWS, 2009)

Population Information and Trends**Population Trends:**

Increasing (USFWS, 2009)

Resiliency:

High (USFWS, 2009)

Representation:

High (USFWS, 2009)

Redundancy:

Moderate (inferred from USFWS, 2009)

Population Growth Rate:

Moderately fast (inferred from USFWS, 2009)

Number of Populations:

19 (NatureServe, 2015)

Population Size:

~4,468,571 (USFWS, 2009)

Population Narrative:

The spring-loving centaury is adapted to disturbance with the relative proportion of energy devoted to seed production, enabling these ruderal species to quickly recover from disturbance (Grime 1977). Based on the life history, anecdotal observations, and assessment of biologists (C. Baldino, Ash Meadows National Wildlife Refuge, pers. comm. 2006a), it is reasonable to conclude the distribution of the spring-loving centaury has increased through colonization of previously disturbed sites since it was listed. They found the spring-loving centaury to be very widespread throughout the Refuge in habitats that included seasonally flooded wetlands to seasonally moist alkali meadows and the edges of some alkali scrub-shrub communities (Bio-West 2008, p. 26). On September 11th, 1997, there were 19 occurrences in Nevada. The total population is now estimated at 4,468,571 individuals on about 800 acres (Bio-West 2008, p. 28). (USFWS, 2009)

Threats and Stressors

Stressor: Habitat loss or degradation from groundwater pumping (USFWS, 2009)

Exposure:**Response:****Consequence:**

Narrative: At the time of listing, groundwater development was a major threat to the entire Ash Meadows ecosystem. Prior to listing, local groundwater pumping within Ash Meadows was responsible for declines in the wetlands in this area. The spring-loving centaury depends on the outflow of springs and near-surface water for its survival. (USFWS, 2009)

Stressor: Habitat loss from surface mining (USFWS, 2009)

Exposure:**Response:****Consequence:**

Narrative: Mining for clay minerals occurs in the Ash Meadows area. Surface disturbance and impacts to rare species that do not have Federal protection are permissible as long as operations comply with Federal and State laws. Currently, there are no active mines or mineral claims within known spring-loving centaury habitat (BLM 2007). New mineral claims and subsequent mining could cause direct loss of spring-loving centaury habitat, as well as indirect impacts by diverting water away from occupied habitat. (USFWS, 2009)

Stressor: Non-native species (USFWS, 2009)

Exposure:**Response:****Consequence:**

Narrative: Over 100 non-native species, approximately 16 percent of the total flora, occur on the Refuge (Service 2006). Of these, salt cedar (*Tamarix ramosissima*), Russian knapweed (*Acroptilon repens*), five hook bassia (*Bassia hyssopifolia*), Malta star thistle (*Centaurea melitensis*), yellow star thistle (*Centaurea solstitialis*), and hoary cress (*Cardaria draba*) are noxious weeds that could potentially threaten the spring-loving centaury (Service 2006). (USFWS, 2009)

Stressor: Climate change (USFWS, 2009)

Exposure:**Response:****Consequence:**

Narrative: The spring-loving centaury is a wetland dependent species. Current climatic modeling predicts the southwestern U.S. is likely to experience increased frequency of regional drought in response to elevated levels of atmospheric carbon dioxide (Seager et al. 2007). The springs and surface streams that support the spring-loving centaury are perennial and they originate from a regional aquifer that includes runoff from the Spring Mountains approximately 100 mi to the northeast (USGS 2005). Other climate predictions suggest the intensity of precipitation events may increase in response to elevated atmospheric carbon dioxide (IPCC 2007). The potential effects of climate change to the regional aquifer that supports Ash Meadow is unknown. (USFWS, 2009)

Recovery**Reclassification Criteria:**

1. All non-native animals and plant species must be eradicated for essential habitat. These non-native species currently include sailfin mollies, mosquito fish, largemouth bass, black bullheads, crayfish, turban snails, wild horses, salt cedar, and Russian olive. (USFWS, 2009)
2. Secure and protect the Ash Meadow aquifer so that all spring flows return to historical discharge rates, and the water level in Devils Hole is maintained at a minimum level of 1.4 feet below the copper washer. (USFWS, 2009)
3. Reestablish water to historic springbrook channels, which are free to barriers that eliminate genetic exchange between populations by preventing movement of native fishes throughout their historic ranges. (USFWS, 2009)
4. The essential habitat must be secure from detrimental human disturbance including mining, OHVs, and the introduction of non-native species (USFWS, 2009).

Delisting Criteria:

1. Criteria for downlisting from endangered to threatened apply in the delisting objectives. (USFWS, 2009)
2. Secure, protect, and maintain natural vegetation, corridors, and adjacent buffer areas for gene flow and dispersal of listed plant species within the essential habitat. (USFWS, 2009)
3. Native plant communities and aquatic communities have been reestablished to historic structure and composition within all essential habitats. (USFWS, 2009)
4. All of the listed species and the candidate plant species are present in all the sites that they have historically occupied as identified in the Recovery Plan. Within each critical habitat unit, the listed plant has a frequency value equal to or greater than the frequency value determined by Task 644 needed as an indicator of a self-sustaining plant population. (USFWS, 2009).

Recovery Actions:

- Recovery actions are not available.

Conservation Measures and Best Management Practices:

- Clarify or resolve the uncertainties regarding the significance of the remaining threats to spring-loving centaury, i.e., groundwater pumping and surface mining. (USFWS, 2009)
- The Service and BLM should continue to work toward the completion of the land and mineral withdrawals for public lands within the Refuge and the ACEC. (USFWS, 2009)
- Research on the role of fire in maintaining habitat for spring-loving centaury is needed, including both wild fire and prescribed burning. (USFWS, 2009)

SPECIES ACCOUNT: *Cercocarpus traskiae* (Catalina Island mountain-mahogany)

Species Taxonomic and Listing Information

Listing Status: Endangered; 09/07/1997; California/Nevada Region (R8)

Physical Description

An evergreen shrub or small tree, 3-8 m tall, with leathery leaves, 2-6 cm long, that are densely covered with white-woolly hairs on the undersides. The petalless flowers (March-May) are also white-woolly. Fruits have a long, plume-like style. (NatureServe, 2015)

Taxonomy

Cercocarpus traskiae has hybridized locally with *C. betuloides* var. *blancheae*, which also occurs on the island. The hybrids have been characterized on morphological bases as well as on allozyme differences (Martin 1988, Rieseberg et al. 1989, Rieseberg 1991). Morphological assessments of hybridization have not always agreed with the results of random amplified polymorphic DNAs (RAPDs) and allozyme studies (Rieseberg and Swensen 1996). (USFWS, 2007)

Historical Range

See current range/distribution.

Current Range

Cercocarpus traskiae is still known to occur naturally only in Wild Boar Gully on the southwestern coast of Santa Catalina Island off the coast of southern California. (USFWS, 2007)

Critical Habitat Designated

Yes;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (USFWS, 2007)

Breeding Season

Adult: March to May (NatureServe, 2015)

Reproduction Narrative

Adult: *Cercocarpus traskiae* has hybridized locally with *C. betuloides* var. *blancheae*, which also occurs on the island. The petalless flowers appear from March to May and produce a single-seeded fruit. (USFWS, 2007; NatureServe, 2015)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Shrubland/chaparral (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 131 and 231 meters (430 and 700 feet) (USFWS, 2007)

Environmental Specificity

Adult: Narrow/specialist (inferred from USFWS, 2007)

Site Fidelity

Adult: High (USFWS, 2007)

Habitat Narrative

Adult: The known natural population is found on soils derived from igneous, saussurite gabbro rock (Knapp 2006), which is restricted to the southwestern coast of Santa Catalina Island. *Cercocarpus traskiae* are found slopes of a steep-sided, narrow, dry arroyo within a coastal sage scrub community. Plants are typically found on steep slopes and near drainage bottoms between 131 and 231 meters (430 and 700 feet) in elevation (the highest elevation on the island is 648 meters [2,125 feet]) (62 FR 42692). (USFWS, 2007; NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Stable (inferred from USFWS, 2007)

Resiliency:

Low (USFWS, 2007)

Representation:

Low (USFWS, 2007)

Redundancy:

Low (USFWS, 2007)

Population Growth Rate:

Very slow (USFWS, 2007)

Number of Populations:

1 (NatureServe, 2015)

Population Size:

~100 (USFWS, 2007)

Population Narrative:

Cercocarpus traskiae now has a population size of seven mature individuals. This is an increase in population size of one plant in the past 40 to 100 years. Twenty-seven of the 102 individuals reported in 2003 are saplings. (USFWS, 2007)

Threats and Stressors

Stressor: Introduced herbivores (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Large introduced herbivores have historically altered the flora and the landscape of Santa Catalina Island. Goats, pigs, bison, and deer were noted at the time of listing. The small size of the current *C. traskiae* population is attributed to the historical presence of goats, deer, and pigs (Rieseberg et al. 1989, Knapp 2006). Goats are known to consume coarse vegetation, including shrubs and trees. This results in reduced vegetation cover and less of a mulch layer (dead herbaceous vegetation) to hold moisture and slow erosion (Coblentz 1980). Lack of plant cover can result in the formation of gullied badlands (Thorne 1967). Pigs create a network of bare trails with compacted soils. The vegetation loses its tiered overlapping structure as shrubs become isolated by the trail network (Martin 1988). In addition to retaining soil moisture for adult plants, surface litter may hold seeds on the steep slopes. We did not elaborate on the threats from bison and deer in the final listing rule. However, these animals are generally found in the area where *C. traskiae* grows. Goats have been eliminated from the island, pigs are nearly gone, and the fenced enclosure in the Wild Boar Gully watershed has greatly decreased the threat from deer and bison. This has allowed the *C. traskiae* plants and other vegetation cover to increase. (USFWS, 2007)

Stressor: Predation (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: The fence erected in 1999 around the plants has reduced the incidence of direct browse damage to *Cercocarpus traskiae* (Knapp 2006). In addition to browsing impacts, the rooting activity of pigs was considered to be directly responsible for low numbers of *C. traskiae* plants (Rieseberg et al. 1989). Pigs uproot seedlings and churn up soil in some canyons (Thorne 1967). As noted above, the number of pigs has now been reduced to one to four animals (Knapp, pers. comm. 2007). A potential concern is that the fence does not completely exclude deer, because evidence of browsing on the *Cercocarpus* was seen in 2003. Seedling heights indicated that some browsing had taken place, and the California Department of Fish and Game was unwilling to issue a depredation permit to dispatch the deer (Knapp 2006). (USFWS, 2007)

Stressor: Fire (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: The listing rule identified fire as a potential threat. Since listing, the construction of the enclosure fence has excluded herbivores and resulted in local increases of vegetative cover. In general, it is not known to what extent the resulting increase of vegetative cover within the

fenced area poses a threat of increased fire frequency for *Cercocarpus traskiae*. Fire is likely infrequent on the island although lightning strikes are known. (USFWS, 2007)

Stressor: Hybridization (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Rieseberg and Gerber (1995) suspect that a critical factor leading to hybridization for a number of plants occurring on the Channel Islands has been habitat disturbance due to the introduction of non-native goats and pigs. We considered the potential for hybridization of *Cercocarpus traskiae* with the more common *C. betuloides* var. *blancheae* to be a threat in the listing rule. Genetic swamping of *C. traskiae* was suggested as a possible outcome of this hybridization. We also stated that Rieseberg et al. (1989) recommended elimination of mature hybrids as a means to preserve the species. Rieseberg and Swensen (1996) considered hybridization a significant threat where the frequency of interspecific mating is high and the population at risk is numerically smaller than the congener. (USFWS, 2007)

Stressor: Stochastic events (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: *Cercocarpus traskiae* now has a population size of seven mature individuals. This is an increase in population size of one plant in the past 40 to 100 years. The greater vulnerability to extinction of small populations is generally attributed to demographic fluctuations, environmental variation, and loss of genetic variability and related problems of inbreeding depression and genetic drift; and/or to natural catastrophes (Primack, 2006; Barrett and Kohn 1991). (USFWS, 2007)

Stressor: Age disparities between individual plants (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: There is a disparity in numbers of individuals of different age classes; i.e., plants are either very old or very young with few age classes in between. There is the potential for mature plants to die naturally before an adequate number of younger reproductive adults are present to maintain even the current genetic diversity and reproductive output. (USFWS, 2007)

Stressor: Genetic diversity (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Limitations on the reproductive partners among the seven mature plants could be another considerable threat to the species' survival and may indicate lower genetic diversity among the mature individuals. (USFWS, 2007)

Stressor: Nonnative plants (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Invasive non-native plants pose perhaps a greater threat than at the time of listing. The balance between effective control of invasive exotic non-natives and increased density of vegetation due to fencing is unknown. The invasive non-native plant management is focused on target species rather than vegetation cover. (USFWS, 2007)

Recovery**Reclassification Criteria:**

Reclassification criteria are not available.

Delisting Criteria:

Delisting criteria are not available.

Recovery Actions:

- Recovery actions are not available.

Conservation Measures and Best Management Practices:

- Establish an effective seed banking program for this species that includes maintenance of genetic diversity and plans to facilitate out-plantings, including ex-situ populations of the species to protect against detrimental stochastic events. (USFWS, 2007)
- Determine the incidence, nature, and management consequences of self-incompatibility in *Cercocarpus traskiae*. (USFWS, 2007)
- Determine the genetic identity of all of the *Cercocarpus* seedlings and saplings present in Wild Boar Gully, as well as that of plants recently deemed to be adults and plants at older outplantings. (USFWS, 2007)
- Determine the potential threat from continuing hybridization of *Cercocarpus traskiae* and co-occurring *C. betuloides* var. *blancheae* and implement management actions to alleviate the threat. (USFWS, 2007)
- Identify the micro-habitat requirements most conducive seedling production and establishment. (USFWS, 2007)
- Determine the best method for establishing additional populations that are self-sustaining and capable of participating in the evolutionary future of the species. Establish success criteria and remediation measures for these established populations. (USFWS, 2007)

SPECIES ACCOUNT: *Cereus eriophorus* var. *fragrans* (Fragrant prickly-apple)

Species Taxonomic and Listing Information

Listing Status: Endangered; 12/2/1985; Southeast Region (R4)

Physical Description

Cereus eriophorus var. *fragrans* is a solitary tree cactus that may have from one to eight, spiny, cane-like, stout, and succulent stems. The columnar stems are 2.5 to 5.0 cm in diameter, and have 10 or 12 ridges alternated with deep, sharp grooves (Benson 1982). Stems may be erect, or for longer stems, the plant may recline over neighboring vegetation. The branching can be extensive, and the roots of this cactus are coarse, fibrous, and shallow (Small 1920). The spine-bearing regions (areoles) are aligned along its ridges about 2 cm apart. Each areole bears 9 to 13 spines, which are mostly grayish and yellowish at the tip, with one spine longer (2 to 4 cm) than the rest. *Cereus eriophorus* var. *fragrans* has initial flower buds that are 1 cm long, white, and exceedingly hairy. Buds often appear on the plant one to two months prior to flower growth. About 9 days after initiation of flower growth, the flower opens (Rae 1995). The flowers are fragrant, showy, solitary, and open only at night. The buds are 12 to 20 cm long when about to open and 7.5 to 10 cm in diameter when open. The ovary bears many lanceolate scales while the flower tube has only a few scattered scales. A tuft of long white hairs (10 to 15 mm long) protrudes from the axil beneath each scale. The sepals are narrowly linear, with green outer sepals and nearly white inner ones. There are numerous spatulate petals, white or pinkish, with unevenly toothed margins. The stamens are numerous and are composed of white filaments and yellow anthers. The style is elongate with 9 to 12 stigmas (FWS 1988). The fruits are attached at the narrower end. They average 4 to 6 cm in diameter and are a dull red. The fruit does not split and has long tufts of white hairs that remain persistent with the scale bases (Leon and Alain 1953). The fruits are swollen at the base and finely pitted; each contains approximately 1,500 black seeds that are about 3 mm long (Rae 1995). (USFWS, 1999)

Taxonomy

The type specimen was collected by John K. Small in 1917 along sand dunes approximately 6 miles (mi) south of Ft. Pierce, Florida, and treated as *Harrisia fragrans* (Britton and Rose 1920). It was separated from other species partly on the basis of having one longer spine than the other 9 to 13 spines per areole (Britton and Rose 1920). Austin (1984) followed the treatment of Lyman Benson (1982) in which *Harrisia* and other cacti were joined together in the genus *Cereus*. Since then, fragrant prickly-apple has consistently been referred to by its former name, *Harrisia*, in references to the flora of the United States and Florida (Chafin 2000; Gann et al. 2002; Flora of North America 2003; Wunderlin and Hansen 2003). The Integrated Taxonomic Information System (2010) was also checked while conducting this review and indicated that the accepted name is *Harrisia fragrans*. Because *Harrisia fragrans* is the name used in peer-reviewed literature and is accepted by the scientific community, we concur with this nomenclature. (USFWS, 2010)

Historical Range

Historically occurred on the east coast of Florida in St. Lucie, Indian River, Brevard, and Volusia Counties (USFWS, 2010)

Current Range

In Florida, in Volusia and St. Lucie Counties, projected to include Brevard and Indiana River Counties. (USFWS, 2010)

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Sexually and by regeneration by vegetative reproduction

Breeding Season

Adult: Plants flower from April to September with two distinct peaks. (USFWS, 2016)

Reproduction Narrative

Adult: Fragrant prickly-apple reproduces sexually and by regeneration by vegetative reproduction. Plants flower from April to September with two distinct peaks. The first peak is in the spring with flowering starting in April and reaching a peak in May. Some sporadic flowering occurs in the summer. In September and October, another minor peak in flowering occurs. Flowering is uncommon in the late fall, and no flowering occurs from January through March. Fruit set follows flowering with a major peak in May and a minor peak in September. A large standing crop of fruit remains on plants for approximately 8 months of the year. According to Rae (1995), mature plants are greater than 41 cm in length. The smallest plant to flower was 14.5 cm in stem length and the smallest plant to set fruit was 41 cm in length. In his study, 63 percent of the mature plants flowered. At two sites in the Savannas State Preserve, in St. Lucie County, 38 and 60 percent of flowers successfully produced fruits and 44 and 61 percent of mature plants successfully set fruit. A positive relationship was observed between total length of the stems and branches of a plant and the total annual production of fruit. The means of seed dispersal are uncertain, but there is evidence that birds consume the fruit of fragrant prickly-apple. Additionally, most individuals of this species are found within the drip line of other plants, suggesting avian seed dispersal. Rodents or gopher tortoises may also distribute the seeds. In addition to sexual reproduction, long stems will occasionally snap off of existing plants. After falling to the ground, stems may re-root at several places creating a small group of genetically identical plants (Rae 1994a). Vegetative growth of this perennial species is slowest from November to March. Growth accelerates in April and May, with the fastest growth occurring from July through September. The growth rate drops off rapidly after September (Rae 1994a, 1995). The fragrant prickly-apple is characterized as a long-lived species with late maturity, low fecundity, and low adult mortality (Rae and Ebert 2002). Larger plants tend to have higher fecundity and lower mortality rates (Rae and Ebert 2002); therefore, the larger individuals in the population are extremely important to overall population health (Rae and Ebert 2002). (USFWS, 2016)

Habitat Type

Adult: Sand pine scrub habitat

Habitat Narrative

Adult: Fragrant prickly-apple occurs in a clumped distribution and prefers early-successional sand pine scrub habitat (Rae 1994b, 1995). The known sites are limited to St. Lucie sand which is excessively well drained (Watts and Stankey 1980), where the water table is normally deeper than 3 m. Water capacity, fertility, and organic matter content are all very low. The most common plant species in this community include sandhill jointweed (*Polygonella fimbriata*), hairy jointweed (*P. ciliata*), tall jointweed (*P. gracilis*), sand live oak (*Quercus geminata*), myrtle oak (*Q. myrtifolia*), cabbage palm (*Sabal palmetto*), and pricklypear (*Opuntia humifusa*). Much of the Atlantic Coastal Ridge was cleared in the 1880s for pineapple plantations, but commercial pineapple cultivation was abandoned by 1920. The vegetative community has yet to regain its previous level of diversity or productivity. The vegetative succession has been arrested and the plant community has not succeeded to the climax sand pine habitat type (Rae 1994a, 1995). This cactus prefers partial shade, which is often provided by surrounding plants that shelter it from sun for a portion of the day (Rae 1994b). Surrounding vegetation is often used for support by fragrant prickly-apple for its long stems. Other plants may serve as nurse plants for the seedlings, protecting them from direct sun, but this has not been studied. As the plant grows, the nursery plant may die, leaving the cacti exposed to a greater intensity of sunlight. Overgrowth and shading by sand live oaks and other species may cause reproductive failure and premature death. Growth and productivity seems to be greater for plants in areas that are partially shaded. (USFWS, 2016)

Dispersal/Migration***Population Information and Trends*****Number of Populations:**

10 (USFWS, 2010)

Population Size:

Less than 3000 individuals (USFWS, 2010)

Population Narrative:

Fragrant prickly-apple was listed as endangered on November 1, 1985, following substantial losses of suitable habitat (50 FR 45621). At the time of listing, fragrant prickly-apple was only known from St. Lucie County (Service 1985). Historically, fragrant prickly-apple occurred in coastal hammock habitats on the east coast of Florida in St. Lucie, Indian River, Brevard, and Volusia Counties, although some accounts in other areas were erroneously reported due to misidentification with Simpson's prickly-apple (*Cereus gracilis* var. *simpsonii*) (Service 1985; Service 1999; Woodmansee et al. 2007). Fragrant prickly-apple was reportedly collected in Everglades National Park (ENP), but this is not confirmed (NPS 2007; Sadle 2009). Because Simpson's prickly-apple commonly occurs in ENP, there is much confusion over identification of these two species, there is no voucher specimen available in herbarium collections for confirmation, the fragrant prickly-apple is limited in distribution, and ENP lacks the habitats believed to support fragrant prickly-apple, it is thought that the species was misidentified (NPS 2007; Sadle 2009). The species is now known to occur on only 10 confirmed sites in Volusia and St. Lucie Counties, primarily on or around Savannas Preserve State Park (SPSP) where the site covers an area approximately 10.0 mi long and 0.5 mi wide and is bisected by the Florida East Coast railway (Bradley et al. 2002; Bradley and Gann 2002; Woodmansee et al. 2007; Florida

Natural Areas Inventory [FNAI] 2009). These cacti are often found to occur in distinct clusters (Bradley et al. 2002; Woodmansee et al. 2007). The occurrence of fragrant prickly-apple in Indian River County is yet unconfirmed because only a single sterile plant was observed on a coastal berm when surveys were conducted in 2006 (Woodmansee et al. 2007; FNAI 2009). Although only confirmed in Volusia and St. Lucie Counties, it is possible that the current range of the species includes Brevard and Indian River Counties, as these counties occur between confirmed locations and appropriate habitat is available (Woodmansee et al. 2007). (USFWS, 2016)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Continued habitat loss, fragmentation, and changes in land use threaten the existence of fragrant prickly-apple. Where plants occur on private sites, development has led to both direct destruction of habitat as a result of land clearing and habitat degradation from lack of management. For example, Woodmansee et al. (2007) suggested that the two extirpated sites in Brevard County were probably lost due to habitat alteration or destruction and severe freezes. Moore (2009) stated that another private site known to contain fragrant prickly-apple was to be sold for development a few years ago. After obtaining permission to salvage the cactus from the property, he returned to find that it had already been removed (Moore 2009). - Threats from development and habitat degradation on private sites are expected to continue and increase. Within the range of fragrant prickly-apple, the human population is predicted to grow from just below 500,000 to nearly 1,000,000 in Volusia County and from approximately 193,000 to more than 563,000 in St. Lucie County between 2005 and 2060 (Zwick and Carr 2006). - Even though 63 percent of the sites around SPSP containing fragrant pricklyapple are publicly owned and not at risk of being developed, the plants on these sites may still be vulnerable to habitat degradation from encroachment of exotic plant species and lack of fire or other mechanical treatment. If sites are not properly managed, ecosystem health may deteriorate. Because the sites are fragmented on a developed landscape, fire management may not always be feasible and encroachment by exotic plant species from neighboring properties is likely. Because population densities tend to vary over time, even those sites with high population densities may be vulnerable if not monitored carefully (Rae in litt. 2010). Therefore, habitat loss, degradation, and fragmentation due to increasing development and lack of management in coastal scrub habitat and the encroachment of exotic plants continue to threaten fragrant prickly-apple. (USFWS, 2010)

Stressor: Overutilization for commercial, recreational, scientific, or educational purposes (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: At the time of listing, overutilization was identified as a potential threat for fragrant prickly-apple, but indiscriminate collecting was not known to occur. Because it is limited in distribution and population sizes are relatively small, indiscriminate collecting could adversely affect the species. Like many other species of cacti, fragrant prickly-apple is vulnerable to unlawful exploitation and collection due to the activities of some collectors and hobbyists.

Enforcement is difficult due to insufficient resources and the remoteness of the plants. There is minor horticultural interest in this species (Bradley and Gann 2002). During the 5 years of monitoring that took place at SPSP, there was no evidence of poaching (Bradley and Gann 2002). However, the salvage of a fragrant prickly-apple from a property slated to be sold for development was planned but never occurred because the plant was mysteriously removed before the rescue could be implemented (Moore 2009). The Service believes that there is a continuing threat from overutilization for commercial or recreational purposes. (USFWS, 2010)

Stressor: Disease or predation (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: When the fragrant prickly-apple was listed as endangered, disease and predation were not known to be threats. However, insects may damage cacti. Moore (2009) noted that young seedlings were damaged when unidentified caterpillars ate the sprouts. A native scale insect, *Diaspis echinocacti*, has been found to destroy stems of the fragrant pricklyapple in SPSP; however, it does not appear to kill the host plant (Bradley et al. 2002a; Bradley and Gann 2002). Root parasitism may occur when fragrant 10 prickly-apple grows in association with tallow wood (*Ximenia Americana*) or graytwig (*Schoepfia chrysophylloides*) but has not been directly observed (Bradley and Gann 2002). Fragrant prickly-apple may also be parasitized by love-vine. There is evidence that birds eat the fruit and serve as a mechanism to disperse seeds (Service 1999). It is also thought that rodents or gopher tortoises may distribute seeds (Service 1999). These occurrences of predation and parasitism are not known to constitute serious threats to the fragrant prickly-apple. (USFWS, 2010)

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: The ESA provides limited protection for the species and its habitat. Existing Federal regulations prohibit the removal or destruction of listed plant species on Federal lands. The fragrant prickly-apple is also listed by the Florida Department of Agriculture and Consumer Services (FDACS) as endangered (5B-40.0055 Regulated Plant Index), but this legislation does not provide any direct habitat protection. State regulations require both written permission from the owner or legal representative and a permit issued by FDACS to collect or remove plants listed as endangered on the Florida Regulated Plant Index. Title 62D2.013 of the Florida Administrative Code prohibits the removal, destruction, or damage of plants from FDEP, Division of Recreation and Park properties. This regulation provides protection for much of the population where it occurs on SPSP. - Existing regulatory mechanisms do not appear to be adequate, as several properties with fragrant prickly-apple on private lands have been developed. Fragrant prickly-apple was potentially impacted in 2005 when heavy equipment was used to push debris into habitat where the species was presumed to occur along the railroad right-of-way (Kaufmann 2005). Multiple portions of potential habitat along the railroad tracks are being purchased and used to dump dredged material from the Intracoastal Waterway along the Indian River. - Because this plant occurs in habitat along the Atlantic coastal ridge, which is desirable for development and other uses due to its elevation, it remains vulnerable to development pressures where it occurs on private property. Where the species occurs on public land, there is protection from development but not necessarily from habitat degradation. (USFWS, 2010)

Stressor: Prescribed fire (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Land management practices such as prescribed fire are important to maintaining the scrub ecosystem. However, the fragrant prickly-apple is intolerant of fire (Bradley and Gann 2002). Because it is thought that the species was historically located along the perimeter of scrub habitat in xeric hammocks, it may not have been affected as frequently by fires that were occurring in adjacent scrub (Bradley and Gann 2002). (USFWS, 2010)

Stressor: Invasive nonnative plant species (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: A large source of habitat degradation is the establishment of invasive plant 11 species such as Brazilian pepper (*Schinus terebinthifolius*), rosary pea (*Abrus precatorius*), white cypress pine (*Callitris glaucophylla*), golden trumpet (*Allamanda cathartica*), cathedral bells (*Kalanchoe pinnata*), chandelier plant (*K. tubiflora*), swamp mahogany (*Eucalyptus robusta*), guinea grass (*Panicum maximum*), and Crow's foot grass (*Dactyloctenium aegyptium*) (Bradley and Gann 2002; Bradley et al. 2002b). These invasive species may impact fragrant prickly-apple growth, reproductive potential, and recruitment by competing for space and nutrients and blocking sunlight (Bradley and Gann 2002). The species frequently grows beneath the canopy of these invasives to take advantage of partial shade and also can be crushed beneath falling limbs or trees not able to withstand hurricane winds (Bradley and Hines 2007). However, herbicides used to control overgrowth, if not properly applied, also pose a threat to the fragrant prickly-apple. Bradley and Hines (2007) noted mortality as a result of off-target herbicide application at SPSP. (USFWS, 2010)

Stressor: Feral hogs, tortoise, and inadequate land management (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Degradation to habitat can also occur from damage by feral hogs (Engeman et al. 2003, 2004). Bradley and Hines (2007) recorded an incident in which feral hog damage killed a fragrant prickly-apple plant. Gopher tortoises may also bury small cacti at the mouth of burrows (Bradley and Gann 2002). Vegetation restoration and management programs are costly, and the availability of funding is never assured; therefore, habitat modification from inadequate management even on protected lands remains an imminent, though moderate, threat. (USFWS, 2010)

Stressor: Climatic events (USFWS 2010)

Exposure:

Response:

Consequence:

Narrative: The species' restriction to specialized habitat, its limited distribution, and its limited reproductive capacity also renders it vulnerable to random natural events, such as freezes and hurricanes. Sea level rise may also threaten cacti on sites with low elevation, such as those at

Canaveral National Seashore (Woodmansee et al. 2007). Woodmansee et al. (2007) suggested that freezing temperatures may have led to the extirpation of the species at one location in Brevard County. Although the species did well through the Category 1 hurricane in 2000 and the Category 2 and 3 storms in 2004 and 2005 (Bradley and Gann 2002; Woodmansee et al. 2007), specific conditions such as storm surge and amount of debris dumping following the event vary greatly with each hurricane and may render sites with few plants vulnerable to destruction. Hurricanes have the potential to adversely affect fragrant prickly-apple populations in other ways. High winds can bring surrounding vegetation crashing down on top of individual cacti, injuring or killing them. Bradley and Hines (2007) found that mortality rates more than tripled at SPSP as a result of hurricane impacts. One colony that was particularly affected was located beneath invasive white cypress pine trees which were not equipped to handle hurricane winds and either fell or lost numerous branches that crushed the cacti below (Bradley and Hines 2007). However, hurricanes also open hammock canopies, allowing light to penetrate and stimulating flowering activity, thus providing conditions that may be favorable to cactus regeneration (Bradley and Gann 2002; Woodmansee et al. 2007). (USFWS, 2010)

Recovery

Reclassification Criteria:

Not defined; 1999 Recovery Plan provided only "stabilization" criteria. (USFWS, 1999)

Delisting Criteria:

1. When at least 15 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)
2. When populations (as defined in criterion 1) in coastal sand pine scrub habitat are distributed across the historical range of the species. (Factors A and E) (USFWS, 2019)
3. When populations (as defined in criterion 1) must be protected via a conservation mechanism and managed (e.g., appropriate burn intervals) such that enough suitable habitat is present for the species to remain viable for the foreseeable future. (Factors A, B, D, and E) (USFWS, 2019)

Recovery Actions:

- 1. Determine distribution of *C. e. var. fragrans*. Known *C. e. var. fragrans* populations occur on well-drained soils indicative of xeric upland plant communities. Much of the xeric upland habitat of Indian River and St. Lucie counties remains botanically unsurveyed and threatened with destruction. Efforts to survey and assess the xeric vegetative communities for *C. e. var. fragrans* are needed to ensure the survival of this species. (USFWS, 1999)
- 2. Protect and enhance existing populations. Of the three populations known, one occurs on private land in residential areas and two occur in Florida's Savannas State Preserve. Additional protection at each of these sites is needed. (USFWS, 1999)
- 3. Conduct research on the biology of *C. e. var. fragrans*. Much of the basic biology and ecology of this species remains poorly understood. If we are to effectively recover the species, more specific biological information will be needed. (USFWS, 1999)
- 4. Monitor *C. e. var. fragrans* populations. Maintain an inventory of naturally reproducing populations to help determine habitat characteristics and natural environmental changes affecting *C. e. var. fragrans*. (USFWS, 1999)

- 5. Provide public information about the fragrant prickly-apple cactus. It is important, and perhaps crucial, to the recovery of this species that governmental agencies, conservation organizations such as the Florida Native Plant Society, and landowners be appropriately informed about this species. Informing the conservation organizations such as the Cactus and Succulent Society is appropriate, but care is needed to avoid unnecessarily revealing localities and to avoid stimulating demand for the species. Efforts must also continue to address the increasing concern that horticultural demand for this and other rare species may not benefit conservation of threatened and endangered species. Public education should identify that commercial production and horticultural uses of endangered species provide little benefit to species, since the recovery of *C. e. var. fragrans* and other rare species requires a self-sustaining, secure, number of natural populations. (USFWS, 1999)
- 6. Establish delisting criteria. Once reclassification is achieved, research and monitoring results may provide data necessary to develop delisting criteria. (USFS, 1999)
- Habitat-level Recovery Actions: - Protect, manage and enhance habitat. None of the habitat for *C. e. var. fragrans* on private land is secure at this time. Efforts to protect these sites are essential since many of the remaining plants occur on private land. - Monitor habitat and ecological processes. Little is known regarding response of *C. e. var. fragrans* to land management actions used in coastal xeric communities. The effects of fire, vegetative cutting, or other measures must be monitored to determine biological and ecological consequences. - Continue public information efforts about xeric vegetative communities and their unique biota. Educational efforts, especially those conducted by private conservation organizations, have been successful in providing important information about xeric plant communities to the public. (USFWS, 1999)

Conservation Measures and Best Management Practices:

- Surveys: • Continue monitoring the SPSP and Volusia County populations on an annual basis and after stochastic events, such as fires. 13 • Conduct additional surveys on other parts of Hutchinson Island South in St. Lucie County, Sebastian Inlet State Park in Brevard and Indian River Counties, spoil islands in Indian River and St. Lucie Counties, Pelican Island National Wildlife Refuge and the southern end of Pine Island in Indian River County, and other potential locations within the historic range. • Re-survey the Pine Island location to confirm the identity of the plant in question. (USFWS, 2010)
- Management: • Continue management actions to remove invasive species with particular care in using mechanical means and herbicide application that may damage cacti; control public access to these areas to avoid human disturbance and to improve habitat conditions. • Continue application of prescribed fire to habitats that support the species while maximizing the number of burn units rather than applying fire to large expanses of habitat. • Consider reducing the canopy in areas where cacti are impacted by too much shade. • Restore coastal hammocks along the eastern slope of the Atlantic Coastal Ridge. • Where unable to restore coastal hammocks, maintain the threeawn (*Aristida gyrans*)/ Sabal palm (*Sabal palmetto*) habitat that fragrant prickly-apple now occupies for the long-term existence of the species. • Control public access and eliminate dumping in areas where fragrant prickly-apple occurs. • Focus conservation efforts on marginal and small sites to preserve the genetic diversity of the species. • Evaluate the feasibility of acquiring private property in Brevard County for reintroduction of the species, identify suitable habitat for additional reintroduction sites in protected areas, and establish reintroduced populations. • Increase the genetic diversity of the species at existing and reintroduced locations. (USFWS, 2010)

- Research: • Conduct demographic studies using a metapopulation approach to understand spatial and temporal variation. Incorporate surveys to evaluate flower and fruit production. • Develop a model to evaluate long-term population growth in relationship to microhabitat conditions (i.e., shade, partial shade, and sun). • Develop mechanisms to improve seedling survival and continue to study seed germination to determine habitat preferences of the species. Evaluate the role of nurse plants that provide shade in the early development of seedlings. • Conduct research on recruitment, mortality, seed bank characteristics, and soil moisture. • Conduct parallel studies on the other two similar cacti in Florida, Simpson's pricklyapple and Aboriginal pricklyapple (*Harrisia aboriginum*), to gain additional insight into fragrant prickly-apple biology and to delineate these species. • Continue genetic research and appropriately apply these results to listing status of all *Harrisia* species in Florida. • Conduct a population-level genetic study using microsatellite markers to determine genetic variation within the species and gene flow in and among sites and to better understand the reproductive mode at low population densities. • Conduct research on the response of fragrant prickly-apple to fire and fire prescriptions necessary to benefit the species. • Identify pollinators and evaluate impacts to insect pollinators from aerial mosquito spraying. • Continue propagation efforts and collect germ plasm from the remaining sites not currently represented in the CPC's National Collection of Endangered Plants, primarily from the Volusia County population. • Evaluate the effects of climate change on the species, including those that result from precipitation pattern changes and temperature rise. (USFWS, 2010)
- Other: • Pursue conservation agreements/implement management recommendations and/or acquire land and investigate incentives to encourage land managers to manage habitat for ecosystem health and listed species. • Acquire private inholdings within the SPSP when willing sellers are identified. • Consider acquiring the Pine Island tract in Indian River County and determine the status of Fairchild Tropical Botanic Garden's ex situ population of plants from this site. • Promote partnerships to share information, conduct collaborative research on coastal scrub habitat conservation, and provide land managers and the interested public with information about the ecosystem, threats, recovery actions, and associated rare biota. • Consider nomenclatural changes to officially designate the name of the fragrant pricklyapple as *Harrisia fragrans*. • Conduct an ad hoc meeting to compile new information, discuss recovery actions, share land management strategies, and set and prioritize 5- and 10-year goals. • Seek opportunities to include the media in conservation efforts to provide information about this species to the public. (USFWS, 2010)

SPECIES ACCOUNT: *Chamaecrista glandulosa* var. *mirabilis* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 4/5/1990; Southeast Region (R4) (USFWS, 2015)

Physical Description

A prostrate, ascending, or erect shrub which may reach up to 1 meter in height. The branches are slender, straight, and wire-like. Leaves are alternate, evenly one-pinnate, 1 to 3 centimeters long, 0.5 to 1 centimeter wide, with some scattered whitish hairs. The stipules are persistent, striate, and about 2 millimeters long. The leaflets are membranaceous, usually in 18 pairs, 3 to 6 millimeters long and 0.5 to 1.5 millimeters wide. The petioles have one to two stipitate glands. The flowers are solitary, with a pedicel about as long as the leaves. The corolla is yellow, about 2 centimeters in diameter, with one petal much larger than the others. Mature fruits (legumes) are glabrous, linear, 2.5 to 4 centimeters long, 3 to 4 millimeters wide, flat, elastically dehiscent, and 12 to 15 seeded (Vivaldi and Woodbury 1980). (USFWS, 1994)

Taxonomy

A member of the Fabaceae family, was first collected by Dr. Agustin Stahl in the mid-nineteenth century. In 1899, Mr. Edward Heller collected the species in Vega Baja. *Chamaecrista glandulosa* var. *mirabilis* has been placed by various authors in the genus *Cassia* as a species (*Cassia mirabilis*) and in the genus *Chamaecrista* both as a species and a variety (*Chamaecrista glandulosa* var. *mirabilis*). Liogier (1988), in the "Descriptive Flora of Puerto Rico and Adjacent Islands," place the taxon as a variety in the genus *Chamaecrista*. (USFWS, 1994)

Historical Range

It is known from the coastal white or siliceous sands in north central Puerto Rico in areas adjacent to the Tortuguero Lagoon Natural Reserve. The species is commonly considered as endemic to mainland Puerto Rico (Axelrod 2011) (USFWS, 2015).

Current Range

Chamaecrista glandulosa var. *mirabilis* occurs in the north central coastal plain of Puerto Rico (USFWS, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual and asexual (USFWS, 2015)

Dependency on Other Individuals or Species

Adult: Hymenoptera spp. (EPA, 2016)

Breeding Season

Adult: Year round (inferred from EPA, 2016)

Reproduction Narrative

Adult: Flowering and fruiting occurs for most of the year, with peaks in February and March. Hymenopterans are pollinators (EPA, 2016). López-Colon et al. (2007) found that the species does not depend on autogamy for pollination. Moreover, López-Colon et al. (2007) reported various pollinators for the species (i.e., Hymenopterans), suggesting that the species reproduction is dependent on interaction with pollinators (USFWS, 2015).

Habitat Type

Adult: Terrestrial (EPA, 2016)

Habitat Vegetation or Surface Water Classification

Adult: Subtropical moist forest (EPA, 2016)

Dependencies on Specific Environmental Elements

Adult: 44 - 88 in. annual rainfall (EPA, 2016)

Environmental Specificity

Adult: Narrow (inferred from USFWS, 2015)

Habitat Narrative

Adult: Vegetation surrounding lagoon is dry evergreen or littoral forest. Species is found growing on almost pure sands without any organic layer, frequently in open areas. It occurs near sea level in the north central coastal plain within the subtropical moist forest life zone, where rainfall ranges from 1,100 to 2,200 mm (44-88 in) per year. It grows on occurring on white silica sands derived from outcrops of granodiorite. They belong to the Algarrobo-Corozo-Arecibo soil association. Soils are deep, excessively drained, low in nutrients, and acidic (EPA, 2016). *Chamaecrista glandulosa* var. *mirabilis* is limited to coastal habitats consisting on white siliceous sands adjacent to wetland areas (USFWS, 2015).

Dispersal/Migration**Dependency on Other Individuals or Species for Dispersal**

Adult: Unknown (EPA, 2016)

Dispersal/Migration Narrative

Adult: Dispersal mechanisms are unknown (EPA, 2015).

Population Information and Trends**Population Trends:**

Unknown (USFWS, 2015)

Species Trends:

Unknown (USFWS, 2015)

Resiliency:

Very low (inferred from USFWS, 2015)

Redundancy:

Low (inferred from USFWS, 2015)

Number of Populations:

4 (USFWS, 2015)

Population Size:

Unknown (USFWS, 2015)

Population Narrative:

In the absence of a long term monitoring and uncertainty about population trends, the Service deems the status of the population as uncertain. There are no accurate estimates on the current number of individuals and populations trends of *C. glandulosa* var. *mirabilis*. There are 4 known populations within northern Puerto Rico (USFWS, 2015).

Threats and Stressors

Stressor: Habitat destruction and modification (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: The northern coast of Puerto Rico between San Juan and Arecibo represents perhaps the most developed and disturbed area on the Island. This zone includes areas that harbors suitable habitat for the species. A variety of development activities (e.g., residential, commercial, highways, etc.) are ongoing, and protected areas on the northern coast are few and most are small. ATV and mountain bikes tracks have been found along the habitat. Human-induced fires could modify the landscape by promoting nonnative trees and grasses, and by diminishing the seed bank of native species (Brandeis and Woodall 2008). In some cases, fires may maintain extensive areas of young forest and grasslands, slowing the recovery (regeneration) of ecosystems, and therefore, impairing the delivery of ecosystem services (Brandeis and Woodall 2008) (USFWS, 2015).

Stressor: Limited distribution (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Other than the Tortuguero Lagoon Natural Reserve, there is no other natural reserve that includes siliceous sands habitat. Therefore, the limited distribution of *C. glandulosa* var. *mirabilis* and its substrate (suitable habitat), makes the species vulnerable to habitat destruction and modification (USFWS, 2015).

Stressor: Climate change (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Climate change is predicted to increase the frequency and strength of tropical storms and also to lead to a gradual rise in sea level. Vulnerability to climate change impacts is a function of sensitivity and exposure to those changes, and the adaptive capacity of the species (Glick et al. 2011). Therefore, shifts of vegetation communities are expected as temperatures and moisture regimes are altered by climate change. Under this scenario, the populations of *C. glandulosa* var. *mirabilis* may be displaced or outcompeted by native or exotic species with wider environmental plasticity. Even a small rise in sea level could represent a very serious threat to the taxon. Sea level rise will also compromise natural recruitment by affecting seed germination and/or the survival of seedlings. Due to its limited range and limited substrate availability, flooding and climate change could likely have an adverse impact on the species as there may not be other areas that harbors suitable habitat for the displacement or colonization by the species (USFWS, 2015).

Stressor: Invasive species (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: In 2013, the USFWS documented areas that harbor habitat for the taxon, are being lost due to changes in the structure of the vegetation. For example, areas that were open white sands with herbaceous vegetation in the 1990s are currently covered by tree species (i.e., *Anacardium occidentale* and *Chrysobalanus icaco*). *Chrysobalanus icaco* is a native species characteristic of coastal vegetation (including sand dunes). However, *A. occidentale* is native to northern South America and Brazil, and is showing an invasive pattern within *C. glandulosa* var. *mirabilis* habitat in Tortuguero Lagoon. *Melaleuca quiquenervia* is another exotic tree species that is already established on the reserve and poses a risk for the ecosystem (Hamilton 2013) (USFWS, 2015).

Recovery**Reclassification Criteria:**

Not available

Delisting Criteria:

1. The known populations are given protected status (USFWS, 2015).
2. At least 3 new populations capable of self-perpetuation are established within protected areas. These should be minimum requirements, and could be expanded upon if the regenerative or propagative potential of natural and ex situ populations proves to be insufficient. On the other hand, if new populations of the species are discovered, it may be preferable to place greater emphasis on protection, rather than on propagation, in order to achieve a minimum number of plants (USFWS, 2015).

Recovery Actions:

- Monitor existing populations (USFWS, 1994).
- Provide protection, through acquisition or conservation easements, for existing populations (USFWS, 1994).

- Conduct research on aspects of the life history of the species and evaluate propagation techniques (USFWS, 1994).
- Conduct propagation and enhance existing populations or establish new ones (USFWS, 1994).

Conservation Measures and Best Management Practices:

- The recovery of the species should focus primarily on the protection of natural known populations and its habitat. Studies and surveys should be conducted to locate and determine the current status of additional wild populations (USFWS, 2015).
- Efforts should be made to identify existing fragments of siliceous sands and to ensure their preservation and ecological restoration (i.e., through USFWS funded projects via the Coastal Program and Partners for Fish and Wildlife Program) should also be undertaken if appropriate sites are found (USFWS, 2015).
- A long term monitoring program should be established to determine population trends of the known populations (USFWS, 2015).
- Since the population dynamics of the species are poorly known, and we do not have enough information to determine what constitutes a viable population. Additional studies should be conducted on the species' phenology, reproductive biology and population structure (USFWS, 2015).
- Studies should be conducted on the patterns of genetic variation, in order to develop a plan to preserve the species' germplasm (USFWS, 2015).
- A signage and outreach program should be implemented to educate the users of the Tortuguero Lagoon Natural Reserve about the species and its habitat (USFWS, 2015).

SPECIES ACCOUNT: *Chamaecrista lineata keyensis* (Big Pine partridge pea)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/31/2016; Southeast Region (R4) (USFWS, 2016)

Physical Description

Chamaecrista lineata var. *keyensis* is a small, prostrate to ascending, perennial, herbaceous shrub that is 10–80 centimeters (cm) (3.9–31.5 inches (in)) tall, with yellow flowers and pinnately compound leaves (each leaf consists of a main stem with multiple leaflets lined up along on each side). It has one to several branched stems arising from a contorted rootstock. New branches are covered in soft, fuzzy hairs. The leaves are 1.7–4.0 cm (0.7–1.6 in) long, with 5 to 9 pairs of leaflets. Flowers consist of five sepals 9–20 mm (0.4–0.8 in) long that are fused together near their bases; five yellow petals 11–15 mm (0.4–0.6 in) long, with one slightly larger than the others; 10 reddish-purple stamens; and a single, elongate style. The fruit is an elongate pod, roughly similar to that of a pea, 33–45 mm (1.3–1.8 in) long and 4.5–5.0 mm (0.19–0.17 in) wide, with a soft fuzzy texture, which turns gray with age and eventually split open to release seeds (Irwin and Barneby 1982, p. 757; Small 1933, pp. 662–663) (USFWS, 2015).

Taxonomy

John Loomis Blodgett was the first to collect *Chamaecrista lineata* var. *keyensis*, sometime between 1838 and 1852, on Big Pine Key (Bradley and Gann 1999, p. 17). Pollard (1894, p. 217) assigned the plants on Big Pine Key to the existing taxon *Cassia grammica*. John K. Small (1903, p. 587; 1913, p. 58) followed this usage, but used the genus *Chamaecrista* (considered a subgenus within *Cassia* or a genus unto itself variously by many authors). In 1917, Pennell (p. 344) recognized the Big Pine Key plant as a distinct endemic species, naming it *Chamaecrista keyensis*. This name was retained by Small (1933, p. 663) in his *Manual of the Southeastern Flora*. In an exhaustive study of *Cassia* and *Chamaecrista*, Irwin and Barneby (1982, p. 757) assigned plants in Florida and parts of the West Indies to the existing taxon *Chamaecrista lineata*, and assigned the Big Pine Key plants to var. *keyensis*, retaining them as endemic to the Florida Keys. Isely (1990, p. 33), Wunderlin (1998, p. 348), and Wunderlin and Hansen (2003, p. 441) have followed this treatment. The online *Atlas of Florida Vascular Plants* (Wunderlin and Hansen 2014, p. 1) uses *Chamaecrista lineata* var. *keyensis*. The *Integrated Taxonomic Information System* (2015, p. 1) uses the name *Chamaecrista lineata* var. *keyensis* and indicates that this taxonomy is accepted. Based upon the best available scientific information, *Chamaecrista lineata* var. *keyensis* is a distinct taxon, endemic to the lower Keys in Monroe County, Florida. Synonyms are *Cassia keyensis* (Pennell) J.F. Macbr and *Chamaecrista keyensis* Pennell. *Chamaecrista lineata* var. *keyensis* is related to, and superficially resembles, *Chamaecrista fasciculata*, the partridge pea, a common species which occurs throughout Florida. (USFWS, 2015)

Historical Range

Chamaecrista lineata var. *keyensis* is endemic to the lower Florida Keys in Monroe County, Florida. Historical records exist for occurrences on five islands: Big Pine Key, No Name Key, Ramrod Key, Cudjoe Key, and Sugarloaf Key (Hodges and Bradley 2006, pp. 20–21) (USFWS, 2015).

Current Range

Florida, Monroe County, on Big Pine Key and Cudjoe Key. (USFWS, 2015)

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Sexual

Adult: very

Habitat Narrative

Adult: Big Pine partridge pea occurs primarily in pine rockland vegetation. Some populations can be found on roadsides (Hodges and Bradley 2005, p. 22) or in cleared lots adjacent to pine rockland. Pine rocklands in the lower Florida Keys are dominated by a canopy of *Pinus elliottii* var. *densa* (South Florida slash pine). The subcanopy is composed of *Thrinax morrisii* (brittle thatch palm), *Psidium longipes* (longstalked stopper), *Metopium toxiferum* (poisonwood), *Byrsonima lucida* (locustberry), *Pithecellobium keyense* (blackbead), and *Coccothrinax argentata* (silver palm) (Bradley 2006, p. 25). Ross and Ruiz (1996, p. 5) found that it occurs primarily in areas where hardwoods are relatively unimportant, and where understory and overstory palms are important. Bradley (2006, p. 26) also found that it preferred open sunny areas, but in contrast to Ross and Ruiz (1996, p. 5) found a negative correlation with palm cover. Big Pine

partridge pea is most likely to be found in canopy openings and requires full sun to partial shade (Muir and Liu 2003, p. 3). It is capable of colonizing disturbed areas within pine rockland habitat, such as dirt roads. It does not persist in damp soil or depressions (Muir and Liu 2003, p. 3). Pine rockland is maintained by relatively frequent fires, which keep the understory woody plants at shrub height (Snyder et al. 1990, pp. 257-263; Carlson et al. 1993, p. 915; Bergh and Wisby 1996, p. 1; Liu et al. 2005a, p. 210; 2005b, p. 71). In the absence of fire, many areas become wooded, eventually succeeding to rockland hammock (i.e., hardwood forest) (Snyder et al. 1990, p. 260). As with other pineland plants, Big Pine partridge pea is shade intolerant, and requires periodic burning to reduce competition from woody vegetation (e.g., shading, leaf litter accumulation) (Carlson et al. 1993, p. 922; Liu et al. 2005a, p. 210; 2005b, p. 71) (USFWS, 2013). *Chamaecrista lineata* var. *keyensis* occurs in pine rocklands of the lower Florida Keys, and adjacent disturbed sites, including roadsides (USFWS, 2016).

Dispersal/Migration***Population Information and Trends*****Population Trends:**

Declining (USFWS, 2013; USFWS, 2015)

Species Trends:

Declining (USFWS, 2013; USFWS, 2015)

Number of Populations:

2 extant occurrences (USFWS, 2015)

Population Size:

>300,000 individuals (USFWS, 2015)

Population Narrative:

The population size of Big Pine partridge pea is apparently much smaller than it was historically. In addition to a reduction in the amount of available habitat, there has also been a reduction in density. Total population size within the Big Pine Key public pine rockland study area (1,181 acres [478 ha]) was estimated to be 816,833 to 1,709,994 in 2005 (pre-Hurricane Wilma, 297 plots) and 178,543 to 458,227 in 2007 (post-Wilma, 285 plots) (Bradley and Saha 2009, p. 12). Since 82 percent of the pine rockland on Big Pine Key is publicly owned, this estimate likely accounts for the majority of the population. Big Pine partridge pea density and percent cover was significantly higher in 2005 compared to 2007 in all plots combined, as well as, separately for northern and southern plots. In 2005, a total of 1,540 plants were counted in 297 plots, whereas in 2007 only 584 plants were counted in 285 plots. In surveys collected immediately after Hurricane Wilma, island-wide population sizes were 38 percent lower than in plots sampled prior to the hurricane (Bradley 2006, p. 35). Mortality rates varied geographically. Small areas of pine rockland were not flooded at all, while in many areas salt water pooled for several days. Bradley (2006, p. 13) sampled 60 plots both before and after the hurricane. These plots were all at the northeast end of the island in a low-lying area. Only 6.25 percent of the plants that were found prior to the hurricane were found after the storm, indicating a major population decline. Similarly, at TNCs Terrestriis Preserve, counts of Big Pine partridge pea declined greatly between 2003 and 2006 in all three study units (Slapcinsky and Gordon 2007, p.

9) (USFWS, 2013). Population data for *Chamaecrista lineata* var. *keyensis* have been collected periodically on Big Pine Key since 1955. Because of the size of Big Pine Key, sample study plots were used, as opposed to a complete search of all potential habitat. Multiple indicators show that the population on Big Pine Key has declined over the past 60 years (Bradley 2006, p. 35). Dickson (1955) and Alexander and Dickson (1972) reported densities of *C. lineata* var. *keyensis* from plots they established on Big Pine Key in 1951 and 1969, respectively. Dickson (1955) reports a mean density of 10,764 plants/ha (26,599 plants/ac). Alexander and Dickson (1972) report a mean density of 27,871 plants/ha (68,872 plants/ac). In 2005, Bradley (2006, p. 35) recorded 2,339 plants/ha (5,780 plants/ac), 23.4 percent and 9.0 percent of the 1955 and 1972 estimates, respectively. Hurricane Wilma, which passed over Big Pine Key on October 24, 2005, generated storm surge in the lower Keys of up to 10 feet (Bradley 2006, p. 11; Hodges 2010, p. 4). In 2007, density had dropped to 820 plant/ha (2,026 plants/ac) and had not fully rebounded after 9 years (Bradley et al. 2015, pp. 21–22). By 2013, density had fallen to 657 plants/ha (1,624 plants/ac) (Bradley et al. 2015, p. 21). In summary, the data from 2005 to 2013 demonstrate a 63.8 percent decline in the density of *C. lineata* var. *keyensis* on Big Pine Key (Bradley et al. 2015, p. 48). A second indicator, the frequency which *Chamaecrista lineata* var. *keyensis* occurred in sample plots on Big Pine Key from data collected in 2005, 2007, and 2013, also show a decline. *Chamaecrista lineata* var. *keyensis* was present in 37 percent of plots in 2005, and 19 percent of plots in 2013, respectively. This represents a 49 percent reduction in the species frequency in study plots (Bradley et al. 2015, p. 48). A third indicator, total population size for *Chamaecrista lineata* var. *keyensis* on publicly owned pine rocklands on Big Pine Key (478 ha (1,181 ac)), was estimated to be 866,659 plants in 2005 (pre-Hurricane Wilma), 391,944 in 2007 (2 years post-Wilma), and 313,914 in 2013 (8 years post-Wilma). This represents a population decrease of 64 percent (Bradley et al. 2015, p. 21). The most recent estimate (2013) of the *Chamaecrista lineata* var. *keyensis* population on Big Pine Key is 313,914 plants (Bradley et al. 2015, p. 21). Since 82 percent of the pine rocklands on Big Pine Key are publicly owned, this estimate likely accounts for the majority of the population. The most recent estimate of the population on Cudjoe Key is 150 plants (Hodges and Bradley 2006, p. 21). The decline in *Chamaecrista lineata* var. *keyensis* can be largely attributed to loss of pine rocklands habitat to development and modification of this habitat due to inadequate fire management. Folk (1991, p. 188) estimated that pine rocklands historically covered 1,049 ha (2,592 ac), about 44 percent of Big Pine Key. Pine rocklands now cover approximately 582 ha (1,438 ac) of Big Pine Key, 56 percent of the historical estimate by Folk (1991) (Bradley 2006, p. 4). Hurricanes and associated storm surge have also impacted population levels (USFWS, 2013).

Threats and Stressors

Stressor: Fire suppression (USFWS, 2015; USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Fire is required to maintain the pine rockland community (Snyder et al. 1990, pp. 257-263; Carlson et al. 1993, p. 915; Bergh and Wisby 1996, p. 1; Liu et al. 2005a, p. 210; Liu et al. 2005b, p. 71). With fire suppression, hardwoods eventually invade pine rocklands and shade out understory species like Big Pine partridge pea. Fire suppression reduces the size of the areas that do burn, and habitat fragmentation prevents fire from moving across the landscape. Accordingly, in the absence of fire, pine rockland communities tend toward becoming tropical hardwood hammock communities. Complete implementation of a prescribed fire program in the lower Keys

has been hampered by an incomplete understanding of the fire ecology in the area, and by public opposition to burning (USFWS, 2015; USFWS, 2013).

Stressor: Pesticide application (USFWS, 2015; USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Application of pesticides to control mosquitoes may be impacting populations of Big Pine partridge pea by limiting pollinator populations. The flowering season of the species overlaps with the peak of mosquito activity and pesticide application to control mosquitoes in June and July (Liu 2003, p. 7). Liu (2003, p. 14) found declines in the population of one genus of pollinator after spraying events. There were no declines with the second known pollinator genus (Liu 2003, p. 14). Reduced pollinator visits likely accounted for lower fruit production (Liu 2003, pp. 16-17). The pesticide application on Big Pine Key will continue to impact pollinator populations and thus the population of Big Pine partridge pea. At present, even with reduced pollinator populations, the species still has a strong reproductive output (Liu et al. 2005a, pp. 205-216). Liu and Koptur (2003, p. 1186) recommended limiting pesticide applications to control mosquitoes to no more than weekly. However, at this time, the likelihood of implementing this reduction is unlikely (USFWS, 2015; USFWS, 2013).

Stressor: Exotic plants (USFWS, 2015; USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Exotic plants have significantly affected pine rocklands. At least 277 taxa of exotic plants are now known from pine rocklands in south Florida (Service 1999, p. 3-175). Bradley (2006, pp. 25-26) found that 12.1 percent of pine rockland plots on Big Pine Key had exotic plants, and that Big Pine partridge pea had a significant negative correlation with exotic species richness in sample plots. The most frequent exotic plant species recorded were *Schinus terebinthifolius* (Brazilian pepper), *Fimbristylis cymosa* (hurricane sedge), *Swietenia mahagoni* (West Indian mahogany), and *Stenotaphrum secundatum* (St. Augustine grass). Some of these may compete directly with Big Pine partridge pea for space and resources, while others have a profound effect on community structure and responses to fire. Brazilian pepper is the most widespread and one of the most invasive species. If left uncontrolled in a fire-suppressed pineland, it will form a dense monospecific canopy almost completely eliminating native vegetation. It will also affect the characteristics of a fire when one does occur. Fires that once burned fairly coolly with mostly pine needle duff for fuel may now burn much hotter and affect the vegetation that develops following fire. For instance, under some post-fire circumstances, *Pteridium aquilinum* var. *caudatum* (dense bracken fern) thickets develop (Ross and Ruiz 1996, p. 4). Therefore, in the presence of exotic species, additional factors must be accounted for in order to manage fire for the benefit of Big Pine partridge pea. At present, Brazilian pepper is largely under control in intact pine rockland on NKDR lands and the Terrestris Preserve (USFWS, 2015; USFWS, 2013).

Stressor: Sea level rise (USFWS, 2015; USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Climate change is likely to increase the occurrence of saltwater intrusion into coastal aquifers as sea level rises and that sea-level rise is projected to extend areas of salinisation of groundwater and estuaries, resulting in a decrease of freshwater availability for humans and ecosystems in coastal areas (IPCCC 2008, pp. 3, 103). From the 1930s to 1950s, increased salinity of coastal waters contributed to the decline of cabbage palm forests in southwest Florida (Williams et al. 1999, pp. 2056-2059), expansion of mangroves into adjacent marshes in the Everglades (Ross et al. 2000, pp. 9, 12-13), and loss of pine rockland in the Keys (Ross et al. 1994, pp. 144, 151-155). Hydrology has a strong influence on plant distribution in these and other coastal areas (IPCC 2008, p. 57). Such communities typically grade from salt to brackish to freshwater species. Human developments will also likely be significant factors influencing whether natural communities can move and persist (IPCC 2008, p. 57; CCSP 2008, p. 7-6). In the Keys, not only are elevation differences between such communities very slight (Ross et al. 1994, p. 146), but the horizontal distances are small as well. Sea level rise poses a significant threat to the species and its habitat. There has been a 15 cm (5.9 inch [in]) rise in sea level over a 70-year period in the vicinity of Big Pine Key (Ross et al. 1994, p. 145). The pine rockland community in the Keys has undergone a reduction due to sea level rise (Ross et al. 1994, p. 149). For example, the pine rockland area on Sugarloaf Key covered 217 acres (88 ha) prior to 1935, and was reduced to 114 acres (46 ha) by 1935 and 74 acres (30 ha) by 1991 (Ross et al. 1994, p. 149). The loss of pine rockland communities was correlated with elevated ground- and soil-water salinity, and loss of upland plant diversity was inferred (Ross et al. 1994, pp. 150-151). In areas affected by sea level rise, communities of halophytic plants replaced pine rockland communities (Ross et al. 1994, p. 152). Sea level rise of the same order likely occurred among the nearby Big Pine and Cudjoe Keys, but the effects have yet to be quantified on those keys. Based on IPCC and other predictions of sea level rise, Clough (2008, p. 23) concluded that a significant proportion of upland habitat will be lost on Big Pine Key by 2100 (USFWS, 2015; USFWS, 2013).

Stressor: Stochastic events (USFWS, 2015; USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Hurricanes and tropical storms are an additional threat, particularly to the extent that they yield storm surges with salt-water overwash. Hurricane storm surges can inundate landscapes with saltwater for varying durations. Klimstra (1986, p. 3) stated, The effects of salt water on pinelands is well established as a consequence of hurricane Betsy, September 8, 1965. After 20 years the site where waters were entrapped for several hours has not yet fully recovered from complete loss of *Pinus*, *Ernodea*, *Randia*, *Pisonia*, and *Metopium* seedlings. The small area of occupancy and somewhat patchy distribution of Big Pine partridge pea renders it susceptible to extinction through such stochastic events. Hurricane Wilma in 2005 resulted in substantial reductions in population size and distribution. The surge reduced the population by as much as 95 percent in some areas (Bradley 2006, p. 13). The long term impacts of this hurricane are uncertain. However, slash pine needle-fall (litter) appears to provide for fire advancement in pine rockland communities. Because large areas of slash pine are dead since Hurricane Wilma, and may remain so, fire may no longer occur and provide important functions that enable the persistence of Big Pine partridge pea and other flora in these communities (USFWS, 2015; USFWS, 2013).

Recovery

Reclassification Criteria:

Not defined.

Delisting Criteria:

Not defined.

Recovery Actions:

- Not defined.

Conservation Measures and Best Management Practices:

- Increase prescribed fires across all pine rockland areas in NKDR and other portions of Big Pine Key, Cudjoe Key, and on islands that formerly has populations of this taxon. (USFWS, 2013)
- Limit pesticide applications to control mosquitoes to once a week to allow pollinator populations time to recover between applications events. Assess and reduce the use of truck-delivered adulticides (permethrins) from roadsides with NKDR lands adjacent. (USFWS, 2013)
- Consider management tools that mimic fire by opening up the pine rockland canopy (e.g., limb cutting, selective thinning). (USFWS, 2013)
- Continue exotic plant control programs in pine rockland habitat. Exotic plants densities in most pine rocklands areas on Pig Pine Key are currently low; management should continue to prevent spread of aggressive exotics. (USFWS, 2013)
- Big Pine partridge pea should be outplanted to islands where it formerly occurred (Muir and Liu 2003, p. 6). Bradley and Saha (2009, p. 4) surveyed No Name and Little Pine Keys in 2007 and 2008. However, Big Pine partridge pea was found to remain extirpated. If it is not found on those islands, outplantings should occur in open understory areas on both islands, which are part of the species historic range. (USFWS, 2013)
- Engage stakeholders to protect the small population on Cudjoe Key that resides strictly along a roadside. Notify Monroe County road maintenance and law enforcement personnel about the location and specific problems that need to be prevented. (USFWS, 2013)

SPECIES ACCOUNT: *Chamaesyce deltoidea pinetorum* (Pineland sandmat)

Species Taxonomic and Listing Information

Listing Status: Threatened; 11/6/2017; Southeast Region (R4) (USFWS, 2017)

Physical Description

Chamaesyce deltoidea ssp. *pinetorum* is an ascending to erect perennial herb. The stems are hairy and often reddish. The leaf blades range from kidney-shaped or triangle-shaped and elliptic to oval. The fruit is a 2-mm broad, pubescent capsule. The seeds are 1 mm long, transversely wrinkled, and yellowish in color. Fruit production is year-round, with a peak in the fall. (USFWS, 2017)

Taxonomy

Chamaesyce deltoidea ssp. *pinetorum* was first described by Small in 1905, based on specimens collected in eastern Miami-Dade County. Initially, Small referred to these specimens as *C. pinetorum* but recognized that it was closely related to *Chamaesyce deltoidea*. Herndon (1993, included *C. pinetorum* within the *C. deltoidea* complex, which is composed of three other taxa, two occurring farther north on the Miami Rock Ridge, and one occurring on Big Pine Key in the lower Florida Keys (Monroe County). The three taxa on the Miami Rock Ridge have distinct, but adjacent, ranges. Subsequently, Herndon (1993) has placed all four taxa at the same taxonomic level, treating each as a distinct subspecies under *Chamaesyce deltoidea* (*C. deltoidea* ssp. *pinetorum*, *C. deltoidea* ssp. *serpyllum*, *C. deltoidea* ssp. *adhaerens*, and *C. deltoidea* ssp. *deltoidea*). *Chamaesyce deltoidea* ssp. *deltoidea* and *C. deltoidea* ssp. *adhaerens* occur north of known *C. deltoidea* ssp. *pinetorum* populations, while *Chamaesyce deltoidea* ssp. *serpyllum* is endemic to Big Pine Key. Wunderlin and Hansen (2016) follow Herndon's treatment in using *C. deltoidea* ssp. *pinetorum*. Some modern authors place the genus *Chamaesyce* into the genus *Euphorbia* sensu lato. If placed into the genus *Euphorbia*, the correct name of pineland sandmat is *Euphorbia deltoidea* ssp. *pinetorum*. The online Atlas of Florida Vascular Plants uses the name *Chamaesyce deltoidea* ssp. *pinetorum* (Small) Herndon (Wunderlin and Hansen 2016, p. 1). NatureServe (2016, p. 1) and FDACS (Coile and Garland 2003, p. 11) indicate that *C. deltoidea* ssp. *pinetorum* is accepted. However, the Integrated Taxonomic Information System (ITIS 2016, p. 1) accepts *Euphorbia deltoidea* ssp. *pinetorum* as the scientific name for the subspecies (Gann 2015, p. 168). We have carefully reviewed all taxonomic data to determine that *C. deltoidea* ssp. *pinetorum* is a valid taxon. (USFWS, 2017)

Historical Range

Chamaesyce deltoidea ssp. *pinetorum* occurred historically only with the southern portion of the Miami Rock Ridge, from Homestead to the Long Pine Key region of Everglades National Park, a range of approximately 42 mi (67.6 km). (USFWS, 2017)

Current Range

The current range of *Chamaesyce deltoidea* ssp. *pinetorum* is similar to the historical range, although 98 percent of the pine rocklands (the species' only habitat) outside of the Everglades National Park has been lost to development. (USFWS, 2017)

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Sexual (USFWS, 2017)

Lifespan

Adult: Somewhat long-lived; 88 percent of plants survived more than 3 years. Extensive root system (USFWS, 2017)

Dependency on Other Individuals or Species

Adult: Pollinators may include bees, flies, ants, and wasps (USFWS, 2017)

Breeding Season

Adult: year-round

Other Reproductive Information

Adult: This species is known to flower and fruit year round. Peaks in fruiting for *C. deltoidea* ssp. *pinetorum* occur in the fall and are stimulated by fire. (USFWS, 2017)

Reproduction Narrative

Adult: Reproduction is sexual, but little is known about the reproductive biology and ecology of the subspecies. Some of the plants recorded as dead during surveys may have instead been in a cryptic phase. Pollinators are unknown; some other species of *Chamaesyce* are completely reliant on insects for pollination and seed production, while others are self-pollinating. Pollinators may include bees, flies, ants, and wasps. (USFWS, 2017)

Habitat Type

Adult: Pine rockland in pockets of clayey marl or on oolitic limestone

Dependencies on Specific Environmental Elements

Adult: Fire is an important element in maintaining the pine rockland habitat.

Tolerance Ranges/Thresholds

Adult: The plants can stand partial inundation with fresh water for a portion of the year, but do not tolerate salinity. (USFWS, 2017)

Habitat Narrative

Adult: *Chamaesyce deltoidea* ssp. *pinetorum* occurs in pine rocklands. Pine rocklands are maintained by regular fire, and are prone to annual flooding for several months during the wet season. However, *C. deltoidea* ssp. *pinetorum* generally occurs in higher elevation pine rocklands at Long Pine Key in Everglades National Park, in areas rarely subject to flooding. See detailed description of Pine Rockland habitat in Additional Habitat Information (USFWS, 2017)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Dispersal is unknown for *Chamaesyce deltoidea* ssp. *pinetorum*; however, many seed capsules in similar *Chamaesyce* species are explosively dehiscent, a form of dispersal that flings seeds far from the parent plant. *Chamaesyce deltoidea* ssp. *pinetorum* is thought to have a similar, but reduced, level of dispersal (USFWS, 2017)

Population Information and Trends**Number of Populations:**

20 extant occurrences; 9 on public conservation lands owned by Miami-Dade County and the NPS.

Population Size:

14,500 to 146,000 individuals (USFWS, 2017)

Population Narrative:

The total population size of *Chamaesyce deltoidea* ssp. *pinetorum* is estimated to be 14,500-146,000 individuals, with the majority of the population occurring on Long Pine Key. However, while *Chamaesyce deltoidea* ssp. *pinetorum* is most abundant within Everglades National Park, pine rockland fragments outside of the Everglades represent about half the subspecies' extant range. (USFWS, 2017)

Threats and Stressors

Stressor: Present or Threatened Destruction, Modification, or Curtailment of Its Habitat or Range

Exposure:

Response:

Consequence:

Narrative: Habitat loss, fragmentation and degradation, and associated pressures from increased human population are major threats this species. These threats are expected to increase as remaining pine rocklands and other habitats are lost to development, placing these plants at greater risk. This species may be impacted when pine rocklands are converted to other uses or when lack of fire causes the conversion to hardwood hammocks or other unsuitable habitats. On public lands, including National Park Service lands and Miami-Dade County-owned lands, implementation of prescribed fire has not been sufficient because of legal constraints (permitting requirements) and inadequate funding. Any populations of this species found on private property could be destroyed due to development. Although efforts are being made to conserve natural areas and apply prescribed fire, most pine rocklands remain in poor fire condition, and the long-term effects of large-scale and wide-ranging habitat modification, destruction, and curtailment will last into the future, while ongoing habitat loss due to population growth, development, and agricultural conversion continues to pose a threat to this species outside of conservation lands.

Stressor: Inadequacy of Existing Regulatory Mechanisms

Exposure:

Response:

Consequence:

Narrative: This species is found on Federal, State and County lands. NPS regulations provide protection at Everglades National Park and Big Cypress National Preserve. These two sites continue to support the largest and best managed populations. State regulations provide protection against trade, but allow private landowners or their agents to clear or remove species on the Florida Regulated Plant Index. State Park regulations provide protection for plants within Florida State Parks. The Natural Forest Communities program in Miami is designed to protect rare and important upland (non-wetlands) habitats in south Florida; however, this regulatory strategy has several limitations that reduce its ability to protect this plant and its habitat. Although many populations of this species are afforded some level of protection because they are on public conservation lands, especially Federal lands, existing regulatory mechanisms vary in strength and scope, and do not provide substantive protection of habitat at this time. They have not led to a sufficient reduction of threats posed to these plants by a wide array of sources. (USFWS, 2017)

Stressor: Other Natural or Manmade Factors Affecting Its Continued Existence

Exposure:

Response:

Consequence:

Narrative: Threats from other natural or manmade factors to this species include nonnative, invasive plants; management practices (such as mowing); recreation (including off-road vehicle use), effects from small population size and isolation; limited geographic range; and stochastic events including hurricanes, storm surges, and wildfires. Additionally, this plant is particularly vulnerable to the effects of climate change, including sea level rise, as changes in the water table, increased soil salinity from partial inundation, and storm surge will likely result in vegetation shifts in the decades prior to the fully anticipated sea level rise. Some of these threats (e.g., nonnative species) may be reduced on public lands due to active programs by Federal, State, and County land managers. Many of the remaining populations of this plant are small and geographically isolated, and genetic variability is likely low, increasing the inherent risk due to overall low resilience of these plants. The threats act together to impact populations of this species. (USFWS, 2017)

Recovery

Reclassification Criteria:

Not defined.

Delisting Criteria:

Not defined.

Recovery Actions:

- Not defined.

Conservation Measures and Best Management Practices:

- Conserve pine rocklands and suitable habitat through purchase or conservation easements (Wendelberger 2003, p. 182).
- Remove exotic plants or hardwoods. Use manual labor, herbicides, and prescribed fire, and once cleared, use proper management to reduce costs of control and to maintain the site free of exotics

(Bradley and Gann 1999, p 26.). Control seed sources in small, fragmented areas surrounded by urban development (Bradley and Gann 1999, p. 26).

- Implement regular, prescribed burns to create or maintain suitable habitat conditions. In general, a mosaic of burns should be used, and the recommended burning regime is 3 to 7 years with summer burns generally preferred to winter burns (Bradley and Gann 1999, p. 26). Where fire has been suppressed for long periods of time, reintroduce fire in a step-wise manner (Bradley and Gann 1999, p. 26; Wendelberger 2003, p. 182). Include a monitoring program to determine effectiveness of the fire prescription (Bradley and Gann 1999, p. 26).
- Monitor and manage pine rockland fragments in Miami-Dade County.
- Continue monitoring rare plants at Long Pine Key (Gann et al. 2006, p. 2). It is important to determine effects (positive or negative) from Everglades restoration and other hydrologic manipulations and changes.
- Resurvey known locations and compare those data with current location data to better understand the stability and size of the population (Wendelberger 2003, p. 183; Maschinski et al. 2005, p. 163).
- Consider ex situ collections (Maschinski et al. 2005, p. 163).
- Assess the need for studies to determine current level of genetic variation remaining in extant occurrences.
- Assess the need to augment the population (Wendelberger 2003, p. 183).

SPECIES ACCOUNT: *Chamaesyce deltoidea serpyllum* (Wedge spurge)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/31/2016; Southeast Region (R4) (USFWS, 2016)

Physical Description

Wedge spurge is a small, prostrate perennial herb. The stems are slender and numerous, radiating out from the tap root. The leaves are more or less triangular. The flowers are cyathia, the specialized inflorescences characteristic of the genus *Euphorbia* and its close relatives. Reproduction is sexual. Some species of *Chamaesyce* are completely reliant on insects for pollination and seed production while others are self pollinating (Bradley and Gann 1999, p. 32). Pollinators may include bees, flies, ants, and wasps (Ehrenfeld 1979, pp. 95-97). No studies of reproductive biology or ecology have been conducted and these topics are poorly known for *Chamaesyce* in general. (USFWS, 2015; USFWS, 2013).

Taxonomy

John K. Small collected plants on Big Pine Key and first described *C. deltoidea* ssp. *serpyllum* as *C. serpyllum*. The taxon was later found to be related to the *C. deltoidea* complex, and subsequently ascribed to it. That complex includes several additional taxa found in the pine rockland flora of Miami-Dade County (Bradley and Gann 1999, p. 31). *Chamaesyce* is distinguished by having the main stem abortive just above the cotyledons. Synonyms include: *Chamaesyce serpyllum* Small and *Euphorbia deltoidea* Engelm. ex Chapman var. *serpyllum* (Small) Oudejans (U.S. Department of Agriculture, Natural Resources Conservation Service 2011, p. 1) (USFWS, 2015; USFWS, 2013).

Historical Range

Florida: Big Pine Key, Monroe County. (USFWS, 2015)

Current Range

Florida: Big Pine Key, Monroe County. The current range of is on Big Pine Key. Small groups of plants are scattered widely across the island (USFWS, 2015).

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Sexual (USFWS, 2013; USFWS, 2015)

Dependency on Other Individuals or Species

Adult: Pollinators may include bees, flies, ants, and wasps (Ehrenfeld 1979, pp. 95-97) (USFWS, 2015)

Reproduction Narrative

Adult: Some species of *Chamaesyce* are completely reliant on insects for pollination and seed production while others are self pollinating (Bradley and Gann 1999, p. 32). No studies of reproductive biology or ecology have been conducted and these topics are poorly known for *Chamaesyce* in general (USFWS, 2013).

Habitat Type

Adult: Pine rocklands (USFWS, 2015).

Dependencies on Specific Environmental Elements

Adult: Pine rockland is maintained by relatively frequent fires (every 2-3 years to a maximum of 15 years), which maintain the understory woody plants at shrub height (Snyder et al. 1990, pp. 257-263; Carlson et al. 1993, p. 915; Bergh and Wisby 1996, p. 1; Liu et al. 2005a, p. 210, Liu et al. 2005b, p. 71). In the absence of fire, many areas become wooded, eventually succeeding to rockland hammock (i.e., hardwood forest) (Snyder et al. 1990, p. 260) (USFWS, 2013).

Environmental Specificity

Adult: High

Habitat Narrative

Adult: *Chamaesyce deltoidea* ssp. *serpyllum* occurs in pine rocklands and adjacent disturbed sites on Big Pine Key, including roadsides. It most often grows directly from crevices in the oolitic limestone substrate (Bradley and Gann 1999, p. 31). Pine rocklands are described in detail for *Chamaecrista lineata* var. *keyensis*, above. Within pine rocklands, *Chamaesyce deltoidea* ssp. *serpyllum* is associated with areas of relatively higher elevation, extensive exposed rock substrate, where the understory is open, hardwood and palm density is low, and native herbaceous species cover and richness are high (Bradley and Saha 2009, p. 26; Ross and Ruiz 1996, p. 6; Bradley 2006, p. 27). Roadsides dominated mostly by native herbs and grasses where exotic lawn grasses are not established are a potentially important habitat for *C. deltoidea* ssp. *serpyllum* (Bradley 2006, p. 37). (USFWS, 2015). Wedge spurge is historically known only from pine rockland vegetation on Big Pine Key (Bradley and Gann 1999, p. 31). Pine rocklands in the lower Florida Keys are dominated by a canopy of *Pinus elliottii* var. *densa* (South Florida slash pine). The subcanopy is composed of *Thrinax morrisii* (brittle thatch palm), *Psidium longipes* (longstalked stopper), *Metopium toxiferum* (poisonwood), *Byrsonima lucida* (locustberry), *Pithecellobium keyense* (blackbead), and *Coccothrinax argentata* (silver palm) (Bradley 2006, p. 25). There is also a rich herbaceous layer composed of grasses and herbs. Limestone bedrock and exposed calcareous rubble are prominent features associated with pine rockland communities (Snyder et al. 1990, pp. 235-236; Ross and Ruiz 1996, p. 4). In addition to the more common associates, wedge spurge can grow in association with other rare taxa, including *Linum arenicola* (sand flax), and *Chamaecrista lineata* var. *keyensis* (Big Pine partridge pea) (Bradley and Gann 1999, p. 32) (USFWS, 2013).

Dispersal/Migration**Motility/Mobility**

Adult: Low

Population Information and Trends

Population Size:

368,557 (USFWS, 2015)

Population Narrative:

Total population size for *Chamaesyce deltoidea* ssp. *serpyllum* on publicly owned pine rocklands on Big Pine Key (478 ha (1,181 acres)) was estimated to be 352,993 plants in 2005 (preHurricane Wilma), 343,255 in 2007 (post-Wilma), and 368,557 in 2013. This represents a slight (4.4 percent) increase in the known population size of from 2005 to 2013 (Bradley et al. 2013, p. 21) (USFWS, 2015).

Threats and Stressors

Stressor: Fire suppression (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: At present, fire suppression may be one of the greatest threats to wedge spurge. While fires may have occurred at least once per decade in the past, the fire frequency since about 1950 has been sharply reduced throughout the island, despite occasional prescribed burns conducted by the Service and TNC (Bergh and Wisby 1996, p. 1). While fire suppression has occurred mostly adjacent to developed areas, all pine rockland areas on Big Pine Key have suffered from lack of fire, including pine rockland within the NKDR. Because of this drop in burn frequency, habitat characteristics have changed. Fire is required to maintain the pine rockland community (Snyder et al. 1990, pp. 257-263; Carlson et al. 1993, p. 915; Bergh and Wisby 1996, p. 1; Liu et al. 2005a, p. 210; Liu et al. 2005b, p. 71). With fire suppression, hardwoods eventually invade pine rocklands and shade out understory species like wedge spurge. Fire suppression reduces the size of the areas that burn, and habitat fragmentation prevents fire from moving across the landscape. Accordingly, in the absence of fire, pine rockland communities tend toward becoming tropical hardwood hammock communities. In many areas, pine rockland communities have been succeeded by tropical hardwood hammock flora (USFWS, 2013).

Stressor: Sea level rise (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Sea level rise is a significant threat to the species and its habitat. There has been a 15 centimeter (5.9 inch) rise in sea level over a 70-year period in the vicinity of Big Pine Key (Ross et al. 1994, p. 145). The pine rockland community in the Keys has undergone a reduction due to sea level rise (Ross et al. 1994, p. 149). For example, the pine rockland area on Sugarloaf Key covered 217 acres (88 ha) prior to 1935, and was reduced to 114 acres (46 ha) by 1935 and 74 acres (30 ha) by 1991 (Ross et al. 1994, p. 149). The loss of pine rockland communities and upland plant diversity was correlated with elevated ground- and soil-water salinity (Ross et al. 1994, pp. 150-151). In areas affected by sea level rise, communities of halophytic plants replaced pine rockland communities (Ross et al. 1994, p. 152). Based on IPCC and other predictions of sea level rise, Clough (2008, p. 23) concluded that a significant proportion of upland habitat will be lost on Big Pine Key by 2100 (USFWS, 2013).

Stressor: Nonnative invasive plants (USFWS, 2013)

Exposure:**Response:****Consequence:**

Narrative: Exotic plants have detrimental impacts on pine rocklands. Some of these are a threat to wedge spurge because they alter community structure and composition or even form dense monocultures in habitats otherwise used by wedge spurge. Some exotic species invade pine rocklands and edge habitats that are otherwise suitable for wedge spurge. Some of these may compete directly with wedge spurge for space and resources, while others have a profound effect on community structure and responses to fire. When habitats are infested by invasive exotics, lack of control (particularly if in conjunction with fire suppression) may result in dense foliage and high fuel loads. If left uncontrolled in a fire-suppressed pineland, invasive species such as Brazilian pepper may form a dense monospecific canopy almost completely eliminating native vegetation. They will also affect the characteristics of a fire when it occurs, and or the structure and composition of plant communities after fire occurs. This results in additional threats to wedge spurge. Where exotic plants are present, the known benefits of prescribed fire for wedge spurge are less certain to occur. When there are fires in infested areas, instead of being relatively cool fires that consume light fuels (e.g., pine needle litter) as in the past, they may burn much hotter and have detrimental effects on the vegetation that develops following fire (USFWS, 2013).

Stressor: Catastrophic events (USFWS, 2013)

Exposure:**Response:****Consequence:**

Narrative: Hurricanes and tropical storms are an additional threat, particularly to the extent that they yield storm surges with salt-water overwash. Hurricane storm surges can inundate landscapes with saltwater for varying durations. Klimstra (1986, p. 3) stated that the effect of salt water on pinelands is well established as a consequence of hurricane Betsy, September 8, 1965. After 20 years the site where waters were entrapped for several hours has not yet fully recovered from complete loss of *Pinus*, *Ernodea*, *Randia*, *Pisonia*, and *Metopium* seedlings. The small area of occupancy and somewhat patchy distribution of wedge spurge renders it susceptible to extinction through such stochastic events. In 2005, Hurricane Wilma resulted in a storm surge that covered most of Big Pine Key with seawater (USFWS, 2013).

Stressor: Demographic and genetic factors (USFWS, 2013)

Exposure:**Response:****Consequence:**

Narrative: The small area, few occurrences, and somewhat patchy distribution of wedge spurge renders it susceptible to extinction risks associated with stochastic demographic, genetic, and environmental events, including catastrophic storms. Further reduction of population size would likely enhance threats associated with genetics and demographic stochasticity (Caughley 1994, p. 217) (USFWS, 2013).

Recovery**Reclassification Criteria:**

Not defined.

Delisting Criteria:

Not defined.

Recovery Actions:

- Not defined.

Conservation Measures and Best Management Practices:

- Increase prescribed fires. Prescribed fires should be conducted across all pine rockland areas in NKDR and other portions of Big Pine Key. NKDR has revised its Comprehensive Conservation Plan; this plan calls for a revised Fire Management Plan. (USFWS, 2013)
- Mechanical treatments to control understory can be effective in preparing for prescribed fires. These techniques will probably be most beneficial in pine rockland areas that have undergone long periods of fire suppression. There are many such areas in the southern half of Big Pine Key. (USFWS, 2013)
- Conduct further research into fuel reduction and fire-wedge spurge interactions, including the effects of mechanical treatments. (USFWS, 2013)
- Establish and maintain fire breaks; quantify before the outcome is determined. (USFWS, 2013)
- Given the large impact of Hurricane Wilma, monitor wedge spurge and community characteristics that are positively correlated with wedge spurge occurrences on multiple spatial scales. (USFWS, 2013)
- Continue exotic plant control programs in pine rockland habitat. Exotic plant densities in most pine rockland areas on Big Pine Key are currently low, and management should continue to prevent spread of invasive exotic plants. (USFWS, 2013)
- NKDR should institute an integrated program of adaptive management in order to prioritize and optimize efforts and objectives pertaining to pine rockland viability, fire regimes, and fuel reduction relative to wedge spurge and other endemic plants. (USFWS, 2013)
- Develop sea level rise and hurricane impact models, and encourage the integration of these models in management efforts in order to enhance their effectiveness. (USFWS, 2013)
- Conduct studies on reproductive biology and ecology of wedge spurge. (USFWS, 2013)
- Consider the need to establish and maintain an ex situ collection of wedge spurge in the future to reduce its vulnerability to catastrophic events, if the trend in population continues to decline. (USFWS, 2013)

SPECIES ACCOUNT: *Cordylanthus tenuis ssp. capillaris* (Pennell's bird's-beak)

Species Taxonomic and Listing Information

Listing Status: Endangered; 03/06/1995; California/Nevada (Region 8)

Physical Description

A branching herbaceous annual of the broomrape family (Orobanchaceae). The plant grows 30 to 60 centimeters (12 to 24 inches) tall, with yellow-green hairless herbage that becomes purplish with age. The leaves are entire (with smooth edges), or those of the primary stem three-parted, and threadlike. The floral bracts are three-parted up to two-thirds of their length, with fine marginal hairs on bracts and calyx (collective term for the sepals or outermost whorl of flower parts). The tubular corolla (collective term for all the petals) is 1.5 centimeters (0.6 inch) long (Chuang and Heckard 1986), and gamet-brown laterally, paler dorsally (Pennell 1950). Each capsule contains 10 to 16 seeds (Chuang and Heckard 1986). (USFWS, 1998; USFWS, 2019b)

Taxonomy

Cordylanthus capillaris (Pennell's bird's-beak) was first described by Pennell (1950). Chuang and Heckard (1986) reclassified the *Cordylanthus* genus and considered Pennell's bird's-beak to be a subspecies: *C. tenuis ssp. capillaris*. At the time of listing, the genus was considered within the snapdragon family (Scrophulariaceae). Presently, the genus *Cordylanthus* is considered within the broomrape family (Orobanchaceae) (Olmstead et al. 2001). (USFWS, 2011)

Historical Range

Known only from the Outer North Coast Ranges floristic province of Sonoma County, California, a range of a few square miles (vicinity of unincorporated Camp Meeker area). (USFWS, 2019b)

Current Range

Known only from the Outer North Coast Ranges floristic province of Sonoma County, California, a range of a few square miles (vicinity of unincorporated Camp Meeker area). (USFWS, 2019b)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (self-incompatible) (USFWS, 2011)

Lifespan

Adult: 1 year (USFWS, 2011)

Dependency on Other Individuals or Species

Adult: Members of the *Cordylanthus* genus require bees for effective pollination (Chuang and Heckard 1986).

