However, while the boreal forest may not have changed substantially within the past 100 years (i.e., permanent or long-term reductions in the quantity or size), it is naturally dynamic with fire and insects representing major disturbance processes (Agee 2000, p. 47) that can create areas temporarily unsuitable for lynx through regeneration of forested stands to early successional conditions (Agee 2000, pp. 62-63). In 2001, the Washington Department of Fish and Wildlife (WDFW) estimated there was approximately 8,923 km^2 (3,445 mi^2) of potential lynx habitat within this geographic unit. Several wildfires affected lynx habitat in the north Cascades during the middle 1990s and early 2000s: 1994 Whiteface Burn (1,554 ha (3,840 ac)); 1994 Thunder Mountain Fire (3,686 ha (9,108 ac)); 2001 Thirty-Mile Fire (2,565 ha (6,338 ha)); and 2001 Farewell Fire (32,278 ha (79760 ac)) (Vanbianchi 2015, p. 23). Subsequent to these fires and incorporating new science on lynx habitat use, Koehler *et al.* (2008, pp. 1521-1522) estimated this geographic unit contained approximately 2,411 km^2 (930 mi^2) of suitable lynx habitat based on studies conducted from 2002 through 2004. More recent wildfires, including the 2006 Tripod Fire (70,644 ha (175,656 ac)) (Vanbianchi 2015, p.23), have affected approximately 1,000 km^2 (386 mi^2) of lynx habitat within this geographic unit (Lynx SSA Team 2016, p. 21). Cumulatively, over the past 2 decades these wildfires have burned greater than 50 percent of the suitable lynx habitat within this geographic unit (Koehler *et al.* 2008, p. 1523). These acres are expected to regenerate back into suitable lynx habitat, but it may take several decades for this to occur.

Lynx Status: In Washington, there is little information on the status of the lynx population prior to the early 1960s (Stinson 2001, p. 13). From 1960-61 to 1990-91 a total of 234 lynx were harvested in Washington, with the most lynx trapped in Ferry County (35 percent of the 234), followed by Okanogan (23 percent) and Stevens (10 percent) counties (Stinson 2001, p. 13). The WDFW identified six lynx management zones (LMZs) in Washington: Okanogan, Vulcan-Tunk, Kettle Range, The Wedge, Little Pend Oreille, and Salmo-Priest (i.e., essentially the Selkirk Mountain Range in northeast Washington (Stinson 2001, p 14). In 2001, the WDFW considered lynx to be present in the Okanogan, Kettle Range, Little Pend Oreille, and Salmon-Priest LMZs; at that time lynx had not been detected in the Wedge LMZ since 1987 nor the Vulcan-Tunk LMZ since 1990 (Stinson 2001, p.15).

In 2001, based on data collected from lynx telemetry studies conducted in the Cascade Range during the 1980's, the WDFW estimated that Washington contained approximately 12,579 km^2 (4,857 mi^2) of lynx habitat which could theoretically support up to 238 lynx (based on a lynx

density of 2.5 lynx/100 km^2) (Koehler 2008, p. 1518; Stinson 2001, p. 16). However, based on professional opinions of individuals knowledgeable about lynx and lynx habitat, the WDFW adjusted this number down suggesting that Washington likely supported fewer than 100 individual lynx (Stinson 2001, p. 16). More recently, Koehler *et al.* (2008, p. 1523), estimated there was approximately 3,800 km^2 (1,467 mi^2) of lynx habitat in Washington potentially supporting up to 87 lynx. This more recent population estimate was based on a study investigating lynx habitat use in the Okanogan from 2002 to 2004, and used a lynx density estimate of 2.3 lynx/100 km^2 derived from a radio-telemetry study conducted on lynx in the Cascades from 1985-1987 (Koehler 1990, pp. 845-847). However, the study area in which the 2.3 lynx/100 km^2 density estimate reported by Koehler (1990, p.847) was derived is located in an area of the northern Cascades known as the "Meadows". During the time of Koehler's (1990, entire) study the Meadows provided some of the best lynx habitat in Washington, whereas most other lynx habitat in Washington is lower in elevation and more highly fragmented (Walker 2005, pp. 3, 6). Thus, the lynx densities Koehler observed in his study area in the Meadows may not translate to lynx densities throughout the rest of lynx habitat in Washington, because as habitat becomes more fragmented and isolated (i.e., marginal), the carrying capacity for a particular species declines. Thus, applying Koehler's estimated lynx density uniformly throughout Washington, may overestimate the overall lynx population capable of being supported in Washington.