Breeding Season

Adult: June to July (USFWS, 2011)

Reproduction Narrative

Adult: Pennell's bird's-beak is an herbaceous annual of the broomrape family (Orobanchaceae) (Olmstead et al. 2001) and it flowers from June through July (Chuang and Heckard 1986).

Members of the *Cordylanthus* genus require bees for effective pollination (Chuang and Heckard 1986). The fruit are capsules containing 10 to 16 seeds (Chuang and Heckard 1986). *C. tenuis* ssp. *capillaris* were found to be self-incompatible (Chuang and Heckard 1986).

Habitat Type

Adult: Terrestrial (USFWS, 2011)

Habitat Vegetation or Surface Water Classification

Adult: Chaparral communities (USFWS, 2011)

Geographic or Habitat Restraints or Barriers

Adult: Restricted to elevations from 45 to 245 meters (148 to 804 feet) (USFWS, 2011)

Spatial Arrangements of the Population

Adult: Colonies (USFWS, 2011)

Habitat Narrative

Adult: *Cordylanthus tenuis* ssp. *capillaris* grows only on serpentine soils among chaparral and closed pine forests (Chuang and Heckard 1986) and are found in colonies. Occurrences range in elevation above mean sea level from 45 to 245 meters (148 to 804 feet) (Calflora 2011, CNPS 2011). *Cordylanthus tenuis* ssp. *capillaris* is associated with Sargent's cypress (*Cupressus sargentii*), Baker's manzanita, and coffeeberry (*Rhamnus californica*) (Chuang and Heckard 1986). (USFWS, 2011)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Unknown (USFWS, 2019a)

Number of Populations:

4 (USFWS, 2019a)

Population Size:

Unknown; fluctuates from well over 10,000 to a few individuals at each location (USFWS, 2019a)

Population Narrative:

In 2011, Pennell's bird's-beak was recognized to occur in five separate locations (USFWS 2011). Currently, Pennell's bird's-beak is known from four locations (CNDDDB 2018). California Natural Diversity Database lists occurrence #1 as mainly within the Harrison Grade Ecological Reserve, owned and managed by CDFW. The fifth occurrence is combined with occurrence #4. Two occurrences (#2 and #4) are within what is now the Bohemia Ecological Preserve. This property is protected under a conservation easement, which is owned and managed by Land Paths since 2012 (E. Mullen, pers. comm. 2018). Occurrence #3 is located on the privately owned Twin Valley Ranch near Porter Creek, about 11 kilometers (6.8 miles) northeast of occurrence #2. However, this site has not been surveyed in the past 20 years. While the status of this population remains unknown, it is assumed to be extant. Anecdotal reports suggest many Pennell's bird's-beak populations exist on private property outside of the before mentioned occurrences in areas where botanical surveys have not been done (G. Cooley, pers. comm. 2018). Biologists with CDFW have observed Pennell's bird's-beak on private properties outside of the reserve boundaries at the Harrison Grade Ecological Reserve (J. Bjerke, in litt. 2018b). The full extent of the population remains unknown. (USFWS, 2019a)

Threats and Stressors

Stressor: Development (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: At the time of listing, development and associated road construction on the private lands containing occurrence 1, which would result in loss, modification, and destruction of *Cordylanthus tenuis* ssp. *capillaris* habitat, were considered potential threats. Development plans had included the donation of 87 hectares (including *C. tenuis* ssp. *capillaris* habitat) to the county for use as a park (Service 1998). However, although some roads were constructed, the development never took place, and the land was subsequently sold. Habitat for *Cordylanthus tenuis* ssp. *capillaris* along Bohemian Highway has been significantly reduced within the past 23 years (Herrick, in litt. 2011). Parts of the talus and bank have been removed and a windrow has been planted in areas known to be previously colonized by *C. tenuis* ssp. *capillaris* (Herrick, in litt. 2011). (USFWS, 2011)

Stressor: Vineyards (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Presently, within the past 5 to 10 years along Stoetz Lane parcels of land have been converted vineyards. The conversion to vineyards of potential *C. tenuis* ssp. *capillaris* habitat continues to threaten populations at CNDDDB occurrence 2 (Herrick, in litt. 2011). (USFWS, 2011)

Stressor: Timber harvest (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: CNDDDB Occurrence 1 is located on property where timber harvesting has occurred since the time of listing (G. Hale, Sonoma Land Trust, in litt. 2011). Similarly, timber harvesting has occurred on the property where Occurrence 6 is located, and may continue in the future (Robertson 2011, Zito 2011). Timber harvesting can cause significant changes in the species richness and diversity in the herbaceous plant layer (Battles et al. 2001, Macdonald and Fenniak 2007). Although some effects of canopy removal can be short-lived, many other effects persist over a much longer timeframe (e.g., disturbance-mediated limitations to dispersal) (Gilliam 2007). Such effects could be detrimental to populations of *C. tenuis* ssp. *capillaris*. Roadside maintenance such as mowing has been reported at occurrence 4, and cattle grazing was reported at occurrence 5 (CNDDDB 2011). (USFWS, 2011)

Stressor: Mowing and grazing (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Mowing and grazing before the plants flower, typically June through July (Chuang and Heckard 1986) would prevent the generation of seeds. As an annual herbaceous plant species, *C. tenuis* ssp. *capillaris* relies on seed banks to maintain population levels. Horses and deer were reported to browse on *Cordylanthus tenuis* ssp. *capillaris*. The site of occurrence 5 has been used for cattle grazing (CNDDDB 2011). In general, however, the number of plants damaged by grazing continues to be unknown. (USFWS, 2011)

Stressor: Diseases (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Due to the hemiparasitic nature of *Cordylanthus tenuis* ssp. *capillaris*, diseases to potential host species may threaten *C. tenuis* ssp. *capillaris* populations. *Phytophthora cinnamomi* is a pathogen causing mortality in a number of native forests and chaparral communities in northern California (Swiecki, in litt. 2008, p. 2). *Phytophthora ramorum* is another pathogen known to cause sudden oak death in at least four coastal California oak species (Garbelotto et al., 2001; Rizzo and Garbelotto 2003). The Service lacks adequate information to determine the potential effects of these pathogens on *Cordylanthus tenuis* ssp. *capillaris*. (USFWS, 2011)

Stressor: Increasing human populations (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Increasing human populations in central California coastal counties were reported to place a great strain on undeveloped wild-lands, such as those found on the serpentine soils (Service 1995). Listed factors include pedestrian and off-road vehicle traffic, hiking and bicycle trails, and unauthorized garbage dumping. These factors can lead to increased erosion, the establishment of non-native, invasive plants, and the fragmentation of the native plant populations (Service 1995). In turn the native plant populations are increasingly susceptible to natural factors that can negatively affect viability, such as fire and disease (Brigham and Schwartz 2010). The limited number and isolated conditions of the *Cordylanthus tenuis* ssp. *capillaris*

populations, resulting from these natural and manmade factors, can render the species susceptible to stochastic extinction (Brigham and Schwartz 2010). (USFWS, 2011)

Stressor: Roadside maintenance (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Roadside maintenance, such as mowing and spraying, and vehicular traffic were mentioned as threats to *Cordylanthus tenuis* ssp. *capillaris* in the 1995 listing (Service 1995). Unauthorized dumping of articles ranging from appliances to bottles also was mentioned as factors affecting *C. tenuis* ssp. *capillaris* (Service 1995). Whereas light road grading was thought to facilitate establishment of *C. tenuis* ssp. *capillaris*, heavy road disturbance may increase the invasion of non-native plant species (Service 1995). (USFWS, 2011)

Stressor: Habitat fragmentation (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Leimu et al. (2006), in meta-analyses of plant studies published between 1987 and 2005, determined that the negative effects of habitat fragmentation (e.g., reduced genetic variation, increased demographic stochasticity) are more common among self-incompatible and rare plant species. *Cordylanthus tenuis* ssp. *capillaris* is not only rare, but also self-incompatible (Chuang and Heckard 1986). Although natural selection pressures have acted over time to create a niche for *C. tenuis* ssp. *capillaris* on serpentine soils, the fragmented nature of serpentine habitats can leave rare plants dependent upon them susceptible to vagaries of stochastic events. Indeed, populations of *C. tenuis* ssp. *capillaris* vary among years (CNDDDB 2011), and the causes for annual variations are not readily apparent. (USFWS, 2011)

Stressor: Climate change (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Current climate change predictions for terrestrial areas in the Northern Hemisphere indicate warmer air temperatures, more intense precipitation events, and increased summer continental drying (Field et al. 1999, Cayan et al. 2005, IPCC 2007). However, predictions of climatic conditions for smaller sub-regions such as California remain uncertain. It is unknown at this time if climate change in California will result in a warmer trend with localized drying, higher precipitation events, or other effects. While we recognize that climate change is an important issue with potential effects to listed species and their habitats, we lack adequate information to make accurate predictions regarding its effects to particular species at this time. (USFWS, 2011)

Stressor: Ozone (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Ozone due to photochemical smog is another potential threat to *Cordylanthus tenuis* ssp. *capillaris*. Several studies have documented harmful effects of increased nitrogen deposition, such as increased foliar injury and growth reduction (e.g., Miller 1992; Grantz and

Yang 1996; Bytnerowicz 2002), yet no information exists specifically for *C. tenuis* ssp. *capillaris*. (USFWS, 2011)

Recovery

Reclassification Criteria:

1. The two confirmed populations of *Cordylanthus tenuis* ssp. *capillaris* (Harrison Grade and Bohemian Highway) are (1) fully protected and managed with the primary intention of preserving the populations in perpetuity; and (2) shown to be stable or increasing over a minimum of 20 years that include the normal precipitation cycle (or longer if suggested by the results of demographic monitoring). (USFWS, 1998)
2. Seed collected from both remaining natural populations is stored at a minimum of two Center for Plant Conservation certified botanic gardens. (USFWS, 1998)
3. Reliable seed germination and propagation techniques for the species are understood. (USFWS, 1998)

Delisting Criteria:

- A/1: Areas of occupied habitat are secured or established and voluntarily protected in perpetuity for at least ten known sites large enough to incorporate the seasonal and spatial variation of new colonies. Protected areas are at least 12 hectares (30 acres), unless future research indicates otherwise. (USFWS, 2019b)
- A/2: The breadth of current genetic variation is represented at protected sites. (USFWS, 2019b)
- A/3: No damage is recorded over the course of 20 years due to trampling or vandalism. (USFWS, 2019b)
- E/1: Plants that are nonnative to serpentine habitats are monitored and controlled at a level that allows for the increase, establishment, and persistence of Pennell's bird's-beak in protected areas on suitable habitat. (USFWS, 2019b)

Recovery Actions:

- 1. Establish or protect additional populations of Pennell's bird's-beak. 1.1 Conduct botanical field surveys to discover additional populations. (Priority 1). 1.2 Protect additional populations through voluntary conservation agreements or land acquisitions. (Priority 1). 1.3 Collect and introduce Pennell's bird's-beak seeds in areas of appropriate habitat on protected lands. (Priority 1). 1.4 Survey reintroduction sites annually to determine abundance and extent. (Priority 2). (USFWS, 2019b)
- 2. Conduct research to increase understanding of Pennell's bird's-beak life history and annual establishment. 2.1 Conduct research to determine the full range (area and extent) of the species. (Priority 3). 2.2 Conduct demographic surveys and long-term monitoring that includes, but is not limited to, habitat surveys, genetic research, host-parasite dynamics, and annual establishment. (Priority 1). 2.3 Investigate and monitor potential management methods to maximize population success. Adapt and modify management as necessary. (Priority 2). (USFWS, 2019b)

- 3. Conduct genetic research to determine if genetically distinct populations exist outside of protected areas. (Priority 3). (USFWS, 2019b)
- 4. Monitor and manage Pennell's bird's-beak populations on protected lands. 4.1 At locations where the plant is protected, establish management plans to ensure the quality of existing habitat is maintained and/or degraded habitat is restored. (Priority 2). 4.2 Conduct regular patrols to deter illegal dumping in habitat. If needed, mitigate the effects of illegal dumping on habitat. (Priority 3). 4.3 Store seeds in at least two Center for Plant Conservation certified facilities. Unless storage techniques and/or research show otherwise, replenish seed stock every 10 years to ensure seed viability. (Priority 2). 4.4 Establish a Service-approved monitoring plan to cover a minimum of 5 years post-delisting. The plan will be ready for implementation at the time of delisting to ensure the ongoing conservation of the species and the continued effectiveness of management actions. Adequate funding must be dedicated in order to implement the delisting management plan. (Priority 3). (USFWS, 2019b)
- Until research shows otherwise, recovery should target securing populations containing a minimum of 2,000 plants each (but preferably more). The probability of population persistence over the long-term is expected to be higher for larger populations because large size decreases the likelihood of reduced viability or population extirpations due to random demographic or genetic events (Barrett and Kohn 1991, Ellstrand and Elam 1993). (USFWS, 1998)
- Protecting and managing populations at the two remaining locations by working with the California Department of Fish and Game and private landowners to ensure long-term survival of the species. Populations on private land should be protected by land acquisition, conservation easements, or other means. In general, the largest possible block of serpentine habitat should be protected at each site. Protection should, at least, involve securing the populations themselves as well as a 150- meter (500-foot) buffer around each population, where possible, to reduce external influences and allow expansion of populations. In addition, other unoccupied habitat at the sites that might provide space for expansion of the populations and habitat for pollinators and seed dispersers must be protected. Management plans emphasizing *Cordylanthus tenuis* ssp. *capillaris* and other special status species in these locations must be developed and implemented. The plans should include provisions for standardized annual monitoring of *Cordylanthus tenuis* ssp. *capillaris* populations to determine demographic trends. The plans should also include strategies to minimize known threats at the sites as well as to identify new threats as they may appear. In particular, threats from off road vehicle use, dumping, and roadside maintenance must be eliminated. If new threats (e.g. invasion of non-natives) are identified or other new information becomes available, management plans need to be reevaluated and revised. (USFWS, 1998)
- Collection and banking of seed in Center for Plant Conservation certified botanic gardens is also a high priority recovery action for *Cordylanthus tenuis* ssp. *capillaris*. Seed banking is prudent to guard against extinction of the species from chance catastrophic events and to provide potential material for enhancement efforts in existing populations, repatriations, and/or introductions to new sites. In the absence of genetic data for *Cordylanthus tenuis* ssp. *capillaris*, seed banking should include collections from all known populations. Care should be taken to ensure that seed collection does not adversely affect the donor populations. (USFWS, 1998)

- Other suitable serpentine habitat should be surveyed to determine whether undiscovered populations exist. If new populations are discovered, they should be protected and managed as discussed above. During these surveys, potential introduction sites might also be identified. (USFWS, 1998)
- Research on seed germination and propagation techniques that take into account the hemiparasitic nature of the plant, the use of burning as a management strategy, and basic research on demography (including soil seed bank) and reproduction (including mating system and pollination). Demographic research would be valuable to identify limiting life history stages. (USFWS, 1998)
- Recommended Future Action from 2011 5-Year Review: Protect known occurrences from threats by acquiring the private lands from willing sellers where *Cordylanthus tenuis* ssp. *capillaris* is known to occur. (USFWS, 2011)
- Recommended Future Action from 2011 5-Year Review: Design and implement a comprehensive survey method for *Cordylanthus tenuis* ssp. *capillaris*. Survey designs should incorporate geographic information systems (G.I.S.) technology to identify additional suitable sites for *C. tenuis* ssp. *capillaris*. (USFWS, 2011)
- Recommended Future Action from 2011 5-Year Review: Work with land owners and land managers to gain access to known and potential suitable sites for *Cordylanthus tenuis* ssp. *capillaris* populations. Annual population surveys of known occurrences should be reported to the CNDDDB. (USFWS, 2011)
- Recommended Future Action from 2011 5-Year Review: Scientific studies should be conducted to identify ideal host species. Chuang and Heckard (1971) have inferred suitable host species for *Cordylanthus tenuis* ssp. *capillaris*, yet individual plant fitness varies with host plant relationships. Studies remain to identify decisively the optimal host species. (USFWS, 2011)
- Recommended Future Action from 2011 5-Year Review: Ascertain the importance of habitat disturbance to *Cordylanthus tenuis* ssp. *capillaris*. Current occurrences are openings among chaparral and conifer woodlands. Management strategies should evaluate the effectiveness of timber removal and fire ecology for the propagation of the species. (USFWS, 2011)
- Recommended Future Action from 2019 5-Year Review: Survey to identify potential habitat. A comprehensive and systematic survey of serpentine habitats for the presence of Pennell's bird's-beak has yet to be conducted. A new occurrence was discovered in 1997 during surveys for a different serpentine plant (CNDDDB 2018). Anecdotal reports suggest additional populations might exist on private property. By identifying these areas and working with local landowners, additional occurrences might be protected in perpetuity. (USFWS, 2019a)
- Recommended Future Action from 2019 5-Year Review: Conduct research to better understand Pennell's bird's-beak life history, demographics, annual establishment, etc. Very little is known about the demographics and life history of Pennell's bird's-beak. Future research should be focused on informing conservation and management decisions. Current occurrences indicate that site disturbance might promote colonization, yet the role of disturbance mechanisms such as fire and flooding is unknown. Conducting long-term 4 demographic surveys and monitoring that include habitat surveys, genetic research, host-parasite dynamics and annual establishment would further recovery goals. (USFWS, 2019a)

SPECIES ACCOUNT: *Cornutia obovata* (Palo de nigua)

Species Taxonomic and Listing Information

Listing Status: Endangered; 4/7/1988; Southeast Region (R4) (USFWS, 2015)

Physical Description

An evergreen tree which reaches 10 to 15 meters in height and 25 centimeters in diameter. The leaves are opposite, simple, obovate, blunt or rounded at the apex. The lower surface of leaves is finely hairy with minute, golden, shiny glandular dots. Leaves may be from 5 to 14 centimeters long and from 4 to 8 centimeters wide. Three or four prominent, ascending, curved veins are present on either side of the mid—vein. Twigs are four-sided, finely hairy and brownish when young. The flower cluster is a terminal panicle, 8 to 30 centimeters in length. Flowers are perfect and zygomorphic. The corolla is bluish or purplish, finely hairy outside with long hairs inside. Fruits are a purplish drupe which contains 3 to 4 seeds (Vivaldi and Woodbury 1981a, Little et al. 1974)(USFWS, 1992).

Taxonomy

Cornutia obovata is a member of the family Verbenaceae (USFWS, 1992).

Historical Range

Cornutia obovata is considered as endemic to the main island of Puerto Rico. *Cornutia obovata* was first collected in 1885 by the German collector Paul Sintenis on the area of Monte Torrecilla in the municipality of Barranquitas in central Puerto Rico (USFWS, 2014).

Current Range

C. obovata currently exists within the following natural areas: Monte Torrecilla, Susúa Commonwealth Forest, Río Abajo Commonwealth Forest, Sumidero Tres Pueblos, and the Arecibo Observatory (USFWS, 2014).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Vegetative (USFWS, 1992); sexual (inferred from EPA, 2016)

Breeding Season

Adult: May - July (EPA, 2016)

Key Resources Needed for Breeding

Adult: Insect and bird pollinators (EPA, 2016)

Reproduction Narrative

Adult: Abundant flowering is observed in June and July; flowering also observed in late May. Observed in September and October. It is pollinated by insects and birds (EPA, 2016). The importance of vegetative reproduction has not been studied; however, field observations indicate that sprouting following cutting or breakage occurs rapidly (USFWS, 1992).

Habitat Type

Adult: Terrestrial (EPA, 2016)

Habitat Vegetation or Surface Water Classification

Adult: Subtropical moist forest, subtropical wet forest, lower montane forest (EPA, 2016)

Geographic or Habitat Restraints or Barriers

Adult: ~730 to 3,300 ft. elevation (USFWS, 2014)

Habitat Narrative

Adult: Occurs in subtropical moist forest and subtropical wet forest life zones in northern and south-central Puerto Rico. Barranquitas in the central mountains, Rio Abajo Commonwealth Forest, and Arecibo Observatory. Most populations occur in semi-evergreen and evergreen seasonal forests of the limestone hills of northern Puerto Rico. Also found in lower montane forest (Mont Torrecilla). Susua population occurs on serpentine-derived soils of the El Cacique-La Taina Complex. Arecibo population is on soils derived from Rock- outcrop-Tanama complex and the Soller-rock outcrop complex. The Barranquitas population is on soils from igneous bedrock of the Humatas clay series. Soils are shallow, well-drained, alkaline, and interspersed between outcrops of hard limestone. Volcanic derived soils that are moderately deep to deep, and moderately acid clays in the Barranquitas area. Also reported historically in serpentine soils, but none of the currently known populations are on serpentine soils (EPA, 2016). Elevations at all sites range from 730-3,300 ft. (USFWS, 2014).

Dispersal/Migration**Dependency on Other Individuals or Species for Dispersal**

Adult: Unknown (EPA, 2016)

Dispersal/Migration Narrative

Adult: Dispersal mechanisms are unknown (EPA, 2016).

Population Information and Trends**Population Trends:**

Unknown (USFWS, 2014)

Species Trends:

Unknown (USFWS, 2014)

Resiliency:

Very low (inferred from EPA, 2016)

Representation:

Very low (inferred from USFWS, 2014)

Redundancy:

Low (inferred from EPA, 2016)

Number of Populations:

7 (EPA, 2016)

Population Size:

~19 (USFWS, 2014)

Population Narrative:

There are 6 populations in the limestone hill area and 1 population in the central mountains (EPA, 2016). The species status is uncertain; little monitoring has been conducted on the natural populations of the species. About 19 individuals currently exist. There is no long-term monitoring of these natural populations, so population trends are unknown (USFWS, 2014).

Threats and Stressors

Stressor: Habitat destruction and modification (USFWS, 2014)

Exposure:

Response:

Consequence:

Narrative: The largest natural population, and type locality at Monte Torrecilla (located on private land), remains threatened by future expansion or maintenance of communication facilities (USFWS, 2014).

Stressor: Stochastic events and climate change (USFWS, 2014)

Exposure:

Response:

Consequence:

Narrative: The low number of populations and individuals pose a threat to the species by making it susceptible to stochastic events such as hurricanes. The effects of landslides are exacerbated for small relic populations as is the case of *C. obovata*. Moreover, the frequency of landslides may increase, as landslides are triggered by severe rain events, whose frequency and severity is expected to increase due to climate change (Hopkinson et al. 2008). For example, given the steep topography of Monte Torrecilla, a massive landslide may extirpate the largest known population of *C. obovata*. Vulnerability to climate change impacts is a function of sensitivity and exposure to those changes, and the adaptive capacity of the species (Glick et al. 2011). Therefore, shifts of vegetation communities are expected as temperatures and moisture regimes are altered by climate change. Under this scenario, the populations of *C. obovata* may be displaced or outcompeted by native or exotic species with wider environmental plasticity. Climate change may also compromise natural recruitment by affecting seed germination and/or the survival of seedlings (USFWS, 2014).

Stressor: Genetic variation (USFWS, 2014)

Exposure:

Response:

Consequence:

Narrative: Along with reduced population size, negative impacts of habitat fragmentation may result in erosion of genetic variation through the loss of alleles by random genetic drift (Honney and Jacquemyn 2007). These factors may limit the ability of a species to respond to a changing environment (Booy et al. 2000). Given the extremely small population size and low number of known natural populations of *C. obovata*, it is likely that their genetic variability is low. As previously indicated, only the population at Monte Torrecilla is composed by 9 individuals, the remaining sites are comprised by 1-5 individuals (USFWS, 2014).

Stressor: Lack of natural recruitment (USFWS, 2014)

Exposure:

Response:

Consequence:

Narrative: Lack of natural recruitment represents one of the major threats to *C. obovata* as there is no evidence of seedlings on the wild despite the production of fruits (Geraldo Hernández, PRDNER, pers. comm. 2013). According to Santiago (2011) germination under nursery conditions seem to be low, suggesting the possibility of selfing on the wild populations. Without natural recruitment or successful augmentation from captive propagated individuals, populations (natural and reintroduced) of *C. obovata* are likely to become extirpated as older individuals naturally die. Despite future efforts to enhance natural populations by planting seedlings and saplings, it is unknown if planted individuals will develop into mature plants capable of reproduction (USFWS, 2014).

Recovery**Reclassification Criteria:**

Not available

Delisting Criteria:

1. The privately owned populations are given protected status (USFWS, 2014).
2. At least three new self-sustaining populations in Commonwealth Forest units such as Río Abajo or Guajataca have been established (USFWS, 2014).

Recovery Actions:

- Monitor existing populations (USFWS, 1992).
- Protect privately-owned populations sites (USFWS, 1992).
- Conduct research on the life history of the species and evaluate methods of propagation (USFWS, 1992).
- Propagate and produce seedlings and saplings for enhancement of existing populations and the establishment of new ones (USFWS, 1992).

Conservation Measures and Best Management Practices:

- Studies should be conducted on the species phenology and reproductive biology to address other limiting factors affecting the species (e.g., lack of pollinators or seed dispersers) (USFWS, 2014).

- The population at Monte Torrecilla should be monitored to collect seed material for recovery purposes. A protocol to collect seed material should be developed and implemented to avoid impacting the natural recruitment of the species (USFWS, 2014).
- All known populations should be marked and monitored on a regular basis, and additional visits should be made after hurricanes or other major disturbances to determine any possible adverse effects on the populations (USFWS, 2014).
- Studies should be conducted of the patterns of genetic variation, in order to develop a plan to preserve the species' germplasm (USFWS, 2014).
- The very small wild populations should urgently be enhanced, using seeds or vegetative propagation (e.g., air layering, tissue culture, etc.) if necessary, taking into account the species' patterns of genetic variation (USFWS, 2014).

SPECIES ACCOUNT: *Coryphantha minima* (Nellie cory cactus)

Species Taxonomic and Listing Information

Listing Status: Endangered; 12/7/1979; Southeast Region (R2) (USFWS, 2016)

Physical Description

E. minima has ovoid to cylindrical, tuberculate, solitary or branching stems from to 1.0 to 4.0 cm (0.4 to 1.6 in) tall and 0.6 to 2.5 cm (0.2 to 1.0 in) wide; when cultivated, the plants often form caespitose clusters with numerous stems. Dense, appressed, peg-like spines, from 15 to 27 per areole, obscure the stems. The flowers have pink to reddish-purple perianths from 1.5 to 2.7 cm (0.6 to 1.1 in) wide. The fruits are green to yellowish, from 1.5 to 7.0 mm (0.06 to 0.3 in) long, and the dark brown to black, pitted seeds are up to 1.0 mm (0.04 in) long. (USFWS, 2012)

Taxonomy

First reported by Baird (1931). There is debate over the systematics of the cactus family. Recognized scientific names for *Escobaria minima* include: *Coryphantha minima* Baird (Baird 1931; Benson 1982; Zimmerman and Parfitt 2011b; Tropicos 2011b; U.S. Fish and Wildlife Service 2011b); *Coryphantha nelliae* Croizat (Croizat 1934); *Escobaria minima* (Baird) D.R. Hunt (Hunt 1978; Anderson 2001; Poole, et al. 2007; Integrated Taxonomic Information System 2011b; Natural Resources Conservation Service 2011b); *Escobaria nelliae* (Croizat) Backeb (Backeberg 1961) and *Mammillaria nelliae* (Croizat) Croizat (Croizat 1942). Common names used for *Escobaria minima* include: Birdfoot cactus (Poole et al. 2007); Dwarf cory cactus (Poole et al. 2007); Least cory cactus (Poole et al. 2007); Nellie cory cactus (Poole et al. 2007; Center for Plant Conservation 2011b; Natural Resources Conservation Service 2011b; U.S. Fish and Wildlife Service 2011b); Nellie's cory cactus (Poole et al. 2007); Nellie's cory-cactus (Anderson 2001); and Nellie's pincushion cactus (Zimmerman and Parfitt 2011b). The Service will continue to classify this species as *Escobaria minima*. Further systematic revisions are expected in the *E. viridiflorus* complex, particularly as genetic studies provide new tools to reveal the phylogeny of the cactus family. (USFWS, 2012)

Historical Range

Near Marathon, in Brewster County, Texas (USFWS, 2012).

Current Range

Near Marathon, in Brewster County, Texas (USFWS, 2012).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (USFWS, 2012)

Lifespan

Adult: Not available, but clearly perennial (USFWS, 2019)

Breeding Season

Adult: April - May (USFWS, 2012)

Key Resources Needed for Breeding

Adult: Insect pollinators (USFWS, 2012)

Reproduction Narrative

Adult: Weniger (1979a, 1979b) observed that *E. minima* flowered in April and May and the fruits ripened by mid-summer. The species is insect pollinated and reproduce entirely by sexually-produced seeds. It begins flowering at three to four years of age. *E. minima* plants produce up to four fruits per year containing 80 to 100 seeds each (USFWS, 2012).

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Creosote bush-mesquite shrub, Chihuahuan Desert scrub (USFWS, 2012)

Geographic or Habitat Restraints or Barriers

Adult: 1,200 - 1,350 m elevation (NatureServe, 2015)

Spatial Arrangements of the Population

Adult: Caespitose clusters (USFWS, 2012)

Environmental Specificity

Adult: Narrow (inferred from USFWS, 2012 and NatureServe, 2015)

Habitat Narrative

Adult: Inhabits rock crevices on novaculite outcrops (a hard, fine-grained, silica-rich rock), in full sun, among sparse Chihuahuan Desert scrub at 1,200-1,350 m elevation (NatureServe, 2015). Within the Caballos formation, *E. minima* grows in novaculite cracks and fragments, often in association with *Selaginella peruviana* (club-moss) (Weniger 1979a, 1979b; U.S. Fish and Wildlife Service 1984a, 1984b; Poole et al. 2007). The vegetation map of Frye et al. (1984) classifies the vegetation of the Caballos novaculite outcrops and of the surrounding valley floors as creosote bush - mesquite shrub (*Larrea tridentata* – *Prosopis glandulosa*) and tobosa - blackgrama grasslands (*Hilaria mutica* – *Bouteloua eriopoda*), respectively. Poole et al. (2007) describe the specific habitats of the endemic plants of the Caballos novaculite as sparse Chihuahuan Desert scrub or sparsely vegetated desert or semi-desert grasslands or shrublands. *E. minima* plants typically occur as dense, caespitose clusters (USFWS, 2012).

Dispersal/Migration**Dispersal**

Adult: Low (inferred from USFWS, 2012)

Dispersal/Migration Narrative

Adult: The seeds apparently fall near the parent plants as fruits decompose and are dispersed by the surface flow of rain water (USFWS, 2012).

Population Information and Trends

Population Trends:

Not available

Number of Populations:

2 (NatureServe, 2015)

Population Size:

> 1 million (USFWS, 2012)

Minimum Viable Population Size:

Unable to determine (USFWS, 2019)

Population Narrative:

Known from only 1 site, 2 populations (NatureServe, 2015). McKinney (2000) estimated that total populations of *E. minima* were more than 1,000,000 (USFWS, 2012).

Threats and Stressors

Stressor: Habitat destruction and modification (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Livestock grazing, wildfires, herbicide usage, and mining are potential and/or minor threats (USFWS, 2012).

Stressor: Collection (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: The evidence of the threat of illicit and unscrupulous collection to *E. minima* is clear; the species has been extirpated from its type location on a publicly-accessible highway ROW – a site well-known to cactus collectors for decades. This cactus species is offered for sale over the internet (B & T World Seeds 2011a, 2011b; High Country Gardens 2011a, 2011b), presumably cultivated legally and ethically from propagated seed or tissue culture rather than seeds or plants collected from the wild. There is no information on the current extent of illicit collection from the remaining wild populations. The restricted access to these remote sites and the vastness of the landscape may provide the best possible protection from this threat (USFWS, 2012).

Stressor: Herbivory (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Herbivory by insects, rodents, and perhaps other animals constitutes a potential threat to *E. minima* (USFWS, 2012).

Stressor: Climate change (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Changes in temperature and rainfall amounts and patterns could alter the species competitive advantages in the unique micro-habitats it occupies. Regardless of how these changes may affect its autecology, the altered synecology may be far more significant. For example, this species might benefit from higher winter temperatures that extend its growing season. Conversely, it might face new threats from a migration of tropical cactus parasites and pathogens into their habitat (USFWS, 2012).

Recovery

Reclassification Criteria:

The downlisting criteria for Nellie's cory cactus are based on the minimum conditions that justify reclassification of the species. We will consider reclassifying Nellie's cory cactus to threatened status when: (USFWS, 2019)

1. Ten or more viable metapopulations are legally protected and managed for the purpose of conserving Nellie's cory cactus and its habitats. Examples include, but are not limited to, conservation easements on private lands, lands owned and managed for conservation by non-profit organizations, and legally-binding long-term management agreements with private landowners. (USFWS, 2019)
2. The 10 or more protected metapopulations described in the previous criterion must each have a minimum viable population size of 1,300 or more mature individuals. (USFWS, 2019)

Delisting Criteria:

Nellie's cory cactus will be considered for delisting when: (USFWS, 2019)

1. Periodic monitoring indicates that the minimum viable population levels of 1,300 mature individuals within each of 10 protected metapopulations (the criteria for downlisting to threatened) have remained stable or have increased over a period of 25 years. Monitoring (censuses) of each protected metapopulation must be conducted at least once every five years. (USFWS, 2019)

Recovery Actions:

- Develop a cooperative agreement with private landowners for the protection and management of the Nellie cory cactus population (USFWS, 1984).
- Initiate and support studies on the population biology and ecology of the Nellie cory cactus (USFWS, 1984).
- Develop a comprehensive trade management plan for all cacti (USFWS, 1984).

SPECIES ACCOUNT: *Coryphantha ramillosa* (Bunched cory cactus)

Species Taxonomic and Listing Information

Listing Status: Threatened; 12/06/1979; Southwest Region (R2) (USFWS, 2016)

Physical Description

The stems of *Coryphantha ramillosa* are dark grayish green, solitary or rarely with a few branches, 6—9 cm (2.4—3.6 in.) long, and 6—9.5 cm (2.4—3.7 in.) in diameter. There are 3—6 central spines per areole: 1 inner, and 2—5 but usually 3 outer. The inner central spine is 25—140 mm (1—1.6 in.) long, and the outer central spines, 17—38.5 mm (.7—1.5 in.) long. The lull white to pale gray radial spines are 12—30 cm (.5—1.2 in.) long. The flowers are 38—65 mm (1.5—2.6 in.) long and 30—50 mm (1.2—2 in.) in diameter. The fruits are 1—2.5 cm (.4—1 in.) long. The seeds are finely raised—reticulate, reniform, reddish—brown, and 1.14—1.5 mm (.06 in.) long (USFWS, 1989). The longer, curving, twisting spines and purplish flowers of *C. ramillosa* distinguished it from the yellow-flowered *C. scheeri* and *C. scolymoides* (Weniger 1979, p. 2). *C. ramillosa* has flattened, overlapping tubercles, relatively few stems, sulca extending from the apex to the base of the tubercles, entire outer perianth segments, and ovoid fruits less than 2 cm long, while *C. macromeris* has cylindrical, widely-spaced tubercles, large numbers of stems, sulca extending only half of the tubercle length, frilled outer perianth segments, and elongate fruits over 3 cm long (Weniger 1979, p. 2; Heil et al. 1985, p. 29). (USFWS, 2018)

Taxonomy

A.R. Davis, of Marathon, Texas, first observed bunched cory cactus at the head of Reagan Canyon in 1936. Cutak (1942) described *Coryphantha ramillosa* based on specimens Davis collected in 1939 (A.R. Davis s.n., MO #12L12260). Weniger (1970) published the species invalidly as *Mammillaria ramillosa* (USFWS 1989, p. 3). *Coryphantha ramillosa* has consistently been recognized as a distinct, valid species. However, since the easternmost populations in Coahuila, Mexico, are now recognized as a distinct subspecies, *santarosa*, the listed entity, bunched cory cactus, is recognized as subspecies *ramillosa*. (USFWS, 2018)

Historical Range

The bunched cory cactus is known only from Brewster and Terrell Counties, Texas and central Coahuila, Mexico. Presumably the present and historic ranges of the bunched cory cactus are similar (USFWS, 1989).

Current Range

As a subspecies, bunched cory cactus is now somewhat more narrowly endemic to a portion of northern Coahuila, Mexico, and portions of Brewster and Terrell Counties in the Big Bend region of Texas. (USFWS, 2018)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual: cross-pollination (USFWS, 1989)

Dependency on Other Individuals or Species

Adult: Halictidae sweat bee (USFWS, 1989)

Breeding Season

Adult: mid-September to October (USFWS, 2018)

Key Resources Needed for Breeding

Adult: Rocks (USFWS, 1989)

Other Reproductive Information

Adult: Although the breeding system of bunched cory cactus has not been documented, Zimmerman (1985, p. 137) stated that most *Coryphantha* species are obligate outcrossers. Schmalzel et al. (1999, p. 20) learned from local observers who were familiar with bunched cory cactus that it flowers from mid-September to October, following rain; the flowers open for 2 or 3 days; populations can flower more than once per season; fruits mature in about 6 to 8 weeks; and fruits persist 1 to 2 months. Stems expand and contract according to the amount of water they contain, confounding direct growth measurements. Consequently, Schmalzel et al. (1999, p. 33) estimated growth by painting the spine clusters of young tubercles and observing tubercle production at intervals for two years. They observed that flowers arose only from tubercles produced during the same season. Based on their estimates of size-age relationships, plants become reproductive at about 9 years, corresponding to a diameter of 40 mm (p. 35). They were unable to observe pollinators, seed dispersal, or seedling recruitment (p. 37). (USFWS, 2018)

Reproduction Narrative

Adult: The bunched cory cactus begins blooming at an age of 5 years. Reports of flowering time vary: Weniger (1979) states April to May, Warnock (1970) states June, and Heil et al. (1985) state July to August. The major pollinator is thought to be a green sweat bee in the family Halictidae. Fruits form from October through December (Heil et al., 1985). In its natural habitat and in cultivation virtually 100 percent of the flowers produce fruits. However, such high fruit set is only likely when plant densities are such that cross pollination is assured (A. Zimmerman, Chihuahuan Desert Research Institute, pers. comm., 1986). There are about 75 seeds per fruit. The best place for seedling survival is under rocks or deep in the cracks of rocks where the seeds are protected from dessication and predation (USFWS, 1989).

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Chihuahuan Desert Scrubland (USFWS, 1989)

Geographic or Habitat Restraints or Barriers

Adult: 2,500 - 3,500 ft. elevation (USFWS, 1989)

Spatial Arrangements of the Population

Adult: Scattered (USFWS, 1989)

Environmental Specificity

Adult: Narrow (inferred from USFWS, 1989)

Habitat Narrative

Adult: It occupies limestone gravel, alluvial soil on foothills and ridges. It is found on the Bouquillas and Santa Elena limestone formation; distributed along cracks in rock ledges at edges of canyons and on hilltops (NatureServe, 2015). It is found primarily as widely scattered populations or individuals. The bunched cory cactus grows in the Chihuahuan Desert Scrubland (Brown and Lowe, 1980). The elevation range for bunched cory cactus is between 750 and 1,050 meters (2,500—3,500 ft.). In the northern part of its range, the species is mostly confined to rocky, well—drained, and full sunlit sites on steep canyon sides and hill summits along the canyons of the Rio Grande (USFWS, 1989).

Dispersal/Migration**Dispersal**

Adult: Low (inferred from USFWS, 1989)

Dispersal/Migration Narrative

Adult: The fruits ripen in December and the seeds are distributed by rodents and ants (USFWS, 1989).

Population Information and Trends**Population Trends:**

Not available

Number of Populations:

7+ (NatureServe, 2015)

Population Size:

Estimated to be > 10,000 individuals (USFWS, 2018)

Minimum Viable Population Size:

Not yet calculated (USFWS, 2018)

Population Narrative:

Schmalzel et al. 1999 obtained permission to conduct surveys of private ranches in Terrell County with the help of Mr. Jim Talbot, a resident of Sanderson, Texas. They confirmed 17 new population sites; Talbot reported three additional sites that the investigators were not able to verify (pp. 21-28). They found 228 bunched cory cactus individuals along 2 km (1.24 mi) of Red House Canyon. Assuming that this density is representative of all populated sites, they estimated the total population would be 10,260 over a span of 90 km in Red House, Lion, Sanderson, Cook, Isinglass, Washboard, and Cedar canyons, and one unnamed canyon (pp. 15-16). Since other populations occur at Reagan, Big, and Rio Grande canyons, as well as a mesa near Seminole Canyon, 10,000 is a conservative estimate of the U.S. population within 30 km

(18.6 mi) of the mouth of Sanderson Canyon (p. 16). However, in contradiction of earlier reports by Weniger (1979, pp. 5,7), the species has never been documented at Black Gap Wildlife Management Area (BGWMA) (Bonnie McKinney, cited in Schmalzel et al. 1999, pp. 27-28), and surveys of Maravillas Canyon (BGWMA) and Mariscal Mountain (BBNP) by Schmalzel's team did not detect bunched cory cactus. They concluded that bunched cory cactus is not rare and should not be listed as threatened under ESA (p. 39). (USFWS, 2018)

Threats and Stressors

Stressor: Habitat or Range destruction, modification, or curtailment (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Intensive range management practices, such as root-plowing and seeding with buffelgrass or other introduced, invasive grasses remains a potential threat, but has not been reported and is unlikely to occur due to the steep terrain and marginal capacity of the habitats for forage production. Some bunched cory cactus individuals may have been trampled at BIBE, due to their proximity to an archeological site (Schmalzel et al. 1999, p. 19). We have no evidence that trampling or habitat destruction has occurred due to increased recreational activity along the Rio Grande scenic river. (USFWS, 2018)

Stressor: Overutilization for commercial, recreational, scientific, or educational purposes (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: From a total of about 75 individuals along transects at BIBE, two disappeared; due to their proximity to visitor access they may have been stolen by poachers (Schmalzel et al. 1999, p. 19). We have no additional evidence of the current extent of illegal collection of this species. Since cactus collection continues to be a popular activity, and rare species collected from the wild are especially valuable to some collectors, bunched cory cactus will probably remain vulnerable to a persistent, low-grade threat of illegal collection. (USFWS, 2018)

Stressor: Disease or predation (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Schmalzel et al. (1999, pp. 19-20) did not observe signs of mammalian herbivory in populations of bunched cory cactus where goats, javelina, and aoudad were abundant. However, they did observe insect frass on stems, indicating the presence of insect parasites (p. 19). Insect parasites cause populations collapses of other small cactuses, such as Tobusch fishhook cactus (USFWS 2017, pp. 27-28, 31, 39-40), and may also cause significant mortality of bunched cory cactus. (USFWS, 2018)

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: The ESA does provide some legal protection for federally-listed plants on land under federal jurisdiction, including the populations of bunched cory cactus at BIBE. Beginning in 2007, USFWS and the U.S. Department of Homeland Security (DHS) interacted extensively regarding the proposed construction of a border wall along the Rio Grande in south and west Texas. A provision of the REAL ID Act of 2005 gives the Secretary of Homeland Security authority to waive other federal laws, including the ESA, in order to expedite construction of border barriers. Hence, the border wall project was exempt from consultation with USFWS under section 7 of the ESA. Nevertheless, DHS and USFWS have coordinated to establish best management practices for the federally listed plants and animals in the project impact area (U.S. Department of Homeland Security 2008). Additional border wall construction has been proposed by the current Administration. If implemented, the border wall and related infrastructure may affect populations and habitats of bunched cory cactus that occur along the Rio Grande. In particular, the only protected population of bunched cory cactus, at BIBE, is near the Rio Grande and could be adversely affected by new construction in that area. Chapter 88 of the Texas Parks and Wildlife Code lists plant species as state-threatened or endangered once they are federally-listed with these statuses. Bunched cory cactus was listed as threatened by the State of Texas on April 29, 1983. The State prohibits taking and/or possession for commercial sale of all or any part of an endangered, threatened, or protected plant from public land. TPWD requires permits for the commercial use of listed plants collected from private land. Scientific permits are required for collection of endangered plants or plant parts from public lands for scientific or educational purposes. In addition to State endangered species regulations, other State laws may apply. State law prohibits the destruction or removal of any plant species from State lands, including BGWMA, without a TPWD permit. (USFWS, 2018)

Stressor: Demographic and genetic consequences of small population sizes (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Small, isolated plant populations are often vulnerable to genetic drift, loss of genetic diversity, and inbreeding depression. However, the population genetics of bunched cory cactus has not been investigated; we have no evidence of the extent of the actual impacts of these potential threats. (USFWS, 2018)

Stressor: Climate change (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: We do not know whether the climate changes that have already occurred have affected the populations or distribution of bunched cory cactus, nor can we predict how the species might be affected by the type and degree of climate changes forecast by the range of models. While many species have adapted to previous climate changes by migrating in latitude or elevation, it is unlikely that this species could migrate, without facilitation, fast enough to match the projected rate of climate change. Changes in temperature and rainfall amounts and patterns could have multiple effects that alter the species' fitness in opposing ways. For example, hotter summers could increase mortality from drought, but warmer winters could reduce mortality from freezing. Regardless of how these changes may affect its autecology, the altered synecology may be more significant. For example, bunched cory cactus might benefit from more frequent or more severe droughts if it tolerates extended drought better than other plants that compete

with it. Conversely, extended drought could reduce pollinator populations, resulting in pollen limitation and reduced reproductive output. At present, we cannot predict how the infinitely complex aggregation of climate changes will affect the synecology of bunched cory cactus populations and habitat. Therefore, we will continue to monitor the species' status and will adapt our recovery and management strategies when necessary to address the changing conditions. (USFWS, 2018)

Recovery

Reclassification Criteria:

Not available

Delisting Criteria:

1. Identify at least three sites where the species can be protected and then carry out protective management measures. One site should be on private land in northeastern Brewster or southwestern Tyrrell County, one site should be in Big Bend National Park, and one site should be in Mexico. Each site should initially contain at least 500 plants and should have enough available habitat to permit population expansion and growth (USFWS, 1989).

2. Monitoring and habitat surveys indicate that a total of a least 10,000 plants is being sustained at the protected and managed sites (USFWS, 1989).

Recovery Actions:

- Remove threats to the bunched cory cactus by enforcement of existing regulations and management for protection. Because of the rarity of the bunched cory cactus the populations must be protected by the enforcement of existing Federal, and State regulations and by management to remove threats to the species. (USFWS, 1989)
- Gather information for use in management. A thorough understanding of the population biology and ecology of the bunched cory cactus is needed to help manage healthy natural populations. (USFWS, 1989)
- Develop a comprehensive trade management plan for all cacti. Studies are needed to determine which species are in trade, the overall trend of trade in listed cacti, and the feasibility of reducing collecting pressure on wild populations by promoting a commercial artificial propagation program. Strategies for effective law enforcement under ESA, CITES, Lacey Act, and State laws need to be developed. The trade study should be national in scope and address all cacti. The results will be used to develop policy and a comprehensive trade management plan for all cacti. (USFWS, 1989)
- Refine propagation techniques to provide nursery stocks and seeds to reduce collecting pressure. The collecting pressure on natural populations could possibly be reduced by refining commercial propagation techniques. This task will be undertaken if findings of the trade management plan indicate that increased commercial propagation is an advisable means of reducing collecting pressure on natural populations. (USFWS, 1989)
- Establish populations at the botanical gardens of research institutions. Even though plants in botanical gardens cannot substitute for healthy populations in natural habitats, a living collection could still contribute significantly to the overall recovery effort. Much information on ecological requirements and reproductive potential could be obtained most easily from a living collection. In addition, a permanent well documented and accessible living collection, together with appropriate seed banking, could provide an important source of material for

non—destructive research, maintenance of wild populations, and public awareness. An adequate living collection would remove the necessity of repeatedly returning to wild populations to collect plants for various recovery projects. (USFWS, 1989)

- Develop public awareness, appreciation, and support for preservation of the bunched cory cactus . Public education is a vital part of the recovery process. The cooperation of the public is essential for the ultimate success of many recovery measures. (USFWS, 1989)
- Recommended Actions from 2018 5-Year Review: To ascertain the degree to which the recovery criteria of bunched cory cactus have been met, we recommend the following: • Develop efficient, quantitative, verifiable methods to estimate population sizes and trends using representative samples of potential habitats and valid statistical analyses. • Recruit Mexican botanists and support studies of the size and geographic distribution of populations in Coahuila and Nuevo León. (USFWS, 2018)
- Recommended Actions from 2018 5-Year Review: The most important recovery actions during the next five years include, but are not limited to, the following: • Revise the recovery plan and recovery criteria to incorporate updated guidance and specific, measurable recovery criteria, including the length of the monitoring period needed to detect demographic trends. Revise the population size criterion to the provisional minimum viable population level of 1,000 to 1,500 mature, reproductive individuals per metapopulation. • Continue to improve the potential habitat model as we learn more about the ecological requirements. • Explore the potential to conserve populations of bunched cory cactus on private lands in Brewster and Terrell counties, Texas through private landowner agreements or other appropriate measures. • Communicate with Mexican agencies, non-profit conservation organizations, and academic institutions to promote the conservation and management of *Coryphantha ramillosa* subspecies in Mexico. • Investigate the population genetics to determine the genetic structure, genetic diversity and extent of inbreeding, evidence of gene flow, and other parameters that will be useful in the conservation and recovery of bunched cory cactus. (USFWS, 2018)

SPECIES ACCOUNT: *Coryphantha robbinsiorum* (Cochise pincushion cactus)

Species Taxonomic and Listing Information

Listing Status: Threatened; 01/09/1986; Southwest Region (R2) (USFWS, 2016)

Physical Description

A spiny succulent with a solitary round stem, 3-5 cm tall. Pale green-yellow flowers appear in March-April, followed in July and August by orange-red fruits (NatureServe, 2015).

Taxonomy

The Cochise pincushion cactus was originally named *Cochiseia robbinsorum* by W.H. Earle (1976). The genus *Cochiseia* was rejected almost immediately. Dr. A.D. Zimmerman (1978) assigned the species to the genus *Coryphantha*, which is currently the most frequently accepted placement. The only other synonym for the species is *Escobaria robbinsorum*, which is subject to an unresolved controversy (USFWS, 1993).

Historical Range

The Cochise pincushion cactus is known from the San Bernardino Valley, southwestern Cochise County, Arizona, and northern Sonora, Mexico (Lopresti 1984) (USFWS, 1993).

Current Range

It occurs in Cochise Co., Arizona and Sonora, Mexico (NatureServe, 2015). It is restricted to three small limestone hills in Cochise County, Arizona, along the U.S./Mexico border (USFWS, 2007).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (inferred from NatureServe, 2015)

Breeding Season

Adult: March - April (USFWS, 2016)

Key Resources Needed for Breeding

Adult: Bee pollinators (USFWS, 1993)

Reproduction Narrative

Adult: Lower reproduction rate than most cacti - estimated average annual production is 3 fruits with 20 seeds per plant (NatureServe, 2015). Flowering begins in mid-March extending to mid-April (USFWS, 2016). Zimmerman (1985) noted the small bees *Perdita opuntiae*, *Ashmeadiella*

opuntiae, and (rarely) *Dialictus* sp. visiting the flowers of *Coryphantha robbinsorum* (USFWS, 1993).

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Semidesert grassland (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Full sunlight (USFWS, 2007)

Geographic or Habitat Restraints or Barriers

Adult: 1,280 - 1,544 m elevation (USFWS, 2016); dense vegetation (inferred from USFWS, 2016)

Spatial Arrangements of the Population

Adult: Scattered with a few dense clumps (USFWS, 2007)

Habitat Narrative

Adult: Inhabits grey limestone hills within a semidesert grassland, with small shrubs, other succulents, and grama grasses (NatureServe, 2015). Found only on one type of high-calcium limestone outcrop in the Mexican Highland vegetation community at elevations of 1,280-1,433 meters (4,200 feet). Soils are thin with a soil crust of lichens, mosses, and algae, and bedrock is very near the surface at occupied sites. Plants tend to be in the open, not underneath other plants. Overall vegetation at occupied sites is sparse (USFWS, 2016). The soils are low in nutrients, with a pH of 7.9 to 8.0. Plants require well-drained substrates and grow in full sunlight. Within their limited habitat (10-16 sq. km), the plants are found scattered, with a few dense clumps ranging from 100-1,000 individuals (Zimmerman 1985) (USFWS, 2007).

Dispersal/Migration**Dispersal**

Adult: Moderate (inferred from USFWS, 1993)

Dispersal/Migration Narrative

Adult: Zimmerman (1985) speculates that seeds are disseminated by rock wrens (*Salpinctes obsoletus*), cactus wrens (*Campylorhynchus brunneicapillus*), mockingbirds (*Mimus polyglottos*), black-throated sparrows (*Amphispiza bilineata*), thrashers (*Toxostoma* sp.), and house finches (*Carpodacus mexicanus*). The bright red, fleshy fruits probably attract the birds. He notes that his unpublished study of rock wrens in a population of *Coryphantha robbinsorum* showed that these birds fly from one *Coryphantha* population to another during their daily activities (USFWS, 1993).

Population Information and Trends**Population Trends:**

Not available

Species Trends:

Declining (USFWS, 2007)

Resiliency:

Very low (inferred from USFWS, 2016)

Redundancy:

Very low (inferred from (NatureServe, 2015)

Number of Populations:

2 (NatureServe, 2015)

Population Narrative:

It occupies 8.8 acres of rangeland (in U.S.?). This species is known only from 1 population in southeastern Arizona and 1 in adjacent Sonora, Mexico (NatureServe, 2015). The known range is very small and limited (USFWS, 2016). Population numbers appear to be declining based on current data (USFWS, 2007).

Threats and Stressors

Stressor: Habitat destruction and modification (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Threats include grazing by livestock and wildlife, and oil/mineral exploration activities. Changes in grazing patterns by the local landowner have minimized the potential effects from livestock grazing. Impacts to populations from mining activities have not been a significant factor. However, each of these activities continues to be a potential threat to populations of Cochise pincushion cacti. Impacts from these threats could increase if land ownership changes or incentives for oil and mineral exploration increase. A new threat that has been escalating over the past 10 years is related to illegal immigration and drug smuggling, and associated law enforcement activities. Plants can be trampled or otherwise damaged or injured. Cochise pincushion cactus habitat is destroyed or altered by foot and vehicle traffic, and there is the potential for the increased incidence of fire. Impacts from border activities have been documented within areas occupied by the Cochise pincushion cactus, but increased law enforcement efforts have, at least temporarily, reduced illegal traffic in the area (USFWS, 2007).

Stressor: Invasive plants (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: An additional threat comes in the form of invasive plant species, especially grasses. Of particular note is the spreading threat to Sonoran and Chihuahuan desert ecosystems resulting from the invasion of buffelgrass (*Pennisetum ciliare*). Buffelgrass can compete for resources with Cochise pincushion cactus, and it also increases the frequency and intensity of fire on the landscape as compared to natural conditions. Such a change in the fire regime could increase Cochise pincushion cactus mortality and alter important habitat microclimates. The recent development of a cold-tolerant strain of buffelgrass by the Agricultural Research Service (2005)

increases the potential for this species to invade areas occupied by the Cochise pincushion cactus. Lehmann's lovegrass (*Eragrostis lehmanniana*) is another invasive grass species in southeastern Arizona (USFWS, 2007).

Stressor: Collection (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: The desirability of this species, coupled with its limited distribution, increases the potential for significant impacts to populations if illegal collection were to occur. No evidence of illegal collection within known populations has been observed. However, collection remains a real threat to this species due to its limited numbers and distribution. Cochise pincushion cacti are available commercially on a limited basis, but if interest in this species increases or commercial availability decreases, pressure to collect plants from the wild may increase. The unique, rare nature of this species increases its desirability among collectors (USFWS, 2007).

Stressor: Insect depredation (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Depredation by insects was documented in the Cochise pincushion cactus long-term monitoring plots in 1994. As a result, mortality of individual plants during that year nearly doubled from the highest mortality previously recorded (see Figure 2). The documentation of this significant depredation event points to the potential for the distribution of this species to be driven by density-dependent insect depredation. As the density of Cochise pincushion cacti increases in a local population, it becomes more vulnerable to insect depredation. At some point, densities may become high enough that conditions favor a significant insect depredation event. Density of cacti is reduced, as is the subsequent depredation by insects. This cycle may repeat itself over time within each of the local populations of Cochise pincushion cactus. As a result, there may be a number of high-density populations within the landscape; however, the density of these populations would eventually be reduced by insect depredation. Low-density populations will gradually increase in density during favorable environmental conditions until they reach a point that favors insect depredation events. In order to determine if this cycle of depredation is indeed a natural component of the population dynamics of the Cochise pincushion cactus, monitoring techniques must be modified to sample the population across its range. Depredation may be a significant driver of the distribution and density of this species. Depredation effects would be amplified in populations suffering from other stressors such as drought (USFWS, 2007).

Stressor: Drought (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Ongoing, long-term drought is occurring within the range of the Cochise pincushion cactus. Drought increases mortality of adults and juveniles and reduces reproduction in populations of this species. Because of the limited number of individual plants and the limited distribution of this species, drought effects may significantly affect its ability to persist on the landscape. A return to normal winter and monsoon precipitation patterns is needed to decrease

this threat. The declining trend in numbers of cacti within monitoring plots is likely evidence of the effects of drought on known populations (USFWS, 2007).

Stressor: Pesticides (USFWS, 2007)

Exposure:

Response:

Consequence:

Narrative: Application of pesticides within or adjacent to the range of the Cochise pincushion cactus could adversely affect these insects and associated ecosystem functions. The potential application of pesticides is most likely associated with rangeland grasshopper control. The application of pesticides remains a potential threat to insects that benefit the Cochise pincushion cactus (USFWS, 2007).

Recovery

Reclassification Criteria:

Not available

Delisting Criteria:

Recovery of this species will require permanent protection and management of the habitat, trade protection through retention of the species on the Highly Safeguarded List of the Arizona Native Plant Law and CITES list following delisting, and demonstration through ten years of monitoring that viable populations are being maintained (USFWS, 1993).

Recovery Actions:

- Conduct biological studies necessary for effective management of the species (USFWS, 1993).
- Develop and implement a habitat management plan in cooperation with the private landowner and Arizona State Land Department (USFWS, 1993).
- Study the population biology of Cochise pincushion cactus to determine the effects of management (USFWS, 1993).
- Protect Cochise pincushion cactus from loss of individuals and habitat (USFWS, 1993).
- Establish an ex situ conservation and research program (USFWS, 1993).
- Define the range and distribution of Cochise pincushion cactus (USFWS, 1993).

Conservation Measures and Best Management Practices:

- Modify the current monitoring protocol to expand the area monitored within the known range of the species. Design the protocol to more effectively evaluate the status of the species across the landscape. Monitoring should be designed to investigate possible density-dependent depredation issues and identify the distribution of both high-density and low-density populations (USFWS, 2007).
- Update the recovery plan with quantifiable criteria for delisting. For example, a goal of establishing 15,000 plants in 50 populations (Recovery Criteria #2) may not be realistic based on current information of the density and distribution of this species (USFWS, 2007).
- In conjunction with #2, evaluate the existing recovery actions outlined in the existing recovery plan and decide which are still appropriate for the species' recovery, based on current information (USFWS, 2007).

- Evaluate the results of Dr. Tom Van Devender's 2007 work on this species in Mexico and increase monitoring efforts in Mexico, if appropriate (USFWS, 2007).
- Continue to coordinate with and involve the landowners/lessees and SBNWR in recovery actions related to the Cochise pincushion cactus (USFWS, 2007).
- Evaluate the genetics of this species to determine variation within and among populations. This information is useful in determining if population augmentation or establishment of new populations is warranted (USFWS, 2007).

SPECIES ACCOUNT: *Coryphantha scheeri* var. *robustispina* (Pima pineapple cactus)

Species Taxonomic and Listing Information

Commonly-used Acronym: PPC

Listing Status: Endangered; 10/25/1993; Southwest Region (R2)

Physical Description

Individuals of *C. scheeri* var. *robustispina* are small, hemispheric to cylindrical, stem succulent perennials of the Cactaceae (cactus family). Individual stems reach 5 to 46 centimeters (cm) (1.9 to 18.1 inches (in)) in height and 5 to 21 cm (1.9 to 8.3 in) in diameter, are comprised primarily of tough, fleshy pulp, and are protected by a leathery outer skin. Stems may be singular or form clumps. The surface of the stems is covered in 2 to 3 cm (0.8 to 1.2 in) long rounded projections called tubercles, each of which is grooved along the upper surface and contains one to several extra-floral nectaries (place that secretes nectar to attract pollinators) along the groove. At the tip of each tubercle, arising from small bumps called areoles, are groupings of 7 to 20 straw-colored spines that darken with age (Roller 1996a, p. 9; Parfitt and Gibson 2004, p. 226). There is an average of two thick central spines, one of which is generally hooked and averages 1.7 millimeters (mm) (0.07 in) thick and 3 cm (1.2 in) long (Baker and Butterworth 2013, p. 996). There are 6 to 16 thinner radial spines about 1.1 to 3.5 cm (1.43 to 1.38 in). The young areoles are densely covered with deciduous wool. The stems of *C. scheeri* ssp. *robustispina* arise from taproots that are deeper than most Sonoran Desert cacti at about 15 cm deep. Lateral roots are found between 2 and 5 cm below the soil surface and extend approximately 1 m (3.28 ft) in length. The flowers of *C. scheeri* ssp. *robustispina* average 6.5 cm (2.6 in) long with pale yellow tepals (petals and sepals) that are variously tinged with red pigments. Flowers generally open early to mid-July following summer rains; fruit matures a few weeks later. The pale green fruits are narrowly ellipsoid, 3.2 to 5.7 cm (1.25 to 2.25 in) long and 1.3 to 1.9 cm (0.5 to 0.75 in) wide, with a soft rind and juicy sweet pulp surrounding a mass of brown to black seeds. (USFWS, 2018a)

Taxonomy

Arthur Schott originally described the taxon as *Mammillaria robustispina* from a collection he made from near El Sásabe, Sonora, Mexico (holotype MO 2017438) and the name was published by George Engelmann in 1856 (*M. robustispina* Schott ex Engelmann). Britton and Rose (1923, pp. 33-34) transferred the species to *Coryphantha* (*C. robustispina*). The name of the taxon was recombined by Benson (1982, p. 820) to *C. scheeri* var. *robustispina* and then again to *C. robustispina* (Schott ex Engelm.) Britton & Rose ssp. *robustispina* by Taylor (1998, pp. 17-18). According to Taylor, the species name *C. robustispina* has priority over the epithet *C. scheeri*. This view is accepted by Anderson (2001, p. 196). Within the 2018 Recovery Plan, however, we refer to the taxon as *C. scheeri* var. *robustispina*, the name in use when the taxon was listed as endangered under the Act in 1993 and how the taxon has been referred to in Service documents since that time. A morphometric study in 2004 suggested that a taxonomic cline exists between all *C. robustispina* occurring between Arizona and Texas and therefore no varieties are valid (Schmalzel et al. 2004, p. 553). Three varieties; *robustispina*, *uncinata* and *scheeri*, have been investigated recently and were shown to be geographically isolated (Baker 2005, p. 6),

significantly different morphologically (Baker 2003, p. 17), and significantly different genetically (Butterworth 2010, p. 14; Baker and Butterworth 2013, p. 996), warranting subspecific division. We accept this varietal differentiation in this document. (USFWS, 2018a)

Historical Range

See Current Range. There is no indication that the historical range of the taxon differs widely from the current known distribution. (USFWS, 2018a)

Current Range

Found across roughly 152,920 ha (377,873 ac) of land within the Altar and Santa Cruz Valleys in Pima and Santa Cruz Counties, Arizona, including some lands that connect the two valleys. (USFWS, 2018a)

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Reproductive Strategy**

Adult: Obligate outcrosser

Lifespan

Adult: Variable, can be 30 or more years (USFWS, 2018a)

Dependency on Other Individuals or Species

Adult: Pollinators

Breeding Season

Adult: Early to mid-July or five to seven days after the first summer rains of at least 3 mm and continues through the monsoon season. (USFWS, 2018a)

Other Reproductive Information

Adult: Flower buds begin to appear in mid-May and the timing is related to photoperiod and rainfall (Roller 1996a, p. 58). Flowering usually occurs in early to mid-July or five to seven days after the first summer rains of at least 3 mm and continues through the monsoon season (Kearney and Peebles 1951, p. 577; Roller 1996a, p. 58; Kidder 2014, entire). Flowers persist for a single day, yet the timing of flowering may assist with pollination, as there are few cactus species which bloom at this same time, resulting in a greater potential for pollination success (McDonald and McPherson 2005, p. 531). Schmalzel (2014, p. 4) suggests that plants do not reach maturity and begin to flower until they are more than 12 years of age and likely between 20 and 25 years of age. (USFWS, 2018a)

Reproduction Narrative

Adult: Pollinators of *C. scheeri* var. *robustispina* are fairly well known. Flowers of the taxon are morphology typical for the subgenus *Cactoideae* and exhibit characteristics considered generalized with respect to pollination, that is, the pollen being easily accessible to many

different types of pollinators. Known pollinators include both native insects and the nonnative European honeybees (*Apis mellifera*) (Roller 1996a, p. 63). *Coryphantha scheeri* var. *robustispina* become isolated from potential pollination after 600 m (1,968.5 ft) and since the taxon is not able to self-pollinate (Service 2000a, p. 4), they are likely to be genetically isolated or inbred after 900 m (2,953 ft; McDonald 2005, p. 30). Pups (offsets of the parent cactus that are genetically identical) produced vegetatively will not increase genetic diversity of the population. (USFWS, 2018a)

Habitat Type

Adult: Semi-desert grasslands, desert scrub and the transition area between the two vegetation types.

Dependencies on Specific Environmental Elements

Adult: Open and transitional areas; deep, silty and gravelly, alluvial soils (USFWS, 2018a)

Tolerance Ranges/Thresholds

Adult: Found at elevations between 728 and 1,280 m (2,388 and 4,200 ft) (USFWS, 2018a)

Habitat Narrative

Adult: *Coryphantha scheeri* var. *robustispina* is typically found in open areas within the Sonoran Desert-scrub and desert-grassland vegetation types and in areas transitional between these vegetation communities. Routson (2003, p. 3) found that individuals of *C. scheeri* var. *robustispina* within the Altar Valley occurred most frequently in disclimax (displaced climax due to disturbance) desert-grassland among woody vegetation on well-drained soils. Many studies describe the subshrubs *Zinnia* species (desert zinnia), *Gutierrezia sarothrae* (snakeweed), *Isocoma tenuisectus* (burroweed), and *Eriogonum* spp. (buckwheat) as common associates. Schmalzel (2000c, p. 2) noted greater rates of mortality among *C. scheeri* var. *robustispina* occurring under the canopies of *Prosopis velutina* (velvet mesquite). Similarly, Kidder (2014, entire) found occupied sites were characterized by overall high incoming solar radiation (Kidder 2015, p. 110). McPherson (2002, p. 3), however, found individuals occur more frequently under the canopy of perennial plants than at a distance of at least 1 m (3.28 ft) from the canopy edge. (USFWS, 2018a)

Dispersal/Migration**Motility/Mobility**

Adult: Low

Dispersal

Adult: Rabbits and rodents act as seed disperses.

Dependency on Other Individuals or Species for Dispersal

Adult: Rabbits and rodents for seed dispersal (USFWS, 2018a)

Dispersal/Migration Narrative

Adult: Fruit and seed dispersal for the taxon is probably facilitated, for the most part, by rodents and, perhaps less so, by ants. It has also been hypothesized that jack rabbits (*Lepus* spp.) may play a key role in fruit and seed dispersal (Westland 2005, p. 33; Schmalzel and McGibbon 2010,

p. 11). In 2001, Westland (2005, p. 33) examined jackrabbit dung and discovered intact *C. scheeri* var. *robustispina* seeds within. They noted that dung increased around plants at the time fruits are maturing. A study conducted by Baker and Routson beginning in 2002 documented that ants were mostly associated with extrafloral nectaries, however there were multiple cases of ants eating the fruits and transporting seeds (Baker 2013, p. 21). This study also documented the presence of a single seed in jackrabbit feces, which supports the jackrabbit dispersal hypothesis (Baker 2013, p. 33). In a study of antelope jackrabbit (*Lepus alleni*) habitat structure and vegetation characteristics, Altemus (2016, p. 10) did not detect a spatial association between the jackrabbits and the presence of *C. scheeri* var. *robustispina*, but suggested further study was warranted, as this was a habitat selection study for the herbivore and did not emphasize the distribution of fruits. Additionally, Harris' antelope squirrels (*Ammospermophilus harrisi*), (USFWS, 2018a)

Additional Life History Information

Adult: Ample seed production, however, does not necessarily equate to persistent seedbanks or recruitment (e.g. see Godinez-Alvarez et al. 2003, p. 183; Aragon and Lasso 2018, p. 1). One field study reported the results of two trials where 200 or more *C. scheeri* var. *robustispina* seeds were planted in close proximity to in situ *C. scheeri* var. *robustispina* adult plants and germination was followed (Schmalzel 2002, p. 7). In the first trial, 16 of 220 seeds germinated in the first year and none in the second. In the second trial, 35 of 200 seeds germinated; 30 in the first year and 5 in the second year of study (Schmalzel 2002, p. 7). In another study, field germination testing from 5 study sites found that *C. scheeri* var. *robustispina* seeds had high germination rates of 88 percent (Roller 1996a, p. 75). Observations from laboratory and shadehouse over a 22-month period showed continuous germination indicating that there is no set dormancy period for the seeds (Roller 1996a, p. 72). (USFWS, 2018a)

Population Information and Trends

Population Size:

Roughly 8000 individuals and 152,920 ha (377,873 ac) of habitat (USFWS, 2018b)

Additional Population-level Information:

Between 1995 and 2007, 45 individual *C. scheeri* var. *robustispina* were monitored in an enclosure on Coronado National Forest land in the Santa Cruz Valley. In 2010, no living plants were found (Coronado National Forest 2010, entire), however, in a partial survey of this area in 2015, some *C. scheeri* var. *robustispina* were found both within and outside of this enclosure (Service 2015b, entire). Similarly, plants are monitored regularly on the Pima County and Palo Alto Pima Pineapple Cactus Conservation Bank properties. On one portion of the County-owned Conservation Bank property in 2006, 67 plants were mapped; when last counted in 2014, 13 of the original 67 plants remained alive and 11 new plants had been found (Pima County 2015, p. 1). Within or adjacent to the Palo Alto Conservation Bank property, 49 plants were found in 2001; as of September, 2015, 9 of the original individuals remained alive and 11 new plants were discovered, for a total of 24 known *C. scheeri* var. *robustispina* (Westland 2015, p. 2). (USFWS, 2018a)

Population Narrative:

We are aware of roughly 8,000 individuals and 152,920 ha (377,873 ac) of habitat within the Altar and Santa Cruz Valleys in Pima and Santa Cruz Counties, Arizona, including acreage of

some lands that connect the two valleys. Maintaining linkages for pollinators and lands dominated by native plants are important for the survival of the taxon. Long-term monitoring plots of *Coryphantha scheeri* var. *robustispina* indicate overall decreases in the number of individuals monitored over time. Attempts at transplanting individuals out of the path of development has resulted in a mix of successes and failures. We are aware of at least 1,837 individuals and tens of thousands of acres of habitat that have been lost, primarily due to development. (USFWS, 2018b)

Threats and Stressors

Stressor: Habitat loss due to commercial development (2018a)

Exposure:

Response:

Consequence:

Narrative: The primary habitats of *C. scheeri* var. *robustispina* are open areas on flat ridge tops or areas with less than 10 percent slope, which are also areas very well suited for human development. Urban and suburban development in the areas south and west of Tucson, Green Valley, and Nogales, Arizona, and mining in the Sierrita Mountains and Green Valley, threats first recognized in the 1980s (Phillips et al. 1981, p. 11; Mills 1991, p. 7; Reichenbacher 1985, p. 21; Service 2000a, p. 7), are responsible for complete and permanent modification of lands that previously supported *C. scheeri* var. *robustispina* and its pollinators. By 2000, the Service estimated that 43 percent of the total habitat surveyed to date had been modified or destroyed due to urbanization (Service 2001a, p. 6). For example, 143 ha (353 ac) of habitat and 47 individual plants were lost to a single housing development project in 1998 (Service 1998c, p. 16). In 2014, 197 ha (487 ac) of suitable *C. scheeri* var. *robustispina* habitat and 99 individual plants were lost to a single infrastructure development project (Service 2014a, p. 33). (USFWS, 2018a)

Stressor: Habitat loss due to nonnative plant invasion and altered fire regimes (USFWS, 2018a)

Exposure:

Response:

Consequence:

Narrative: *Coryphantha scheeri* var. *robustispina* occur in both the desert-grassland and desert-scrubland plant communities, especially in the ecotone of the two (Roller 1996a, p. 9). Invasive nonnative grasses in both communities compete with native plants for water and nutrients, reduce community composition and structure, and alter fire frequency and intensity. Historically, low severity fires that occurred every 10 to 20 years in grasslands, or every 250 years in deserts, likely posed no threat to the long-term survival of *C. scheeri* var. *robustispina* individuals. When invaded by invasive nonnative grasses, fire frequency and intensity increase, leading to the deterioration of both natural grassland and desert communities. Invasive nonnative grasses produce more fine fuels than native vegetation, allowing for a more uniform and higher intensity burn compared with the discontinuous fuels of some native grasslands and deserts, thus reducing the number of microsite refuges safe from fire. *Coryphantha scheeri* var. *robustispina* is not fire adapted, but may survive fires through refugia (e.g. older soils or spaces between native plants), chance, shrinking into the ground, reproducing through basal resprouting, or possibly recolonization from a surviving seedbank, barring adequate rainfall to allow for survival. Further research into the relationship of fire, drought, nonnative species, soil types, and *C. scheeri* var. *robustispina* and their seedbanks would help to better understand the tolerance of this taxon to wildland and prescription fires. Research into desert-scrubland and desert-grassland restoration

(e.g. removal of nonnative grasses and the establishment of native plants) is also essential, as this is a large-scale problem currently without large-scale solutions. (USFWS, 2018a)

Stressor: Effects of Livestock Grazing (USFWS, 2018a)

Exposure:

Response:

Consequence:

Narrative: Some livestock grazing practices that occurred in the past have resulted in enduring landscape-level impacts, because recovery in dryland ecosystems is slow or stagnant. Historically overgrazed lands have altered microclimate and hydrology, increased soil compaction and erosion, reduced structural complexity and abundance of the vegetation community, and species composition; all of which may impact the current suitability of habitat for *C. scheeri* var. *robustispina* in certain areas of its range. In general, poorly managed livestock grazing may negatively impact *C. scheeri* var. *robustispina* seedlings and adult plants through soil erosion, soil compaction, hydrologic and micro-climatic changes, and invasion or expansion of invasive nonnative grasses. Low to moderate intensity grazing however, may also aid *C. scheeri* var. *robustispina* through the creation of open areas temporarily free of competition and with reduced fuels (Service 2000a, p. 9). Additional research into the relationships between livestock use and *C. scheeri* var. *robustispina* is needed to determine both the benefits of grazing and the threshold at which disturbance no longer benefits the taxon. In addition, research is needed into restoration of native species and fire regimes on desert grasslands and desertscrub. (USFWS, 2018a)

Stressor: Recreation and Border Activity (USFWS, 2018a)

Exposure:

Response:

Consequence:

Narrative: Off-road vehicle use and illegal border activity contribute to the overall degradation of *C. scheeri* var. *robustispina* habitat. In addition, individual *C. scheeri* var. *robustispina* have been run over by off-road vehicles. Although these activities could impact individual *C. scheeri* var. *robustispina*, off-road vehicles and illegal border activity are not likely significant sources of mortality for the taxon as a whole. (USFWS, 2018a)

Stressor: Overutilization for commercial, recreational, scientific, or educational purposes (USFWS, 2018a)

Exposure:

Response:

Consequence:

Narrative: Illegal collection of *C. scheeri* var. *robustispina* is difficult to detect and only one incident has been reported in recent years. Although illegal collection could impact *C. scheeri* var. *robustispina*, it is not as significant a threat for the taxon as previously thought. The determination to not designate critical habitat for the species has helped reduce this threat by not making maps publically available, and continued outreach and education related to the issue of illegal collection remain important tools in the conservation of this taxon. (USFWS, 2018a)

Stressor: Disease or Predation (USFWS, 2018a)

Exposure:

Response:

Consequence:

Narrative: In general, cacti are susceptible to attacks from numerous types of insects, and *C. scheeri* var. *robustispina* is no exception. The interior flesh of cacti provides both a nesting area and food source for beetles, weevils, and other insects. Once an infestation has occurred, cacti can die from the feeding and tunneling activities of insects or from the introduction of fungus or disease. Plants already stressed from prolonged drought are more susceptible to insect attack and disease, as drought may cause physiological stress responses in plants, such as limiting their photosynthesis and cell. Predation by mammals and insects occurs on both adult *C. scheeri* var. *robustispina* and seedlings. Primary insect predators of *C. scheeri* var. *robustispina* are the native *Gerstaeckeria* sp. (cactus weevil), the native *Moneilema* sp. (cactus beetle), and the native *Cactobrosis* sp. (pyralid moth). Ants have been documented on *C. scheeri* var. *robustispina* and will consume seed, however they are not specialists of *C. scheeri* var. *robustispina*. O'Dowd and Hay (1980, p. 539) suggest that ants may also aid in reducing the seedbank of competing plant species. Predation of *Coryphantha scheeri* var. *robustispina* by mammals is well-documented. Harris' antelope squirrel), antelope jackrabbits and desert cottontails are known to eat stem material of *C. scheeri* var. *robustispina*, especially when other food sources are scarce, such as in times of drought. Researchers have documented *C. scheeri* var. *robustispina* mortality caused by javelina (*Pecari tajacu*). These and other animals can also impact cacti by digging under stems, or, at least for larger animals, knocking over or trampling stems. In summary, there are many insect and mammalian predators to *C. scheeri* var. *robustispina* adults and seedlings. Predation increases during times of drought and following damage to a cacti's protective spines, such as post-fire. Many individual *C. scheeri* var. *robustispina* die or become disposed to death annually from predation which has been recorded on numerous occasions over the past decade. (USFWS, 2018a)

Stressor: Inadequacy of existing regulatory mechanisms (USFWS, 2018a)

Exposure:

Response:

Consequence:

Narrative: Because most *C. scheeri* var. *robustispina* occur on private and State Trust lands, they and their habitats are not subject to Federal protection unless there is a Federal nexus to a proposed action. Habitat loss due to urbanization remains a substantial threat to *C. scheeri* var. *robustispina* on these lands. Although best management practices may be implemented with regard to development, nonnative plant invasion and associated alteration of fire regimes, recreation, border issues, and the presence of livestock, management is not continuous across the range of the species and *C. scheeri* var. *robustispina* remain vulnerable to these threats and stressors. There are no regulations in place that address stressors to *C. scheeri* var. *robustispina* and its habitat from predation, drought and climate change, or small population size. (USFWS, 2018a)

Stressor: Drought and Climate Change (USFWS, 2018a)

Exposure:

Response:

Consequence:

Narrative: Cacti are vulnerable to disturbance because they grow slowly, their germination and establishment occurs with low frequency, and they have little capability to recover from disturbance (Portilla 2011, p. 509). Disturbance can reduce recruitment, survival, fecundity, and population growth; disturbance coupled with drought, however, can exacerbate negative

impacts on cacti. In summary, since the late 1990s, the southwestern United States has been experiencing drought conditions and increasing high temperatures. Climatic predictions suggest continued less frequent, but perhaps more intense, summer precipitation, reduced winter precipitation, and increasing temperatures in this region. Drought and increased temperatures increase *C. scheeri* var. *robustispina* stress, reduce defenses to predation and disease, and reduce reproduction, among other impacts. These impacts will continue to affect *C. scheeri* var. *robustispina* and its habitat throughout its range into the foreseeable future. (USFWS, 2018a)

Stressor: Small Population Size and Isolation (USFWS, 2018a)

Exposure:

Response:

Consequence:

Narrative: High species diversity within the vegetative community is important to the survival of *C. scheeri* var. *robustispina*, as this cactus is not abundant enough to sustain its main pollinators. A key pollinator for *C. scheeri* var. *robustispina* is *Diadasia rinconis*, a cactus specialist bee which requires species of *Cylindropuntia*, *Opuntia*, and *Ferocactus* to survive. *C. scheeri* var. *robustispina* is a sparsely distributed plant that requires habitat connectivity and proximity to other plants for effective pollination. Large scale threats and stressors such as habitat degradation and regional drought increase the potential for isolation and genetic loss. Current information indicates that roughly 98 percent of all known *C. scheeri* var. *robustispina* occur within 900 m (2,952.8 ft) of one another. Should development or other threats or stressors remove or cause the deterioration of corridors and connectivity, this could result in genetic isolation and inbreeding. (USFWS, 2018a)

Recovery

Reclassification Criteria:

1. Threats and Habitat Criterion: At least 8,094 hectares (ha) (20,000 acres [ac]) of *C. scheeri* var. *robustispina* habitat per recovery unit are documented to be of optimal quality and remain that way through successful resource management, land conservation, and restoration techniques such as in situ germination. At least 24,281 ha (60,000 ac) of *C. scheeri* var. *robustispina* habitat per recovery unit are documented to be of good quality and remain that way in perpetuity. Habitat is considered optimal quality when it: is protected for conservation purposes; is managed in a manner that promotes the long-term survival of *C. scheeri* var. *robustispina*; has less than 20 percent cover of *C. ciliaris*, *E. lehmanniana*, or other invasive nonnative plant species that alter ecosystem function; contains contiguous habitat and corridors for pollinators; and the *C. scheeri* var. *robustispina* population is observed to be stable or increasing. Habitat is considered good quality when the cover of *C. ciliaris*, *E. lehmanniana*, or other nonnative plants that alter ecosystem function remains between 20 and 35 percent; the land is managed in such a way that promotes the continued existence or expansion of long-term survival of *C. scheeri* var. *robustispina*. Collectively, this represents approximately 42 percent of the known range of *C. scheeri* var. *robustispina*. Additional acres of lesser quality *C. scheeri* var. *robustispina* also exist throughout the range of the species; some of which occurs on lands where ongoing efforts may continue to improve habitat quality. (USFWS, 2018a)

2. Conserve, protect, and restore mature *C. scheeri* var. *robustispina* individuals, their seedbanks (approximately 10 meters), and habitat for pollinators (approximately 900 meter radius) in each recovery unit through resource management, land conservation, and restoration techniques

such as in situ germination. Quantitative monitoring, using a standardized monitoring protocol, of established plots across a variety of land ownerships and land management scenarios, with landowner support, is conducted within each of the two recovery units every 3 to 5 years. Plots demonstrate that the population is stable or increasing a minimum of 10 years over a 15-year period. (USFWS, 2018a)

Delisting Criteria:

The first two criteria for downlisting must be met or surpassed, and monitoring must demonstrate that the population is increasing for a minimum of 20 years over a 30-year period. The additional time necessary to achieve delisting ensures continued population viability. Additionally, it will allow land managers to continue to reduce threats to *C. scheeri* var. *robustispina* from nonnative species invasion achieved during downlisting and track the long-term effectiveness of management. The additional time will also allow land managers to develop methods to reduce anticipated cost and effort needed to maintain habitat and population viability absent the protections of the Act. (USFWS, 2018a)

Recovery Actions:

- Conserve existing and newly discovered *C. scheeri* var. *robustispina* and associated habitat, including unoccupied areas that provide habitat and connectivity for pollinators. Promote urban planning for compact urban development, increase open space preservation and management (e.g. restrictions on trash dumping, off road vehicle use, placement of pedestrian trails, etc.), and connective habitat corridors. Engage in land acquisition to reduce habitat fragmentation and increase connectivity. Develop conservation easements for the protection of *C. scheeri* var. *robustispina* on private lands. Develop and monitor conservation mitigation banking to promote the protection of *C. scheeri* var. *robustispina* habitat. (USFWS, 2018a)
- Restore quality *C. scheeri* var. *robustispina* habitat in the U.S. and Mexico. Develop and implement land management plans that support and promote the taxon, including through the reduction of nonnative plant species and unnatural fire regimes, soil erosion, soil compaction, and headcutting. Work toward a better understanding of transplanting and seeding requirements for *C. scheeri* var. *robustispina* which could be implemented in appropriate habitat. (USFWS, 2018a)
- Develop range-wide standardized long-term monitoring of individuals in established plots, as well as their habitats, threats, and stressors. Monitor individuals in established plots across the range of the taxon using a tested standard protocol to enable an understanding of the long-term trend of the species, its habitat, threats, and stressors. Check the effectiveness of management actions by monitoring individuals subjected to natural and prescribed fire, mechanical site disturbance, various grazing regimes, various restoration techniques, and other management considerations. Monitor in situ grown and transplanted individuals for effectiveness of sowing, planting, and transplanting protocols. (USFWS, 2018a)
- Encourage scientific study to improve our understanding of *C. scheeri* var. *robustispina* biology, ecology, abundance, status, threats, stressors, viability, propagation, restoration of individuals and of habitats, distribution, and genetics in the United States and Mexico. Identify information gaps, compatible land uses, threats, stressors, and appropriate management actions that lead to the conservation of the taxon. Conduct surveys in appropriate habitat, using a tested standard protocol, to better understand the geographic range and habitat requirements of the taxon. Investigate the feasibility of alternative survey

methodologies, such as the use of detection dogs, drones, and distance sampling. Conduct research related to the biology, ecology, abundance, status, threats, stressors, viability, propagation, restoration of individuals and of habitat, and genetics of the taxon. (USFWS, 2018a)

- Maintain plants in captivity at botanic gardens and seeds at seed storage facilities; encourage research into propagation, in situ seed planting, and transplanting methods. Promote the propagation and planting of individuals ex situ at botanic gardens for conservation and public education purposes. Maintain seed from plants across the geographic range of the taxon for conservation purposes. Develop effective approaches to in situ conservation. (USFWS, 2018a)
- Develop public outreach, collaborative partnerships, and agreements with private landowners in the United States and Mexico that encourage *C. scheeri* var. *robustispina* conservation. Increase public outreach regarding threats, stressors, and conservation measures relating to *C. scheeri* var. *robustispina* in both the United States and Mexico. Develop collaborative partnerships and agreements with private landowners that result in management plans or that otherwise encourage *C. scheeri* var. *robustispina* conservation in the United States and Mexico. Develop a recovery implementation team comprised of species experts, agency and non-government agency partners, landowners, and stakeholders to meet regularly, review progress, discuss problems, and revise this plan as needed. (USFWS, 2018a)

SPECIES ACCOUNT: *Coryphantha sneedii* var. *leei* (Lee pincushion cactus)

Species Taxonomic and Listing Information

Listing Status: Threatened; 11/26/1979; Southwest Region (R2)

Physical Description

Both the Sneed and Lee pincushion cacti are many branched, forming tight clumps of up to 100 or more stems. Individual stems are cylindroid or spherical to club-shaped, 2.5-7.5 cm long (1.0-2.9 inches) and 1-3 cm in diameter (0.4- 1.2 inches) with tubercles up to 3mm long (0.12 inches). The tubercles are persistent and hard after fall of the spines. The spines hide the stem. The central spines are acicular, white, tipped with pink and brown, 3-14 cm long (1.2-5.5 inches) and about 6-17 per areole. The radial spines are white, 3-12 mm long (0.2-0.47 inches) and 35-90 per areole. The flowers are about 1.2 cm tall (0.5 inches) and of equal diameter, not opening widely; they are brownish-pink to pale rose with pink filaments and bright orange anthers. The fruits are greyish-green, or greenish tinged with brown, or rarely pinkish when ripe. They are clavate up to 1.5 cm long (0.6 inches) and 6 mm in diameter (0.24 inches). The seeds are reddish-brown, 0.7-1 mm long (.027-.039 inches), and 1.25-1.5 mm broad (.049-.059 inches) (Benson, 1982). In the Lee pincushion cactus, the spines are deflexed on medium and small stems, slanting from the top of the tubercle toward the main portion of the stem; the flowers are dull medium brownish-pink; the seeds are 1 mm long (.039 inches) and 1.5 mm broad (.059 inches) (Benson, 1982).(USFWS, 1986)

Taxonomy

In the recent taxonomic publications (Kartesz 1999; Baker and Johnson 2000; Anderson 2001), both varieties of *Coryphantha sneedii* are placed in the genus *Escobaria* Britton and Rose. Baker and Johnson (2000) note that this genus is sometimes considered a subgenus of *Coryphantha*. Anderson (2001) uses the genus *Escobaria* in his book "The Cactus Family," stating that the International Cactaceae Systematics Group has accepted this genus. (USFWS, 2015)

Historical Range

Coryphantha sneedii var. *leei* is known only from the Guadalupe Mountains in New Mexico (Eddy County), within, and immediately adjacent to, Carlsbad Caverns National Park. At the time of listing, it was known to only occur in "several canyons" (Weniger 1969). (USFWS, 2015)

Current Range

Occurs in the Guadalupe Mountains (Eddy County) of New Mexico (NatureServe, 2015). This subspecies includes individuals from six canyons scattered in populations of low abundance over approximately 22 kilometers (14 miles) of the Guadalupe Mountains including BLM lands (Carlsbad District). (USFWS, 2015)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources**Reproductive Strategy**

Adult: Asexual: vegetative (USFWS, 1986; see dispersal narrative); sexual (inferred from USFWS, 1986)

Breeding Season

Adult: March - April (USFWS, 1986)

Key Resources Needed for Breeding

Adult: Winter and spring moisture, soils seed bank (USFWS, 1986)

Reproduction Narrative

Adult: Most Lee pincushion cacti bloom after 3 - 4 years. Plants bud in late March or early April; fruit formation is from August to November. Winter and spring moisture is important for bud set. Each fruit produces about 26 seeds and a flowering stem produces about 6 fruits. A typical plant may produce over 1,000 seeds per year. Since seeds can remain viable for up to 10 years, the soil probably contains a sizeable seed bank (USFWS, 1986).

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Chaparral (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: 1,220-1,800 m elevation (NatureServe, 2015)

Environmental Specificity

Adult: Narrow (inferred from NatureServe, 2015)

Habitat Narrative

Adult: It is restricted to the Tansil Limestone Formation and grows only on north-facing limestone ledges, slopes and ridgetops, at 1,220-1,800 m elevation; precipitation averages 30 cm/year, in interior chaparral communities. The limestones are generally hard, resistant to erosion, and support a sparse vegetation of low shrubs, some rosette-forming perennials, many cacti, and both annual and perennial herbs (USFWS, 1986; NatureServe, 2015).

Dispersal/Migration**Dispersal**

Adult: Low (inferred from USFWS, 1986)

Dispersal/Migration Narrative

Adult: Only about 10% of all stems are of the non-flowering type, and these are broken off by animals or shifting rocks and may root, establishing new plants. Most fruits are eaten by insects or rodents who probably scatter a few seeds in the process. Birds have also been observed to feed on the fruits and should at least occasionally serve as dispersal agents. If a fruit is not

eaten, weathering breaks down the fruit wall causing the seeds to be dispersed by wind or rain (USFWS, 1986).

Population Information and Trends

Population Trends:

Not available

Number of Populations:

6 (USFWS, 2015)

Population Size:

1,000 - 2,000 (USFWS, 1986)

Population Narrative:

Presently, *Coryphantha sneedii* var. *leei* is known from very limited portions of six canyons in the Guadalupe Mountains (USFWS, 2015). There are an estimated 1,000 - 2,000 plants (Heil and Brack, 1985a) (USFWS, 1986).

Threats and Stressors

Stressor: Fire (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Presently, the threat of wild and prescribed fires in or around occupied *Coryphantha sneedii* var. *leei* habitat could prove problematic to its survival. Most of the park has burned since 1941 (NPS 2005, map, p. 6). While lightning ignitions probably took place frequently in the Guadalupe Mountains, most fires were likely quite localized and less intense prior to fire suppression (NPS 2005). Fire suppression in many ecosystems creates more uniform fuel loads that support more landscape-scale high intensity fires (NPS 2005). Specific impacts of wild and prescribed fire on *Coryphantha sneedii* var. *leei* are inconclusive (USFWS, 2015).

Stressor: Longhorn cactus beetle (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: There has been one observation of adult *Moneilema armatum* (longhorn cactus beetle) on *C. sneedii* var. *leei*, eating portions of this cactus. It is unknown what impact, if any, longhorn beetles have on this species (USFWS, 2015).

Stressor: Climate change (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Growing seasons are becoming longer and warmer in many regions (Parmesan 2007) including the southwest (Cayan et al. 2001; Easterling 2002; Lenart et al. 2007; Enquist and Gory 2008). Earlier soil moisture stress would result in decreased flowering and reproduction, and

because this cactus has a limited distribution, we would predict a substantial population reduction with a long-term warming trend. Munson et al. (2014) predicts declines in vegetative cover including cacti in Chihuahuan Desert habitats due to climate change. *Coryphantha* spp. are likely to have experienced and rebounded from periods of drought in the past. However, should substantial climate change materialize with increased severity and frequency of drought, it would likely reduce the long-term survivorship of this species (USFWS, 2015).

Recovery

Reclassification Criteria:

Not applicable. (USFWS, 1986)

Delisting Criteria:

The Lee pincushion cactus will be considered for delisting when:

1. All core populations demonstrate stable or increasing trends in abundance over a 20-year period. This will be based on periodic demographic trend monitoring and analysis implemented under the recovery actions. (USFWS, 2019)
- 2a. Maintain a minimum of three geographically separated core populations for each species over a 20-year period. (USFWS, 2019)
- 2b. A minimum of one new core population will be discovered (use Criterion 1) or established outside the current range and wholly separated geographically from the other core populations, and remain occupied for 10 years out of the 20-year survey period. (USFWS, 2019)
- 3a. Maintain genetic diversity within all core populations as measured by the fixation indices inbreeding coefficient (FIS) at or within one standard deviation of the FIS of a closely related species with similar reproductive strategies and demonstrated acceptable viability. (USFWS, 2019)
- 3b. Maintain presence in 80 percent of subpopulations over 20-year monitoring period and outside of the core populations, with any subpopulation extirpations compensated by a newly identified or colonized subpopulation. (USFWS, 2019)
4. Develop and implement a Habitat Management Plan (HMP) for Sneed and Lee pincushion cacti conservation. (USFWS, 2019)
5. A Service approved post-delisting monitoring plan will be implemented. (USFWS, 2019)

Recovery Actions:

- Remove threats of collecting by enforcement of existing regulations. Because of the rarity of the Lee pincushion cactus, the populations must be protected by enforcement of existing international, Federal, and State regulations. Determine the extent and impacts of collecting. Develop and implement a law enforcement strategy. Publicize successful law enforcement actions. (USFWS, 1986)
- Manage existing habitat for protection of the cactus. Habitat management for the Lee pincushion cactus should be done through existing agency management procedures and

- through cooperation with private landowners. The following should be accomplished. Agencies should remain informed of the location and status of Lee pincushion cactus populations. Develop and implement habitat management plans for all populations on public lands. Seek cooperation of landowners to protect and maintain populations on private lands. (USFWS, 1986)
- Gather information for use in management. In-depth knowledge of the plant's growth, distribution, population biology and ecology is needed to understand habitat requirements. The knowledge gained can be used to help sustain and manage healthy natural populations. Study population biology and ecology. Develop techniques to artificially propagate and transplant the Lee pincushion cactus. Inventory known populations and search for new populations in the Franklin and Guadalupe Mountains. (USFWS, 1986)
 - Develop a comprehensive trade management plan for all cacti. Studies are needed to determine what species are in trade, the overall trend of trade in listed cacti, and the feasibility of reducing collecting pressure on wild populations by promoting a commercial, artificial propagation program. Strategies for effective implementation of law enforcement responsibilities under ESA, CITES, Lacey Act, and State laws need to be developed. These studies should be national in scope and address all cacti. The results will be used to develop policy and a comprehensive trade management plan for all cacti. (USFWS, 1986)
 - Develop public awareness, appreciation and support for preservation of the Lee pincushion cactus. Education of the public is a vital part of the recovery process. The cooperation of the public is essential to the ultimate success of the foregoing recovery measures. (USFWS, 1986)
 - Recommendations for Future Actions from 2015 5-Year Review:
 - Determine if the genus associated with this species needs to be changed from *Coryphantha* to *Escobaria* on all future Service documents.
 - Revise the recovery plan for these species to incorporate new information on taxonomy, biology, ecology, and threats with management recommendations. Objective and measurable recovery criteria for down and de listing of the species should be developed which address all listing factors relevant to this species.
 - Develop a *Coryphantha sneedii* var. *leei* and *C. sneedii* var. *sneedii* multi-agency working group to share and disseminate information regarding this listed species to promote education, protection, and recovery.
 - Develop standardized survey and monitoring protocols for these species to be conducted annually by well trained personnel. Continue monitoring of known sites as well as adding new sites to provide a robust dataset for long-term trend analysis. Incorporate fire and climate change factors into long-term monitoring data collection.
 - Develop a mitigation banking requirement (a system whereby project proponents pay for plants to be preserved in an area suitable for their preservation as mitigation for losses incurred during projects).
 - Implement and monitor new transplant projects with experimental manipulations (watering, shading, planting depth, etc.) and controls to determine required establishment needs.
 - Provide legally grown seeds and plants of *Coryphantha sneedii* var. *leei* and *C. sneedii* var. *sneedii*, as the known populations allow, to the commercial succulent trade, but law enforcement must remain vigilant against the theft of cacti throughout its range.
 - Provide viable *Coryphantha sneedii* var. *leei* and *C. sneedii* var. *sneedii* seeds to a seed bank operating under the Center for Plant Conservation guidelines.
 - Collect data on seed dispersal and growth past the germination stage, timing of seed set, and seedling establishment to more clearly define the vulnerable life history stages of these species.
 - Determine microhabitat needs of these species ("nurse" plants, pollinators, precipitation needs- amount and timing, slope and aspect requirements,

disturbance patterns, etc.) to further quantify potential habitat for a transplant and mitigation site. (USFWS, 2015)

SPECIES ACCOUNT: *Coryphantha sneedii* var. *sneedii* (Sneed pincushion cactus)

Species Taxonomic and Listing Information

Listing Status: Endangered; 12/07/1979; Southwest Region (R2)

Physical Description

Both the Sneed and Lee pincushion cacti are many branched, forming tight clumps of up to 100 or more stems. Individual stems are cylindroid or spherical to club-shaped, 2.5-7.5 cm long (1.0-2.9 inches) and 1-3 cm in diameter (0.4- 1.2 inches) with tubercles up to 3mm long (0.12 inches). The tubercles are persistent and hard after fall of the spines. The spines hide the stem. The central spines are acicular, white, tipped with pink and brown, 3-14 cm long (1.2-5.5 inches) and about 6-17 per areole. The radial spines are white, 3-12 mm long (0.2-0.47 inches) and 35-90 per areole. The flowers are about 1.2 cm tall (0.5 inches) and of equal diameter, not opening widely; they are brownish-pink to pale rose with pink filaments and bright orange anthers. The fruits are greyish-green, or greenish tinged with brown, or rarely pinkish when ripe. They are clavate up to 1.5 cm long (0.6 inches) and 6 mm in diameter (0.24 inches). The seeds are reddish-brown, 0.7-1 mm long (.027-.039 inches), and 1.25-1.5 mm broad (.049-.059 inches) (Benson, 1982). In the Sneed pincushion cactus, the stems have spines that are not deflexed but spread parallel to the stem surface; the flowers are pale, or medium to rose, magenta; the seeds are 0.75 mm long (.03 inches), and 1.25 mm broad (.049 inches) (Benson, 1982). (USFWS, 1986)

Taxonomy

In the recent taxonomic publications (Kartesz 1999; Baker and Johnson 2000; Anderson 2001), both varieties of *Coryphantha sneedii* are placed in the genus *Escobaria* Britton and Rose. Baker and Johnson (2000) note that this genus is sometimes considered a subgenus of *Coryphantha*. Anderson (2001) uses the genus *Escobaria* in his book "The Cactus Family," stating that the International Cactaceae Systematics Group has accepted this genus. Further elucidation of the taxonomic relationships of the *C. sneedii* complex, including *Escobaria guadalupensis*, is needed in order to understand the distribution and abundance of *C. sneedii* var. *sneedii* (USFWS, 2015).

Historical Range

Coryphantha sneedii var. *sneedii* is a regional endemic along the Texas/New Mexico border (USFWS, 2015). It was historically known only from the Anthony Gap area of the Franklin mountains in Dona Ana County, New Mexico. (USFWS, 1986)

Current Range

It occurs in western Texas and nearby southern New Mexico (between El Paso and Las Cruces) (NatureServe, 2015). It possibly occurs in the Guadalupe Mountains; in Dona Ana and Eddy Counties, New Mexico, and El Paso County in Texas (USFWS, 2015).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources**Reproductive Strategy**

Adult: Asexual: vegetative (USFWS, 1986); sexual (inferred from USFWS, 1986)

Breeding Season

Adult: March - April, sometimes July - August (USFWS, 1986)

Key Resources Needed for Breeding

Adult: Rocks (USFWS, 1986; NatureServe, 2015)

Reproduction Narrative

Adult: A second blooming season has rarely been observed in July and August usually following summer rains. The best seedling survival is under rocks or deep in the cracks of rocks where seedlings are protected (USFWS, 1986; NatureServe, 2015). One type of stem remains small and probably serves to start new plants when they break off. Most Sneed pincushion cacti bloom after 3 - 4 years. Plants bud from March to April with the principal blooming period in April and fruit formation from August to November. Fruits from Slaughter Canyon averaged about 18 seeds per fruit. With about 11 flowering stems per plant, about 140 seeds per plant are produced each year (USFWS, 1986).

Habitat Type

Adult: Terrestrial (USFWS, 1986; NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Desert and desert grassland (USFWS, 1986; NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: 1,220-1,800 m elevation (USFWS, 1986; NatureServe, 2015)

Environmental Specificity

Adult: Narrow (inferred from USFWS, 1986; NatureServe, 2015)

Habitat Narrative

Adult: It is restricted to limestone ledges and the rocky slopes of limestone mountains in desert and desert grassland habitats; 1,220-1,800 m elevation; precipitation 19.7 - 40.0 cm/year; and grows in cracks on vertical cliffs or ledges. The limestones are generally hard, resistant to erosion, and support a sparse vegetation of low shrubs, some rosette-forming perennials, many cacti, and both annual and perennial herbs (USFWS, 1986; NatureServe, 2015).

Dispersal/Migration**Dispersal**

Adult: Low to moderate (inferred from USFWS, 1986)

Dispersal/Migration Narrative

Adult: The fruits have a prune-like odor when ripe and attract rodents which are likely dispersal agents. Birds have been noted to feed on the fruits and should serve as dispersal agents. Some fruits crumble with age, and water disperses the seeds (USFWS, 1986).

Population Information and Trends

Population Trends:

Not available

Number of Populations:

20 (USFWS, 1986)

Population Size:

Possibly > 100,000 (USFWS, 1986)

Population Narrative:

There are 20 documented localities for this taxon. Heil and Brack (1985a) have estimated the total number of sneed pincushion cacti in Carlsbad Caverns National Park to exceed 100,000. This figure needs verification through quantitative sampling (USFWS, 1986).

Threats and Stressors

Stressor: Fire (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Most of the park has burned since 1941 (NPS 2005, map, p. 6). While lightning ignitions probably took place frequently in the Guadalupe Mountains, most fires were likely quite localized and less intense prior to fire suppression (NPS 2005). Fire suppression in many ecosystems creates more uniform fuel loads that support more landscape-scale high intensity fires (NPS 2005). However, specific impacts of wild and prescribed fire on *C. sneedii* var. *sneedii* are still inconclusive (USFWS, 2015).

Stressor: Climate change (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Growing seasons are becoming longer and warmer in many regions (Parmesan 2007) including the southwest (Cayan et al. 2001; Easterling 2002; Lenart et al. 2007; Enquist and Gory 2008). Earlier soil moisture stress would result in decreased flowering and reproduction, and because this cactus has a limited distribution, we would predict a substantial population reduction with a long-term warming trend. Munson et al. (2014) predicts declines in vegetative cover including cacti in Chihuahuan Desert habitats due to climate change. *Coryphantha* spp. are likely to have experienced and rebounded from periods of drought in the past. However, should substantial climate change materialize with increased severity and frequency of drought, it would likely reduce the long-term survivorship of this species (USFWS, 2015).

Recovery

Reclassification Criteria:

Downlisting of the Sneed pincushion cactus to threatened can be initiated when:

1. Six or more secure populations are established with at least three each near the eastern (Guadalupe Mountains) and western (Franklin Mountains and southern Organ Mountains) limits of the plant's known range. Populations will be considered secure when land managing agencies, organizations or individuals have developed and implemented habitat management plans for the Sneed pincushion cactus. At a minimum, the plans should contain methods for securing populations against present and future potential threats, methods for accurately quantifying population sizes, and methods for monitoring populations to determine their stability, growth, or decline. (USFWS, 1986)
2. When the known number of plants in these six secure populations totals 20,000. (USFWS, 1986)

Delisting Criteria:

The Sneed pincushion cactus will be considered for delisting when:

1. All core populations demonstrate stable or increasing trends in abundance over a 20-year period. This will be based on periodic demographic trend monitoring and analysis implemented under the recovery actions. (USFWS, 2019)
2. Maintain a minimum of three geographically separated core populations for each species over a 20-year period. (USFWS, 2019)
- 3a. Maintain genetic diversity within all core populations as measured by the fixation indices inbreeding coefficient (FIS) at or within one standard deviation of the FIS of a closely related species with similar reproductive strategies and demonstrated acceptable viability. (USFWS, 2019)
- 3b. Maintain presence in 80 percent of subpopulations over 20-year monitoring period and outside of the core populations, with any subpopulation extirpations compensated by a newly identified or colonized subpopulation. (USFWS, 2019)
4. Develop and implement a Habitat Management Plan (HMP) for Sneed pincushion cacti conservation. (USFWS, 2019)
5. A Service approved post-delisting monitoring plan will be implemented. (USFWS, 2019)

Recovery Actions:

- Remove threats of collecting by enforcement of existing regulations. Because of the rarity of the Sneed pincushion cactus, the populations must be protected by enforcement of existing international, Federal, and State regulations. Determine the extent and impacts of collecting. Develop and implement a law enforcement strategy. Publicize successful law enforcement actions. (USFWS, 1986)
- Manage existing habitat for protection of the cactus. Habitat management for the Sneed pincushion cactus should be done through existing agency management procedures and

- through cooperation with private landowners. The following should be accomplished. Agencies should remain informed of the location and status of Sneed pincushion cactus populations. Develop and implement habitat management plans for all populations on public lands. Seek cooperation of landowners to protect and maintain populations on private lands. (USFWS, 1986)
- Gather information for use in management. In-depth knowledge of the plant's growth, distribution, population biology and ecology is needed to understand habitat requirements. The knowledge gained can be used to help sustain and manage healthy natural populations. Study population biology and ecology. Inventory known populations and search for new populations in the Franklin and Guadalupe Mountains. (USFWS, 1986)
 - Develop a comprehensive trade management plan for all cacti. Studies are needed to determine what species are in trade, the overall trend of trade in listed cacti, and the feasibility of reducing collecting pressure on wild populations by promoting a commercial, artificial propagation program. Strategies for effective implementation of law enforcement responsibilities under ESA, CITES, Lacey Act, and State laws need to be developed. These studies should be national in scope and address all cacti. The results will be used to develop policy and a comprehensive trade management plan for all cacti. (USFWS, 1986)
 - Develop public awareness, appreciation and support for preservation of the Sneed pincushion cactus. Education of the public is a vital part of the recovery process. The cooperation of the public is essential to the ultimate success of the foregoing recovery measures. (USFWS, 1986)
 - Recommendations for Future Actions from 2015 5-Year Review:
 - Determine if the genus associated with this species needs to be changed from *Coryphantha* to *Escobaria* on all future Service documents.
 - Revise the recovery plan for these species to incorporate new information on taxonomy, biology, ecology, and threats with management recommendations. Objective and measurable recovery criteria for down and de listing of the species should be developed which address all listing factors relevant to this species.
 - Develop a *Coryphantha sneedii* var. *leei* and *C. sneedii* var. *sneedii* multi-agency working group to share and disseminate information regarding this listed species to promote education, protection, and recovery.
 - Develop standardized survey and monitoring protocols for these species to be conducted annually by well trained personnel. Continue monitoring of known sites as well as adding new sites to provide a robust dataset for long-term trend analysis. Incorporate fire and climate change factors into long-term monitoring data collection.
 - Develop a mitigation banking requirement (a system whereby project proponents pay for plants to be preserved in an area suitable for their preservation as mitigation for losses incurred during projects).
 - Implement and monitor new transplant projects with experimental manipulations (watering, shading, planting depth, etc.) and controls to determine required establishment needs.
 - Provide legally grown seeds and plants of *Coryphantha sneedii* var. *leei* and *C. sneedii* var. *sneedii*, as the known populations allow, to the commercial succulent trade, but law enforcement must remain vigilant against the theft of cacti throughout its range.
 - Provide viable *Coryphantha sneedii* var. *leei* and *C. sneedii* var. *sneedii* seeds to a seed bank operating under the Center for Plant Conservation guidelines.
 - Collect data on seed dispersal and growth past the germination stage, timing of seed set, and seedling establishment to more clearly define the vulnerable life history stages of these species.
 - Determine microhabitat needs of these species ("nurse" plants, pollinators, precipitation needs- amount and timing, slope and aspect requirements, disturbance patterns, etc.) to further quantify potential habitat for a transplant and mitigation site. (USFWS, 2015)

SPECIES ACCOUNT: *Crescentia portoricensis* (Higuero de sierra)

Species Taxonomic and Listing Information

Listing Status: Endangered; 12/4/1987; Southeast Region (R4) (USFWS, 2015)

Physical Description

A vine-like shrub or small tree which may reach up to 6 meters (20 feet) in height and 8 centimeters (3 inches) in diameter. The bark is gray and the branches long and slender. The glabrous leaves vary from 5 to 15 centimeters (2 to 6 inches) in length and 2 to 8 centimeters (3/4 to 3 inches) in width and are whorled in groups of 3 to 5 at the nodes. The leaves are simple, widest above the middle, entire, leathery, dark shiny—green above, with a rounded or blunt apex and a tapered base. The petiole is from 1 to 2 centimeters (1/4 to 5/8 inch) long (Little et al., 1974, Vivaldi and Woodbury 1981) - The perfect flowers are solitary at the axil of the leaves or along the branches. The calyx is leathery, tubular, 2-lobed, and about 2 centimeters (3/4 inch) long. The corolla is yellowish— white with the 5 united petals forming a bell-shaped tube approximately 4 centimeters (1 and 1/2 inches) long. The four stamens are attached to the base of the petals. The fruit is dark green when mature, cylindric, hard and leathery, indehiscent, approximately 10 centimeters (4 inches) long and 3 centimeters (1 and 1/4 inches) wide (Little et al. 1974, Vivaldi and Woodbury 1981). (USFWS, 1991)

Taxonomy

A member of the Bignoniaceae family (USFWS, 1991).

Historical Range

This species is endemic to Puerto Rico and found only in the Maricao Commonwealth Forest and the Susua Commonwealth Forest (USFWS, 1991).

Current Range

Presently known from only 7 sites in Puerto Rico: five within the Maricao Commonwealth Forest and two within the nearby Susua Commonwealth Forest (USFWS, 1991). Specific locations include Quebrada Piedras and Río Seco in the Maricao Commonwealth Forest, and Quebrada Peces in the Susúa Commonwealth Forest. Within the Susúa Forest, Breckon et al. (1992) reported three main populations comprised by 10 localities along three water bodies (Quebrada Grande, Río Loco and Quebrada Peces), all tributaries of the Río Loco drainage. Three populations within the Maricao Commonwealth Forest are located in the Rio Maricao watershed, steep slopes along the Quebrada Seca river, and along a small tributary of the Rio Lajas river below El Salto de Curet. Additional MCF populations are found along the Quebrada Piedras, Rio Bonelli, Rio Cupeyes and Rio Postrero (USFWS, 2017).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Vegetative (USFWS, 1991)

Key Resources Needed for Breeding

Adult: Likely bat pollinators (EPA, 2016)

Other Reproductive Information

Adult: Breckon and Kolterman (1993) stated that the species is in danger of hybridization with the introduced *Crescentia cujete*. These authors reported a natural population of *C. linearifolia* (native to Puerto Rico) located along State Road PR 116 in the Lajas Valley that was apparently hybridizing with *C. cujete*. They mentioned that trees that appear to be “pure” *C. linearifolia* are infrequent in the population; the majority of the trees are apparently hybrids. *Crescentia cujete* is probably native to Mexico and north Central America. Cancel (2010) recorded individuals of *C. cujete* within the Susúa Commonwealth forests in the proximity of a population of *C. portoricensis*. Nonetheless, Cancel (2010) did not find evidence of hybridization in any of the wild *C. portoricensis* populations he studied. However, he recorded evidence of hybridization in several ex situ collections of *C. portoricensis* (i.e., Quebradillas and Caguas Botanical Garden). (USFWS, 2017).

Reproduction Narrative

Adult: Produces fruits year round and is probably pollinated by bats (EPA, 2016). Sprouting has been observed in some individuals but the importance of this vegetative reproduction is unknown (USFWS, 1991). All surveys have found no evidence of natural seedling establishment which indicates that the species is apparently depending on asexual reproduction (Breckon et al. 1992; Breckon and Kolterman 1993; Breckon and Kolterman 1994; and Breckon and Kolterman 1996; Cancel 2010). Breckon et al. (1992) and Breckon and Kolterman (1993) observed evidence of asexual or vegetative reproduction, which occurred when the terminal portion of the arching branches came in contact with the ground and layering (producing roots). In particular, Breckon and Kolterman (1994) observed that a portion of the plant tagged as #168 in the Susúa Commonwealth Forest, had separated from the parent plant, had rooted, and was in good condition. (USFWS, 2017).

Habitat Type

Adult: Terrestrial (EPA, 2016)

Habitat Vegetation or Surface Water Classification

Adult: Subtropical moist and wet forest, riparian (EPA, 2016)

Geographic or Habitat Restraints or Barriers

Adult: ~820 to 2624 ft. elevation (EPA, 2016)

Habitat Narrative

Adult: Subtropical moist and wet forest life zones. Found along banks of streams, usually within a meter of the water's edge. Topography is mountainous with steep slopes and ravines. Vegetation in the forests is semi-evergreen to deciduous. Serpentine-derived soils, area has serpentine outcrops interspersed with Nipe and Rosario clay soils (derived from serpentine). Occurs around 820 to 2624 ft. elevation (EPA, 2016).

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Seeds are dispersed by water (flooding of streams) (EPA, 2016).

Population Information and Trends**Population Trends:**

Not available

Resiliency:

Very low (inferred from USFWS, 1991)

Redundancy:

Low (USFWS, 1991)

Number of Populations:

7 (USFWS, 1991). During his research, Cancel (2010) reported at least 532 individuals of *C. portoricensis* within eleven populations (USFWS, 2017).

Population Size:

~100 (USFWS, 1991). Several new populations have been found and the number of known individuals has increased to more than 500. The current number of known individuals has increased to over 500 plants within these Commonwealth forests. More recently, José Sustache (2015; PRDNER botanist) reported about 15 individuals within a previously unreported area adjacent to Cabañas del Monte del Estado in Maricao. We currently estimate at least 547 individuals of *C. portoricensis* in the wild (including individuals located by Jose Sustache). (USFWS, 2017).

Population Narrative:

It is found in only two areas of southwestern Puerto Rico. A total of approximately 100 individuals occur in the 7 populations known (USFWS, 1991).

Threats and Stressors

Stressor: Habitat destruction and modification (USFWS, 1991). As of 2019: the majority of the suitable habitat for the species is protected and managed for conservation, and the impacts by forest management do not occur on a regular basis and are limited to maintenance of existing trails and recreational areas. Therefore, destruction, modification or curtailment of their habitat (Factor A) is considered a low and non-imminent threat for this species. (USFWS, 2019)

Exposure:**Response:****Consequence:**

Narrative: Historically, the most important factors affecting the abundance and distribution of *Crescentia portoricensis* have been both the direct and indirect effects of deforestation. Much of the Susua Forest and parts of the Maricao Forest were cut for cultivation, grazing, charcoal production, and wood prior to their designation as public forests. Land use practices in upland areas resulted in increased flash flooding and erosion of stream banks, the habitat for this species. Small intake dams, trails, and recreational use of the more accessible areas also threaten

the species (USFWS, 1991). This includes road construction and activity, particularly along State Road PR 362. (USFWS, 2017).

Stressor: Flash floods (USFWS, 1991)

Exposure:

Response:

Consequence:

Narrative: The “Quebrada Peces” population in Susúa, composed of only six known individuals, although within a protected Commonwealth Forest, is located close to a heavily traveled access road to the Forest. All known individuals are located on steep stream banks and are exposed to the threat of elimination by erosion and flash flooding. The Maricao populations are also subject to a variety of threats. Here the species is found along drainage areas subject to flash floods which may uproot plants (USFWS, 1991).

Stressor: Erosion (USFWS, 2017).

Exposure:

Response:

Consequence:

Narrative: All populations are threatened with increased erosion by deforestation and poor management practices occurring upstream outside the forest. According to Cancel (2010), erosion may explain why the numbers of individuals in the Río Lajas and Quebrada Seca in Maricao, and Arroyo del Tanque in Susúa have decreased as compared to the data provided by Breckon and Kolterman from 1991 to 1995. Moreover, the loss of individuals in the Río Maricao could be explained by the construction of a small dam in the river and the effect of hurricanes. Based on the monitoring of this population by Breckon and Kolterman (1992), and by Cancel (2010), there was a decline in number of individuals likely due to river overflow and erosion of the river bank during hurricanes events (i.e., Hurricane Georges in 1998). Despite documentation of additional populations, loss of individuals due to erosion along river margins and landslides may have a major detrimental effect on the species, particularly since recruitment is not documented on these populations. (USFWS, 2017).

Stressor: *Rattus rattus* predation (USFWS, 2017). Considered the most significant threat as of 2019. (USFWS, 2019).

Exposure:

Response:

Consequence:

Narrative: Breckon et al. (1992) found several fruits of *C. portoricensis* that had been gnawed on, and in some cases the contents had been eaten; presumably by the introduced rat, *Rattus rattus*. Breckon et al. (1992) recommended further studies to determine if rat predation of fruits accounted for the absence of seedlings in the wild. Cancel (2010) also found evidence of rat predation in the *C. portoricensis* population at Quebrada Peces, Susúa commonwealth Forest. The predated fruit found by Cancel was green and was still hanging on the plant at the time of his observation. Evidence of predation was also observed in 2010 by Service biologist O. Monsegur, along the headwaters of Río Maricao (Maricao Commonwealth Forest). A ripe fruit was found submerged in the river with clear rodent teeth marks around the pericarp, with intact seed material that was set for germination and showed 80% germination. Although other *Crescentia* spp. have been reported to be dispersed by rodents (Kubitzki and Ziburski 1994), the existing evidence of predation and the lack of natural recruitment of the species, lead us to concur with

Breckon et al. (1992), who suggested that exotic rats (*Rattus rattus*) might be negatively impacting *C. portoricensis*. It is likely that the majority of the fruits are eaten before the seed material has fully developed and any seed (embryo) left by rodents might be immature and not able to germinate. (USFWS, 2017). There is evidence that the absence of recruitment is being caused by rats preying on (Factor C) and/or damaging the fruits and seeds of *higiiero de sierra* (USFWS 2017). It is likely that the majority of the fruits are eaten before the seed material has fully developed and any seed (embryo) left by rodents might be immature and not able to germinate. (USFWS, 2019).

Stressor: Genetic diversity and hybridization (USFWS, 2017).

Exposure:

Response:

Consequence:

Narrative: Along with a small population size, negative impacts of habitat fragmentation may result in erosion of genetic variation through the loss of alleles by random genetic drift (Honnay and Jacquemyn 2007), which may also limit the ability of a species to respond to a changing environment (Booy et al. 2000). This may be due to the founder effect or a genetic bottleneck during the history of the species. This might well be the case of *C. portoricensis* following the massive deforestation island wide in Puerto Rico, and that reached its peak prior to the designation of the Maricao and Susúa forests as conservation areas (Cancel 2010). Species with low fruit set and no evidence of natural recruitment as the case of *C. portoricensis* were likely adversely affected by this deforestation. Thus, another factor that would be expected to contribute to a low genetic diversity in *C. portoricensis* is its apparent reliance on asexual reproduction. A preponderance of asexual reproduction on this species would be expected to be reflected in genetic differences of individuals among different river drainages (Cancel 2010). Moreover, in the absence of natural recruitment, where seedlings are a result of crosspollination among adult individuals, the clones produced through asexual reproduction are expected to reduce the genetic variability of the species. Additionally, it is known that species of the genus *Crescentia* hybridize with related species (Gentry 1980), but Cancel (2010) did not find evidence of hybridization in any of the wild populations he studied. Nonetheless, Cancel (2010) reported plants of *C. portoricensis* with fruits of intermediate size and shape, suggesting hybridization on cultivated material in the municipality of Quebradillas. Hybridization of *C. portoricensis* also has been documented in the nursery of Para La Naturaleza (O. Monsegur, USFWS, pers. obs., 2009). Hybridization with other species of the genus should be avoided both in situ and ex situ, to safeguard the integrity of this narrow endemic species. (USFWS, 2017).

Stressor: Natural recruitment (USFWS, 2017).

Exposure:

Response:

Consequence:

Narrative: Neither Breckon et al. (1992), Cancel (2010), nor any Service biologist has documented evidence of seedlings in the wild despite the evidence of high germination rates (about 80%) of seed material collected from wild populations when propagated in nursery conditions. Factors such as the lack of a native seed disperser and/or appropriate microhabitat conditions for germination may explain the absence of natural recruitment in the wild. Nonetheless, the Maricao and Susúa Commonwealth Forests harbor very good stands of native vegetation, including some remnants of pristine forest, suggesting that ecological conditions are suitable. However, available evidence strongly suggests that predation of fruits by rats is a major factor

preventing the establishment of seedlings of *C. portoricensis* (see Factor C), and thus compromise the long term recovery of the species. (USFWS, 2017).

Recovery

Reclassification Criteria:

Existing populations and their habitats are protected and at least four new populations are established in protected areas (USFWS, 1991). At least four new populations capable of self-perpetuation have been established within suitable protected areas such as Commonwealth forests. The plan specifies that these four populations should be considered a minimum requirement, and should be expanded upon if the regenerative or propagative potential of natural and ex situ populations proves to be insufficient. (USFWS, 2017).

The plan also specifies that if new populations of the species are discovered, it may be preferable to place greater emphasis on protection, rather than on propagation, to achieve a minimum number of plants. (USFWS, 2017).

Delisting Criteria:

1. Existing eleven (11) populations of higiiro de sierra within the Maricao and Susua Commonwealth Forests are enhanced and managed such that they show a stable or increasing population trend, evidenced by natural recruitment, and multiple age classes (addresses Factor A, C, and E). (USFWS, 2019).
2. Threats reduction and management activities (e.g., control of predation by rats, best management practices during forest management activities) have been implemented to a degree that the species will remain viable for the foreseeable future (addresses Factor A, C, and E). (USFWS, 2019).

Recovery Actions:

- Monitor existing populations (USFWS, 1991).
- Provide protection for existing populations and their habitat (USFWS, 1991).
- Conduct research on the life history of the species, evaluate methods of propagation, and locate introduction sites (USFWS, 1991).
- Propagate and produce seedlings for enhancement of existing populations and for the establishment of new populations at identified sites (USFWS, 1991). Added in 2017: The populations that are actively producing fruits should be monitored to collect seed material for recovery purposes. (USFWS, 2017). Added in 2019: Develop a protocol for the propagation and reintroduction of higiiro de sierra in collaboration with partners. The protocol should address avoiding hybridization and insect pests. This revised action supplements Task 4: Establishment of new populations. (USFWS, 2019).
- 2017 Recommendation 1. Develop a plan for the long term monitoring of the known populations of *C. portoricensis* in order to establish population trends and to record any evidence of natural recruitment. (USFWS, 2017).
- 2017 Recommendation 2. Conduct further studies to address possible adverse effects of fruit predation by rats (*Rattus rattus*), and to determine if rats provides some mechanism for seed dispersal or if they damage the seed embryo. (USFWS, 2017). Refinement in 2019: Research should be conducted focused on the potential factors that affect higiiro de sierra

recruitment in the wild in order to assess the need to control rats in the wild or the need for other actions to enhance recruitment. This new action should be included within Task 3: Research. (USFWS, 2019).

- 2017 Recommendation 3. Studies should be conducted to determine the patterns of genetic variation within and among populations in order to develop a plan to preserve the species genetic variability and to manage populations effectively. (USFWS, 2017).
Refinement in 2019: Assess Higuero de Sierra genetic structure along its known range that may inform the need for specific propagation efforts and the need for long-term seed banking. This new action should be included within Task 3: Research. (USFWS, 2019).
- 2017 Recommendation 4. Further studies should be conducted on the species reproductive biology to address other limiting factors (e.g., lack of pollinators or seed dispersers). (USFWS, 2017).

Conservation Measures and Best Management Practices:

- Although there is no documentation that *Crescentia portoricensis* has been taken for horticultural purposes, it may be recognized as having ornamental potential in the future. Propagation has been attempted by cuttings and seed by the Fairchild Tropical Garden of Miami, Florida. Germination of the many small seeds collected in August 1989, has been successful, however, it is not known yet whether ex situ propagation could provide a source of material for reintroduction of the species in Puerto Rico (C. Lippincott pers. comm.) (USFWS, 1991).
- The Puerto Rico Department of Natural Resources has constructed barriers along the Susua Forest access road in order to discourage parking. In addition, the Department has installed a fence at the entrance to the “Quebrada Feces” in order to reduce visitation to the area (USFWS, 1991).

SPECIES ACCOUNT: *Crotalaria avonensis* (Avon Park harebells)

Species Taxonomic and Listing Information

Listing Status: Endangered; 5/27/1993; Southeast Region (R4) (USFWS, 2015)

Physical Description

Avon Park harebells (*Crotalaria avonensis*) is a spreading, perennial herb with one to three moderately hairy, flowering stems that may grow 2 to 10 cm above the surface. It has a large taproot, up to 14 mm thick and 40 cm long. The leaves of this plant are 8 to 19 mm long, broadly elliptic or round, somewhat succulent, and coated with white or yellowish-white hairs. The stems terminate in flowering racemes. Flowering is from March until June. The flower, shaped like a typical pea flower, has a yellow corolla 8 to 9 mm long. The seed pods are inflated and 14 to 25 mm long. These pods are tan to grey or maroon, and can be nearly as long as the upright stems that hold them in place. The pods contain up to 18 seeds, chestnut to maroon in color and 3.4 to 3.8 mm long by 2.4 to 2.6 mm wide. The plant generally appears to resemble clusters of fuzzy grayish leaves hugging the ground and sometimes appears bushy (DeLaney and Wunderlin 1989). (USFWS, 1999)

Taxonomy

C. avonensis is a member of the pea family (Fabaceae/Leguminosae). This small herb with large seed pods was not named until 1989, evidently because very few specimens had ever been collected and they had not been examined by taxonomists. This species is most closely related to *C. rotundifolia*, a variable species that ranges from Virginia to Panama (DeLaney and Wunderlin 1989). *Crotalaria* is a very large, mostly tropical genus that includes a number of robust annual weeds, all with inflated “rattlebox” seed pods. It has been suggested that this endemic is a relic of the Miocene on the southern Lake Wales Ridge (DeLaney and Wunderlin 1989). (USFWS, 1999)

Historical Range

See Current Range.

Current Range

Avon Park harebells is one of the most narrowly distributed of the Lake Wales Ridge endemics, having only been identified at three sites in Polk and Highlands counties. Its distribution includes the Avon Park Lakes acquisition area and the Saddleblanket Lakes State Preserve in Polk County, and the Carter Creek acquisition area in Highlands County. (USFWS, 1999)

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Insect pollinated

Breeding Season

Adult: Flowering begins in mid-March and continues until June. (USFWS, 1999)

Other Reproductive Information

Adult: Flowering begins in mid-March and continues profusely until June. After flowering, this deciduous plant enters a vegetative phase, forming clusters of stems that give a clumped or rosette appearance. They are then dormant from late fall or early winter until March (DeLaney and Wunderlin 1989). Demographic information on pollinators, seed dispersers, and seed viability is lacking for this species. (USFWS, 1999)

Reproduction Narrative

Adult: Avon Park harebells are pollinated by insects, but visitation rates are very low. The plant is reproductively challenged, with less than 10 percent of flowers producing fruits. Seeds contribute to a persistent seed bank lasting at least three years. Seedlings have moderate survival and commonly begin flowering after 6-8 years (Menges et al. 2016). (USFWS, 2019)

Habitat Type

Adult: Scrub flatwoods rosemary scrub and pine scrub

Habitat Narrative

Adult: This species inhabits scrub communities found on the Lake Wales Ridge where it typically grows in full sun, on bare white sand, or in association with clumps of *Cladonia* lichens. However, it may also occur in the partial shade of other plants (DeLaney and Wunderlin 1989). It may also grow along trails, open edges, or previously disturbed roadbeds. The soils associated with this species have been classified as Archbold and Satellite sands (The Nature Conservancy 1991). Like other small scrub endemics, it appears to depend on bare patches of sand to become established. (USFWS, 1999)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: No information available (USFWS, 1999)

Population Information and Trends**Number of Populations:**

2 (USFWS, 2019)

Population Narrative:

Historically and currently, the species is known from just two populations. One population occurs partially in the unprotected Avon Park Lakes subdivision and continues to decline as vacant lots supporting the plant are developed (Menges et al. 2016). Part of this population is protected at a second site, The Nature Conservancy's Saddle Blanket Scrub Preserve. The second population is at the Florida Fish and Wildlife Conservation Commission's (FWC) Carter Creek unit of the Lake Wales Ridge Wildlife Management Area (LWRWEA). The unprotected Avon Park Lakes site hosts the largest number of plants, likely consisting of thousands. The Saddle Blanket site supported 531 plants in 2006 (Service 2007). The size of the Carter Creek population is unknown, but likely is in the thousands, based on Menges et al. (2016). Avon Park harebells has

been reintroduced at two conservation sites which have to date been successful in establishing plants that have flowered and produced seed. The FNAI 2015 Element Tracking Summary (FNAI 2015) identifies 6 occurrences, 2 of these are protected at Saddle Blanket Preserve, and represent portions of the larger Avon Park Lakes population. Two others are FWC protected areas that represent the Carter Creek population. The final two occurrences represent unprotected portions of the Avon Park Lakes population. (USFWS, 2019)

Threats and Stressors

Stressor: Habitat destruction or modification

Exposure:

Response:

Consequence:

Narrative: This species is restricted to xeric scrub habitats in one or more of the interior Central Florida counties of Polk, Highlands, Hendry, Osceola, and Lake, where habitat destruction from development continues to occur and development pressure remains high. Areal extent of post-Columbian xeric upland habitat loss on the Lake Wales Ridge is estimated to exceed 85 percent (Weekley et al. 2008a). Increasing pressure from population growth is likely to result in further loss of these habitats going forward. Carr and Zwick (2016) analyzed existing land use and landscape patterns to identify areas (including central Florida) most likely for development to accommodate a growing human population. They suggests that Florida's 2070 population will be early 15 million persons greater than in 2010, for an estimated total of 33,721,828. Using these figures, they estimated relative losses to agriculture, open space, and conservation to other land uses. If trends continue, they estimate 34 percent of land will be developed by 2070, up from 19 percent in 2010. At the same time, conservation lands will increase less than 1 percent (from 9,269,000 acres in 2010 to 9,525,000 acres by 2070). Overall, loss of habitat to development, primarily on private lands, will likely continue in Central Florida, eliminating populations and reducing the area of suitable habitat for these species. Therefore, habitat on protected lands are critical for the recovery of this scrub plants. (USFWS, 2019)

Stressor: Lack of adequate fire management

Exposure:

Response:

Consequence:

Narrative: Fire is necessary to maintain the scrub habitats upon which this species depends. Historically, lightning-induced fires were a vital component in maintaining native vegetation within the scrub community. Fire suppression started on a regional scale on the Central Florida ridges about 80 years ago. Due to the extent of residential and agricultural development throughout Central Florida, fire has all but disappeared from the region as a widespread, natural phenomenon. Prescribed fire is a crucial management component for maintenance of all scrub habitats. Because of the difficulties of applying prescribed fire on an ever-increasing urban landscape, imperiled species on unmanaged sites will almost certainly disappear over time (Turner et al. 2006). In managed areas, prescribed fire is essential to manage habitats and restore or maintain suitable conditions for scrub species. (USFWS, 2019)

Stressor: Limited geographic range

Exposure:

Response:

Consequence:

Narrative: This species occurs within a relatively limited geographic range in Central Florida. The limited geographic range in combination with the loss of habitat has resulted in a highly fragmented landscape where the remaining scrub areas and their residing species have become more and more isolated from each other, thereby making resiliency, redundancy, and representation more challenging to achieve. The effects of habitat fragmentation on species richness have been exhaustively studied (MacArthur and Wilson 1967, Diamond 1975, 1978; Simberloff and Abele 1976, 1982; Zimmerman and Bierregaard 1986). For most taxonomic groups, large habitat patches in close proximity to each other provide for the greatest species diversity and minimize extinction probabilities. On the contrary, small patches that are isolated are less likely to preserve species that would otherwise be common in the mosaic of communities that existed before isolation. Since at least the Pleistocene, Florida scrub has been characterized by an insular, discontinuous distribution, but the degree of habitat fragmentation seen today is unprecedented and certainly will contribute to increases in extinction rates among scrub-dependent plants and animals. (USFWS, 2019)

Recovery**Reclassification Criteria:**

Not developed. (USFWS, 1999)

Delisting Criteria:

1. At least 20 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (USFWS, 2019)
2. Populations (as defined in criterion 1) in yellow sand scrub and scrubby flatwoods habitats are distributed across the known range of the species. (USFWS, 2019)
3. Populations are protected and managed via a conservation mechanism to a degree that enough suitable habitat is present for the species to remain viable for the foreseeable future. (USFWS, 2019)

Recovery Actions:

- Determine current distribution of *C. avonensis*. This species' known distribution is isolated to Polk and Highlands counties. Additional surveys of scrub habitat with appropriate soils should be conducted in these two counties. A geographic information systems database should be developed to map existing populations and to assess the species' status and trends over time. The database should contain information on locations, population sizes, and status. This information should also be used for project review and in land acquisition activities. (USFWS, 1999)
- Protect and enhance existing populations. Much of the native xeric uplands on the Lake Wales Ridge and surrounding counties have been converted to agriculture or residential development. The remaining habitat is fragmented into small parcels and in many cases, isolated. (USFWS, 1999)
- Conduct research on life history characteristics. Much of the basic biology and ecology of this species remains poorly understood. To effectively recover this species, more specific biological information is needed. (USFWS, 1999)

- Develop standardized monitoring. Standardized monitoring needs to be developed for this and other listed scrub species to determine the effect of management actions. (USFWS, 1999)
- Provide public information about *C. avonensis*. It is important that governmental agencies, conservation organizations, and private land owners be appropriately informed about this species. (USFWS, 1999)
- Establish reclassification criteria. Once the population is stabilized, research and monitoring results may provide data necessary to develop reclassification criteria. (USFWS, 1999)
- Habitat-Level Recovery Actions: Prevent degradation of existing habitat. Provide public information about scrub and its unique biota. (USFWS, 1999)

SPECIES ACCOUNT: *Cryptantha crassipes* (Terlingua Creek cat's-eye)

Species Taxonomic and Listing Information

Listing Status: Endangered; 09/30/1991; Southwest Region (R2) (USFWS, 2016)

Physical Description

A silvery-gray perennial herb with erect stems, 1.5-2.5 dm tall, growing out of a mound of basal leaves. Flowers (late March-early June) are white with yellow throats (NatureServe, 2015).

Taxonomy

Cryptantha crassipes belongs to the Borage (Boraginaceae) family (USFWS, 1993).

Historical Range

See current range/distribution.

Current Range

Only occurs in in southern Brewster Co., Tex. in gypseous clays (NatureServe, 2015).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual: cross-pollination (USFWS, 1993)

Lifespan

Adult: Unknown; long-lived perennial (USFWS, 1993)

Breeding Season

Adult: March - June (USFWS, 1993)

Key Resources Needed for Breeding

Adult: Insect pollinators, likely bees (USFWS, 1993)

Reproduction Narrative

Adult: This species is long-lived perennial nature with apparently low and/or erratic recruitment. Flowering can begin as early as late March and continue until early June. Recent study by Hughes (1992) has confirmed heterostyly, and he found the two forms in approximately a 1:1 ratio. Such heterostyly suggests that the species is an obligate outcrosser, thus requiring some sort of pollinator. Although the exact identity of the pollinator(s) is not known, preliminary studies indicate that the agents are small bees (Hughes 1992). How long individual plants live is not known (USFWS, 1993).

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Trans-Pecos shrub savannah (USFWS, 1993)

Geographic or Habitat Restraints or Barriers

Adult: 3,150 - 3450 ft. elevation (USFWS, 1993)

Environmental Specificity

Adult: Very narrow (inferred from NatureServe, 2015 and USFWS, 1993)

Habitat Narrative

Adult: Low hills and gentle slopes composed of a platy, yellowish limestone formation with a high level of clay and gypsum. These areas are nearly devoid of vegetation due to the gypsum soils and the very dry nature of the site. (NatureServe, 2015). The Terlingua Creek cat's-eye grows on xeric, barren, gypsiferous, low rounded hills and gentle slopes composed of small platelets of silty limestone in the Trans-Pecos shrub savannah. Site elevations vary from 3,150 to 3,450 feet. Vegetation cover is less than 10% (USFWS, 1993).

Dispersal/Migration**Dispersal**

Adult: Low to moderate (inferred from USFWS, 1993)

Dispersal/Migration Narrative

Adult: Dispersal is probably carried out by water, insects, or small mammals (USFWS, 1993).

Population Information and Trends**Population Trends:**

Not available

Species Trends:

Unknown (USFWS, 1993)

Resiliency:

Very low (inferred from USFWS, 1993)

Redundancy:

Very low (inferred from USFWS, 1993)

Number of Populations:

1 (inferred from USFWS, 1993)

Population Size:

< 5,000 (USFWS, 1993)

Population Narrative:

It is known from 10 sites within a six-mile (10 kilometer) radius in west Texas. Less than 5000 plants are known. It is not known whether populations are stable, increasing, or declining (USFWS, 1993).

Threats and Stressors

Stressor: Habit destruction and modification (USFWS, 1993)

Exposure:

Response:

Consequence:

Narrative: Ranch tracks and numerous subdivision roads have been blazed across the area, probably destroying some plants in their path and fragmenting the habitat and some populations. These routes have also opened the way for modern recreational use (off—road vehicles ((ORVs)), mountain bikes, hiking and horseback riding groups). Although road maintenance is minimal and few tracks have been observed in the habitat, the area lacks any fencing or gates to confine wheeled vehicles. Tracks and roads take scores of years to disappear in this extremely arid environment. A significant portion of the known individual plants are on various 5, 10, and 20 acre (2, 4, and 8 hectare) tracts sold by a local resort developer. The potential for habitat destruction, if owners develop these tracts, is a threat to some plants.

Stressor: Stochastic events (USFWS, 1993)

Exposure:

Response:

Consequence:

Narrative: *Cryptantha crassipes* is particularly vulnerable to impacts and threats because of its narrow habitat specificity, extremely limited distribution, and low numbers of individuals. The species is found only on an uncommon rock formation, which is scattered within the geologic mosaic of the Big Bend region. The small occupied area and low numbers make the species vulnerable to chance extinction events from disease, natural or man-caused catastrophes, genetic drift (loss of genetic variability and thence adaptability), etc. In addition, the habitat is quite arid, which in many growing seasons may limit the species from reaching its full reproductive potential. If numbers fall below critical levels, populations may no longer be able to survive cycles with several seasons that do not allow successful reproduction (USFWS, 1993).

Stressor: Loss of pollinators (USFWS, 1993)

Exposure:

Response:

Consequence:

Narrative: Pollinators are potentially very important. The species is likely an obligate outcrosser reliant on insects that are probably also narrow endemics (known only from a limited geographic area). Conditions or activities that harm these pollinators could secondarily harm *Cryptantha crassipes* (USFWS, 1993).

Recovery

Reclassification Criteria:

Not available

Delisting Criteria:

Develop and implement management plans that insure the long-term protection and stability of a minimum of three population centers. There should be a total of at least 20 viable populations across the three population centers with each population comprised of no fewer than 1000 plants and being capable of long-term, self-perpetuating reproduction (USFWS, 1993).

Recovery Actions:

- Establish protected sites and develop management plans (USFWS, 1993).
- Maintain reserve seed bank/cultivated populations (USFWS, 1993).
- Gather biological information necessary for management decisions (USFWS, 1993).
- Search for new populations (USFWS, 1993).
- Develop plans for augmentation and/or establishment of new populations, if feasible, at suitable sites (USFWS, 1993).

Conservation Measures and Best Management Practices:

- The only conservation measure initiated so far is seed storage collection. The National Seed Storage Lab in Fort Collins, Colorado contains 200 field—collected seeds and the Desert Botanical Garden in Phoenix, Arizona retains 820 field collected seeds (USFWS, 1993).
- Barry Hughes, a graduate student at Sul Ross State University, has begun studies on the reproductive biology of *Cryptantha crassipes*, about which little is known. He has reported germination rates of about 75% and 40—50% in two trials and has developed some simple techniques to increase success in transplanting seedlings (Hughes, pers. comm., 1993) during cultivation studies (USFWS, 1993).
- The Desert Botanical Garden in Phoenix, Arizona, working with the Center for Plant Conservation, has performed two germination experiments to determine the best growing medium for germination and seedling growth (Pritchett-Kozak and Ecker 1992) (USFWS, 1993).

SPECIES ACCOUNT: *Cucurbita okeechobeensis* ssp. *okeechobeensis* (Okeechobee gourd)

Species Taxonomic and Listing Information

Listing Status: Endangered; 8/11/1993; Southeast Region (R4) (USFWS, 2015)

Physical Description

A vigorous annual vine. Stems are nearly smooth. Leaves are alternate and paired, and have with long helical tendrils. The leaf blades have 5-7 shallow lobes. Flowers are cream-colored to nearly white, 6-7 cm long, narrowly bell-shaped. (NatureServe, 2015)

Taxonomy

Small (1922, 1930) originally described the gourds he found in the pond apple forest surrounding Lake Okeechobee as *Pepo okeechobeensis*. Bailey (1930) transferred the Okeechobee gourd to the genus *Cucurbita*, which includes pumpkins and squashes. Bailey (1943) subsequently described two new gourd species, *C. martinezii* and *C. lundelliana*. These two gourds were proven to be closely related to the Okeechobee gourd. Closely related gourds with cream-colored corollas (all others in the genus *Cucurbita* are bright yellow) are found in Florida and in Mexico, near the Gulf Coast. The Florida plants were described as the Okeechobee gourd (Bailey 1930) and the Mexican plants were designated (Bailey 1943) as the Martinez gourd (*C. martinezii*). However, Robinson and Puchalski (1980) showed through isozyme analysis that there was only a single allelic difference between the two varieties. The (ESA) does not allow Federal listing of disjunct populations of widespread plant species. Since the Mexican gourds are moderately abundant, and considering the findings of Robinson, the FWS originally opposed listing of the Okeechobee gourd. A later study by Walters and Decker-Walters (1991), also using isozyme analysis, showed a difference of just one allele. However, they calculated an estimated time since divergence of about 450,000 years between the Martinez and Okeechobee gourds, and concluded that they should be considered distinct at the subspecies level. Walters and Decker-Walters (1993) rearranged the nomenclature, designating the Florida gourds as *Cucurbita okeechobeensis* (Small) Bailey ssp. *okeechobeensis*, and assigning the Mexican gourds to the subspecies *C. okeechobeensis* ssp. *martinezii* (Bailey) Andres and Nabhan ex T. Walters and Decker Walters. The FWS concurred with this finding, and because the ESA allows protection of distinct subspecies, the Okeechobee gourd was subsequently listed as endangered. (USFWS, 1999)

Historical Range

Historically found on the southern shore of Lake Okeechobee, in Palm Beach County, Florida, and formerly in the Everglades area of Florida. (USFWS, 1999)

Current Range

In Florida, on the shore of Lake Okeechobee in Glades and Palm Baech Counties, along the middle St. Johns river in Volusia County. (USFWS, 1999)

Critical Habitat Designated

No;

Life History**Food/Nutrient Resources****Key Resources Needed for Breeding**

Adult: Insect pollinators (EPA, 2016)

Reproduction Narrative

Adult: Pollination occurs via insects (EPA, 2016). Based on closely related gourds, a variety of insects are likely to be available, including bees, flies, and squash beetles. Typically, male flowers greatly outnumber female flowers and where pollinators are rare, decreased fruit set may be observed (M. Minno, Eco Cognizant, Inc., personal communication 1998) (USFWS, 1999).

Habitat Type

Adult: Wetland (EPA, 2016); terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forested wetland, temporary pool, field (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Low water levels (USFWS, 2009)

Habitat Narrative

Adult: Originally found in swampy forests and hammocks on muck soils. Today, this species is restricted to disturbed areas that are not cultivated, such as ditch banks and wet road shoulders. It is sensitive to changes in hydrology and freezing. (NatureServe, 2015). Occurs at Lake Okeechobee and the other along the St. Johns River; limited to areas along the shoreline and a few islands in the lake and along the St. Johns River. Inhabits open organic soils exposed by low water levels (EPA, 2016). The gourd is ephemeral by nature, often only growing when habitat conditions are favorable, and its growth habit of climbing amongst the tree canopy precludes the ability to count individual plants. This subspecies employs a strategy of growing on open organic soils exposed by low water levels with little to no competition, producing numerous seeds with somewhat long viability, and experiencing vegetative decline when competition increases or water levels rise (Moyroud 2009b) (USFWS, 2009). The gourd readily climbs any plant that will provide a trellis; in both Lake Okeechobee and the St. Johns River, the Okeechobee gourd grows on elderberry (*Sambucus canadensis*) and buttonbush (*Cephalanthus occidentalis*). Around Lake Okeechobee, the gourd is frequently associated with alligator nests. These disturbed sites provide areas where competition is reduced and elevated areas that promote the growth of elderberry, button bush, and other erect bushes and shrubs. Around Lake Okeechobee, the gourd relies on pond apple trees to support its vines above rising water levels during the wet season.

Dispersal/Migration**Dispersal**

Adult: Unknown (USFWS, 1999)

Dependency on Other Individuals or Species for Dispersal

Adult: Possibly marsh rabbits (USFWS, 1999)

Dispersal/Migration Narrative

Adult: Seeds are dispersed by birds and mammals (EPA, 2016). High lake levels facilitate dispersal. Although the exact mechanism for seed dispersal of the Okeechobee gourd is unknown, Walters et al. (1992) suggest that Okeechobee gourds disperse by floating in water bodies (in canals and along the shore of islands in Lake Okeechobee); however, no information is available regarding the distances seeds may disperse. Walters et al. (1992) also indicate that marsh rabbits are the main terrestrial disperser of gourd seeds, but others suggest that rabbits are only a predator of these seeds and are unlikely to be significant seed dispersers (M. Minno, Eco-Cognizant, Inc., personal communication 1998) (USFWS, 1999).

Population Information and Trends**Population Trends:**

> 95% decline (NatureServe, 2015)

Species Trends:

Declining (USFWS, 2009)

Number of Populations:

2 (USFWS, 2009)

Population Size:

1 - 1000 individuals (NatureServe, 2015)

Population Narrative:

At least 50 gourds were found at one site by Walters and Decker-Walters in 1990-1991. In winter and early spring of 1990-1991 Walters and Decker-Walters found the Okeechobee gourd at 11 sites along the lake shores (Martin, 1992). The estimated population size is up to 1,000 individuals. The species has already lost 95% of its former range (J.K. Small, 1930) (NatureServe, 2015). The species status is declining; fires destroyed no plants were found on the spoil islands that once supported substantial populations. The Okeechobee gourd is only found in Florida in two natural populations, one on Lake Okeechobee and the other along the St. Johns River. Very little genetic variation was observed within any of the three populations evaluated, and differences between populations were minor with nothing to differentiate between the Lake Okeechobee and St. Johns River populations of the Okeechobee gourd (Decker-Walters 2002c) (USFWS, 2009).

Threats and Stressors

Stressor: Habitat destruction and modification (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Continued habitat degradation and loss threaten the existence of Okeechobee gourd. Decker-Walters (2002c) stated that factors that reduce the availability of habitat (e.g., lack of fluctuation in water levels and aggressive weeds) pose a large threat to the subspecies. In

addition, several factors related to human values (e.g., water storage, flood control, navigation) and ecological values (e.g., waterfowl, fisheries, littoral zone vegetation, water quality, snail kite recovery, and others) that affect management decisions can potentially conflict (Service 1999). At this time, the habitat seems stable along the St. Johns River; however, proposed water withdrawals for alternative public water supplies may affect suitability for the Okeechobee gourd (Minno 2009). Permanent inundation of suitable soils prevents germination of gourd seeds, and changes in water level management that would reduce the likelihood of low water can threaten the subspecies. Within the range of Okeechobee gourd in the Lake Okeechobee region, the human population is predicted to grow from nearly 11,000 to over 17,000 in Glades County between 2005 and 2060 and from approximately 1,270,000 to over 2,700,000 in Palm Beach County (Zwick and Carr 2006). Population growth is expected to increase water demands and recreational pressure on the lake. Within the range of the St. Johns River gourd population, the number of residents in Volusia County is projected to increase over the same time period from nearly 500,000 to over 940,000 and nearly triple in Lake County from just over 260,000 to more than 700,000 (Zwick and Carr 2006) (USFWS, 2009).

Stressor: Competition (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Okeechobee gourd plants are not strong competitors and are often outcompeted by more aggressive plant species (Decker-Walters 2002c). Weed competitors include moonflower, common reed (*Phragmites australis*), Virginia saltmarsh mallow (*Kosteletzkya virginica*), camphorweed (*Pluchea* sp.), melaleuca (*Melaleuca quinquenervia*), *Sesbania* sp., and *Polygonum* spp. (Decker-Walters 2002a; 2002c) (USFWS, 2009).

Stressor: Herbicide usage (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Although necessary for control of exotic plants, herbicide use also poses a threat to the Okeechobee gourd. The occurrences at one of the sites along the St. Johns River were destroyed in 2005 where herbicide was sprayed, and the site is no longer suitable (Minno and Minno 2005). Herbicides are routinely sprayed around Lake Okeechobee to keep waterways free of aquatic vegetation (USFWS, 2009).

Stressor: Disease (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Minno and Minno (1998) reported finding powdery mildew fungus (*Sphaerotheca fuliginea*), a hyperparasitic fungus (*Ampelomyces quisqualis*), mites (e.g., *Bevipalpus* sp., *Propioseius meridionalis*, and *Galendromus mcgregori*), melonworm (*Diaphania hyalinata*), pickleworm (*Diaphania nitidalis*), sowbugs, grasshoppers, leaf-footed bugs, and scales (*Saissetia neglecta*) on leaves of the Okeechobee gourd along the St. Johns River. Little damage to the plants was observed except as a result of the powdery mildew fungus, melonworm, and pickleworm in which older leaves were killed and infected fruit was aborted (Minno and Minno 1998). During the 2002 survey on Lake Okeechobee's Torrey Island, Okeechobee gourd plants

appeared productive but unhealthy, and plants tested positive for several viruses, including cucumber mosaic virus, squash mosaic virus, and watermelon mosaic virus (Decker-Walters 2002a). Signs of viral infection (leaf puckering) were also seen on one of the FWC spoil islands, but few vines from the St. Johns River population exhibited signs of viral infection (Decker-Walters 2002a). The author believed that the Lake Okeechobee population may be affected by more diseases and insects as a result of local agricultural activities in the area, such as the production of squash, but suggested that reproduction may not be substantially affected (Decker-Walters 2002a) (USFWS, 2009).

Stressor: Predation (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Insect predation was observed on Okeechobee gourd plants on one of the FWC spoil islands on Lake Okeechobee in 2002 (e.g., striped cucumber beetle [*Acalymma vittatum*], pickleworm, and melonworm) (Decker-Walters 2002a). Extensive herbivory by marsh rabbits (*Sylvilagus palustris*) was observed on one of the FWC spoil islands on Lake Okeechobee and appeared to have devastated the plants on this island; the other spoil island seemed to be unaffected by herbivory (Decker-Walters 2002c). Decker-Walters (2002c) suggested that rabbits, as well as wild pigs (*Sus scrofa*), present a threat to the subspecies through predation of seeds. Plants in the St. Johns River population were healthier in 2002 and exhibited no signs of insect damage (Decker-Walters 2002a) (USFWS, 2009).

Stressor: Small population size (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Small populations are susceptible to inbreeding depression, which compounds the effects of other threats, such as reduced resistance to herbivore damage and viral infections (Stephenson et al. 2004). Because Okeechobee gourds are ephemeral in nature, they tend to appear and disappear from sites, depending upon growing conditions (Service 1999). No stable core population remains south of the lake to ensure survival as a result of poor growing conditions (e.g., the permanent inundation of suitable soils as a result of water-level regulation) (Service 1999). Even during natural environmental fluctuations, the subspecies may be more vulnerable to localized extinction because of small population sizes (Nee 2009). The presence of the large core population in the pond-apple forest around the lake in the past may have maintained viability of the ephemeral populations on the islands by providing a source for seeds (Nee 2009). Fewer individuals occur along the St. Johns River, making this small population more susceptible to catastrophic events than the lake population (Decker-Walters 2002a). Growing near water and in swamps helps to buffer plants from winter freezes which can kill exposed stems and leaves (Minno 2009). Because plants of the St. Johns River population survive mostly from stems growing along the ground or through dense vegetation, they may be more susceptible to the effects of freezes (Minno 2009) (USFWS, 2009).

Recovery

Reclassification Criteria:

1. The Okeechobee gourd is protected at all known sites within Lake Okeechobee (USFWS, 1999).
2. Plants on Kreamer, Torry and Ritta Islands and the southern Rim Canal of Lake Okeechobee produce fruit at each of these locations at least every other year (their [i.e., fruit] absence for a period of two or more consecutive years will violate this requirement) (USFWS, 1999).
3. The distribution of fruiting plants is expanded within Lake Okeechobee either by the discovery of additional sites or by translocation (USFWS, 1999).
4. One or two sites are established outside of the southeastern quadrant of Lake Okeechobee (outside of Palm Beach County) (USFWS, 1999).
5. A stable, self-sustaining population of the Okeechobee gourd is established within the South Florida Ecosystem outside of Lake Okeechobee (USFWS, 1999).
6. Measures of vitality are developed and monitored at each of the sites described above (USFWS, 1999).
7. Based on the results of research on the viability of seeds following prolonged submergence and the survival of plants under rising water stages, the water regulation schedule for Lake Okeechobee is found not to jeopardize the continued existence of the Okeechobee gourd (USFWS, 1999).

Delisting Criteria:

1. At least 20 populations exhibit a stable or increasing trend, evidenced by natural recruitment and multiple age classes. (addresses Factor A) (USFWS, 2019)
2. Populations (as defined in criterion 1) occur in marsh and swamp habitats and are distributed across the historical range of the species. (addresses Factors A and E) (USFWS, 2019)
3. Populations (as defined in criterion 1) must be protected via a conservation mechanism or managed such that enough suitable habitat is present for the species to remain viable for the foreseeable future. (addresses Factors A and E) (USFWS, 2019)

Recovery Actions:

- Maintain information on the distribution and status of the Okeechobee gourd. Conduct regularly scheduled surveys. Individuals should be encouraged to provide information on sightings of the Okeechobee gourd. (USFWS, 1999).
- Protect and enhance existing populations. Ensure that spraying for control of aquatic vegetation does not harm or kill Okeechobee gourd plants. Assess the effect of Melaleuca and Brazilian pepper control efforts (both cut-and-squirt and aerial spraying methods); use techniques to avoid direct impact on Okeechobee gourd plants. Use provisions of section 7 of the ESA to protect the Okeechobee gourd. Augment natural populations of the Okeechobee gourd. (USFWS, 1999).
- Initiate research on the life history and genetics of the Okeechobee gourd. Test experimentally the viability of Okeechobee gourd seeds kept submerged for long periods (1 to 3 years). Characterize the range of soil conditions where the Okeechobee gourd

currently grows and provide detailed mapping of soil types in southeastern Lake Okeechobee. Through field surveys, determine dates of germination under natural conditions. Test experimentally the effect of seasonally rising water level on the survival of young plants. After information is available from the research studies described above and the annual field surveys, conduct population viability and risk assessment studies particularly with respect to water regulation schedule alternatives for Lake Okeechobee. Investigate the role of animals in dispersing seeds of the Okeechobee gourd. Document the potential ecological relationship between the American alligator and the Okeechobee gourd. Investigate the genetic distance between the two known populations of the Okeechobee gourd. (USFWS, 1999)

- Monitor existing populations of the Okeechobee gourd. Determine the most effective approach to monitor the condition of the Okeechobee gourd. After determining the most effective methods and indices, conduct monitoring on an annual basis. (USFWS, 1999)
- Increase public awareness about the Okeechobee gourd. Public awareness can be addressed through a variety of strategies, including, but not limited to, classroom programs, newspaper and magazine articles, public information displays at boat ramps in Lake Okeechobee, and outreach to fishing and airboating clubs. (USFWS, 1999)
- Habitat-level Recovery Actions: Prevent degradation of existing Okeechobee gourd habitat. Restore areas to suitable habitat. Research the acute and long-term tolerance of the Okeechobee gourd and other wetland plants to herbicides commonly used to control nuisance species of aquatic vegetation. Monitor habitat/ecological processes. Increase public awareness of ecological relationships, environmental stressors, and restoration activities in the South Florida Ecosystem. (USFWS, 1999)

Conservation Measures and Best Management Practices:

- Conduct regular surveys to monitor growth and reproduction, especially from late November through mid-February when many trees are leafless and fruit are easy to see (USFWS, 2009).
- Monitor the spoil islands of Lake Okeechobee to evaluate how the plants respond in a restricted environment with other competitive colonizers and observe the establishment of the seed bank (USFWS, 2009).
- Monitor future translocation sites (USFWS, 2009).
- Continue research to evaluate temporal changes in the prevalence of the three viruses found and to determine the extent to which the fitness of Okeechobee gourd populations is being negatively impacted (USFWS, 2009).
- Conduct experiments on dry fruits from plants grown under controlled conditions (e.g., in the greenhouse) to explore the buoyancy of dried-fruit seeds in greater detail (USFWS, 2009).
- Continue to assess dormancy mechanisms and test viability limits through longer immersion periods of seeds (USFWS, 2009).
- Conduct buried seed experiments in Lake Okeechobee or St. Johns River soils (USFWS, 2009).
- Directly evaluate each gourd population for viral loads, determine the percentage of progeny that may carry the squash mosaic virus, and conduct off-site viral-inoculation experiments of progeny to evaluate degree of tolerance and reproductive impacts (USFWS, 2009).
- Re-evaluate the relationships amongst subspecies of *Cucurbita okeechobeensis* using modern molecular techniques and new morphological characteristics (USFWS, 2009).
- Continue research on fluctuations in abundance of the gourd in response to water conditions, particularly extended periods of high water, to determine the level of risk to the long-term survival of the subspecies (USFWS, 2009).

- Research the acute and long-term tolerance of the Okeechobee gourd and other wetland plants to herbicides commonly used to control nuisance species of aquatic vegetation (USFWS, 2009).
- Conduct population viability and risk assessment studies, particularly with respect to water regulation schedule alternatives for Lake Okeechobee (USFWS, 2009).
- Eradicate exotic weeds (e.g., *Ipomoea alba*) in locations that support gourds and take care when planting native trees to prevent introduction of these weeds (USFWS, 2009).
- Use controlled burns to open up areas of overly dense herbaceous and/or shrubby vegetation in lake littoral zones and marshes (USFWS, 2009).
- Prevent cultural (i.e., human caused) eutrophication of lakes and marshes (USFWS, 2009).
- Avoid disruptive changes to the riparian habitat along the St. Johns River where the population occurs (USFWS, 2009).
- Ensure that water-level regulation is compatible with management needs of the Okeechobee gourd (USFWS, 2009).
- Ensure aquatic vegetation management practices are compatible with recovery of the subspecies (USFWS, 2009).
- Consider Okeechobee gourd and the creation of habitat in planning phases of Everglades restoration (USFWS, 2009).
- Restore habitat by planting pond apple and cypress where appropriate (USFWS, 2009).
- Establish a translocation protocol, locate potential sites, and translocate plants to identified sites (USFWS, 2009).
- Ensure that the St. Johns River and Lake Okeechobee populations are not grown together in collections to avoid hybridization. If hybridization is suspected, hybrid material should not be used for reintroduction (USFWS, 2009).
- Develop recovery criteria for the Okeechobee gourd population along the St. Johns River (USFWS, 2009).

SPECIES ACCOUNT: *Cyanea (=Delissea) rivularis* (Haha, Oha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/10/1996; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Delissea rivularis, a member of the bellflower family, is a shrub, unbranched or branched near the base, with hairy stems 4 to 5 m (13 to 16 ft) long. The leaves are arranged in a rosette at the tips of the stems. The elliptic to lance-shaped leaves are 20 to 30 cm (8 to 12 in) long and 3 to 8 cm (1.2 to 3.2 in) wide, with minutely toothed margins. Both leaf surfaces are covered with hairs. Six to 12 flowers are arranged on an inflorescence stalk 4 to 8 cm (1.6 to 3.2 in) long, each having an individual stalk 10 to 15 mm (0.4 to 0.6 in) in length. The curved, hairy flowers are white with blue longitudinal stripes, 30 to 40 mm (1.2 to 1.6 in) long, with one dorsal knob. The fruit is a spherical, dark purple berry 10 to 15 mm (0.4 to 0.6 in) in diameter. (USFWS, 1998)

Taxonomy

In his 2005 treatment of the genus *Delissea*, Thomas Lammers reclassified this species as *Cyanea rivularis*, with no change in the range or distribution of the species (Lammers 2005). The species will be referred to as *Cyanea rivularis* in the remainder of this review. (USFWS, 2010)

Historical Range

Historically, *Delissea rivularis* was found at Waiakealoha waterfall (location unknown), Waialae Valley, Hanakoa Valley, and Kaholuamano on the island of Kauai. (USFWS, 1998)

Current Range

Known in Kauai. (NatureServe, 2015)

Critical Habitat Designated

Yes; 2/27/2003.

Legal Description

On February 27, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Cyanea (=Delissea) rivularis* on the island of Kauai, Hawaii (68 FR 9116 - 9479).

Critical Habitat Designation

The critical habitat designation for *Cyanea (=Delissea) rivularis* includes one unit totaling 2,100 acres in Kauai County, Hawaii. The unit is Kauai 11—*Delissea rivularis*—a.

Kauai 11—*Delissea rivularis*—a: This unit is critical habitat for *Delissea rivularis* and is 851 ha (2,102 ac) on State land (Alakai Wilderness Preserve, Halelea Forest Reserve, Hono o Na Pali NAR, and Na Pali Coast State Park). This unit contains Keanapuka, Moaalele, Pihea, and Waiahuakua Summits. This unit provides habitat for three populations of 300 mature, reproducing individuals of the shortlived perennial *Delissea rivularis* and is currently occupied with 40 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable. The habitat features contained in this unit that are essential for

this species include, but are not limited to, steep slopes near streams in *Metrosideros polymorpha* *Cheirodendron trigynum* montane wet or mesic forest. Although we do not feel that there is enough habitat that currently exists to reach the recovery goal of 8 to 10 populations for this species, this unit is of an appropriate size so that each potential recovery population on Kauai within the unit is geographically separated enough to avoid destruction by one naturally occurring catastrophic event.

Primary Constituent Elements/Physical or Biological Features

Within this unit, the currently known primary constituent elements of critical habitat include, but are not limited to, the habitat components provided by:

(i) Steep slopes near streams in *Metrosideros polymorpha* *Cheirodendron trigynum* montane wet or mesic forest and containing one or more of the following native plant species: *Boehmeria grandis*, *Broussaisia arguta*, *Carex* spp., *Coprosma* spp., *Diplazium sandwichianum*, *Dubautia knudsenii*, *Hedyotis foggiana*, *Ilex anomala*, *Machaerina angustifolia*, *Melicope anisata*, *Melicope clusiifolia*, *Pipturus* spp., *Psychotria hexandra*, or *Sadleria* spp.; and

(ii) Elevations between 823 and 1,307 m (2,701 and 4,286 ft).

Special Management Considerations or Protections

The following management actions are important: Feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas deemed essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas deemed essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Not available.

Habitat Type

Adult: Terrestrial and palustrine (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Riparian, forest- hardwood, forest/woodland (NatureServe, 2015)

Environmental Specificity

Adult: Medium, with some key requirements (USFWS, 1998)

Habitat Narrative

Adult: *Delissea rivularis* is found on steep slopes in ohia-olapa montane wet or mesic forest, near streams. Associated native species include kanawao, *Athyrium* sp., *Carex* sp., *Coprosma* sp. (pilo), and *Sadleria* sp. (amau) (USFWS 1996). (USFWS, 1998)

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Not available.

Population Information and Trends

Population Trends:

Not available.

Resiliency:

Very low (inferred from USFWS, 2010)

Redundancy:

Very low (inferred from USFWS, 2010)

Number of Populations:

3 (USFWS, 2010; USFWS, 2017))

Population Size:

9 wild individuals and 60 outplanted individuals (USFWS, 2017)

Population Narrative:

Known populations continue to decline. In 1994, there were 20 individuals at Hanakoa, currently there are fewer than 10 (HMBP 2010; Tangalin 2008; PEPP 2016). In 1998, there were 30 individuals at upper Hanakapiai, but by 2013, fewer than 10 remained (HBMP 2010; PEPP 2012, 2013, NTBG 2016a-c). In 2000, there was one individual at Kawaikoi; however, this individual could not be relocated in 2013 (PEPP 2013). An individual observed at Blue Hole has not been seen since 1988. The 2016 IUCN review estimates three “subpopulations” (considered by USFWS as populations) totaling nine individuals. With continued decline, the wild individuals could soon be extirpated, as indicated by the Plant Extinction Prevention Program (PEPP) reports (PEPP 2011, 2012, 2013, 2014, 2015, 2016). (USFWS, 2017)

Threats and Stressors

Stressor: Invasive plants (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Invasive introduced plant species compete with and crowd out *Cyanea rivularis*. These include *Clidemia hirta* (Koster’s curse), *Hedychium gardnerianum* (Kahili ginger), *Erigeron karvinskianus* (daisy fleabane), *Kalanchoe pinnata* (airplant), *Cyperus meyenianus* (NCN), *Paspalum urvillei* (vasey grass), *Rubus argutus* (prickly Florida blackberry), *R. rosifolius*

(thimbleberry), and *Juncus planifolius* (bog rush) (Perlman 2008; Tangalin 2008; Wood 2008). (USFWS, 2010)

Stressor: Feral ungulates (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Other threats are from feral ungulates (pigs) that modify the landscape and increase soil erosion (Perlman 2008). (USFWS, 2010)

Stressor: Landslide (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: In Hanakoa, a collapsed ledge killed a couple of individuals and other individuals were damaged by a small landslide (Tangalin 2008). (USFWS, 2010)

Stressor: Herbivory by rats and slugs (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: The bark of *Cyanea rivularis* individuals in Hanakoa was scarred from chewing by rats or slugs (Tangalin 2008). (USFWS, 2010)

Stressor: Climate change (USFWS, 2010; USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Climate change may also pose a threat to *Cyanea rivularis*. However, current climate change models do not allow us to predict specifically what those effects, and their extent, would be for this species. (USFWS, 2010); Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. This assessment identified how vulnerable 63 species of *Cyanea* are to climate change, but did not specifically assess *Cyanea rivularis* due to lack of data due to rarity. As the average vulnerability score for the 63 assessed species of *Cyanea* is 0.627 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change), it is likely that *Cyanea rivularis* has similar vulnerability to climate change. Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2017)

Stressor: Small population size (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: *Cyanea rivularis* that are endemic to small portions of a single island are inherently more vulnerable to extinction than widespread species because of the higher risks posed to a few

populations and individuals by random demographic fluctuations and localized catastrophes such as hurricanes, landslides, flooding and disease outbreaks. (USFWS, 2010)

Stressor: Hurricanes (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Hurricanes were accidentally not highlighted in the last five year review. In November 1982, Hurricane Iwa struck the Hawaiian Islands, with wind gusts exceeding 100 miles per hour (mph) (161 kilometers per hour (kph)), causing extensive damage, especially on the islands of Niihau, Kauai, and Oahu (Businger 1998). In September 1992, Hurricane Iniki, a category 4 hurricane with maximum sustained wind speeds recorded at 140 mph (225 kph), passed directly over the island of Kauai. Many forest trees were destroyed (Perlman 1992), which opened the canopy and facilitated the invasion of nonnative plants (Kitayama and Mueller-Dombois 1995). A destructive hurricane holds the potential of driving a localized endemic species to extinction in a single event, and 70 percent of all listed plant species on Kauai are only found on Kauai. Hurricanes pose an ongoing and ever-present threat because they can happen at any time, although their occurrence is not predictable. Tropical cyclone frequency and intensity are projected to change as a result of climate change over the next 100 to 200 years (Vecchi and Soden 2007; Emanuel et al. 2008; Yu et al. 2010). In the central Pacific, modeling projects an increase of up to two additional tropical cyclones per year in the main Hawaiian Islands by 2100 (Murakami et al. 2013). (USFWS, 2017)

Recovery

Reclassification Criteria:

1. A total of five to seven populations of each taxon should be documented on Kauai where they now occur or occurred historically. (USFWS, 1998)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1998)
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered. (USFWS, 1998)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Kauai where they now occur or occurred historically. (USFWS, 1998)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1998)
3. Each population should persist at this level for a minimum of 5 consecutive years. (USFWS, 1998)

Recovery Actions:

- In order to prevent this taxon from going extinct, propagation efforts and the maintenance of adequate genetic stock ex situ should be continued. Additional wild seeds should be collected periodically until the cryopreservation method of long-term storage is perfected. This will insure that viable seed stock is available for outplanting. (USFWS, 1998)
- A long-range management plan to control alien plant species in the upper Hanakoa Valley, upper Hanakapiai drainage and on State land within the Hono O Na Pali Natural Area Reserve needs to be developed. Once an active management plan for control of alien plants in these areas is in place, site selection and outplanting should occur to prevent wild stocks from declining further. (USFWS, 1998)
- A management plan to control rats should be developed. This should include the use of the currently approved Diphacinone bait blocks and ultimately a more broad-scale method such as aerial dispersal of rodenticide. (USFWS, 1998)
- Surveys and inventories—Continue to survey for populations of *Cyanea rivularis* in areas of potentially suitable habitat. Identify protected sites for reintroduction and augmentation. (USFWS, 2017)
- Predator and herbivore monitoring and control—Determine and implement effective control methods for slugs. Implement effective control methods for rodents. (USFWS, 2017)
- Ungulate monitoring and control—Protect all occurrences against browsing and disturbances from feral ungulates. Construct and maintain fenced exclosures around all populations. Placement of small-scale fencing around the few remaining wild individuals is critical to prevent extinction. (USFWS, 2017)
- Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations. Control invasive nonnative plant species around all populations that compete with the species. (USFWS, 2017)
- Captive propagation genetic storage and reintroduction—Continue to collect material for storage and propagation for reintroduction from wild plants without representation. Maintain viable ex situ collections. (USFWS, 2017)
- Reintroduction and translocation—Continue to reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. Work with Hawaii DOFAW to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species. (USFWS, 2017)
- Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from landslides. Create erosion protection to prevent landslides at known populations, if possible. (USFWS, 2017)

Conservation Measures and Best Management Practices:

- Conduct rat and slug control around known plants. (USFWS, 2010)
- Fence areas where this species grows to protect against ungulate damage. (USFWS, 2010)
- Create erosion protection to prevent landslides, if possible. (USFWS, 2010)
- Collect material for genetic storage and propagation for reintroduction. (USFWS, 2010)
- Identify protected sites for reintroduction and augmentation. (USFWS, 2010)
- Work with Hawaii Division of Forestry and Wildlife to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species. (USFWS, 2010)
- Update the listed entity on 50 CFR 17 to match the currently recognized taxonomy. (USFWS, 2010)

SPECIES ACCOUNT: *Cyanea (=Rollandia) crispa* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 03/28/1994; Pacific Region (R1) (USFWS, 2016)

Physical Description

Cyanea crispa is a short-lived perennial in the Campanulaceae (bellflower family). It is an unbranched shrub with leaves that are 30.0 to 75.0 cm (12 to 30 in) long and 9.0 to 16.0 cm (3.5 to 6.5 in) wide, which are clustered at the ends of succulent stems that are 0.3 to 1.3 m (1.0 to 4.3 ft) long. The flowers are 4.0 to 6.0 cm (1.6 to 2.4 in) long with a magenta color and dark longitudinal stripes. The globe-shaped berries are about 1.0 cm (2.54 in) long. *C. crispa* is distinguished from other species in this endemic Hawaiian genus by its leaf shape, distinct calyx lobes, length of the flowers, and stalks of flower clusters (Wagner et al.1999).

Taxonomy

Cyanea crispa is a short-lived perennial in the Campanulaceae (bellflower family). It is an unbranched shrub with leaves that are 30.0 to 75.0 cm (12 to 30 in) long and 9.0 to 16.0 cm (3.5 to 6.5 in) wide, which are clustered at the ends of succulent stems that are 0.3 to 1.3 m (1.0 to 4.3 ft) long. The flowers are 4.0 to 6.0 cm (1.6 to 2.4 in) long with a magenta color and dark longitudinal stripes. The globe-shaped berries are about 1.0 cm (2.54 in) long. *C. crispa* is distinguished from other species in this endemic Hawaiian genus by its leaf shape, distinct calyx lobes, length of the flowers, and stalks of flower clusters (Wagner et al.1999).

Historical Range

Historically, *Cyanea crispa* was known from scattered locations throughout the upper elevations of the Koolau Mountains of Oahu from Kaipapau Valley to Waialae Iki Ridge.

Current Range

This species is now known from 11 occurrences with a total of 65 individuals at Aihualama (1 individual), Kaipapau (3), Kapakahi (1), Kawaipapa (1), Maakua (2), Makua (10), Maunawili (1), Pia (20), Pukele (6), upper Kawaiiki (5), and Wailupe (15) (HINHP Database 2001). The known occurrences of *C. crispa* are in decline, and those that remain occur in small clusters that are widely dispersed (Service 1998a).

Critical Habitat Designated

Yes; 9/18/2012.

Legal Description

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea (=Rollandia) crispa* (Haha) under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Cyanea (=Rollandia) crispa* (77 FR 57648-57862). The critical habitat designation includes 19 critical habitat units, which encompass approximately 31,995 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Cyanea (=Rollandia) crispa* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs

necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Cyanea* (=Rollandia) *crispa* includes 19 critical habitat units, covering three ecosystem types, which encompass approximately 31,995 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Mesic—Units 4, 5, 6, 7; Oahu—Lowland Wet—Units 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16; Oahu—Wet Cliff—Units 6, 7, 8.

Oahu—Lowland Mesic—Unit 4 [20 ac (8 ha)]. This area consists of 20 ac (8 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, between the Waipilopilo and Hanaimoa gulches, on State-owned land within the Hauula Forest Reserve. Oahu—Lowland Mesic—Unit 5 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, in Maakua Gulch and ridge; is State-owned; and within the Hauula FR. Oahu—Lowland Mesic—Unit 6 [247 ac (100 ha)]. This area consists of 12 ac (5 ha) State land and 235 ac (95 ha) of privately owned land in the lowland mesic ecosystem on the windward side of the Koolau Mountains, inland of Kaaawa Point, and is partially within Ahupuaa O Kahana State Park. Oahu—Lowland Mesic—Unit 7 [1,669 ac (676 ha)]. This area consists of 681 ac (276 ha) of State land, 129 ac (52 ha) of City and County of Honolulu land, and 852 ac (345 ha) of privately-owned land in the lowland mesic ecosystem on the leeward side of the Koolau Mountains, on Waialae Nui ridge.

Oahu—Lowland Wet—Unit 6 [790 ac (320 ha)]. This area consists of 790 ac (320 ha) of privately owned land in the lowland wet ecosystem, in privately owned land on the windward side of the Koolau Mountains, and includes Kahawainui, Ihiihi, Wailele, and Koloa gulches. Oahu—Lowland Wet—Unit 7 [1,787 ac (723 ha)]. This area consists of 1,499 ac (606 ha) of State land and 288 ac (117 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, within the Kaipapau and Hauula Forest Reserves and Sacred Falls State Park, from Puukainapuaa to Kaluanui (Sacred Falls). Oahu—Lowland Wet—Unit 8 [3,041 ac (1,231 ha)]. This area consists of 1,386 ac (561 ha) of State land and 1,655 ac (670 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, partially within the Ahupuaa O Kahana State Park, including Waihoi Springs, and Punaluu, Kahana, Waikane, Waikeekee, and Uwao streams. Oahu—Lowland Wet—Unit 9 [15,728 ac (6,365 ha)]. This area consists of 3,827 ac (1,545 ha) of State land, 147 ac (60 ha) of City and County of Honolulu land, 4,509 ac (1,825 ha) of Federal land (U.S. Fish and Wildlife Service), and 7,245 ac (2,932 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, partially within the Ewa FR Waimano Section and the Oahu Forest National Wildlife Refuge. This area extends along the Koolau summit from Waipio to Manaiki Stream. Oahu—Lowland Wet—Unit 10 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) of privately-owned land in the lowland wet ecosystem in private land on the windward side of the Koolau Mountains, along Kaalaea Stream. Oahu—Lowland Wet—Unit 11 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) in the lowland wet ecosystem, owned by the City and County of Honolulu on the windward side of the Koolau Mountains, along Waihee Stream. Oahu—Lowland Wet—Unit 12 [53 ac (21 ha)]. This area consists of 28 ac (11 ha) of City and County of Honolulu land and 26 ac (10 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, along Kahaluu Stream and tributary. Oahu—Lowland Wet—Unit 13 [75 ac (30 ha)]. This area consists of 74 ac (30 ha) of City and County of Honolulu land and 1 ac

(0.5 ha) of State land in the lowland wet ecosystem on the windward side of the Koolau Mountains, along Heeia Stream and tributaries. Oahu—Lowland Wet— Unit 14 [478 ac (193 ha)]. This area consists of 274 ac (111 ha) of State land, 195 ac (79 ha) of City and County of Honolulu land, and 9 ac (4 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, extending from the Wilson Tunnel area southeast to Moole Stream. Oahu— Lowland Wet—Unit 15 [407 ac (165 ha)]. This area consists of 407 ac (165 ha) in the lowland wet ecosystem in State of Hawaii Department of Land and Natural Resources Land Division land on the windward side of the Koolau Mountains in Maunawili Valley, including Omao and Maunawili streams and Kapakahi and Pikoakea Springs. Oahu—Lowland Wet—Unit 16 [2,507 ac (1,014 ha)]. This area consists of 1,533 ac (621 ha) of State land, 365 ac (148 ha) of City and County of Honolulu land, and 608 (246 ha) of privately owned land in the lowland wet ecosystem in on the leeward side of the Koolau Mountains, partly within the Honolulu Watershed Forest Reserve, extending from the eastern side of Nuuanu Valley southeast along the Koolau summit to Kulepeamo Ridge.