Relative to the Okanogan LMZ (i.e., the north Cascades), which supports the only known persistent breeding population of lynx in Washington State, in 2001, the WDFW estimated the LMZ could support a maximum of 149 lynx (Stinson 2001, p. 16). This number was derived by estimating that the LMZ contains approximately 8,923 km^2 (3,445 mi^2) of lynx habitat (which was decreased by 33 percent to account for unsuitable areas) combined with an average lynx population density estimate of 2.5 lynx/100km^2 derived from two studies conducted in the 1980s (Stinson 2001, p. 16). The estimated quantity of lynx habitat was based on mapping areas supporting the forest-type and physiographic characteristics identified as being used by lynx during telemetry studies conducted in the 1980s (Koehler *et al.* 2008, p. 1518), irrespective of the current condition (successional stage, or stand type, structure, or age, etc.) of the habitat. The estimation of lynx habitat was based purely on forested areas potentially supporting a forest-type potential of subalpine fir/Engelmann spruce, and the physiographic characteristics of elevations greater than 1,400 m (4593 ft) on mild to moderate slopes (Koehler *et al.* 2008, p. 1518), and did not consider whether the area was recently burned, harvested, etc. Recognizing that new information on lynx and snowshoe hare habitat use patterns had been learned since the 1980's, and that several large, stand-replacing fires had burned in lynx habitat, Koehler *et al.* (2008, entire) conducted a lynx telemetry study in the Okanogan from 2002 to 2004 to reassess the suitability of lynx habitat. They estimated that the Cascades contained approximately 2,411 km^2 (930 mi^2) of suitable lynx habitat based on mapping areas supporting Engelmann spruce/subalpine fir forests with moderate canopy cover on flat to moderate slopes at elevations from 1,525 m (5003 ft) to 1,829 m (6000 ft) (Koehler *et al.* 2008, pp. 1521-1522). Therefore, at that time and using Koehler's (1990, p. 847) lynx density estimate of 2.3 lynx/100 km^2, the Cascades could theoretically support approximately 55 individual lynx.

From 1985 to 1987, the movements of five adult male and two adult female radio-collared lynx were monitored by Koehler (1990, entire) in the Cascades of north-central Washington. During the study two kittens were also captured and ear-tagged (Koehler 1990, p. 847). Results of the study indicated female average home range size was 39 km^2 (15 mi^2) and average male home range size was 69 km^2 (27 mi^2). Based on occupancy of the 640 km^2 study area by 15 adult lynx, adult lynx density was estimated to be 2.3 adults/100 km^2. Annual adult survival rates of the radio-collared lynx were 0.73 in 1986 and 1.00 in 1987, and kitten mortality was high at 88 percent with only 1 of 8 known kittens surviving its first year (Koehler 1990, p. 847).

As stated previously, fire is a common disturbance factor in boreal forests (Agee 2000, p. 47). Fire return intervals within western subalpine fir forests in the Cascades range from 109 to 250 years (Agee, 2000, p. 50) with typically high fire intensities in lynx habitat resulting in extensive areas of regenerating forest (Agee, 2000, p. 53). Maletzke assessed the effects of recent fires in the Cascades and their potential impacts to the lynx population there as follows:

> "From 1990-2002, there were about 2,600 km^2 of lynx habitat in the Okanogan (Eastern Cascades) area, and female home ranges were estimated at 39 – 41 km^2, suggesting the potential to support roughly 90-115 resident females (home ranges include "matrix" or non-habitat). By 2014, habitat had been reduced by fire to about 1,600 km^2, and habitat loss and fragmentation resulted in female home ranges increasing to an estimated 91 km^2, with a potential to support roughly 27 resident females" (Lynx Workshop Report 2016, p. 21).

Therefore, using Maletzke's method and assuming a 2:1 sex ratio of females to males, the total theoretical lynx population that may have been supported in the Cascades prior to 2002 may have ranged between 135 and 172 individual lynx. Subsequent to the fires the total theoretical lynx population potentially supported in the Cascades has been reduced to approximately 40 individual lynx, which potentially represents a 70 percent to 77 percent decline in the lynx population. Note: while the area (lynx habitat in the Cascade range) used to generate the population estimate of 55 lynx in the Cascades prior to the fires based on Koehler's (1990, p. 847) lynx density estimate is the same as the area used by Maletzke to generate his population estimate of 90 – 115 resident females based on simulated female home ranges with an empirically derived size and arbitrary minimum threshold of habitat, the two dissimilar population estimates used differing methodologies, and thus the population estimates themselves are not comparable. However, using Koehler's lynx density estimate of 2.3 lynx/100 km^2 and applying it to the 1,600 km^2 of lynx habitat remaining after the fires results in an estimated lynx population of approximately 37 individual lynx, which represents an approximate 33 percent reduction in the lynx population. Further informing the effects of these recent fires in the Cascades on lynx habitat is illustrated by evaluating the average size of a female lynx home range prior to and after the fires. Prior to the fires, Koehler (1990, p. 847) estimated an average female lynx home range size of 39 km^2 (15 mi^2), whereas after the fires Maletzke estimated the average female home range size had increased to 91 km^2 (35 mi^2) (Lynx Workshop Report 2016, p. 21). The important point is the recent large, stand replacing fires in the Cascades has resulted in significant temporary losses of lynx habitat, and thus the ability of the Cascades to support a persistent and viable reproducing lynx population may have been significantly impacted. The

areas impacted by these recent fires are expected to regenerate into suitable lynx habitat, but it may take 35-40 years to do so (Lynx Workshop Report 2016, p. 21).

Factors Affecting Current Condition: In 1993, lynx were classified by the Washington Fish and Wildlife Commission as a state threatened species (Stinson 2001, p. 22). On July 12, 2016, the WDFW recommended that the Washington Fish and Wildlife Commission uplist the lynx from a state threatened to a state endangered species (WDFW 2016, p.1). According to the Draft Washington State Periodic Status Review for the Lynx, the WDFW recommended listing the lynx as endangered due to: 1) observed range contraction in Washington following protection efforts; 2) the substantial loss of habitat in the last 20 years; and 3) the ongoing and anticipated threats to lynx population persistence.

Within Washington, the vast majority of lynx habitat is administered by the Okanogan/Wenatchee (OWNF) and Colville (CNF) National Forests. The North Cascades (aka the Okanogan LMZ in north-central Washington), which supports the only known, long-term persistent lynx breeding population in Washington, and within which critical habitat was designated for lynx in 2014 (79 FR 54782), is administered by the OWNF. Subsequent to listing lynx under the ESA, the Forest Service entered into a Conservation Agreement (CA) with the Service in 2000 (USFS and USFWS 2000, entire), which was revised and extended in 2006 (USFS and USFWS 2006, entire). The CA committed the ONWF and CNF to use the Lynx Conservation Assessment and Strategy (LCAS) for management of lynx and its habitat on their ownerships, and will remain in place until the forests amend or revise their individual LRMPs.

The LCAS, which was also developed pursuant to the listing by an interagency team comprised of USFS, BLM, Service, and NPS personnel, identified four primary risk factors potentially exerting population level effects upon the status of lynx: climate change, vegetation management, wildland fire management, and habitat fragmentation. To promote conservation of lynx and its habitat, the LCAS contains conservation measures addressing the identification and maintenance of lynx habitat (foraging, denning, and connectivity habitats) on federal lands. Toward this end, the LCAS recommends that federal land managers identify and map lynx habitat on their ownerships, and delineate LAUs containing the mapped lynx habitat, within which the effects of management actions on lynx habitat will be monitored and analyzed. The LCAS also recommends that the size of LAUs should be based on the average size of a female lynx home range and contain year-round habitat components (i.e., foraging and denning habitat). Thus, in Washington, and the north Cascades specifically, it appears that the single threat for which lynx were listed under the ESA (i.e., inadequacy of regulatory mechanisms) has largely been addressed through the development of the LCAS, and CA between the Forest Service and Service which commits the Forest Service, specifically for Washington the OWNF and CNF, to use the LCAS in the management of lynx habitat on their ownerships and when designing and implementing projects within LAUs.