Oahu—Wet Cliff—Unit 6 [151 ac (61 ha)]. This area consists of 151 ac (61 ha) in the wet cliff ecosystem on State land on the windward side of the Koolau Mountains in Kaipapau Gulch, entirely within the Kaipapau Forest Reserve. Oahu—Wet Cliff—Unit 7 [144 ac (58 ha)]. This area consists of 144 ac (58 ha) in the wet cliff ecosystem in State land on the windward side of the Koolau Mountains in Hauula Gulch, entirely within the Hauula Forest Reserve. Oahu—Wet Cliff—Unit 8 [4,649 ac (1,881 ha)]. This area consists of 1,479 ac (598 ha) of State land, 1,281 ac (519 ha) of City and County of Honolulu land, 5 ac (2 ha) of Federal land, and 1,884 ac (762 ha) of privately owned land, in the wet cliff ecosystem along the summit of the Koolau Mountains, overlapping portions of Sacred Falls State Park, the Waiahole FR (Waiahole and Iolekaa sections), the Kaneohe and Honolulu Watershed FRs, and the Nuana Pali State Wayside.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea* (=Rollandia) *crispa* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Cyanea* (=Rollandia) *crispa* occurs within the Lowland mesic, Lowland wet and Wet cliff ecosystems in the Koolau Mountain caldera complex:

Oahu—Lowland Mesic—Units 4, 5, 6, 7. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. (E) Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. (E) Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Oahu—Lowland Wet—Units 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16. (A) Elevation: <3,000 ft (<1,000 m). (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. (D) Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. (E) Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. (E) Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Oahu—Wet Cliff—Units 6, 7, 8. (A) Elevation: unrestricted. (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: >65 degree slope, shallow soils, weathered lava. (D) Canopy: None. (E)

Subcanopy: Broussaisia, Cheirodendron, Leptecophylla, Metrosideros. (E) Understory: Bryophytes, Ferns, Coprosma, Dubautia, Kadua, Peperomia.

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Cyanea (=Rollandia) crispa* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: *C. crispa* was observed flower in April and fruiting in June and September. Little else is known about its flowering cycle, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors (Service 1998a; 59 FR 14482).

Habitat Type

Adult: Wet forest

Habitat Narrative

Adult: – *Cyanea crispa* is found in a variety of habitats ranging from steep slopes in open mesic forests to gentle slopes or moist gullies in closed wet forests and along stream banks at elevations between 56 and 959 m (184 and 3,146 ft). Associated native plant species include *Antidesma platyphylla*, *Boehmeria grandis*, *Broussaisia argutus*, *Christella cyatheoides*, *Cibotium chamissoi*, *Cyrtandra* spp., *Diospyros* sp., *Dubautia* sp., *Metrosideros polymorpha*, *Perrottetia sandwicensis*, *Pipturus albidus*, *Pisonia umbellifera*, *Psychotria* sp., or *Touchardia latifolia* (HINHP Database 2001; Service 1998a).

Dispersal/Migration

Population Information and Trends

Threats and Stressors

Stressor:

Exposure:

Response:

Consequence:

Narrative: The major threats to *Cyanea crispa* are habitat alteration and predation by feral pigs; competition with non-native plant species; predation by rats; and extinction due to naturally occurring stochastic events and/or reduced reproductive vigor, both resulting from the small number of remaining individuals, their limited gene pool, and their restricted distribution. The

non-native plant species *Arthrostemma ciliatum*, *Clidemia hirta*, *Psidium cattleianum*, *Psidium guajava*, *Pterolepis glomerata*, *Rubus rosifolius*, *Schinus terebinthifolius*, *Setaria palmifolia*, and *Zingiber zerumbet* threaten *C. crispa* by altering its habitat and competing with it for nutrients, light, and space. The types of stochastic events most likely to affect *C. crispa* are landslides, hurricanes, or flooding (Service 1998a; 59 FR 14482).

Recovery

Conservation Measures and Best Management Practices:

- A State-wide management plan should be developed and implemented for the long-term conservation of all known occurrences of *Cyanea crispa*. This plan should also include broader landscape actions that are needed for the recovery of this plant throughout its range. The recovery plan for this species identifies the following important conservation actions. Fences should be constructed around the known occurrences of *C. crispa* to exclude feral pigs. Control or removal of pigs from these areas and the broader landscape will alleviate impacts to native ecosystems and will promote nature regeneration. Non-native plant species should be removed from the fenced areas and from the general vicinity of all known occurrences of *C. crispa*. Rats are a serious threat to most occurrences of *C. crispa* and should be controlled in the vicinity of each known occurrence and over the broader landscape. This should include use of currently-approved rodenticide bait blocks and, when approved, aerial dispersal of rodenticide (Service 1998a). Occurrences of *C. crispa* with only a few remaining individuals should be given priority for implementation of conservation actions.
- Ongoing Conservation Actions *Cyanea crispa* is being propagated at the Lyon Arboretum, the Army Environmental nursery and the National Tropical Botanical Garden. In addition, seeds are being stored at the Lyon Arboretum seed storage facility (Service 2002). The Hawaii Division of Forestry and Wildlife has been controlling pigs in Hidden Valley, however site visits have revealed abundant pig sign with many individuals of *C. crispa* defoliated or dead (Service 1998a). The Service is currently not aware of any other conservation efforts for this species.

SPECIES ACCOUNT: *Cyanea acuminata* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/10/1996; Pacific Region (R1) (USFWS, 2016)

Physical Description

Cyanea acuminata is a short-lived perennial and a member of the Campanulaceae (bellflower family). It is an unbranched shrub 0.3 to 2 m (1 to 6.6 ft) tall with inversely lance-shaped to narrowly egg-shaped or elliptic leaves 11.0 to 32.0 cm (4.3 to 12.6 in) long and 3.0 to 9.0 cm (1.2 to 3.5 in) wide. The flowers are 3.0 to 3.5 cm (1.2 to 1.4 in) long, white, and occasionally have a purplish tinge. The globe-shaped berries are yellow to yellowish orange. *C. acuminata* is distinguished from others in this endemic Hawaiian genus by the color of the petals and fruit and length of the calyx lobes, flowering stalk, and leaf stalks (Wagner et al.1999).

Historical Range

Historically, *Cyanea acuminata* was known from 31 scattered occurrences in the Koolau Mountains of Oahu. Currently, between 172 and 208 plants are known from 18 occurrences in both the Koolau and Waianae Mountains at East Makaleha (2 individuals), Halemano (6), Kaala (18), Kaalaea (30), Kahana near Puu Kaaumakua (3-4), Kahuku Cabin (1), Kaipapau (40 to 50), Kaluanui and Maakua (12), Kawaiiki (1), Konahuanui (20 to 40), Makaua (3), Pia (4), Poamoho (12-17), Pukele (1), Puu Keahiakahoe (3), Puu O Kona (1), south Kaukonahua (5), and Waahila (10) (HINHP Database 2001). The number of occurrences and the range of *C. acuminata* are declining (U.S. Army 2003a).

Current Range

Current range: Oahu. Historically no additional range.

Critical Habitat Designated

Yes; 9/18/2012.

Legal Description

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea acuminata* (Haha) under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Cyanea acuminata* (77 FR 57648-57862). The critical habitat designation includes 32 critical habitat units, which encompass approximately 39,247 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Cyanea acuminata* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Cyanea acuminata* includes 32 critical habitat units, covering four ecosystem types, which encompass approximately 39,247 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Mesic—

Units 1, 2, 3, 4, 5, 6, 7; Oahu—Lowland Wet—Units 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16; Oahu—Montane Wet—Unit 1; Oahu—Wet Cliff—Units 1, 2, 3, 4, 5, 6, 7, 8 .

Oahu—Lowland Mesic—Unit 1 [4,448 ac (1,800 ha)]. This area consists of 3,565 ac (1,443 ha) of State land, 583 ac (236 ha) of City and County of Honolulu land, 22 ac (9 ha) of Federal land, and 277 ac (112 ha) of privately owned land in the lowland mesic ecosystem in the Waianae Mountains, encompassing a large area including the north slopes of Mt. Kaala, from the Pahole NAR to the Kaala NAR, and south to the Waianae Kai Forest Reserve (FR). Oahu—Lowland Mesic—Unit 2 [1,063 ac (430 ha)]. This area consists of 1,063 ac (430 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Puuhapapa south to Puukaua. Oahu—Lowland Mesic—Unit 3 [353 ac (143 ha)]. This area consists of 353 ac (143 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Pohakea Pass to Kaiakuakai Gulch. Oahu—Lowland Mesic—Unit 4 [20 ac (8 ha)]. This area consists of 20 ac (8 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, between the Waipilopilo and Hanaimoa gulches, on State-owned land within the Hauula Forest Reserve. Oahu—Lowland Mesic—Unit 5 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, in Maakua Gulch and ridge; is State-owned; and within the Hauula FR. Oahu—Lowland Mesic—Unit 6 [247 ac (100 ha)]. This area consists of 12 ac (5 ha) State land and 235 ac (95 ha) of privately owned land in the lowland mesic ecosystem on the windward side of the Koolau Mountains, inland of Kaaawa Point, and is partially within Ahupuaa O Kahana State Park. Oahu—Lowland Mesic—Unit 7 [1,669 ac (676 ha)]. This area consists of 681 ac (276 ha) of State land, 129 ac (52 ha) of City and County of Honolulu land, and 852 ac (345 ha) of privately-owned land in the lowland mesic ecosystem on the leeward side of the Koolau Mountains, on Waialae Nui ridge.

Oahu—Lowland Wet—Unit 1 [541 ac (219 ha)]. This area consists of 428 ac (173 ha) of State land and 112 ac (46 ha) of City and County of Honolulu land in the lowland wet ecosystem on the windward side of the Waianae Mountains, and partially within the Mokuleia and Waianae Kai Forest Reserves. Oahu—Lowland Wet—Unit 2 [20 ac (8 ha)]. This area consists of 19 ac (8 ha) of State land in the lowland wet ecosystem on the windward side of the Waianae Mountains at Puuhapapa. Oahu—Lowland Wet—Unit 3 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland wet ecosystem on the windward side of the Waianae Mountains at Puukanehoa. Oahu—Lowland Wet—Unit 4 [27 ac (11 ha)]. This area consists of 27 ac (11 ha) in the lowland wet ecosystem on the windward side of the Waianae Mountains on State land at Puukaua. Oahu—Lowland Wet—Unit 5 [74 ac (30 ha)]. This area consists of 74 ac (30 ha) of State land in the lowland wet ecosystem, on the windward side of the Waianae Mountains at Palikea. Oahu—Lowland Wet—Unit 6 [790 ac (320 ha)]. This area consists of 790 ac (320 ha) of privately owned land in the lowland wet ecosystem, in privately owned land on the windward side of the Koolau Mountains, and includes Kahawainui, Ihihi, Waialele, and Koloa gulches. Oahu—Lowland Wet—Unit 7 [1,787 ac (723 ha)]. This area consists of 1,499 ac (606 ha) of State land and 288 ac (117 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, within the Kaipapau and Hauula Forest Reserves and Sacred Falls State Park, from Puukainapuaa to Kaluanui (Sacred Falls). Oahu—Lowland Wet—Unit 8 [3,041 ac (1,231 ha)]. This area consists of 1,386 ac (561 ha) of State land and 1,655 ac (670 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, partially within the Ahupuaa O Kahana State Park, including Waihoi Springs, and Punaluu, Kahana, Waikane, Waikēēē, and Uwao streams. Oahu—Lowland Wet—Unit 9 [15,728 ac (6,365 ha)]. This area consists of 3,827 ac (1,545 ha) of State land, 147 ac (60 ha) of City and County of Honolulu land,

4,509 ac (1,825 ha) of Federal land (U.S. Fish and Wildlife Service), and 7,245 ac (2,932 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, partially within the Ewa FR Waimano Section and the Oahu Forest National Wildlife Refuge. This area extends along the Koolau summit from Waipio to Manaiki Stream. Oahu—Lowland Wet—Unit 10 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) of privately-owned land in the lowland wet ecosystem in private land on the windward side of the Koolau Mountains, along Kaalaea Stream. Oahu—Lowland Wet—Unit 11 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) in the lowland wet ecosystem, owned by the City and County of Honolulu on the windward side of the Koolau Mountains, along Waihee Stream. Oahu—Lowland Wet—Unit 12 [53 ac (21 ha)]. This area consists of 28 ac (11 ha) of City and County of Honolulu land and 26 ac (10 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, along Kahaluu Stream and tributary. Oahu—Lowland Wet—Unit 13 [75 ac (30 ha)]. This area consists of 74 ac (30 ha) of City and County of Honolulu land and 1 ac (0.5 ha) of State land in the lowland wet ecosystem on the windward side of the Koolau Mountains, along Heeia Stream and tributaries. Oahu—Lowland Wet—Unit 14 [478 ac (193 ha)]. This area consists of 274 ac (111 ha) of State land, 195 ac (79 ha) of City and County of Honolulu land, and 9 ac (4 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, extending from the Wilson Tunnel area southeast to Moole Stream. Oahu—Lowland Wet—Unit 15 [407 ac (165 ha)]. This area consists of 407 ac (165 ha) in the lowland wet ecosystem in State of Hawaii Department of Land and Natural Resources Land Division land on the windward side of the Koolau Mountains in Maunawili Valley, including Omao and Maunawili streams and Kapakahi and Pikoakea Springs. Oahu—Lowland Wet—Unit 16 [2,507 ac (1,014 ha)]. This area consists of 1,533 ac (621 ha) of State land, 365 ac (148 ha) of City and County of Honolulu land, and 608 (246 ha) of privately owned land in the lowland wet ecosystem in on the leeward side of the Koolau Mountains, partly within the Honolulu Watershed Forest Reserve, extending from the eastern side of Nuuanu Valley southeast along the Koolau summit to Kulepeamo Ridge.

Oahu—Montane Wet—Unit 1 [370 ac (150 ha)]. This area consists of 18 ac (7 ha) of City and County of Honolulu land, 352 ac (142 ha) of State land, and less than 1 ac (less than one ha) of privately-owned land in the montane wet ecosystem at the summit of the Waianae Mountains at Kaala, and partially within the Mokuleia Forest Reserve and the Kaala Natural Area Reserve.

Oahu—Wet Cliff—Unit 1 [235 ac (95 ha)]. This area consists of 167 ac (68 ha) of State land, 68 ac (28 ha) of City and County of Honolulu land, and less than 1 ac (less than 1 ha) of privately owned land in the wet cliff ecosystem in the Waianae Mountains, near the summit of Kaala, and partially within the Mokuleia and Waianae Kai FRs and the Kaala Natural Area Reserve. Oahu—Wet Cliff—Unit 2 [3 ac (1 ha)]. This area consists of 3 ac (1 ha) of State land in the wet cliff ecosystem in the Waianae Mountains at Puuhapapa, within a small area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. Oahu—Wet Cliff—Unit 3 [16 ac (6 ha)]. This area consists of 16 ac (6 ha) in the wet cliff ecosystem on State land in the Waianae Mountains at Puukanehoa, partially within an area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. Oahu—Wet Cliff—Unit 4 [23 ac (9 ha)]. This area consists of 23 ac (9 ha) in the wet cliff ecosystem on State land in the Waianae Mountains at Puukaua, partially overlapping an area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and recently acquired by the State. Oahu—Wet Cliff—Unit 5 [31 ac (13 ha)]. This area consists of 31 ac (13 ha) of State land in the wet cliff ecosystem in the Waianae Mountains, at Palikea and north

of Palikea. Oahu—Wet Cliff—Unit 6 [151 ac (61 ha)]. This area consists of 151 ac (61 ha) in the wet cliff ecosystem on State land on the windward side of the Koolau Mountains in Kaipapau Gulch, entirely within the Kaipapau Forest Reserve. Oahu—Wet Cliff—Unit 7 [144 ac (58 ha)]. This area consists of 144 ac (58 ha) in the wet cliff ecosystem in State land on the windward side of the Koolau Mountains in Hauula Gulch, entirely within the Hauula Forest Reserve. Oahu—Wet Cliff—Unit 8 [4,649 ac (1,881 ha)]. This area consists of 1,479 ac (598 ha) of State land, 1,281 ac (519 ha) of City and County of Honolulu land, 5 ac (2 ha) of Federal land, and 1,884 ac (762 ha) of privately owned land, in the wet cliff ecosystem along the summit of the Koolau Mountains, overlapping portions of Sacred Falls State Park, the Waiahole FR (Waiahole and Iolekaa sections), the Kaneohe and Honolulu Watershed FRs, and the Nuana Pali State Wayside.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea acuminata* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Cyanea acuminata* occurs within the Lowland mesic, Lowland wet and Wet cliff ecosystems in the Waianae Mountain caldera complex and the Koolau Mountain caldera complex, and occurs within the Montane wet ecosystem in the Waianae Mountain caldera complex:

Oahu—Lowland Mesic—Units 1, 2, 3, 4, 5, 6, 7. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. (E) Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. (F) Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Oahu—Lowland Wet—Units 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16. (A) Elevation: <3,000 ft (<1,000 m). (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. (D) Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. (E) Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. (F) Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Oahu—Montane Wet—Unit 1. (A) Elevation: 3,300–6,600 ft (1,000-2,000 m). (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: Well-developed soils, montane bogs. (D) Canopy: *Acacia*, *Charpentiera*, *Cheirodendron*, *Metrosideros*. (E) Subcanopy: *Broussaisia*, *Cibotium*, *Eurya*, *Ilex*, *Myrsine*. (F) Understory: Ferns, *Carex*, *Coprosma*, *Leptecophylla*, *Oreobolus*, *Rhynchospora*, *Vaccinium*.

Oahu—Wet Cliff—Units 1, 2, 3, 4, 5, 6, 7, 8. (A) Elevation: unrestricted. (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: >65 degree slope, shallow soils, weathered lava. (D) Canopy: None. (E) Subcanopy: *Broussaisia*, *Cheirodendron*, *Leptecophylla*, *Metrosideros*. (F) Understory: Bryophytes, Ferns, *Coprosma*, *Dubautia*, *Kadua*, *Peperomia*.

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Cyanea acuminata* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes,

landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: *Cyanea acuminata* has been observed fruiting in February and November. Little else is known about its flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors (Service 1998a).

Habitat Type

Adult: Slopes and stream banks in wet or mesic forest or shrubland

Habitat Narrative

Adult: Wet forests in gulch bottoms, on gulch slopes and on ridgecrests. (NatureServe, 2015). *Cyanea acuminata* typically grows on slopes, ridges, or stream banks between 216 and 1,208 m (708 and 3,962 ft) in elevation. The plants are found in *Metrosideros polymorpha*-*Dicranopteris linearis*, *Acacia koa*-*M. polymorpha* wet or mesic forest or shrubland, or *Diospyros sandwicensis*-*M. polymorpha* lowland mesic forest with one or more of the following associated native species: *Antidesma* sp., *Broussaisia arguta*, *Chamaesyce* sp., *Charpentiera* sp., *Cyrtandra* spp., *Diplazium sandwichianum*, *Dryopteris sandwicensis*, *Dubautia laxa*, *Freycinetia arborea*, *Hibiscus* sp., *Hedyotis* sp., *Ilex anomala*, *Labordia* sp., *Machaerina* sp., *Melicope* spp., *Perrottetia sandwicensis*, *Phyllostegia* sp., *Pipturus albidus*, *Pisonia* sp., *Psychotria* sp., *Sadleria* sp., *Syzygium sandwicensis*, *Touchardia latifolia*, and *Wikstroemia* sp. (HINHP Database 2001; Wagner et al. 1999).

Dispersal/Migration

Population Information and Trends

Resiliency:

Fragility unknown. (NatureServe, 2015)

Representation:

Fragility unknown. (NatureServe, 2015)

Redundancy:

Fragility unknown. (NatureServe, 2015)

Number of Populations:

6 - 20 (NatureServe, 2015)

Population Size:

1 - 1000 individuals (NatureServe, 2015)

Adaptability:

Fragility unknown. (NatureServe, 2015)

Population Narrative:

Fragility unknown. Fewer than 100 plants currently known. Estimated less than 3000 total plants. 14 current (between 1982 and 1997) and 17 historical occurrences. (NatureServe, 2015)

Threats and Stressors**Stressor:****Exposure:****Response:****Consequence:**

Narrative: The major threats to *Cyanea acuminata* are habitat degradation and destruction by feral pigs and goats; potential impacts from military activities; predation by slugs; predation by rats; and competition with the non-native plant species such as *Ageratina adenophora*; *Aleurites moluccana*, *Clidemia hirta*, *Cordyline fruticosa*, *Dioscorea* sp., *Erigeron karvinskianus*, *Musa* sp., *Passiflora suberosa*, *Psidium cattleianum*, *Rubus argutus*, and *Schinus terebinthifolius*. In addition, *C. acuminata* is threatened by the risk of extinction from naturally occurring stochastic events (such as landslides, hurricanes, or flooding) and from reduced reproductive vigor, both due to the small number of remaining individuals (HINHP Database 2001; Service 1998a; 61 FR 53089).

Recovery**Conservation Measures and Best Management Practices:**

- A State-wide management plan should be developed and implemented for the long-term conservation of all known occurrences of *Cyanea acuminata*. This plan should also include broader landscape actions that are needed for the recovery of this plant throughout its range. The recovery plan for this species identifies the following important conservation actions. Fences should be constructed around the known populations of *C. acuminata* to exclude feral pigs. Feral pigs should be controlled or removed from these areas to alleviate their impact on native ecosystems and promote germination of *C. acuminata* over a greater landscape. Where fences are not feasible due to topography, other means of ungulate control should be extensively employed. Occurrences that have only a few remaining individuals should be give priority for remove non-native plants and fence construction. Rats should be controlled in the vicinity of known occurrences and over the broader landscape needed to sustain this plant. This should include the use of the approved rodenticides and, when approved, aerial dispersal of rodenticide. Ongoing Conservation Actions: This species is in genetic storage at the Lyon Arboretum and the National Tropical Botanical Garden (Service 2002). The Service is currently not aware of any other conservation efforts for this species.

SPECIES ACCOUNT: *Cyanea asarifolia* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 02/25/1994; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Cyanea asarifolia, a member of the bellflower family, is a sparingly branched shrub 0.3 to 1 m (1 to 3.3 ft) tall. The heart-shaped leaves are 8.5 to 10.5 cm (3.3 to 4.1 in) long and 7 to 8 cm (2.8 to 3.1 in) wide with leaf stalks 12 to 15 cm (4.7 to 5.9 in) long. Thirty to 40 flowers are clustered on a stalk 25 to 30 mm (1 to 1.2 in) long, each having an individual stalk 7 to 10 mm (0.3 to 0.4 in) in length. The slightly curved flowers are white with purple stripes, 20 to 22 mm (0.8 to 0.9 in) long, and about 3.5 mm (0.1 in) wide with spreading lobes. The five anthers have tufts of white hairs at the tips. The nearly spherical fruit is a dark purple berry about 1 cm (0.4 in) long. (USFWS, 1995)

Taxonomy

Recently, St. John (1987d, St. John and Takeuchi 1987) placed the genus *Cyanea* in synonymy with *Dehissea*, resulting in the new combination *Delissea asarifolia*, but Lammers (1990) retains both genera in the currently accepted treatment of the family. (USFWS, 1995)

Current Range

This species is restricted to Kauai. (NatureServe, 2015)

Critical Habitat Designated

Yes; 2/27/2003.

Legal Description

On February 27, 2003, the U.S. Fish and Wildlife Service (Service), designate critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Cyanea asarifolia* on the island of Kauai, Hawaii (68 FR 9116 - 9479).

Critical Habitat Designation

The critical habitat designation for *Cyanea asarifolia* includes two units totaling 3,848 acres in Kauai County, Hawaii. The units are Kauai 4—*Cyanea asarifolia*—a and Kauai 10—*Cyanea asarifolia*—b.

Kauai 4—*Cyanea asarifolia*—a: This unit is critical habitat for *Cyanea asarifolia* and is 656 ha (1,619 ac) on State (Kealia and Moloaa Forest Reserves) and private land. This unit contains Ke Ana Kolea, Mount Namahana, and Anahola, Kekoiki, Leleiwi, and Puu Awa Summits. This unit provides habitat for three populations of 300 mature, reproducing individuals of the short-lived perennial *Cyanea asarifolia* and is currently unoccupied. This unit provides habitat that is essential to the establishment of additional populations on Kauai in order to reach recovery goals. The habitat features contained in this unit that are essential for this species include, but are not limited to, pockets of soil on sheer, wet rock cliffs and waterfalls in lowland wet forests. This unit is geographically separated from the other unit designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe.

Kauai 10—*Cyanea asarifolia*—b: This unit is critical habitat for *Cyanea asarifolia* and is 903 ha (2,232 ac) on State (Lihue-Koloa Forest Reserve) and private land. This unit contains Iole, Kalalea, Kamanu, and Palikea Summits. This unit provides habitat for seven populations of 300 mature, reproducing individuals of the short-lived perennial *Cyanea asarifolia* and is currently occupied with 4 or 5 plants. This unit is essential to the conservation of the taxon because it supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable. The habitat features contained in this unit that are essential for this species include, but are not limited to, pockets of soil on sheer wet rock cliffs and waterfalls in lowland wet forests. This unit is geographically separated from the other unit designated as critical habitat for this island-endemic species, in order to avoid all recovery populations from being destroyed by one naturally occurring catastrophe.

Primary Constituent Elements/Physical or Biological Features

Within these units, the currently known primary constituent elements of critical habitat include, but are not limited to, the habitat components provided by:

(i) Pockets of soil on sheer wet rock cliffs and waterfalls in lowland wet forests and containing one or more of the following native plant species: *Bidens* spp., *Dubautia plantaginea*, *Hedyotis centranthoides*, *Hedyotis elatior*, *Lysimachia filifolia*, *Machaerina angustifolia*, *Metrosideros polymorpha*, or *Panicum lineale*; and

(ii) Elevations between 182 and 1,212 m (597 and 3,976 ft).

Special Management Considerations or Protections

The following management actions are important: feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas deemed essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas deemed essential for the recovery of the species; monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: Not available.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Cliff (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Wet regions (NatureServe, 2015)

Environmental Specificity

Adult: Medium, with some key requirements (USFWS, 1995)

Habitat Narrative

Adult: This species typically grows in pockets of soil on sheer rock cliffs in lowland wet forests at an elevation of approximately 330 meters (1,080 feet). Associated plant taxa include ferns, *Hedyotis elatior* (manono), ohia, *Touchardia latifolia* (olona), and *Urera giabra* (opuhe) (USFWS 1994a). (USFWS, 1995)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

Very low (inferred from USFWS, 2009)

Representation:

Very low (inferred from USFWS, 2009)

Redundancy:

Very low (inferred from USFWS, 2009)

Number of Populations:

3 (USFWS, 2016)

Population Size:

134 (USFWS, 2016)

Population Narrative:

Currently only one wild population containing 20 to 30 individuals is known. (USFWS, 2009); In 2009 a second population was found, and the two known populations totaled 58 individuals (PEPP 2009). By 2012, it was estimated these two populations totaled over 100 individuals, and the species was downgraded from the PEPP list (plants with fewer than 50 individuals in the wild) to POP (taxa that have more than 50 individuals but remain extremely vulnerable; PEPP 2014). Currently, those two populations only have 20 and 54 individuals. However, in 2017 a third population was discovered, also in the Blue Hole area, with 60 individuals (Kishida 2017, in litt.). Fruit are collected and the known populations are monitored for weeds. (USFWS, 2017)

Threats and Stressors

Stressor: Hurricanes and rock slides (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: The major threats to this species remain the risk of extinction from naturally occurring events, such as hurricanes and rock slides. (USFWS, 2009)

Stressor: Small population size (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Reduced reproductive vigor remains a threat due to the small number of existing individuals. (USFWS, 2009)

Stressor: Predation (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Predation by introduced slugs and rodents [black rats (*Rattus rattus*) and mice (*Mus musculus*)]. (USFWS, 2009)

Stressor: Invasive introduced plants (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Competition from invasive introduced plant species is a threat to *C. asarifolia*. (USFWS, 2009)

Stressor: Habitat degradation (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Habitat degradation by feral pigs (*Sus scrofa*) continues to be a threat. (USFWS, 2009)

Stressor: Invertebrate predation or herbivory (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: An observation of nonnative snails (that consume seedlings and leaves) was made at one population (PEPP 2014). (USFWS, 2017)

Stressor: Landslides and flooding destruction or degradation of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Flooding is a threat to some individuals (NTBG 2010; PEPP 2014). (USFWS, 2017)

Stressor: Climate change loss or degradation of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. This assessment concluded that *Cyanea asarifolia* is highly vulnerable to the impacts of climate change with a vulnerability score of 0.532 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2017)

Recovery

Reclassification Criteria:

1. A total of five to seven populations of each taxon should be documented on Kauai and at least one other island where they now occur or occurred historically. (USFWS, 1995)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1995)
3. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered. (USFWS, 1995)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Kauai and at least one other island where they now occur or occurred historically. (USFWS, 1995)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1995)
3. Each population should persist at this level for a minimum of five consecutive years. (USFWS, 1995)

Recovery Actions:

- propagation efforts and the maintenance of adequate genetic stock ex situ should be undertaken immediately, as well as the protection of remaining wild individuals from feral pigs, slugs and rodents. (USFWS, 1995)
- The plan begins with the protection and management of current habitats of the Kauai cluster taxa. Current threats are addressed through fencing and/or hunting to control ungulates; control of alien plants; protection from fire; control of rodents and slugs; control of insects pests and disease; protection from human disturbance; collection, storage and maintenance of genetic material; and, a comprehensive monitoring program. (USFWS, 1995)

- A research program is also recommended to study the growth and reproductive viability of each taxon, determine the parameters of viable populations of each taxon, study the reproductive strategy and pollinators of each taxon, study possible pests and diseases, and use the results of such research to improve management practices. (USFWS, 1995)
- A program of augmentation of very small populations and re establishment of new populations within the historical range of the species is also needed. (USFWS, 1995)
- A public education program is also needed to increase public awareness and support for plant recovery efforts. (USFWS, 1995)
- Finally, the recovery objectives should be refined and revised as new information becomes available. (USFWS, 1995)
- Surveys and inventories—Survey the geographical and historic range of *Cyanea asarifolia* for additional populations. (USFWS, 2017)
- Ungulate monitoring and control—Construct enclosure fences or determine other methods to protect individuals from the negative impacts of feral pigs to prevent imminent extinction. Protect all occurrences against disturbances from feral ungulates. (USFWS, 2017)
- Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations. (USFWS, 2017)
- Captive propagation for genetic storage and reintroduction—Continue propagation efforts for maintenance of genetic stock. (USFWS, 2017)
- Reintroduction and translocation—Establish new populations within historic range or suitable habitat where threats have been controlled. (USFWS, 2017)
- Predator and herbivore monitoring and control—Determine and implement adequate slug control methods. (USFWS, 2017)
- Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from landslides. (USFWS, 2017)
- Genetic research—Conduct a genetic analysis of the species to determine variability within extant wild individuals. (USFWS, 2017)
- Population biology research—Study *Cyanea asarifolia* populations to determine viable population size and structure, geographical distribution, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. (USFWS, 2017)

Conservation Measures and Best Management Practices:

- Collect fruit from all wild individuals and any reintroduced individuals that set seed to add to the genetic diversity of the ex situ material. (USFWS, 2009)
- Construct enclosure fences to protect individuals from the negative impacts of feral pigs. (USFWS, 2009)
- Enhance current natural populations to increase numbers of individuals. (USFWS, 2009)
- Establish new populations within historical range or suitable habitat where threats have been controlled. (USFWS, 2009)
- Determine and implement adequate rat and slug control methods. (USFWS, 2009)
- Survey the geographical and historical range of *Cyanea asarifolia* for additional populations. (USFWS, 2009)
- Assess genetic variability within extant populations. (USFWS, 2009)

- Study *Cyanea asarifolia* populations with regard to population size and structure, geographical distribution, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. (USFWS, 2009)

SPECIES ACCOUNT: *Cyanea asplenifolia* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 06/27/2013; Pacific Region (Region 1) (USFWS, 2017)

Physical Description

A shrub, 1.3-2 m tall with unbranched or sparingly branched stems. Leaves deeply cut and fern-like. Racemes axillary. Corollas tubular, gently curved. (NatureServe, 2015)

Taxonomy

A member of the bellflower family (Campanulaceae) (USFWS, 2016).

Historical Range

This species was known historically from Waihee Valley and Kaanapali on west Maui, and Halehaku ridge on east Maui (Lammers 1999, p. 445; HBMP 2010). (USFWS, 2016)

Current Range

Endemic to the island of Maui in the state of Hawaii. (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea asplenifolia* (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes nine detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea asplenifolia* includes nine CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Lowland Mesic—Unit 1 consists of 1,147 ac (464 ha) of State land, 241 ac (97 ha) of privately owned land, and 494 ac (200 ha) of federally owned land (Haleakala National Park), from Manawainui Valley to Kukuiula on the eastern slopes of east Maui. This unit is occupied by the plants *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, and *Huperzia mannii*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Mesic—Unit 1 is not known to be occupied by *Ctenitis squamigera* or *Solanum incompletum*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 1 (and) *Palmeria dolei*—Unit 2—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 2— Lowland Wet This area consists of 6,616 ac (2,677 ha) of State land, 7,425 ac (3,005 ha) of privately owned land, and 2,038 ac (825 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Kipahulu Valley on the northern and eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia samuelii*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Huperzia mannii*, *Melicope balloui*, and *M. ovalis*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 1 is not known to be occupied by the plants *Clermontia oblongifolia* ssp. *mauiensis*, *C. peleana*, *Mucuna sloanei* var. *persericea*, *Phyllostegia haliakalae*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 2 (and) *Palmeria dolei*—Unit 3—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 3— Lowland Wet (and) *Newcombia cumingi*—Unit 1—Lowland Wet This area consists of 65 ac (26 ha) of State land at Moomoku, on the northwestern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Santalum haleakalae* var. *lanaiense*. Although Maui—Lowland Wet—Unit 2 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendrion pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, or *Wikstroemia villosa*, by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), or by the Newcomb's tree snail (*Newcombia cumingi*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 3 (and) *Palmeria dolei*—Unit 4—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 4— Lowland Wet This area consists of 1,247 ac (505 ha) of State land at Honanana Gulch on the northeastern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). They are occupied by the plants *Bidens conjuncta*, *Cyanea asplenifolia*, and *Pteris lidgatei*. These units also contain unoccupied habitat that is essential to the conservation of these species

by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 3 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielirectum*, *Bidens micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 4 (and) *Palmeria dolei*—Unit 5—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 5— Lowland Wet This area consists of 864 ac (350 ha) of State land at Kahakuloa Valley on the northeastern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). They are occupied by the plants *Bidens conjuncta* and *Cyanea asplenifolia*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 4 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielirectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 5 (and) *Palmeria dolei*—Unit 6—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 6— Lowland Wet This area consists of 30 ac (12 ha) of State land at Iao Valley on the eastern side of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). Although Maui—Lowland Wet—Unit 5 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielirectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation

and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 6 (and) *Palmeria dolei*—Unit 7—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 7— Lowland Wet This area consists of 136 ac (55 ha) of State land at Honokowai and Wahikuli valleys on the western slopes of west Maui. These units include the mixed hermland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Santalum haleakalae* var. *lanaiense*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 6 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielirectum*, *Bidens conjuncta*, *Bidens micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendrion pyriformium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 7 (and) *Palmeria dolei*—Unit 8—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 8— Lowland Wet This area consists of 898 ac (364 ha) of State land at Olowalu Valley, on the southern slopes of west Maui. These units include the mixed hermland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Alectryon macrococcus*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 7 is not currently occupied by the plants *Asplenium dielirectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendrion pyriformium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 8 (and) *Palmeria dolei*—Unit 9—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 9— Lowland Wet This area consists of 230 ac (93 ha) of State land at upper Ukumehame Gulch, on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). Although Maui—Lowland Wet—Unit 8 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformum*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea asplenifolia* critical habitat consists of two components. Lowland mesic (east Maui) and Lowland wet (east Maui and west Maui) (81 FR 17790-18110):

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Ecosystem: Lowland Wet. Elevation: <3,330 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight

plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet

Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylothea* ssp. *pentamera*, *B. campylothea* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Not available.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Lowland wet and lowland mesic ecosystem (see population narrative)

Environmental Specificity

Adult: Very narrow to moderate. (NatureServe, 2015)

Habitat Narrative

Adult: *Cyanea asplenifolia* is found on moist to wet forests on gulch slopes. (NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Decline of 10-50% (NatureServe, 2015)

Resiliency:

Low (inferred from NatureServe, 2016)

Redundancy:

Low (inferred from NatureServe, 2016)

Number of Populations:

8 (USFWS, 2016)

Population Size:

~200 (USFWS, 2016)

Population Narrative:

Short-term population trends indicate a decline of 10-50% (NatureServe, 2015). On west Maui, in the lowland wet ecosystem, there are 3 occurrences totaling 14 individuals in the Puu Kukui Preserve and two occurrences totaling 5 individuals in the West Maui NAR. On east Maui, *C. asplenifolia* is found in 1 occurrence each in the lowland mesic ecosystem in Haleakala National Park (53 individuals) and Kipahulu FR (140 individuals), and 1 occurrence in the lowland wet ecosystem in the Makawao FR (5 individuals) (TNC 2007; Oppenheimer 2008b, in litt, 2010b, in litt.; PEPP 2008, p. 48; Welton and Haus 2008, p. 12; NTBG 2009c, pp. 3–5; HBMP 2010; Welton 2010a, in litt.). Currently, *C. asplenifolia* is known from 8 occurrences totaling fewer than 200 individuals (USFWS, 2016).

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (pigs, goats, axis deer, and cattle), nonnative plants, fire, landslides, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Fire can destroy dormant seeds and plants, even in steep and inaccessible areas. Successive fires can remove habitat for native species by altering microclimate conditions favorable to alien plants. Landslides destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:**Consequence:**

Narrative: Predation and herbivory by nonnative animal species (pigs, goats, axis deer, and cattle) is considered an ongoing threat to *Cyanea asplenifolia* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

Recovery**Reclassification Criteria:**

Not available.

Delisting Criteria:

Not available.

Recovery Actions:

- Not available.

Conservation Measures and Best Management Practices:

- Not available.

SPECIES ACCOUNT: *Cyanea calycina* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/18/2012; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Cyanea calycina (Haha), an unbranched shrub in the bellflower family (Campanulaceae). (USFWS, 2012)

Taxonomy

Kartesz's Synthesis (1999) and the Hawaii Heritage Program follow a treatment recognizing *Cyanea calycina* as a species, distinct from *C. lancolata*. Formerly treated as a member of the genus *Rollandia*, however, Tom Lammers (Lammers et al. 1993) have merged all of the species of this endemic Hawaiian genus under *Cyanea*. (NatureServe, 2015)

Current Range

Cyanea calycina (Haha) is found in both the Waianae and Koolau Mountains of Oahu. (USFWS, 2012)

Critical Habitat Designated

Yes; 9/18/2012.

Legal Description

On September 18, 2012, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea calycina* (Haha) under the Endangered Species Act of 1973, as amended (Act) (77 FR 57648-57862). The critical habitat designation includes 32 critical habitat units, which encompass approximately 39,247 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Cyanea calycina* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Cyanea calycina* includes 32 critical habitat units, covering four ecosystems type, which encompasses approximately 39,247 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Mesic—Units 1, 2, 3, 4, 5, 6, 7 Oahu— Lowland Wet—Units 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16; Oahu—Montane Wet—Unit 1; Oahu—Wet Cliff—Units 1, 2, 3, 4, 5, 6, 7, 8.

Oahu—Lowland Mesic—Unit 1 [4,448 ac (1,800 ha)]. This area consists of 3,565 ac (1,443 ha) of State land, 583 ac (236 ha) of City and County of Honolulu land, 22 ac (9 ha) of Federal land, and 277 ac (112 ha) of privately owned land in the lowland mesic ecosystem in the Waianae Mountains, encompassing a large area including the north slopes of Mt. Kaala, from the Pahole NAR to the Kaala NAR, and south to the Waianae Kai Forest Reserve (FR). Oahu—Lowland Mesic—Unit 2 [1,063 ac (430 ha)]. This area consists of 1,063 ac (430 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Puuhapapa south to Puukaua. Oahu—Lowland Mesic—Unit 3 [353 ac (143 ha)]. This area consists of 353 ac (143 ha) in the

lowland mesic ecosystem on the windward side of the Waianae Mountains, from Pohakea Pass to Kaiakuakai Gulch. Oahu—Lowland Mesic—Unit 4 [20 ac (8 ha)]. This area consists of 20 ac (8 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, between the Waipilopilo and Hanaimoa gulches, on State-owned land within the Hauula Forest Reserve. Oahu—Lowland Mesic—Unit 5 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, in Maakua Gulch and ridge; is State-owned; and within the Hauula FR. Oahu—Lowland Mesic—Unit 6 [247 ac (100 ha)]. This area consists of 12 ac (5 ha) State land and 235 ac (95 ha) of privately owned land in the lowland mesic ecosystem on the windward side of the Koolau Mountains, inland of Kaaawa Point, and is partially within Ahupuaa O Kahana State Park. Oahu—Lowland Mesic—Unit 7 [1,669 ac (676 ha)]. This area consists of 681 ac (276 ha) of State land, 129 ac (52 ha) of City and County of Honolulu land, and 852 ac (345 ha) of privately-owned land in the lowland mesic ecosystem on the leeward side of the Koolau Mountains, on Waialae Nui ridge.

Oahu—Lowland Wet—Unit 1 [541 ac (219 ha)]. This area consists of 428 ac (173 ha) of State land and 112 ac (46 ha) of City and County of Honolulu land in the lowland wet ecosystem on the windward side of the Waianae Mountains, and partially within the Mokuleia and Waianae Kai Forest Reserves. Oahu—Lowland Wet—Unit 2 [20 ac (8 ha)]. This area consists of 19 ac (8 ha) of State land in the lowland wet ecosystem on the windward side of the Waianae Mountains at Puuhapapa. Oahu—Lowland Wet—Unit 3 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland wet ecosystem on the windward side of the Waianae Mountains at Puukanehoa. Oahu—Lowland Wet—Unit 4 [27 ac (11 ha)]. This area consists of 27 ac (11 ha) in the lowland wet ecosystem on the windward side of the Waianae Mountains on State land at Puukaua. Oahu—Lowland Wet—Unit 5 [74 ac (30 ha)]. This area consists of 74 ac (30 ha) of State land in the lowland wet ecosystem, on the windward side of the Waianae Mountains at Palikea. Oahu—Lowland Wet—Unit 6 [790 ac (320 ha)]. This area consists of 790 ac (320 ha) of privately owned land in the lowland wet ecosystem, in privately owned land on the windward side of the Koolau Mountains, and includes Kahawainui, Ihiihi, Wailele, and Koloa gulches. Oahu—Lowland Wet—Unit 7 [1,787 ac (723 ha)]. This area consists of 1,499 ac (606 ha) of State land and 288 ac (117 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, within the Kaipapau and Hauula Forest Reserves and Sacred Falls State Park, from Puukainapuaa to Kaluanui (Sacred Falls). Oahu—Lowland Wet—Unit 8 [3,041 ac (1,231 ha)]. This area consists of 1,386 ac (561 ha) of State land and 1,655 ac (670 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, partially within the Ahupuaa O Kahana State Park, including Waihoi Springs, and Punaluu, Kahana, Waikane, Waikēēē, and Uwao streams. Oahu—Lowland Wet—Unit 9 [15,728 ac (6,365 ha)]. This area consists of 3,827 ac (1,545 ha) of State land, 147 ac (60 ha) of City and County of Honolulu land, 4,509 ac (1,825 ha) of Federal land (U.S. Fish and Wildlife Service), and 7,245 ac (2,932 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, partially within the Ewa FR Waimano Section and the Oahu Forest National Wildlife Refuge. This area extends along the Koolau summit from Waipio to Manaiki Stream. Oahu—Lowland Wet—Unit 10 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) of privately-owned land in the lowland wet ecosystem in private land on the windward side of the Koolau Mountains, along Kaalaea Stream. Oahu—Lowland Wet—Unit 11 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) in the lowland wet ecosystem, owned by the City and County of Honolulu on the windward side of the Koolau Mountains, along Waihee Stream. Oahu—Lowland Wet—Unit 12 [53 ac (21 ha)]. This area consists of 28 ac (11 ha) of City and County of Honolulu land and 26 ac (10 ha) of privately-owned land in the lowland wet ecosystem on the windward

side of the Koolau Mountains, along Kahaluu Stream and tributary. Oahu—Lowland Wet—Unit 13 [75 ac (30 ha)]. This area consists of 74 ac (30 ha) of City and County of Honolulu land and 1 ac (0.5 ha) of State land in the lowland wet ecosystem on the windward side of the Koolau Mountains, along Heeia Stream and tributaries. Oahu—Lowland Wet—Unit 14 [478 ac (193 ha)]. This area consists of 274 ac (111 ha) of State land, 195 ac (79 ha) of City and County of Honolulu land, and 9 ac (4 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, extending from the Wilson Tunnel area southeast to Moole Stream. Oahu—Lowland Wet—Unit 15 [407 ac (165 ha)]. This area consists of 407 ac (165 ha) in the lowland wet ecosystem in State of Hawaii Department of Land and Natural Resources Land Division land on the windward side of the Koolau Mountains in Maunawili Valley, including Omao and Maunawili streams and Kapakahi and Pikoakea Springs. Oahu—Lowland Wet—Unit 16 [2,507 ac (1,014 ha)]. This area consists of 1,533 ac (621 ha) of State land, 365 ac (148 ha) of City and County of Honolulu land, and 608 (246 ha) of privately owned land in the lowland wet ecosystem in on the leeward side of the Koolau Mountains, partly within the Honolulu Watershed Forest Reserve, extending from the eastern side of Nuuanu Valley southeast along the Koolau summit to Kulepeamoa Ridge.

Oahu—Montane Wet—Unit 1 [370 ac (150 ha)]. This area consists of 18 ac (7 ha) of City and County of Honolulu land, 352 ac (142 ha) of State land, and less than 1 ac (less than one ha) of privately-owned land in the montane wet ecosystem at the summit of the Waianae Mountains at Kaala, and partially within the Mokuleia Forest Reserve and the Kaala Natural Area Reserve.

Oahu—Wet Cliff—Unit 1 [235 ac (95 ha)]. This area consists of 167 ac (68 ha) of State land, 68 ac (28 ha) of City and County of Honolulu land, and less than 1 ac (less than 1 ha) of privately owned land in the wet cliff ecosystem in the Waianae Mountains, near the summit of Kaala, and partially within the Mokuleia and Waianae Kai FRs and the Kaala Natural Area Reserve. Oahu—Wet Cliff—Unit 2 [3 ac (1 ha)]. This area consists of 3 ac (1 ha) of State land in the wet cliff ecosystem in the Waianae Mountains at Puuhapapa, within a small area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. Oahu—Wet Cliff—Unit 3 [16 ac (6 ha)]. This area consists of 16 ac (6 ha) in the wet cliff ecosystem on State land in the Waianae Mountains at Puukanehoa, partially within an area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and was recently acquired by the State. Oahu—Wet Cliff—Unit 4 [23 ac (9 ha)]. This area consists of 23 ac (9 ha) in the wet cliff ecosystem on State land in the Waianae Mountains at Puukaua, partially overlapping an area that was part of the Honouliuli Preserve, managed by The Nature Conservancy of Hawaii, and recently acquired by the State. Oahu—Wet Cliff—Unit 5 [31 ac (13 ha)]. This area consists of 31 ac (13 ha) of State land in the wet cliff ecosystem in the Waianae Mountains, at Palikea and north of Palikea. Oahu—Wet Cliff—Unit 6 [151 ac (61 ha)]. This area consists of 151 ac (61 ha) in the wet cliff ecosystem on State land on the windward side of the Koolau Mountains in Kaipapau Gulch, entirely within the Kaipapau Forest Reserve. Oahu—Wet Cliff—Unit 7 [144 ac (58 ha)]. This area consists of 144 ac (58 ha) in the wet cliff ecosystem in State land on the windward side of the Koolau Mountains in Hauula Gulch, entirely within the Hauula Forest Reserve. Oahu—Wet Cliff—Unit 8 [4,649 ac (1,881 ha)]. This area consists of 1,479 ac (598 ha) of State land, 1,281 ac (519 ha) of City and County of Honolulu land, 5 ac (2 ha) of Federal land, and 1,884 ac (762 ha) of privately owned land, in the wet cliff ecosystem along the summit of the Koolau Mountains, overlapping portions of Sacred Falls State Park, the Waiahole FR (Waiahole and Iolekaa sections), the Kaneohe and Honolulu Watershed FRs, and the Nuana Pali State Wayside.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea calycina* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Cyanea calycina* occurs within the Lowland mesic, Lowland wet and Wet cliff ecosystems in the Waianae Mountain caldera complex and the Koolau Mountain caldera complex. *Cyanea calycina* also occurs within the Montane wet ecosystem in the Waianae Mountain caldera complex:

Oahu—Lowland Mesic—Units 1, 2, 3, 4, 5, 6, 7. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: Acacia, Diospyros, Metrosideros, Myrsine, Pouteria, Santalum. (E) Subcanopy: Dodonaea, Freycinetia, Leptecophylla, Melanthera, Osteomeles, Pleomele, Psydrax. (E) Understory: Carex, Dicranopteris, Diplazium, Elaphoglossum, Peperomia.

7 Oahu—Lowland Wet—Units 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16. (A) Elevation: <3,000 ft (<1,000 m). (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. (D) Canopy: Antidesma, Metrosideros, Myrsine, Pisonia, Psychotria. (E) Subcanopy: Cibotium, Claoxylon, Kadua, Melicope. (E) Understory: Alyxia, Cyrtandra, Dicranopteris, Diplazium, Machaerina, Microlepia.

Oahu—Montane Wet—Unit 1. (A) Elevation: 3,300–6,600 ft (1,000-2,000 m). (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: Well-developed soils, montane bogs. (D) Canopy: Acacia, Charpentiera, Cheiropendron, Metrosideros. (E) Subcanopy: Broussaisia, Cibotium, Eurya, Ilex, Myrsine. (E) Understory: Ferns, Carex, Coprosma, Leptecophylla, Oreobolus, Rhynchospora, Vaccinium.

Oahu—Wet Cliff—Units 1, 2, 3, 4, 5, 6, 7, 8. (A) Elevation: unrestricted. (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: >65 degree slope, shallow soils, weathered lava. (D) Canopy: None. (E) Subcanopy: Broussaisia, Cheiropendron, Leptecophylla, Metrosideros. (E) Understory: Bryophytes, Ferns, Coprosma, Dubautia, Kadua, Peperomia.

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Cyanea calycina* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Not available.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 1,800 and 3,920 feet (USFWS, 2012)

Environmental Specificity

Adult: Very narrow to moderate. (NatureServe, 2015)

Habitat Narrative

Adult: *Cyanea calycina* (Haha), an unbranched shrub in the bellflower family (Campanulaceae), is found in both the Waianae and Koolau Mountains of Oahu in the lowland mesic, lowland wet, montane wet, and wet cliff ecosystems (Lammers 1999, p. 483; Wagner and Herbst 2003, p. 17; TNC 2007; HBMP 2008). In the Waianae Mountains, *C. calycina* occurs in *Acacia-Metrosideros-Dicranopteris* (koa- ohia-uluhe) forests at elevations between 1,800 and 3,920 ft (550 and 1,195 m), and in the Koolau Mountains this species occurs in wet *Metrosideros-Dicranopteris* forest and shrubland at elevations between 1,830 and 3,000 ft (558 and 900 m) (HBMP 2008). (USFWS, 2012)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Unknown (NatureServe, 2015)

Resiliency:

Low (inferred from NatureServe, 2015)

Redundancy:

Low (inferred from NatureServe, 2015)

Population Growth Rate:

Unknown (NatureServe, 2015)

Number of Populations:

40 occurrences (USFWS, 2012)

Population Size:

300-350 (USFWS, 2012)

Population Narrative:

Currently, *C. calycina* is found from Pahole in the northern portion of the Waianae Mountains south along the summit to Palawai, in 18 occurrences totaling at least 170 individuals (U.S. Army 2006; HBMP 2008). Currently, 22 occurrences totaling between 155 and 169 individuals are known, from the most northern point at Kamananui Gulch along the summit ridges south to Konahuanui (U.S. Army 2006; HBMP 2008). The combined 40 occurrences total 325 to 339 individuals. (USFWS, 2012)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative plants, animals (pigs and goats), fire, and climate change. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. Fire can destroy dormant seeds as well as the plants themselves, even in steep or inaccessible areas. Successive fires that burn farther and farther into native habitat destroy native plants, and remove habitat for native species by altering microclimate conditions favorable to alien plants. The projected effects of climate change will likely exacerbate the effects of the other threats to the species (USFWS, 2012).

Stressor: Predation and herbivory (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (pigs, goats, rats, and slugs) is considered an ongoing threat to *Cyanea calycina* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2012).

Stressor: Trampling by humans (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: *Cyanea calycina* faces the threat of trampling. Visitors on foot, horseback, and motorbikes may pose threats to *C. calycina* directly due to trampling and other direct damage, and indirectly due to being a source of fire ignition in areas in the southern Waianae Mountains. Human impacts, such as trampling by hikers, has been documented as a threat to *C. calycina* in the northern Waianae Mountains, between Kaala and Puu Kalena summits (USFWS, 2012).

SPECIES ACCOUNT: *Cyanea copelandii* ssp. *copelandii* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 03/04/1994; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Cyanea copelandii subsp. *copelandii* is a small epiphytic shrub that grows 1-6.7 ft (0.3-2 m) tall (Lammers 1990). Rooting at the nodes, its weak stems clamber on rocks and tree trunks. Oblance-shaped leaf blades 4.9-10.6 in (10-27 cm) long and 1.4-3.3 in (3.5-8.5 cm) wide are dark green on the upper surface and hairy on the lower surface. Leaf blade margins have small teeth and the base of the blade is attached to a leafstalk that is 1-3.9 in (2.5-10 cm) long. Clusters of 5 to 12 flowers are attached to a main flower cluster stalk (peduncle) 0.8-1.8 in (2-4.5 cm) long. Each flower is then attached to a flower stalk (pedicel) 0.2-0.6 in (0.4-1.6 cm) long. The calyx and the petals are fused at the base into a tube 0.2-0.4 in (0.6-1 cm) long. Calyx lobes are small and triangular, 0.08-0.2 in (2-4 mm) long. The petals, 1.5-1.7 in (3.7-4.2 cm) long, are yellowish but appear rose because of long dark red hairs that cover the surface. Five spreading petal lobes are fused into a tube. Berries are ob-oval, 0.3-0.6 in (0.7-1.5 cm) long and dark orange. (USFWS, 1996)

Historical Range

Known only from a few historical specimens from the district of Puna on the island of Hawaii. (NatureServe, 2015)

Current Range

No current range; last collected in 1957. (NatureServe, 2015).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (inferred from USFWS, 1996)

Dependency on Other Individuals or Species

Adult: Honeycreeper pollinates flowers (NatureServe, 2015)

Reproduction Narrative

Adult: This taxon was observed in fruit and flower during December 1914 (HHP 1991f1). The loss of Hawaiian honeycreepers has likely resulted in elimination of the bird pollinator for this plant. (USFWS, 1996)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 2,200 and 5,232 feet (USFWS, 1996)

Environmental Specificity

Adult: Medium, with some key requirements (USFWS, 1996)

Habitat Narrative

Adult: The habitat of *Cyanea copelandii* subsp. *copelandii* is montane wet forest dominated by *Cibotium* spp., at elevations between 2,200 to 5,232 ft (660 to 1,600 m) (Lammers 1990). The Hawaiian Heritage Program (1991f) gives 2,200 to 2,900 ft (660 to 880 m) as the elevational range of this taxon. *Cibotium* is the only genus recorded as an associate of this taxon (HHP 1991f). (USFWS, 1996)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

None (USFWS, 2012)

Representation:

None (USFWS, 2012)

Redundancy:

None (USFWS, 2012)

Number of Populations:

0 (USFWS, 2012)

Population Size:

0 (USFWS, 2012)

Population Narrative:

In 2010, there were no known individuals or populations of *Cyanea copelandii* subsp. *copelandii* (USFWS 2010). (USFWS, 2012)

Threats and Stressors

Stressor: Ungulates (NatureServe, 2015)

Exposure:**Response:****Consequence:**

Narrative: The greatest threat to *Cyanea copelandii* ssp. *copelandii* is grazing by feral ungulates and its rarity (USFWS 1996). (NatureServe, 2015)

Stressor: Predation (NatureServe, 2015)

Exposure:**Response:****Consequence:**

Narrative: Possible predation of fruit and seeds by black rats and the loss of its avian pollinator, the Hawaiian Honeycreeper also threaten this species reproduction success (USFWS 1996).

Stressor: Small population size (USFWS, 2012)

Exposure:**Response:****Consequence:**

Narrative: Low numbers – increased likelihood of stochastic extinction due to changes in demography, the environment, genetics, or other factors (USFWS 1994, 1996; Plant Extinction Prevention Program 2010). (USFWS, 2012)

Stressor: Climate change (USFWS, 2012)

Exposure:**Response:****Consequence:**

Narrative: Climate change may also pose a threat to this species. However, current climate change analyses in the Pacific Islands lack sufficient spatial resolution to make predictions on impacts to this species. The Pacific Islands Climate Change Cooperative (PICCC) has currently funded climate modeling that will help resolve these spatial limitations. The Service anticipates high spatial resolution climate outputs by 2013. (USFWS, 2012)

Recovery**Reclassification Criteria:**

1. A total of five to seven populations of each taxon should be documented on the Big Island and at least one other island where it now occurs or occurred historically, if it is not endemic to the Big Island. (USFWS, 1996)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1996)
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered. (USFWS, 1996)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on the Big Island and at least 1 other island where they now occur or occurred historically, if it is not endemic to the Big Island. (USFWS, 1996)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 individuals per population for short-lived perennials. (USFWS, 1996)
3. Each population should persist at this level for a minimum of 5 consecutive years. (USFWS, 1996)

Recovery Actions:

- This taxon should be located in the wild, and seeds and/or tissue collected for propagation and maintenance of ex situ genetic stock. (USFWS, 1996)
- Additional populations will need to be established and, along with the extant population, protected from ungulates and other threats. (USFWS, 1996)

Conservation Measures and Best Management Practices:

- A thorough survey of the areas where the last known *Cyanea copelandii* subsp. *copelandii* occurred should be undertaken, focusing on the southeastern slope of Mauna Loa, near Glenwood. (USFWS, 2012)
- If the species is rediscovered, genetic material for ex situ maintenance should be collected, and the existing population protected. (USFWS, 2012)
- If the species is rediscovered, work with Hawaii Division of Forestry and Wildlife to initiate planning and contribute to implementation of ecosystem-level restoration and management for sites to reintroduce this species. (USFWS, 2012)

SPECIES ACCOUNT: *Cyanea copelandii* ssp. *haleakalaensis* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 09/03/1999; Pacific Region (R1) (USFWS, 2016)

Physical Description

A liana-like shrub 0.3-2 m tall. Flowers appear to be pale rose in color (NatureServe, 2015).

Taxonomy

A member of the bellflower family. In 1987, St. John (1987b) merged the two genera *Cyanea* and *Delissea*, formally recognizing only *Delissea*, the genus with priority. This change resulted in the combination *D. haleakalaensis*. Lammers retains both genera in the currently accepted treatment of the Hawaiian members of the family, and in 1988 he recognized *C. haleakalaensis* as a subspecies of *C. copelandii*, publishing the new combination *C. copelandii* ssp. *haleakalaensis* (Lammers 1988, 1999) (USFWS, 2002).

Historical Range

It is endemic to East Maui (USFWS, 2011). Historically (prior to 1970), *Cyanea copelandii* ssp. *haleakalaensis* was reported from the windward side of Haleakala and from Waikamoi to Kipahulu Valley on the island of Maui (USFWS, 2002).

Current Range

Currently (since 1970), this taxon is known from three populations within the East Maui Watershed Partnership in Haiku Uka, the ridge above Kuhiwa Valley, and Kipahulu Valley within Haleakala National Park and Hanawi Natural Area Reserve (Lammers 1999; U.S. Fish and Wildlife Service 1999b, 2002b, Warshauer 1998; Hawaii Natural Heritage Program Database 2001; Geographic Decision Systems International 2001; Medeiros et al. 1998) (USFWS, 2002).

Critical Habitat Designated

Yes; 5/14/2003.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea copelandii* ssp. *haleakalaensis* (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes 11 detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea copelandii* ssp. *haleakalaensis* includes 11 CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Lowland Mesic—Unit 1 consists of 1,147 ac (464 ha) of State land, 241 ac (97 ha) of privately owned land, and 494 ac (200 ha) of federally owned land (Haleakala National Park), from Manawainui Valley to Kukuiula on the eastern slopes of east Maui. This unit is occupied by the plants *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, and *Huperzia mannii*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic

ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Mesic—Unit 1 is not known to be occupied by *Ctenitis squamigera* or *Solanum incompletum*, we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 1 (and) *Palmeria dolei*—Unit 2—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 2—Lowland Wet This area consists of 6,616 ac (2,677 ha) of State land, 7,425 ac (3,005 ha) of privately owned land, and 2,038 ac (825 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Kipahulu Valley on the northern and eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia samuelii*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Huperzia mannii*, *Melicope balloui*, and *M. ovalis*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 1 is not known to be occupied by the plants *Clermontia oblongifolia* ssp. *mauiensis*, *C. peleana*, *Mucuna sloanei* var. *persericea*, *Phyllostegia haliakalae*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 1 (and) *Palmeria dolei*—Unit 10—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 10—Montane Wet This area consists of 1,313 ac (531 ha) of State land and 798 ac (323 ha) of privately owned land, at Haiku Uka on the northern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Cyanea duvalliorum*, *C. maritae*, *C. mceldowneyi*, *Huperzia mannii*, *Melicope balloui*, and *Phyllostegia pilosa*, and by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 1 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary

for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 2 (and) *Palmeria dolei*—Unit 11—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 11— Montane Wet This area consists of 4,075 ac (1,649 ha) of State land, 9,633 ac (3,898 ha) of privately owned land, and 875 ac (354 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Puukaukanu and upper Waihoi Valley, on the northern and northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Geranium hanaense*, *G. multiflorum*, and *Wikstroemia villosa*, and by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 2 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea glabra*, *C. maritae*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, and *Schiedea jacobii*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 3 (and) *Palmeria dolei*—Unit 12—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 12— Montane Wet This area consists of 2,228 ac (902 ha) of federally owned land (Haleakala National Park) in Kipahulu Valley, on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. maritae*, and *Melicope ovalis*, and by the forest bird, kiwikiu (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 3 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea duvalliorum*, *C. glabra*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest bird, the akohekohe (*Palmeria dolei*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small

numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 4 (and) *Palmeria dolei*—Unit 13—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 13— Montane Wet This area consists of 180 ac (73 ha) of State land and 1,653 ac (669 ha) of federally owned land (Haleakala National Park), in Kaapahu Valley on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *Cyrtandra ferripilosa*, and *Huperzia mannii*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 4 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea duvalliorum*, *C. glabra*, *C. mceldowneyi*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 5 (and) *Palmeria dolei*—Unit 14—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 14— Montane Wet This area consists of 222 ac (90 ha) of State land, and 165 ac (67 ha) of federally owned land (Haleakala National Park), near Kaumakani on the eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units area occupied by the plant *Bidens campylotheca* ssp. *pentamera*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 5 is not currently occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 1 (and) *Palmeria dolei*—Unit 30—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 30— Wet Cliff This area consists of 290 ac (117 ha) of privately owned land along the wall of Keanae Valley on the northern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). Although Maui—Wet Cliff— Unit 1 is not currently occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Cyanea copelandii* ssp. *haleakalaensis*, *Cyanea horrida*, *Melicope ovalis*, *Phyllostegia bracteata*, *P. haliakalae*, or *Plantago princeps*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 2 (and) *Palmeria dolei*—Unit 31—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 31— Wet Cliff This area consists of 475 ac (192 ha) of State land, 20 ac (8 ha) of privately owned land, and 912 ac (369 ha) of federally owned land (Haleakala National Park), from Kalapawili Ridge along Kipahulu Valley and north to Puuhoolio, on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). They are occupied by the plants *Bidens campylotheca* ssp. *waihoiensis*, *Cyanea copelandii* ssp. *haleakalaensis*, *Melicope ovalis*, *Phyllostegia bracteata*, and *Plantago princeps*. These units also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Wet Cliff—Unit 2 is not known to be occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Cyanea horrida*, or *Phyllostegia haliakalae*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 3 (and) *Palmeria dolei*—Unit 32—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 32— Wet Cliff This area consists of 5 ac (2 ha) of State land and 433 ac (175 ha) federally owned land (Haleakala National Park) along the south rim of Kipahulu Valley on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). Although Maui—Wet Cliff— Unit 3 is not currently occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. horrida*, *Melicope ovalis*, *Phyllostegia bracteata*, *P. haliakalae*, or *Plantago princeps*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 4 (and) *Palmeria dolei*—Unit 33—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 33—Wet Cliff This area consists of 184 ac (75 ha) of State land along the north wall of Waihoi Valley, on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). They are occupied by the plant *Bidens campylotheca* ssp. *pentamera* and *B. campylotheca* ssp. *waihoiensis*, and contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Wet Cliff—Unit 4 is not known to be occupied by the plants *Cyanea copelandii* ssp. *haleakalaensis*, *C. horrida*, *Melicope ovalis*, *Phyllostegia bracteata*, *P. haliakalae*, or *Plantago princeps*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea copelandii* ssp. *haleakalaensis* critical habitat consists of four components. Lowland mesic (east Maui), Lowland wet (east Maui), Montane wet (east Maui) and Wet cliff (east Maui) (81 FR 17790-18110):

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Ecosystem: Lowland Wet. Elevation: <3,330 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Ecosystem: Montane Wet. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: >75 in (>190 cm). Substrate: Well-developed soils, montane bogs. Canopy: *Acacia*, *Charpentiera*, *Cheirodendron*, *Metrosideros*. Subcanopy: *Broussaisia*, *Cibotium*, *Eurya*, *Ilex*, *Myrsine*. Understory: *Ferns*, *Carex*, *Coprosma*, *Leptecophylla*, *Oreobolus*, *Rhynchospora*, *Vaccinium*.

Ecosystem: Wet Cliff. Elevation: unrestricted. Annual precipitation: >75 in (>190 cm). Substrate: >65 degree slope, shallow soils, weathered lava. Canopy: None. Subcanopy: *Broussaisia*, *Cheirodendron*, *Leptecophylla*, *Metrosideros*. Understory: *Bryophytes*, *Ferns*, *Coprosma*, *Dubautia*, *Kadua*, *Peperomia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the

conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through

6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D’Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History**Food/Nutrient Resources****Lifespan**

Adult: < 10 years (USFWS, 2011)

Breeding Season

Adult: Unknown (USFWS, 2002)

Key Resources Needed for Breeding

Adult: Unknown (USFWS, 2002)

Reproduction Narrative

Adult: It is a short-lived perennial (fewer than ten years) (USFWS, 2011). Flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors are unknown (U.S. Fish and Wildlife Service 1999b, 2002b) (USFWS, 2002).

Habitat Type

Adult: Terrestrial (NatureServe, 2015); riparian (USFWS, 2002)

Habitat Vegetation or Surface Water Classification

Adult: Montane and mesic koa and ohia forest, wet scree (USFWS, 2002)

Geographic or Habitat Restraints or Barriers

Adult: 2,015 - 4,625 ft. elevation (USFWS, 2002)

Habitat Narrative

Adult: Inhabits wet forests (NatureServe, 2015). *Cyanea copelandii* ssp. *haleakalaensis* is found on stream banks and wet scree (a sloping mass of rocks at the base of a cliff) slopes and forest understory in montane wet or mesic forest dominated by *Acacia koa* (koa) and/or *Metrosideros polymorpha* (ohia) at elevations between 615 and 1,410 meters (2,015 to 4,625 feet) (USFWS, 2002).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: The fruits of *Cyanea copelandii* subsp. *haleakalaensis* are able to float and disperse via stream flow (Oppenheimer 2009) (USFWS, 2011).

Population Information and Trends**Population Trends:**

Not available

Resiliency:

Very low (inferred from USFWS, 2011)

Redundancy:

High (inferred from USFWS, 2011)

Number of Populations:

25 (USFWS, 2011)

Population Size:

300-500 (USFWS, 2018)

Population Narrative:

Currently, there are 25 widely distributed populations containing more than 300 individuals in East Maui (Bily et al. 2008) (USFWS, 2011).; Additional, new occurrences of *Cyanea copelandii* subsp. *haleakalaensis* were found at Kūhiwa Valley (about 10 individuals), Kawaipapa (at least one individual), and at 'Ohe'o (Kīpahulu; large patches) (Oppenheimer 2018, in litt.). Including those populations last monitored in 2007 (Wailua Iki and east Makaīwa), the total number of individuals remains around 300 to 500 (Bruegmann et al. 2016; Oppenheimer 2018, in litt.). (USFWS, 2018)

Threats and Stressors

Stressor: Nonnative species (USFWS, 2011)

Exposure:

Response:**Consequence:**

Narrative: Feral pigs (*Sus scrofa*) degrade habitat at most sites, although little pig damage was observed at the Wailua Nui region. Invasive introduced plant species that degrade habitat and compete with *Cyanea copelandii* subsp. *haleakalaensis* include *Ageratina adenophora* (sticky snakeroot), *Axonopus fissifolius* (carpetgrass), *Clidemia hirta* (Koster's curse), *Cortaderia jubata* (pampas grass), *Hedychium flavescens* (yellow ginger), *H. gardnerianum* (Kahili ginger), *Hypochoeris radicata* (hairy cat's ear), *Juncus planifolius* (rush), *Paspalum conjugatum* (Hilo grass), *P. urvillei* (vasey grass), *Pluchea carolinensis* (sourbush), *Prunella vulgaris* (selfheal), *Psidium cattleianum* (strawberry guava), *Rhynchospora caduca* (beak rush), *Rubus argutus* (blackberry), *Setaria palmifolia* (palmgrass), *Rubus rosifolius* (thimbleberry), and *Tibouchina herbacea* (glorybush) (Oppenheimer 2009; Perlman 2009; Wood 2009) (USFWS, 2011).

Stressor: Stochastic events (USFWS, 2011)

Exposure:**Response:****Consequence:**

Narrative: Flooding and landslides are also a threat to *Cyanea copelandii* subsp. *haleakalaensis* (Oppenheimer 2009) (USFWS, 2011).

Stressor: Predation (USFWS, 2011)

Exposure:**Response:****Consequence:**

Narrative: Seed predation by rats (*Rattus* spp.) and consumption of leaves and stems by slugs (unidentified species) and mongoose (*Herpestes javanicus*) are threats to *Cyanea copelandii* subsp. *haleakalaensis* (Perlman 2009; USFWS 2002; Wood 2009) (USFWS, 2011).

Stressor: Climate change (USFWS, 2011; USFWS, 2018))

Exposure:**Response:****Consequence:**

Narrative: Climate change may pose a threat to this subspecies. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawai'i using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) was conducted at the species level and concluded that *Cyanea copelandii* is vulnerable to the impacts of climate change, with a vulnerability score of 0.447 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2018)

Stressor: Lack of adequate hunting regulations (USFWS, 2018)

Exposure:**Response:****Consequence:**

Narrative: Three populations of *Cyanea copelandii* subsp. *haleakalaensis* occur in state hunting areas (Puohokamoa, Waiokamilo to Wailua Iki, and Kawaiipapa). Nonnative feral ungulates pose a

major ongoing threat to all native species, including *C. copelandii* subsp. *haleakalaensis*, through destruction and modification of habitat, and through direct herbivory or predation. Feral pigs have been noted as a threat to the species. Public hunting areas are not fenced and game mammals have unrestricted access to most areas across the landscape, regardless of underlying land use designation; therefore, any unfenced populations are at risk (DLNR 2010). (USFWS, 2018)

Stressor: Lack of adequate biosecurity legislation (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Invasion of the State of Hawai'i by invasive nonnative plant species, and destruction of habitat and competition by nonnative plants are threats to *Cyanea copelandii* subsp. *haleakalaensis*. The U.S. Department of Agriculture, Animal and Plant Health Inspection Service, Plant Protection and Quarantine, is authorized to prevent the introduction or dissemination of animal and plant pests on all ships, aircraft, and their cargo and baggage arriving in the U.S. and its territories; however, pest species continue to enter the State. In addition, Federal import regulations do not address many species that could be pests in Hawai'i (CGAPS 2009; Ikuma et al. 2002). (USFWS, 2018)

Stressor: Invasive species (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Established invasive plant species competition—Nonnative plant species, particularly *Clidemia hirta* (*clidemia*), compete with *Cyanea copelandii* subsp. *haleakalaensis* for water, light, and nutrients (HNP 2012). *Clidemia hirta* is widespread and naturalized in forests throughout Hawai'i. (USFWS, 2018)

Stressor: Reduced viability due to low numbers (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Small, isolated populations often exhibit reduced levels of genetic variability, which diminishes the species' capacity to adapt and respond to environmental changes, thereby lessening the probability of long-term persistence (Barrett and Kohn 1991; Newman and Pilson 1997). The problems associated with small population size and vulnerability to random demographic fluctuations or natural catastrophes are further magnified by synergistic interactions with other threats, such as anthropogenic impacts like habitat loss from human development or predation by nonnative species. Very small plant populations may experience reduced reproductive vigor due to ineffective pollination or inbreeding depression. Small numbers are noted as a cause of loss of reproductive vigor of *Cyanea copelandii* subsp. *haleakalaensis* (Bruegmann et al. 2016). (USFWS, 2018)

Recovery

Reclassification Criteria:

1. A total of five to seven populations should be documented on islands where it now occurs or occurred historically (USFWS, 2002).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure with the following minimum numbers of mature individuals per population: 300 for short-lived perennials (USFWS, 2002).
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 2002).

Delisting Criteria:

1. A total of 8 to 10 populations should be documented on islands where it now occurs or occurred historically (USFWS, 2002).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with the following minimum numbers of mature individuals per population: 300 for short-lived perennials (USFWS, 2002).
3. Each population should persist at this level for a minimum of five consecutive years (USFWS, 2002).

Recovery Actions:

- Protect habitat and control threats (USFWS, 2002).
- Expand existing wild populations (USFWS, 2002).
- Conduct essential research (USFWS, 2002).
- Develop and maintain monitoring plans (USFWS, 2002).
- Reestablish wild populations within the historic range (USFWS, 2002).
- Validate and revise recovery criteria (USFWS, 2002).
- Construct exclosures to protect populations against feral ungulates (USFWS, 2002).
- Maintain adequate genetic stock (USFWS, 2002).
- Control competing alien plant species (USFWS, 2002).
- Enhance wild populations and establish new populations (USFWS, 2002).
- Surveys and inventories—Continue to survey for additional populations of *Cyanea copelandii* subsp. *haleakalaensis* in areas of potentially suitable habitat. (USFWS, 2018)
- Ungulate monitoring and control—Continue to construct and maintain fenced exclosures to protect individuals from the negative impacts of feral ungulates. Protect all occurrences against browsing and habitat disturbances from feral ungulates. (USFWS, 2018)
- Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations. Control invasive nonnative species that compete with the species around all populations. (USFWS, 2018)
- Climate change adaptation strategy—Assess the modeled effects of climate change on this subspecies, and determine future landscape needed for the recovery of the subspecies. (USFWS, 2018)
- Captive propagation for genetic storage and reintroduction—Continue propagation efforts for maintenance of genetic stock. (USFWS, 2018)

- Reintroduction and translocation—Reintroduce individuals into suitable habitat within historic range, and outside of Haleakalā National Park, that is being managed for known threats to this subspecies. (USFWS, 2018)
- Predator and herbivore monitoring and control—Implement effective control methods for rodents at the last known location. Develop and implement an effective method of slug control (USFWS, 2018)
- Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from landslides and flooding. (USFWS, 2018)

Conservation Measures and Best Management Practices:

- Fence all populations to provide protection against the negative impacts of feral ungulates (USFWS, 2011).
- Maintain adequate genetic stock for populations outside the National Park, as well as those in the Park boundaries (USFWS, 2011).
- Control invasive introduced plant species in all populations (USFWS, 2011).
- Control rats in the vicinity of these populations (USFWS, 2011).
- Develop and implement an effective method of slug control (USFWS, 2011).
- Propagate for reintroduction augmentation (USFWS, 2011).
- Conduct a thorough survey throughout the current and historical range of the species to determine the current status (USFWS, 2011).
- Work with Hawaii Division of Forestry and Wildlife, National Park Service, East Maui Watershed Partnership Program, and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2011).

SPECIES ACCOUNT: *Cyanea dolichopoda* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 05/14/2010; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Cyanea dolichopoda (haha) is a shrub in the bellflower family (Campanulaceae). Shrub, 1 m tall, erect, with stem unbranched. Leaf blades ovate or oblong, 6.5-10 cm long, 3.7-5.8 cm wide, bases cordate, often markedly asymmetric. Petioles 9-16 cm long, slender. Inflorescences (not fully expanded) spreading or pendent, 8-11-flowered. Corollas (in bud) pinkish. (NatureServe, 2015; USFWS, 2016)

Current Range

Cyanea dolichopoda was first collected in 1990 at Blue Hole, Kauai. The only mature individual and two seedlings could not be relocated after Hurricane Iniki in 1992. Currently, there are no known individuals. (USFWS, 2017)

Critical Habitat Designated

Yes; 4/13/2010.

Legal Description

On April 13, 2010, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea dolichopoda* (`Akoko) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes three critical habitat units (CHUs), in Hawaii (75 FR 18960-19165).

Critical Habitat Designation

The critical habitat designation for *Cyanea dolichopoda* includes three CHUs in Kauai County, Hawaii. Note: This species may no longer occur naturally in the wild, therefore there is no known occupied critical habitat for this species. The critical habitat units for this species have been determined to be essential to the conservation of the species because the area provides for the reestablishment of populations within the species' historical range (75 FR 18960-19165).

Kauai—Wet Cliff—Section 1: Wet Cliff—Section 1 consists of 190 ac (77 ha) in the wet cliff ecosystem, including cliffs along the rim of Kalalau Valley from Alealeau to Pihea, on Stateowned land in the Na Pali Coast State Park and the Hono o Na Pali NAR (Figure 6-A). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70b, and is occupied by the plant *Chamaesyce remyi* var. *remyi*. This section includes the wet cliffs, the moisture regime, and subcanopy and understory plant species identified as PCEs in the wet cliff ecosystem (Table 3). Although Wet Cliff—Section 1 is not known to be occupied by the plants *Chamaesyce remyi* var. *kauaiensis*, *Cyanea dolichopoda*, *Cyrtandra oenobarbara*, *C. paliku*, *Dubautia plantaginea* ssp. *magnifolia*, *Lysimachia iniki*, *L. pendens*, *L. venosa*, and *Platydesma rostrata*, we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historical range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Wet Cliff—Section 2: Wet Cliff—Section 2 consists of 784 ac (317 ha) in the wet cliff ecosystem, and includes the cliffs at the headwaters of the Wailua River or “Blue Hole,” on State (778 ac, 315 ha) and privately owned (6 ac, 3 ha) land in the LihueKoloa Forest Reserve (Figure 6-B). There are 489 ac (198 ha) within previously designated critical habitat and 296 ac (120 ha) of newly designated critical habitat on State-owned land. The portion of the section that is in previously designated critical habitat falls within Critical Habitat Unit 10 of 50 CFR 17.99(a)(1), Map 36b. The newly designated portion of the section comprises Critical Habitat Unit 18 of 50 CFR 17.99(a)(1), Map 217a. This section is occupied by the plants *Chamaesyce remyi* var. *kauaiensis*, *Cyrtandra oenobarba*, *Dubautia plantaginea* ssp. *magnifolia*, *Lysimachia iniki*, *L. pendens*, and *Platydesma rostrata*. The section includes the wet cliffs, the moisture regime, and subcanopy and understory plant species identified as PCEs in the wet cliff ecosystem (Table 3). Although Wet Cliff—Section 2 is not known to be occupied by the plants *Chamaesyce remyi* var. *remyi*, *Cyanea dolichopoda*, *Cyrtandra paliku*, and *Lysimachia venosa*, we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Wet Cliff—Section 3: Wet Cliff—Section 3 consists of 61 ac (24 ha) in the wet cliff ecosystem, including cliffs below Kekoiki, on State (8 ac, 3 ha) and privately owned (53 ac, 22 ha) land in the Halelea, Moloaa and Kealia forest reserves (Figure 6-C). There are 23 ac (9 ha) of newly designated critical habitat on privately owned land within this section. That portion of the section that falls within previously designated critical habitat is within Critical Habitat Unit 4 of 50 CFR 17.99(a)(1), Map 5a. The newly designated portion of the section comprises Critical Habitat Unit 19 of 50 CFR 17.99(a)(1), Map 217b. This section is occupied by the plant *Cyrtandra paliku*, and includes the wet cliffs, the moisture regime, and subcanopy and understory plant species identified as PCEs in the wet cliff ecosystem (Table 3). Although Wet Cliff—Section 3 is not known to be occupied by the plants *Chamaesyce remyi* var. *kauaiensis*, *C. remyi* var. *remyi*, *Cyanea dolichopoda*, *Cyrtandra oenobarba*, *Dubautia plantaginea* ssp. *magnifolia*, *Lysimachia iniki*, *L. pendens*, *L. venosa*, and *Platydesma rostrata*, we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea dolichopoda* critical habitat consists of one component (Wet cliff) (75 FR 18960-19165):

Ecosystem: Wet Cliff. Elevation: unrestricted. Annual precipitation: >75 in (>190 cm). Substrate: >65 degree slope, shallow soils, weathered lava. Canopy: None. Subcanopy: *Broussaisia*, *Cheirodendron*, *Leptecophylla*, *Metrosideros*. Understory: *Bryophytes*, *Ferns*, *Coprosma*, *Dubautia*, *Kadua*, *Peperomia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contains the physical or biological features essential to the conservation of the species that may require special management considerations or protection. It is recognized that activities in and adjacent to areas designated as critical habitat may affect one or more of the PCEs found in these areas. Special management is needed throughout each of the designated critical habitat units. The following discussion of special management needs is applicable to each of the 47 Kauai species for which we are designating critical habitat. These 47 Kauai species include 41 species that are currently found in the wild, and 6 species that are not currently extant in the wild. For each of the 41 Kauai species found in the wild, we have determined that the features essential to their conservation are primarily dependent on maintaining the successful functioning of the ecosystem(s) in which they occur (Tables 3 and 4). In some cases, additional species-specific primary constituent elements have also been identified (Table 4). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical and biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, predation by nonnative species, competition with nonnative species, hurricanes, landslides, flooding, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by feral ungulates (pigs, goats, and black-tailed deer). Feral ungulates also impact the habitat through predation and trampling. The State of Hawaii provides game mammal (feral pigs and goats, and black-tailed deer) hunting opportunities on one or more State-designated public hunting areas on the islands of Kauai, Oahu, Maui, Molokai, Lanai, and Hawaii (Hawaii Administrative Rules 13-123; DLNR 2009a). Management of game animals by the State ranges from providing maximal sustained public hunting opportunities and benefits (e.g., “sustained yield”) in some areas to game animal removal by State staff, or their designees, in other areas (DLNR 2009b). Public hunting areas are not fenced, and game mammals have unrestricted access to most areas across the landscape, regardless of the underlying land use designation. While fences are sometimes built to provide protection from game mammals to the natural resources within the fenced area, the current number and locations of fences are not sufficient to prevent habitat destruction and degradation. Without special management, the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new alien plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species will help to address the threat presented by fire to three critical habitat areas in particular (Kauai—Lowland Mesic— Section 1, Kauai—Montane Mesic— Section 2, and Kauai—Dry Cliff— Section 1; see Table 5 for corresponding CFR unit numbers). This threat is primarily due to the presence of nonnative species, such as the grasses *Andropogon* sp. and *Setaria* sp., which increase the fuel load and quickly regenerate after a fire. These species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D’Antonio and Vitousek 1992, pp. 64– 66; Brooks et al. 2004, p. 680). In addition, five sections (Kauai—Dry

Cliff—Section 1, Kauai—Dry Cliff— Section 2, Kauai—Wet Cliff—Section 1, Kauai—Wet Cliff—Section 2, and Kauai—Wet Cliff—Section 3; see Table 5 for corresponding CFR unit numbers) may require special management to reduce the threat of landslides and flooding, which threaten to further degrade the habitat conditions and have the potential to eliminate some species in their entirety (e.g., *Schiedea attenuata*). In summary, we find that each of the areas we are designating as critical habitat contains features essential to the conservation of the species that may require special management considerations or protection to ensure the conservation of the 47 Kauai species. These special management considerations and protections are required to preserve and maintain the essential features provided to these species by the ecosystems upon which they depend. A more detailed discussion of each of these threats is presented above, under the Summary of Factors Affecting the Species section.

Life History

Food/Nutrient Resources

Habitat Type

Adult: Terrestrial (inferred from NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Cliffs (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: High rainfall (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at approximately 2,300 feet (USFWS, 2010)

Environmental Specificity

Adult: Medium, with some key requirements (USFWS, 2010)

Habitat Narrative

Adult: *Cyanea dolichopoda* occurs in a deep and extremely wet valley head surrounded on three sides by vertical cliffs 900 meters (m) (2,953 feet (ft)) high and laced with waterfalls. The vegetation is an unusual mix of shrubland and low-statured rainforest on saturated rocky ground. The canopy is just 1 to 3 m (3.3 to 9.9 ft) tall, and the ground layer is rich in ferns and fern allies (Lammers and Lorence 1993). The canopy is *Metrosideros polymorpha* (ohia) lowland wet shrubland with the associated native species *Cyanea asarifolia* (haha), *Cyrtandra* sp. (haiwale), *Kadua elatior* (awiwi), *Lysimachia filifolia* (NCN), *Pipturus albidus* (mamake), *Touchardia latifolia* (olona) (NTBG 1990; Lammers and Lorence 1993). (USFWS, 2017)

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Not available.

Population Information and Trends

Population Trends:

Not available.

Redundancy:

Very low (inferred from NatureServe, 2015)

Number of Populations:

1 (NatureServe, 2015)

Population Narrative:

In June 1990, a single mature individual and a few seedlings of an undescribed species of *Cyanea* was discovered on the south side of Blue Hole, a relatively inaccessible site located at the headwaters of the Wailua River, at about 700 m (2,297 ft) elevation (NTBG 1990; Lammers and Lorence 1993). The species was named *Cyanea dolichopoda*. In October 1992, six weeks after Hurricane Iniki, a survey revealed that all known individuals of this species had been destroyed. It is likely that additional plants survive on cliffs surrounding Blue Hole, although the vertical aspect and great height of the cliffs makes them difficult to explore (Lammers and Lorence 1993; Perlman 2007, as cited in USFWS 2010a). Numerous surveys have been conducted at the holotype region, along with nearby locations, but no individuals have ever been located (Wood 2015). (USFWS, 2017)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from non-native plants, hurricanes, landslides, and climate change. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Landslides destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities.

Stressor: Predation and herbivory (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species present an immediate and significant threat to *Cyanea dolichopoda* throughout its range due to , and documented mechanical damage by nonnative invertebrates (USFWS, 2010).

Stressor: Small populations (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: *Cyanea dolichopoda* has not been confirmed to persist in the wild. This species is not in storage or propagation, but individuals familiar with this species believe it may possibly remain extant and that much of its suitable habitat (lowland mesic, lowland wet, and wet cliff) on Kauai remains to be surveyed (USFWS, 2010).