The WADNR manages approximately 4 percent of the lynx habitat within portions of each of the delineated LMZs (WADNR 2006, p.9) in Washington State, including the Loomis State Forest that is located in the north Cascades of north-central Washington within the Okanogan LMZ. In

1996, the WADNR developed and implemented a Lynx Habitat Management Plan (1996 Lynx Plan) in response to listing of the lynx as a state threatened species by Washington State (WADNR 1996, entire). Subsequent to federally listing the lynx as threatened under the ESA, in 2006 the WADNR implemented a modified Lynx Habitat Management Plan (2006 Lynx Plan) incorporating new science into its 1996 Lynx Plan pertaining to lynx management (WADNR 2006, entire). Among other things, the WADNR 2006 Lynx Plan contains management standards and guidelines to avoid the incidental taking (as defined by the ESA) of lynx. These standards and guidelines address maintenance of lynx denning and foraging habitat, as well as habitat connectivity within and between LAUs and lynx populations within Washington (i.e., LMZs) and Canada.

For example, the WADNR 2006 Lynx Plan includes, among other things: (1) Encouraging genetic integrity at the species level by preventing bottlenecks between British Columbia and Washington by limiting size and shape of temporary non-habitat along the border and maintaining major routes of dispersal between British Columbia and Washington; (2) Maintaining connectivity between subpopulations by maintaining dispersal routes between and within zones and arranging timber harvest activities that result in temporary non-habitat patches among watersheds so that connectivity is maintained within each zone; (3) Maintaining the integrity of requisite habitat types within individual home ranges by maintaining connectivity between and integrity within home ranges used by individuals and/or family groups; and (4) Providing a diversity of successional stages within each LAU and connecting denning sites and foraging sites with forested cover without isolating them with open areas by prolonging the persistence of snowshoe hare habitat and retaining coarse woody debris for denning sites. The 2006 Lynx Plan also describes how WADNR will monitor and evaluate the implementation and effectiveness of the plan. The WADNR has been managing for lynx for almost two decades, and the Service has concluded that the management strategies implemented are effective. In the final revised critical habitat designation, published in the Federal Register on February 25, 2009 (74 FR 8657–8658), we determined that the benefits of excluding lands managed in accordance with the WADNR 2006 Lynx Plan outweighed the benefits of including them in the designation, and that doing so would not result in extinction of the species. We, therefore, again are considering excluding 164.2 mi^2 of lands managed in accordance with the WADNR 2006 Lynx Plan from the revised lynx critical habitat designation.

Recent wildfires have temporarily eliminated or reduced the quality of greater than 50 percent of lynx habitat within the north Cascades (Koehler *et al.* 2008, p. 1523), which has significantly affected the status of and current viability of the lynx population within this geographic unit. As discussed below under *Potential Threats/Stressors/Factors Influencing Viability*, there is significant risk of potential future wildfires to further affect the viability of lynx in this geographic unit. Recent wildfire severity, extent, and intensity in lynx habitat within this geographic unit may have been influenced by climate change (Westerling *et al.* 2006, pp. 942-943), and as discussed below, climate change may similarly affect the future viability of lynx within this geographic unit.

4.2.5 Unit 5 - Greater Yellowstone Area

Unit Description: This geographic unit includes the parts of southwestern Montana and northwestern Wyoming the Service designated as critical habitat (Unit 5) for lynx in 2014 (79 FR 54825-54826). It encompasses approximately 23,691 km^2 (9,147 mi^2) in portions of Carbon, Gallatin, Park, Stillwater, and Sweetgrass Counties in Montana; and Fremont, Lincoln, Park, Sublette, and Teton Counties in Wyoming, with ownership that is 97.5 percent federal (USFS, NPS, and BLM); 2.2 percent private; and 0.3 percent State. This unit includes parts of Grand Teton and Yellowstone national parks and the Bridger-Teton, Custer-Gallatin, and Shoshone national forests, and lands managed by the BLM's Kemmerer and Pinedale Districts. It includes parts of the Absaroka, Beartooth, Gallatin, Gros Ventre, Salt River, Teton, Wind River, and Wyoming mountain ranges. This unit is not directly connected to lynx habitats and populations in Canada or to other DPS populations, although lynx dispersing from the north likely arrived intermittently into the area historically and, more recently, some lynx released into Colorado traveled into and through this unit (see Devineau *et al.* 2010, p. 526). Relative to other DPS lynx populations, this unit is about 145 km (90 mi) southeast of the Northwestern Montana/Northeastern Idaho unit, and roughly 400 km (250 mi) northwest of the Western Colorado geographic unit.