Stressor: Established ecosystem-altering invasive plant modification and destruction of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Invasive introduced plant species modify habitats occupied by native plant species by changing the availability of light, altering soil-water regimes, modifying nutrient cycling, and changing the fire characteristics of the native plant community. Invasive introduced plants impacting *Cyanea dolichopoda* are *Erigeron karvinskianus* (daisy fleabane), *Psidium* spp. (guava), and *Toona ciliata* (Australian red cedar) (KRCF 2014). (USFWS, 2017)

Stressor: Lack of adequate hunting regulations (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Nonnative feral ungulates pose a major ongoing threat to native species through destruction and modification of habitat, and by direct herbivory or predation. Management of game animals by the State ranges from providing maximal sustained public hunting opportunities and benefits (i.e., sustained yield) in some areas, with one animal allowed per day; to other areas with as few as one animal allowed per year (DLNR 2010). Public hunting areas are not fenced and game mammals have unrestricted access to most areas across the landscape, regardless of underlying land use designation. The only known population of *Cyanea dolichopoda* occurred in a State hunting area in Lihue-Koloa Forest Reserve (mammal hunting area). This area is not fenced. (USFWS, 2017)

Stressor: Lack of adequate biosecurity legislation (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Invasion of the State of Hawaii by invasive nonnative plant species, and destruction of habitat and competition by nonnative plants are threats to *Cyanea dolichopoda*. The U.S. Department of Agriculture, Animal and Plant Health Inspection Service, Plant Protection and Quarantine, is authorized to prevent the introduction or dissemination of animal and plant pests on all ships, aircraft, and their cargo and baggage arriving in the U.S. and its territories; however, pest species continue to enter the State. In addition, Federal import regulations do not address many species that could be pests in Hawaii (CGAPS 2009; Ikuma et al. 2002). (USFWS, 2017)

Recovery

Reclassification Criteria:

To meet the interim stage of recovery of *Cyanea dolichopoda*, 600 mature individuals are needed in one population and all major threats must be controlled around the population designated for recovery at this stage. There should also be demonstrated regeneration of

seedlings and growth to at least sapling stage for woody species and documented replacement regeneration within each of the target populations. The population must be adequately represented in an ex situ collection as defined in the Center for Plant Conservation's guidelines (Guerrant et al. 2004). Adequate monitoring must be in place and conducted to assess individual plant survival, population trends, trends of major limiting factors, and response of major limiting factors to management. (USFWS, 2017)

In addition to achieving 5 to 10 populations with 1,000 mature individuals per population and all of the goals of the interim stage, all target populations must be stable, secure, and naturally reproducing for a minimum of 10 years. Species-specific management actions are not ruled out. Downlisting should not be considered until an adequate population viability analysis (PVA) has been conducted to assess needed numbers more accurately based on current management and monitoring data collected at regular intervals determined by demographic parameters of the species, although they should only be one of the factors used in making a decision to downlist. Information necessary for the PVA that should be available through monitoring (ideally annually) includes: major limiting factors, breeding system, population structure and density, and proven management methods for major threats. (USFWS, 2017)

Delisting Criteria:

In addition to achieving 5 to 10 populations with 1,000 mature individuals per population and all of the goals of the interim and downlisting stages, all target populations must be stable, secure, naturally reproducing, and within secure and viable habitats for a minimum of 20 years. Species-specific management actions must no longer be necessary, but ecosystem-wide management actions are not ruled out if there are long-term agreements in place to continue management. These numbers are initial targets, but may be revised upward as additional information is available, including adequate PVAs for individual species based on current management and monitoring data collected at regular intervals determined by demographic parameters of the species, although they should only be one of the factors used in making a decision to delist. Genetic analyses should be conducted to ensure that adequate genetic representation is present within and among populations compared to the initial variation assessed in the interim stage. Numbers need to be considered on a species-by-species basis. (USFWS, 2017)

Recovery Actions:

- Assess the distribution, current status, and potential future distribution of existing ecosystems and determine the most important sites for ecosystem management. Make use of landscape modeling, spatial analysis, remote sensing technology, and existing survey data to better understand species distributions and priority ecosystem areas for targeting future surveys. (USFWS, 2010)
- Initiate control of ecosystem-modifying threats, such as ungulates and invasive introduced plant species, as soon as possible within the highest priority management units. (USFWS, 2010)
- Stabilize and protect remaining extant populations of the 45 plants and 2 bird species. Conduct systematic, island-wide surveys for additional populations. Make use of landscape modeling, spatial analysis, remote sensing technology, and existing survey data to better understand distributions and priority areas for targeting future surveys. (USFWS, 2010)
- Restore and maintain multiple viable populations of the 45 plants and 2 bird species by protecting, restoring, and maintaining existing habitats or areas with potential for restoration that are within their historical range. (USFWS, 2010)

- Conduct research on control methods for introduced slugs and avian malaria. (USFWS, 2010)
- Develop an augmentation plan to collect and propagate seed from the 45 plant species that can later be utilized for population restoration, augmentation, and reintroduction. (USFWS, 2010)
- Prevent the influx of new pests and invasive species into recovery areas. Increase the efforts of the Kauai Invasive Species Committee and improve border security. (USFWS, 2010)
- Prioritize research studies that will provide information and tools aiding in the mitigation of known threats and limiting factors of the species and ecosystems. (USFWS, 2010)
- Increase outreach effort and coordination with State agencies and private landowners regarding ecosystem conservation. Promote opportunities to assist in the recovery of these species through Habitat Conservation Plans, Safe Harbor Agreements, and through various conservation partnerships funded by State and Federal agencies and private organizations. (USFWS, 2010)
- Surveys and inventories—Survey suitable habitat to find new populations. Consider utilizing Unmanned Aerial Vehicles to survey inaccessible cliff habitat to confirm extirpation from the Blue Hole known location. (USFWS, 2017)
- Ungulate monitoring and control—Fence any populations found to protect them from the impacts of feral ungulates. Control feral ungulates within fenced exclosures. (USFWS, 2017)
- Invasive plant monitoring and control—Control invasive plant species around any populations found. (USFWS, 2017)
- Captive propagation for genetic storage and reintroduction—Collect material for genetic storage and propagation for reintroduction from any individuals found. (USFWS, 2017)
- Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from landslides and storms. (USFWS, 2017)
- Based on the recovery criteria above, consider development of a recovery plan. (USFWS, 2017)

Conservation Measures and Best Management Practices:

SPECIES ACCOUNT: *Cyanea dunbarii* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/10/1996; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Cyanea dunbarii is a branched shrub 1.5 to 2 m (4.9 to 6.6 ft) tall. The oval to broadly elliptic leaves are 10 to 22 cm (3.9 to 8.7 in) long and 6 to 14 cm (2.4 to 5.5 in) wide, with irregularly lobed or cleft margins. The flowers are arranged in groups of six to eight on a stalk, which is 3 to 7 cm (1.2 to 2.8 in) long. The corolla is white, tinged or striped with pale lilac and 30 to 38 mm (1.2 to 1.5 in) long. The corolla is slightly curved, with spreading lobes three-fourths as long as the tube. This species is distinguished from others in this endemic Hawaiian genus by the lack of prickles on the stems and the irregularly lobed and cleft leaf margins (Lammers 1990). (USFWS, 1998)

Taxonomy

A member of the bellflower family (Campanulaceae) (USFWS, 1998).

Historical Range

Historically known from Waihanau and Waialaie valleys on Molokai. (NatureServe, 2015)

Current Range

This species is current known from Mokokoko Gulch on Molokai. (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/18/2003.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea dunbarii* (aka *Cyanea dunbariae*) (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes five detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea dunbarii* includes five CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Molokai—Lowland Mesic—Unit 1 (and) *Palmeria dolei*—Unit 37—Lowland Mesic (and) *Pseudonestor xanthophrys*—Unit 37— Lowland Mesic This area consists of 3,489 ac (1,412 ha) of State land, and 5,281 ac (2,137 ha) of privately owned land, from Waihanu Gulch to Mapulehu, in central Molokai. These units are occupied by the plants *Alectryon macrococcus*, *Ctenitis squamigera*, *Cyanea dunbariae*, *C. mannii*, *C. profuga*, *Cyperus fauriei*, *Cyrtandra filipes*, *Gouania hillebrandii*, *Labordia triflora*, *Neraudia sericea*, *Santalum haleakalae* var. *lanaiense*, *Schiedea lydgatei*, *S. sarmentosa*, *Silene alexandri*, *S. lanceolata*, *Spermolepis hawaiiensis*, and *Zanthoxylum hawaiiense*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). These units also contain unoccupied

habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Lowland Mesic—Unit 1 is not known to be occupied by *Asplenium dielirectum*, *Bonamia menziesii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea procera*, *C. solanacea*, *Diplazium molokaiense*, *Festuca molokaiensis*, *Flueggea neowawraea*, *Isodendrion pyriformis*, *Kadua laxiflora*, *Melicope mucronulata*, *M. munroi*, *M. reflexa*, *Phyllostegia haliakalae*, *P. mannii*, *P. pilosa*, *Sesbania tomentosa*, *Stenogyne bifida*, or *Vigna o-wahuensis*, or the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Lowland Wet—Unit 1 (and) *Palmeria dolei*—Unit 38—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 38— Lowland Wet This area consists of 2,195 ac (888 ha) of State land, and 754 ac (305 ha) of privately owned land (partly within The Nature Conservancy's Pelekunu Preserve), from Pelekunu Valley to Wailau Valley, in north-central Molokai. These units are occupied by the plant *Cyrtandra filipes*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Lowland Wet—Unit 1 is not known to be occupied by *Asplenium dielirectum*, *Bidens wiebkii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea dunbariae*, *C. grimesiana* ssp. *grimesiana*, *C. solanacea*, *Lysimachia maxima*, *Melicope reflexa*, *Peucedanum sandwicense*, *Phyllostegia hispida*, *P. mannii*, *Plantago princeps*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Lowland Wet—Unit 2 (and) *Palmeria dolei*—Unit 39—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 39— Lowland Wet This area consists of 1,356 ac (549 ha) of State land and 594 ac (241 ha) of privately owned land, from Kahanui to Pelekunu Valley, in north-central Molokai. These units are occupied by the plant *Lysimachia maxima*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Lowland Wet—Unit 2 is not known to be occupied by *Asplenium dielirectum*, *Bidens wiebkii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea dunbariae*, *C. grimesiana* ssp. *grimesiana*, *C. solanacea*, *Cyrtandra filipes*, *Melicope reflexa*, *Peucedanum sandwicense*, *Phyllostegia hispida*, *P. mannii*, *Plantago princeps*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary

for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Lowland Wet—Unit 3 consists of 94 ac (38 ha) of State land, and 3,125 ac (1,265 ha) of privately owned land, from Waiahookalo gulch to Moaula stream and Puniuohua, on eastern Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). Although Molokai—Lowland Wet—Unit 3 is not known to be occupied by *Asplenium dielerectum*, *Bidens wiebkei*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea dunbariae*, *C. grimesiana* ssp. *grimesiana*, *C. solanacea*, *Cyrtandra filipes*, *Lysimachia maxima*, *Melicope reflexa*, *Peucedanum sandwicense*, *Phyllostegia hispida*, *P. mannii*, *Plantago princeps*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Montane Mesic—Unit 1 (and) *Palmeria dolei*—Unit 42—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 42—Montane Mesic This area consists of 257 ac (104 ha) of State land, and 559 ac (226 ha) of privately owned land from Kamiloloa to Makolelau in central Molokai. These units are occupied by the plants *Alectryon macrococcus*, *Bidens wiebkei*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Montane Mesic—Unit 1 is not known to be occupied by *Asplenium dielerectum*, *Cyanea dunbariae*, *C. mannii*, *C. procera*, *C. solanacea*, *Cyperus fauriei*, *Kadua laxiflora*, *Melicope mucronulata*, *Neraudia sericea*, *Plantago princeps*, or *Stenogyne bifida*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwiku* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea dunbarii* critical habitat consists of three components. Lowland mesic (Molokai), Lowland wet (Molokai) and Montane mesic (Molokai) (81 FR 17790-18110):

Ecosystem: Lowland Mesic. Elevation: <3,300 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Shallow soils, little to no herbaceous layer. Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*,

Melanthera, Osteomeles, Pleomele, Psydrax. Understory: Carex, Dicranopteris, Diplazium, Elaphoglossum, Peperomia.

Ecosystem: Lowland Wet. Elevation: <3,330 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: Antidesma, Metrosideros, Myrsine, Pisonia, Psychotria. Subcanopy: Cibotium, Claoxylon, Kadua, Melicope. Understory: Alyxia, Cyrtandra, Dicranopteris, Diplazium, Machaerina, Microlepia.

Ecosystem: Montane Mesic. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Deep ash deposits, thin silty loams. Canopy: Acacia, Ilex, Metrosideros, Myrsine, Nestegis, Nothocestrum, Pisonia, Pittosporum, Psychotria, Sophora, Zanthoxylum. Subcanopy: Alyxia, Charpentiera, Coprosma, Dodonaea, Kadua, Labordia, Leptecophylla, Phyllostegia, Vaccinium. Understory: Ferns, Carex, Peperomia.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire,

drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (inferred from USFWS, 1998)

Reproduction Narrative

Adult: Cyanea dunbarii was observed in flower, with immature fruit, in September (Hawaii Heritage Program (HHP) 1 993b). (USFWS, 1998)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 600 to 1,220 meters (USFWS, 1998)

Environmental Specificity

Adult: Medium, with some key requirements (USFWS, 1998)

Habitat Narrative

Adult: This species inhabits moist and wet forests on gulch slopes and gulch bottoms in hardwood forests (NatureServe, 2015). Cyanea dunbarii is found in mesic to wet Dicranopteris linearis (uluhe)-Metrosideros polymorpha (ohia) forest on moderate to steep slopes along a stream (HHP 1993a3; USEWS 1996a). Associated species include Perrottetia sandwicensis (olomea), Pipturus albidus (mamaki), Clermontia kakeana (haha), Cheirodendron trigynum (olapa), and Freycinetia arborea (ieie) (USEWS 1996a). This species typically grows on the sides of deep gulches in ohia-dominated mesic to wet forests at elevations of about 600 to 1,220 meters (1,980 to 4,000 feet) (USFWS 1992). (USFWS, 1998)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

Very low (inferred from USFWS, 2014)

Redundancy:

Very low (inferred from USFWS, 2014)

Number of Populations:

2 (USFWS, 2014; USFWS, 2018)

Population Size:

1 wild individuals, 28 outplanted individuals (USFWS, 2018)

Population Narrative:

There are two known populations of *Cyanea dunbariae*, both on the island of Molokai. The population at Mokomoko or Kapuna springs has declined to four individuals (Plant Extinction Prevention Program [PEPP] 2013). (USFWS, 2014); The population of four individuals reported in the last 5-year review had as many as 10 individuals at the time of designation of critical habitat in 2016; however, currently this population has declined to only one individual (PEPP 2017a). (USFWS, 2018)

Threats and Stressors

Stressor: Habitat alteration by pigs and deer (NatureServe, 2015)

Exposure:

Response:

Consequence:

Narrative: Alteration of habitat, especially the side gulch, is occurring due to the activities of feral pigs and axis deer and (USFWS 2008). (NatureServe, 2015)

Stressor: Predation (NatureServe, 2015)

Exposure:

Response:

Consequence:

Narrative: These plants are also threatened by slug and rat predation and bird damage (USFWS 2008). Rats (*Rattus* spp.) are a potential threat since they are in the area and are known to eat stems and fruits of other species of *Cyanea* (Cuddihy and Stone 1990). Axis deer (*Axis axis*) and pigs (*Sus scrofa*) are potential threats to this species, since they occur in areas adjacent to the only known population (USEWS 1996a; Ed Misaki, TNCH. personal communication 1991). Slugs (including *Milax gagates*) are widespread in Hawaii and a serious threat to many native plant taxa. Slugs feed preferentially on plants with fleshy leaves, stems, and fruits, including all taxa in the family Campanulaceae in Hawaii (Loyal Mehrhoff USEWS, in litt. 1995). (USFWS, 1998; NatureServe, 2015)

Stressor: Non-native plants (NatureServe, 2015)

Exposure:

Response:

Consequence:

Narrative: Non-native invasive plants that alter the habitat and compete with *C. dunbariae* include *Buddleia asiatica* (butterfly bush), *Commelina diffusa* (dayflower), *Erigeron karvinskianus* (daisy fleabane), *Hedychium* sp. (ginger), *Kalanchoe pinnata* (airplant), *Musa* sp. (banana), *Ricinus communis* (castor bean), *Psidium cattleianum* (strawberry guava), *Psidium guajava* (common guava), and *Rubus rosifolius* (thimbleberry) (USFWS 2008). (NatureServe, 2015)

Stressor: Small population size (NatureServe, 2015)

Exposure:

Response:

Consequence:

Narrative: Due to extremely small population size, natural disasters such as hurricanes, landslides, and droughts can be devastating (USFWS 2008). (NatureServe, 2015)

Stressor: Climate change (USFWS, 2014; USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Cyanea dunbariae* is highly vulnerable to the impacts of climate change. Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2014); The assessment by Fortini et al. (2013) concluded that *Cyanea dunbariae* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.727 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2018)

Stressor: Landslides and flooding destruction or degradation of habitat (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Landslides have been reported as a threat to *Cyanea dunbariae*. The only known individuals of this species occur in a steep, rocky area along a stream. Landslides, including tree falls and erosion associated with them, can have a significant effect on small populations by destabilizing substrate, altering hydrological patterns, and by damaging and destroying individual plants (PEPP 2014; Stearns 1985). (USFWS, 2018)

Stressor: Lack of adequate hunting regulations (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: The only known wild population of *Cyanea dunbariae* on Moloka'i occurs in a State hunting area in the Moloka'i Forest Reserve (FR). Nonnative feral ungulates pose a major ongoing threat to native species through destruction and modification of habitat, and through direct herbivory or predation. In addition, public hunting areas are not fenced and game mammals have unrestricted access to most areas across the landscape, regardless of underlying land use designation; therefore, any unfenced populations are at risk (DLNR 2010). Only one reintroduced population is protected within an enclosure. (USFWS, 2018)

Recovery

Reclassification Criteria:

1. A total of five to seven populations of each taxon should be documented on Molokai. (USFWS, 1998)

2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population. (USFWS, 1998)
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered. (USFWS, 1998)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Molokai. (USFWS, 1998)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 300 mature individuals per population. (USFWS, 1998)
3. Each population should persist at this level for a minimum of 5 consecutive years. (USFWS, 1998)

Recovery Actions:

- Immediate actions necessary for the prevention of extinction of these taxa include controlling or excluding ungulates (where possible); alien plant control; protection from fire; population and plant community monitoring and management; ex situ propagation (such as in a nursery or arboretum); and augmentation of populations, as appropriate. (USFWS, 1998)
- Long-term activities necessary for the perpetuation of these taxa in their natural habitats additionally include baseline and long-term research; public education; maintenance of fenced areas, fire breaks and fuel breaks; long-term monitoring and management of populations and communities; and re-establishment of populations within the historic ranges of some taxa. (USFWS, 1998)
- Further research regarding current range, reproduction and reproductive status, pollinators, life history, limiting factors, habitat requirements, and minimum viable population sizes is needed to facilitate appropriate management decisions regarding the long-term perpetuation of each of these taxa. (USFWS, 1998)
- Surveys and inventories—Survey for additional populations of *Cyanea dunbariae* in areas of potentially suitable habitat. (USFWS, 2018)
- Ungulate monitoring and control—Continue to construct fenced exclosures to protect individuals from the negative impacts of feral ungulates. Protect all occurrences against browsing and habitat disturbances from feral ungulates to prevent extinction. (USFWS, 2018)
- Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations. Control invasive nonnative species that compete with the species around all populations. (USFWS, 2018)
- Captive propagation for genetic storage and reintroduction—Continue to conduct research on seed storage techniques to increase seed viability for adequate genetic representation. Continue propagation efforts for maintenance of genetic stock. (USFWS, 2018)
- Reintroduction and translocation—Continue to reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. (USFWS, 2018)

- Predator and herbivore monitoring and control—Implement effective control methods for rodents at the last known location. Research and implement effective control methods for slugs.(USFWS, 2018)
- Stochastic events—Build resiliency and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from landslides. (USFWS, 2018)
- Climate change adaptation strategy—Assess the modeled effects of climate change on this species, and determine future landscape needed for the recovery of the species. (USFWS, 2018)
- Alliance and partnership development—Continue to work with partners in planning and implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2018)

Conservation Measures and Best Management Practices:

- Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. Evaluate genetic resources currently in storage to determine the need to place additional genetic resources in long-term storage due to this species' high vulnerability to climate change. (USFWS, 2014)
- Continue augmenting current natural populations to increase numbers of individuals. (USFWS, 2014)
- Eradicate invasive introduced plants within ungulate exclosures and maintain the exclosures free of invasive introduced plants. (USFWS, 2014)
- Maintain existing exclosures and monitor for potential incursions. (USFWS, 2014)
- Continue monitoring all individuals at both Mokomoko and Kalamaula. (USFWS, 2014)
- Control slugs and rodents within the vicinity of all known *C. dunbariae* populations. (USFWS, 2014)
- Increase numbers of populations and individuals scattered through historic range to reduce impacts from landslides and flooding. (USFWS, 2014)
- Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change. (USFWS, 2014)
- Initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2014)

SPECIES ACCOUNT: *Cyanea duvalliorum* (haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 06/27/2013; Pacific Region (Region 1) (USFWS, 2016b)

Physical Description

Cyanea duvalliorum (haha), a short-lived perennial tree in the bellflower family (Campanulaceae). (USFWS, 2016)

Current Range

Found only in the east Maui mountains (Lammers 2004). (USFWS, 2016a)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea duvalliorum* (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea duvalliorum* includes six CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Lowland Wet—Unit 1 (and) *Palmeria dolei*—Unit 2—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 2— Lowland Wet This area consists of 6,616 ac (2,677 ha) of State land, 7,425 ac (3,005 ha) of privately owned land, and 2,038 ac (825 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Kipahulu Valley on the northern and eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia samuelii*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Huperzia mannii*, *Melicope balloui*, and *M. ovalis*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 1 is not known to be occupied by the plants *Clermontia oblongifolia* ssp. *mauiensis*, *C. peleana*, *Mucuna sloanei* var. *persericea*, *Phyllostegia haliakalae*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 1 (and) *Palmeria dolei*—Unit 10—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 10— Montane Wet This area consists of 1,313 ac (531 ha) of State land and 798 ac (323 ha) of privately owned land, at Haiku Uka on the northern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Cyanea duvalliorum*, *C. maritae*, *C. mceldowneyi*, *Huperzia mannii*, *Melicope balloui*, and *Phyllostegia pilosa*, and by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 1 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 2 (and) *Palmeria dolei*—Unit 11—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 11— Montane Wet This area consists of 4,075 ac (1,649 ha) of State land, 9,633 ac (3,898 ha) of privately owned land, and 875 ac (354 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Puukaukanu and upper Waihoi Valley, on the northern and northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Geranium hanaense*, *G. multiflorum*, and *Wikstroemia villosa*, and by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 2 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea glabra*, *C. maritae*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, and *Schiedea jacobii*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 3 (and) *Palmeria dolei*—Unit 12—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 12— Montane Wet This area consists of 2,228 ac (902 ha) of federally owned

land (Haleakala National Park) in Kipahulu Valley, on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. maritae*, and *Melicope ovalis*, and by the forest bird, *kiwikiu* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 3 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea duvalliorum*, *C. glabra*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest bird, the *akohekohe* (*Palmeria dolei*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 4 (and) *Palmeria dolei*—Unit 13—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 13— Montane Wet This area consists of 180 ac (73 ha) of State land and 1,653 ac (669 ha) of federally owned land (Haleakala National Park), in Kaapahu Valley on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *Cyrtandra ferripilosa*, and *Huperzia mannii*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 4 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea duvalliorum*, *C. glabra*, *C. mceldowneyi*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 5 (and) *Palmeria dolei*—Unit 14—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 14— Montane Wet This area consists of 222 ac (90 ha) of State land, and 165 ac (67 ha) of federally owned land (Haleakala National Park), near Kaumakani on the eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological

features in the montane wet ecosystem (see Table 5). These units area occupied by the plant *Bidens campylotheca* ssp. *pentamera*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 5 is not currently occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea duvalliorum* critical habitat consists of two components. Lowland wet (east Maui) and Montane wet (east Maui) (81 FR 17790-18110):

Ecosystem: Lowland Wet. Elevation: <3,330 ft (<1,000 m).. Annual precipitation: 50–75 in (130–190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Ecosystem: Montane Wet. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: >75 in (>190 cm). Substrate: Well-developed soils, montane bogs. Canopy: *Acacia*, *Charpentiera*, *Cheirodendron*, *Metrosideros*. Subcanopy: *Broussaisia*, *Cibotium*, *Eurya*, *Ilex*, *Myrsine*. Understory: Ferns, *Carex*, *Coprosma*, *Leptecophylla*, *Oreobolus*, *Rhynchospora*, *Vaccinium*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The

125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant

species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Not available.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Habitat Narrative

Adult: Lowland wet and montane wet ecosystems in the East Maui mountains (USFWS 2012).
(NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

Low (inferred from NatureServe, 2015)

Redundancy:

Low (inferred from NatureServe, 2015)

Number of Populations:

2 (NatureServe, 2015)

Population Size:

71 wild, 135 outplanted (NatureServe, 2015)

Population Narrative:

Currently there are 2 occurrences with an approximate total of 71 individuals in the montane wet ecosystem near Makawao FR, with an additional 135 individuals outplanted in Waikamoi Preserve (TNC 2007; NTBG 2009d, p. 2; Oppenheimer 2010a, in litt.). (USFWS, 2016a)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (pigs), nonnative plants, flooding, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Flooding destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (pigs, rats, and slugs) is considered an ongoing threat to *Cyanea duvalliorum* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

SPECIES ACCOUNT: *Cyanea eleeleensis* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 05/13/2010; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Cyanea eleeleensis is a shrub in the bell flower family (Campanulaceae), 1.8 meters (6.0 feet) tall with glabrous (hairless) stems. Leaves are oblanceolate (longer than wide, with widest point above the middle), 38.5 to 40.5 centimeters (cm) (15 to 16 inches (in)) long and 11.5 cm (4.5 in) wide, with the upper surface green and the lower surface pale green. The inflorescence is 11- to 20-flowered and densely short-pubescent. Calyx lobes are triangular, 4 to 5 millimeters (mm) (0.16 to 0.2 inches (in)) long, and 3 mm (0.12 in) wide. The corolla is bilabiate (two-lipped) and tubed, 46 to 47 mm (1.8 to 1.9 in) long, purple with lighter longitudinal stripes, with a ventral (front or inward) lip cut to its middle into three linear lobes. Berries are subglobose (almost spherical), 12 mm (0.5 in) long, 14 mm (0.6 in) in diameter, purple, and crowned by persistent calyx lobes. Seeds are unknown (Lammers 1992). (USFWS, 2017)

Taxonomy

A member of the bellflower family (Campanulaceae) (USFWS, 2010).

Historical Range

This species was discovered in Wainiha Valley on the island of Kauai in 1977, in one population noted as “fewer than 10” individuals (Lammers 1992, p. 129; K. Wood, pers. comm. 2000; HBMP 2007) (USFWS, 2010).

Current Range

Individuals of this species were not observed in extensive surveys conducted in August 2001, June 2002, March 2013, October 2013, April 2014, July 2014, and September 2014, in areas at or adjacent to the original location, and in nearby gulches (Wood 2006, pers. comm.; Wood 2012; Wood 2015). Much of the suitable habitat for this species on Kauai has not been surveyed; however, the latest analysis for this species conducted by IUCN has assessed it as regionally extinct (Bruegmann et al. 2016). (USFWS, 2017)

Critical Habitat Designated

Yes; 4/13/2010.

Legal Description

On April 13, 2010, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea eleeleensis* (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six critical habitat units (CHUs), in Hawaii (75 FR 18960-19165).

Critical Habitat Designation

The critical habitat designation for *Cyanea eleeleensis* includes six CHUs in Kauai County, Hawaii. Note: This species may no longer occur naturally in the wild, therefore there is no known occupied critical habitat for this species. The critical habitat units for this species have been

determined to be essential to the conservation of the species because the area provides for the reestablishment of populations within the species' historical range (75 FR 18960-19165).

Kauai—Lowland Wet—Section 1: Lowland Wet—Section 1 consists of 1,164 ac (471 ha) in the lowland wet ecosystem (117 ac (47.4 ha) on State land; 1,047 ac (424 ha) on private land), including wet forest extending from Kulanalilia into Limahuli Valley to Honoonapali, in the Halelea Forest Reserve (Figure 2-A). The section includes 1,099 ac (445 ha) of State and privately owned land within previously designated critical habitat and 65 ac (26 ha) of newly designated critical habitat on private land. The area that falls within designated critical habitat lies within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and newly designated Critical Habitat Unit 20, Map 217c. This section is occupied by the plants *Chamaesyce remyi* var. *remyi*, *Charpentiera densiflora*, *Labordia helleri*, and *Phyllostegia renovans*. This section also contains unoccupied habitat that is essential to the conservation of these four species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet—Section 1 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Melicope paniculata*, *M. puberula*, *Platydesma rostrata*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 2: Lowland Wet—Section 2 consists of 172 ac (70 ha) in the lowland wet ecosystem, including wet forest extending from Alealau to Pohakea, within the Hono o Na Pali NAR and the Na Pali Coast State Park (Figure 2-A, above). The entire section is State-owned and within previously designated critical habitat; it falls within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and is occupied by the plant *Melicope puberula*. This section also contains unoccupied habitat that is essential to the conservation of this species by providing the physical and biological features necessary for the expansion of the existing wild population. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet—Section 2 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *C. remyi* var. *remyi*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Labordia helleri*, *Melicope paniculata*, *Phyllostegia renovans*, *Platydesma rostrata*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 3: Lowland Wet—Section 3 consists of 756 ac (306 ha) in the lowland wet ecosystem, including wet forest in upper Wainiha Valley, on privately owned land in the Halelea Forest Reserve (Figure 2-B). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and is occupied by

the plants *Chamaesyce remyi* var. *kauaiensis*, *Cyrtandra oenobarba*, *Melicope puberula*, *Phyllostegia renovans*, and *Stenogyne kealiae*. This section also contains unoccupied habitat that is essential to the conservation of these five species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet–Section 3 is not known to be occupied by the species *Chamaesyce remyi* var. *remyi*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Dubautia imbricata* ssp. *imbricata*, *Labordia helleri*, *Melicope paniculata*, *Platydesma rostrata*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 4: Lowland Wet–Section 4 consists of 591 ac (239 ha) in the lowland wet ecosystem, including wet forest at the head of Lumahai Valley, on State (10 ac, 4.1 ha) and privately owned (581 ac, 235 ha) land in the Halelea Forest Reserve (Figure 2-B, above). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and is occupied by the plants *Chamaesyce remyi* var. *remyi*, *Cyrtandra oenobarba*, *Melicope paniculata*, *Phyllostegia renovans*, and *Platydesma rostrata*. This section also contains unoccupied habitat that is essential to the conservation of these five species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet–Section 4 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Dubautia imbricata* ssp. *imbricata*, *Labordia helleri*, *Melicope puberula*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population numbers of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 5: Lowland Wet–Section 5 consists of 1,541 ac (624 ha) in the lowland wet ecosystem, including wet forest extending from the headwaters of the Wailua River at “Blue Hole” south to Iole, on State (442 ac, 179 ha) and privately owned (1,099 ac, 445 ha) land in the Lihue-Koloa Forest Reserve (Figure 2-C). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 10 of 50 CFR 17.99(a)(1), Map 36a, and is occupied by the plants *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Melicope paniculata*, *Phyllostegia renovans*, and *Platydesma rostrata*. This section also contains unoccupied habitat that is essential to the conservation of these five species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet–Section 5 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *C. remyi* var. *remyi*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C.*

kuhihewa, *Labordia helleri*, *Melicope puberula*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 6: Lowland Wet—Section 6 consists of 789 ac (319 ha) in the lowland wet ecosystem, including wet forest extending from Kapalaoa to Kanaele Bog and Lauahihaihai in the Wahiawa Mountains, on State (134 ac, 54 ha) and privately owned (655 ac, 265 ha) land in the Lihue-Koloa Forest Reserve (Figure 2-D). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 10 of 50 CFR 17.99(a)(1), Map 36a, and is occupied by the plants *Chamaesyce remyi* var. *remyi*, *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Platydesma rostrata*, and *Tetraplasandra bisattenuata*. This section also contains unoccupied habitat that is essential to the conservation of these five species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet—Section 6 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuuhihewa*, *Labordia helleri*, *Melicope paniculata*, *M. puberula*, *Phyllostegia renovans*, *Stenogyne kealiae*, and *Tetraplasandra flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea eleeleensis* critical habitat consists of one component (Lowland wet) (75 FR 18960-19165):

Ecosystem: Lowland Wet. Elevation: <3,000 ft (<914 m). Annual precipitation: >75 in (>190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepidia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contains the physical or biological features essential to the conservation of the species that may require special management considerations or protection. It is recognized that activities in and adjacent to areas designated as critical habitat may affect one or more of the PCEs found in these areas. Special management is needed throughout each of the designated critical habitat units. The following discussion of special management needs is applicable to each of the 47 Kauai species for which we are designating critical habitat. These 47 Kauai species include 41 species that are currently found in the wild, and 6 species that are not currently extant in the wild. For each of the 41 Kauai species found in

the wild, we have determined that the features essential to their conservation are primarily dependent on maintaining the successful functioning of the ecosystem(s) in which they occur (Tables 3 and 4). In some cases, additional species-specific primary constituent elements have also been identified (Table 4). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical and biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, predation by nonnative species, competition with nonnative species, hurricanes, landslides, flooding, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by feral ungulates (pigs, goats, and black-tailed deer). Feral ungulates also impact the habitat through predation and trampling. The State of Hawaii provides game mammal (feral pigs and goats, and black-tailed deer) hunting opportunities on one or more State-designated public hunting areas on the islands of Kauai, Oahu, Maui, Molokai, Lanai, and Hawaii (Hawaii Administrative Rules 13-123; DLNR 2009a). Management of game animals by the State ranges from providing maximal sustained public hunting opportunities and benefits (e.g., “sustained yield”) in some areas to game animal removal by State staff, or their designees, in other areas (DLNR 2009b). Public hunting areas are not fenced, and game mammals have unrestricted access to most areas across the landscape, regardless of the underlying land use designation. While fences are sometimes built to provide protection from game mammals to the natural resources within the fenced area, the current number and locations of fences are not sufficient to prevent habitat destruction and degradation. Without special management, the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new alien plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species will help to address the threat presented by fire to three critical habitat areas in particular (Kauai—Lowland Mesic— Section 1, Kauai—Montane Mesic— Section 2, and Kauai—Dry Cliff— Section 1; see Table 5 for corresponding CFR unit numbers). This threat is primarily due to the presence of nonnative species, such as the grasses *Andropogon* sp. and *Setaria* sp., which increase the fuel load and quickly regenerate after a fire. These species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D’Antonio and Vitousek 1992, pp. 64– 66; Brooks et al. 2004, p. 680). In addition, five sections (Kauai—Dry Cliff—Section 1, Kauai—Dry Cliff— Section 2, Kauai—Wet Cliff—Section 1, Kauai—Wet Cliff—Section 2, and Kauai—Wet Cliff—Section 3; see Table 5 for corresponding CFR unit numbers) may require special management to reduce the threat of landslides and flooding, which threaten to further degrade the habitat conditions and have the potential to eliminate some species in their entirety (e.g., *Schiedea attenuata*). In summary, we find that each of the areas we are designating as critical habitat contains features essential to the conservation of the species that may require special management considerations or protection to ensure the conservation of the 47 Kauai species. These special management considerations and protections are required to preserve and maintain the essential features provided to these species by the ecosystems upon

which they depend. A more detailed discussion of each of these threats is presented above, under the Summary of Factors Affecting the Species section.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: Not available.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Wet forest (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Lowland wet ecosystem (USFWS, 2010)

Geographic or Habitat Restraints or Barriers

Adult: Occurs ~699 ft. elevation (USFWS, 2010)

Environmental Specificity

Adult: Unknown (NatureServe, 2015)

Habitat Narrative

Adult: This species is found in wet forests. (NatureServe, 2015) It is reported from the lowland wet ecosystem (Lammers 1992, p. 129; TNCH 2007). It was found growing in a shaded gulch in wet forest, surrounded by steep, precipitous cliffs of Pali Eleele, at an elevation of 699 ft (213 m) (HBMP 2007; Lammers 1992, p. 129) (USFWS, 2010).

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Not available.

Population Information and Trends

Population Trends:

Unknown (NatureServe, 2015)

Resiliency:

Very low (inferred from NatureServe, 2015)

Redundancy:

Very low (inferred from NatureServe, 2015)

Population Growth Rate:

Unknown (NatureServe, 2015)

Number of Populations:

1 (NatureServe, 2015)

Population Size:

0 (USFWS, 2017)

Population Narrative:

Known from one population totaling less than 10 individuals in 1977. Known only from the type specimen collected in 1977. Unknown if still extant. Survey conducted in 2004 but was not found. (NatureServe, 2015) Collections for genetic storage and ex situ (off site) propagation were not made at the time of the 1977 discovery. Since its discovery in 1977, subsequent surveys for this species have not been conducted in the original (type) location. Although individuals of this species were not observed in surveys conducted in August 2001 and June 2002 in areas adjacent to the original location, much of the suitable habitat (Metrosideros lowland wet forest) for this species on Kauai has not been surveyed. If surveys are conducted, additional individuals are likely to be found (S. Perlman and K. Wood, pers. comm. 2007) (USFWS, 2010).

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from non-native plants, pigs, hurricanes, landslides, and climate change. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Landslides destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities.

Stressor: Predation and herbivory - Ungulate, Rodent, Slug (USFWS, 2010; USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species present an immediate and significant threat to *Cyanea eleleensis* throughout its range due to documented browsing and trampling by pigs, goats, and deer, and documented mechanical damage by rats and nonnative invertebrates (USFWS, 2010).; Herbivory by pigs has been noted as a threat to this species (Wood 2000, in. litt.; DLNR 2005). Herbivory by rats (*Rattus* spp.) has been 11 noted as a threat to

Cyanea eleeleensis (DLNR 2005). Rats eat virtually every part of plants and at every stage: fleshy fruits, seeds, flowers, stems, leaves, shoots, seedlings, and roots (Russell 1980; Cuddihy and Stone 1990). The effects on plants range from reduced vigor and decreased reproduction to mortality of individuals and complete lack of recruitment. Herbivory by slugs has been reported as a threat to many *Cyanea* species (Wood 2000, in. litt.; DLNR 2005; U.S. Army Garrison 2005). (USFWS, 2017)

Stressor: Small populations (USFWS, 2010)

Exposure:

Response:

Consequence:

Narrative: *Cyanea eleeleensis* has not been confirmed to persist in the wild. This species is not in storage or propagation, but individuals familiar with this species believe it may possibly remain extant and that much of its suitable habitat (lowland mesic, lowland wet, and wet cliff) on Kauai remains to be surveyed (USFWS, 2010).

Stressor: Ungulate degradation of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Feral pigs (*Sus scrofa*) modify and degrade habitat by disturbing and destroying vegetative cover, trampling plants and seedlings, reducing or eliminating plant regeneration by damaging seeds and seedlings, and increasing erosion by creating large areas of bare soil. Feral pigs are reported in the area where *Cyanea eleeleensis* was last observed (Wood 2000, in. litt.; DLNR 2005; Bruegmann et al. 2016). (USFWS, 2017)

Stressor: Landslides and flooding destruction or degradation of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Landslides can have a significant effect on small populations or individuals of *Cyanea eleeleensis*. Landslides and erosion due to natural weathering destabilize substrates, damage and destroy individuals plants, and alter hydrological patterns (Wood 2000, in. litt.; Bruegmann et al. 2016). (USFWS, 2017)

Stressor: Hurricanes—Loss and degradation of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: In November 1982, Hurricane Iwa struck the Hawaiian Islands, with wind gusts exceeding 100 miles per hour (mph) (161 kilometers per hour (kph)), causing extensive damage, especially on the islands of Niihau, Kauai, and Oahu (Businger 1998). In September 1992, Hurricane Iniki, a category 4 hurricane with maximum sustained wind speeds recorded at 140 mph (225 kph), passed directly over the island of Kauai. Many forest trees were destroyed (Perlman 1992), which opened the canopy and facilitated the invasion of nonnative plants (Kitayama and Mueller-Dombois 1995). A destructive hurricane holds the potential of driving a localized endemic species to extinction in a single event. Hurricanes pose an ongoing and ever-present threat because they can happen at any time, although their occurrence is not

predictable. Tropical cyclone frequency and intensity are projected to change as a result of climate change over the next 100 to 200 years (Vecchi and Soden 2007; Emanuel et al. 2008; Yu et al. 2010). In the central Pacific, modeling projects an increase of up to two additional tropical cyclones per year in the main Hawaiian Islands by 2100 (Murakami et al. 2013). (USFWS, 2017)

Stressor: Lack of adequate biosecurity legislation (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Invasion of the State of Hawaii by invasive nonnative plant species, and destruction of habitat and competition by nonnative plants are threats to *Cyanea eleleensis*. Pest species have caused the extinction of native species, the destruction of native forests, and the spread of disease. The U.S. Department of Agriculture, Animal and Plant Health Inspection Service, Plant Protection and Quarantine, is authorized to prevent the introduction or dissemination of animal and plant pests on all ships, aircraft, and their cargo and baggage arriving in the U.S. and its territories; however, pest species continue to enter the State. In addition, Federal import regulations do not address many species that could be pests in Hawaii (CGAPS 2009; Ikuma et al. 2002). (USFWS, 2017)

Stressor: Invasive species—Established invasive plant species competition (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Nonnative plant species are a high and imminent threat to *Cyanea eleleensis* though very little is known about the specific nonnative plant threats in its only known location in Wainiha Valley (Wood 2000, in. litt.; DLNR 2005, Bruegmann et al. 2016). Nonnative plants compete for water, light, and nutrients. (USFWS, 2017)

Stressor: Stochastic events—Reduced viability due to low numbers (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Small, isolated populations often exhibit reduced levels of genetic variability, which diminishes the species' capacity to adapt and respond to environmental changes, thereby lessening the probability of long-term persistence (Barrett and Kohn 1991; Newman and Pilson 1997; HBMP 2010). The problems associated with small population size and vulnerability to random demographic fluctuations or natural catastrophes are further magnified by synergistic interactions with other threats, such as anthropogenic impacts like habitat loss from human development or predation by nonnative species. Very small plant populations may experience reduced reproductive vigor due to ineffective pollination or inbreeding depression (Wood 2000, in. litt.; DLNR 2005). (USFWS, 2017)

Recovery

Reclassification Criteria:

5 to 10 populations with 1,000 mature individuals per population (USFWS, 2017)

1,200 mature individuals are needed in one population and all major threats must be controlled around the population designated for recovery at this stage. There should also be demonstrated regeneration of seedlings and growth to at least sapling stage for woody species and documented replacement regeneration within each of the target populations. The population must be adequately represented in an ex situ collection as defined in the Center for Plant Conservation's guidelines (Guerrant et al. 2004). Adequate monitoring must be in place and conducted to assess individual plant survival, population trends, trends of major limiting factors, and response of major limiting factors to management. (USFWS, 2017)

all target populations must be stable, secure, and naturally reproducing for a minimum of 10 years (USFWS, 2017)

Downlisting should not be considered until an adequate population viability analysis (PVA) has been conducted to assess needed numbers more accurately based on current management and monitoring data collected at regular intervals determined by demographic parameters of the species, although they should only be one of the factors used in making a decision to downlist. (USFWS, 2017)

Delisting Criteria:

In addition to achieving 5 to 10 populations with 1,000 mature individuals per populations and all of the goals of the interim and downlisting stages, all target populations must be stable, secure, naturally reproducing, and within secure and viable habitats for a minimum of 20 years. (USFWS, 2017)

Recovery Actions:

- Assess the distribution, current status, and potential future distribution of existing ecosystems and determine the most important sites for ecosystem management. Make use of landscape modeling, spatial analysis, remote sensing technology, and existing survey data to better understand species distributions and priority ecosystem areas for targeting future surveys. (USFWS, 2010)
- Initiate control of ecosystem-modifying threats, such as ungulates and invasive introduced plant species, as soon as possible within the highest priority management units. (USFWS, 2010)
- Stabilize and protect remaining extant populations of the 45 plants and 2 bird species. Conduct systematic, island-wide surveys for additional populations. Make use of landscape modeling, spatial analysis, remote sensing technology, and existing survey data to better understand distributions and priority areas for targeting future surveys. (USFWS, 2010)
- Restore and maintain multiple viable populations of the 45 plants and 2 bird species by protecting, restoring, and maintaining existing habitats or areas with potential for restoration that are within their historical range. (USFWS, 2010)
- Conduct research on control methods for introduced slugs and avian malaria. (USFWS, 2010)
- Develop an augmentation plan to collect and propagate seed from the 45 plant species that can later be utilized for population restoration, augmentation, and reintroduction. (USFWS, 2010)
- Prevent the influx of new pests and invasive species into recovery areas. Increase the efforts of the Kauai Invasive Species Committee and improve border security. (USFWS, 2010)

- Prioritize research studies that will provide information and tools aiding in the mitigation of known threats and limiting factors of the species and ecosystems. (USFWS, 2010)
- Increase outreach effort and coordination with State agencies and private landowners regarding ecosystem conservation. Promote opportunities to assist in the recovery of these species through Habitat Conservation Plans, Safe Harbor Agreements, and through various conservation partnerships funded by State and Federal agencies and private organizations. (USFWS, 2010)
- Surveys and inventories—Survey suitable habitat to find new populations. (USFWS, 2017)
- Ungulate monitoring and control—Fence any populations found to protect them from the impacts of feral ungulates. Control feral ungulates within fenced exclosures. (USFWS, 2017)
- Invasive plant monitoring and control—Control invasive plant species around any populations found. (USFWS, 2017)
- Predator and herbivore monitoring and control—Implement effective measures to control rodents around any populations found. (USFWS, 2017)
- Predator and herbivore control research—Develop and implement adequate slug control methods. (USFWS, 2017)
- Captive propagation for genetic storage and reintroduction—Collect material for genetic storage and propagation for reintroduction from any individuals found. (USFWS, 2017)
- Reintroduction and translocation—Reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species if any individuals are found. (USFWS, 2017)
- Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from landslides and storms. (USFWS, 2017)
- Based on the recovery criteria above, consider development of a recovery plan. (USFWS, 2017)

Conservation Measures and Best Management Practices:

- Not available.

SPECIES ACCOUNT: *Cyanea gibsonii* (= *C. macrostegia* ssp. *g.*) (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 09/20/1991; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Cyanea macrostegia ssp. *gibsonii*, a member of the bellflower family (Campanulaceae), is a palm-like tree 1 to 7 m (3.3 to 23 ft) tall. The leaves are elliptic or oblong, about 20 to 80 cm (7.9 to 31.5 in) long and 6.5 to 20 cm (2.6 to 7.9 in) wide; the upper surface is usually smooth, while the lower is covered with fine hairs. The leaf stem is often covered with small prickles throughout its length. The inflorescences are horizontal and clustered among the leaves, each bearing 5 to 15 curved flowers that are blackish-purple externally and white or pale lilac within. The fruit is a yellowish-orange berry about 1.5 to 3 cm (0.6 to 1.2 in) long. The following combination of characters separates this taxon from the other members of the genus on Lana'i: calyx lobes oblong, narrowly oblong, or ovate in shape; and the calyx and corolla both more than 0.5 cm (0.2 in) wide (Lammers in Wagner et al. 1990, Rock 1919, Wimmer 1943). (USFWS, 1994)

Taxonomy

Cyanea macrostegia ssp. *gibsonii* was originally described by William Hillebrand as *Cyanea gibsonii* based on his 1870 collection from Lana'i "on the highest wooded ridge" (Lana'ihale) (Hillebrand 1888). Lammers (1988) reclassified *Cyanea gibsonii* to subspecific status within *Cyanea macrostegia* due to similarities between the taxa also noted by other botanists (Rock 1919, Wimmer 1943). (USFWS, 1994); We proposed a taxonomic change for this species in 2012 and accepted the new name *Cyanea gibsonii* in the final critical habitat rule for 135 species on Moloka'i, Lāna'i, Maui, and Kaho'olawe on March 30, 2016 (81 FR 17790). (USFWS, 2018)

Current Range

This species current range is restricted to Lanai. (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea macrostegia* ssp. *gibsonii* (Haha) under the Endangered Species Act of 1973, as amended (Act) (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea macrostegia* ssp. *gibsonii* includes an unknown number of CHUs in Maui County, Hawaii. The number of CHUs is unknown because all CHUs reside on Lanai and there is not detailed CHU information for Lanai (81 FR 17790-18110).

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea macrostegia* ssp. *gibsonii* critical habitat consists of two components. Montane wet (Lanai) and Wet cliff (Lanai) (81 FR 17790-18110):

Ecosystem: Montane Wet. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: >75 in (>190 cm). Substrate: Well-developed soils, montane bogs. Canopy: *Acacia*, *Charpentiera*, *Cheirodendron*, *Metrosideros*. Subcanopy: *Broussaisia*, *Cibotium*, *Eurya*, *Ilex*, *Myrsine*. Understory: *Ferns*, *Carex*, *Coprosma*, *Leptecophylla*, *Oreobolus*, *Rhynchospora*, *Vaccinium*.

Ecosystem: Wet Cliff. Elevation: unrestricted. Annual precipitation: >75 in (>190 cm). Substrate: >65 degree slope, shallow soils, weathered lava. Canopy: None. Subcanopy: *Broussaisia*, *Cheirodendron*, *Leptecophylla*, *Metrosideros*. Understory: *Bryophytes*, *Ferns*, *Coprosma*, *Dubautia*, *Kadua*, *Peperomia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the

critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: *Cyanea macrostegia* ssp. *gibsonii* was seen flowering in the month of July (Rock 1919); however, details of its flowering period are not known. (USFWS, 1994)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland, shrubland/chaparral (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Wet environment (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 760 and 970 meters (USFWS, 1994)

Environmental Specificity

Adult: Low, with few key requirements (USFWS, 1994)

Habitat Narrative

Adult: *Cyanea macrostegia* ssp. *gibsonii* is found in wet forests and shrublands in gulch bottoms or on gulch sides. The habitat of *Cyanea macrostegia* ssp. *gibsonii* is the Lowland Wet Forest community. It has been observed to grow on flat to moderate or steep slopes, usually on lower gulch slopes or gulch bottoms, often at edges of streambanks, probably due to vulnerability to ungulate damage at more accessible locations. Sites are sunny to shady, mesic to wet with clay or other soil substrate. *C. macrostegia* ssp. *gibsonii* has been reported from elevations of 760-970 meters (2490-3180 feet). Associated vegetation includes native ferns, shrubs, trees in wet *Metrosideros* forest or *Diolooterygium*-*Metrosideros* shrubland (sometimes with *Dicranopteris*), *Perrottetia*, *Scaevola chamissoniana*, *PiDturus*, *Antidesma*, *Freycinetia*, *Psychotria*, *Cyrtandra*, *Dicranopteris*, *Broussaisia*, *Cheirodendron*, *Clermontia*, *Dubautia*, *Hedyotis*, *Ilex*, *Labordia*, *Melicope*, *Pneumatopteris*, and *Sadleria*, and the alien *Rubus rosifolius*. (USFWS, 1994; NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

Very low (inferred from USFWS, 2014)

Redundancy:

Very low (inferred from USFWS, 2014)

Number of Populations:

3 (USFWS, 2014; USFWS, 2018))

Population Size:

24 wild (USFWS, 2018)

Population Narrative:

In 2013, there were three populations of *Cyanea macrostegia* subsp. *gibsonii* containing approximately ten mature wild individuals (Plant Extinction Prevention Program [PEPP] 2013). The number of individuals has decreased from the estimated range of 14 to 24 wild individuals reported in the previous 5-year review (USFWS 2008). (USFWS, 2014); In the previous 5-year review for 2014 there were three populations of *Cyanea gibsonii* that totaled only 10 individuals. Since that time, with continuing surveys, some new individuals and a population (two subpopulations) were discovered. There are no remaining individuals of the three observed at Wai'opa in 2006 (PEPP 2016). At Hauola, three of the four individuals were reported to have died (PEPP 2017a). At Lāna'ihale, there are four new individuals, and 10 individuals with four that are likely clones (PEPP 2017a, 2018). Two new small subpopulations have been located at Wai'alalā-Pu'uali'i that total approximately eight individuals (Oppenheimer 2018, in litt.; PEPP 2016). In summary, there are three populations totaling as many as 23 individuals. (USFWS, 2018)

Threats and Stressors

Stressor: Climate change (USFWS, 2014; USFWS, 2018))

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Cyanea gibsonii* is highly vulnerable to the impacts of climate change. Furthermore, *C. gibsonii* was identified as a "wink-out" species, defined as a species that is projected to lose more than 99 percent of its current climate envelope (areas that contain the full range of climate conditions under which the species is known to occur) by 2100. Therefore, additional management actions are urgently needed to conserve this taxon into the future. (USFWS, 2014); The assessment by Fortini et al. (2013) concluded that *Cyanea gibsonii* is extremely vulnerable to the impacts of climate change, with a vulnerability score of 0.914 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). In addition, this assessment classified *C. gibsonii* as a "wink-out" species. "Wink-out" species are those species with no future climate envelope. No projected suitable climate areas exist for the species to persist in the future. Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2018)

Stressor: Drought and reduced viability (USFWS, 2014)

Exposure:

Response:

Consequence:

Narrative: Drought mortality and reduced viability – In 2010, drought was reported as a threat to *C. gibsonii* (PEPP 2011, 2012). (USFWS, 2014)

Stressor: Browsing and habitat disturbance by deer (USFWS, 1994)

Exposure:

Response:

Consequence:

Narrative: Browsing and habitat disturbance by axis deer. Deer have not yet fully invaded the current habitat of this taxon, though they have directly (through browsing and trampling) and indirectly (through opening up avenues for invasion of alien plants by their trampling) contributed to the taxon's decline. Browsing and habitat disturbance by axis deer promise to eliminate *Cyanea macrostegia* ssp. *gibsonii* if drastic management efforts are not undertaken. (USFWS, 1994)

Stressor: Alien plant species (USFWS, 1994)

Exposure:

Response:

Consequence:

Narrative: Encroaching alien plant species. Kahili ginger (*Hedychium gardnerianum*) was observed overgrowing the only plant found at one of the Kaiholena sites in 1989 CR. Hobdy, personal communication 1992). Even small pockets of virtually undisturbed forest in the heads of gulches on the upper slopes of Lana' ihale are being invaded by *Psidium cattleianum*, *Myrica fava*, *Leptospermum scoparium*, *Pluchea symphytifolia*, *Melinis minutiflora*, *Rubus rosifolius*, *Paspalum conjugatum*, and other alien species. These alien species have become pervasive on adjacent ridges since the forest floor is bombarded by alien propagules, and natural openings, or openings created by habitat disturbance by axis deer, provide ample sites for these aliens to obtain a foothold. Continuing disturbance by axis deer exacerbates the alien plant invasion problem. (USFWS, 1994)

Stressor: Small population size (USFWS, 1994)

Exposure:

Response:

Consequence:

Narrative: The very small number of extant individuals. With at most only 75-80 individuals in many small populations, the limited local gene pools may depress reproductive vigor. (USFWS, 1994)

Stressor: Loss of pollinators (USFWS, 1994)

Exposure:

Response:

Consequence:

Narrative: The probable loss of appropriate pollinators. Since native birds may have been the pollinators of *Cyanea macrostegia* ssp. *gibsonii*, their decline is very likely to pose a major, though undocumented, threat. (USFWS, 1994)

Recovery

Reclassification Criteria:

1. A total of five to seven populations are documented on Lanai and at least one other island where they now occur or occurred historically. (USFWS, 1994)

2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1994)

3. Each of these populations must persist at this level for at least 5 consecutive years before downlisting is considered. (USFWS, 1994)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Lanai and at least one other island where they now occur or occurred historically. (USFWS, 1994)

2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum or 300 mature individuals per population for short-lived perennials. (USFWS, 1994)

3. Each population should persist at this level for at least 5 consecutive years before delisting is considered. (USFWS, 1994)

Recovery Actions:

- Protect habitat of current populations and manage threats. (USFWS, 1994)
- Conduct research essential to conservation of the species. (USFWS, 1994)
- Expand current populations. (USFWS, 1994)
- Establish new populations as needed to reach recovery objectives. (USFWS, 1994)
- Validate and revise recovery objectives. (USFWS, 1994)
- Surveys and inventories—Continue to survey for additional populations of *Cyanea gibsonii* in areas of potentially suitable habitat. (USFWS, 2018)
- Ungulate monitoring and control—Continue to construct and maintain fenced exclosures to protect individuals from the negative impacts of feral ungulates. Protect all occurrences against browsing and habitat disturbances from feral ungulates to prevent imminent extinction. (USFWS, 2018)
- Invasive plant monitoring and control—Continue to control established ecosystem-altering nonnative invasive plant species around all populations. Continue to control invasive nonnative species that compete with the species around all populations. (USFWS, 2018)
- Captive propagation for genetic storage and reintroduction—Continue propagation efforts for maintenance of genetic stock. Continue to reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. (USFWS, 2018)
- Predator and herbivore monitoring and control—Implement effective control methods for rodents and slugs within the vicinity of all known *Cyanea gibsonii* populations. (USFWS, 2018)
- Population biology viability monitoring and analysis—Continue monitoring wild individuals. (USFWS, 2018)
- Stochastic events—Build resiliency and redundancy—Continue to augment populations by reintroduction into protected habitat. (USFWS, 2018)
- Climate change adaptation strategy—Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change. As this species is likely to

“wink out” by 2100, ensure that adequate genetic storage is maintained as viable material. (USFWS, 2018)

- Alliance and partnership development—Continue to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2018)

Conservation Measures and Best Management Practices:

- Survey geographical and historical range for a current assessment of the species’ status. (USFWS, 2014)
- Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. Evaluate genetic resources currently in storage to determine the need to place additional genetic resources in long-term storage due to this species’ vulnerability to climate change. (USFWS, 2014)
- Fence remaining populations to protect them from the impacts of feral ungulates. (USFWS, 2014)
- Eradicate invasive introduced plant species within ungulate exclosures and maintain the exclosures free of invasive introduced plants. (USFWS, 2014)
- Control slugs (unidentified species) and rodents within the vicinity of all known *C. gibsonii* populations. (USFWS, 2014)
- Continue monitoring wild individuals. (USFWS, 2014)
- Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change. As a species likely to wink out by 2100, ensure that adequate genetic storage is maintained as viable material. (USFWS, 2014)
- Initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2014)

Species Taxonomic and Listing Information

Listing Status: Endangered; 09/03/1999; Pacific Region (R1) (USFWS, 2016)

Physical Description

Branched shrubs, of unknown height. Flowers are white, often tinged pale lilac (NatureServe, 2015).

Taxonomy

A member of the bellflower family (Campanulaceae). In 1981, St. John elevated *C. knudsenii* var. *glabra* to full species status as *C. glabra* (St. John 1981). Lammers, in the most recent treatment of the Hawaiian members of the family, upheld the species name, and included as a synonym *C. holophylla* var. *obovata*, a taxon originally collected on West Maui by William Hillebrand and later formally named by Joseph Rock (Rock 1919). Other synonyms of *Cyanea glabra* include *C. scabra* var. *variabilis*, *Delissea glabra*, *D. holophylla* var. *obovata*, and *D. scabra* var. *variabilis* (Lammers 1999; Rock 1919) (USFWS, 2002).

Historical Range

Historically (prior to 1970), *Cyanea glabra* has been reported from West Maui and on Haleakala, East Maui (USFWS, 2002).

Current Range

On West Maui, *Cyanea glabra* occurs in both forks of Kauaula Valley (USFWS, 2011).

Critical Habitat Designated

Yes; 5/14/2003.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea glabra* (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes 16 detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea glabra* includes 16 CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Lowland Wet—Unit 2 (and) *Palmeria dolei*—Unit 3—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 3—Lowland Wet (and) *Newcombia cumingi*—Unit 1—Lowland Wet This area consists of 65 ac (26 ha) of State land at Moomoku, on the northwestern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Santalum haleakalae* var. *lanaiense*. Although Maui—Lowland Wet—Unit 2 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C.*

kunthiana, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauensis*, or *Wikstroemia villosa*, by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), or by the Newcomb's tree snail (*Newcombia cumingi*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 3 (and) *Palmeria dolei*—Unit 4—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 4— Lowland Wet This area consists of 1,247 ac (505 ha) of State land at Honanana Gulch on the northeastern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). They are occupied by the plants *Bidens conjuncta*, *Cyanea asplenifolia*, and *Pteris lidgatei*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 3 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielarectum*, *Bidens micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Remya mauensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 4 (and) *Palmeria dolei*—Unit 5—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 5— Lowland Wet This area consists of 864 ac (350 ha) of State land at Kahakuloa Valley on the northeastern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). They are occupied by the plants *Bidens conjuncta* and *Cyanea asplenifolia*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 4 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielarectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of

these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 5 (and) *Palmeria dolei*—Unit 6—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 6— Lowland Wet This area consists of 30 ac (12 ha) of State land at Iao Valley on the eastern side of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). Although Maui—Lowland Wet—Unit 5 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 6 (and) *Palmeria dolei*—Unit 7—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 7— Lowland Wet This area consists of 136 ac (55 ha) of State land at Honokowai and Wahikuli valleys on the western slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Santalum haleakalae* var. *lanaiense*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 6 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens conjuncta*, *Bidens micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 7 (and) *Palmeria dolei*—Unit 8—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 8— Lowland Wet This area consists of 898 ac (364 ha) of State land at Olowalu Valley, on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species

identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Alectryon macrococcus*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 7 is not currently occupied by the plants *Asplenium dielirectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwiku* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 8 (and) *Palmeria dolei*—Unit 9—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 9— Lowland Wet This area consists of 230 ac (93 ha) of State land at upper Ukumehame Gulch, on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). Although Maui—Lowland Wet—Unit 8 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielirectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwiku* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 1 (and) *Palmeria dolei*—Unit 10—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 10— Montane Wet This area consists of 1,313 ac (531 ha) of State land and 798 ac (323 ha) of privately owned land, at Haiku Uka on the northern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Cyanea duvalliorum*, *C. maritae*, *C. mceldowneyi*, *Huperzia mannii*, *Melicope balloui*, and *Phyllostegia pilosa*, and by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwiku* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 1 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp.

haleakalaensis, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 2 (and) *Palmeria dolei*—Unit 11—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 11— Montane Wet This area consists of 4,075 ac (1,649 ha) of State land, 9,633 ac (3,898 ha) of privately owned land, and 875 ac (354 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Puukaukanu and upper Waihoi Valley, on the northern and northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Geranium hanaense*, *G. multiflorum*, and *Wikstroemia villosa*, and by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 2 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea glabra*, *C. maritae*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, and *Schiedea jacobii*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 3 (and) *Palmeria dolei*—Unit 12—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 12— Montane Wet This area consists of 2,228 ac (902 ha) of federally owned land (Haleakala National Park) in Kipahulu Valley, on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. maritae*, and *Melicope ovalis*, and by the forest bird, *kiwikiu* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 3 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea duvalliorum*, *C. glabra*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P.*

mannii, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest bird, the akohekohe (*Palmeria dolei*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 4 (and) *Palmeria dolei*—Unit 13—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 13— Montane Wet This area consists of 180 ac (73 ha) of State land and 1,653 ac (669 ha) of federally owned land (Haleakala National Park), in Kaapahu Valley on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *Cyrtandra ferripilosa*, and *Huperzia mannii*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 4 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea duvalliorum*, *C. glabra*, *C. mceldowneyi*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 5 (and) *Palmeria dolei*—Unit 14—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 14— Montane Wet This area consists of 222 ac (90 ha) of State land, and 165 ac (67 ha) of federally owned land (Haleakala National Park), near Kaumakani on the eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plant *Bidens campylotheca* ssp. *pentamera*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 5 is not currently occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the

reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 1 (and) *Palmeria dolei*—Unit 18—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 18— Montane Mesic This area consists of 6,593 ac (2,668 ha) of State land, 707 ac (286 ha) of privately owned land, and 3,672 ac (1,486 ha) of federally owned land (Haleakala National Park), from Kealahou to Puualae, nearly circumscribing the summit of Haleakala on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Asplenium dielirectum*, *A. peruvianum* var. *insulare*, *Clermontia lindseyana*, *Cyanea horrida*, *C. obtusa*, *Cyrtandra ferripilosa*, *C. oxybapha*, *Diplazium molokaiense*, *Geranium arboreum*, *G. multiflorum*, *Huperzia mannii*, *Melicope adscendens*, and *Neraudia sericea*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 1 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. micrantha* ssp. *kalealaha*, *Cyanea glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. kunthiana*, *C. mceldowneyi*, *Phyllostegia bracteata*, *P. mannii*, *Santalum haleakalae* var. *lanaiense*, *Wikstroemia villosa*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 6 (and) *Palmeria dolei*—Unit 35—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 35— Wet Cliff This area consists of 1,858 ac (752 ha) of State land, and 253 ac (102 ha) of privately owned land, at the summit ridges of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). They are occupied by the plants *Alectryon macrococcus*, *B. conjuncta*, *Ctenitis squamigera*, *Cyrtandra munroi*, *Remya mauiensis*, and *Santalum haleakalae* var. *lanaiense*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Wet Cliff—Unit 6 is not known to be occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Bonamia menziesii*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Isodendrion pyriformum*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, or *Tetramolopium capillare*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 7 (and) *Palmeria dolei*—Unit 36—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 36—Wet Cliff This area consists of 556 ac (225 ha) of State land along Honokowai ridge on the northwestern side of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). These units are occupied by the plants *Cyrtandra filipes* and *C. munroi*, and contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Wet Cliff—Unit 7 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. conjuncta*, *Bonamia menziesii*, *Ctenitis squamigera*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Tetramolopium capillare*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 8 consists of 337 ac (137 ha) of State land along Kahakuloa ridge on the north side of west Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). Although Maui—Wet Cliff—Unit 8 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. conjuncta*, *Bonamia menziesii*, *Ctenitis squamigera*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Tetramolopium capillare*, we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea glabra* critical habitat consists of four components. Lowland wet (west Maui), Montane wet (east Maui), Montane mesic (east Maui) and Wet cliff (west Maui) (81 FR 17790-18110):

Ecosystem: Lowland Wet. Elevation: <3,330 ft (<1,000 m).. Annual precipitation: 50–75 in (130–190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Ecosystem: Montane Wet. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: >75 in (>190 cm). Substrate: Well-developed soils, montane bogs. Canopy: *Acacia*, *Charpentiera*,

Cheirodendron, Metrosideros. Subcanopy: Broussaisia, Cibotium, Eurya, Ilex, Myrsine.
Understory: Ferns, Carex, Coprosma, Leptecophylla, Oreobolus, Rhynchospora, Vaccinium.

Ecosystem: Montane Mesic. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Deep ash deposits, thin silty loams. Canopy: Acacia, Ilex, Metrosideros, Myrsine, Nestegis, Nothocestrum, Pisonia, Pittosporum, Psychotria, Sophora, Zanthoxylum. Subcanopy: Alyxia, Charpentiera, Coprosma, Dodonaea, Kadua, Labordia, Leptecophylla, Phyllostegia, Vaccinium. Understory: Ferns, Carex, Peperomia.

Ecosystem: Wet Cliff. Elevation: unrestricted. Annual precipitation: >75 in (>190 cm). Substrate: >65 degree slope, shallow soils, weathered lava. Canopy: None. Subcanopy: Broussaisia, Cheirodendron, Leptecophylla, Metrosideros. Understory: Bryophytes, Ferns, Coprosma, Dubautia, Kadua, Peperomia.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire,

drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History

Food/Nutrient Resources

Lifespan

Adult: < 10 years (USFWS, 2011)

Breeding Season

Adult: Unknown (USFWS, 2002)

Key Resources Needed for Breeding

Adult: Unknown (USFWS, 2002)

Reproduction Narrative

Adult: *Cyanea glabra* is a short-lived perennial (fewer than ten years) (USFWS, 2011). Flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors are unknown (U.S. Fish and Wildlife Service 1999b, 2002b) (USFWS, 2002).

Habitat Type

Adult: Terrestrial (NatureServe, 2015); riparian (USFWS, 2002)

Habitat Vegetation or Surface Water Classification

Adult: Ohia and koa wet forest (USFWS, 2011)

Geographic or Habitat Restraints or Barriers

Adult: 1,360 - 5,150 ft. elevation (USFWS, 2002)

Habitat Narrative

Adult: Inhabits wet forests on gulch slopes (NatureServe, 2015). On West Maui in the Kauaula Valley, the habitat is *Metrosideros polymorpha* (ohia) wet forest. The habitat in which *Cyanea glabra* occurs on East Maui is wet forest with *Metrosideros polymorpha* and *Acacia koa* (koa) forming the canopy with an understory of uluhe mat ferns dissected by riparian vegetation. (USFWS, 2011). *Cyanea glabra* is found on soil and rock stream banks at elevations between 415 and 1,570 meters (1,360 to 5,150 feet) (USFWS, 2002).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Not available

Resiliency:

Very low (inferred from USFWS, 2011; see current range/distribution)

Number of Populations:

1 (USFWS, 2018)

Population Size:

300 wild, 1 outplanted (USFWS, 2018)

Population Narrative:

In the 2011 5-year review, there were no known populations of *Cyanea glabra* on Maui because of uncertain taxonomic identity of some individuals. Since that time, plants from west Maui previously identified as *C. glabra* were studied closely and were found to represent a new species, which was then described as *C. kauaulaensis* (Oppenheimer and Lorence 2012). Plants on east Maui at Kīpahulu and Kaʻāpahu are now recognized as *C. maritae* (Lammers 2004). In 2007, a new population of *C. glabra* was found on east Maui along West Wailua Iki stream, consisting of “100s” of individuals (Oppenheimer 2018, in litt.). Currently, this population is estimated to total about 300 individuals (Oppenheimer 2018, in litt.). (USFWS, 2018)

Threats and Stressors

Stressor: Nonnative species (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Pigs (*Sus scrofa*) and flooding are threats to *Cyanea glabra* habitat on East Maui (USFWS 2002). Invasive introduced plants which compete with this species and degrade the habitat include *Ageratina adenophora* (sticky snakeroot), *A. riparia* (spreading mist flower), *Buddleia asiatica* (dog tail), *Clidemia hirta* (Koster’s curse), *Coffea arabica* (coffee), *Cordyline fruticosa* (ti), *Erigeron karvinskianus* (daisy fleabane), *Hedychium gardnerianum* (Kahili ginger), *Oplismenus hirtellus* (basketgrass), *Rubus argutus* (blackberry) *R. rosifolius* (thimbleberry), and *Tibouchina herbacea* (glory bush) (Perlman 2009; Wood 2009). On West Maui, invasive introduced plants include *Coffea arabica* (coffee) and *Erigeron karvinskianus* (daisy fleabane). In Waihoi, they include *Hedychium coronarium* (white ginger) and *Miconia calvescens* (miconia) (H. Oppenheimer, pers. comm. 2009) (USFWS, 2011).

Stressor: Predation (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Seed predation by rats (*Rattus rattus*), and eating of leaves and stems by slugs (various species) and two-spotted leafhoppers (*Sophonia rufofascia*) are primary threats to this rare species (Perlman 2009; USFWS 2002) (USFWS, 2011).

Stressor: Climate change (USFWS, 2011; USFWS, 2018))

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaiʻi using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Cyanea glabra* is vulnerable to the impacts of climate change, with a vulnerability score of 0.504 (on a scale of 0 being not

vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2018)

Stressor: Stochastic events (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: In addition to all of the other threats, species like *Cyanea glabra* that are endemic to small portions of a single island are inherently more vulnerable to extinction than widespread species because of the higher risks posed to a few populations and individuals by random demographic fluctuations and localized catastrophes such as hurricanes, landslides, flooding and disease outbreaks. The extent of these natural processes on this single island endemic are exacerbated by anthropogenic threats, such as habitat loss for human development or predation by introduced species (USFWS 2002) (USFWS, 2011).

Recovery

Reclassification Criteria:

1. A total of five to seven populations should be documented on islands where it now occurs or occurred historically (USFWS, 2002).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure with the following minimum numbers of mature individuals per population: 300 for short-lived perennials (USFWS, 2002).
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 2002).

Delisting Criteria:

1. A total of 8 to 10 populations should be documented on islands where it now occurs or occurred historically (USFWS, 2002).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with the following minimum numbers of mature individuals per population: 300 for short-lived perennials (USFWS, 2002).
3. Each population should persist at this level for a minimum of five consecutive years (USFWS, 2002).

Recovery Actions:

- Protect habitat and control threats (USFWS, 2002).
- Expand existing wild populations (USFWS, 2002).
- Conduct essential research (USFWS, 2002).
- Develop and maintain monitoring plans (USFWS, 2002).
- Reestablish wild populations within the historic range (USFWS, 2002).
- Validate and revise recovery criteria (USFWS, 2002).

- Construct exclosures to protect the single remaining wild population against feral ungulates (USFWS, 2002).
- Maintain adequate genetic stock (USFWS, 2002).
- Control competing alien plant species (USFWS, 2002).
- Enhance wild populations and establish new populations (USFWS, 2002).
- Reduce threats from rodent and slug predation (USFWS, 2002).
- Conduct research into, and implement, control methods for the two-spotted leafhopper (USFWS, 2002).
- Surveys and inventories—Survey for additional populations of *Cyanea glabra* in areas of potentially suitable habitat. (USFWS, 2018)
- Ungulate monitoring and control—Continue to construct and maintain fenced exclosures to protect individuals from the negative impacts of feral ungulates. Protect all occurrences against browsing and habitat disturbances from feral ungulates to prevent imminent extinction. (USFWS, 2018)
- Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations. Control invasive nonnative species that compete with the species around all populations. (USFWS, 2018)
- Captive propagation for genetic storage and reintroduction—Continue collection and propagation efforts for maintenance of genetic stock. (USFWS, 2018)
- Reintroduction and translocation—Continue to reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. (USFWS, 2018)
- Predator and herbivore monitoring and control—Implement effective control methods for rodents at the last known location. Develop and implement effective control methods for slugs. Develop and implement effective control methods for the two-spotted leaf hopper. (USFWS, 2018)
- Stochastic events—Build resiliency and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from landslides and flooding. (USFWS, 2018)
- Climate change adaptation strategy—Assess the modeled effects of climate change on this species and use to determine future landscape needed for recovery of the species. (USFWS, 2018)
- Alliance and partnership development—Continue to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2018)

Conservation Measures and Best Management Practices:

- Survey Waihoi Valley to relocate plants documented in 1970s (USFWS, 2011).
- Determine taxonomic status of all populations that may be *Cyanea glabra* (USFWS, 2011).
- Collect propagules for reintroduction and genetic storage when true *Cyanea glabra* are found (USFWS, 2011).
- Fence wild populations to exclude ungulates in any discovered populations (USFWS, 2011).
- Control rats within any discovered populations (USFWS, 2011).
- Reintroduce populations within protected suitable habitat (USFWS, 2011).
- Develop and implement an effective control method for slugs (USFWS, 2011).
- Develop and implement effective control methods for the two-spotted leaf hopper (USFWS, 2011).
- Control invasive introduced plants competing with any *Cyanea glabra* found (USFWS, 2011).

- Work with Haleakala National Park, East Maui Watershed Partnership, and other land managers to initiate planning and contribute to implementation of ecosystem level restoration and management to benefit this species (USFWS, 2011).
- Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species (USFWS, 2011).

SPECIES ACCOUNT: *Cyanea grimesiana* ssp. *grimesiana* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/10/1996; Pacific Region (R1) (USFWS, 2016)

Physical Description

A shrub 1 to 3.2 m tall, unbranched or sparingly branched. The leaves are deeply cut, and fern-like. Flowers are purplish or greenish to yellowish white, often suffused or striped with magenta. (NatureServe, 2015)

Taxonomy

A member of the bellflower family (Campanulaceae) (USFWS, 1999). Due to taxonomic changes, the taxon originally listed as endangered in 1996 as *Cyanea grimesiana* subsp. *grimesiana* currently includes (1) *Cyanea grimesiana* subsp. *grimesiana*, (2) *Cyanea munroi*, (3) *Cyanea magnicalyx*, (4) *Cyanea mauensis*, (5) *Cyanea cylindrocalyx*, and (6) *Cyanea grimesiana* subsp. *obatae* (Lammers 2004) (USFWS, 2011).

Historical Range

Numerous historical occurrences were reported from the Koolau Mountains prior to 1969 (Hawaii Biodiversity and Mapping Program 2009) (USFWS, 2011). Historically, *Cyanea grimesiana* ssp. *grimesiana* was known from at least 40 populations located in the Waianae and Koolau Mountains on Oahu, Wailau Valley and Puu Kahea on Molokai, central and northern Lanai, and scattered locations on Maui (USFWS 1996a; Heidi Bornhorst, formerly with TNCH, and S. Perlman, in litt. 1992) (USFWS, 1999).

Current Range

Known from Oahu and Molokai. The taxon was last observed on Molokai in 1991 (USFWS, 2012; NatureServe, 2015). On Oahu, *Cyanea grimesiana* subsp. *grimesiana* occurs in the Waianae Mountains (USFWS, 2011).

Critical Habitat Designated

Yes; 3/18/2003.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea grimesiana* ssp. *grimesiana* (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea grimesiana* ssp. *grimesiana* (Haha) under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Cyanea grimesiana* ssp. *grimesiana* (77 FR 57648-57862). The critical habitat designation includes 23 critical habitat units, which encompass approximately 33,624 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Cyanea grimesiana* ssp. *grimesiana* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs

necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Cyanea grimesiana* ssp. *grimesiana* includes six CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Molokai—Lowland Wet—Unit 1 (and) *Palmeria dolei*—Unit 38—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 38— Lowland Wet This area consists of 2,195 ac (888 ha) of State land, and 754 ac (305 ha) of privately owned land (partly within The Nature Conservancy's Pelekunu Preserve), from Pelekunu Valley to Wailau Valley, in north-central Molokai. These units are occupied by the plant *Cyrtandra filipes*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Lowland Wet—Unit 1 is not known to be occupied by *Asplenium dielerectum*, *Bidens wiebkei*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea dunbariae*, *C. grimesiana* ssp. *grimesiana*, *C. solanacea*, *Lysimachia maxima*, *Melicope reflexa*, *Peucedanum sandwicense*, *Phyllostegia hispida*, *P. mannii*, *Plantago princeps*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Lowland Wet—Unit 2 (and) *Palmeria dolei*—Unit 39—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 39— Lowland Wet This area consists of 1,356 ac (549 ha) of State land and 594 ac (241 ha) of privately owned land, from Kahanui to Pelekunu Valley, in north-central Molokai. These units are occupied by the plant *Lysimachia maxima*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Lowland Wet—Unit 2 is not known to be occupied by *Asplenium dielerectum*, *Bidens wiebkei*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea dunbariae*, *C. grimesiana* ssp. *grimesiana*, *C. solanacea*, *Cyrtandra filipes*, *Melicope reflexa*, *Peucedanum sandwicense*, *Phyllostegia hispida*, *P. mannii*, *Plantago princeps*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Lowland Wet—Unit 3 consists of 94 ac (38 ha) of State land, and 3,125 ac (1,265 ha) of privately owned land, from Waiahookalo gulch to Moaula stream and Puniuhua, on eastern

Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). Although Molokai—Lowland Wet—Unit 3 is not known to be occupied by *Asplenium dielarectum*, *Bidens wiebkei*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea dunbariae*, *C. grimesiana* ssp. *grimesiana*, *C. solanacea*, *Cyrtandra filipes*, *Lysimachia maxima*, *Melicope reflexa*, *Peucedanum sandwicense*, *Phyllostegia hispida*, *P. mannii*, *Plantago princeps*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Wet Cliff—Unit 1 (and) *Palmeria dolei*—Unit 43—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 43—Wet Cliff This area consists of 1,395 ac (565 ha) of State land, and 212 ac (86 ha) of privately owned land, and encircles the plateau between Pelekunu and Wailau valleys, in north-central Molokai. These units are occupied by the plants *Brighamia rockii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea munroi*, and *Hibiscus arnottianus* ssp. *immaculatus*, and include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Wet Cliff—Unit 1 is not known to be occupied by *Cyanea grimesiana* ssp. *grimesiana*, *Hesperomannia arborescens*, *Phyllostegia hispida*, *Pteris lidgatei*, or *Stenogyne bifida*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Wet Cliff—Unit 2 (and) *Palmeria dolei*—Unit 44—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 44—Wet Cliff This area consists of 462 ac (187 ha) of State land, and 806 ac (326 ha) of privately owned land (partly within The Nature Conservancy's Pelekunu Preserve), along the rim of Pelekunu Valley from Kipapa Ridge to Mapulehu, in central Molokai. These units are occupied by the plants *Clermontia oblongifolia* ssp. *brevipes* and *Phyllostegia hispida*, and include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Wet Cliff—Unit 2 is not known to be occupied by *Brighamia rockii*, *Canavalia molokaiensis*, *Cyanea grimesiana* ssp. *grimesiana*, *C. munroi*, *Hesperomannia arborescens*, *Hibiscus arnottianus* ssp. *immaculatus*, *Pteris lidgatei*, or *Stenogyne bifida*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable

habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Wet Cliff—Unit 3 consists of 1,137 ac (460 ha) of State land, and 225 ac (91 ha) of privately owned land, along the rim of Wailau Valley from Mapulehu to Kahiwa Gulch, in eastern Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). Although Molokai—Wet Cliff—Unit 3 is not known to be occupied by *Brighamia rockii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea grimesiana* ssp. *grimesiana*, *C. munroi*, *Hesperomannia arborescens*, *Hibiscus arnottianus* ssp. *immaculatus*, *Phyllostegia hispida*, *Pteris lidgatei*, or *Stenogyne bifida*, we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

The critical habitat designation for *Cyanea grimesiana* ssp. *grimesiana* includes 23 critical habitat units, covering two ecosystem types, which encompasses approximately 33,624 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Mesic—Units 1, 2, 3, 4, 5, 6, 7; Oahu—Lowland Wet—Units 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16.

Oahu—Lowland Mesic—Unit 1 [4,448 ac (1,800 ha)]. This area consists of 3,565 ac (1,443 ha) of State land, 583 ac (236 ha) of City and County of Honolulu land, 22 ac (9 ha) of Federal land, and 277 ac (112 ha) of privately owned land in the lowland mesic ecosystem in the Waianae Mountains, encompassing a large area including the north slopes of Mt. Kaala, from the Pahole NAR to the Kaala NAR, and south to the Waianae Kai Forest Reserve (FR). Oahu—Lowland Mesic—Unit 2 [1,063 ac (430 ha)]. This area consists of 1,063 ac (430 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Puuhapapa south to Puukaua. Oahu—Lowland Mesic—Unit 3 [353 ac (143 ha)]. This area consists of 353 ac (143 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Pohakea Pass to Kaiakuakai Gulch. Oahu—Lowland Mesic—Unit 4 [20 ac (8 ha)]. This area consists of 20 ac (8 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, between the Waipilopilo and Hanaimoa gulches, on State-owned land within the Hauula Forest Reserve. Oahu—Lowland Mesic—Unit 5 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, in Maakua Gulch and ridge; is State-owned; and within the Hauula FR. Oahu—Lowland Mesic—Unit 6 [247 ac (100 ha)]. This area consists of 12 ac (5 ha) State land and 235 ac (95 ha) of privately owned land in the lowland mesic ecosystem on the windward side of the Koolau Mountains, inland of Kaaawa Point, and is partially within Ahupuaa O Kahana State Park. Oahu—Lowland Mesic—Unit 7 [1,669 ac (676 ha)]. This area consists of 681 ac (276 ha) of State land, 129 ac (52 ha) of City and County of Honolulu land, and 852 ac (345 ha) of privately-owned land in the lowland mesic ecosystem on the leeward side of the Koolau Mountains, on Waialae Nui ridge.

Oahu—Lowland Wet—Unit 1 [541 ac (219 ha)]. This area consists of 428 ac (173 ha) of State land and 112 ac (46 ha) of City and County of Honolulu land in the lowland wet ecosystem on the windward side of the Waianae Mountains, and partially within the Mokuleia and Waianae Kai

Forest Reserves. Oahu—Lowland Wet—Unit 2 [20 ac (8 ha)]. This area consists of 19 ac (8 ha) of State land in the lowland wet ecosystem on the windward side of the Waianae Mountains at Puuhapapa. Oahu—Lowland Wet—Unit 3 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland wet ecosystem on the windward side of the Waianae Mountains at Puukanehoa. Oahu—Lowland Wet—Unit 4 [27 ac (11 ha)]. This area consists of 27 ac (11 ha) in the lowland wet ecosystem on the windward side of the Waianae Mountains on State land at Puukaua. Oahu—Lowland Wet—Unit 5 [74 ac (30 ha)]. This area consists of 74 ac (30 ha) of State land in the lowland wet ecosystem, on the windward side of the Waianae Mountains at Palikea. Oahu—Lowland Wet—Unit 6 [790 ac (320 ha)]. This area consists of 790 ac (320 ha) of privately owned land in the lowland wet ecosystem, in privately owned land on the windward side of the Koolau Mountains, and includes Kahawainui, Ihihi, Wailele, and Koloa gulches. Oahu—Lowland Wet—Unit 7 [1,787 ac (723 ha)]. This area consists of 1,499 ac (606 ha) of State land and 288 ac (117 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, within the Kaipapau and Haula Forest Reserves and Sacred Falls State Park, from Puukainapuaa to Kaluanui (Sacred Falls). Oahu—Lowland Wet—Unit 8 [3,041 ac (1,231 ha)]. This area consists of 1,386 ac (561 ha) of State land and 1,655 ac (670 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, partially within the Ahupuaa O Kahana State Park, including Waihoi Springs, and Punaluu, Kahana, Waikane, Waikēē, and Uwao streams. Oahu—Lowland Wet—Unit 9 [15,728 ac (6,365 ha)]. This area consists of 3,827 ac (1,545 ha) of State land, 147 ac (60 ha) of City and County of Honolulu land, 4,509 ac (1,825 ha) of Federal land (U.S. Fish and Wildlife Service), and 7,245 ac (2,932 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, partially within the Ewa FR Waimano Section and the Oahu Forest National Wildlife Refuge. This area extends along the Koolau summit from Waipio to Manaiki Stream. Oahu—Lowland Wet—Unit 10 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) of privately-owned land in the lowland wet ecosystem in private land on the windward side of the Koolau Mountains, along Kaalaea Stream. Oahu—Lowland Wet—Unit 11 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) in the lowland wet ecosystem, owned by the City and County of Honolulu on the windward side of the Koolau Mountains, along Waihee Stream. Oahu—Lowland Wet—Unit 12 [53 ac (21 ha)]. This area consists of 28 ac (11 ha) of City and County of Honolulu land and 26 ac (10 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, along Kahaluu Stream and tributary. Oahu—Lowland Wet—Unit 13 [75 ac (30 ha)]. This area consists of 74 ac (30 ha) of City and County of Honolulu land and 1 ac (0.5 ha) of State land in the lowland wet ecosystem on the windward side of the Koolau Mountains, along Heeia Stream and tributaries. Oahu—Lowland Wet—Unit 14 [478 ac (193 ha)]. This area consists of 274 ac (111 ha) of State land, 195 ac (79 ha) of City and County of Honolulu land, and 9 ac (4 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, extending from the Wilson Tunnel area southeast to Moole Stream. Oahu—Lowland Wet—Unit 15 [407 ac (165 ha)]. This area consists of 407 ac (165 ha) in the lowland wet ecosystem in State of Hawaii Department of Land and Natural Resources Land Division land on the windward side of the Koolau Mountains in Maunawili Valley, including Omao and Maunawili streams and Kapakahi and Pikoakea Springs. Oahu—Lowland Wet—Unit 16 [2,507 ac (1,014 ha)]. This area consists of 1,533 ac (621 ha) of State land, 365 ac (148 ha) of City and County of Honolulu land, and 608 (246 ha) of privately owned land in the lowland wet ecosystem in on the leeward side of the Koolau Mountains, partly within the Honolulu Watershed Forest Reserve, extending from the eastern side of Nuuanu Valley southeast along the Koolau summit to Kulepeamoa Ridge.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea grimesiana* ssp. *grimesiana* critical habitat consists of two components. Lowland wet (Molokai) and Wet cliff (Molokai) (81 FR 17790-18110):

Ecosystem: Lowland Wet. Elevation: *Cyanea grimesiana*. Annual precipitation: 50–75 in (130–190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Ecosystem: Wet Cliff. Elevation: unrestricted. Annual precipitation: >75 in (>190 cm). Substrate: >65 degree slope, shallow soils, weathered lava. Canopy: None. Subcanopy: *Broussaisia*, *Cheirodendron*, *Leptecophylla*, *Metrosideros*. Understory: *Bryophytes*, *Ferns*, *Coprosma*, *Dubautia*, *Kadua*, *Peperomia*.

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea grimesiana* ssp. *grimesiana* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Cyanea grimesiana* ssp. *grimesiana* occurs within the Lowland mesic and Lowland wet ecosystems in the Waianae Mountain caldera complex and the Koolau Mountain caldera complex:

Oahu—Lowland Mesic—Units 1, 2, 3, 4, 5, 6, 7. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. (E) Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. (E) Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Oahu—Lowland Wet—Units 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16. (A) Elevation: <3,000 ft (<1,000 m). (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. (D) Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. (E) Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. (E) Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight

plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; MauiWet

Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Cyanea grimesiana* ssp. *grimesiana* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual (inferred from USFWS, 1999)

Lifespan

Adult: < 10 years (USFWS, 2011)

Breeding Season

Adult: July - August (USFWS, 1999)

Reproduction Narrative

Adult: *Cyanea grimesiana* subsp. *grimesiana* is a short-lived perennial (fewer than 10 years) (USFWS, 2011). Little is known about the life history of this plant. On Molokai, flowering plants have been reported in July and August (USFWS, 1999).