Habitat Description: In northwestern Wyoming and the GYA, lynx are generally associated with Englemann spruce-subalpine fir and lodgepole pine of the Rocky Mountain Conifer Forest vegetation class, as described above (Section 4.1.3) for the northwestern Montana, although this habitat and, thus, lynx typically occur at higher elevations (2,000-3,000 m [6,550-9,850 ft]) in the GYA (McKelvey *et al.* 2000a, p. 245; ILBT 2013, p. 60). Potential lynx habitat in much of the GYA is naturally marginal (patchier and composed in many places of drier forest types), with fewer shrubs and a more open understory, and generally low to marginal hare densities, resulting in a spatially-limited distribution of lynx with large home ranges (Squires *et al.* 2003, pp. 5, 12-13; 68 FR 40090; 71 FR 66010, 66029; 74 FR 8624, 8643–8644; Hodges *et al.* 2009, entire; Berg and Gese 2010, p. 1750; 79 FR 54796; Lynx SSA Team 2016, p. 45). Among the three national forests that contribute lands to this geographic unit, potential lynx habitat was mapped on about 42 percent of the total national forest area (both inside and outside this SSA unit; USFWS 2007, pp. 32, 95, 122-123).

In Yellowstone National Park, 7,732 km^2 (2,985 mi^2; about 86 percent of the park) is considered "lynx forest types" (65 FR 16073), but only 2,784 km^2 (1,075 mi^2; 31 percent of the park, 36 percent of lynx forest types) is estimated to be potential lynx habitat (68 FR 40086). However, hares were completely absent from more than 36 percent of surveyed stands in Yellowstone National Park, and 96 percent had estimated hare densities below the 0.5 hare/ha threshold thought necessary to support resident lynx (Hodges *et al.* 2009, 870, 873-877). In contrast, estimated hare densities were >= 0.48 hares/ha in all surveyed stands on the Bridger-Teton National Forest in the southern portion of the GYA, with highest densities (1.7 hares/ha) in 30-70-year-old regenerating lodgepole pine stands with dense horizontal cover, and densities of 1.2 - 1.6 hares/ha in mature multi-storied spruce-fir and mixed spruce-fir (containing aspen or lodgepole pine) stands (Berg *et al.* 2012, p. 1483). In the central Wyoming Range in the southern part of this unit, hare tracks were more abundant in seral aspen stands with a

significant spruce-subalpine fir component than in aspen stands with little or no spruce-fir, and hares appeared to be absent from pure aspen stands except where they bordered spruce/fir areas (Endeavor Wildlife Research 2009, p. 4). The only lynx den sites described for this unit (the natal den and a subsequent maternal den of one female in 1998) occurred in a mature subalpine fir-lodgepole pine forest in the Wyoming Range, where coarse woody debris and high sapling density provided dense horizontal cover (Squires and Laurion 2000, pp. 346-347).

Average annual snowfall in this unit ranges from about 127 cm (50 in) in Bozeman and 556 cm (219 in) in West Yellowstone, Montana, on the northern and northwestern peripheries of the unit, respectively, to 280-310 cm (110-122 in) in Alpine, Dubois, and Jackson, WY near the central and southern peripheries, with most snow falling from November to March in each place (https://snowfall.weatherdb.com/d/a/Montana; accessed 8/17/2016). In potential lynx habitats on the Bridger-Teton National Forest in the southern half of this unit, deep snow persisted from late October through May (Berg *et al.* 2012, p. 1481).

Habitat Status: Potential lynx habitats in this unit are currently designated as critical habitat in accordance with the ESA. Over 97 percent (23,109 km^2 [8,922 mi^2]) of this unit is in federal ownership, including 18,877 km^2 (7,292 mi^2) in national forests under USFS management, 3,944 km^2 (1,523 mi^2) in national parks managed by NPS, and 271 km^2 (105 mi^2) managed by BLM. As described above in section 3.1.1, USFS lands in this unit are managed in accordance with the NRLMD, which formally amended all forest plans to adopt and implement lynx conservation measures (USFS 2007, pp. 8-30 and Attachment 1, pp. 1-9) that were developed based on the scientific findings and recommendations of the LCAS (Ruediger *et al.* 2000, pp. pp. 7-1 - 7-18). Similarly, the BLM in 2008 and 2010 revised its RMPs for the Pinedale and Kemmerer districts, respectively, to include conservation measures and BMPs for lynx based on the LCAS (BLM 2008, pp. A18-10 - A18-15; BLM 2010, pp. A-9 - A-12). On lands with developmental land-use allocations, these amended forest plans and the revised BLM RMPs provide guidance on the kinds of activities that can and cannot be implemented in important lynx habitats and thresholds for the proportions of lynx habitat in LAUs that can be in an unsuitable state at any given time and how much can be converted from suitable to (temporarily) unsuitable over particular time frames. Implementation of these plans has likely benefitted lynx by providing a consistently-applied framework for conserving and restoring important hare and lynx habitats.