Habitat Type

Adult: Terrestrial (NatureServe, 2015); riparian (USFWS, 1999)

Habitat Vegetation or Surface Water Classification

Adult: Koa-ohia-uluhe lowland mesic forest; koa-ohia mesic forest (USFWS, 2011)

Geographic or Habitat Restraints or Barriers

Adult: 1,150 - 3,100 ft. elevation (USFWS, 1999)

Habitat Narrative

Adult: Inhabits moist forests in gulch bottoms and gulch slopes. (NatureServe, 2015). In the Waianae Mountains of Oahu, the habitat of *Cyanea grimesiana* subsp. *grimesiana* is *Acacia koa* (*koa*) – *Metrosideros polymorpha* (*ohia*) – *Dicranopteris linearis* (*uluhe*) lowland mesic forest (Puu Pane), with associated native species. In the Koolau Mountains of Oahu, the habitat where *Cyanea grimesiana* subsp. *grimesiana* occurs is *Acacia koa* – *Metrosideros polymorpha* mesic forest (USFWS, 2011). *Cyanea grimesiana* ssp. *grimesiana* is typically found in mesic forest often dominated by *ohia* or *ohia* and *koa*, or on rocky or steep slopes of stream banks, at elevations between 350 and 945 meters (1,150 and 3,100 feet) (USFWS, 1999).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Not available

Number of Populations:

4 (NatureServe, 2015)

Population Size:

0 wild individuals, <50 outplanted individuals (USFWS, 2018)

Minimum Viable Population Size:

Three populations with a minimum of 50 mature plants each (USFWS, 2011)

Population Narrative:

One population of three individuals and a single seedling was seen in 2000 in Mt. Kaala Natural Area Reserve, Puu Pane, on the north facing slopes of Mt. Kaala, in the Waianae Mountains at 671 meters (2,200 feet) elevation (Perlman 2009a; USFWS 1999). Another population of *Cyanea grimesiana* was reported from North Haleauau Gulch on the Schofield Barracks Military Reservation, last seen in 1992. In the back of Makaha Valley, in 2005, Steve Perlman of the National Tropical Botanical Garden, Ane Bakutis of the Plant Extinction Prevention Program, and Amy Tsuneyoshi of the Honolulu Board of Water Supply saw one individual without flowers or fruits at 689 meters (2,260 feet) elevation (Perlman 2009a). To be considered stable, a minimum of three populations should be documented on islands where they now occur or occurred historically. For the species to be considered stable, each of these populations must be naturally reproducing and increasing in number, with a minimum of 50 mature individuals per population. There are currently no known wild individuals and 3 outplanted individuals (USFWS, 2011). On Oahu there are five to six individuals in four occurrences in the Waianae and Koolau Mountains" (U.S. Army 2006; HBMP 2008 cited by USFWS 2012; NatureServe, 2015).; As

discussed in the previous review in 2011, this subspecies is found in the Ko'olau Mountains of Oahu, and historically on Moloka'i. Those individuals in the Waianae Mountains of Oahu have been determined to be *C. grimesiana* subsp. *obatae*. Currently, on O'ahu, there are no wild individuals of *C. grimesiana* subsp. *grimesiana* remaining at its last known location (PEPP 2013). The occurrence on Moloka'i has not been observed since 2004, and was searched for but not relocated in 2009 (Lammers 2004; PEPP 2009). (USFWS, 2018)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (pigs, goats, and axis deer), nonnative plants, fire, landslides, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Fire can destroy dormant seeds and plants, even in steep and inaccessible areas. Successive fires can remove habitat for native species by altering microclimate conditions favorable to alien plants. Landslides destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (pigs, goats, axis deer, rats, and slugs) is considered an ongoing threat to *Cyanea grimesiana grimesiana* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

Stressor: Small populations (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: *Cyanea grimesiana grimesiana* faces the threat of limited numbers (i.e., there are fewer than 50 individuals in the wild). *Cyanea grimesiana grimesiana* has not been observed since 1991 on Molokai (USFWS, 2013).

Stressor: Climate change loss or degradation of habitat (USFWS, 2018)

Exposure:**Response:****Consequence:**

Narrative: Climate change may pose a threat to this subspecies. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawai'i using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) was conducted at the species level and concluded that *Cyanea grimesiana* is vulnerable to the impacts of climate change, with a vulnerability score of 0.497 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions will be needed to conserve this taxon into the future. (USFWS, 2018)

Stressor: Lack of adequate hunting regulations (USFWS, 2018)

Exposure:**Response:****Consequence:**

Narrative: The last known population of *Cyanea grimesiana* subsp. *grimesiana* on Moloka'i occurred in a state hunting area in the Moloka'i Forest Reserve. The last known population of this subspecies on Oahu occurred on private land between two State hunting areas. Nonnative feral ungulates pose a major ongoing threat to native species through destruction and modification of habitat, and through direct herbivory or predation. The last known populations on O'ahu and Moloka'i were not fenced and feral pigs have been noted as a threat to the species. Public hunting areas are not fenced and game mammals have unrestricted access to most areas across the landscape, regardless of underlying land use designation; therefore, any unfenced populations are at risk (DLNR 2010). (USFWS, 2018)

Recovery**Reclassification Criteria:**

- 1) A total of five to seven populations should be documented on islands where they now occur or occurred historically (USFWS, 1999).
- 2) Each of these populations must be naturally reproducing, stable or increasing in number, and secure with 300 minimum numbers of mature individuals per population (for short-lived perennials) (USFWS, 1999).
- 3) Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 1999).

Delisting Criteria:

- 1) A total of 8 to 10 populations should be documented on islands where they now occur or occurred historically (USFWS, 1999).
- 2) Each of these populations must be naturally reproducing, stable or increasing in number, and secure with 300 minimum numbers of mature individuals per population (for short-lived perennials) (USFWS, 1999).

3) Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 1999).

Recovery Actions:

- Protect habitat and control threats (USFWS, 1999).
- Expand existing wild populations (USFWS, 1999).
- Conduct essential research (USFWS, 1999).
- Develop and maintain monitoring plans (USFWS, 1999).
- Reestablish wild populations within the historic range (USFWS, 1999).
- Validate and revise recovery criteria (USFWS, 1999).
- Construct exclosures to protect populations against feral and wild ungulates (USFWS, 1999).
- Control competing alien plant species (USFWS, 1999).
- Maintain adequate genetic stock (USFWS, 1999).
- Enhance wild populations and establish new populations (USFWS, 1999).
- Protect endangered plants from fire (USFWS, 1999).
- Surveys and inventories—Survey for additional populations of *Cyanea grimesiana* subsp. *grimesiana* in historical locations and appropriate remaining habitat for new occurrences. (USFWS, 2018)
- Ungulate monitoring and control—Construct and maintain fenced exclosures to protect reintroduced individuals from the negative impacts of feral ungulates. Protect all occurrences against browsing and habitat disturbances from feral ungulates to prevent imminent extinction. (USFWS, 2018)
- Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations. Control invasive nonnative species that compete with the species around all populations. (USFWS, 2018)
- Captive propagation for genetic storage and reintroduction—Continue propagation efforts for maintenance of genetic stock. (USFWS, 2018)
- Reintroduction and translocation—Continue to reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this subspecies. (USFWS, 2018)
- Stochastic events—Reduced viability due to low numbers—Continue seed collection, seed storage, propagation, out planting efforts for this subspecies. (USFWS, 2018)
- Predator and herbivore monitoring and control—Implement effective control methods for rodents and slugs at the last known location and at reintroduced populations. (USFWS, 2018)
- Habitat and natural process management and restoration—Strategic planning—Work with Hawai'i Division of Forestry and Wildlife and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this subspecies. (USFWS, 2018)
- Climate change adaptation strategy—Assess the modeled effects of climate change on this subspecies and use to determine future landscape needed for the recovery of the subspecies. (USFWS, 2018)

Conservation Measures and Best Management Practices:

- Monitor known populations and collect any available seed for genetic storage and reintroduction (USFWS, 2011).

- Maintain or build fences around existing populations to protect them from the negative impacts of ungulates (USFWS, 2011).
- Control invasive introduced species around known populations (USFWS, 2011).
- Develop and implement methods to control rats and slugs (USFWS, 2011).
- Propagate to augment the existing populations (USFWS, 2011).
- Establish additional populations within protected suitable habitat (USFWS, 2011).
- Survey historical locations and appropriate remaining habitat for new individuals (USFWS, 2011).
- Work with Hawaii Division of Forestry and Wildlife and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2011).
- Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species (USFWS, 2011).

SPECIES ACCOUNT: *Cyanea grimesiana* ssp. *obatae* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 06/27/1994; Pacific Region (R1) (USFWS, 2016)

Physical Description

It is a single-stemmed or sparingly branched shrub 1 to 3.2 m (3.3 to 10.5 ft) tall, with leaves clustered at the stem tips. The wide, deeply lobed, pinnate leaves are 27 to 58 cm (10.6 to 22.8 in) long and 14 to 32-cm (5.5 to 12.6 in) wide. The tubular flowers are purple or green to yellow-white and 5.5 to 8.0-cm (2.2 to 3.1 in) long. The elliptical orange berries are 1.8 to 3.0-cm (0.7 to 1.2 in) long. *Cyanea grimesiana* ssp. *obatae* can be distinguished from the two other subspecies of *C. grimesiana* by its short, narrow calyx lobes that are not fused and do not overlap (Wagner et al 1999; Makua Implementation Team 2003) (USFWS, 2016).

Taxonomy

A member of the Campanulaceae (bellflower family). The genus *Cyanea* is one of the largest Hawaiian plant genera and incorporates a high proportion of rare taxa, including 28 endangered taxa, 1 threatened taxon, 8 candidates for listing, and 17 species of concern (Service 2006a, Hawaii Biodiversity and Mapping Program 2006) (USFWS, 2016).

Historical Range

Distribution *Cyanea grimesiana* ssp. *obatae* is a species endemic to Oahu. Survey data indicate *C. grimesiana* ssp. *obatae* historically was known from an area extending for about 6.5 km (4 mi) in the southern Waianae Mountains (59 FR 32932) (USFWS, 2016).

Current Range

Currently occurs in the Waianae Mountains of Oahu (NatureServe, 2015). Many of the occurrences that have been monitored over the last 15 to 20 years have either died out or have greatly declined in numbers; most of the known occurrences have been recently discovered. One naturally occurring plant was recently discovered at Makaha, which represents a new occurrence for this subspecies. A new, naturally occurring plant was also recently discovered in the Central Kaluaa population unit (USFWS, 2016).

Critical Habitat Designated

Yes; 6/17/2003.

Legal Description

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea grimesiana* ssp. *obatae* (Haha) under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Cyanea grimesiana* ssp. *obatae* (77 FR 57648-57862). The critical habitat designation includes 17 critical habitat units, which encompass approximately 8,022 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Cyanea grimesiana* ssp. *obatae* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs

necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Cyanea grimesiana* ssp. *obatae* includes 17 critical habitat units, covering three ecosystem types, which encompass approximately 8,022 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Mesic—Units 1, 2, 3, 4, 5, 6, 7; Oahu—Lowland Wet—Units 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16.

Oahu—Lowland Mesic—Unit 1 [4,448 ac (1,800 ha)]. This area consists of 3,565 ac (1,443 ha) of State land, 583 ac (236 ha) of City and County of Honolulu land, 22 ac (9 ha) of Federal land, and 277 ac (112 ha) of privately owned land in the lowland mesic ecosystem in the Waianae Mountains, encompassing a large area including the north slopes of Mt. Kaala, from the Pahole NAR to the Kaala NAR, and south to the Waianae Kai Forest Reserve (FR). Oahu—Lowland Mesic—Unit 2 [1,063 ac (430 ha)]. This area consists of 1,063 ac (430 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Puuhapapa south to Puukaua. Oahu—Lowland Mesic—Unit 3 [353 ac (143 ha)]. This area consists of 353 ac (143 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Pohakea Pass to Kaiakuakai Gulch.

Oahu—Lowland Wet—Unit 1 [541 ac (219 ha)]. This area consists of 428 ac (173 ha) of State land and 112 ac (46 ha) of City and County of Honolulu land in the lowland wet ecosystem on the windward side of the Waianae Mountains, and partially within the Mokuleia and Waianae Kai Forest Reserves. Oahu—Lowland Wet—Unit 2 [20 ac (8 ha)]. This area consists of 19 ac (8 ha) of State land in the lowland wet ecosystem on the windward side of the Waianae Mountains at Puuhapapa. Oahu—Lowland Wet—Unit 3 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland wet ecosystem on the windward side of the Waianae Mountains at Puukanehoa. Oahu—Lowland Wet—Unit 4 [27 ac (11 ha)]. This area consists of 27 ac (11 ha) in the lowland wet ecosystem on the windward side of the Waianae Mountains on State land at Puukaua. Oahu—Lowland Wet—Unit 5 [74 ac (30 ha)]. This area consists of 74 ac (30 ha) of State land in the lowland wet ecosystem, on the windward side of the Waianae Mountains at Palikea.

Oahu—Dry Cliff—Unit 1 [49 ac (20 ha)]. This area consists of 49 ac (20 ha) in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the rim of Makua Valley. Oahu—Dry Cliff—Unit 2 [412 ac (167 ha)]. This area consists of 320 ac (130 ha) of State land and 91 ac (37 ha) of City and County of Honolulu land in the dry cliff ecosystem, on the leeward side of the Waianae Mountains, along the ridge from Keaau to Ohikilolo. Oahu—Dry Cliff—Unit 3 [450 ac (182 ha)]. This area consists of 349 ac (141 ha) of City and County of Honolulu land and 101 ac (41 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the eastern rim of Makaha Valley along Kamaileunu Ridge. Oahu—Dry Cliff—Unit 4 [24 ac (10 ha)]. This area consists of 24 ac (10 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along Kauaopuu ridge, which divides Waianae Kai and Lualualei valleys. Oahu—Dry Cliff—Unit 6 [149 ac (60 ha)]. This area consists of 149 ac (60 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Lualualei Valley from Puukanehoa to Puukaua. Oahu—Dry Cliff—Unit 7a [68 ac (27 ha)]. This area consists of 68 ac (27 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley to Pohakea. Oahu—Dry Cliff—Unit 7b [38

ac (16 ha)]. This area consists of 38 ac (16 ha) of State land in the dry cliff ecosystem on the leeward side of the Waianae Mountains, along the rim of Lualualei Valley at Palikea. Oahu—Dry Cliff—Unit 8 [259 ac(105 ha)]. This area consists of 259 ac (105 ha) in the dry cliff ecosystem on the leeward side of the Waianae Mountains, on State land along the rim of Nanakuli Valley from Palehua to Puumanawanua, and partially within the Nanakuli Forest Reserve.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea grimesiana* ssp. *obatae* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Cyanea grimesiana* ssp. *obatae* occurs within the lowland wet, Dry cliff and lowland mesic ecosystems in the Waianae Mountain caldera complex :

Oahu—Lowland Mesic—Units 1, 2, 3. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. (E) Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. (E) Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Oahu—Lowland Wet—Units 1, 2, 3, 4, 5. (A) Elevation: <3,000 ft (<1,000 m). (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. (D) Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. (E) Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. (E) Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Oahu—Dry Cliff—Units 1, 2, 3, 4, 5, 6, 7a, 7b, 8. (A) Elevation: unrestricted. (B) Annual Precipitation: < 75 in (<190 cm). (C) Substrate: >65 degree slope, rocky talus. (D) Canopy: None. (E) Subcanopy: *Antidesma*, *Chamaesyce*, *Diospyros*, *Dodonaea*. (E) Understory: *Bidens*, *Eragrostis*, *Melanthera*, *Schiedea*.

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Cyanea grimesiana* ssp. *obatae* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History

Food/Nutrient Resources

Reproductive Strategy

Adult: Sexual: self-pollination, cross-pollination (USFWS, 2016)

Lifespan

Adult: < 10 years, based on genus (USFWS, 2016)

Breeding Season

Adult: Year round (USFWS, 2016)

Key Resources Needed for Breeding

Adult: Presumably birds (USFWS, 2016)

Reproduction Narrative

Adult: This subspecies may produce flowers and fruits year round, depending on rainfall. The long tubular flowers and orange berries of this taxon suggest pollination and seed dispersal by birds may be common; however, the plants are capable of self-pollination and isolated plants have been found with viable seeds. *Cyanea grimesiana* ssp. *obatae* presumably lives less than 10 years like other *Cyanea* of similar size (Makua Implementation Team 2003) (USFWS, 2016).

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Diverse mesic to wet lowland forest (USFWS, 2016)

Geographic or Habitat Restraints or Barriers

Adult: Occurs at 1,325 - 3,528 ft. elevation (USFWS, 2016)

Habitat Narrative

Adult: Inhabits moist forests, in gulch bottoms or lower gulch slopes (NatureServe, 2015). *Cyanea grimesiana* ssp. *obatae* typically grows on steep, moist, shaded slopes in diverse mesic to wet lowland forests at elevations between 404 and 1,075 m (1,325 and 3,528 ft). It often grows on steep, vertical embankments in rock or a mix of rock and soil (USFWS, 2016).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Significant increase since 1994 (USFWS, 2016)

Resiliency:

Very low (inferred from NatureServe, 2015; see current range/distribution)

Representation:

Low (USFWS, 2016)

Redundancy:

Low (inferred from USFWS, 2016)

Number of Populations:

6 (USFWS, 2016)

Population Size:

254 (USFWS, 2016)

Minimum Viable Population Size:

100 mature, reproducing individuals (USFWS, 2016)

Additional Population-level Information:

76% of individuals are from propagated stock (USFWS, 2016)

Population Narrative:

At the time of listing in 1994, there were approximately 18 known individuals in three occurrences (59 FR 32932). Currently, there are 254 total individuals in six population units, located on State and private lands (Table SB 9) (U.S. Army Garrison 2005b; 68 FR 35950). None of the currently known population units of this subspecies contain 100 mature, reproducing individuals (the minimum number required for stabilized population as defined in the Makua Implementation Plan). Demographic data for this species indicate that about 76 percent of all currently existing individuals of *Cyanea grimesiana* ssp. *obatae* are augmentations or reintroductions from greenhouse-propagated stock. Augmentations have been outplanted at five separate locations, including all three stabilization population units; four locations are on land owned by The Nature Conservancy of Hawaii and one location is on State land. This subspecies is easy to propagate and outplant. Plants produce ample viable seed but the genetic base is limited owing to the low number of founder individuals (USFWS, 2016).

Threats and Stressors

Stressor: Habitat degradation (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: Threats include alien plants and feral ungulates (NatureServe, 2015). Occurrences of *Cyanea grimesiana* ssp. *obatae* are vulnerable to extirpation from habitat degradation by feral ungulates; competition with various non-native plants; wildfire; and military activities (USFWS, 2016).

Stressor: Predation (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: Recruitment is limited by rats and slugs, which attack plants of all size classes. Major rat damage has occurred to five mature plants in West Makaleha population unit, and slugs prey on plants of all size/age classes. Slugs likely attack all members of this genus, as suggested by investigations of the related *Cyanea superba* ssp. *superba*. Slug predation killed half of 14 outplants at the North Branch of South Ekahanui population unit, and the remaining plants are in

poor condition most likely due to the stress of predation (U.S. Army Garrison 2005b) (USFWS, 2016).

Stressor: Stochastic events (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: Reduced reproductive vigor due to small population size and limited distribution as well as direct destruction of individual plants by rat or slug predation, erosion, landslides, and rockslides is a threat (59 FR 32932; 68 FR 35950; Service 1995a, 1998). This subspecies tends to fluctuate widely in population size and has a recent history of decline; any catastrophic disturbance during a major low point could extirpate one or more population units or result in subspecies extinction in the wild (Makua Implementation Team 2003). The science of conservation biology has documented a general pattern of population collapse for a wide range of plant and animal species (Dennis et al 1991; Schemske et al 1994; Morris et al 1999; Menges 2000). According to this pattern, *C. grimesiana* ssp. *obatae* already is in a phase of “quasi-extinction” with numbers that have declined to the point where demographic stochasticity alone can result in extirpation (USFWS, 2016).

Stressor: Loss of pollinators (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: The long-billed, nectar-feeding native Hawaiian birds that were the presumed pollinators of *C. grimesiana* ssp. *obata* have been almost totally extirpated from the Waianae Mountains. Although this subspecies is capable of self-pollination, the loss of its natural pollinators has likely resulted in decreased genetic variability (Makua Implementation Team 2003) (USFWS, 2016).

Stressor: Climate change (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Current climate change analyses in the Pacific Islands lack sufficient spatial resolution to make predictions on impacts to this species. The Pacific Islands Climate Change Cooperative (PICCC) has currently funded climate modeling that will help resolve these spatial limitations. We anticipate high spatial resolution climate outputs by 2013 (USFWS, 2012).

Recovery

Reclassification Criteria:

1. A total of five to seven populations should be documented on Oahu and at least one other island where they now occur or occurred historically (USFWS, 1998).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure, with a minimum of 300 mature individuals per population (for short-lived perennials) (USFWS, 1998).

3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 1998).

Delisting Criteria:

1. A total of 8 to 10 populations should be documented on Oahu and at least one other island where they now occur or occurred historically (USFWS, 1998).

2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure, with a minimum of 300 mature individuals per population (for short-lived perennials) (USFWS, 1998).

3. Each population should persist at this level for a minimum of 5 consecutive years (USFWS, 1998).

Recovery Actions:

- Protect habitat and control threats (USFWS, 1998).
- Expand existing wild populations (USFWS, 1998).
- Conduct essential research (USFWS, 1998).
- Develop and maintain monitoring plans (USFWS, 1998).
- Reestablish wild populations within historic range (USFWS, 1998).
- Validate and revise recovery criteria (USFWS, 1998).
- Construct enclosures to protect populations against feral pigs (USFWS, 1998).
- Control competing alien plant species within enclosures (USFWS, 1998).
- Reduce threat from rats (USFWS, 1998).

Conservation Measures and Best Management Practices:

- The fence at the Palikea (South Palawai) population unit needs to be expanded to increase the area for future outplantings. The Makaha plant is not within the management subunit that will be fenced in 2007; it is scheduled for fencing in 2009. The number of *C. grimesiana* ssp. *obatae* founders represented at reintroduction sites needs to be increased and equalized. Research on slug control in forest settings is needed to find ways to reduce invertebrate threats to *C. grimesiana* ssp. *obatae* and associated native plants (USFWS, 2016).
- The Makua Implementation Team (2003) has developed stabilization protocols for *Cyanea grimesiana* ssp. *obatae*, which are incorporated in the Makua Implementation Plan Addendum (U.S. Army Garrison 2005a). All population units (except Makaha) are protected by fenced enclosures. Reintroductions within the North Branch of South Ekahanui population unit are within the management unit fence, although the naturally occurring site (now extirpated) is not. The Army and the State have been augmenting occurrences in the Pahole to West Makaleha population unit, and The Nature Conservancy of Hawaii has been augmenting occurrences in the Palikea (South Palawai) population unit. Rat control grids (toxicant bait stations and snap traps) are maintained during the *C. grimesiana* ssp. *obatae* fruiting season at all population units except Pahole and Palikea Gulch. This subspecies is located in occurrences over four management units where it will also benefit from population unit and/or ecosystem-level protection: Pahole, West Makaleha, Kaluaa and Waieli, and Palikea (USFWS, 2016).
- The Army recently assisted The Nature Conservancy in an “aggressive” outplanting that involved reintroduction of relatively small plants at the Central Kaluaa population unit (U.S. Army Garrison 2005b). Smaller plants require a shorter growing time in the nursery, are easier to transport, and

can be planted in more locations such as steep slopes where wild plants are known to occur. However, the mortality of these small outplants was greater than that of larger outplants. This aggressive approach of outplanting smaller individuals may be justified for this subspecies because of the large amount of seed available (U.S. Army Garrison 2005b). In addition, this subspecies is represented in several ex situ collections, which in 2005 included 11 cuttings in a nursery (Harold L. Lyon Arboretum), 51 mature fruit in storage or awaiting processing at a nursery (Army Environmental Division, Oahu), 4,465 ungerminated seeds in a nursery (Harold L. Lyon Arboretum), 215,000 seeds in seed storage (Lyon Arboretum Seed Storage Facility), and 642 seedlings in a nursery (Harold L. Lyon Arboretum) (Service 2005b) (USFWS, 2016).

- Captive propagation for genetic storage and reintroduction: Continue to collect seeds from tagged individuals, keeping close track of the maternal source for use in ex situ propagation. Continue to collect seeds from all existing populations and send to at least two or three different venues for propagation (USFWS, 2012).
- Reintroduction / translocation implementation – Continue to reintroduce the species back into its known historical range (USFWS, 2012).
- Ungulate exclosures: Continue to construct fenced exclosures around existing and reintroduced populations to provide protection from feral ungulates. Monitor fenced exclosures for evidence of breaching by feral ungulates (USFWS, 2012).
- Ungulate control – Continue to protect all populations against disturbances from feral ungulates (USFWS, 2012).
- Ecosystem-altering invasive plant species control – Continue to control invasive introduced plant species around all populations (USFWS, 2012).
- Predator / herbivore control – Continue to implement effective control methods for rodents (USFWS, 2012).
- Surveys / inventories – Conduct thorough surveys of appropriate habitat in historical locations to determine the current status of *Cyanea grimesiana* subsp. *obatae* (USFWS, 2012).
- Threats research: Conduct studies to develop and implement control methods for slugs around all known populations. Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species (USFWS, 2012).
- Fire protection – Develop and implement a fire management plan for all populations of *Cyanea grimesiana* subsp. *obatae* (USFWS, 2012).
- Invertebrate control research – Conduct studies to determine the effects of the twospotted leaf hopper on populations of *Cyanea grimesiana* subsp. *obatae*. If research identifies that control is necessary, develop and implement effective control techniques (USFWS, 2012).
- Population viability monitoring – Study *Cyanea grimesiana* subsp. *obatae* populations with regard to population size and structure, geographical distribution, flowering cycles, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats (USFWS, 2012).
- Alliance and partnership development – Work with the U.S. Army and other land managers to continue planning and contribute to implementation of ecosystem-level restoration and management to benefit this species (USFWS, 2012).

SPECIES ACCOUNT: *Cyanea hamatiflora* ssp. *carlsonii* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 03/04/1994; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Cyanea hamatiflora Rock subsp. *carlsonii* (Rock) Lammers is a palm-like tree that grows 9.8-26 ft (3-8 m) tall and has tan sap (Lammers 1990). The leaf blades are 20-31 in (50-80 cm) long and 3-5.5 in (8-14 cm) wide and are without a leaf stalk. Five to 10 flowers are in clusters at the end of a main cluster stalk (peduncle) 0.6-1.2 in (1.5-3 cm) long. Each flower is subtended by a stalk (pedicel) 0.2-0.5 in (0.5-1.2 cm) long. The sepals and the petals are fused at the base into an oboval tube (hypanthium) 0.5-1.2 in (1.2-3 cm) long and 0.2-0.5 in (0.6-1.2 cm) wide. The calyx has five narrowly oblong lobes 1.2-1.8 in (3-4.5 cm) long and 0.2 in (0.5 cm) wide. Magenta petals are fused into a tube 2.3-3.1 in (6-8 cm) long and 0.2-0.4 in (0.6-1.1 cm) wide, which is down-curved. The top of the tube is 1-lipped with five down-curved lobes. Berries are red and oboval, 1.2-1.8 in (3-4.5 cm) long and 0.8-1.0 in (2-2.7 cm) wide. (USFWS, 1996)

Taxonomy

The species is composed of two subspecies: *Cyanea hamatiflora* subsp. *carlsonii* is an endangered taxon endemic to the Big Island; *Cyanea hamatiflora* subsp. *hamatiflora* occurs only on East Maui and is relatively common. *C. h.* subsp. *carlsonii* is distinguished from other taxa in the genus by calyx lobes that are longer and wider (Lammers 1990). (USFWS, 1996)

Historical Range

Cyanea hamatiflora subsp. *carlsonii*, known only from the westside of the Big Island, is a fairly recent discovery by Rock and Carlson (1957). (USFWS, 1996)

Current Range

This species current range is restricted to the Kona region of Hawaii. (NatureServe, 2015)

Critical Habitat Designated

Yes; 7/2/2003.

Legal Description

On July 2, 2003, the U.S. Fish and Wildlife Service (Service), designated critical habitat pursuant to the Endangered Species Act of 1973, as amended (Act), for *Cyanea hamatiflora* ssp. *Carlsonii* on the island of Hawaii (68 FR 39623 - 39722).

Critical Habitat Designation

The critical habitat designation for *Cyanea hamatiflora* ssp. *Carlsonii* includes four units totaling 4,744 acres in Hawaii county, Hawaii. The units are Hawaii 11—*Cyanea hamatiflora* ssp. *carlsonii*—a, Hawaii 14—*Cyanea hamatiflora* ssp. *carlsonii*—b, Hawaii 15—*Cyanea hamatiflora* ssp. *carlsonii*—c, Hawaii 16—*Cyanea hamatiflora* ssp. *carlsonii*—d. Two of the units, “Hawaii 11—*Cyanea hamatiflora* ssp. *carlsonii*—a” and “Hawaii 16—*Cyanea hamatiflora* ssp. *carlsonii*—d” currently are occupied. These two units are each essential to the conservation of *C. hamatiflora* ssp. *carlsonii* because each supports an extant colony of this species and includes habitat that is important for the expansion of the present population, which is currently considered nonviable.

Each of the two currently unoccupied units is essential to the conservation of the species because each supports habitat that is necessary for the establishment of additional populations in order to reach recovery goals. The four critical habitat units are geographically separated in order to avoid destruction of habitat for all populations by one naturally occurring catastrophic event. The designation of these four units provides habitat for a total of eight populations of *C. hamatiflora* ssp. *carlsonii*, each with 300 mature, reproducing individuals.

Hawaii 11—*Cyanea hamatiflora* ssp. *carlsonii*—a [92 ha (227 ac)]: This unit contains no named natural features and lies completely within the Waiaha watershed. The unit, which is completely within the Honuaua Forest Reserve, provides habitat for 1 population of 300 individuals and is currently occupied by about 14 individuals. This unit provides the northernmost critical habitat within the species' historical range.

Hawaii 14—*Cyanea hamatiflora* ssp. *carlsonii*—b [597 ha (1,475 ac)]: This unit contains no named natural features and lies completely within the Kiilae watershed. The unit, which is completely within the Kona Unit of Hakalau Forest NWR, provides habitat for 2 populations of 300 individuals and is currently unoccupied.

Hawaii 15—*Cyanea hamatiflora* ssp. *carlsonii*—c [1,045 ha (2,583 ac)]: This unit contains no named natural features, lies completely within the Kiilae watershed, and contains portions of the South Kona Forest Reserve. The unit provides habitat for 4 populations of 300 individuals and is currently unoccupied.

Hawaii 16—*Cyanea hamatiflora* ssp. *carlsonii*—d [186 ha (459 ac)]: This unit contains no named natural features, it lies completely within the Kiilae watershed, and is completely within Kipahoe NAR. The unit provides habitat for 1 population of 300 individuals is currently occupied by 1 individual. This unit provides the southernmost critical habitat within the species' historical range.

Primary Constituent Elements/Physical or Biological Features

Habitat features that are essential for this species include, but are not limited to, mesic montane forest dominated by *Metrosideros polymorpha* or *Acacia koa*.

Special Management Considerations or Protections

The Service publishes this final rule acknowledging that they have incomplete information regarding many of the primary biological and physical requirements for this species. However, both the Act and the relevant court orders require the Service to proceed with designation at this time based on the best information available. As new information accrues, the Service may consider reevaluating the boundaries of areas that warrant critical habitat designation.

The following management actions are important in providing a conservation benefit to the species: feral ungulate control; wildfire management; nonnative plant control; rodent control; invertebrate pest control; maintenance of genetic material of the endangered and threatened plant species; propagation, reintroduction, and augmentation of existing populations into areas essential for the recovery of the species; ongoing management of the wild, outplanted, and augmented populations; maintenance of natural pollinators and pollinating systems, when known; habitat management and restoration in areas essential for the recovery of the species;

monitoring of the wild, outplanted, and augmented populations; rare plant surveys; and control of human activities/access.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: This taxon was observed in flower during December 1980 (HHP1991g1) and August 1995 (C. Corn, DOFAW, pers. comm., 1996). Seeds were collected by Hawaii Division of Forestry and Wildlife (DOFAW) in October 1991 and November 1995. (USFWS, 1996)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 4,000 and 5,700 feet (USFWS, 1996)

Environmental Specificity

Adult: Medium, with some key requirements (USFWS, 1996)

Habitat Narrative

Adult: This species is found in wet forests on old volcanic substrates. The habitat of *Cyanea hamatiflora* subsp. *carlsonii* is mesic montane forest dominated by *Metrosideros polymorpha* at elevations between 4,000 to 5,700 ft (1,220 to 1,740 m) (Lammers 1990, HHP 1991g1-g2). Associated native plants include *A'lyoporum sandwicense* A. Gray (naio), *Hedyotis* (pilo), and *Zanthoxylum* (a'e). (USFWS, 1996; NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

Low (inferred from USFWS, 2015)

Redundancy:

Low (inferred from USFWS, 2015)

Number of Populations:

3 (USFWS, 2015)

Population Size:

4-6 wild, 41 to 2,606 reintroduced (USFWS, 2015)

Population Narrative:

Overall, the numbers of individuals have decreased from the 17 wild individuals reported in the previous 5-year review, to approximately four to six wild individuals in two populations in 2014. There are three reintroduced populations containing approximately 41 to 2,606 individuals. (USFWS, 2015)

Threats and Stressors

Stressor: Climate change (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Climate change destruction or degradation of habitat – Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *C. hamatiflora* is minimally vulnerable to the impacts of climate change. (USFWS, 2015)

Stressor: Non-native invasive plants (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: The major threats to *Cyanea hamatiflora* ssp. *carlsonii* are competition from invasive introduced plant species, particularly pasture grasses at the Olelomoana population and *Passiflora mollissima* (banana poka) at Honuaula. These invasive species compete with individuals of *C. hamatiflora* ssp. *carlsonii* for nutrients, water and light (USFWS 1996; Plant Extinction Prevention 2007). (USFWS, 2009)

Stressor: Grazing, trampling, and browsing by ungulates (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Grazing and trampling by cattle (*Bos taurus*) continues to be a major threat to the two populations (USFWS 1994). Habitat destruction and damage to the individual plants by feral pigs (*Sus scrofa*) are a concern for the Honuaula population (Plant Extinction Prevention Program 2007). Browsing and trampling of the surrounding habitat by feral goats (*Capra hircus*) is also a potential threat (USFWS 1991, 1996, 2008). (USFWS, 2009)

Stressor: Small population size (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: Extinction due to random environmental events and/or reduced reproductive vigor due to the small number of existing populations and individuals are a concern for *Cyanea hamatiflora* ssp. *carlsonii*. The Olelomoana population occurs on private lands and is unfenced (Plant Extinction Prevention 2007). Species like *C. hamatiflora* ssp. *carlsonii* that are endemic to small portions of a single island are inherently more vulnerable to extinction than widespread species because of the higher risks posed to a few populations and individuals by random demographic fluctuations and localized catastrophes such as hurricanes, landslides, flooding and disease outbreaks. When considered on their own, the natural processes associated with being a single island endemic do not affect *C. hamatiflora* ssp. *carlsonii* to such a degree that it is threatened or endangered with extinction in the foreseeable future, but these natural processes can exacerbate the threat from anthropogenic factors, such as habitat loss from or predation by introduced species (USFWS 1996). (USFWS, 2009)

Recovery

Reclassification Criteria:

1. A total of five to seven populations of each taxon should be documented on the Big Island and at least one other island where it now occurs or occurred historically, if it is not endemic to the Big Island. (USFWS, 1996)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1996)
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered. (USFWS, 1996)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on the Big Island and at least 1 other island where they now occur or occurred historically, if it is not endemic to the Big Island. (USFWS, 1996)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 individuals per population for short-lived perennials. (USFWS, 1996)
3. Each population should persist at this level for a minimum of 5 consecutive years. (USFWS, 1996)

Recovery Actions:

- Current populations need to be protected from ungulates, and banana poka and other alien species controlled, to the extent possible, within the taxon's habitat. Propagation and outplanting efforts should be encouraged and continued. (USFWS, 1996)

Conservation Measures and Best Management Practices:

- Continue collection of genetic resources for storage, future propagation and reintroducing into protected suitable habitat within historical range. (USFWS, 2009)
- Control introduced invasive plant species around wild and outplanted plants. (USFWS, 2009)
- Construct large-scale fences around all naturally occurring and reintroduced individuals to exclude feral ungulates. (USFWS, 2009)
- Control rats around wild and outplanted individuals. (USFWS, 2009)
- Collect fruit from any reintroduced individuals that set seed to add to the genetic diversity of the ex situ material. (USFWS, 2009)
- Initiate planning and contribute to implementation of ecosystem level restoration and management to benefit this species. (USFWS, 2009)
- Assess the genetic variability within the two extant populations. (USFWS, 2009)
- Study *Cyanea hamatiflora* ssp. *carlsonii* populations with regard to population size and structure, geographical distribution, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats. (USFWS, 2009)
- Survey geographical and historical range for a current assessment of the species' status. (USFWS, 2015)
- Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. (USFWS, 2015)
- Maintain existing fences and fence remaining populations to protect them from the impacts of feral ungulates. (USFWS, 2015)
- Eradicate invasive introduced plants within ungulate exclosures and maintain exclosures free of invasive plants. (USFWS, 2015)
- Continue monitoring wild and reintroduced individuals. (USFWS, 2015)
- Initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2015)

SPECIES ACCOUNT: *Cyanea hamatiflora* ssp. *hamatiflora* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 09/03/1999; Pacific Region (R1) (USFWS, 2016)

Physical Description

A perennial palm-like tree 3 - 8 meters tall. Slightly curved, tubed flowers are magenta (NatureServe, 2015).

Taxonomy

A member of the bellflower family. In 1987, St. John (St. John 1987b) merged the two genera *Cyanea* and *Delissea*, formally recognizing only *Delissea*, the genus with priority. This change resulted in the combination *D. hamatiflora*. In 1988, Lammers upheld *Cyanea* as a separate genus and combined *C. carlsonii* with this species, resulting in two subspecies: *C. hamatiflora* ssp. *carlsonii* and the nominative *C. hamatiflora* ssp. *hamatiflora* (Lammers 1988, 1999) (USFWS, 2002).

Historical Range

Historically (prior to 1970), *Cyanea hamatiflora* ssp. *hamatiflora* was known from the windward (northeastern) side of Haleakala, stretching from Puu o Kaka'e to Manawainui on the island of Maui (USFWS, 2002).

Current Range

Currently known from windward slopes of Haleakala, East Maui (NatureServe, 2015).

Critical Habitat Designated

Yes; 5/14/2003.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea hamatiflora* ssp. *hamatiflora* (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea hamatiflora* ssp. *hamatiflora* includes six CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Lowland Wet—Unit 1 (and) *Palmeria dolei*—Unit 2—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 2— Lowland Wet This area consists of 6,616 ac (2,677 ha) of State land, 7,425 ac (3,005 ha) of privately owned land, and 2,038 ac (825 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Kipahulu Valley on the northern and eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *waihoi*ensis, *Clermontia samuelii*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakala*ensis, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. kunthiana*, *C. maritae*, *C.*

mceldowneyi, *Huperzia mannii*, *Melicope balloui*, and *M. ovalis*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 1 is not known to be occupied by the plants *Clermontia oblongifolia* ssp. *mauiensis*, *C. peleana*, *Mucuna sloanei* var. *persericea*, *Phyllostegia haliakalae*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 2 (and) *Palmeria dolei*—Unit 11—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 11—Montane Wet This area consists of 4,075 ac (1,649 ha) of State land, 9,633 ac (3,898 ha) of privately owned land, and 875 ac (354 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Puukaukanu and upper Waihoi Valley, on the northern and northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Geranium hanaense*, *G. multiflorum*, and *Wikstroemia villosa*, and by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 2 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea glabra*, *C. maritae*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, and *Schiedea jacobii*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 3 (and) *Palmeria dolei*—Unit 12—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 12—Montane Wet This area consists of 2,228 ac (902 ha) of federally owned land (Haleakala National Park) in Kipahulu Valley, on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. maritae*, and *Melicope ovalis*, and by the forest bird, kiwikiu (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 3 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Clermontia oblongifolia* ssp.

mauiensis, *C. samuelii*, *Cyanea duvalliorum*, *C. glabra*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest bird, the akohekohe (*Palmeria dolei*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 4 (and) *Palmeria dolei*—Unit 13—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 13— Montane Wet This area consists of 180 ac (73 ha) of State land and 1,653 ac (669 ha) of federally owned land (Haleakala National Park), in Kaapahu Valley on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *Cyrtandra ferripilosa*, and *Huperzia mannii*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 4 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea duvalliorum*, *C. glabra*, *C. mceldowneyi*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 5 (and) *Palmeria dolei*—Unit 14—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 14— Montane Wet This area consists of 222 ac (90 ha) of State land, and 165 ac (67 ha) of federally owned land (Haleakala National Park), near Kaumakani on the eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units area occupied by the plant *Bidens campylotheca* ssp. *pentamera*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 5 is not currently occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*,

or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 1 (and) *Palmeria dolei*—Unit 18—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 18— Montane Mesic This area consists of 6,593 ac (2,668 ha) of State land, 707 ac (286 ha) of privately owned land, and 3,672 ac (1,486 ha) of federally owned land (Haleakala National Park), from Kealahou to Puualae, nearly circumscribing the summit of Haleakala on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Asplenium dielirectum*, *A. peruvianum* var. *insulare*, *Clermontia lindseyana*, *Cyanea horrida*, *C. obtusa*, *Cyrtandra ferripilosa*, *C. oxybapha*, *Diplazium molokaiense*, *Geranium arboreum*, *G. multiflorum*, *Huperzia mannii*, *Melicope adscendens*, and *Neraudia sericea*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 1 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. micrantha* ssp. *kalealaha*, *Cyanea glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. kunthiana*, *C. mceldowneyi*, *Phyllostegia bracteata*, *P. mannii*, *Santalum haleakalae* var. *lanaiense*, *Wikstroemia villosa*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea hamatiflora* ssp. *hamatiflora* critical habitat consists of three components. Lowland wet (east Maui), Montane wet (east Maui) and Montane mesic (east Maui) (81 FR 17790-18110):

Ecosystem: Lowland Wet. Elevation: <3,330 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Ecosystem: Montane Wet. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: >75 in (>190 cm). Substrate: Well-developed soils, montane bogs. Canopy: *Acacia*, *Charpentiera*, *Cheirodendron*, *Metrosideros*. Subcanopy: *Broussaisia*, *Cibotium*, *Eurya*, *Ilex*, *Myrsine*. Understory: Ferns, *Carex*, *Coprosma*, *Leptecophylla*, *Oreobolus*, *Rhynchospora*, *Vaccinium*.

Ecosystem: Montane Mesic. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Deep ash deposits, thin silty loams. Canopy: *Acacia*, *Ilex*,

Metrosideros, Myrsine, Nestegis, Nothocestrum, Pisonia, Pittosporum, Psychotria, Sophora, Zanthoxylum. Subcanopy: Alyxia, Charpentiera, Coprosma, Dodonaea, Kadua, Labordia, Leptecophylla, Phyllostegia, Vaccinium. Understory: Ferns, Carex, Peperomia.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special

management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylothea* ssp. *pentamera*, *B. campylothea* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History**Food/Nutrient Resources****Lifespan**

Adult: < 10 years (USFWS, 2014)

Breeding Season

Adult: Unknown (USFWS, 2002)

Other Reproductive Information

Adult: Unknown (USFWS, 2002)

Reproduction Narrative

Adult: It is a short-lived perennial (fewer than 10 years) (USFWS, 2014). Flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors are unknown (U.S. Fish and Wildlife Service 1999b, 2002b) (USFWS, 2002).

Habitat Type

Adult: Terrestrial (USFWS, 2002)

Habitat Vegetation or Surface Water Classification

Adult: Koa and ohia montane wet forest (USFWS, 2002)

Geographic or Habitat Restraints or Barriers

Adult: 2,510 - 5,100 ft. elevation (USFWS, 2002)

Habitat Narrative

Adult: Typical habitat for this taxon is montane wet forest dominated by *Metrosideros polymorpha* (ohia), with a *Cibotium* spp. (hapuu) and/or native shrub understory or closed *Acacia koa* (koa)-*Metrosideros polymorpha* wet forest at elevations between 765 and 1,555 meters (2,510 to 5,100 feet) (U.S. Fish and Wildlife Service 1999b, 2002b; Hawaii Natural Heritage Program Database 2001; R. Hobdy et al., personal communication 2001) (USFWS, 2002).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Not available

Species Trends:

Slightly increasing (USFWS, 2014)

Resiliency:

Very low (inferred from NatureServe, 2015; see current range/distribution)

Number of Populations:

8 populations (USFWS, 2018)

Population Size:

<400 wild individuals, 50 outplanted individuals (USFWS, 2018)

Population Narrative:

There are currently between 458 and 558 individuals in the wild, including both mature and immature individuals (Maui Nui Task Force 2010; USFWS 2012). The number of individuals has slightly increased from an estimated range of 382 to 482 individuals reported in the previous 5-year review (USFWS, 2014).; In the last 5-year review for *Cyanea hamatiflora* subsp. *hamatiflora*

in 2014, there were between 458 and 558 individuals at three general locations (Kīpahulu, Koʻolau Forest Reserve (FR), and lower Hanawī on east Maui. Currently, populations remain on private lands near and inside the Koʻolau Forest Reserve (west of upper Waiokamilo stream, West Wailua Nui stream, West Wailua Iki stream) as well as in Hanawī Natural Area Reserve (NAR), and in Haleakalā National Park (NP). There are an estimated 300 individuals in the Park (Robertson 2016, in litt.). New populations have been discovered in and near the Koʻolau FR at Waikamoi stream (1 individual), Honomanū stream (3 individuals), upper and lower Haipuaʻena stream (4 to 10 individuals), the cliff area of upper Keʻanae (2 individuals); and at three locations in Kīpahulu Valley in Haleakalā NP (39 to 42 individuals) (Oppenheimer 2018, in litt.). In summary, these populations total fewer than 400 individuals on windward east Maui. (USFWS, 2018)

Threats and Stressors

Stressor: Climate change (USFWS, 2014; USFWS, 2018))

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Cyanea hamatiflora* ssp. *hamatiflora* is moderately vulnerable to the impacts of climate change (USFWS, 2014).; Climate change may pose a threat to this subspecies. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaiʻi using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Cyanea hamatiflora* is vulnerable to the impacts of climate change, with a vulnerability score of 0.378 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Additional management actions may be needed to conserve this taxon into the future. (USFWS, 2018)

Stressor: Nonnative species (USFWS, 2002)

Exposure:

Response:

Consequence:

Narrative: This species is threatened by habitat degradation and/or destruction by feral pigs and competition with the alien plants *Miconia calvescens* (velvet tree), *Clidemia hirta* (Koster's curse), and *Ageratina adenophora* (Maui pamakani) (USFWS, 2002).

Stressor: Predation (USFWS, 2002)

Exposure:

Response:

Consequence:

Narrative: Rats and slugs (USFWS, 2002).

Stressor: Invasive species—Established invasive plant species competition (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: When a Hawaiian koa moth (*Scotorythra paludicola*) infested Haleakalā NP lands, it caused vast defoliations of the native tree and major forest component, *Acacia koa*, its host plant. In turn, a nonnative invasive plant, *Clidemia hirta* (Koster's curse), already present in the Park, quickly occupied newly opened areas when the koa canopy was removed. This nonnative plant formed a dense understory where more than half of the known *Cyanea hamatiflora* subsp. *hamatiflora* occur. Because of this invasion, access to monitor these populations is difficult, and it is unknown what effect the rapid increase in *Clidemia* is having on the native flora, including *C. hamatiflora* subsp. *hamatiflora* (Robertson 2016, in litt.). (USFWS, 2018)

Recovery**Reclassification Criteria:**

1. A total of five to seven populations should be documented on islands where it now occurs or occurred historically (USFWS, 2002).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure with the following minimum numbers of mature individuals per population: 300 for short-lived perennials (USFWS, 2002).
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 2002).

Delisting Criteria:

1. A total of 8 to 10 populations should be documented on islands where it now occurs or occurred historically (USFWS, 2002).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with the following minimum numbers of mature individuals per population: 300 for short-lived perennials (USFWS, 2002).
3. Each population should persist at this level for a minimum of five consecutive years (USFWS, 2002).

Recovery Actions:

- Protect habitat and control threats (USFWS, 2002).
- Expand existing wild populations (USFWS, 2002).
- Conduct essential research (USFWS, 2002).
- Develop and maintain monitoring plans (USFWS, 2002).
- Reestablish wild populations within the historic range (USFWS, 2002).
- Validate and revise recovery criteria (USFWS, 2002).
- Construct exclosures to protect populations against feral ungulates (USFWS, 2002).
- Maintain adequate genetic stock (USFWS, 2002).
- Control competing alien plant species (USFWS, 2002).
- Enhance wild populations and establish new populations (USFWS, 2002).
- Reduce threats from rodent and slug predation (USFWS, 2002).

- Surveys and inventories—Continue to survey for additional populations of *Cyanea hamatiflora* subsp. *hamatiflora* in areas of potentially suitable habitat. (USFWS, 2018)
- Ungulate monitoring and control—Continue to construct and maintain fenced exclosures to protect individuals from the negative impacts of feral ungulates. (USFWS, 2018)
- Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations. Control invasive nonnative species that compete with the species around all populations. (USFWS, 2018)
- Predator and herbivore monitoring and control—Implement effective control methods for rodents at all known populations. Research and implement effective control methods for slugs. Determine which invertebrate(s) are damaging fruits and research effective control methods. (USFWS, 2018)
- Captive propagation for genetic storage and reintroduction—Continue propagation efforts for maintenance of genetic stock and reintroduction. (USFWS, 2018)
- Reintroduction and translocation—Continue to reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this subspecies. (USFWS, 2018)
- Climate change adaptation strategy—Research the suitability of habitat for reintroducing this subspecies in the future due to the impacts of climate change. (USFWS, 2018)
- Alliance and partnership development—Continue to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2018)

Conservation Measures and Best Management Practices:

- Captive propagation for genetic storage and reintroduction – Evaluate genetic resources currently in storage to determine the need to place additional genetic resources in long-term storage due to this species’ vulnerability to climate change. Continue seed collection for ex situ genetic storage and reintroduction (USFWS, 2014).
- Reintroduction / translocation – Augment populations as genetically appropriate individuals become available in nurseries and as habitat is protected (USFWS, 2014).
- Surveys / inventories – Survey the geographical and historical range for a current assessment of the species’ status (USFWS, 2014).
- Ungulate monitoring and control – Fence remaining populations to protect them from the impacts of feral ungulates (USFWS, 2014).
- Invasive plant monitoring and control – Control invasive introduced plant species within the vicinity of *C. hamatiflora* ssp. *hamatiflora* populations (USFWS, 2014).
- Predator / herbivore monitoring and control – Control rodents and slugs within the vicinity of all known *C. hamatiflora* ssp. *hamatiflora* populations (USFWS, 2014).
- Threats – predator / herbivore control research – Determine what invertebrates are damaging *C. hamatiflora* ssp. *hamatiflora* fruits (USFWS, 2014).
- Climate change adaptation strategy – Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change (USFWS, 2014).
- Alliance and partnership development –Initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon (USFWS, 2014).

SPECIES ACCOUNT: *Cyanea horrida* (haha nui)

Species Taxonomic and Listing Information

Listing Status: Endangered; 06/27/2013; Pacific Region (Region 1) (USFWS, 2017)

Physical Description

A palm-like tree, 1-4 m tall. Leaves are deeply lobed. Flowers are blackish purple or greenish white suffused with purple. (NatureServe, 2015)

Taxonomy

A member of the bellflower family (Campanulaceae) (USFWS, 2016).

Historical Range

This species was known historically from the slopes of Haleakala (Lammers 1999, p. 453; HBMP 2010) (USFWS, 2016).

Current Range

This species current range is restricted to East Maui. (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea horrida* (Haha nui) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes ten detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea horrida* includes ten CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Montane Wet—Unit 1 (and) Palmeria dolei—Unit 10—Montane Wet (and) Pseudonestor xanthophrys—Unit 10— Montane Wet This area consists of 1,313 ac (531 ha) of State land and 798 ac (323 ha) of privately owned land, at Haiku Uka on the northern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Cyanea duvalliorum*, *C. maritae*, *C. mceldowneyi*, *Huperzia mannii*, *Melicope balloui*, and *Phyllostegia pilosa*, and by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 1 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope ovalis*,

Peperomia subpetiolata, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 2 (and) *Palmeria dolei*—Unit 11—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 11— Montane Wet This area consists of 4,075 ac (1,649 ha) of State land, 9,633 ac (3,898 ha) of privately owned land, and 875 ac (354 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Puukaukanu and upper Waihoi Valley, on the northern and northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Geranium hanaense*, *G. multiflorum*, and *Wikstroemia villosa*, and by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 2 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea glabra*, *C. maritae*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, and *Schiedea jacobii*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 3 (and) *Palmeria dolei*—Unit 12—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 12— Montane Wet This area consists of 2,228 ac (902 ha) of federally owned land (Haleakala National Park) in Kipahulu Valley, on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. maritae*, and *Melicope ovalis*, and by the forest bird, *kiwikiu* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 3 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea duvalliorum*, *C. glabra*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest bird, the *akohekohe* (*Palmeria dolei*), we have determined this area to be essential for the

conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 4 (and) *Palmeria dolei*—Unit 13—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 13— Montane Wet This area consists of 180 ac (73 ha) of State land and 1,653 ac (669 ha) of federally owned land (Haleakala National Park), in Kaapahu Valley on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *Cyrtandra ferripilosa*, and *Huperzia mannii*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 4 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea duvalliorum*, *C. glabra*, *C. mceldowneyi*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 5 (and) *Palmeria dolei*—Unit 14—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 14— Montane Wet This area consists of 222 ac (90 ha) of State land, and 165 ac (67 ha) of federally owned land (Haleakala National Park), near Kaumakani on the eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units area occupied by the plant *Bidens campylotheca* ssp. *pentamera*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 5 is not currently occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small

numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 1 (and) *Palmeria dolei*—Unit 18—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 18— Montane Mesic This area consists of 6,593 ac (2,668 ha) of State land, 707 ac (286 ha) of privately owned land, and 3,672 ac (1,486 ha) of federally owned land (Haleakala National Park), from Kealahou to Puualae, nearly circumscribing the summit of Haleakala on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Asplenium dielirectum*, *A. peruvianum* var. *insulare*, *Clermontia lindseyana*, *Cyanea horrida*, *C. obtusa*, *Cyrtandra ferripilosa*, *C. oxybapha*, *Diplazium molokaiense*, *Geranium arboreum*, *G. multiflorum*, *Huperzia mannii*, *Melicope adscendens*, and *Neraudia sericea*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 1 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. micrantha* ssp. *kalealaha*, *Cyanea glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. kunthiana*, *C. mcelandneyi*, *Phyllostegia bracteata*, *P. mannii*, *Santalum haleakalae* var. *lanaiense*, *Wikstroemia villosa*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 1 (and) *Palmeria dolei*—Unit 30—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 30— Wet Cliff This area consists of 290 ac (117 ha) of privately owned land along the wall of Keanae Valley on the northern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). Although Maui—Wet Cliff— Unit 1 is not currently occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Cyanea copelandii* ssp. *haleakalaensis*, *Cyanea horrida*, *Melicope ovalis*, *Phyllostegia bracteata*, *P. haliakalae*, or *Plantago princeps*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 2 (and) *Palmeria dolei*—Unit 31—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 31— Wet Cliff This area consists of 475 ac (192 ha) of State land, 20 ac (8 ha) of privately owned land, and 912 ac (369 ha) of federally owned land (Haleakala National Park), from Kalapawili Ridge along Kipahulu Valley and north to Puuhoolio, on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). They are occupied by the plants *Bidens campylotheca* ssp.

waihoiensis, *Cyanea copelandii* ssp. *haleakalaensis*, *Melicope ovalis*, *Phyllostegia bracteata*, and *Plantago princeps*. These units also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Wet Cliff—Unit 2 is not known to be occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Cyanea horrida*, or *Phyllostegia haliakalae*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 3 (and) *Palmeria dolei*—Unit 32—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 32—Wet Cliff This area consists of 5 ac (2 ha) of State land and 433 ac (175 ha) federally owned land (Haleakala National Park) along the south rim of Kipahulu Valley on east Maui. These units include the mixed hermland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). Although Maui—Wet Cliff—Unit 3 is not currently occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. horrida*, *Melicope ovalis*, *Phyllostegia bracteata*, *P. haliakalae*, or *Plantago princeps*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 4 (and) *Palmeria dolei*—Unit 33—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 33—Wet Cliff This area consists of 184 ac (75 ha) of State land along the north wall of Waihoi Valley, on the northeastern slopes of east Maui. These units include the mixed hermland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). They are occupied by the plant *Bidens campylotheca* ssp. *pentamera* and *B. campylotheca* ssp. *waihoiensis*, and contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Wet Cliff—Unit 4 is not known to be occupied by the plants *Cyanea copelandii* ssp. *haleakalaensis*, *C. horrida*, *Melicope ovalis*, *Phyllostegia bracteata*, *P. haliakalae*, or *Plantago princeps*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea horrida* critical habitat consists of three

components. Montane wet (east Maui), Montane mesic (east Maui) and Wet cliff (east Maui) (81 FR 17790-18110):

Ecosystem: Montane Wet. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: >75 in (>190 cm). Substrate: Well-developed soils, montane bogs. Canopy: *Acacia*, *Charpentiera*, *Cheirodendron*, *Metrosideros*. Subcanopy: *Broussaisia*, *Cibotium*, *Eurya*, *Ilex*, *Myrsine*. Understory: Ferns, *Carex*, *Coprosma*, *Leptecophylla*, *Oreobolus*, *Rhynchospora*, *Vaccinium*.

Ecosystem: Montane Mesic. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Deep ash deposits, thin silty loams. Canopy: *Acacia*, *Ilex*, *Metrosideros*, *Myrsine*, *Nestegis*, *Nothocestrum*, *Pisonia*, *Pittosporum*, *Psychotria*, *Sophora*, *Zanthoxylum*. Subcanopy: *Alyxia*, *Charpentiera*, *Coprosma*, *Dodoniaea*, *Kadua*, *Labordia*, *Leptecophylla*, *Phyllostegia*, *Vaccinium*. Understory: Ferns, *Carex*, *Peperomia*.

Ecosystem: Wet Cliff. Elevation: unrestricted. Annual precipitation: >75 in (>190 cm). Substrate: >65 degree slope, shallow soils, weathered lava. Canopy: None. Subcanopy: *Broussaisia*, *Cheirodendron*, *Leptecophylla*, *Metrosideros*. Understory: Bryophytes, Ferns, *Coprosma*, *Dubautia*, *Kadua*, *Peperomia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or

protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Not available.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Montane mesic, montane wet, and wet cliff ecosystems (see population narrative)

Habitat Narrative

Adult: This species is found in wet forests. (NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

Very low (inferred from NatureServe, 2015)

Redundancy:

Very low (inferred from NatureServe, 2015)

Number of Populations:

12 (USFWS, 2016)

Population Size:

44 (USFWS, 2016)

Population Narrative:

Currently, *C. horrida* is known from 12 occurrences totaling 44 individuals in the montane mesic, montane wet, and wet cliff ecosystems in Waikamoi Preserve, Hanawai Natural Area Reserve, and Haleakala National Park on east Maui (TNC 2007; PEPP 2009, p. 52; HBMP 2010; Oppenheimer 2010c, in litt.; PEPP 2010, pp. 46–47; TNCH 2010a, p. 1). (USFWS, 2016)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (pigs), nonnative plants, drought, flooding, landslides, trampling, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Drought, flooding, and landslides destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. Human trampling and hiking damaged to plants has been observed. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (pigs, rats, and slugs) is considered an ongoing threat to *Cyanea horrida* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

Stressor: Small populations (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: *Cyanea horrida* faces the threat of limited numbers (i.e., there are fewer than 50 individuals in the wild). The only known wild occurrences are susceptible to threats from habitat degradation or loss by flooding, landslides, or tree falls, or a combination of these, because of their locations in lowland wet, montane wet, and wet cliff ecosystems (USFWS, 2013).

Recovery

Reclassification Criteria:

Not available.

Delisting Criteria:

Not available.

Recovery Actions:

- Not available.

Conservation Measures and Best Management Practices:

- Not available.

SPECIES ACCOUNT: *Cyanea humboldtiana* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/10/1996; Pacific Region (R1) (USFWS, 2016)

Physical Description

Cyanea humboldtiana is a member of the Campanulaceae (bellflower family). It is a short-lived perennial shrub with unbranched woody stems 1 to 2 m (3.2 to 6.6 ft) tall and inversely egg-shaped to broadly elliptic leaves, 18 to 45 cm (7.1 to 17.7 in) long and 7 to 16 cm (3 to 6 in) wide. The leaf edges are hardened and have shallow, ascending rounded teeth. The dark magenta or white flowers are 6 to 7.5 cm (2.4 to 3.0 in) long and form axillary racemes. The fruit is an elliptic shaped pale orange-yellow berry 1.0 to 1.4 cm (0.4 to 0.6 in) long. *C. humboldtiana* is distinguished from other members of this endemic Hawaiian genus by its long and downward bending flowering stalk (Wagner et al. 1999).

Historical Range

Cyanea humboldtiana was known historically from 17 occurrences in the central and southern parts of the Koolau Mountains of Oahu.

Current Range

Currently, between 184 and 334 plants are known from seven occurrences at Kaluanui (1), Konahuanui (25), Maakua (6), Puu Keahiakahoe (100 to 200), Wailupe and Pia (50 to 100), Opaeha Midreach (1), and Poamoho trail (1) (HINHP Database 2001; K. Kawelo, U.S. Army, pers. comm. 2003; J. Lau, HINHP, pers. comm. 2003). They are declining in number and populations are small and widely dispersed with restricted distribution (Service 1998a).

Critical Habitat Designated

Yes; 9/18/2012.

Legal Description

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea humboldtiana* (Haha) under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Cyanea humboldtiana* (77 FR 57648-57862). The critical habitat designation includes 14 critical habitat units, which encompass approximately 30,056 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Cyanea humboldtiana* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Cyanea humboldtiana* includes 14 critical habitat units, covering two ecosystem types, which encompass approximately 30,056 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Wet—Units 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16; Oahu—Wet Cliff—Units 6, 7, 8

Oahu—Lowland Wet—Unit 6 [790 ac (320 ha)]. This area consists of 790 ac (320 ha) of privately owned land in the lowland wet ecosystem, in privately owned land on the windward side of the Koolau Mountains, and includes Kahawainui, Ihiihi, Wailele, and Koloa gulches. Oahu—Lowland Wet—Unit 7 [1,787 ac (723 ha)]. This area consists of 1,499 ac (606 ha) of State land and 288 ac (117 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, within the Kaipapau and Hauula Forest Reserves and Sacred Falls State Park, from Puukainapuaa to Kaluanui (Sacred Falls). Oahu—Lowland Wet—Unit 8 [3,041 ac (1,231 ha)]. This area consists of 1,386 ac (561 ha) of State land and 1,655 ac (670 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, partially within the Ahupuaa O Kahana State Park, including Waihoi Springs, and Punaluu, Kahana, Waikane, Waikēē, and Uwao streams. Oahu—Lowland Wet—Unit 9 [15,728 ac (6,365 ha)]. This area consists of 3,827 ac (1,545 ha) of State land, 147 ac (60 ha) of City and County of Honolulu land, 4,509 ac (1,825 ha) of Federal land (U.S. Fish and Wildlife Service), and 7,245 ac (2,932 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, partially within the Ewa FR Waimano Section and the Oahu Forest National Wildlife Refuge. This area extends along the Koolau summit from Waipio to Manaiki Stream. Oahu—Lowland Wet—Unit 10 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) of privately-owned land in the lowland wet ecosystem in private land on the windward side of the Koolau Mountains, along Kaalaea Stream. Oahu—Lowland Wet—Unit 11 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) in the lowland wet ecosystem, owned by the City and County of Honolulu on the windward side of the Koolau Mountains, along Waihee Stream. Oahu—Lowland Wet—Unit 12 [53 ac (21 ha)]. This area consists of 28 ac (11 ha) of City and County of Honolulu land and 26 ac (10 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, along Kahaluu Stream and tributary. Oahu—Lowland Wet—Unit 13 [75 ac (30 ha)]. This area consists of 74 ac (30 ha) of City and County of Honolulu land and 1 ac (0.5 ha) of State land in the lowland wet ecosystem on the windward side of the Koolau Mountains, along Heeia Stream and tributaries. Oahu—Lowland Wet—Unit 14 [478 ac (193 ha)]. This area consists of 274 ac (111 ha) of State land, 195 ac (79 ha) of City and County of Honolulu land, and 9 ac (4 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, extending from the Wilson Tunnel area southeast to Moole Stream. Oahu—Lowland Wet—Unit 15 [407 ac (165 ha)]. This area consists of 407 ac (165 ha) in the lowland wet ecosystem in State of Hawaii Department of Land and Natural Resources Land Division land on the windward side of the Koolau Mountains in Maunawili Valley, including Omao and Maunawili streams and Kapakahi and Pikoakea Springs. Oahu—Lowland Wet—Unit 16 [2,507 ac (1,014 ha)]. This area consists of 1,533 ac (621 ha) of State land, 365 ac (148 ha) of City and County of Honolulu land, and 608 (246 ha) of privately owned land in the lowland wet ecosystem in on the leeward side of the Koolau Mountains, partly within the Honolulu Watershed Forest Reserve, extending from the eastern side of Nuuanu Valley southeast along the Koolau summit to Kulepeamoa Ridge.

Oahu—Wet Cliff—Unit 6 [151 ac (61 ha)]. This area consists of 151 ac (61 ha) in the wet cliff ecosystem on State land on the windward side of the Koolau Mountains in Kaipapau Gulch, entirely within the Kaipapau Forest Reserve. Oahu—Wet Cliff—Unit 7 [144 ac (58 ha)]. This area consists of 144 ac (58 ha) in the wet cliff ecosystem in State land on the windward side of the Koolau Mountains in Hauula Gulch, entirely within the Hauula Forest Reserve. Oahu—Wet Cliff—Unit 8 [4,649 ac (1,881 ha)]. This area consists of 1,479 ac (598 ha) of State land, 1,281 ac (519 ha) of City and County of Honolulu land, 5 ac (2 ha) of Federal land, and 1,884 ac (762 ha) of privately owned land, in the wet cliff ecosystem along the summit of the Koolau Mountains,

overlapping portions of Sacred Falls State Park, the Waiahole FR (Waiahole and Iolekaa sections), the Kaneohe and Honolulu Watershed FRs, and the Nuuanu Pali State Wayside.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea humboldtiana* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Cyanea humboldtiana* occurs within the Lowland wet and Wet cliff ecosystems in the Koolau Mountain caldera complex:

Oahu—Lowland Wet—Units 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16. (A) Elevation: <3,000 ft (<1,000 m). (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. (D) Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. (E) Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. (E) Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Oahu—Wet Cliff—Units 6, 7, 8. (A) Elevation: unrestricted. (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: >65 degree slope, shallow soils, weathered lava. (D) Canopy: None. (E) Subcanopy: *Broussaisia*, *Cheirodendron*, *Leptecophylla*, *Metrosideros*. (E) Understory: Bryophytes, Ferns, *Coprosma*, *Dubautia*, *Kadua*, *Peperomia*.

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Cyanea humboldtiana* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: *Cyanea humboldtiana* has been observed in flower from September through January. Little else is known about its flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors (Service 1998a).

Habitat Narrative

Adult: Wet shrublands and forests on ridgcrests and sides of ridges. Usually in the cloud zone (NatureServe, 2015). *Cyanea humboldtiana* is usually found in wet *Metrosideros polymorpha*-*Dicranopteris linearis* lowland forest and shrub between 261 and 959 m (856 and 3,146 ft). Associated native plant species include *Acacia koa*, *Bobea elatior*, *Broussaisia arguta*, *Cibotium chamissoi*, *Dubautia laxa*, *Hedyotis terminalis*, *Ilex anomala*, *Machaerina angustifolia*, *Melicope* sp., *Phyllostegia* sp., *Psychotria mariniana*, *Sadleria* sp., *Scaevola mollis*, *Syzygium sandwicensis*, *Wikstroemia* sp., and ferns (HINHP Database 2001).

Dispersal/Migration***Population Information and Trends*****Resiliency:**

Unknown. (NatureServe, 2015)

Representation:

Unknown. (NatureServe, 2015)

Redundancy:

Unknown. (NatureServe, 2015)

Number of Populations:

1 - 5 (NatureServe, 2015)

Population Size:

1 - 1000 individuals (NatureServe, 2015)

Adaptability:

Unknown. (NatureServe, 2015)

Population Narrative:

Unknown. Between 100 and 220 plants are known. Estimate less than 300 plants. 3 current (between 1982 and 1997) and 14 historical occurrences. (NatureServe, 2015)

Threats and Stressors**Stressor:****Exposure:****Response:****Consequence:**

Narrative: The major threats to *Cyanea humboldtiana* are habitat degradation and destruction by feral pigs, predation by rats, competition with the non-native plant species, and a risk of extinction from naturally occurring stochastic events and/or reduced reproductive vigor due to the small number of remaining occurrences. The non-native plants *Axonopus fissifolius*, *Clidemia hirta*, *Erigeron karvinskianus*, *Psidium cattleianum*, and *Pterolepis glomerata* threaten *C. humboldtiana* by altering its habitat and competing with it for nutrients, light, and space. The types of stochastic events most likely to affect *C. koolauensis* are landslides, hurricanes, or flooding. The Konahuanui summit occurrence is also threatened by trampling by hikers (HINHP Database 2001; Service 1998a; 61 FR 53089).

Recovery***Conservation Measures and Best Management Practices:***

- A State-wide management plan should be developed and implemented for the long-term conservation of all known occurrences of *Cyanea humboldtiana*. This plan should also include

broader landscape actions that are needed for the recovery of this plant throughout its range. The recovery plan for this species identifies the following important conservation actions. Exclosures should be constructed around the known occurrences to reduce impacts from feral pigs. Subsequent control or removal of pigs from these areas will alleviate their impact on native ecosystems. Specific efforts should be made to control non-native plants and protect occurrences, with priority given to occurrences that have only a few remaining individuals. Occurrences of this species on Oahu may be seriously threatened by rat predation. A rat control plan should be developed and implemented which will include the use of the currently-approved rodenticide bait blocks and ultimately a more broad-scale method such as aerial dispersal of rodenticide (Service 1998a). Ongoing Conservation Actions: No specific conservation measures have been undertaken for *Cyanea humboldtiana* statewide. There are no representatives of this species ex situ. However, this species may benefit from habitat level management for other KLOA species (U.S. Army 2003a).

SPECIES ACCOUNT: *Cyanea kauaulaensis* (No common name)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/31/2016; Pacific Region (R1) (USFWS, 2016)

Physical Description

This species is 6.5 to 13 ft. (2 to 4 m) tall, and is distinguished from other *Cyanea* species by its many-branched habit, with branches often rooting when coming in contact with the soil. Leaves are glabrous and narrow (2 to 3 in (5 to 7 cm) wide), clustered near the end of the branches, flowers are white and tubular, and fruit are bright orange (Oppenheimer and Lorence 2012, pp. 15–23) (USFWS, 2015).

Taxonomy

A member of the bellflower family (Campanulaceae) (USFWS, 2015).

Historical Range

Known only from Kaua`ula and Waikapu valleys on leeward western Maui (NatureServe, 2015).

Current Range

It occurs on leeward west Maui. Currently, *C. kauaulaensis* is known from Kauaula Valley (approximately 50 individuals) and Waikapu Valley (12 individuals) (Oppenheimer and Lorence 2012, pp. 15–16, 20) (USFWS, 2015).

Critical Habitat Designated

No;

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: Not available

Habitat Type

Adult: Terrestrial, riparian (USFWS, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Lowland wet *Metrosideros* forest (USFWS, 2015; NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: 2,400 - 3,000 ft. elevation (USFWS, 2015)

Habitat Narrative

Adult: It occurs on talus or basalt boulder-strewn slopes along perennial streams at 2,400 to 3,000 ft. (730 to 900 m), in the lowland wet ecosystem (TNCH 2007; HBMP 2010; Oppenheimer and Lorence 2010, pp. 17–18) (USFWS, 2015). The plant community represents a *Metrosideros* lowland wet forest" (Oppenheimer and Lorence 2012; NatureServe, 2015).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Not available

Resiliency:

Very low (inferred from USFWS, 2015; see current range/distribution)

Redundancy:

Very low (inferred from USFWS, 2014)

Number of Populations:

2 (USFWS, 2014; USFWS, 2015)

Population Size:

62 (USFWS, 2014; USFWS, 2015)

Population Narrative:

Currently, *Cyanea kauaulaensis* is limited to 62 individuals distributed between two occurrences (USFWS, 2014).

Threats and Stressors

Stressor: Small population size/poor recruitment (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: The greatest threats to this species currently are the low numbers of occurrences and individuals, its limited range, poor seedling recruitment, and loss of pollinators and dispersal agents (Oppenheimer and Lorence 2012, p. 20) (USFWS, 2015).

Stressor: Predation (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Rats and slugs are noted as a threat to *Cyanea kauaulaensis* by herbivory and seed predation (Oppenheimer and Lorence 2012, p. 20). Rats are omnivorous and eat almost any type of food (Nelson 2012, in litt.) (USFWS, 2015).

Stressor: Nonnative plants (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Nonnative plants modify and destroy native habitat and outcompete native species, negatively affecting *C. kauaulaensis* and its habitat (Oppenheimer and Lorence 2012, p. 20) (USFWS, 2015).

Stressor: Landslides and flooding (USFWS, 2015)

Exposure:

Response:

Consequence:

Narrative: Because of the terrain, landslides and flooding may impact this species (Oppenheimer and Lorence 2012, pp. 20–21). Landslides can modify and destroy riparian and stream habitat by direct physical damage, and create disturbed areas leading to invasion by nonnative plants, as well as damaging or destroying plants directly (USFWS, 2015).

Recovery**Reclassification Criteria:**

Not available - this species does not have a recovery plan.

Delisting Criteria:

Not available - this species does not have a recovery plan.

Recovery Actions:

- Not available - this species does not have a recovery plan.

Conservation Measures and Best Management Practices:

- PEPP has collected seeds from at least 32 of the adult plants, in addition to implementing propagation of nursery stock at the Lyon Arboretum, National Tropical Botanical Gardens, and Olinda Rare Plant Facility (Oppenheimer and Lorence 2012, p. 21). Restoration outplanting into appropriate habitat and ex situ seed storage is also underway (Oppenheimer and Lorence 2012, p. 21). So far, one-hundred plants have been outplanted near the extant individuals in Kauaula Valley (Oppenheimer and Lorence 2012, p. 21) (USFWS, 2014).
- The Maui Invasive Species Committee (MISC) is working to control the nonnative plant *Cortaderia* (Oppenheimer and Lorence 2012, p. 21) (USFWS, 2014).
- Continue to survey for populations of *Cyanea kauaulaensis* in areas of potentially suitable habitat (USFWS, 2014).
- Expand propagation efforts for maintenance of genetic stock (USFWS, 2014).
- Reintroduce individuals into suitable habitat within historical range that is being managed for additional known threats (e.g., nonnative animals and plants) to this species (USFWS, 2014).

USFWS. 2015. Endangered and Threatened Wildlife and Plants

SPECIES ACCOUNT: *Cyanea kolekoleensis* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 05/13/2010; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Cyanea kolekoleensis is a shrub in the bell flower family (Campanulaceae), 1.5 to 1.9 meters (4.9 to 6.2 feet) tall with a glabrous, unbranched stem and narrowly elliptic leaves. The upper leaf surfaces are green and glabrous while the lower surfaces are greenish white and glabrous with a sparsely pubescent midrib. Flowers are white and purple striped (Lammers 1992). (USFWS, 2017)

Taxonomy

Cyanea kolekoleensis was first collected on Kauai in September 1979 and named *Delissea kolekoleensis* by Harold St. John (1987). In 1992, Lammers reexamined the type specimen and named the species *Cyanea kolekoleensis* (Lammers 1992). This combination has been maintained by Wagner et al. (2012), the most recent treatment of Hawaiian flora. (USFWS, 2017)

Historical Range

First collected in 1979 in Wahiawa Drainage (southern Kauai), the last observation of *Cyanea kolekoleensis* was in 1998 (NTBG 1998). (USFWS, 2017)

Current Range

The current range is restricted to the Wahiawa Mountains in southern Kauai. (USFWS, 2017)

Critical Habitat Designated

Yes; 4/13/2010.

Legal Description

On April 13, 2010, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea kolekoleensis* (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six critical habitat units (CHUs), in Hawaii (75 FR 18960-19165).

Critical Habitat Designation

The critical habitat designation for *Cyanea kolekoleensis* includes six CHUs in Kauai County, Hawaii. Note: This species may no longer occur naturally in the wild, therefore there is no known occupied critical habitat for this species. The critical habitat units for this species have been determined to be essential to the conservation of the species because the area provides for the reestablishment of populations within the species' historical range (75 FR 18960-19165).

Kauai—Lowland Wet—Section 1: Lowland Wet—Section 1 consists of 1,164 ac (471 ha) in the lowland wet ecosystem (117 ac (47.4 ha) on State land; 1,047 ac (424 ha) on private land), including wet forest extending from Kulanalilia into Limahuli Valley to Honoanapali, in the Halelea Forest Reserve (Figure 2-A). The section includes 1,099 ac (445 ha) of State and privately owned land within previously designated critical habitat and 65 ac (26 ha) of newly designated

critical habitat on private land. The area that falls within designated critical habitat lies within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and newly designated Critical Habitat Unit 20, Map 217c. This section is occupied by the plants *Chamaesyce remyi* var. *remyi*, *Charpentiera densiflora*, *Labordia helleri*, and *Phyllostegia renovans*. This section also contains unoccupied habitat that is essential to the conservation of these four species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet–Section 1 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Melicope paniculata*, *M. puberula*, *Platydesma rostrata*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 2: Lowland Wet–Section 2 consists of 172 ac (70 ha) in the lowland wet ecosystem, including wet forest extending from Alealau to Pohakea, within the Hono o Na Pali NAR and the Na Pali Coast State Park (Figure 2-A, above). The entire section is State-owned and within previously designated critical habitat; it falls within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and is occupied by the plant *Melicope puberula*. This section also contains unoccupied habitat that is essential to the conservation of this species by providing the physical and biological features necessary for the expansion of the existing wild population. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet–Section 2 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *C. remyi* var. *remyi*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Labordia helleri*, *Melicope paniculata*, *Phyllostegia renovans*, *Platydesma rostrata*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 3: Lowland Wet–Section 3 consists of 756 ac (306 ha) in the lowland wet ecosystem, including wet forest in upper Wainiha Valley, on privately owned land in the Halelea Forest Reserve (Figure 2-B). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and is occupied by the plants *Chamaesyce remyi* var. *kauaiensis*, *Cyrtandra oenobarba*, *Melicope puberula*, *Phyllostegia renovans*, and *Stenogyne kealiae*. This section also contains unoccupied habitat that is essential to the conservation of these five species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet–Section 3 is not known to be occupied by the species *Chamaesyce remyi* var. *remyi*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Dubautia imbricata* ssp. *imbricata*, *Labordia*

helleri, *Melicope paniculata*, *Platydesma rostrata*, *Tetraplasandra bisattenuata*, and *T. flynii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 4: Lowland Wet—Section 4 consists of 591 ac (239 ha) in the lowland wet ecosystem, including wet forest at the head of Lumahai Valley, on State (10 ac, 4.1 ha) and privately owned (581 ac, 235 ha) land in the Halelea Forest Reserve (Figure 2-B, above). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and is occupied by the plants *Chamaesyce remyi* var. *remyi*, *Cyrtandra oenobarba*, *Melicope paniculata*, *Phyllostegia renovans*, and *Platydesma rostrata*. This section also contains unoccupied habitat that is essential to the conservation of these five species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet—Section 4 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Dubautia imbricata* ssp. *imbricata*, *Labordia helleri*, *Melicope puberula*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population numbers of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 5: Lowland Wet—Section 5 consists of 1,541 ac (624 ha) in the lowland wet ecosystem, including wet forest extending from the headwaters of the Wailua River at “Blue Hole” south to Iole, on State (442 ac, 179 ha) and privately owned (1,099 ac, 445 ha) land in the Lihue-Koloa Forest Reserve (Figure 2-C). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 10 of 50 CFR 17.99(a)(1), Map 36a, and is occupied by the plants *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Melicope paniculata*, *Phyllostegia renovans*, and *Platydesma rostrata*. This section also contains unoccupied habitat that is essential to the conservation of these five5 species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet—Section 5 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *C. remyi* var. *remyi*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Labordia helleri*, *Melicope puberula*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 6: Lowland Wet—Section 6 consists of 789 ac (319 ha) in the lowland wet ecosystem, including wet forest extending from Kapalaoa to Kanaele Bog and Lauahihaihai in the Wahiawa Mountains, on State (134 ac, 54 ha) and privately owned (655 ac, 265 ha) land in the Lihue-Koloa Forest Reserve (Figure 2-D). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 10 of 50 CFR 17.99(a)(1), Map 36a, and is occupied by the plants *Chamaesyce remyi* var. *remyi*, *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Platydesma rostrata*, and *Tetraplasandra bisattenuata*. This section also contains unoccupied habitat that is essential to the conservation of these five species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet—Section 6 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Labordia helleri*, *Melicope paniculata*, *M. puberula*, *Phyllostegia renovans*, *Stenogyne kealiae*, and *Tetraplasandra flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea kolekoleensis* critical habitat consists of one component (Lowland wet) (75 FR 18960-19165):

Ecosystem: Lowland Wet. Elevation: <3,000 ft (<914 m). Annual precipitation: >75 in (>190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contains the physical or biological features essential to the conservation of the species that may require special management considerations or protection. It is recognized that activities in and adjacent to areas designated as critical habitat may affect one or more of the PCEs found in these areas. Special management is needed throughout each of the designated critical habitat units. The following discussion of special management needs is applicable to each of the 47 Kauai species for which we are designating critical habitat. These 47 Kauai species include 41 species that are currently found in the wild, and 6 species that are not currently extant in the wild. For each of the 41 Kauai species found in the wild, we have determined that the features essential to their conservation are primarily dependent on maintaining the successful functioning of the ecosystem(s) in which they occur (Tables 3 and 4). In some cases, additional species-specific primary constituent elements have also been identified (Table 4). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical and biological features essential to the conservation of all of these species include

habitat destruction and modification by feral ungulates, predation by nonnative species, competition with nonnative species, hurricanes, landslides, flooding, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by feral ungulates (pigs, goats, and black-tailed deer). Feral ungulates also impact the habitat through predation and trampling. The State of Hawaii provides game mammal (feral pigs and goats, and black-tailed deer) hunting opportunities on one or more State-designated public hunting areas on the islands of Kauai, Oahu, Maui, Molokai, Lanai, and Hawaii (Hawaii Administrative Rules 13-123; DLNR 2009a). Management of game animals by the State ranges from providing maximal sustained public hunting opportunities and benefits (e.g., “sustained yield”) in some areas to game animal removal by State staff, or their designees, in other areas (DLNR 2009b). Public hunting areas are not fenced, and game mammals have unrestricted access to most areas across the landscape, regardless of the underlying land use designation. While fences are sometimes built to provide protection from game mammals to the natural resources within the fenced area, the current number and locations of fences are not sufficient to prevent habitat destruction and degradation. Without special management, the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new alien plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species will help to address the threat presented by fire to three critical habitat areas in particular (Kauai—Lowland Mesic— Section 1, Kauai—Montane Mesic— Section 2, and Kauai—Dry Cliff— Section 1; see Table 5 for corresponding CFR unit numbers). This threat is primarily due to the presence of nonnative species, such as the grasses *Andropogon* sp. and *Setaria* sp., which increase the fuel load and quickly regenerate after a fire. These species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D’Antonio and Vitousek 1992, pp. 64– 66; Brooks et al. 2004, p. 680). In addition, five sections (Kauai—Dry Cliff—Section 1, Kauai—Dry Cliff— Section 2, Kauai—Wet Cliff—Section 1, Kauai—Wet Cliff—Section 2, and Kauai—Wet Cliff—Section 3; see Table 5 for corresponding CFR unit numbers) may require special management to reduce the threat of landslides and flooding, which threaten to further degrade the habitat conditions and have the potential to eliminate some species in their entirety (e.g., *Schiedea attenuata*). In summary, we find that each of the areas we are designating as critical habitat contains features essential to the conservation of the species that may require special management considerations or protection to ensure the conservation of the 47 Kauai species. These special management considerations and protections are required to preserve and maintain the essential features provided to these species by the ecosystems upon which they depend. A more detailed discussion of each of these threats is presented above, under the Summary of Factors Affecting the Species section.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: This species was observed flowering in September, fruiting when visited in October (1992) and immature fruit were collected for Lyon Arboretum (NTBG 1991, 1998; Lyon Arboretum 2007). (USFWS, 2017)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 2,125 and 2,500 feet (USFWS, 2010)

Habitat Narrative

Adult: This species is found in gulches in wet forests. *Cyanea kolekoleensis* (haha), a shrub in the bellflower family (Campanulaceae), occurs in wet *Metrosideros polymorpha* forest in the lowland wet ecosystem at elevations of 2,125 to 2,500 ft (650 to 765 m) (Lammers 1992, p. 130; HBMP 2007; TNCH 2007). (USFWS, 2010; NatureServe, 2015); *Cyanea kolekoleensis* occurs in *Metrosideros polymorpha* (ohia) forest in the lowland wet ecosystem between 650 to 765 meters (2,125 to 2,500 feet) elevation (Lammers 1992; HBMP 2010; TNCH 2007). In the Wahiawa Mountains, associated native plant species include *Antidesma platyphyllum* (hame), *Athyrium microphyllum* (akolea), *Broussaisia arguta* (kanawao), *Cheirodendron* spp. (olapa), *Cibotium glaucum* (hapuu), *Cyrtandra pickeringii* (haiwale), *Deparia* sp. (NCN), *Dicranopteris linearis* (uluhe), *Diplazium sandwichianum* (hoio), *Diplopterygium pinnatum* (uluhe lau nui), *Dubautia imbricata* (naenae), *Dubautia laxa* (naenae pua melemele), *Elaphoglossum* sp. (moe o Maui), *Embelia pacifica* (kilioe), *Freycinetia arborea* (ie ie), *Hesperomannia lydgatei* (NCN), *Ilex anamola* (kawau), *Kadua affinis* (manono), *Kadua tryblum* (NCN), *Labordia degeneri* (kamakahala), *L. lydgatei* (kamakahala), *Machaerina* sp. (uki), *Melicope* sp. (alani), *Myrsine linearifolia* (kolea), *Perrottetia sandwicensis* (olomea), *Pittosporum glabrum* (hoawa), *Platydesma rostrata* (pilo kea lau lili), *Polyscias* sp. (ohe), *Pritchardia* sp. (loulou), *Psychotria hexandra* (kopiko), *Syngium sandwicensis* (ohia ha), and *Viola helenae* (NCN) (NTBG 1991, 1993, 1995, 1996, 1998; HBMP 2010). (USFWS, 2017)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Number of Populations:

0 (USFWS, 2017)

Population Size:

0 (USFWS, 2017)

Population Narrative:

Only a single plant is known, although more may exist in nearby poorly explored areas. First discovered in 1987 in the Wahiawa drainage, the last known *C. kolekoleensis* was observed in 1992. There is currently 1 historical occurrence. (USFWS, 2010; NatureServe, 2015); First collected in 1979 in Wahiawa Drainage, the last observation of *Cyanea kolekoleensis* was in 1998 (NTBG 1998). However, there are many areas within Wahiawa Drainage, from Mount Kahili to Kapalaoa and the Hanapepe Valley rim area that are within the species' habitat type and have not been surveyed specifically for this species. As a result, species experts are confident that additional individuals could be found in the above unexplored areas (Perlman 2007, in litt.). Additional surveys are identified as necessary to determine if this species is still extant (Kishida and Wood 2015). (USFWS, 2017)

Threats and Stressors

Stressor: Ungulate degradation of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Feral pigs (*Sus scrofa*) modify and degrade habitat by disturbing and destroying vegetative cover, trampling plants and seedlings, reducing or eliminating plant regeneration by damaging seeds and seedlings, and increasing erosion by creating large areas of bare soil. Feral pigs are reported in the area where *Cyanea kolekoleensis* was last observed (NTBG 1996; HBMP 2010). (USFWS, 2017)

Stressor: Landslides and flooding destruction or degradation of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Landslides can have a significant effect on small populations or individuals of *Cyanea kolekoleensis*. Landslides and erosion due to natural weathering destabilize substrates, damage and destroy individual plants, and alter hydrological patterns (HBMP 2010). (USFWS, 2017)

Stressor: Stochastic events—Reduced viability due to low numbers (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Small, isolated populations often exhibit reduced levels of genetic variability, which diminishes the species' capacity to adapt and respond to environmental changes, thereby lessening the probability of long-term persistence (Barrett and Kohn 1991; Newman and Pilson 1997; HBMP 2010). The problems associated with small population size and vulnerability to random demographic fluctuations or natural catastrophes are further magnified by synergistic interactions with other threats, such as anthropogenic impacts like habitat loss from human development or predation by nonnative species. Very small plant populations may experience reduced reproductive vigor due to ineffective pollination or inbreeding depression (DLNR 2005). (USFWS, 2017)

Stressor: Hurricanes—Loss and degradation of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: In November 1982, Hurricane Iwa struck the Hawaiian Islands, with wind gusts exceeding 100 miles per hour (mph) (161 kilometers per hour (kph)), causing extensive damage, especially on the islands of Niihau, Kauai, and Oahu (Businger 1998). In September 1992, Hurricane Iniki, a category 4 hurricane with maximum sustained wind speeds recorded at 140 mph (225 kph), passed directly over the island of Kauai. Many forest trees were destroyed (Perlman 1992), which opened the canopy and facilitated the invasion of nonnative plants (Kitayama and Mueller-Dombois 1995). A destructive hurricane holds the potential of driving a localized endemic species to extinction in a single event. Hurricanes pose an ongoing and ever-present threat because they can happen at any time, although their occurrence is not predictable. Tropical cyclone frequency and intensity are projected to change as a result of climate change over the next 100 to 200 years (Vecchi and Soden 2007; Emanuel et al. 2008; Yu et al. 2010). In the central Pacific, modeling projects an increase of up to two additional tropical cyclones per year in the main Hawaiian Islands by 2100 (Murakami et al. 2013). (USFWS, 2017)

Stressor: Climate change loss or degradation of habitat (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. This assessment concluded that *Cyanea kolekoleensis* is highly vulnerable to the impacts of climate change, giving this species a vulnerability score of 0.812 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). In addition, the analysis found that *C. kolekoleensis* has no overlap between current and future climate envelopes, and is unlikely to easily tolerate expected changes in climate within its current climate envelope. This limitation means this species must either endure in suitable microrefugia within its current envelope or move to newly available climate-compatible areas to avoid extinction. Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2017)

Stressor: Rodent predation or herbivory (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Herbivory by rats (*Rattus* spp.) has been noted as a threat to plants in the Wahiawa Mountains, including *Cyanea kolekoleensis* (USFWS 1994). Rats eat virtually every part of plants and at every stage: fleshy fruits, seeds, flowers, stems, leaves, shoots, seedlings, and roots (Russell 1980; Cuddihy and Stone 1990). The effects on plants range from reduced vigor and decreased reproduction to mortality of individuals and complete lack of recruitment. (USFWS, 2017)

Stressor: Slug herbivory (USFWS, 2017)

Exposure:

Response:**Consequence:**

Narrative: While not directly observed in this species, slug herbivory is typical for species in this family (USFWS 2010a). (USFWS, 2017)

Stressor: Lack of adequate biosecurity legislation (USFWS, 2017)

Exposure:**Response:****Consequence:**

Narrative: Invasion of the State of Hawaii by invasive nonnative plant species, and destruction of habitat and competition by nonnative plants are threats to *Cyanea kolekoleensis*. The U.S. Department of Agriculture, Animal and Plant Health Inspection Service, Plant Protection and Quarantine, is authorized to prevent the introduction or dissemination of animal and plant pests on all ships, aircraft, and their cargo and baggage arriving in the U.S. and its territories; however, pest species continue to enter the State. In addition, Federal import regulations do not address many species that could be pests in Hawaii (CGAPS 2009; Ikuma et al. 2002). (USFWS, 2017)

Stressor: Invasive species—Established invasive plant species competition (USFWS, 2017)

Exposure:**Response:****Consequence:**

Narrative: Nonnative plant species, especially *Psidium cattleianum* (strawberry guava) and *Rubus rosifolius* (thimbleberry), are a high and imminent threat to *Cyanea kolekoleensis* (NTBG 1993, 1996, 1998). Nonnative plants compete for water, light, and nutrients. (USFWS, 2017)

Recovery**Reclassification Criteria:**

Not available.

Delisting Criteria:

Not available.

Recovery Actions:

- Assess the distribution, current status, and potential future distribution of existing ecosystems and determine the most important sites for ecosystem management. Make use of landscape modeling, spatial analysis, remote sensing technology, and existing survey data to better understand species distributions and priority ecosystem areas for targeting future surveys. (USFWS, 2010)
- Initiate control of ecosystem-modifying threats, such as ungulates and invasive introduced plant species, as soon as possible within the highest priority management units. (USFWS, 2010)
- Stabilize and protect remaining extant populations of the 45 plants and 2 bird species. Conduct systematic, island-wide surveys for additional populations. Make use of landscape modeling, spatial analysis, remote sensing technology, and existing survey data to better understand distributions and priority areas for targeting future surveys. (USFWS, 2010)

- Restore and maintain multiple viable populations of the 45 plants and 2 bird species by protecting, restoring, and maintaining existing habitats or areas with potential for restoration that are within their historical range. (USFWS, 2010)
- Conduct research on control methods for introduced slugs and avian malaria. (USFWS, 2010)
- Develop an augmentation plan to collect and propagate seed from the 45 plant species that can later be utilized for population restoration, augmentation, and reintroduction. (USFWS, 2010)
- Prevent the influx of new pests and invasive species into recovery areas. Increase the efforts of the Kauai Invasive Species Committee and improve border security. (USFWS, 2010)
- Prioritize research studies that will provide information and tools aiding in the mitigation of known threats and limiting factors of the species and ecosystems. (USFWS, 2010)
- Increase outreach effort and coordination with State agencies and private landowners regarding ecosystem conservation. Promote opportunities to assist in the recovery of these species through Habitat Conservation Plans, Safe Harbor Agreements, and through various conservation partnerships funded by State and Federal agencies and private organizations. (USFWS, 2010)

Conservation Measures and Best Management Practices:

SPECIES ACCOUNT: *Cyanea koolauensis* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/10/1996; Pacific Region (R1) (USFWS, 2016)

Physical Description

Cyanea koolauensis is a member of the Campanulaceae (bellflower family). It is a short-lived perennial shrub 1 to 1.5 m (3.5 to 5 ft) tall with unbranched woody stems and linear to narrowly elliptic leaves 16 to 37 cm (6.3. to 14.6 in) long and 1.5 to 4.0 cm (0.6 to 1.6 in) wide with a whitish underside. The leaf edges are hardened with shallow, ascending rounded teeth. The magenta flowers are 5 to 9 cm (2.0 to 3.5 in) long and form axillary racemes. The fruit is a yellow, orange or purple globose berry, and the smooth and shiny seeds are brown to black. *C. koolauensis* is distinguished from other species in this endemic Hawaiian genus by the leaf shape and width; the whitish green lower leaf surface; and the lengths of the leaf stalks, calyx lobes, and hypanthium (base of flower) (Wagner et al. 1999).

Historical Range

Cyanea koolauensis was known historically from 27 occurrences scattered throughout the Koolau Mountains on Oahu.

Current Range

Currently, 18 occurrences totaling 101 to 104 individuals are known from the Aiea Ridge trail (2 individuals), Halawa (3), Kalahao (3 to 5), Kalihi-Nuuanu Ridge (1), Lulumahu (6), Manana trail (1), Niu and Wailupe (6), Waialae Nui Ridge (2), Waimalu (2), Kawainui-Kaipapau-Kawailoa (35), upper Helemano (7), lower Helemano- Opaeha (4), Poamoho (4), Kawaiiki-Kawainui (4), Kawailoa trail (10), north Kaukonahua (1), south Kaukonahua (9), and Malaeakahana-Waimea summit (1 to 2) in the Koolau Mountains (HINHP Database 2001). Occurrences of *C. koolauensis* are declining, and the current locations are small and widely dispersed (HINHP Database 2001; Service 1998a; J. Lau, pers. comm. 2003; K. Kawelo, pers. comm. 2003).

Critical Habitat Designated

Yes; 9/18/2012.

Legal Description

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea koolauensis* (Haha) under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Cyanea koolauensis* (77 FR 57648-57862). The critical habitat designation includes 11 critical habitat units, which encompass approximately 25,112 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Cyanea koolauensis* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Cyanea koolauensis* includes 11 critical habitat units, covering one ecosystem type, which encompasses approximately 25,112 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Wet—Units 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16.

Oahu—Lowland Wet—Unit 6 [790 ac (320 ha)]. This area consists of 790 ac (320 ha) of privately owned land in the lowland wet ecosystem, in privately owned land on the windward side of the Koolau Mountains, and includes Kahawainui, Ihiihi, Wailele, and Koloa gulches. Oahu—Lowland Wet—Unit 7 [1,787 ac (723 ha)]. This area consists of 1,499 ac (606 ha) of State land and 288 ac (117 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, within the Kaipapau and Haula Forest Reserves and Sacred Falls State Park, from Puukainapuaa to Kaluanui (Sacred Falls). Oahu—Lowland Wet—Unit 8 [3,041 ac (1,231 ha)]. This area consists of 1,386 ac (561 ha) of State land and 1,655 ac (670 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, partially within the Ahupuaa O Kahana State Park, including Waihoi Springs, and Punaluu, Kahana, Waikane, Waikēē, and Uwao streams. Oahu—Lowland Wet—Unit 9 [15,728 ac (6,365 ha)]. This area consists of 3,827 ac (1,545 ha) of State land, 147 ac (60 ha) of City and County of Honolulu land, 4,509 ac (1,825 ha) of Federal land (U.S. Fish and Wildlife Service), and 7,245 ac (2,932 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, partially within the Ewa FR Waimano Section and the Oahu Forest National Wildlife Refuge. This area extends along the Koolau summit from Waipio to Manaiki Stream. Oahu—Lowland Wet—Unit 10 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) of privately-owned land in the lowland wet ecosystem in private land on the windward side of the Koolau Mountains, along Kaalaea Stream. Oahu—Lowland Wet—Unit 11 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) in the lowland wet ecosystem, owned by the City and County of Honolulu on the windward side of the Koolau Mountains, along Waihee Stream. Oahu—Lowland Wet—Unit 12 [53 ac (21 ha)]. This area consists of 28 ac (11 ha) of City and County of Honolulu land and 26 ac (10 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, along Kahaluu Stream and tributary. Oahu—Lowland Wet—Unit 13 [75 ac (30 ha)]. This area consists of 74 ac (30 ha) of City and County of Honolulu land and 1 ac (0.5 ha) of State land in the lowland wet ecosystem on the windward side of the Koolau Mountains, along Heeia Stream and tributaries. Oahu—Lowland Wet—Unit 14 [478 ac (193 ha)]. This area consists of 274 ac (111 ha) of State land, 195 ac (79 ha) of City and County of Honolulu land, and 9 ac (4 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, extending from the Wilson Tunnel area southeast to Moole Stream. Oahu—Lowland Wet—Unit 15 [407 ac (165 ha)]. This area consists of 407 ac (165 ha) in the lowland wet ecosystem in State of Hawaii Department of Land and Natural Resources Land Division land on the windward side of the Koolau Mountains in Maunawili Valley, including Omao and Maunawili streams and Kapakahi and Pikoakea Springs. Oahu—Lowland Wet—Unit 16 [2,507 ac (1,014 ha)]. This area consists of 1,533 ac (621 ha) of State land, 365 ac (148 ha) of City and County of Honolulu land, and 608 ac (246 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, partly within the Honolulu Watershed Forest Reserve, extending from the eastern side of Nuuanu Valley southeast along the Koolau summit to Kulepeamo Ridge.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea koolauensis* critical habitat consists of

the following components according to ecosystem type (77 FR 57648-57862). Note: *Cyanea koolauensis* occurs within the indicated ecosystem in the Koolau Mountain caldera complex:

Oahu—Lowland Wet—Units 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16. (A) Elevation: <3,000 ft (<1,000 m). (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. (D) Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. (E) Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. (E) Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Ctenitis squamigera* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: *Cyanea koolauensis* has been observed in flower and fruit from May through August. Little else is known about its flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, and limiting factors (Service 1998a).

Habitat Type

Adult: wet forest

Habitat Narrative

Adult: *Cyanea koolauensis* is usually found on slopes, stream banks, and ridge crests in wet *Metrosideros polymorpha*-*Dicranopteris linearis* wet forest at elevations between 163 and 959 m (535 and 3,146 ft). Associated native plant species include *Acacia koa*, *Antidesma platyphyllum*, *Bidens* sp., *Bobea elatior*, *Broussaisia arguta*, *Cibotium* sp., *Diplopterygium pinnatum*, *Dubautia* sp., *Hedyotis* sp., *Machaerina* sp., *Melicope* sp., *Pittosporum* sp., *Pritchardia martii*, *Psychotria mariniana*, *Sadleria* sp., *Scaevola* sp., *Syzygium sandwicensis*, or *Wikstroemia* sp. (HINHP Database 2001; Wagner et al. 1999).

Dispersal/Migration

Population Information and Trends

Threats and Stressors

Stressor:

Exposure:

Response:**Consequence:**

Narrative: The major threats to *Cyanea koolauensis* are habitat degradation and destruction by feral pigs; potential impacts from military activities; trail clearing; potential predation by rats; competition with non-native plant species; trampling from foot traffic; and a risk of extinction from naturally occurring stochastic events and/or reduced reproductive vigor due to the small number of remaining individuals. The non-native plant species *Clidemia hirta*, *Heliocarpus popayanensis*, *Psidium cattleianum*, and *Pterolepis glomerata* threaten *C. koolauensis* by altering its habitat and competing with it for nutrients, light, and space. The types of stochastic events most likely to affect *C. koolauensis* are landslides, hurricanes, or flooding (HINHP Database 2001; Service 1998a; 61 FR 53089).

Recovery**Conservation Measures and Best Management Practices:**

- A State-wide management plan should be developed and implemented for the long-term conservation of all known occurrences of *Cyanea koolauensis*. This plan should also include broader landscape actions that are needed for the recovery of this plant throughout its range. The recovery plan for this species identifies the following important conservation actions. Fences should be constructed around all known occurrences of *C. koolauensis* to reduce impacts from feral pigs and trampling. In areas where fencing is not feasible, control or removal of pigs should be implemented to benefit the native ecosystem that is needed to sustain this plant. Non-native plants should be removed from the vicinity of all known occurrences of *C. koolauensis*. Ex situ propagation should be initiated using seeds from individuals spread across the current range of the species. The threat of rat predation should be assessed and, if it is considered significant, rats should be controlled in the vicinity of all known occurrences of *C. koolauensis* and across the broader landscape using bait boxes and aerial dispersal of rodenticide, when approved (Service 1998a). Priority for these and other conservation actions should be given to occurrences that have only a few remaining individuals. Ongoing Conservation Actions: No specific conservation measures have been undertaken for *Cyanea koolauensis* statewide by other agencies. There are no representatives of this species ex situ (U.S. Army 2003a). The Service is currently not aware of any other conservation efforts for this species.

SPECIES ACCOUNT: *Cyanea kuhihewa* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 05/13/2010; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Cyanea kuhihewa is a shrub in the bell flower family (Campanulaceae), 0.4 to 2.3 meters (1.2 to 7.4 feet) tall with unbranched erect stems 0.4 to 0.5 centimeters (cm) (0.2 inches (in)) in diameter. Leaves are glabrous, 31 to 38 cm (12 to 15 in) long, 1.2 to 1.5 cm (0.5 to 0.6 in) wide, and slightly paler below. Inflorescences are ascending (growing obliquely upward), 5- to 8-flowered, with a peduncle (flower stalk) 10 to 16 millimeters (mm) (0.4 to 0.6 in) long and sparsely pubescent (with soft hairs). Calyx lobes are triangular, 1.4 to 1.5 mm (0.06 in) long, and 0.9 to 1.1 mm (0.04 in) wide. The corolla (flower petals) is rose-purple with lobes edged in white, 47 to 53 mm (1.9 to 2.1 in) long, with a curved tube 28 to 33 mm (1.1 to 1.3 in) long and 5.3 mm (0.2 in) at the base. Seeds are ellipsoid, dark brown or black, 0.7 to 0.8 mm (0.03 in) long, and 0.3 to 0.4 mm (0.01 to 0.02 in) wide, smooth, and shiny (Lammers 1996). (USFWS, 2017)

Taxonomy

A member of the bellflower family (Campanulaceae) (USFWS, 2010).; *Cyanea kuhihewa* was first described by Lammers (1996) based on a collection made by Wood et al. in 1991. This species is recognized as a distinct taxon by Wagner and Herbst (2003) and Wagner et al. (2012), the most recently accepted Hawaiian plant taxonomy. (USFWS, 2017)

Historical Range

On May 10, 1991, *Cyanea kuhihewa* was discovered in Limahuli Valley (Wood et al. 2001). At that time there were 12 individuals. (USFWS, 2017)

Current Range

Known only from the type locality in Limahuli Valley on the island of Kauai, state of Hawaii (USFWS, 2017).

Critical Habitat Designated

Yes; 4/13/2010.

Legal Description

On April 13, 2010, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea kuhihewa* (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six critical habitat units (CHUs), in Hawaii (75 FR 18960-19165).

Critical Habitat Designation

The critical habitat designation for *Cyanea kuhihewa* includes six CHUs in Kauai County, Hawaii. Note: This species may no longer occur naturally in the wild, therefore there is no known occupied critical habitat for this species. The critical habitat units for this species have been determined to be essential to the conservation of the species because the area provides for the reestablishment of populations within the species' historical range (75 FR 18960-19165).

Kauai—Lowland Wet—Section 1: Lowland Wet—Section 1 consists of 1,164 ac (471 ha) in the lowland wet ecosystem (117 ac (47.4 ha) on State land; 1,047 ac (424 ha) on private land), including wet forest extending from Kulanalilia into Limahuli Valley to Honoonapali, in the Halelea Forest Reserve (Figure 2-A). The section includes 1,099 ac (445 ha) of State and privately owned land within previously designated critical habitat and 65 ac (26 ha) of newly designated critical habitat on private land. The area that falls within designated critical habitat lies within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and newly designated Critical Habitat Unit 20, Map 217c. This section is occupied by the plants *Chamaesyce remyi* var. *remyi*, *Charpentiera densiflora*, *Labordia helleri*, and *Phyllostegia renovans*. This section also contains unoccupied habitat that is essential to the conservation of these four species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet—Section 1 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Melicope paniculata*, *M. puberula*, *Platydesma rostrata*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 2: Lowland Wet—Section 2 consists of 172 ac (70 ha) in the lowland wet ecosystem, including wet forest extending from Alealau to Pohakea, within the Hono o Na Pali NAR and the Na Pali Coast State Park (Figure 2-A, above). The entire section is Stateowned and within previously designated critical habitat; it falls within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and is occupied by the plant *Melicope puberula*. This section also contains unoccupied habitat that is essential to the conservation of this species by providing the physical and biological features necessary for the expansion of the existing wild population. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet—Section 2 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *C. remyi* var. *remyi*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Labordia helleri*, *Melicope paniculata*, *Phyllostegia renovans*, *Platydesma rostrata*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 3: Lowland Wet—Section 3 consists of 756 ac (306 ha) in the lowland wet ecosystem, including wet forest in upper Wainiha Valley, on privately owned land in the Halelea Forest Reserve (Figure 2-B). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and is occupied by the plants *Chamaesyce remyi* var. *kauaiensis*, *Cyrtandra oenobarba*, *Melicope puberula*, *Phyllostegia renovans*, and *Stenogyne kealiae*. This section also contains unoccupied habitat that

is essential to the conservation of these five species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet–Section 3 is not known to be occupied by the species *Chamaesyce remyi* var. *remyi*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Dubautia imbricata* ssp. *imbricata*, *Labordia helleri*, *Melicope paniculata*, *Platydesma rostrata*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 4: Lowland Wet–Section 4 consists of 591 ac (239 ha) in the lowland wet ecosystem, including wet forest at the head of Lumahai Valley, on State (10 ac, 4.1 ha) and privately owned (581 ac, 235 ha) land in the Halelea Forest Reserve (Figure 2-B, above). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 11 of 50 CFR 17.99(a)(1), Map 70a, and is occupied by the plants *Chamaesyce remyi* var. *remyi*, *Cyrtandra oenobarba*, *Melicope paniculata*, *Phyllostegia renovans*, and *Platydesma rostrata*. This section also contains unoccupied habitat that is essential to the conservation of these five species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet–Section 4 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Dubautia imbricata* ssp. *imbricata*, *Labordia helleri*, *Melicope puberula*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population numbers of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 5: Lowland Wet–Section 5 consists of 1,541 ac (624 ha) in the lowland wet ecosystem, including wet forest extending from the headwaters of the Wailua River at “Blue Hole” south to Iole, on State (442 ac, 179 ha) and privately owned (1,099 ac, 445 ha) land in the Lihue-Koloa Forest Reserve (Figure 2-C). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 10 of 50 CFR 17.99(a)(1), Map 36a, and is occupied by the plants *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Melicope paniculata*, *Phyllostegia renovans*, and *Platydesma rostrata*. This section also contains unoccupied habitat that is essential to the conservation of these five species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet–Section 5 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *C. remyi* var. *remyi*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Labordia helleri*, *Melicope puberula*, *Stenogyne kealiae*, *Tetraplasandra bisattenuata*, and *T. flynnii*, we have determined this area to be essential for the conservation and recovery of

these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Kauai—Lowland Wet—Section 6: Lowland Wet—Section 6 consists of 789 ac (319 ha) in the lowland wet ecosystem, including wet forest extending from Kapalaoa to Kanaele Bog and Lauahihaihai in the Wahiawa Mountains, on State (134 ac, 54 ha) and privately owned (655 ac, 265 ha) land in the Lihue-Koloa Forest Reserve (Figure 2-D). The entire section is within previously designated critical habitat, falling within Critical Habitat Unit 10 of 50 CFR 17.99(a)(1), Map 36a, and is occupied by the plants *Chamaesyce remyi* var. *remyi*, *Cyrtandra oenobarba*, *Dubautia imbricata* ssp. *imbricata*, *Platydesma rostrata*, and *Tetraplasandra bisattenuata*. This section also contains unoccupied habitat that is essential to the conservation of these five species by providing the physical and biological features necessary for the expansion of the existing wild populations. This section includes the lowland wet forest, the moisture regime, and canopy, subcanopy, and understory plant species identified as PCEs in the lowland wet ecosystem (Table 3). Although Lowland Wet—Section 6 is not known to be occupied by the species *Chamaesyce remyi* var. *kauaiensis*, *Charpentiera densiflora*, *Cyanea eleeleensis*, *C. kolekoleensis*, *C. kuhihewa*, *Labordia helleri*, *Melicope paniculata*, *M. puberula*, *Phyllostegia renovans*, *Stenogyne kealiae*, and *Tetraplasandra flynnii*, we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the physical and biological features necessary for the reestablishment of wild populations within their historic range. Due to the small numbers of individuals or low population sizes of each of these species, each requires suitable habitat and space for expansion or reintroduction to achieve recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea kuhihewa* critical habitat consists of one component (Lowland wet) (75 FR 18960-19165):

Ecosystem: Lowland Wet. Elevation: <3,000 ft (<914 m). Annual precipitation: >75 in (>190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contains the physical or biological features essential to the conservation of the species that may require special management considerations or protection. It is recognized that activities in and adjacent to areas designated as critical habitat may affect one or more of the PCEs found in these areas. Special management is needed throughout each of the designated critical habitat units. The following discussion of special management needs is applicable to each of the 47 Kauai species for which we are designating critical habitat. These 47 Kauai species include 41 species that are currently found in the wild, and 6 species that are not currently extant in the wild. For each of the 41 Kauai species found in the wild, we have determined that the features essential to their conservation are primarily dependent on maintaining the successful functioning of the ecosystem(s) in which they occur

(Tables 3 and 4). In some cases, additional species-specific primary constituent elements have also been identified (Table 4). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical and biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, predation by nonnative species, competition with nonnative species, hurricanes, landslides, flooding, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by feral ungulates (pigs, goats, and black-tailed deer). Feral ungulates also impact the habitat through predation and trampling. The State of Hawaii provides game mammal (feral pigs and goats, and black-tailed deer) hunting opportunities on one or more State-designated public hunting areas on the islands of Kauai, Oahu, Maui, Molokai, Lanai, and Hawaii (Hawaii Administrative Rules 13-123; DLNR 2009a). Management of game animals by the State ranges from providing maximal sustained public hunting opportunities and benefits (e.g., “sustained yield”) in some areas to game animal removal by State staff, or their designees, in other areas (DLNR 2009b). Public hunting areas are not fenced, and game mammals have unrestricted access to most areas across the landscape, regardless of the underlying land use designation. While fences are sometimes built to provide protection from game mammals to the natural resources within the fenced area, the current number and locations of fences are not sufficient to prevent habitat destruction and degradation. Without special management, the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat in this rule requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new alien plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species will help to address the threat presented by fire to three critical habitat areas in particular (Kauai—Lowland Mesic— Section 1, Kauai—Montane Mesic— Section 2, and Kauai—Dry Cliff— Section 1; see Table 5 for corresponding CFR unit numbers). This threat is primarily due to the presence of nonnative species, such as the grasses *Andropogon* sp. and *Setaria* sp., which increase the fuel load and quickly regenerate after a fire. These species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D’Antonio and Vitousek 1992, pp. 64– 66; Brooks et al. 2004, p. 680). In addition, five sections (Kauai—Dry Cliff—Section 1, Kauai—Dry Cliff— Section 2, Kauai—Wet Cliff—Section 1, Kauai—Wet Cliff—Section 2, and Kauai—Wet Cliff—Section 3; see Table 5 for corresponding CFR unit numbers) may require special management to reduce the threat of landslides and flooding, which threaten to further degrade the habitat conditions and have the potential to eliminate some species in their entirety (e.g., *Schiedea attenuata*). In summary, we find that each of the areas we are designating as critical habitat contains features essential to the conservation of the species that may require special management considerations or protection to ensure the conservation of the 47 Kauai species. These special management considerations and protections are required to preserve and maintain the essential features provided to these species by the ecosystems upon which they depend. A more detailed discussion of each of these threats is presented above, under the Summary of Factors Affecting the Species section.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: The type specimen collected by Wood et al. in May 1991 had unopened buds; while specimens collected in June were in full anthesis (the period during which a flower is fully open and functional; Lammers 1996). Seeds of this species were collected in August (Lammers 1996). (USFWS, 2017)

Habitat Type

Adult: Terrestrial and palustrine (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Riparian, forest- hardwood, forest/woodland (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: The only known occurrence is located on the bank of a stream in wet forest. (NatureServe, 2015); lowland wet ecosystem (USFWS, 2010)

Geographic or Habitat Restraints or Barriers

Adult: Found at an elevation of 1,680 feet (USFWS, 2010)

Environmental Specificity

Adult: Unknown (NatureServe, 2015)

Habitat Narrative

Adult: *Cyanea kuhihewa* (haha) is reported from *Metrosideros polymorpha*-*Dicranopteris linearis* wet forest at an elevation of 1,680 ft (512 m) in the lowland wet ecosystem (Lammers 1996, pp. 238–240; HBMP 2007; TNCH 2007). The only known occurrence is located on the bank of a stream in wet forest. (USFWS, 2010; NatureServe, 2015); *Cyanea kuhihewa* is typically found in *Metrosideros polymorpha* (ohia)–*Dicranopteris linearis* (uluhe) lowland wet forest at 512 meters (1,680 feet) elevation. Associated native plant species include *Antidesma platyphyllum* (hame), *Athyrium microphyllum* (akolea), *Bidens* spp. (kookoolau), *Bohea* spp. (ahakea), *Boehmeria grandis* (akolea), *Cibotium* spp. (hapuu), *Clermontia* spp. (oha wai), *Cyrtandra* spp. (haiwale), *Diploterigium pinnatum* (uluhe lau nui), *Dubautia knudsenii* (naenae), *Eurya sandwicensis* (anini), *Freycinetia arborea* (ie ie), *Kadua acuminata* (au), *K. tryblidium* (no common name), *Ilex anomala* (kawau), *Isodendron longifolium* (aupaka), *Machaerina* spp. (uki), *Melicope* spp. (alani), *Pisonia* spp. (papala kepau), *Perrottetia sandwicensis* (olomea), *Pipturus* spp. (mamaki), *Polyscias* spp. (ohe), *Psychotria* spp. (kopiko), *Sadleria* spp. (amau), and *Wikstroemia* spp. (akia) (NTBG 1991, 1994; Lammers 1996; HBMP 2010). (USFWS, 2017)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Short-term trends indicate a decline of >70% (NatureServe, 2015)

Resiliency:

None (NatureServe, 2015)

Redundancy:

None (NatureServe, 2015)

Population Growth Rate:

Unknown (NatureServe, 2015)

Number of Populations:

0 (There is suitable habitat to be surveyed; however, it occurs in steep, remote areas that are difficult to access) (USFWS, 2017)

Population Size:

0 (USFWS, 2017)

Population Narrative:

Short-term population trends indicate a decline of >70%. As of 1997 six individuals remained. As of 2003, no individuals existed in the wild (Russell 2004). This species is no longer extant in the wild. It was known from its type locality on Kauai, Hawaii, however, as of 2003 the last individual died (Russell 2004). (NatureServe, 2015) In a 1994 survey for *C. kuhihewa*, seven individuals were observed, most of which were damaged by a nonnative insect, the two-spotted leafhopper (*Sophonia rufofascia*) (NTBG Provenance Report 1994). In 2001, only one individual plant remained, which was observed dead in 2003 (Wood et al. 2002, p. 3; S. Perlman, pers. comm. 2003a). Prior to that time, seeds and tissue were collected for genetic storage and propagation; however, this species is no longer in storage or propagation (Wood et al. 2002, p. 3; Bender 2006, p. 1; N. Sugii, Lyon Arboretum, pers. comm. 2006; V. Pence, Cincinnati Zoo and Botanical Garden, pers. comm. 2007; D. Burney, NTBG, pers. comm. 2009). Much of the suitable habitat (Metrosideros lowland wet forest) for this species on Kauai has not been surveyed (USFWS, 2010).; On May 10, 1991, *Cyanea kuhihewa* was discovered in Limahuli Valley (Wood et al. 2001). At that time there were 12 individuals. In a 1994 survey for *C. kuhihewa*, seven individuals were observed, most of which were damaged by a nonnative insect, the two-spotted leafhopper (*Sophonia rufofascia*; Wood 1994). In 2001, only one plant remained, and was observed dead in 2003 (Wood et al. 2002; Perlman 2006, in litt.). Prior to that time, seeds and tissue were collected for genetic storage and propagation; however, attempts were unsuccessful and this species is no longer in storage or propagation (Wood et al. 2002; Lyon Arboretum 2016; Burney 2007, in litt.). There is suitable habitat to be surveyed; however, it occurs in steep, remote areas that are difficult to access (Lorence 2016). (USFWS, 2017)

Threats and Stressors

Stressor: Ungulate degradation of habitat (USFWS, 2017)

Exposure:

Response:**Consequence:**

Narrative: Feral pigs (*Sus scrofa*) modify and degrade habitat by disturbing and destroying vegetative cover, trampling plants and seedlings, reducing or eliminating plant regeneration by damaging seeds and seedlings, and increasing erosion by creating large areas of bare soil. Feral pigs are reported in the area where *Cyanea kuhihewa* was last observed (HBMP 2010). (USFWS, 2017)

Stressor: Established ecosystem-altering invasive plant species degradation of habitat (USFWS, 2017)

Exposure:**Response:****Consequence:**

Narrative: Invasive introduced plant species modify habitats occupied by native plant species by changing the availability of light, altering soil-water regimes, modifying nutrient cycling, and changing the fire characteristics of the native plant community. Invasive introduced plants impacting *Cyanea kuhihewa* are *Andropogon virginicus* (broomsedge), *Clidemia hirta* (Koster's curse), and *Schizachyrium condensatum* (little bluestem) (NTBG 1997; HBMP 2010). (USFWS, 2017)

Stressor: Stochastic events—Reduced viability due to low numbers (USFWS, 2017)

Exposure:**Response:****Consequence:**

Narrative: Small, isolated populations often exhibit reduced levels of genetic variability, which diminishes the species' capacity to adapt and respond to environmental changes, thereby lessening the probability of long-term persistence (Barrett and Kohn 1991; Newman and Pilson 1997; HBMP 2010). The problems associated with small population size and vulnerability to random demographic fluctuations or natural catastrophes are further magnified by synergistic interactions with other threats, such as anthropogenic impacts like habitat loss from human development or predation by nonnative species. Very small plant populations may experience reduced reproductive vigor due to ineffective pollination or inbreeding depression (DLNR 2005). (USFWS, 2017)

Stressor: Hurricanes—Loss and degradation of habitat (USFWS, 2017)

Exposure:**Response:****Consequence:**

Narrative: In November 1982, Hurricane Iwa struck the Hawaiian Islands, with wind gusts exceeding 100 miles per hour (mph) (161 kilometers per hour (kph)), causing extensive damage, especially on the islands of Niihau, Kauai, and Oahu (Businger 1998). In September 1992, Hurricane Iniki, a category 4 hurricane with maximum sustained wind speeds recorded at 140 mph (225 kph), passed directly over the island of Kauai. Many forest trees were destroyed (Perlman 1992), which opened the canopy and facilitated the invasion of nonnative plants (Kitayama and Mueller-Dombois 1995). A destructive hurricane holds the potential of driving a localized endemic species to extinction in a single event. Hurricanes pose an ongoing and ever-present threat because they can happen at any time, although their occurrence is not predictable. Tropical cyclone frequency and intensity are projected to change as a result of

climate change over the next 100 to 200 years (Vecchi and Soden 2007; Emanuel et al. 2008; Yu et al. 2010). In the central Pacific, modeling projects an increase of up to two additional tropical cyclones per year in the main Hawaiian Islands by 2100 (Murakami et al. 2013). (USFWS, 2017)

Stressor: Ungulate predation or herbivory (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Herbivory by feral pigs has been noted as a threat to this species (HBMP 2010). (USFWS, 2017)

Stressor: Rodent predation or herbivory (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Herbivory by rats (*Rattus* spp.) has been noted as a threat to *Cyanea kuhihewa* (Wood et al. 2002, Perlman 2006, in litt.; Perlman 2003, in litt.; HBMP 2010). Rats eat virtually every part of plants and at every stage: fleshy fruits, seeds, flowers, stems, leaves, shoots, seedlings, and roots (Russell 1980; Cuddihy and Stone 1990). The effects on plants range from reduced vigor and decreased reproduction to mortality of individuals and complete lack of recruitment. (USFWS, 2017)

Stressor: Invertebrate predation or herbivory (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Damage to *Cyanea kuhihewa* by a nonnative insect, the two-spotted leafhopper (*Sophonia rufofascia*) was observed in 1994 (HBMP 2010). Leafhoppers feed on plant leaves, causing prominent yellowing of the leaves, leading to stunting of the plant or death of the plant (University of Hawaii Crop Knowledge Master 2007). (USFWS, 2017)

Stressor: Slug herbivory (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: While not directly observed in this species, slug herbivory is typical for species in this family (Wood et al. 2002, Perlman 2006, in litt.; HBMP 2010). (USFWS, 2017)

Stressor: Lack of adequate biosecurity legislation (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Invasion of the State of Hawaii by invasive nonnative plant species, and destruction of habitat and competition by nonnative plants are threats to *Cyanea kuhihewa*. The U.S. Department of Agriculture, Animal and Plant Health Inspection Service, Plant Protection and Quarantine, is authorized to prevent the introduction or dissemination of animal and plant pests on all ships, aircraft, and their cargo and baggage arriving in the U.S. and its territories; however,

pest species continue to enter the State. In addition, Federal import regulations do not address many species that could be pests in Hawaii (CGAPS 2009; Ikuma et al. 2002). (USFWS, 2017)

Stressor: Invasive species—Established invasive plant species competition (USFWS, 2017)

Exposure:

Response:

Consequence:

Narrative: Nonnative plant species, especially *Andropogon virginicus*, *Clidemia hirta*, and *Schizachyrium condensatum*, are a high and imminent threat to *Cyanea kuhihewa* (NTBG 1997; HBMP 2010). Nonnative plants compete for water, light, and nutrients. (USFWS, 2017)

Recovery

Reclassification Criteria:

To meet the interim stage of recovery of *Cyanea kuhihewa*, 1,200 mature individuals are needed in one population and all major threats must be controlled around the population designated for recovery at this stage. There should also be demonstrated regeneration of seedlings and growth to at least sapling stage for woody species and documented replacement regeneration within the target population. The population must be adequately represented in an ex situ collection as defined in the Center for Plant Conservation's guidelines (Guerrant et al. 2004). Adequate monitoring must be in place and conducted to assess individual plant survival, population trends, trends of major limiting factors, and response of major limiting factors to management. (USFWS, 2017)

In addition to achieving five populations with 1,000 mature individuals and all of the goals of the interim stage, the target population must be stable, secure, and naturally reproducing for a minimum of 10 years. Species-specific management actions are not ruled out. Downlisting should not be considered until an adequate population viability analysis (PVA) has been conducted to assess needed numbers more accurately based on current management and monitoring data collected at regular intervals determined by demographic parameters of the species, although they should only be one of the factors used in making a decision to downlist. Information necessary for the PVA that should be available through monitoring (ideally annually) includes: major limiting factors, breeding system, population structure and density, and proven management methods for major threats. (USFWS, 2017)

Delisting Criteria:

In addition to achieving five populations with 1,000 mature individuals per population and all of the goals of the interim and downlisting stages, all target populations must be stable, secure, naturally reproducing, and within secure and viable habitats for a minimum of 20 years. Species-specific management actions must no longer be necessary, but ecosystem-wide management actions are not ruled out if there are long-term agreements in place to continue management. These numbers are initial targets, but may be revised upward as additional information is available, including adequate PVAs for individual species based on current management and monitoring data collected at regular intervals determined by demographic parameters of the species, although they should only be one of the factors used in making a decision to delist. Genetic analyses should be conducted to ensure that adequate genetic representation is present within and among populations compared to the initial variation assessed in the interim stage. Numbers need to be considered on a species-by-species basis. (USFWS, 2017)

Recovery Actions:

- Assess the distribution, current status, and potential future distribution of existing ecosystems and determine the most important sites for ecosystem management. Make use of landscape modeling, spatial analysis, remote sensing technology, and existing survey data to better understand species distributions and priority ecosystem areas for targeting future surveys. (USFWS, 2010)
- Initiate control of ecosystem-modifying threats, such as ungulates and invasive introduced plant species, as soon as possible within the highest priority management units. (USFWS, 2010)
- Stabilize and protect remaining extant populations of the 45 plants and 2 bird species. Conduct systematic, island-wide surveys for additional populations. Make use of landscape modeling, spatial analysis, remote sensing technology, and existing survey data to better understand distributions and priority areas for targeting future surveys. (USFWS, 2010)
- Restore and maintain multiple viable populations of the 45 plants and 2 bird species by protecting, restoring, and maintaining existing habitats or areas with potential for restoration that are within their historical range. (USFWS, 2010)
- Conduct research on control methods for introduced slugs and avian malaria. (USFWS, 2010)
- Develop an augmentation plan to collect and propagate seed from the 45 plant species that can later be utilized for population restoration, augmentation, and reintroduction. (USFWS, 2010)
- Prevent the influx of new pests and invasive species into recovery areas. Increase the efforts of the Kauai Invasive Species Committee and improve border security. (USFWS, 2010)
- Prioritize research studies that will provide information and tools aiding in the mitigation of known threats and limiting factors of the species and ecosystems. (USFWS, 2010)
- Increase outreach effort and coordination with State agencies and private landowners regarding ecosystem conservation. Promote opportunities to assist in the recovery of these species through Habitat Conservation Plans, Safe Harbor Agreements, and through various conservation partnerships funded by State and Federal agencies and private organizations. (USFWS, 2010)
- Surveys and inventories—Survey for populations of *Cyanea kuhihewa* in areas of potentially suitable habitat. (USFWS, 2017)
- Ungulate monitoring and control—Construct small-scale protective fences around all known individuals to prevent imminent extinction. Protect all occurrences against disturbances from feral ungulates. (USFWS, 2017)
- Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around any populations. (USFWS, 2017)
- Predator and herbivore monitoring and control—Implement effective measures to control feral pigs around any populations. (USFWS, 2017)
- Predator and herbivore control research—Develop and implement adequate two-spotted leafhopper and slug control methods. (USFWS, 2017)
- Captive propagation for genetic storage and reintroduction—Collect and propagate genetic material for long-term genetic storage. (USFWS, 2017)
- Stochastic events---Build resilience and redundancy - Increase numbers of populations and individuals scattered through historic range to reduce impacts from landslides and storms. (USFWS, 2017)

- Based on the recovery criteria above, consider development of a recovery plan. (USFWS, 2017)

Conservation Measures and Best Management Practices:

- Not available.

SPECIES ACCOUNT: *Cyanea kunthiana* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 06/27/2013; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Shrubs 0.5-1.5 m tall. Stems subherbaceous, woody only at the base, unbranched or sparingly branched. Racemes axillary, with 8-24 flowers. Corollas whitish with pale lilac longitudinal stripes or dark purplish. (NatureServe, 2015)

Current Range

Cyanea kunthiana is endemic to the island of Maui in the state of Hawaii. It occurs on both of Maui's main mountain masses, West Maui and East Maui. (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea kunthiana* (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes 16 detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea kunthiana* includes 16 CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Lowland Wet—Unit 1 (and) *Palmeria dolei*—Unit 2—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 2— Lowland Wet This area consists of 6,616 ac (2,677 ha) of State land, 7,425 ac (3,005 ha) of privately owned land, and 2,038 ac (825 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Kipahulu Valley on the northern and eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia samuelii*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Huperzia mannii*, *Melicope balloui*, and *M. ovalis*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 1 is not known to be occupied by the plants *Clermontia oblongifolia* ssp. *mauiensis*, *C. peleana*, *Mucuna sloanei* var. *persericea*, *Phyllostegia haliakalae*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwiku* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 2 (and) *Palmeria dolei*—Unit 3—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 3— Lowland Wet (and) *Newcombia cumingi*—Unit 1—Lowland Wet This area consists of 65 ac (26 ha) of State land at Moomoku, on the northwestern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Santalum haleakalae* var. *lanaiense*. Although Maui—Lowland Wet—Unit 2 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielirectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendrion pyrifolium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, or *Wikstroemia villosa*, by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), or by the Newcomb's tree snail (*Newcombia cumingi*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 3 (and) *Palmeria dolei*—Unit 4—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 4— Lowland Wet This area consists of 1,247 ac (505 ha) of State land at Honanana Gulch on the northeastern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). They are occupied by the plants *Bidens conjuncta*, *Cyanea asplenifolia*, and *Pteris lidgatei*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 3 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielirectum*, *Bidens micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendrion pyrifolium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 4 (and) *Palmeria dolei*—Unit 5—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 5— Lowland Wet This area consists of 864 ac (350 ha) of State land at Kahakuloa Valley on the northeastern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). They are occupied by the plants *Bidens conjuncta* and *Cyanea asplenifolia*. These units also

contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 4 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 5 (and) *Palmeria dolei*—Unit 6—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 6— Lowland Wet This area consists of 30 ac (12 ha) of State land at Iao Valley on the eastern side of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). Although Maui—Lowland Wet—Unit 5 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 6 (and) *Palmeria dolei*—Unit 7—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 7— Lowland Wet This area consists of 136 ac (55 ha) of State land at Honokowai and Wahikuli valleys on the western slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Santalum haleakalae* var. *lanaiense*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 6 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens conjuncta*, *Bidens micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have

determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 7 (and) *Palmeria dolei*—Unit 8—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 8— Lowland Wet This area consists of 898 ac (364 ha) of State land at Olowalu Valley, on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Alectryon macrococcus*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 7 is not currently occupied by the plants *Asplenium dielerectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 8 (and) *Palmeria dolei*—Unit 9—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 9— Lowland Wet This area consists of 230 ac (93 ha) of State land at upper Ukumehame Gulch, on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). Although Maui—Lowland Wet—Unit 8 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 1 (and) *Palmeria dolei*—Unit 10—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 10— Montane Wet This area consists of 1,313 ac (531 ha) of State land and 798 ac (323 ha) of privately owned land, at Haiku Uka on the northern slopes of east Maui. These

units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Cyanea duvalliorum*, *C. maritae*, *C. mceldowneyi*, *Huperzia mannii*, *Melicope balloui*, and *Phyllostegia pilosa*, and by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 1 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 2 (and) *Palmeria dolei*—Unit 11—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 11— Montane Wet This area consists of 4,075 ac (1,649 ha) of State land, 9,633 ac (3,898 ha) of privately owned land, and 875 ac (354 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Puukaukanu and upper Waihoi Valley, on the northern and northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Geranium hanaense*, *G. multiflorum*, and *Wikstroemia villosa*, and by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 2 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea glabra*, *C. maritae*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, and *Schiedea jacobii*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 3 (and) *Palmeria dolei*—Unit 12—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 12— Montane Wet This area consists of 2,228 ac (902 ha) of federally owned land (Haleakala National Park) in Kipahulu Valley, on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane

wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. maritae*, and *Melicope ovalis*, and by the forest bird, *kiwiku* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 3 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea duvalliorum*, *C. glabra*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest bird, the *akohekohe* (*Palmeria dolei*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 4 (and) *Palmeria dolei*—Unit 13—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 13—Montane Wet This area consists of 180 ac (73 ha) of State land and 1,653 ac (669 ha) of federally owned land (Haleakala National Park), in Kaapahu Valley on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *Cyrtandra ferripilosa*, and *Huperzia mannii*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 4 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea duvalliorum*, *C. glabra*, *C. mceldowneyi*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwiku* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 5 (and) *Palmeria dolei*—Unit 14—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 14—Montane Wet This area consists of 222 ac (90 ha) of State land, and 165 ac (67 ha) of federally owned land (Haleakala National Park), near Kaumakani on the eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plant *Bidens campylotheca* ssp. *pentamera*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of

the existing wild populations. Although Maui—Montane Wet—Unit 5 is not currently occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 6 (and) *Palmeria dolei*—Unit 15—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 15—Montane Wet This area consists of 1,113 ac (451 ha) of State land, and 286 ac (116 ha) of privately owned land, at the summit and surrounding areas on west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). They are occupied by the plants *Bidens conjuncta*, *Calamagrostis hillebrandii*, *Cyanea kunthiana*, *Geranium hillebrandii*, *Myrsine vaccinioides*, and *Sanicula purpurea*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 6 is not known to be occupied by the plants *Acaena exigua*, *Cyrtandra oxybapha*, *Huperzia mannii*, *Phyllostegia bracteata*, or *Platanthera holochila*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 7 (and) *Palmeria dolei*—Unit 16—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 16—Montane Wet This area consists of 80 ac (32 ha) of State land near Hanaula and Pohakea Gulch on the southeastern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). They are occupied by the plants *Cyrtandra oxybapha* and *Platanthera holochila*, and contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 7 is not known to be occupied by the plants *Acaena exigua*, *Bidens conjuncta*, *Calamagrostis hillebrandii*, *Cyanea kunthiana*, *Geranium hillebrandii*, *Huperzia mannii*, *Myrsine vaccinioides*, *Phyllostegia bracteata*, or *Sanicula purpurea*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 1 (and) *Palmeria dolei*—Unit 18—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 18— Montane Mesic This area consists of 6,593 ac (2,668 ha) of State land, 707 ac (286 ha) of privately owned land, and 3,672 ac (1,486 ha) of federally owned land (Haleakala National Park), from Kealahou to Puualae, nearly circumscribing the summit of Haleakala on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Asplenium dielerectum*, *A. peruvianum* var. *insulare*, *Clermontia lindseyana*, *Cyanea horrida*, *C. obtusa*, *Cyrtandra ferripilosa*, *C. oxybapha*, *Diplazium molokaiense*, *Geranium arboreum*, *G. multiflorum*, *Huperzia mannii*, *Melicope adscendens*, and *Neraudia sericea*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 1 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. micrantha* ssp. *kalealaha*, *Cyanea glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. kunthiana*, *C. mceldowneyi*, *Phyllostegia bracteata*, *P. mannii*, *Santalum haleakalae* var. *lanaiense*, *Wikstroemia villosa*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea kunthiana* critical habitat consists of three components. Lowland wet (east Maui and west Maui), Montane wet (east Maui and west Maui) and Montane mesic (east Maui) (81 FR 17790-18110):

Ecosystem: Lowland Wet. Elevation: <3,330 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Ecosystem: Montane Wet. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: >75 in (>190 cm). Substrate: Well-developed soils, montane bogs. Canopy: *Acacia*, *Charpentiera*, *Cheirodendron*, *Metrosideros*. Subcanopy: *Broussaia*, *Cibotium*, *Eurya*, *Ilex*, *Myrsine*. Understory: Ferns, *Carex*, *Coprosma*, *Leptecophylla*, *Oreobolus*, *Rhynchospora*, *Vaccinium*.

Ecosystem: Montane Mesic. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Deep ash deposits, thin silty loams. Canopy: *Acacia*, *Ilex*, *Metrosideros*, *Myrsine*, *Nestegis*, *Nothocestrum*, *Pisonia*, *Pittosporum*, *Psychotria*, *Sophora*, *Zanthoxylum*. Subcanopy: *Alyxia*, *Charpentiera*, *Coprosma*, *Dodonaea*, *Kadua*, *Labordia*, *Leptecophylla*, *Phyllostegia*, *Vaccinium*. Understory: Ferns, *Carex*, *Peperomia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant

species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D’Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Not available.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Environmental Specificity

Adult: Unknown (NatureServe, 2015)

Habitat Narrative

Adult: *Cyanea kunthiana* was known to occur in the montane mesic ecosystem in the east Maui mountains in upper Kipahulu Valley, in Haleakala National Park and Kipahulu FR (HBMP 2010). Currently, in the east Maui mountains, *C. kunthiana* occurs in the lowland wet and montane wet

ecosystems in Waikamoi Preserve, Hanawi NAR, East Bog, Kaapahu, and Kipahulu Valley. In the west Maui mountains, *C. kunthiana* occurs in the lowland wet and montane wet ecosystems at Eke Crater, Kahoolawe ridge, and at the junction of the Honokowai, Hahakea, and Honokohau gulches (TNC 2007; HBMP 2008; NTBG 2009e, pp. 1–3; HBMP 2010; Oppenheimer 2010a, in litt.; Perlman 2010, in litt.). (USFWS, 2010)

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Not available.

Population Information and Trends

Population Trends:

Short-term trends indicate a decline of 10-70%, whereas long-term trends suggest a decline of 10-90% (NatureServe, 2015)

Resiliency:

Low (inferred from NatureServe, 2015)

Population Growth Rate:

Moderate decline (NatureServe, 2015)

Number of Populations:

15 occurrences (NatureServe, 2015)

Population Size:

400 individuals (NatureServe, 2015)

Population Narrative:

Short-term population trends indicate a decline of 10-70%, whereas long-term trends suggest a decline of 10-90%. The 15 occurrences total 165 individuals, although botanists speculate that this species may total as many as 400 individuals with further surveys of potential habitat on east and west Maui (TNC 2007; HBMP 2010; Fay 2010, in litt.; Oppenheimer 2010a, in litt.; Osternak 2010, in litt.). (USFWS, 2010; NatureServe, 2015)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (pigs), nonnative plants, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include

competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (pigs, rats, and slugs) is considered an ongoing threat to *Cyanea kunthiana* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

SPECIES ACCOUNT: *Cyanea lanceolata* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/18/2012; Pacific Region (Region 1) (USFWS, 2016)

Historical Range

Historically, this species was wide- ranging along the Koolau Mountains, from the northern Schofield-Waikane area to Wailupe at the southern end of the range. (USFWS, 2012)

Current Range

Cyanea lanceolata is endemic to the Koolau Mountains on Oahu. It has been recorded from the southern and central portions of the mountain range. All of the records for the species are from the leeward (southwestern) side of the range with the exception of a single historic record from the range's windward (northeastern) side. (NatureServe, 2015)

Critical Habitat Designated

Yes; 9/18/2012.

Legal Description

On September 18, 2012, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea lanceolata* (Haha) under the Endangered Species Act of 1973, as amended (Act) (77 FR 57648-57862). The critical habitat designation includes 15 critical habitat units, which encompass approximately 27,051 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Cyanea lanceolata* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Cyanea lanceolata* includes 15 critical habitat units, covering two ecosystem types, which encompass approximately 27,051 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Mesic—Units 4, 5, 6, 7; Oahu—Lowland Wet—Units 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16.

Oahu—Lowland Mesic—Unit 4 [20 ac (8 ha)]. This area consists of 20 ac (8 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, between the Waipilopilo and Hanaimoa gulches, on State-owned land within the Hauula Forest Reserve. Oahu—Lowland Mesic—Unit 5 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, in Maakua Gulch and ridge; is State-owned; and within the Hauula FR. Oahu—Lowland Mesic—Unit 6 [247 ac (100 ha)]. This area consists of 12 ac (5 ha) State land and 235 ac (95 ha) of privately owned land in the lowland mesic ecosystem on the windward side of the Koolau Mountains, inland of Kaaawa Point, and is partially within Ahupuaa O Kahana State Park. Oahu—Lowland Mesic—Unit 7 [1,669 ac (676 ha)]. This area consists of 681 ac (276 ha) of State land, 129 ac (52 ha) of City and County of Honolulu land, and 852 ac (345 ha) of privately-owned land in the lowland mesic ecosystem on the leeward side of the Koolau Mountains, on Waialae Nui ridge.

Oahu—Lowland Wet—Unit 6 [790 ac (320 ha)]. This area consists of 790 ac (320 ha) of privately owned land in the lowland wet ecosystem, in privately owned land on the windward side of the Koolau Mountains, and includes Kahawainui, Ihiihi, Wailele, and Koloa gulches. Oahu—Lowland Wet—Unit 7 [1,787 ac (723 ha)]. This area consists of 1,499 ac (606 ha) of State land and 288 ac (117 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, within the Kaipapau and Haula Forest Reserves and Sacred Falls State Park, from Puukainapuaa to Kaluanui (Sacred Falls). Oahu—Lowland Wet—Unit 8 [3,041 ac (1,231 ha)]. This area consists of 1,386 ac (561 ha) of State land and 1,655 ac (670 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, partially within the Ahupuaa O Kahana State Park, including Waihoi Springs, and Punaluu, Kahana, Waikane, Waikēē, and Uwao streams. Oahu—Lowland Wet—Unit 9 [15,728 ac (6,365 ha)]. This area consists of 3,827 ac (1,545 ha) of State land, 147 ac (60 ha) of City and County of Honolulu land, 4,509 ac (1,825 ha) of Federal land (U.S. Fish and Wildlife Service), and 7,245 ac (2,932 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, partially within the Ewa FR Waimano Section and the Oahu Forest National Wildlife Refuge. This area extends along the Koolau summit from Waipio to Manaiki Stream. Oahu—Lowland Wet—Unit 10 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) of privately-owned land in the lowland wet ecosystem in private land on the windward side of the Koolau Mountains, along Kaalaea Stream. Oahu—Lowland Wet—Unit 11 [124 ac (50 ha)]. This area consists of 124 ac (50 ha) in the lowland wet ecosystem, owned by the City and County of Honolulu on the windward side of the Koolau Mountains, along Waihee Stream. Oahu—Lowland Wet—Unit 12 [53 ac (21 ha)]. This area consists of 28 ac (11 ha) of City and County of Honolulu land and 26 ac (10 ha) of privately-owned land in the lowland wet ecosystem on the windward side of the Koolau Mountains, along Kahaluu Stream and tributary. Oahu—Lowland Wet—Unit 13 [75 ac (30 ha)]. This area consists of 74 ac (30 ha) of City and County of Honolulu land and 1 ac (0.5 ha) of State land in the lowland wet ecosystem on the windward side of the Koolau Mountains, along Heeia Stream and tributaries. Oahu—Lowland Wet—Unit 14 [478 ac (193 ha)]. This area consists of 274 ac (111 ha) of State land, 195 ac (79 ha) of City and County of Honolulu land, and 9 ac (4 ha) of privately owned land in the lowland wet ecosystem on the leeward side of the Koolau Mountains, extending from the Wilson Tunnel area southeast to Moole Stream. Oahu—Lowland Wet—Unit 15 [407 ac (165 ha)]. This area consists of 407 ac (165 ha) in the lowland wet ecosystem in State of Hawaii Department of Land and Natural Resources Land Division land on the windward side of the Koolau Mountains in Maunawili Valley, including Omao and Maunawili streams and Kapakahi and Pikoakea Springs. Oahu—Lowland Wet—Unit 16 [2,507 ac (1,014 ha)]. This area consists of 1,533 ac (621 ha) of State land, 365 ac (148 ha) of City and County of Honolulu land, and 608 (246 ha) of privately owned land in the lowland wet ecosystem in on the leeward side of the Koolau Mountains, partly within the Honolulu Watershed Forest Reserve, extending from the eastern side of Nuuanu Valley southeast along the Koolau summit to Kulepeamoa Ridge.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea lanceolata* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Cyanea lanceolata* occurs within the Lowland mesic and Lowland wet ecosystems in the Koolau Mountain caldera complex :

Oahu—Lowland Mesic—Units 4, 5, 6, 7. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: Acacia, Diospyros, Metrosideros, Myrsine, Pouteria, Santalum. (E) Subcanopy: Dodonaea, Freycinetia, Leptecophylla, Melanthera, Osteomeles, Pleomele, Psydrax. (E) Understory: Carex, Dicranopteris, Diplazium, Elaphoglossum, Peperomia.

Oahu—Lowland Wet—Units 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16. (A) Elevation: <3,000 ft (<1,000 m). (B) Annual Precipitation: >75 in (>190 cm). (C) Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. (D) Canopy: Antidesma, Metrosideros, Myrsine, Pisonia, Psychotria. (E) Subcanopy: Cibotium, Claoxylon, Kadua, Melicope. (E) Understory: Alyxia, Cyrtandra, Dicranopteris, Diplazium, Machaerina, Microlepia.

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Cyanea lanceolata* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: Not available.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Wet environments (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found in shady locations; occur at elevations between 1,000 and 2,500 feet (NatureServe, 2015; USFWS, 2012)

Spatial Arrangements of the Population

Adult: Scattered (USFWS, 2012)

Environmental Specificity

Adult: Unknown (NatureServe, 2015)

Habitat Narrative

Adult: This species is found in wet and mesic forests, primarily in valleys and gulch bottoms and on gulch sides, and occasionally on ridge tops. *Cyanea Lanceolata* occurs at elevations between 1,000 and 2,500 feet (305 and 760 m) (Wagner et al. 1999, p. 483; Wagner and Herbst 2003, p. 17; TNC 2007; HBMP 2008). Many communities where present are dominated by *Acacia koa*, including *Koa (Acacia) Lowland Mesic Forest* communities. Found in shady locations - grows upward into the *koa* branches, but does not overtop them. Currently, there are 4 known occurrences sparsely scattered over a much smaller area of the southern Koolau range. (NatureServe, 2015; USFWS, 2012)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Short-term trends suggest a decline of 10-30% (NatureServe, 2015)

Resiliency:

Low (inferred from NatureServe, 2015)

Redundancy:

Low (inferred from NatureServe, 2015)

Population Growth Rate:

Unknown (NatureServe, 2015)

Number of Populations:

4 occurrences (NatureServe, 2015)

Population Size:

~60 individuals (NatureServe, 2015)

Population Narrative:

Short-term population trends suggest a decline of 10-30%. The U.S. Fish and Wildlife Service reports 20 populations of this species from Oahu (USFWS 2004). The Hawaii Biodiversity and Mapping Program indicates that there are four current (1990-2005) occurrences (J. Lau 2005). It is unclear how many occurrences these 20 populations make up. Currently, there are 4 known occurrences, totaling fewer than 60 individuals, sparsely scattered over a much smaller area of the southern Koolau range. (USFWS, 2012; NatureServe, 2015)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative plants, animals (pigs), rockfalls, landslides, and climate change. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. Rockfalls and landslides destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. The projected effects of climate change will likely exacerbate the effects of the other threats to the species (USFWS, 2012).

Stressor: Predation and herbivory (USFWS, 2012)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (pigs, goats, rats, and slugs) is considered an ongoing threat to *Cyanea lanceolata* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2012).

SPECIES ACCOUNT: *Cyanea lobata* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 05/15/1992; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Cyanea lobata, a member of the bellflower family (Campanulaceae), is a sparingly branched shrub 1.3-2.3 meters (4.3-7.5 feet) tall with smooth to somewhat rough stems and oblong, irregularly lobed leaves 30-50 cm (12-20 in) long, which may be broader at the end than at the base. The tops of the leaves are smooth; the lower surfaces may be rough and/or downy along the veins. The leaf stalks (petioles) are 7-22 cm (3-9 in) long and are somewhat rough. Flower clusters (inflorescences) occur on stalks 30-75 mm (1.2-3.0 in) long bearing 5-12 flowers, each on an individual stalk 18-35 mm (0.7-1.4 in) long. The base of each flower is 8-12 mm (0.3-0.5 in) long and 3-6 mm (0.1-0.2 in) wide. The flowers are partially tubular, curved, greenish-white or purplish, 60-70 mm (2.4-2.8 in) long and 5-11 mm (0.2-0.4 in) wide, downy at least on the spreading lobes, which are approximately as long as the tube. The berries are yellow and spherical. (USFWS, 1997)

Taxonomy

Lanuners (in Wagner et al. 1990) treated *Cyanea baldwinii* as a synonym of *Cyanea lobata*. St. John and Takeuchi (1987) questioned the distinctions between the two closely related Hawaiian endemic genera *Cyanea* and *Delissea*. St. John (1987) merged the two genera under the older generic name *Delissea*, creating the new combinations, *Delissea baldwinii* (Forbes and Munro) St. John and *Delissea lobata* (H. Mann) St. John. A recent treatment of the genus *Cyanea* (Lammers in Wagner et al. 1990) did not accept the generic changes proposed by St. John (1987). This short-lived perennial is endangered and has two recognized subspecies: *Cyanea lobata* subsp. *lobata*, endemic to the island of Maui, and *C. lobata* subsp. *baldwinii*, endemic to the island of Lanai (USFWS 2011). (USFWS, 1997; USFWS, 2014)

Historical Range

Historically, *Cyanea lobata* was known from Lanai and West Maui (Lammers in Wagner et al. 1990). (USFWS, 1997)

Current Range

Cyanea lobata is current known from West Maui. (NatureServe, 2015)

Critical Habitat Designated

Yes; 5/14/2003.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea lobata* (ssp. *baldwinii* and ssp. *lobata*) (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes ten detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea lobata* (ssp. *baldwinii* and ssp. *lobata*) includes ten detailed CHUs in Maui County, Hawaii with detailed unit information. There are also an unknown number of units on Lanai that contain this species (number of units is unknown because detailed unit descriptions for Lanai are not available) (81 FR 17790-18110).

Maui—Lowland Wet—Unit 2 (and) *Palmeria dolei*—Unit 3—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 3— Lowland Wet (and) *Newcombia cumingi*—Unit 1—Lowland Wet This area consists of 65 ac (26 ha) of State land at Moomoku, on the northwestern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Santalum haleakalae* var. *lanaiense*. Although Maui—Lowland Wet—Unit 2 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendrion pyriformum*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, or *Wikstroemia villosa*, by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), or by the Newcomb's tree snail (*Newcombia cumingi*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 3 (and) *Palmeria dolei*—Unit 4—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 4— Lowland Wet This area consists of 1,247 ac (505 ha) of State land at Honanana Gulch on the northeastern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). They are occupied by the plants *Bidens conjuncta*, *Cyanea asplenifolia*, and *Pteris lidgatei*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 3 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendrion pyriformum*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 4 (and) *Palmeria dolei*—Unit 5—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 5— Lowland Wet This area consists of 864 ac (350 ha) of State land at

Kahakuloa Valley on the northeastern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). They are occupied by the plants *Bidens conjuncta* and *Cyanea asplenifolia*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 4 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 5 (and) *Palmeria dolei*—Unit 6—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 6— Lowland Wet This area consists of 30 ac (12 ha) of State land at Iao Valley on the eastern side of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). Although Maui—Lowland Wet—Unit 5 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 6 (and) *Palmeria dolei*—Unit 7—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 7— Lowland Wet This area consists of 136 ac (55 ha) of State land at Honokowai and Wahikuli valleys on the western slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Santalum haleakalae* var. *lanaiense*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 6 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens conjuncta*, *Bidens micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C.*

magnicalyx, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 7 (and) *Palmeria dolei*—Unit 8—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 8— Lowland Wet This area consists of 898 ac (364 ha) of State land at Olowalu Valley, on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Alectryon macrococcus*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 7 is not currently occupied by the plants *Asplenium dielarectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 8 (and) *Palmeria dolei*—Unit 9—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 9— Lowland Wet This area consists of 230 ac (93 ha) of State land at upper Ukumehame Gulch, on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). Although Maui—Lowland Wet—Unit 8 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielarectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 6 (and) *Palmeria dolei*—Unit 35—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 35— Wet Cliff This area consists of 1,858 ac (752 ha) of State land, and 253 ac (102 ha) of privately owned land, at the summit ridges of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). They are occupied by the plants *Alectryon macrococcus*, *B. conjuncta*, *Ctenitis squamigera*, *Cyrtandra munroi*, *Remya mauiensis*, and *Santalum haleakalae* var. *lanaiense*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Wet Cliff—Unit 6 is not known to be occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Bonamia menziesii*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Isodendron pyriformis*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, or *Tetramolopium capillare*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 7 (and) *Palmeria dolei*—Unit 36—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 36— Wet Cliff This area consists of 556 ac (225 ha) of State land along Honokowai ridge on the northwestern side of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). These units are occupied by the plants *Cyrtandra filipes* and *C. munroi*, and contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Wet Cliff—Unit 7 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. conjuncta*, *Bonamia menziesii*, *Ctenitis squamigera*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Isodendron pyriformis*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Tetramolopium capillare*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 8 consists of 337 ac (137 ha) of State land along Kahakuloa ridge on the north side of west Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). Although Maui—Wet Cliff— Unit 8 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. conjuncta*, *Bonamia menziesii*, *Ctenitis squamigera*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*,

Hesperomannia arborescens, *H. arbuscula*, *Isodendrion pyriformis*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lydgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Tetramolopium capillare*, we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea lobata* (ssp. *baldwinii* and ssp. *lobata*) critical habitat consists of three components. Montane wet for ssp. *baldwinii* in Lanai and Lowland wet and Wet cliff in west Maui (81 FR 17790-18110):

Ecosystem: Montane Wet. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: >75 in (>190 cm). Substrate: Well-developed soils, montane bogs. Canopy: *Acacia*, *Charpentiera*, *Cheirodendron*, *Metrosideros*. Subcanopy: *Broussaia*, *Cibotium*, *Eurya*, *Ilex*, *Myrsine*. Understory: Ferns, *Carex*, *Coprosma*, *Leptecophylla*, *Oreobolus*, *Rhynchospora*, *Vaccinium*.

Ecosystem: Lowland Wet. Elevation: <3,330 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Ecosystem: Wet Cliff. Elevation: unrestricted. Annual precipitation: >75 in (>190 cm). Substrate: >65 degree slope, shallow soils, weathered lava. Canopy: None. Subcanopy: *Broussaia*, *Cheirodendron*, *Leptecophylla*, *Metrosideros*. Understory: Bryophytes, Ferns, *Coprosma*, *Dubautia*, *Kadua*, *Peperomia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other

Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyriformis*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C.*

samuelii, Ctenitis squamigera, Cyanea asplenifolia, C. copelandii ssp. haleakalaensis, C. duvalliorum, C. hamatiflora ssp. hamatiflora, C. horrida, C. kunthiana, C. magnicalyx, C. mannii, C. maritae, C. mceldowneyi, C. profuga, C. solanacea, Cyrtandra filipes, C. munroi, Diplazium molokaiense, Dubautia plantaginea ssp. humilis, Geranium hanaense, G. multiflorum, Hesperomannia arborescens, Huperzia mannii, Kadua laxiflora, Lysimachia lydgatei, L. maxima, Melicope balloui, M. ovalis, Phyllostegia hispida, P. mannii, P. pilosa, Plantago princeps, Platanthera holochila, Pteris lidgatei, Remya mauiensis, Santalum haleakalae var. lanaiense, Schiedea laui, Stenogyne bifida, S. kauaulaensis, Wikstroemia villosa, and Zanthoxylum hawaiiense) found on steep slopes and cliffs, or in narrow gulches.

Life History**Food/Nutrient Resources****Lifespan**

Adult: Long-lived, >15 years (USFWS, 1997)

Breeding Season

Adult: August to February (USFWS, 1997)

Reproduction Narrative

Adult: Though a low, soft-wooded shrub, this species can be relatively long-lived. The sole individual of this species known from Lanai was discovered as an adult in 1919 and was still living in 1934, some 15 years later (Degener 1936). Cyanea lobata is known to flower from August to February, even in individuals as small as 50 centimeters (19.7 inches) in height (Rock 1919, Degener 1936). (USFWS, 1997)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Dependencies on Specific Environmental Elements

Adult: Moist and wet environments (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 1,805 and 3,000 feet (USFWS, 1997)

Habitat Narrative

Adult: Cyanea lobata is found in moist and wet forests in gulches. Cyanea lobata has been seen and collected on steep streambanks at elevations of 550-915 meters (1,805-3,000 feet). (USFWS, 1997; NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

Very low (inferred from USFWS, 2014)

Redundancy:

Very low (inferred from USFWS, 2014)

Number of Populations:

3 (USFWS, 2018)

Population Size:

3 wild individuals (Maui), 2 wild individuals (Lānaʻi), 36 outplanted individuals (USFWS, 2017)

Population Narrative:

In 2013, the single population of *C. lobata* subsp. *baldwinii* on Lanai contained two mature wild individuals (Plant Extinction Prevention Program [PEPP] 2013). There are two populations of *C. lobata* subsp. *lobata* on Maui containing three wild mature individuals (PEPP 2013). The number of individuals has decreased from the three individuals reported for *C. lobata* subsp. *baldwinii* and four individuals reported for *C. lobata* subsp. *lobata* in the previous 5-year review (USFWS 2011). (USFWS, 2014); As reported in the 5-year review in 2014, *Cyanea lobata* subsp. *baldwinii* was known from one population of two individuals at Lānaʻihale on Lānaʻi. Two individuals at another population at Hauola Gulch have not been observed since 2012. Currently, there are still only two individuals at Lānaʻihale (PEPP 2016, 2017a). Also in 2014, we reported two populations of *C. lobata* subsp. *lobata* on west Maui totaling three individuals. Currently, there are two individuals at Hāʻena Nui (Kapunakea Preserve) and one individual at Honokōhau Gulch (Puʻu Kukui Watershed Preserve) on west Maui (Oppenheimer 2018, in litt.; PEPP 2017a). Two individuals at a third population at Honokōwai have not been observed since 2016 and this population is considered to be extirpated (PEPP 2016). • In 2012, the Service proposed revision of critical habitat for *Cyanea lobata* subsp. *baldwinii*, and the proposed rule identified one critical habitat unit on Lānaʻi in the montane wet ecosystem (238 ac, 101 ha) (77 FR 34464, July 11, 2012). In the final rule published in 2016, the Service excluded critical habitat for this subspecies on the island of Lānaʻi because, as demonstrated by the ongoing conservation activities by the private landowner, their commitment to develop the Lānaʻi Natural Resources Plan, and a memorandum of understanding with the Service, exclusion from critical habitat would provide greater long-term benefits to the subspecies than designation of critical habitat (USFWS 2015; 81 FR 17790, March 30, 2016). Also in 2016, 10 critical habitat units were designated in two ecosystems (lowland wet and wet cliff) on west Maui for *C. lobata* subsp. *lobata* (6,474 ac, 2,621 ha) (81 FR 17790, March 30, 2016). (USFWS, 2018)

Threats and Stressors

Stressor: Climate change (USFWS, 2014; USFWS, 2017)

Exposure:

Response:**Consequence:**

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Cyanea lobata* is moderately vulnerable to the impacts of climate change. Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2014); The assessment by Fortini et al. (2013) was conducted at the species level and concluded that *Cyanea lobata* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.644 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). *C. lobata* subsp. *lobata* and subsp. *baldwinii* are the only two subspecies in this taxon. Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2018)

Stressor: Drought (USFWS, 2014; USFWS, 2018)

Exposure:**Response:****Consequence:**

Narrative: Drought mortality and reduced viability – In 2010, drought was reported as a threat to *C. lobata* subsp. *balwinii* (PEPP 2011, 2012). (USFWS, 2014); Drought is observed to be a threat to both subspecies of *Cyanea lobata* on Lānaʻi and Maui (Spork-Koehler and Chau 2016). Over the past 100 years, the Hawaiian Islands have experienced an annual decline in precipitation from just over 9 percent, increasing to as much as 15 percent within the last 20 years (US-NSTC 2008; Chu and Chen 2005; Diaz 2005). Drought affects plants directly by desiccation. The increase in drought frequency and intensity leads to a self-perpetuating cycle of increase in cover of nonnative plants, increase in the number of fires, and an increase of erosion (US-GCRP 2009; Warren 2011). Recent episodes of drought have also driven axis deer farther into urban and forested areas in search of food, increasing their negative impacts to native vegetation from herbivory and trampling (Waring 1996, in litt; Nishibayashi 2001, in litt.). (USFWS, 2018)

Stressor: Invasive plants (USFWS, 2014)

Exposure:**Response:****Consequence:**

Narrative: Incipient invasive plant species – *Erigeron karvinskianus* (daisy fleabane) was discovered at the Lanai population containing *C. lobata* subsp. *balwinii* (PEPP 2013). This invasive species has not been previously reported from the island of Lanai (PEPP 2013). (USFWS, 2014)

Stressor: Feral pigs (USFWS, 1997)

Exposure:**Response:****Consequence:**

Narrative: Habitat degradation by feral pigs is a major threat to any *Cyanea lobata* populations or individuals located in areas accessible to pigs on West Maui. (USFWS, 1997)

Stressor: Collecting (USFWS, 1997)

Exposure:

Response:**Consequence:**

Narrative: Illegal collecting for scientific or horticultural purposes or excessive visits by individuals interested in seeing rare plants could result from increased publicity and would seriously threaten *Cyanea lobata*. Because of the few (if any) remaining individuals in existence, collection of whole plants or reproductive parts and/or site degradation caused by excessive foot traffic, would adversely impact the gene pool and threaten the survival of the taxon. (USFWS, 1997)

Stressor: Small population size (USFWS, 1997)

Exposure:**Response:****Consequence:**

Narrative: The likely very small number of remaining individuals—if there are any— of *Cyanea lobata* and the limited and scattered distribution of the species are threats since a single natural or human caused environmental disturbance could easily be catastrophic to all or part of the populations. In addition, the limited gene pool may depress reproductive vigor. Finally, cross-pollination would be a problem for single, isolated individuals. (USFWS, 1997)

Stressor: Fire destruction or degradation of habitat (USFWS, 2018)

Exposure:**Response:****Consequence:**

Narrative: Fire is reported to be a threat to *Cyanea lobata* subsp. *lobata* on west Maui (Spork-Koehler and Chau 2016). Fire can destroy dormant seeds as well as individual plants. Successive fires burn farther and farther into native habitat and alter microclimate conditions to further alter habitat conditions to favor nonnative plants. Nonnative plants convert native plant communities to nonnative dominated plant communities (D'Antonio and Vitousek 1992; Tunison et al. 2002). Increasing episodes of drought, expansion of invasive grass cover, and temperature increases, have led to an increase in the number of wildfires on Maui (Trauernicht et al. 2015). (USFWS, 2018)

Recovery**Reclassification Criteria:**

1. A total of five to seven populations of each taxon should be documented on Maui and at least one other island where they now occur or occurred historically. (USFWS, 1997)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1997)
3. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered. (USFWS, 1997)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Maui and at least one other island where they now occur or occurred historically. (USFWS, 1997)
2. Each population must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1997)
3. Each population should persist at this level for a minimum of five consecutive years. (USFWS, 1997)

Recovery Actions:

- Search for any individuals of this species in former habitat. (USFWS, 1997)
- If plants are located, create new populations. (USFWS, 1997)
- Surveys and inventories—Continue to survey for additional populations of both subspecies of *Cyanea lobata* in areas of potentially suitable habitat. (USFWS, 2018)
- Ungulate monitoring and control—Continue to construct and maintain large-scale and small-scale fenced enclosures to protect individuals from the negative impacts of feral ungulates and to prevent imminent extinction in the wild. (USFWS, 2018)
- Invasive plant monitoring and control—Continue to control established ecosystem-altering nonnative invasive plant species around all populations. Continue to control invasive nonnative species that compete with the species around all populations. Research and develop potential biological control agents for the nonnative plants *Clidemia hirta* and *Tibouchina herbacea* that modify and destroy habitat of, and outcompete, both subspecies of *Cyanea lobata*. (USFWS, 2018)
- Captive propagation for genetic storage and reintroduction—Evaluate genetic resources currently in storage to determine the need to place additional genetic resource into long-term storage due to these subspecies' vulnerability to climate change. Continue propagation efforts for maintenance of genetic stock. (USFWS, 2018)
- Reintroduction and translocation—Continue to reintroduce individuals into suitable habitat within historic range that is being managed for known threats to both subspecies. (USFWS, 2018)
- Fire monitoring and control—Develop and implement fire prevention management plans. (USFWS, 2018)
- Predator and herbivore monitoring and control—Implement effective control methods for rodents at wild and reintroduced populations. Develop and implement effective control methods for slugs. (USFWS, 2018)
- Stochastic events—Build resiliency and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from erosion and drought. (USFWS, 2018)
- Climate change adaptation strategy—Research the suitability of habitat for reintroducing these subspecies in the future due to impacts from climate change. (USFWS, 2018)
- Alliance and partnership development—Continue to initiate, plan, and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2018)

Conservation Measures and Best Management Practices:

- Survey geographical and historical range for a current assessment of the species' status. (USFWS, 2014)
- Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. Evaluate genetic resources currently in storage to determine the need to place additional genetic resources in long-term storage due to this species' vulnerability to climate change. (USFWS, 2014)
- Fence remaining populations to protect them from the impacts of feral ungulates. (USFWS, 2014)
- Eradicate invasive introduced plant species within ungulate exclosures and maintain the exclosures free of invasive introduced plants. (USFWS, 2014)
- Control slugs and rodents within the vicinity of all known *C. lobata* populations. (USFWS, 2014)
- Continue monitoring wild and outplanted individuals. (USFWS, 2014)
- Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change. (USFWS, 2014)
- Initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2014)

SPECIES ACCOUNT: *Cyanea longiflora* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/10/1996; Pacific Region (R1) (USFWS, 2016)

Physical Description

It is a single-stemmed or sparingly branched shrub 1 to 3 m (3.3 to 9.8 ft) tall. The leaves are 30 to 55 cm (11.7 to 21.5 in) long and clustered at the stem tips. The tubular, dark magenta flowers are 6 to 9 cm (2.3 to 3.5 in) long. The pear-shaped orange berries are 10 to 12 mm (3.9 to 4.7 in) long (Wagner et al 1999; Makua Implementation Team 2003) (USFWS, 2016).

Taxonomy

A member of the Campanulaceae (bellflower family). The genus *Cyanea* is one of the largest Hawaiian plant genera and incorporates a high proportion of rare taxa, including 28 endangered taxa, one threatened taxon, eight candidates for listing, and 17 species of concern (Service 2006a, Hawaii Biodiversity and Mapping Program 2006) (USFWS, 2016).

Historical Range

Cyanea longiflora is a species endemic to Oahu. Survey data indicate *C. longiflora* historically was known from five occurrences in the Waianae Mountains and six occurrences in the Koolau Mountains (USFWS, 2016).

Current Range

Currently, only the Waianae occurrences are extant, however, they have declined in numbers of known individuals since the listing (USFWS, 2016).

Critical Habitat Designated

Yes; 6/17/2003.

Legal Description

On June 17, 2003, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea longiflora* (Haha) under the Endangered Species Act of 1973, as amended (Act) (68 FR 35950-36348). On September 18, 2012 the Service published a Final Rule revising the 2003 designation of critical habitat designation for *Cyanea longiflora* (77 FR 57648-57862). The critical habitat designation includes 7 critical habitat units, which encompass approximately 7,823 acres on the Island of Oahu, Hawaii.

The critical habitat designation for *Cyanea longiflora* includes areas that were determined by the Service to be occupied at the time of listing, and also includes unoccupied suitable habitat that is essential to the conservation of this species by providing the PCEs necessary for reintroductions and expansion of the existing wild populations within their historical range.

Critical Habitat Designation

The critical habitat designation for *Cyanea longiflora* includes 7 critical habitat units, covering one ecosystem type, which encompasses approximately 7,823 acres on the Island of Oahu, Hawaii (77 FR 57648-57862). The designated critical habitats include: Oahu—Lowland Mesic—Units 1, 2, 3, 4, 5, 6, 7.

Oahu—Lowland Mesic—Unit 1 [4,448 ac (1,800 ha)]. This area consists of 3,565 ac (1,443 ha) of State land, 583 ac (236 ha) of City and County of Honolulu land, 22 ac (9 ha) of Federal land, and 277 ac (112 ha) of privately owned land in the lowland mesic ecosystem in the Waianae Mountains, encompassing a large area including the north slopes of Mt. Kaala, from the Pahole NAR to the Kaala NAR, and south to the Waianae Kai Forest Reserve (FR). Oahu—Lowland Mesic—Unit 2 [1,063 ac (430 ha)]. This area consists of 1,063 ac (430 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Puuhapapa south to Puukaua. Oahu—Lowland Mesic—Unit 3 [353 ac (143 ha)]. This area consists of 353 ac (143 ha) in the lowland mesic ecosystem on the windward side of the Waianae Mountains, from Pohakea Pass to Kaiakuakai Gulch. Oahu—Lowland Mesic—Unit 4 [20 ac (8 ha)]. This area consists of 20 ac (8 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, between the Waipilopilo and Hanaimoa gulches, on State-owned land within the Hauula Forest Reserve. Oahu—Lowland Mesic—Unit 5 [29 ac (12 ha)]. This area consists of 29 ac (12 ha) in the lowland mesic ecosystem on the windward side of the Koolau Mountains, in Maakua Gulch and ridge; is State-owned; and within the Hauula FR. Oahu—Lowland Mesic—Unit 6 [247 ac (100 ha)]. This area consists of 12 ac (5 ha) State land and 235 ac (95 ha) of privately owned land in the lowland mesic ecosystem on the windward side of the Koolau Mountains, inland of Kaaawa Point, and is partially within Ahupuaa O Kahana State Park. Oahu—Lowland Mesic—Unit 7 [1,669 ac (676 ha)]. This area consists of 681 ac (276 ha) of State land, 129 ac (52 ha) of City and County of Honolulu land, and 852 ac (345 ha) of privately-owned land in the lowland mesic ecosystem on the leeward side of the Koolau Mountains, on Waialae Nui ridge.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea longiflora* critical habitat consists of the following components according to ecosystem type (77 FR 57648-57862). Note: *Cyanea longiflora* occurs within the indicated ecosystem in the Waianae Mountain caldera complex and was known historically (last observed > 20 yrs ago) from indicated ecosystem in the Koolau Mountain caldera complex:

Oahu—Lowland Mesic—Units 1, 2, 3, 4, 5, 6, 7. (A) Elevation: <3,300 ft (<914 m). (B) Annual Precipitation: 50–75 in (130–190 cm). (C) Substrate: Shallow soils, little to no herbaceous layer. (D) Canopy: *Acacia*, *Diospyros*, *Metrosideros*, *Myrsine*, *Pouteria*, *Santalum*. (E) Subcanopy: *Dodonaea*, *Freycinetia*, *Leptecophylla*, *Melanthera*, *Osteomeles*, *Pleomele*, *Psydrax*. (F) Understory: *Carex*, *Dicranopteris*, *Diplazium*, *Elaphoglossum*, *Peperomia*.

Special Management Considerations or Protections

Special management considerations or protections are necessary throughout the critical habitat areas designated for *Cyanea longiflora* to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by feral ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified for this species.

Life History

Food/Nutrient Resources**Reproductive Strategy**

Adult: Sexual: cross-pollination, self-pollination (USFWS, 2016)

Lifespan

Adult: < 10 years, based on genus (USFWS, 2016)

Key Resources Needed for Breeding

Adult: Presumably birds (USFWS, 2016)

Reproduction Narrative

Adult: The long tubular flowers and orange berries of this taxon suggest pollination and seed dispersal by birds may be common. As with other *Cyanea* species with long tubular flowers, *C. longiflora* likely was pollinated by nectar-feeding birds. However, it is capable of self-pollination, as evidenced by the fact that isolated plants produce viable seeds. *Cyanea longiflora* presumably lives less than 10 years like other *Cyanea* of similar size (Makua Implementation Team 2003) (USFWS, 2016).

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Mesic Acacia koa-Metrosideros polymorpha forests (USFWS, 2016)

Geographic or Habitat Restraints or Barriers

Adult: Occurs at 479 - 3,906 ft. elevation (USFWS, 2016)

Habitat Narrative

Adult: Inhabits moist forests on ridgecrests, gulch slopes and gulch bottoms (NatureServe, 2015). *Cyanea longiflora* usually grows below ridge crests and on upper gulch slopes in mesic Acacia koa-Metrosideros polymorpha forests at elevations between 146 and 1,191 m (479 and 3,906 ft) (USFWS, 2016).

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available

Population Information and Trends**Population Trends:**

Decreasing since 1996

Resiliency:

Very low (inferred from USFWS, 2016; see current range/distribution)

Redundancy:

Low (inferred from USFWS, 2016)

Number of Populations:

3 (USFWS, 2016)

Population Size:

171 (USFWS, 2016)

Minimum Viable Population Size:

75 mature, reproducing individuals (USFWS, 2016)

Population Narrative:

At the time of listing in 1996, there were over 200 individuals in five occurrences (61 FR 53089). Currently, there are 171 total individuals in three population units, located on State and city/county lands (Table SB 10) (U.S. Army Garrison 2006d; 68 FR 35950). None of the currently known population units of this subspecies contain 75 mature, reproducing individuals (the minimum number required for stabilized population defined in the Makua Implementation Plan) (USFWS, 2016).

Threats and Stressors

Stressor: Nonnative plants (USFWS, 2009).

Exposure:

Response:

Consequence:

Narrative: Competition from invasive introduced plant species is another major threat, competing for light, space and water resources. The most serious plant species impacting *C. longiflora* include *Psidium cattleianum* (strawberry guava), *Clidemia hirta* (Koster's curse) and *Rubus argutus* (prickly Florida blackberry) (USFWS 1996, 1998, 2003, 2007) (USFWS, 2009).

Stressor: Predation (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: Recruitment probably is limited by slugs, which attack plants of all size classes in this genus (USFWS, 2016).

Stressor: Stochastic events (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: This species is threatened by reduced reproductive vigor due to small population size and limited distribution as well as direct destruction of individual plants by rat or slug predation, erosion, landslides, and rockslides (61 FR 53089; 68 FR 35950; Service 1998a). This species tends to fluctuate widely in population size and has a history of local decline; any catastrophic disturbance during a major low point could extirpate one or more population units or result in species extinction in the wild (Makua Implementation Team 2003). The science of conservation biology has documented a general pattern of population collapse for a wide range of plant and

animal species (Dennis et al 1991; Schemske et al 1994; Morris et al 1999; Menges 2000). According to this pattern, *C. longiflora* already is in a phase of “quasi-extinction” with numbers that have declined to the point where demographic stochasticity alone can result in extirpation (USFWS, 2016). Individuals growing on ridges are vulnerable to direct destruction by erosion, landslides, and rockslides (USFWS 2007; 2009).

Stressor: Loss of pollinators (USFWS, 2016)

Exposure:

Response:

Consequence:

Narrative: The long-billed, nectar-feeding native Hawaiian birds that were the presumed pollinators of *C. longiflora* have been almost totally extirpated from the Waianae Mountains. Although this species is capable of self-pollination, the loss of its natural pollinators has likely resulted in decreased genetic variability (Makua Implementation Team 2003) (USFWS, 2016).

Stressor: Feral pigs (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: The major threats to *Cyanea longiflora* include degradation and loss of habitat from feral pigs (*Sus scrofa*) (USFWS, 2009).

Stressor: Human disturbance (USFWS, 2009)

Exposure:

Response:

Consequence:

Narrative: The population from Makaha to Waianae Kai occurs near a trail and vandalism of plants was reported for this population as plant heads were snapped off from two mature tagged plants. There is also potential impact from military activities. The Kapuna to West Makaleha and Pahole populations are located within low and very low fire risk zones for military training-related wildfire, and the Makaha to Waianae Kai population unit is at risk of fire from illegal campfires (USFWS 2007) (USFWS, 2009).

Recovery

Reclassification Criteria:

1. A total of five to seven populations should be documented on Oahu and at least one other island where they now occur or occurred historically (USFWS, 1998).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure, with a minimum of 300 mature individuals per population (for short-lived perennials) (USFWS, 1998).
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered (USFWS, 1998).

Delisting Criteria:

1. A total of 8 to 10 populations should be documented on Oahu and at least one other island where they now occur or occurred historically (USFWS, 1998).
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure, with a minimum of 300 mature individuals per population (for short-lived perennials) (USFWS, 1998).
3. Each population should persist at this level for a minimum of 5 consecutive years (USFWS, 1998).

Recovery Actions:

- Protect habitat and control threats (USFWS, 1998).
- Expand existing wild populations (USFWS, 1998).
- Conduct essential research (USFWS, 1998).
- Develop and maintain monitoring plans (USFWS, 1998).
- Reestablish wild populations within historic range (USFWS, 1998).
- Validate and revise recovery criteria (USFWS, 1998).
- Construct enclosures to protect populations against feral pigs (USFWS, 1998).
- Control competing alien plant species within enclosures (USFWS, 1998).
- Reduce threat of rat predation (USFWS, 1998).
- Provide protection from fire (USFWS, 1998).

Conservation Measures and Best Management Practices:

- Research on slug control in forest settings is needed to find ways to reduce invertebrate threats to *C. longiflora* and associated native plants (USFWS, 2016).
- The Makua Implementation Team (2003) has developed stabilization protocols for *Cyanea longiflora*, which are incorporated in the Makua Implementation Plan Addendum (U.S. Army Garrison 2005a). This species is located in occurrences over four management units where it will benefit from population unit and/or ecosystem-level protection: Pahole, Upper Kapuna, West Makaleha, and Makaha and Waianae Kai (USFWS, 2016).
- In 2005, this species was represented in ex situ collections that included two cuttings in nurseries (Army Environmental Division, Oahu, and Harold L. Lyon Arboretum), 209 ungerminated seeds in a nursery (Harold L. Lyon Arboretum), 79,173 seeds in seed storage (Lyon Arboretum Seed Storage Facility), and 90 seedlings in a nursery (Harold L. Lyon Arboretum) (Service 2005b) (USFWS, 2016).
- Continue collecting mature fruit from wild individuals particularly for the augmentation of existing populations (USFWS, 2009).
- Continue control of introduced invasive plant species around wild and reintroduced plants (USFWS, 2009).
- Control rats around wild and outplanted individuals (USFWS, 2009).
- Complete large-scale fences around all naturally occurring and reintroduced individuals to control feral ungulates (USFWS, 2009).
- Continue outreach to the community groups near the Makaha population to reduce vandalism (USFWS, 2009).
- Continue reintroducing individuals into protected suitable habitat within historical range and augmenting wild populations (USFWS, 2009).
- Continue research for effective slug control methods (USFWS, 2009).
- Survey historical distribution and habitat for additional populations (USFWS, 2009).

- Assess genetic variability within the populations (USFWS, 2009).
- Study *Cyanea longifolia* populations with regard to population size and structure, geographical distribution, flowering cycles, pollination vectors, seed dispersal agents, longevity, specific environmental requirements, limiting factors, and threats (USFWS, 2009).

SPECIES ACCOUNT: *Cyanea magnicalyx* (haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 06/27/2013; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Cyanea magnicalyx, a member of the bellflower family (Campanulaceae), is a shrub with branched stems, from 1.5 to 3 meters (5 to 10 feet) tall. Leaves are glabrous, 36 to 55 centimeters (cm) (14 to 22 inches (in)) long and up to 27 cm (11 in) wide with pinnately cleft margins 0.4 to 4.5 cm (0.2 to 1.8 in) wide between the segments. Racemes are 6- to 15-flowered. Flowers are yellowish-white and striped with purple, 65 to 70 mm (2.6 to 2.8 in) long, glabrous, with corolla tube laterally compressed. Mature fruit and seeds are not described (Lammers 2004). (USFWS, 2018)

Taxonomy

This species was first described as *Cyanea grimesiana* subsp. *grimesiana*. The distribution of this subspecies at that time included the islands of O‘ahu, Moloka‘i, Lāna‘i, and Maui. Subsequently, Lammers (1998) recognized morphological differences in the broadly circumscribed *Cyanea grimesiana* group and published new combinations for the plants reported from Maui (*C. mauiensis*) and Lāna‘i (*C. munroi*). Plants reported from Moloka‘i were identified as either *C. munroi* or *C. grimesiana* subsp. *grimesiana*. In 2004, Lammers recognized further differences in the plants reported from Maui and described a new species, *C. magnicalyx*, known only from west Maui. The range of *C. grimesiana* subsp. *grimesiana* now includes only O‘ahu and Moloka‘i (Lammers 1998; Lammers 2004). We evaluated the effects of the five factors described in section 4(a)(1) of the Endangered Species Act on *C. magnicalyx* and determined that this species warranted endangered status under the Act (78 FR 32014, May 28, 2013). *Cyanea magnicalyx* is recognized as a distinct taxon in Lammers (2004) and in Wagner et al. (2012) the most recently accepted Hawaiian plant taxonomy. (USFWS, 2018)

Historical Range

Historically, two populations of *Cyanea magnicalyx* from west Maui were formerly classified as *C. grimesiana* subsp. *grimesiana*. (USFWS, 2018)

Current Range

Cyanea magnicalyx is found in west Maui. (USFWS, 2018)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea magnicalyx* (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes 14 detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea magnicalyx* includes 14 CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Lowland Wet—Unit 2 (and) *Palmeria dolei*—Unit 3—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 3— Lowland Wet (and) *Newcombia cumingi*—Unit 1—Lowland Wet This area consists of 65 ac (26 ha) of State land at Moomoku, on the northwestern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Santalum haleakalae* var. *lanaiense*. Although Maui—Lowland Wet—Unit 2 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielirectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendrion pyriformium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, or *Wikstroemia villosa*, by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), or by the Newcomb's tree snail (*Newcombia cumingi*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 3 (and) *Palmeria dolei*—Unit 4—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 4— Lowland Wet This area consists of 1,247 ac (505 ha) of State land at Honanana Gulch on the northeastern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). They are occupied by the plants *Bidens conjuncta*, *Cyanea asplenifolia*, and *Pteris lidgatei*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 3 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielirectum*, *Bidens micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendrion pyriformium*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 4 (and) *Palmeria dolei*—Unit 5—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 5— Lowland Wet This area consists of 864 ac (350 ha) of State land at Kahakuloa Valley on the northeastern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native

plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). They are occupied by the plants *Bidens conjuncta* and *Cyanea asplenifolia*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 4 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielirectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwiku* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 5 (and) *Palmeria dolei*—Unit 6—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 6— Lowland Wet This area consists of 30 ac (12 ha) of State land at Iao Valley on the eastern side of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). Although Maui—Lowland Wet—Unit 5 is not known to be occupied by the plants *Alectryon macrococcus*, *Asplenium dielirectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwiku* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 6 (and) *Palmeria dolei*—Unit 7—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 7— Lowland Wet This area consists of 136 ac (55 ha) of State land at Honokowai and Wahikuli valleys on the western slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Santalum haleakalae* var. *lanaiense*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 6 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielirectum*, *Bidens conjuncta*, *Bidens micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriformis*, *Kadua laxiflora*, *Peucedanum sandwicense*,

Phyllostegia bracteata, *Pteris lidgatei*, *Remya mauiensis*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 7 (and) *Palmeria dolei*—Unit 8—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 8— Lowland Wet This area consists of 898 ac (364 ha) of State land at Olowalu Valley, on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plant *Alectryon macrococcus*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 7 is not currently occupied by the plants *Asplenium dielerectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriform*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Wet—Unit 8 (and) *Palmeria dolei*—Unit 9—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 9— Lowland Wet This area consists of 230 ac (93 ha) of State land at upper Ukumehame Gulch, on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). Although Maui—Lowland Wet—Unit 8 is not currently occupied by the plants *Alectryon macrococcus*, *Asplenium dielerectum*, *Bidens conjuncta*, *B. micrantha* ssp. *kalealaha*, *Clermontia oblongifolia* ssp. *mauiensis*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. glabra*, *C. kunthiana*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Hesperomannia arborescens*, *H. arbuscula*, *Huperzia mannii*, *Isodendron pyriform*, *Kadua laxiflora*, *Peucedanum sandwicense*, *Phyllostegia bracteata*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 2 (and) *Palmeria dolei*—Unit 19—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 19— Montane Mesic This area consists of 124 ac (50 ha) of State land at Helu and the upper reaches of Puehuhunui on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plants *Ctenitis squamigera*, *Cyanea magnicalyx*, *Diplazium molokaiense*, *Lysimachia lydgatei*, *Remya mauiensis*, and *Santalum haleakalae* var. *lanaiense*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 2 is not known to be occupied by the plants *Geranium hillebrandii*, *Huperzia mannii*, *Stenogyne kauaulaensis*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 3 (and) *Palmeria dolei*—Unit 20—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 20— Montane Mesic This area consists of 174 ac (70 ha) of State land at Lihau on the southwestern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plant *Geranium hillebrandii*, and contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 3 is not known to be occupied by the plants *Ctenitis squamigera*, *Cyanea magnicalyx*, *Diplazium molokaiense*, *Huperzia mannii*, *Lysimachia lydgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Stenogyne kauaulaensis*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 4 (and) *Palmeria dolei*—Unit 21—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 21— Montane Mesic This area consists of 72 ac (29 ha) of State land at Halepohaku on the southern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). Although Maui—Montane Mesic—Unit 4 is not known to be occupied by the plants *Ctenitis squamigera*, *Cyanea magnicalyx*, *Diplazium molokaiense*, *Geranium hillebrandii*, *Huperzia mannii*, *Lysimachia lydgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Stenogyne kauaulaensis*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their

small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 5 (and) *Palmeria dolei*—Unit 22—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 22— Montane Mesic This area consists of 170 ac (69 ha) of State land at the upper reaches of Manawainui Gulch on the southeastern slopes of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plants *Remya mauiensis* and *Santalum haleakalae* var. *lanaiense*, and contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 5 is not known to be occupied by the plants *Ctenitis squamigera*, *Cyanea magnicalyx*, *Diplazium molokaiense*, *Geranium hillebrandii*, *Huperzia mannii*, *Lysimachia lydgatei*, *Stenogyne kauaulaensis*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 6 (and) *Palmeria dolei*—Unit 35—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 35— Wet Cliff This area consists of 1,858 ac (752 ha) of State land, and 253 ac (102 ha) of privately owned land, at the summit ridges of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). They are occupied by the plants *Alectryon macrococcus*, *B. conjuncta*, *Ctenitis squamigera*, *Cyrtandra munroi*, *Remya mauiensis*, and *Santalum haleakalae* var. *lanaiense*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Wet Cliff—Unit 6 is not known to be occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Bonamia menziesii*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Isodendron pyriformis*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, or *Tetramolopium capillare*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 7 (and) *Palmeria dolei*—Unit 36—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 36— Wet Cliff This area consists of 556 ac (225 ha) of State land along Honokowai ridge on the northwestern side of west Maui. These units include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). These units are occupied by the plants *Cyrtandra filipes* and *C. munroi*, and contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the

expansion of the existing wild populations. Although Maui—Wet Cliff—Unit 7 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. conjuncta*, *Bonamia menziesii*, *Ctenitis squamigera*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Tetramolopium capillare*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Wet Cliff—Unit 8 consists of 337 ac (137 ha) of State land along Kahakuloa ridge on the north side of west Maui. This unit includes the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). Although Maui—Wet Cliff—Unit 8 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. conjuncta*, *Bonamia menziesii*, *Ctenitis squamigera*, *Cyanea glabra*, *C. lobata*, *C. magnicalyx*, *Cyrtandra filipes*, *C. munroi*, *Dubautia plantaginea* ssp. *humilis*, *Gouania vitifolia*, *Hesperomannia arborescens*, *H. arbuscula*, *Isodendron pyrifolium*, *Kadua laxiflora*, *Lysimachia lydgatei*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, or *Tetramolopium capillare*, we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea magnicalyx* critical habitat consists of three components. Lowland wet (west Maui), Montane mesic (west Maui) and Wet cliff (west Maui) (81 FR 17790-18110):

Ecosystem: Lowland Wet. Elevation: <3,330 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Ecosystem: Montane Mesic. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Deep ash deposits, thin silty loams. Canopy: *Acacia*, *Ilex*, *Metrosideros*, *Myrsine*, *Nestegis*, *Nothocestrum*, *Pisonia*, *Pittosporum*, *Psychotria*, *Sophora*, *Zanthoxylum*. Subcanopy: *Alyxia*, *Charpentiera*, *Coprosma*, *Dodonaea*, *Kadua*, *Labordia*, *Leptecophylla*, *Phyllostegia*, *Vaccinium*. Understory: Ferns, *Carex*, *Peperomia*.

Ecosystem: Wet Cliff. Elevation: unrestricted. Annual precipitation: >75 in (>190 cm). Substrate: >65 degree slope, shallow soils, weathered lava. Canopy: None. Subcanopy: *Broussaisia*,

Cheirodendron, Leptecophylla, Metrosideros. Understory: Bryophytes, Ferns, Coprosma, Dubautia, Kadua, Peperomia.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into

native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History

Food/Nutrient Resources

Breeding Season

Adult: This species flowers primarily from September to October (Lammers 2004). (USFWS, 2018)

Reproduction Narrative

Adult: This species flowers primarily from September to October (Lammers 2004). (USFWS, 2018)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Cliff, forest- hardwood, forest/woodland (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: 450 meters (1,476 feet) elevation (USFWS, 2018)

Habitat Narrative

Adult: This species is found in lowland wet, montane mesic, and wet cliff ecosystems on West Maui. (NatureServe, 2015); Typical habitat for this species includes mesic forest and shrubland at 450 meters (1,476 feet) elevation on west Maui (Lammers 2004). *Cyanea magnicalyx* occurs on west Maui in at Kaluanui Stream in a subgulch of Honokōhau Valley and in Olowalu Gulch in *Metrosideros polymorpha*–*Cibotium* spp. (‘ōhi’a–hāpu‘u) mesic forest with the associated native plant species *Antidesma platyphyllum* (hame), *Broussaisia arguta* (kanawao), *Cheirodendron trigynum* (‘ōlapa), *Clermontia kakeana* (‘ōhā wai), *Cyanea angustifolia* (hāhā), *C. lobata* (hāhā), *Cyrtandra grayana* (ha’iwale), *C. grayi* (ha’iwale), *Dicranopteris linearis* (uluhe), *Diplazium sandwichianum* (hō‘i‘o), *Dodonaea viscosa* (‘a‘ali‘i), *Freycinetia arborea* (‘ie‘ie), *Ilex anomala* (kāwa‘u), *Kadua acuminata* (au), *Melicope hawaiiensis* (mokihana kūkae moa), *Myrsine lessertiana* (kōlea lau nui), *Nestegis sandwicensis* (olopua), *Polyscias hawaiiensis* (‘ohe), *Syzygium sandwicensis* (‘ōhi’a hā), and *Xylosma hawaiiense* (a‘e) (Wood 2009, in litt.). In ‘Īao Valley on west Maui, the vegetative community is *Pisonia* (pāpala kēpau) forest with *Metrosideros polymorpha* and associated native species including *Antidesma platyphyllum*, *Asplenium nidus* (‘ēkaha), *Chrysodracon auwahiensis* (hala pepe), *Cyrtandra grayi*, *Charpentiera obovata* (pāpala), *Cheirodendron trigynum*, *Claoxylon sandwicense* (po‘olā), *Freycinetia arborea*, *Kadua acuminata*, *K. affinis* (manono), *Nothocestrum longifolium* (‘aiea), *Perrottetia sandwicensis* (olomea), *Pittosporum glabrum* (hō‘awa), *Planchonella sandwicensis* (‘āla‘a), *Psychotria mauensis* (‘ōpiko), and *Xylosma hawaiiense* (Oppenheimer 2009, in litt.; Wood 2009, in litt.). (USFWS, 2018)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

Very low (inferred from USFWS, 2016)

Redundancy:

Very low (inferred from USFWS, 2016)

Number of Populations:

3 (USFWS, 2016; USFWS, 2018)

Population Size:

3 wild individuals, 97 outplanted individuals (USFWS, 2018)

Population Narrative:

Currently, there are seven individuals in three occurrences on west Maui: Two individuals in Kaluanui, a subgulch of Honokohau Valley, in the lowland wet ecosystem; four individuals in Lao Valley in the wet cliff ecosystem; and one individual in a small drainage south of the Kauaula rim, in the montane mesic ecosystem (Lammers 2004, p. 87; Perlman 2009b in litt.; Wood 2009d, in litt.). (USFWS, 2016)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (pigs), nonnative plants, fire, landslides, treefalls, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. Fire can destroy dormant seeds and plants, even in steep and inaccessible areas. Successive fires can remove habitat for native species by altering microclimate conditions favorable to alien plants. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Fire can destroy dormant seeds and plants, even in steep and inaccessible areas. Successive fires can remove habitat for native species by altering microclimate conditions favorable to alien plants. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Landslides and treefalls destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (pigs, rats, and slugs) is considered an ongoing threat to *Cyanea magnicalyx* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

Stressor: Stochastic events—Reduced viability due to low numbers (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Small, isolated populations often exhibit reduced levels of genetic variability, which diminishes the species' capacity to adapt and respond to environmental changes, thereby

lessening the probability of long-term persistence (Barrett and Kohn 1991; Newman and Pilson 1997). The problems associated with small population size and vulnerability to random demographic fluctuations or natural catastrophes are further magnified by synergistic interactions with other threats, such as anthropogenic impacts like habitat loss from human development or predation by nonnative species. *Cyanea magnicalyx* is currently known from only three wild individuals on west Maui (Oppenheimer 2018, in litt.). Although reintroduction of individuals is ongoing, fewer than 50 percent of those individuals persist beyond five years (PEPP 2010, 2011, 2012, 2013, 2014, 2015, 2017a). (USFWS, 2018)

Stressor: Ungulate degradation of habitat (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Feral ungulates modify and degrade habitat by disturbing and destroying vegetative cover, trampling plants and seedlings, reducing or eliminating plant regeneration by damaging seeds and seedlings, and increasing erosion by creating large areas of bare soil (Loope 1998; van Riper and van Riper 1982). Feral pigs (*Sus scrofa*) and evidence of their activities have been observed at wild and reintroduced occurrences of *Cyanea magnicalyx* at Honolua-Kaluanui-Honokōhau, Īao Valley, Kahana, and Pūehuehu Nui-Launiupoko (Keir et al. 2015; NTBG 2004a, 2004b, 2004c, PEPP 2010, 2012, 2013, 2015). (USFWS, 2018)

Stressor: Established ecosystem-altering invasive plant modification and degradation of habitat (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Invasive introduced plant species modify habitats occupied by native plant species by changing the availability of light, altering soil-water regimes, modifying nutrient cycling, and changing the fire characteristics of the native plant community (Cuddihy and Stone 1990). Habitat modification and destruction by invasive introduced plants negatively affects *Cyanea magnicalyx* at all locations where it occurs on west Maui. The nonnative plants with the greatest impacts include *Ageratina adenophora* (Maui pāmakani), *Blechnum appendiculatum* (no common name), *Buddleja asiatica* (dog tail), *Casuarina equisetifolia* (ironwood), *Clidemia hirta* (Koster's curse), *Cordyline fruticosa* (ki), *Grevillea robusta* (silk oak), *Psidium cattleianum* (strawberry guava), *P. guajava* (common guava), *Rubus rosifolius* (thimbleberry), *Schinus terebinthifolius* (christmasberry), and *Tibouchina herbacea* (cane tibouchina) (Keir et al. 2015; NTBG 2004a, 2004b, 2006a). (USFWS, 2018)

Stressor: Landslides and flooding destruction or degradation of habitat (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Landslides have been reported as a threat to individuals of *Cyanea magnicalyx* at Īao Valley and Honolua-Honokōhau (Keir et al. 2015; PEPP 2010, 2011, 2012). Landslides and erosion due to natural weathering destabilizes substrates, damages and destroys individual plants, and alters hydrological patterns (Stearns 1985). (USFWS, 2018)

Stressor: Drought degradation of habitat (USFWS, 2018)

Exposure:**Response:****Consequence:**

Narrative: Drought is observed to be a threat to *Cyanea magnicalyx* at Pūehuehu Nui-Launiupoko, Honokōhau, Olowalu, Īao Valley, and Kahana (PEPP 2010, 2012, 2013, 2014, 2015, 2017a). Over the past 100 years, the Hawaiian Islands have experienced an annual decline in precipitation from just over 9 percent, increasing to as much as 15 percent within the last 20 years (US-NSTC 2008; Chu and Chen 2005; Diaz et al. 2005). Drought affects plants directly by desiccation. The increase in drought frequency and intensity leads to a self-perpetuating cycle of increase in cover of nonnative plants, increase in the number of fires, and an increase of erosion (US-GCRP 2009; Warren 2011). Recent episodes of drought have also driven deer farther into urban and forested areas in search of food, increasing their negative impacts to native vegetation from herbivory and trampling (Waring 1996, in litt; Nishibayashi 2001, in litt.). (USFWS, 2018)

Stressor: Climate change loss or degradation of habitat (USFWS, 2018)

Exposure:**Response:****Consequence:**

Narrative: Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawai'i using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. At the time of the analysis, individuals of *Cyanea magnicalyx* were believed to be *C. grimesiana* subsp. *grimesiana*, and the assessment concluded that the subspecies is vulnerable to the impacts of climate change with a vulnerability score of 0.497 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Those individuals on west Maui now known as *Cyanea magnicalyx* have a much smaller range than *C. grimesiana* subsp. *grimesiana*, and may be more vulnerable. Therefore, additional management actions are needed to conserve this taxon into the future. We will update this information for *C. magnicalyx* as it becomes available. (USFWS, 2018)

Stressor: Rodent predation or herbivory (USFWS, 2018)

Exposure:**Response:****Consequence:**

Narrative: Herbivory by rats is noted to be a threat to *Cyanea magnicalyx* at Honolulu, Kaluanui-Honokōhau, Īao Valley, Pūehuehu Nui-Launiupoko, Kahana, and Waikapū (NTBG 2004a, 2004b, 2004c; Oppenheimer 2018, in litt.; PEPP 2010, 2011, 2012, 2013, 2014, 2015). Rats eat virtually every part of plants and at every stage: fleshy fruits, seeds, flowers, stems, leaves, shoots, seedlings, and roots (Russell 1980; Cuddihy and Stone 1990). The effects on plants range from reduced vigor and decreased reproduction to mortality of individuals and complete lack of recruitment. (USFWS, 2018)

Stressor: Invertebrate predation or herbivory (USFWS, 2018)

Exposure:**Response:****Consequence:**

Narrative: Herbivory by slugs has been noted as a threat to this species at Honolulu, Kaluanui-Honokōhau, Īao Valley, Pūehuehu Nui-Launiupoko, Kahana, Waikapū, and Olowalu (NTBG 2004a,

2004b, 2004c; PEPP 2010, 2011, 2012, 2013, 2014, 2015, 2017a). The effects on plants range from reduced vigor and decreased reproduction to mortality of individuals. (USFWS, 2018)

Stressor: Lack of adequate hunting regulations (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Current and historic habitat of *Cyanea magnicalyx* at Olowalu and Pūehuehu Nui is within State hunting areas. Public hunting areas are not fenced and game mammals have unrestricted access to most areas across the landscape, regardless of underlying land use designation; therefore, any unfenced populations are at risk (DLNR 2010). (USFWS, 2018)

Recovery

Reclassification Criteria:

To meet the interim stage of recovery of *Cyanea magnicalyx*, 300 mature individuals are needed in each of three populations and all major threats must be controlled around the populations designated for recovery at this stage. There should also be demonstrated regeneration of seedlings and growth to at least sapling stage for woody species and documented replacement regeneration within each of the target populations. The populations must be adequately represented in an ex situ collection as defined in the Center for Plant Conservation's guidelines (Guerrant et al. 2004). Adequate monitoring must be in place and conducted to assess individual plant survival, population trends, trends of major limiting factors, and response of major limiting factors to management. (USFWS, 2018)

In addition to achieving 5 to 10 populations with 500 mature individuals per population and all of the goals of the interim stage, all target populations must be stable, secure, and naturally reproducing for a minimum of 10 years. Species-specific management actions are not ruled out. Downlisting should not be considered until an adequate population viability analysis (PVA) has been conducted to assess needed numbers more accurately based on current management and monitoring data collected at regular intervals determined by demographic parameters of the species, although they should only be one of the factors used in making a decision to downlist. Information necessary for the PVA that should be available through monitoring (ideally annually) includes major limiting factors, breeding system, population structure and density, and proven management methods for major threats. (USFWS, 2018)

Delisting Criteria:

In addition to achieving 5 to 10 populations with 500 mature individuals per population and all of the goals of the interim and downlisting stages, all target populations must be stable, secure, naturally reproducing, and within secure and viable habitats for a minimum of 20 years. Species-specific management actions must no longer be necessary, but ecosystem-wide management actions are not ruled out if there are long-term agreements in place to continue management. These numbers are initial targets, but may be revised upward as additional information is available, including adequate PVAs for individual species based on current management and monitoring data collected at regular intervals determined by demographic parameters of the species, although they should only be one of the factors used in making a decision to delist. Genetic analyses should be conducted to ensure that adequate genetic representation is

present within and among populations compared to the initial variation assessed in the interim stage. Numbers need to be considered on a species-by-species basis. (USFWS, 2018)

Recovery Actions:

- Surveys and inventories—Continue to survey for populations of *Cyanea magnicalyx* in areas of potentially suitable habitat. (USFWS, 2018)
- Ungulate monitoring and control—Protect all occurrences against browsing and disturbances from feral ungulates. Construct and maintain fenced enclosures around existing populations and reintroductions to prevent imminent extinction. (USFWS, 2018)
- Invasive plant monitoring and control—Continue to control established ecosystem-altering nonnative invasive plant species around all populations. Continue to control invasive nonnative plant species that compete with *Cyanea magnicalyx*. (USFWS, 2018)
- Rodent predation or herbivory control—Continue to implement effective measures to control rodents around all populations. (USFWS, 2018)
- Invertebrate predation or herbivory control—Continue to implement effective measures to control slugs around all populations. (USFWS, 2018)
- Captive propagation for genetic storage and reintroduction—Continue to secure ex situ stocks with complete representation of remaining individuals. (USFWS, 2018)
- Reintroduction and translocation—Continue to reintroduce individuals into suitable habitat within historic range that is being managed for known threats to this species. (USFWS, 2018)
- Stochastic events—Build resilience and redundancy—Increase numbers of populations and individuals scattered throughout historic range to reduce impacts from landslides and drought. (USFWS, 2018)
- Climate change adaptation strategy—Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change. (USFWS, 2018)
- Alliance and partnership development—Continue to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2018)

Conservation Measures and Best Management Practices:

- Not available.

SPECIES ACCOUNT: *Cyanea mannii* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 10/08/1992; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Cyanea mannii, a member of the bellflower family, is a branched shrub 1.5 to 3 m (5 to 10 ft) tall. The leaves are narrowly elliptic or lance shaped, 12 to 21 cm (4.7 to 8.3 in) long and 2.5 to 5 cm (1 to 2 in) wide, and have petioles 2.2 to 10 cm (0.9 to 3.9 in) long and hardened teeth along the leaf margins. Each flower cluster, arising from the axil of a leaf on a stalk 20 to 35 mm (0.8 to 1.4 in) long, comprises 6 to 12 flowers, each on a stalk 8 to 12 mm (0.3 to 0.5 in) long. Each flower has a smooth, green hypanthium, which measures about 4 to 6 mm (0.2 in) long and 3 to 5 mm (0.1 to 0.2 in) wide and is topped by triangular calyx lobes 3 to 5 mm (0.1 to 0.2 in) long and 2 to 3 mm (0.08 to 0.1 in) wide. The purplish corolla forms a nearly upright tube 30 to 35 mm (1.2 to 1.4 in) long and 3 to 4 mm (0.1 to 0.2 in) wide, which ends in five spreading lobes. Berries have not been observed. (USFWS, 1996)

Historical Range

Historically, *Cyanea mannii* was known only from Kalae on East Molokai (USEWS 1992). (USFWS, 1996)

Current Range

This species is current found in Molokai. (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/18/2003.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea mannii* (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes four detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea mannii* includes four CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Molokai—Lowland Mesic—Unit 1 (and) *Palmeria dolei*—Unit 37—Lowland Mesic (and) *Pseudonestor xanthophrys*—Unit 37— Lowland Mesic This area consists of 3,489 ac (1,412 ha) of State land, and 5,281 ac (2,137 ha) of privately owned land, from Waianui Gulch to Mapulehu, in central Molokai. These units are occupied by the plants *Alectryon macrococcus*, *Ctenitis squamigera*, *Cyanea dunbariae*, *C. mannii*, *C. profuga*, *Cyperus fauriei*, *Cyrtandra filipes*, *Gouania hillebrandii*, *Labordia triflora*, *Neraudia sericea*, *Santalum haleakalae* var. *lanaiense*, *Schiedea lydgatei*, *S. sarmentosa*, *Silene alexandri*, *S. lanceolata*, *Spermolepis hawaiiensis*, and *Zanthoxylum hawaiiense*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland mesic ecosystem (see Table 5). These units also contain unoccupied

habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Lowland Mesic—Unit 1 is not known to be occupied by *Asplenium dielarectum*, *Bonamia menziesii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea procera*, *C. solanacea*, *Diplazium molokaiense*, *Festuca molokaiensis*, *Flueggea neowawraea*, *Isodendrion pyriformis*, *Kadua laxiflora*, *Melicope mucronulata*, *M. munroi*, *M. reflexa*, *Phyllostegia haliakalae*, *P. mannii*, *P. pilosa*, *Sesbania tomentosa*, *Stenogyne bifida*, or *Vigna o-wahuensis*, or the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Montane Wet—Unit 2 (and) *Palmeria dolei*—Unit 41—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 41— Montane Wet This area consists of 871 ac (353 ha) of State land, and 39 ac (16 ha) of privately owned land, from Honukaupu to Olokui (between Pelekunu and Wailau valleys), in north-central Molokai. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). Although Molokai— Montane Wet—Unit 2 is not known to be occupied by *Adenophorus periers*, *Bidens wiebkei*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea mannii*, *C. procera*, *C. profuga*, *C. solanacea*, *Hesperomannia arborescens*, *Lysimachia maxima*, *Melicope reflexa*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Pteris lidgatei*, *Schiedea laui*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Montane Wet—Unit 3 consists of 77 ac (31 ha) of State land, and 726 ac (294 ha) of privately owned land, above the east rim of Wailau Valley on eastern Molokai. This unit is occupied by the plant *Melicope reflexa*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Montane Wet—Unit 3 is not known to be occupied by *Adenophorus periers*, *Bidens wiebkei*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea mannii*, *C. procera*, *C. profuga*, *C. solanacea*, *Hesperomannia arborescens*, *Lysimachia maxima*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Pteris lidgatei*, *Schiedea laui*, *Stenogyne bifida*, or *Zanthoxylum hawaiiense*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Montane Mesic—Unit 1 (and) *Palmeria dolei*—Unit 42—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 42— Montane Mesic This area consists of 257 ac (104 ha) of State land, and 559 ac (226 ha) of privately owned land from Kamiloloa to Makolelau in central Molokai. These units are occupied by the plants *Alectryon macrococcus*, *Bidens wiebkei*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai— Montane Mesic—Unit 1 is not known to be occupied by *Asplenium dielerectum*, *Cyanea dunbariae*, *C. mannii*, *C. procera*, *C. solanacea*, *Cyperus fauriei*, *Kadua laxiflora*, *Melicope mucronulata*, *Neraudia sericea*, *Plantago princeps*, or *Stenogyne bifida*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea mannii* critical habitat consists of two components. Lowland mesic (east Maui) and Lowland wet (east Maui and west Maui) (81 FR 17790-18110):

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*,

Schiedea jacobii, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkii*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*,

Hesperomannia arborescens, Huperzia mannii, Kadua laxiflora, Lysimachia lydgatei, L. maxima, Melicope balloui, M. ovalis, Phyllostegia hispida, P. mannii, P. pilosa, Plantago princeps, Platanthera holochila, Pteris lidgatei, Remya mauiensis, Santalum haleakalae var. lanaiense, Schiedea laui, Stenogyne bifida, S. kauaulaensis, Wikstroemia villosa, and Zanthoxylum hawaiiense) found on steep slopes and cliffs, or in narrow gulches.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Cyanea mannii was observed in flower during July 1984 (HHP 1990e). (USFWS, 1996)

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 1,000 and 1,220 meters (USFWS, 1996)

Habitat Narrative

Adult: This species is found in moist forests on gulch sides and in gulch bottoms. This species typically grows on the sides of deep gulches in ohia dominated mesic to wet forests at elevations of about 1,000 to 1,220 meters (3,300 to 4,000 feet) (USEWS 1992). Associated plant taxa include akia, olapa, Dicranopteris linearis (uluhe), and Vaccinium (ohelo) (USFWS 1992). (USFWS, 1996; NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

Very low (inferred from USFWS, 2011)

Redundancy:

Very low (inferred from USFWS, 2011)

Number of Populations:

6-8 (USFWS, 2018)

Population Size:

64-114 wild individuals (USFWS, 2018)

Population Narrative:

Since the exact numbers of individuals were often not recorded by field botanists, currently there are approximately less than 200 individuals of *Cyanea mannii* on Molokai in an unknown number of populations. There are currently 9 known occurrences. (USFWS, 2011; NatureServe, 2015); In the 2011 5-year review, there were eight populations of *Cyanea mannii* totaling fewer than 200 individuals. Between 2007 and 2008, there were four individuals observed at Kapuna Spring, two individuals observed at Waihānau Stream, and five individuals observed at the headwaters of east Kawela (Oppenheimer 2010, in litt.). The current status of these populations is unknown, no new information was available. One of the eight populations, at Mokokoko, totals between 50 and 100 individuals (Bakutis 2018, in litt.). There may possibly be three other locations with greater than 40 individuals each, but these observations are from the early 1990s. Other locations from old observations had only a few individuals each. (USFWS, 2018)

Threats and Stressors

Stressor: Pigs and deer (USFWS, 1996)

Exposure:

Response:

Consequence:

Narrative: Feral pigs and Axis deer threaten and modify the habitat of *Cyanea mannii*. (USFWS, 1996)

Stressor: Rats (USFWS, 1996)

Exposure:

Response:

Consequence:

Narrative: Rats may feed on the fruit or other parts of the plant, as shown by predation on related species. (USFWS, 1996)

Stressor: Small population size (USFWS, 1996)

Exposure:

Response:

Consequence:

Narrative: Because of the small number of remaining individuals, one random naturally occurring event could extirpate a significant proportion of the populations (USFWS 1992). (USFWS, 1996)

Stressor: Invasive introduced plants (USFWS, 2011)

Exposure:

Response:

Consequence:

Narrative: Invasive introduced plant species are a threat to *Cyanea mannii* and include *Ageratum conyzoides* (goatweed), *Ageratina riparia* (spreading mist flower), *Axonopus fissifolius* (narrow leaved carpetgrass), *Buddleia asiatica* (dog tail), *Christella dentata* (downy wood fern), *Drymaria cordata* (tropical chickweed), *Erigeron karvinskianus* (daisy fleabane), *Hedychium* sp. (ginger), *Hypochoeris radicata* (hairy cat's ear), *Lantana camara* (lantana), *Melinis minutiflora* (molasses

grass), *Pluchea carolinensis* (sourbush), *Psidium guajava* (common guava), *Nephrolepis* sp. (NCN), *Ricinus communis* (castor bean), *Rubus rosifolius* (thimbleberry), *Sacciolepis indica* (Glenwood grass), *Schinus terebinthifolius* (Christmas berry), and *Setaria parvula* (yellow foxtail) (National Tropical Botanical Garden 2009; Perlman 2009; Wood 2009; Wood and Perlman 2002). (USFWS, 1996)

Stressor: Climate change loss or degradation of habitat (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawai'i using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under climate change. The assessment by Fortini et al. (2013) concluded that *Cyanea mannii* is highly vulnerable to the impacts of climate change, with a vulnerability score of 0.844 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2018)

Stressor: Fire destruction or degradation of habitat (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Fire is reported to be a threat to *Cyanea mannii* on Moloka'i (Keir et al. 2016). Fire can destroy dormant seeds as well as individual plants. Successive fires burn farther and farther into native habitat and alter microclimate conditions to further alter habitat conditions to favor nonnative plants. Nonnative plants convert native plant communities to nonnative dominated plant communities (D'Antonio and Vitousek 1992; Tunison et al. 2002). Increasing episodes of drought, expansion of invasive grass cover, and temperature increases, have led to an increase in the number of wildfires on Moloka'i (Trauernicht et al. 2015). (USFWS, 2018)

Stressor: Drought degradation of habitat (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Drought is observed to be a threat to *Cyanea mannii* on Moloka'i (Keir et al. 2016). Over the past 100 years, the Hawaiian Islands have experienced an annual decline in precipitation from just over 9 percent, increasing to as much as 15 percent within the last 20 years (US-NSTC 2008; Chu and Chen 2005; Diaz 2005). Drought affects plants directly by desiccation. The increase in drought frequency and intensity leads to a self-perpetuating cycle of increase in cover of nonnative plants, increase in the number of fires, and an increase of erosion (US-GCRP 2009; Warren 2011). Recent episodes of drought have also driven axis deer farther into urban and forested areas in search of food, increasing their negative impacts to native vegetation from herbivory and trampling (Waring 1996, in litt; Nishibayashi 2001, in litt.). (USFWS, 2018)

Stressor: Landslides and flooding destruction or degradation of habitat(USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Landslides are reported to be a threat to *Cyanea mannii* (Keir et al. 2016). Populations of this species occur in steep, rocky areas along streams or at headwaters of streams. Landslides, including tree falls and erosion associated with them, can have a significant effect on small populations by destabilizing substrate, altering hydrological patterns, and by damaging and destroying individual plants (Stearns 1985). (USFWS, 2018)

Stressor: Lack of adequate hunting regulations (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Four populations of *Cyanea mannii* on Moloka'i occur in a State hunting area. Nonnative feral ungulates pose a major ongoing threat to native species through destruction and modification of habitat, and through direct herbivory or predation. Only one population is fenced and habitat destruction and modification, and predation, by pigs, goats, and axis deer have been noted as threats to the species. In addition, public hunting areas are not fenced and game mammals have unrestricted access to most areas across the landscape, regardless of underlying land use designation; therefore, any unfenced populations are at risk (DLNR 2010). (USFWS, 2018)

Recovery**Reclassification Criteria:**

1. A total of five to seven populations of each taxon should be documented on Molokai and at least one other island where they now occur or occurred historically. (USFWS, 1996)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1996)
3. Each population should persist at this level for a minimum of 5 consecutive years before downlisting is considered. (USFWS, 1996)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Molokai and at least 1 other island where they now occur or occurred historically. (USFWS, 1996)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1996)
3. Each population should persist at this level for a minimum of 5 consecutive years. (USFWS, 1996)

Recovery Actions:

- Propagation and maintenance of genetic stock ex situ, and protection of remaining wild individuals from threats. (USFWS, 1996)
- The plan proposes the delineation of management units to conserve not only these taxa, but their habitats as well. These units should be managed to preserve as many native species (flora and fauna) as possible, through threat-control and forest-restoration programs. (USFWS, 1996)
- The next step in the recovery of these species is augmentation of small populations and re-establishment of new populations within the historical range of the species. (USFWS, 1996)
- A research program is also recommended to study the growth and reproductive viability of each taxon, determine the parameters of viable populations of each taxon, study the reproductive strategy and pollinators of each taxon, and study possible pests and diseases. (USFWS, 1996)
- Finally, the recovery criteria should be refined and revised as new information becomes available. (USFWS, 1996)
- Surveys and inventories—Continue to survey for additional populations of *Cyanea mannii* in areas of potentially suitable habitat. Regularly monitor known populations. (USFWS, 2018)
- Ungulate monitoring and control—Continue to construct and maintain fenced exclosures to protect individuals from the negative impacts of feral ungulates and to prevent imminent extinction in the wild. (USFWS, 2018)
- Invasive plant monitoring and control—Continue to control established ecosystem-altering nonnative invasive plant species around all populations. Continue to control invasive nonnative species that compete with the species around all populations. (USFWS, 2018)
- Captive propagation for genetic storage and reintroduction—Begin collection and propagation efforts for maintenance of genetic stock. (USFWS, 2018)
- Reintroduction and translocation—Begin reintroduction of individuals into suitable habitat within historic range that is being managed for known threats to this species. (USFWS, 2018)
- Fire monitoring and control—Develop and implement fire prevention management plans. (USFWS, 2018)
- Predator and herbivore monitoring and control—Implement effective control methods for rodents at wild and reintroduced populations. Develop and implement effective control methods for slugs. (USFWS, 2018)
- Stochastic events—Build resiliency and redundancy—Increase numbers of populations and individuals scattered through historic range to reduce impacts from erosion and drought. (USFWS, 2018)
- Climate change adaptation strategy—Research the suitability of habitat for reintroducing this species in the future due to impacts from climate change. (USFWS, 2018)
- Alliance and partnership development—Continue to initiate, plan, and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2018)
- (USFWS, 2018)
- (USFWS, 2018)

Conservation Measures and Best Management Practices:

- Survey to determine the current status of all wild and reintroduced populations. (USFWS, 2011)
- Monitor known populations. (USFWS, 2011)
- Collect seeds from each population for genetic storage and potentially, for reintroduction. (USFWS, 2011)

- Fence all populations to provide protection from the negative impacts of feral ungulates. (USFWS, 2011)
- Control invasive introduced plant species around all populations. (USFWS, 2011)
- Develop and implement methods to control slugs. (USFWS, 2011)
- Control rats in the vicinity of these populations. (USFWS, 2011)
- Propagate to augment existing populations. (USFWS, 2011)
- Establish additional populations within protected suitable habitat. (USFWS, 2011)
- Work with Hawaii Division of Forestry and Wildlife and other land managers to initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this species. (USFWS, 2011)
- Assess the modeled effects of climate change on this species, and use to determine future landscape needed for the recovery of the species. (USFWS, 2011)

SPECIES ACCOUNT: *Cyanea maritae* (haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 06/27/2013; Pacific Region (R1) (USFWS, 2016)

Physical Description

A shrub in the bellflower family (Campanulaceae). (USFWS, 2012)

Historical Range

Historically, specimens were collected from the northwestern slopes of Haleakala in the Waiohiwi watershed and east to Kipahulu in the early 1900s. (USFWS, 2012)

Current Range

Known only from East Maui. (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea maritae* (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes six detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea maritae* includes six CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Lowland Wet—Unit 1 (and) *Palmeria dolei*—Unit 2—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 2— Lowland Wet This area consists of 6,616 ac (2,677 ha) of State land, 7,425 ac (3,005 ha) of privately owned land, and 2,038 ac (825 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Kipahulu Valley on the northern and eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia samuelii*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Huperzia mannii*, *Melicope balloui*, and *M. ovalis*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 1 is not known to be occupied by the plants *Clermontia oblongifolia* ssp. *mauiensis*, *C. peleana*, *Mucuna sloanei* var. *persericea*, *Phyllostegia haliakalae*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes,

suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 1 (and) *Palmeria dolei*—Unit 10—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 10— Montane Wet This area consists of 1,313 ac (531 ha) of State land and 798 ac (323 ha) of privately owned land, at Haiku Uka on the northern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Cyanea duvalliorum*, *C. maritae*, *C. mceldowneyi*, *Huperzia mannii*, *Melicope balloui*, and *Phyllostegia pilosa*, and by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 1 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 2 (and) *Palmeria dolei*—Unit 11—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 11— Montane Wet This area consists of 4,075 ac (1,649 ha) of State land, 9,633 ac (3,898 ha) of privately owned land, and 875 ac (354 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Puukaukanu and upper Waihoi Valley, on the northern and northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Geranium hanaense*, *G. multiflorum*, and *Wikstroemia villosa*, and by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 2 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea glabra*, *C. maritae*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, and *Schiedea jacobii*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 3 (and) *Palmeria dolei*—Unit 12—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 12— Montane Wet This area consists of 2,228 ac (902 ha) of federally owned land (Haleakala National Park) in Kipahulu Valley, on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. maritae*, and *Melicope ovalis*, and by the forest bird, *kiwiku* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 3 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea duvalliorum*, *C. glabra*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest bird, the *akohekohe* (*Palmeria dolei*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 4 (and) *Palmeria dolei*—Unit 13—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 13— Montane Wet This area consists of 180 ac (73 ha) of State land and 1,653 ac (669 ha) of federally owned land (Haleakala National Park), in Kaapahu Valley on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *Cyrtandra ferripilosa*, and *Huperzia mannii*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 4 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea duvalliorum*, *C. glabra*, *C. mceldowneyi*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwiku* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 5 (and) *Palmeria dolei*—Unit 14—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 14— Montane Wet This area consists of 222 ac (90 ha) of State land, and 165

ac (67 ha) of federally owned land (Haleakala National Park), near Kaumakani on the eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plant *Bidens campylotheca* ssp. *pentamera*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 5 is not currently occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea maritae* critical habitat consists of two components. Lowland wet (east Maui) Montane wet (east Maui) (81 FR 17790-18110):

Ecosystem: Lowland Wet. Elevation: <3,330 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Ecosystem: Montane Wet. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: >75 in (>190 cm). Substrate: Well-developed soils, montane bogs. Canopy: *Acacia*, *Charpentiera*, *Cheirodendron*, *Metrosideros*. Subcanopy: *Broussaisia*, *Cibotium*, *Eurya*, *Ilex*, *Myrsine*. Understory: Ferns, *Carex*, *Coprosma*, *Leptecophylla*, *Oreobolus*, *Rhynchospora*, *Vaccinium*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight

plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; MauiWet

Cliff—Units 6 and 7; and MolokaiMontane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylothea* ssp. *pentamera*, *B. campylothea* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Habitat Narrative

Adult: This species is found in lowland wet and montane wet ecosystems of East Maui (USFWS 2012). (NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

Very low (inferred from USFWS, 2016)

Redundancy:

Very low (inferred from USFWS, 2016)

Number of Populations:

4 (USFWS, 2016)

Population Size:

~50 (USFWS, 2016)

Population Narrative:

Currently, there are 4 occurrences, totaling between 23 and 50 individuals in Kipahulu, Kaapahu, west Kahakapao, and in the Koolau FR. (USFWS, 2016)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (pigs), nonnative plants, landslides, treefalls, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Landslides and treefalls destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response: Predation and herbivory by nonnative animal species (pigs, rats, and slugs) is considered an ongoing threat to *Cyanea maritae* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

Consequence:

Narrative: Predation and herbivory by nonnative animal species (pigs, rats, and slugs) is considered an ongoing threat to *Cyanea maritae* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

Stressor: Small populations (USFWS, 2013)

Exposure:

Response: *Cyanea maritae* faces the threat of limited numbers (i.e., there are fewer than 50 individuals in the wild). The only known wild occurrences are susceptible to threats from habitat

degradation or loss by flooding, landslides, or tree falls, or a combination of these, because of their locations in lowland wet, montane wet, and wet cliff ecosystems (USFWS, 2013).

Consequence:

Narrative: *Cyanea maritae* faces the threat of limited numbers (i.e., there are fewer than 50 individuals in the wild). The only known wild occurrences are susceptible to threats from habitat degradation or loss by flooding, landslides, or tree falls, or a combination of these, because of their locations in lowland wet, montane wet, and wet cliff ecosystems (USFWS, 2013).

SPECIES ACCOUNT: *Cyanea marksii* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 11/29/2013; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Palm-like trees, 2 m tall. Leaves dimorphic. Juvenile plants with leaf blades 13-18 cm long, 5.5-7 cm wide, upper surface aculeate, lower surface pubescent and aculeate. Mature plants with leaf blades oblong to oblanceolate, 25-31 cm long, 8-12 cm wide, upper surface smooth or muricate, lower surface pubescent. Racemes 5-8-flowered, clustered among the leaves. Corollas blackish purple externally, white within, 70-80 mm long. (NatureServe, 2015)

Taxonomy

This species is related c. *Macrostegia* and c. *Tritomantha*. (NatureServe, 2015)

Historical Range

See current range/distribution.

Current Range

Cyanea marksii is endemic to the island of Hawaii in the Hawaiian Islands. It is known only from the district of South Kona, which is on the western flank of Mauna Loa, an active volcano. It has been recorded only from a small portion of South Kona inland

SPECIES ACCOUNT: *Cyanea mauiensis* (haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 6/27/2013; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Stout branching or single-stemmed shrubs 1-3.3 m tall. Leaf blades 30-45 cm long, 20-30 cm wide, pinnately divided with 9-12 segments on each side, segments lacinate. Racemes 6-10-flowered. Corollas almost white. (NatureServe, 2015)

Taxonomy

Treated as a synonym within *Cyanea grimesiana* ssp. *grimesiana* in the Hawaii Manual (Wagner et al., 1990); recognized as a species in the Manual's Supplement (Wagner and Herbst, 1999) and by Kartesz (1999 Synthesis). (NatureServe, 2015)

Historical Range

See current range/distribution.

Current Range

Cyanea mauiensis is endemic to the island of Maui in the state of Hawaii. The species has not been observed in about 100 years. (NatureServe, 2015)

Critical Habitat Designated

Yes;

Population Information and Trends**Population Trends:**

Not available.

Resiliency:

None

Redundancy:

None

Number of Populations:

None known (USFWS, 2016)

Population Size:

0 (USFWS, 2016)

Population Narrative:

This species was last observed on Maui about 100 years ago (Lammers 2004, pp. 84–85; TNC 2007). Although there are no documented occurrences of this species known today, botanists believe this species may still be extant as all potentially suitable lowland mesic and dry cliff habitat has not been surveyed. (USFWS, 2016)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (pigs), nonnative plants, fire, landslides, treefalls, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Fire can destroy dormant seeds and plants, even in steep and inaccessible areas. Successive fires can remove habitat for native species by altering microclimate conditions favorable to alien plants. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Landslides and treefalls destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (pigs , rats, and slugs) is considered an ongoing threat to *Cyanea mauiensis* throughout the species range. SPECIES ACCOUNT: *Cyanea mceldowneyi* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 05/15/1992; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

Cyanea mceldowneyi, a plant of the bellflower family (Campanulaceae) is an unbranched shrub 2-3 meters (6.6-9.8 feet) tall with rough to prickly stems. Leaves of adult plants are oblong to inverted lance shaped, 20-35 cm (7.9-13.8 in) long, and 5-9 cm (2.0-3.5 in) wide. The leaves have smooth to somewhat rough green upper surfaces and pale green, lightly downy undersides and are characterized by thickened, finely toothed edges and a pointed wedge-shaped base on smooth to rough leaf stalks (petioles) 3.5-6 cm (1.4-2.4 in) long. Juveniles exhibit leaves that are oval to egg shaped (large end at tip), 15-22 cm (5.9-8.7 in) long and 5-9 cm (2.0-3.5 in) wide with prickly green upper surfaces; pale-green, downy and prickly undersides; thickened, toothed edges; and a rounded base on prickly leaf stalks (petioles) 2.5-4.5 cm (1.0-1.8 in) long. Flower clusters (inflorescences) occur on stalks (peduncles) 15-30 mm (0.6-1.2 in) long bearing five to seven flowers, each flower on an individual stalk (pedicel) 10-14 mm (0.4-0.6 in) long. The base of each flower is approximately 5 mm (0.2 in) long and 4 mm (0.2 in) wide. The flowers are partially tubular, curved, rough-surfaced and white with purple longitudinal stripes. Flowers are approximately 40 mm (1.6 in) long and 8 mm (0.3 in) wide, with the spreading lobes being about as long as the tube. The appearance and size of the berries are unknown. (USFWS, 1997)

Taxonomy

Rock (1957) considered this taxon most closely related to *Cyanea rollandioides* Rock, now a synonym of *Cyanea platyphylla* (Gray) Hillebr., endemic to Hawaii Island. St. John and Takeuchi (1987) questioned the distinctions between the two closely related Hawaiian endemic genera, *Cyanea* and *Delissea*. St. John (1987) merged the two genera under the older generic name *Delissea*, creating the new combinations, *Delissea baldwinii* (Forbes and Munro) St. John and *Delissea lobata* (H. Mann) St. John. A recent treatment of the genus *Cyanea* (Lammers in Wagner et al. 1990) did not accept the generic changes proposed by St. John (1987). (USFWS, 1997)

Historical Range

Historically, *Cyanea mceldowneyi* is known from rainforest from west of Waikamoi to Honomanu on northwestern Haleakala, Maui. (USFWS, 1997)

Current Range

Endemic to windward East Maui. (NatureServe, 2015)

Critical Habitat Designated

Yes; 5/14/2003.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea mceldowneyi* (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes seven detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea mceldowneyi* includes seven CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Lowland Wet—Unit 1 (and) *Palmeria dolei*—Unit 2—Lowland Wet (and) *Pseudonestor xanthophrys*—Unit 2— Lowland Wet This area consists of 6,616 ac (2,677 ha) of State land, 7,425 ac (3,005 ha) of privately owned land, and 2,038 ac (825 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Kipahulu Valley on the northern and eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia samuelii*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Huperzia mannii*, *Melicope balloui*, and *M. ovalis*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Wet—Unit 1 is not known to be occupied by the plants *Clermontia oblongifolia* ssp. *mauiensis*, *C. peleana*, *Mucuna sloanei* var. *persericea*, *Phyllostegia haliakalae*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these lowland wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 1 (and) *Palmeria dolei*—Unit 10—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 10— Montane Wet This area consists of 1,313 ac (531 ha) of State land and 798 ac (323 ha) of privately owned land, at Haiku Uka on the northern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Cyanea duvalliorum*, *C. maritae*, *C. mceldowneyi*, *Huperzia mannii*, *Melicope balloui*, and *Phyllostegia pilosa*, and by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 1 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 2 (and) *Palmeria dolei*—Unit 11—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 11— Montane Wet This area consists of 4,075 ac (1,649 ha) of State land, 9,633 ac (3,898 ha) of privately owned land, and 875 ac (354 ha) of federally owned land (Haleakala National Park), from Haiku Uka to Puukaukanu and upper Waihoi Valley, on the northern and northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Geranium hanaense*, *G. multiflorum*, and *Wikstroemia villosa*, and by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwiku* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 2 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea glabra*, *C. maritae*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, and *Schiedea jacobii*, we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 3 (and) *Palmeria dolei*—Unit 12—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 12— Montane Wet This area consists of 2,228 ac (902 ha) of federally owned land (Haleakala National Park) in Kipahulu Valley, on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. maritae*, and *Melicope ovalis*, and by the forest bird, *kiwiku* (*Pseudonestor xanthophrys*). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 3 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea duvalliorum*, *C. glabra*, *C. horrida*, *C. kunthiana*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest bird, the *akohekohe* (*Palmeria dolei*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 4 (and) *Palmeria dolei*—Unit 13—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 13— Montane Wet This area consists of 180 ac (73 ha) of State land and

1,653 ac (669 ha) of federally owned land (Haleakala National Park), in Kaapahu Valley on the northeastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units are occupied by the plants *Clermontia samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *Cyrtandra ferripilosa*, and *Huperzia mannii*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 4 is not known to be occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *Cyanea duvalliorum*, *C. glabra*, *C. mceldowneyi*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Wet—Unit 5 (and) *Palmeria dolei*—Unit 14—Montane Wet (and) *Pseudonestor xanthophrys*—Unit 14—Montane Wet This area consists of 222 ac (90 ha) of State land, and 165 ac (67 ha) of federally owned land (Haleakala National Park), near Kaumakani on the eastern slopes of east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane wet ecosystem (see Table 5). These units area occupied by the plant *Bidens campylotheca* ssp. *pentamera*. These units also contain unoccupied habitat that is essential to the conservation of this species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Wet—Unit 5 is not currently occupied by the plants *Adenophorus periens*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *waihoiensis*, *Clermontia oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Cyanea copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. maritae*, *C. mceldowneyi*, *Cyrtandra ferripilosa*, *Diplazium molokaiense*, *Geranium hanaense*, *G. multiflorum*, *Huperzia mannii*, *Melicope balloui*, *M. ovalis*, *Peperomia subpetiolata*, *Phyllostegia bracteata*, *P. haliakalae*, *P. mannii*, *P. pilosa*, *Platanthera holochila*, *Schiedea jacobii*, or *Wikstroemia villosa*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane wet species because it provides the PCEs necessary for the reestablishment of wild populations within the historical ranges of the species. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 1 (and) *Palmeria dolei*—Unit 18—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 18—Montane Mesic This area consists of 6,593 ac (2,668 ha) of State land, 707 ac (286 ha) of privately owned land, and 3,672 ac (1,486 ha) of federally owned land (Haleakala National Park), from Kealahou to Puualae, nearly circumscribing the summit of Haleakala on east Maui. These units include the mixed herbland and shrubland, the moisture

regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Asplenium dielirectum*, *A. peruvianum* var. *insulare*, *Clermontia lindseyana*, *Cyanea horrida*, *C. obtusa*, *Cyrtandra ferripilosa*, *C. oxybapha*, *Diplazium molokaiense*, *Geranium arboreum*, *G. multiflorum*, *Huperzia mannii*, *Melicope adscendens*, and *Neraudia sericea*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 1 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. micrantha* ssp. *kalealaha*, *Cyanea glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. kunthiana*, *C. mceldowneyi*, *Phyllostegia bracteata*, *P. mannii*, *Santalum haleakalae* var. *lanaiense*, *Wikstroemia villosa*, or *Zanthoxylum hawaiiense*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea mceldowneyi* critical habitat consists of three components. Lowland wet (east Maui), Montane wet (east Maui) and Montane mesic (east Maui) (81 FR 17790-18110):

Ecosystem: Lowland Wet. Elevation: <3,330 ft (<1,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Clays; ashbeds; deep, well drained soils; lowland bogs. Canopy: *Antidesma*, *Metrosideros*, *Myrsine*, *Pisonia*, *Psychotria*. Subcanopy: *Cibotium*, *Claoxylon*, *Kadua*, *Melicope*. Understory: *Alyxia*, *Cyrtandra*, *Dicranopteris*, *Diplazium*, *Machaerina*, *Microlepia*.

Ecosystem: Montane Wet. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: >75 in (>190 cm). Substrate: Well-developed soils, montane bogs. Canopy: *Acacia*, *Charpentiera*, *Cheirodendron*, *Metrosideros*. Subcanopy: *Broussaisia*, *Cibotium*, *Eurya*, *Ilex*, *Myrsine*. Understory: Ferns, *Carex*, *Coprosma*, *Leptecophylla*, *Oreobolus*, *Rhynchospora*, *Vaccinium*.

Ecosystem: Montane Mesic. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Deep ash deposits, thin silty loams. Canopy: *Acacia*, *Ilex*, *Metrosideros*, *Myrsine*, *Nestegis*, *Nothocestrum*, *Pisonia*, *Pittosporum*, *Psychotria*, *Sophora*, *Zanthoxylum*. Subcanopy: *Alyxia*, *Charpentiera*, *Coprosma*, *Dodonaea*, *Kadua*, *Labordia*, *Leptecophylla*, *Phyllostegia*, *Vaccinium*. Understory: Ferns, *Carex*, *Peperomia*.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is

needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass),

and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: Not available.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 925 and 1,280 meters (USFWS, 1997)

Environmental Specificity

Adult: Medium, with some key requirements (USFWS, 1997)

Habitat Narrative

Adult: The habitat of *Cyanea mceldowneyi* is montane wet forest with mixed *Metrosideros* and *Acacia koa*. This species is found in moist and wet forests in gulch bottoms and on gulch sides. A detailed description of the habitat, species composition, etc., in the vicinity is given by Kitayama and Mueller-Dombois (1992). *Cyanea mceldowneyi* typically grows at elevations between 925 and 1,280 meters (3,034 and 4,200 feet). Associated native plants include *Melicope clusifolia*, *Hedyotis*, *Metrosideros polymorpha*, *Acacia koa*, *Clermontia arborescens*, *Diplazium sandwichianum*, *Broussaisia arguta*, *Cibotium*, *Cyrtandra*, *Dicranopteris linearis*, and

Cheirodendron trigynum (USFWS 1992a; HPCC 1994). Associated alien plants include Ageratina adenophora, Rubus argutus, Setaria palmifolia, and Tibouchina herbacea. (USFWS, 1997; NatureServe, 2015)

Dispersal/Migration

Dispersal/Migration Narrative

Adult: Not available.

Population Information and Trends

Population Trends:

Not available.

Resiliency:

Low (inferred from USFWS, 2014)

Redundancy:

Low (inferred from USFWS, 2014)

Number of Populations:

13 (USFWS, 2018)

Population Size:

>100 wild (USFWS, 2018)

Population Narrative:

Overall, the numbers of individuals have increased from approximately 60 wild individuals reported in the previous 5-year review to more than 100 wild individuals (USFWS 2012). There are currently 3 known occurrences and 1 historical occurrence. (USFWS, 2014; NatureServe, 2015); The previous 5-year review reported three new populations of Cyanea mceldowneyi on private land totaling 22 mature individuals, two immature individuals, and two seedlings. Between 2012 and 2013, four new populations were observed at Honomāʻele Stream (one individual), Kawakoe Gulch (five sites, four in poor health), Kūhiwa Valley, and in the Koʻolau Forest Reserve (scattered individuals) (NTBG 2012, 2013a, b; PEPP 2013). Currently, all known populations on east Maui are estimated to total just over 100 individuals (Oppenheimer 2018, in litt.). (USFWS, 2018)

Threats and Stressors

Stressor: Climate change (USFWS, 2014; USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Climate change may pose a threat to this species. Fortini et al. (2013) conducted a landscape-based assessment of climate change vulnerability for native plants of Hawaii using high resolution climate change projections. Climate change vulnerability is defined as the relative inability of a species to display the possible responses necessary for persistence under

climate change. The assessment by Fortini et al. (2013) concluded that *C. mceldowneyi* is moderately vulnerable to the impacts of climate change. Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2014); The assessment by Fortini et al. (2013) concluded that *Cyanea mceldowneyi* is vulnerable to the impacts of climate change, with a vulnerability score of 0.531 (on a scale of 0 being not vulnerable to 1 being extremely vulnerable to climate change). Therefore, additional management actions are needed to conserve this taxon into the future. (USFWS, 2018)

Stressor: Herbivory by slugs (USFWS, 2014)

Exposure:

Response:

Consequence:

Narrative: Herbivory by slugs has been reported as a new threat to this species (PEPP 2009). (USFWS, 2014)

Stressor: Herbivory by rats (USFWS, 2014)

Exposure:

Response:

Consequence:

Narrative: Predation or herbivory by rats have been reported as a threat to this species (PEPP 2009). (USFWS, 2014)

Stressor: Non-native invasive plants (USFWS, 2014)

Exposure:

Response:

Consequence:

Narrative: Newly observed invasive introduced plants that are a threat to *C. mceldowneyi* include *Hedychium coronarium* (white ginger), *Spathiphyllum cannifolium* (spathe flower), and *Psidium cattleianum* (strawberry guava) (PEPP 2013). (USFWS, 2014)

Stressor: Flooding (USFWS, 2014)

Exposure:

Response:

Consequence:

Narrative: Flooding is a threat to this species (PEPP 2013). (USFWS, 2014)

Stressor: Feral pigs (USFWS, 1997)

Exposure:

Response:

Consequence:

Narrative: Habitat degradation and physical destruction by feral pigs is the major threat to *Cyanea mceldowneyi*. This species has undergone a substantial decline since the late 1970s in the vicinity of the Lower Waikamoi Flume, clearly attributable to direct impacts of feral pigs (A.C. Medeiros and R.W. Hobdy, personal communication 1994). (USFWS, 1997)

Stressor: Alien plants (USFWS, 1997)

Exposure:

Response:

Consequence:

Narrative: Habitat degradation by feral pigs works in concert with invasion of alien plant species. As of 1994, palm grass (*Setaria palmifolia*) is rapidly spreading unchecked into the habitat of *Cyanea mceldowneyi*. Palm grass invades the stream banks where *C. mceldowneyi* grows, forming dense stands and displacing native vegetation. (USFWS, 1997)

Stressor: Lack of adequate hunting regulations (USFWS, 2018)

Exposure:

Response:

Consequence:

Narrative: Six of the 13 locations where *Cyanea mceldowneyi* is found on east Maui are within a State hunting area. Nonnative feral ungulates pose a major ongoing threat to native species through destruction and modification of habitat, and through direct herbivory or predation. Habitat destruction and modification by pigs and goats has been noted as a threat to the species. Only two populations are within fenced habitat in Hanawā Natural Area Reserve (NAR). In addition, public hunting areas are not fenced and game mammals have unrestricted access to most areas across the landscape, regardless of underlying land use designation; therefore, any unfenced populations are at risk (DLNR 2010). (USFWS, 2018)

Recovery**Reclassification Criteria:**

1. A total of five to seven populations of each taxon should be documented on Maui and at least one other island where they now occur or occurred historically. (USFWS, 1997)
2. Each of these populations must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials, and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1997)
3. Each population should persist at this level for a minimum of five consecutive years before downlisting is considered. (USFWS, 1997)

Delisting Criteria:

1. A total of 8 to 10 populations of each taxon should be documented on Maui and at least one other island where they now occur or occurred historically. (USFWS, 1997)
2. Each population must be naturally reproducing, stable or increasing in number, and secure from threats, with a minimum of 100 mature individuals per population for long-lived perennials and a minimum of 300 mature individuals per population for short-lived perennials. (USFWS, 1997)
3. Each population should persist at this level for a minimum of five consecutive years. (USFWS, 1997)

Recovery Actions:

- Protect habitat of known populations of *Cyanea mceldowneyi*, especially the large population. (USFWS, 1997)

- Construct a series of exclosures to protect extant populations in the lower Waikamoi area. (USFWS, 1997)
- Establish new outplanted populations within protected (i.e., fenced) appropriate habitat in the Waikamoi area. Some of the same areas could also be used for outplanting *Clermontia oblongifolia* ssp. *mautensis*. Do weed control if it is needed and can be done without undue ground disturbance. (USFWS, 1997)
- Determine status of Honomanu population and manage appropriately. If this population is extant and pigs are present, consider low-impact construction of woven-wire exclosure to protect from feral pigs. Do weed control if needed and practical without undue ground disturbance. (USFWS, 1997)
- Surveys and inventories—Continue to survey for additional populations of *Cyanea mceldowneyi* in areas of potentially suitable habitat. Regularly monitor known populations. (USFWS, 2018)
- Ungulate monitoring and control—Fence known populations to protect them from the impacts of feral ungulates. (USFWS, 2018)
- Invasive plant monitoring and control—Control established ecosystem-altering nonnative invasive plant species around all populations. Control invasive nonnative species that compete with the species around all populations, especially focusing on *Clidemia hirta* (Koster's curse), *Tibouchina herbacea* (glorybush), and *Hedychium gardnerianum* (kahili ginger). (USFWS, 2018)
- Predator and herbivore monitoring and control—Implement effective control methods for rodents at wild and reintroduced populations. Develop and implement effective control methods for slugs. (USFWS, 2018)
- Captive propagation for genetic storage and reintroduction—Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. Evaluate genetic resources currently in storage to determine the effects of long-term storage due to this species' vulnerability to climate change. (USFWS, 2018)
- Reintroduction and translocation—Begin reintroduction of individuals into suitable habitat within historic range that is being managed for known threats to this species. (USFWS, 2018)
- Population viability monitoring and analysis—Monitor all wild populations on east Maui. (USFWS, 2018)
- Climate change adaptation strategy—Research the suitability of habitat for reintroducing this species in the future due to impacts from climate change. (USFWS, 2018)
- Alliance and partnership development—Continue to initiate, plan, and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2018)

Conservation Measures and Best Management Practices:

- Continue surveying geographical and historical range for a current assessment of the species' status. (USFWS, 2014)
- Continue collection of genetic resources for storage, propagation, and reintroduction into protected suitable habitat within historical range. (USFWS, 2014)
- Evaluate genetic resources currently in storage to determine the need to place additional genetic resources in long-term storage due to this species' vulnerability to climate change. (USFWS, 2014)
- Fence remaining populations to protect them from the impacts of feral ungulates. (USFWS, 2014)

- Control invasive introduced plant species within the vicinity of all known individuals especially focusing on *Clidemia hirta* (Koster's curse), *Tibouchina herbacea* (glorybush), and *Hedychium gardnerianum* (kahili ginger) (PEPP 2013). (USFWS, 2014)
- Control slugs and rodents within the vicinity of all known *C. mceldowneyi* populations. (USFWS, 2014)
- Monitor wild populations on East Maui. (USFWS, 2014)
- Research the suitability of habitat for reintroducing this species in the future due to the impacts of climate change. (USFWS, 2014)
- Initiate planning and contribute to implementation of ecosystem-level restoration and management to benefit this taxon. (USFWS, 2014)

SPECIES ACCOUNT: *Cyanea munroi* (haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 06/27/2013; Pacific Region (Region 1) (USFWS, 2016a)

Physical Description

Cyanea munroi (haha), a short-lived perennial shrub in the bellflower family (Campanulaceae). (USFWS, 2016b)

Taxonomy

Treated as a synonym within *Cyanea grimesiana* ssp. *grimesiana* in the Hawaii Manual (Wagner et al., 1990); recognized as a distinct species in the Manual's Supplement (Wagner and Herbst 1999) and by Kartesz (1999, Synthesis). (NatureServe, 2015)

Historical Range

Endemic to Molokai and Lanai. (NatureServe, 2015)

Current Range

Endemic to Molokai and Lanai. (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea munroi* (haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes three detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea munroi* includes three CHUs in Maui County, Hawaii with detailed unit information. There are also an unknown number of units on Lanai that contain this species (number of units is unknown because detailed unit descriptions for Lanai are not available). Note also that *C. munroi* is used as the abbreviated plant name in some of the detailed unit descriptions and it is unclear if these refer to *Cyanea munroi* or *Cyrtandra munroi* (or both) as both species are found in the Wet cliff ecosystem (81 FR 17790-18110).

Molokai—Wet Cliff—Unit 1 (and) *Palmeria dolei*—Unit 43—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 43—Wet Cliff This area consists of 1,395 ac (565 ha) of State land, and 212 ac (86 ha) of privately owned land, and encircles the plateau between Pelekunu and Wailau valleys, in north-central Molokai. These units are occupied by the plants *Brighamia rockii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea munroi*, and *Hibiscus arnottianus* ssp. *immaculatus*, and include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations Although Molokai—Wet Cliff—Unit 1 is not known to be occupied by

Cyanea grimesiana ssp. *grimesiana*, *Hesperomannia arborescens*, *Phyllostegia hispida*, *Pteris lidgatei*, or *Stenogyne bifida*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Wet Cliff—Unit 2 (and) *Palmeria dolei*—Unit 44—Wet Cliff (and) *Pseudonestor xanthophrys*—Unit 44—Wet Cliff This area consists of 462 ac (187 ha) of State land, and 806 ac (326 ha) of privately owned land (partly within The Nature Conservancy's Pelekunu Preserve), along the rim of Pelekunu Valley from Kipapa Ridge to Mapulehu, in central Molokai. These units are occupied by the plants *Clermontia oblongifolia* ssp. *brevipes* and *Phyllostegia hispida*, and include the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Molokai—Wet Cliff—Unit 2 is not known to be occupied by *Brighamia rockii*, *Canavalia molokaiensis*, *Cyanea grimesiana* ssp. *grimesiana*, *C. munroi*, *Hesperomannia arborescens*, *Hibiscus arnottianus* ssp. *immaculatus*, *Pteris lidgatei*, or *Stenogyne bifida*, or by the forest birds, the akohekohe (*Palmeria dolei*) and kiwikiu (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Molokai—Wet Cliff—Unit 3 consists of 1,137 ac (460 ha) of State land, and 225 ac (91 ha) of privately owned land, along the rim of Wailau Valley from Mapulehu to Kahiwa Gulch, in eastern Molokai. This unit includes the mixed herbland and shrubland, the moisture regime, and the subcanopy and understory native plant species identified as physical or biological features in the wet cliff ecosystem (see Table 5). Although Molokai—Wet Cliff—Unit 3 is not known to be occupied by *Brighamia rockii*, *Canavalia molokaiensis*, *Clermontia oblongifolia* ssp. *brevipes*, *Cyanea grimesiana* ssp. *grimesiana*, *C. munroi*, *Hesperomannia arborescens*, *Hibiscus arnottianus* ssp. *immaculatus*, *Phyllostegia hispida*, *Pteris lidgatei*, or *Stenogyne bifida*, we have determined this area to be essential for the conservation and recovery of these wet cliff species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea munroi* critical habitat consists of one component. Wet cliff (Lanai and Molokai) (81 FR 17790-18110):

Ecosystem: Wet Cliff. Elevation: unrestricted. Annual precipitation: >75 in (>190 cm). Substrate: >65 degree slope, shallow soils, weathered lava. Canopy: None. Subcanopy: *Broussaisia*,

Cheirodendron, Leptecophylla, Metrosideros. Understory: Bryophytes, Ferns, Coprosma, Dubautia, Kadua, Peperomia.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into

native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History**Food/Nutrient Resources****Reproduction Narrative**

Adult: Not available.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 200 and 730 meters (NatureServe, 2015)

Habitat Narrative

Adult: This species is found in mesic to wet forests at elevations between 200-730 meters. (NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Resiliency:**

Very low (inferred from NatureServe, 2015)

Redundancy:

Very low (inferred from NatureServe, 2015)

Number of Populations:

1 (NatureServe, 2015)

Population Size:

2 individuals (NatureServe, 2015)

Population Narrative:

No individuals known on Molokai (last observed in 2001), and only two individuals on Lanai at a single location (TNC 2007; HBMP 2008; Oppenheimer 2010; Perlman 2008.; Wood 2009 cited by USFWS 2012). (NatureServe, 2015)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (goats and axis deer), nonnative plants, treefalls, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Treefalls destabilize substrates, damage and destroy individual plants, and alter hydrological patterns, which result in changes to native plant and animal communities. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (goats, axis deer, rats, and slugs) is considered an ongoing threat to *Cyanea munroi* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

Stressor: Small populations (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: *Cyanea munroi* faces the threat of limited numbers (i.e., there are fewer than 50 individuals in the wild). The only known wild occurrences are susceptible to threats from habitat degradation or loss by flooding, landslides, or tree falls, or a combination of these, because of their locations in lowland wet, montane wet, and wet cliff ecosystems (USFWS, 2013).

Recovery

SPECIES ACCOUNT: *Cyanea obtusa* (Haha)

Species Taxonomic and Listing Information

Listing Status: Endangered; 06/27/2013; Pacific Region (Region 1) (USFWS, 2016)

Physical Description

A branched shrub, 2-5 m tall. Racemes axillary, with 6-12 flowers. Corollas purplish. (NatureServe, 2015)

Taxonomy

Genus endemic to Hawaiian islands, species endemic to Maui. (NatureServe, 2015)

Current Range

Endemic to the island of Maui in the state of Hawaii, the species is still extant on both West Maui and East Maui. (NatureServe, 2015)

Critical Habitat Designated

Yes; 3/30/2016.

Legal Description

On March 30, 2016, the U.S. Fish and Wildlife Service (Service) designated critical habitat for *Cyanea obtusa* (Haha) under the Endangered Species Act of 1973, as amended (Act). The critical habitat designation includes three detailed critical habitat units (CHUs), in Hawaii (81 FR 17790-18110).

Critical Habitat Designation

The critical habitat designation for *Cyanea obtusa* includes three CHUs in Maui County, Hawaii with detailed unit information (81 FR 17790-18110).

Maui—Lowland Dry—Unit 5 consists of 3,615 ac (1,463 ha) of State land, and 43 ac (17 ha) of privately owned land, from Panaewa to Manawainui on the western and southern slopes of west Maui. This unit is occupied by the plants *Asplenium dielerectum*, *Bidens campylotheca* ssp. *pentamera*, *Cenchrus agrimonioides*, *Gouania hillebrandii*, *Kadua coriacea*, *Remya mauensis*, *Santalum haleakalae* var. *lanaiense*, and *Spermolepis hawaiiensis*, and *Tetramolopium capillare*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 5 is not known to be occupied by *Ctenitis squamigera*, *Cyanea obtusa*, *Hesperomannia arbuscula*, *Hibiscus brackenridgei*, *Lysimachia lydgatei*, *Neraudia sericea*, *Schiedea salicaria*, *Sesbania tomentosa*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Lowland Dry—Unit 6 consists of 3 ac (1 ha) of State land, and 237 ac (96 ha) of privately owned land, from Paleaahu Gulch to Puu Hona on the southern slopes of west Maui. This unit is occupied by the plants *Hibiscus brackenridgei* and *Schiedea salicaria*, and includes the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the lowland dry ecosystem (see Table 5). This unit also contains unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Lowland Dry—Unit 6 is not known to be occupied by *Asplenium dielerectum*, *Bidens campylotheca* ssp. *pentamera*, *Cenchrus agrimonoides*, *Ctenitis squamigera*, *Cyanea obtusa*, *Gouania hillebrandii*, *Hesperomannia arbuscula*, *Kadua coriacea*, *Lysimachia lydgatei*, *Neraudia sericea*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Sesbania tomentosa*, *Spermolepis hawaiiensis*, *Tetramolopium capillare*, or *T. remyi*, we have determined this area to be essential for the conservation and recovery of these lowland dry species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Maui—Montane Mesic—Unit 1 (and) *Palmeria dolei*—Unit 18—Montane Mesic (and) *Pseudonestor xanthophrys*—Unit 18—Montane Mesic This area consists of 6,593 ac (2,668 ha) of State land, 707 ac (286 ha) of privately owned land, and 3,672 ac (1,486 ha) of federally owned land (Haleakala National Park), from Kealahou to Puualae, nearly circumscribing the summit of Haleakala on east Maui. These units include the mixed herbland and shrubland, the moisture regime, and canopy, subcanopy, and understory native plant species identified as physical or biological features in the montane mesic ecosystem (see Table 5). They are occupied by the plants *Argyroxiphium sandwicense* ssp. *macrocephalum*, *Asplenium dielerectum*, *A. peruvianum* var. *insulare*, *Clermontia lindseyana*, *Cyanea horrida*, *C. obtusa*, *Cyrtandra ferripilosa*, *C. oxybapha*, *Diplazium molokaiense*, *Geranium arboreum*, *G. multiflorum*, *Huperzia mannii*, *Melicope adscendens*, and *Neraudia sericea*. These units also contain unoccupied habitat that is essential to the conservation of these species by providing the PCEs necessary for the expansion of the existing wild populations. Although Maui—Montane Mesic—Unit 1 is not known to be occupied by the plants *Alectryon macrococcus*, *Bidens campylotheca* ssp. *pentamera*, *B. micrantha* ssp. *kalealaha*, *Cyanea glabra*, *C. hamatiflora* ssp. *hamatiflora*, *C. kunthiana*, *C. mceldowneyi*, *Phyllostegia bracteata*, *P. mannii*, *Santalum haleakalae* var. *lanaiense*, *Wikstroemia villosa*, or *Zanthoxylum hawaiiense*, or by the forest birds, the *akohekohe* (*Palmeria dolei*) and *kiwikiu* (*Pseudonestor xanthophrys*), we have determined this area to be essential for the conservation and recovery of these montane mesic species because it provides the PCEs necessary for the reestablishment of wild populations within their historical range. Due to their small numbers of individuals or low population sizes, suitable habitat and space for expansion or reintroduction are essential to achieving population levels necessary for recovery.

Primary Constituent Elements/Physical or Biological Features

Primary constituent elements (PCEs) are the physical and biological features of critical habitat essential to a species' conservation. The PCEs of *Cyanea obtusa* critical habitat consists of two components. Lowland dry (west Maui) Montane mesic (east Maui) (81 FR 17790-18110):

Ecosystem: Lowland Dry. Elevation: <3,300 ft (<1,000 m). Annual precipitation: <50 in (<130 cm). Substrate: Weathered silty loams to stony clay, rocky ledges, littleweathered lava. Canopy: *Diospyros*, *Myoporum*, *Pleomele*, *Santalum*. Subcanopy: *Chamaesyce*, *Dodonaea*, *Leptecophylla*,

Osteomeles, Psydrax, Scaevola, Wikstroemia. Understory: Alyxia, Artemisia, Bidens, Chenopodium, Nephrolepis, Peperomia, Sicyos.

Ecosystem: Montane Mesic. Elevation: 3,300–6,500 ft (1,000–2,000 m). Annual precipitation: 50–75 in (130–190 cm). Substrate: Deep ash deposits, thin silty loams. Canopy: Acacia, Ilex, Metrosideros, Myrsine, Nestegis, Nothocestrum, Pisonia, Pittosporum, Psychotria, Sophora, Zanthoxylum. Subcanopy: Alyxia, Charpentiera, Coprosma, Dodonaea, Kadua, Labordia, Leptecophylla, Phyllostegia, Vaccinium. Understory: Ferns, Carex, Peperomia.

Special Management Considerations or Protections

When designating critical habitat, we assess whether the specific areas within the geographical area occupied by the species at the time of listing contain features that are essential to the conservation of the species and which may require special management considerations or protection. In identifying critical habitat in occupied areas, we determine whether those areas that contain the features essential to the conservation of the species require any special management actions. Although the determination that special management may be required is not a prerequisite to designating critical habitat in unoccupied areas, special management is needed throughout all of the critical habitat units in this final rule. The following discussion of special management needs is therefore applicable to each of the Maui Nui species for which we are designating critical habitat in this rule. In this final rule, we are designating critical habitat for 125 of the 135 species for which we proposed critical habitat. For the reasons described below (see Exclusions Based on Other Relevant Factors), we are not designating critical habitat for eight plants (*Abutilon eremitopetalum*, *Cyanea gibsonii*, *Kadua cordata* ssp. *remyi*, *Labordia tinifolia* var. *lanaiensis*, *Pleomele fernaldii*, *Portulaca sclerocarpa*, *Tetramolopium lepidotum* ssp. *lepidotum*, and *Viola lanaiensis*) and two tree snails (*Partulina semicarinata* and *P. variabilis*). The 125 species for which we are designating critical habitat include 108 plant and animal species that are currently found in the wild on Molokai, Maui, and Kahoolawe; (10 plant species which were historically found on one or more of these islands, but are currently found only on other Hawaiian Islands (*Adenophorus periens*, *Clermontia peleana*, *Cyanea grimesiana* ssp. *grimesiana*, *Cyperus trachysanthos*, *Eugenia koolauensis*, *Gouania vitifolia*, *Isodendron pyrifolium*, *Kadua coriacea*, *Nototrichium humile*, and *Solanum incompletum*), 6 plant species that may not be currently extant in the wild (*Acaena exigua*, *Cyanea glabra*, *Phyllostegia bracteata*, *P. haliakalae*, *Schiedea jacobii*, and *Tetramolopium capillare*), and 1 plant species, *Kokia cookei*, which exists only in cultivation. For each of the 108 species currently found in the wild on Molokai, Maui, and Kahoolawe, we have determined that the features essential to their conservation are those required for the successful functioning of the ecosystem(s) in which they occur (see Tables 5 and 6, above). As described earlier, in some cases, additional species-specific primary constituent elements were also identified (see Table 6, above). Special management considerations or protections are necessary throughout the critical habitat areas designated here to avoid further degradation or destruction of the habitat that provides those features essential to their conservation. The primary threats to the physical or biological features essential to the conservation of all of these species include habitat destruction and modification by nonnative ungulates, competition with nonnative species, hurricanes, landslides, rockfalls, flooding, fire, drought, and climate change. Additionally, the rosy wolf snail poses a threat to the Newcomb's tree snail and mosquito-borne diseases pose threats to the two forest birds. The reduction of these threats will require the implementation of special management actions within each of the critical habitat areas identified in this final rule. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative

ungulates (pigs, goats, mouflon sheep, axis deer, and cattle). Nonnative ungulates also impact the habitat through predation and trampling. Without this special management, habitat containing the features that are essential for the conservation of these species will continue to be degraded and destroyed. All designated critical habitat requires active management to address the ongoing degradation and loss of native habitat caused by nonnative plants. Special management is also required to prevent the introduction of new nonnative plant species into native habitats. Particular attention is required in nonnative plant control efforts to avoid creating additional disturbances that may facilitate the further introduction and establishment of invasive plant seeds. Precautions are also required to avoid the inadvertent trampling of listed plant species in the course of management activities. The active control of nonnative plant species would help to address the threat posed by fire to 31 of the designated ecosystem critical habitat units in particular: Maui-Coastal—Units 4 through 7; Maui-Lowland Dry—Units 1 through 6; Maui-Lowland Mesic—Units 1 and 2; Maui-Montane Mesic—Units 1, 2, and 5; Maui-Dry Cliff—Units 1, 5, and 7; Kahoolawe-Coastal—Units 1 through 3; Kahoolawe-Lowland Dry—Units 1 and 2; Molokai-Coastal—Units 1, 2, 3, 6, and 7; Molokai-Lowland Dry—Units 1 and 2; and Molokai-Lowland Mesic—Unit 1. This threat is largely a result of the presence of nonnative plant species such as the grasses *Andropogon virginicus* (broomsedge), *Cenchrus* spp. (sandbur, buffelgrass), and *Melinis minutiflora* (molasses grass), that increase the fuel load and quickly regenerate after a fire. These nonnative grass species can outcompete native plants that are not adapted to fire, creating a grass-fire cycle that alters ecosystem functions (D'Antonio and Vitousek 1992, pp. 64–66; Brooks et al. 2004, p. 680). Nine of the ecosystem critical habitat units (Maui-Lowland Wet—Units 1 and 4; Maui-Montane Wet—Units 1 through 3; Maui-Montane Mesic—Unit 2; Maui Wet Cliff—Units 6 and 7; and Molokai Montane Wet—Unit 1) may require special management to reduce the threat of landslides, rockfalls, and flooding. These threaten to further degrade habitat conditions in these units and have the potential to eliminate some occurrences of 50 plant species (e.g., *Adenophorus periens*, *Alectryon macrococcus*, *Asplenium peruvianum* var. *insulare*, *Bidens campylotheca* ssp. *pentamera*, *B. campylotheca* ssp. *waihoiensis*, *B. conjuncta*, *B. wiebkei*, *Bonamia menziesii*, *Clermontia oblongifolia* ssp. *brevipes*, *C. oblongifolia* ssp. *mauiensis*, *C. samuelii*, *Ctenitis squamigera*, *Cyanea asplenifolia*, *C. copelandii* ssp. *haleakalaensis*, *C. duvalliorum*, *C. hamatiflora* ssp. *hamatiflora*, *C. horrida*, *C. kunthiana*, *C. magnicalyx*, *C. mannii*, *C. maritae*, *C. mceldowneyi*, *C. profuga*, *C. solanacea*, *Cyrtandra filipes*, *C. munroi*, *Diplazium molokaiense*, *Dubautia plantaginea* ssp. *humilis*, *Geranium hanaense*, *G. multiflorum*, *Hesperomannia arborescens*, *Huperzia mannii*, *Kadua laxiflora*, *Lysimachia lydgatei*, *L. maxima*, *Melicope balloui*, *M. ovalis*, *Phyllostegia hispida*, *P. mannii*, *P. pilosa*, *Plantago princeps*, *Platanthera holochila*, *Pteris lidgatei*, *Remya mauiensis*, *Santalum haleakalae* var. *lanaiense*, *Schiedea laui*, *Stenogyne bifida*, *S. kauaulaensis*, *Wikstroemia villosa*, and *Zanthoxylum hawaiiense*) found on steep slopes and cliffs, or in narrow gulches.

Life History

Food/Nutrient Resources

Reproduction Narrative

Adult: Not available.

Habitat Type

Adult: Terrestrial (NatureServe, 2015)

Habitat Vegetation or Surface Water Classification

Adult: Forest- hardwood, forest/woodland (NatureServe, 2015)

Geographic or Habitat Restraints or Barriers

Adult: Found at elevations between 902 and 1,487 meters. (NatureServe, 2015)

Environmental Specificity

Adult: Unknown (NatureServe, 2015)

Habitat Narrative

Adult: Cyanea obtusa is found along moist gulch slopes in Metrosidero polymorpha mixed mesic forests at an elevation of 951 meters. It has also been observed on steep sections of watercourses in Metrosideros-Acacia-Cheirodendron montane mesic forests at an elevation of 902-1,487 meters (Russell 2004). (NatureServe, 2015)

Dispersal/Migration**Dispersal/Migration Narrative**

Adult: Not available.

Population Information and Trends**Population Trends:**

Unknown (NatureServe, 2015)

Resiliency:

Very low (inferred from NatureServe, 2015)

Redundancy:

Very low (inferred from NatureServe, 2015)

Population Growth Rate:

Unknown (NatureServe, 2015)

Number of Populations:

1 (USFWS, 2016)

Population Size:

1-30 (USFWS, 2016; NatureServe, 2015)

Population Narrative:

In 1999, additional plants were found, increasing the known populations to six and the known number of individuals to approximately 30 (Russell 2002, Russell 2004). Currently, this species is known from one occurrence of only a few individuals in the montane mesic ecosystem on east Maui. (NatureServe, 2015; USFWS, 2016)

Threats and Stressors

Stressor: Habitat destruction or modification (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Adverse impacts on habitat of this species have been identified from nonnative animals (pigs, goats, axis deer, and cattle), nonnative plants, fire, and hurricanes. The effects by nonnative animals includes the destruction of vegetative cover; trampling of plants and seedlings; direct consumption of native vegetation; soil disturbance; dispersal of alien plant seeds on hooves and coats, and through the spread of seeds in feces; and creation of open, disturbed areas conducive to further invasion by nonnative pest species. The effects of nonnative plants on native plant species include competition and displacement; competition may be for water, light, or nutrients, or it may involve allelopathy (chemical inhibition of other plants). Fire can destroy dormant seeds as well as plants themselves, even in steep or inaccessible areas. Successive fires that burn farther and farther into native habitat destroy native plants and remove habitat for native species by altering microclimate conditions favorable to alien plants. Hurricanes adversely impact native Hawaiian terrestrial habitat by destroying native vegetation, opening the canopy and thus modifying the availability of light, and creating disturbed areas conducive to invasion by nonnative pest species. Potential adverse impacts from climate change have also been identified (USFWS, 2013).

Stressor: Predation and herbivory (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: Predation and herbivory by nonnative animal species (pigs, goats, axis deer, cattle, rats, and slugs) is considered an ongoing threat to *Cyanea obtusa* throughout the species range. Non-native animals cause mechanical damage to plants and destruction of plant parts (branches, fruits, and seeds) (USFWS, 2013).

Stressor: Small populations and hybridization (USFWS, 2013)

Exposure:

Response:

Consequence:

Narrative: *Cyanea obtusa* faces the threat of limited numbers (i.e., there are fewer than 50 individuals in the wild). *Cyanea obtusa* is susceptible to predation by feral pigs, goats, axis deer, and cattle, and to direct destruction and habitat degradation and loss by fire because the only two known individuals of this species are not protected from direct predation by ungulates, or from fire. Hybridization will adversely impact this species because it may lead to extinction of one or both of the original genotypically distinct species. On east Maui, the species *Cyanea obtusa* is known from two individuals, but only hybrids between *C. obtusa* and the more abundant *C. elliptica* are known on west Maui (USFWS, 2013).

Recovery

Reclassification Criteria:

Not available.

Delisting Criteria:

Not available.

Recovery Actions:

- Not available.

Conservation Measures and Best Management Practices:

- Not available.