As elsewhere in the DPS (Squires *et al.* 2010, p. 1656; ILBT 2013, pp. 20, 27), winter foraging habitat is likely the most limiting habitat for lynx in this unit, and denning habitat is not thought to be limiting. Standards, guidelines and BMPs in the NRLMD and in revised BLM plans restrict vegetation management activities that could reduce winter snowshoe hare habitat and direct the creation or retention of coarse woody debris in areas where denning habitat may be lacking (USFS 2007, Attachment 1, pp. 2-5; BLM 2008, pp. A18-10 - A18-15; BLM 2010, pp. A-9 - A-12). Snow conditions in this unit also appear to remain suitable to allow lynx to outcompete other terrestrial hare predators. Gonzalez *et al.* (2007, pp. 4-7) compared the highest-precision lynx occurrence data in the contiguous U.S. from 1966-1998 with snow-cover data available for those locations and concluded that lynx require nearly continuous snow cover from December through March. The authors modeled the probability of suitable snow across North America,

showing that most of this geographic unit has a 95 percent probability of providing snow cover conditions supportive of lynx presence (Gonzalez *et al.* 2007, p. 12).

This unit includes substantial areas in nondevelopmental land-use allocations, including (in addition to Yellowstone and Grand Teton national parks) the Absaroka-Beartooth, Bridger, Gros Ventre, Lee Metcalf, Northern Absaroka, Teton, and Washakie designated wilderness areas. Among the three national forests that contribute to this unit, 75 percent of potential lynx habitat is in designated wilderness or roadless areas (USFWS 2007, p. 34). Management activities in these areas are unlikely to adversely impact lynx and hare habitats.

Large parts of Yellowstone National Park burned in the extensive wildfires of 1988. Although the extent to which those fires may have impacted potential lynx habitats is uncertain, some of the burned areas may soon reach a stage of regeneration capable of supporting increased densities of hares, perhaps increasing the likelihood that lynx could reestablish and maintain home ranges in some parts of the park (Lynx SSA Team 2016, p. 45).

Because non-federal lands make up less than 3 percent of lynx habitats in this unit, it is unlikely that activities on those lands have impacted lynx populations or meaningfully influenced the unit's current capacity to support resident lynx.

Overall, although naturally fragmented and patchily-distributed, potential lynx habitat in this geographic unit appears to be largely intact relative to historic conditions and disturbance regimes, with only a small proportion apparently impacted by past management (timber harvest and precommercial thinning) activities (65 FR 16072). Despite some likely localized impacts of past timber management and infrastructure (e.g., highway, railroad) development, past management activities do not appear to have diminished this unit's ability to support resident lynx or to have created barriers to lynx movement, or to have had other landscape- or population-level effects.

In summary, much of this geographic unit occurs in national parks, designated wilderness and roadless areas, or other nondevelopmental land-use allocations, where management activities with the potential to adversely affect lynx habitat generally do not occur. Almost all lands with developmental land-use allocations in this unit are managed by the USFS to conserve and maintain lynx and hare habitats under management plans that were formally revised in 2007 in accordance with the NRLMD and based on the scientific findings and conservation recommendations of the LCAS. A small proportion of lands with developmental allocations occurs on BLM lands where management plans also were revised recently (2008 and 2010) to adopt conservation measures identified in the LCAS. Implementation of these USFS and BLM plans likely precludes landscape-level management-related adverse impacts to the vast majority of existing lynx and hare habitats in this unit. Nonetheless, past management activities that occurred prior to implementation of current regulations and other conservation efforts may exert continuing influence on current habitat quality in some places. Additionally, because lynx habitats in this unit are naturally highly-fragmented and, in most places, support low landscape-level hare densities, relatively minor impacts, especially to hare and lynx winter foraging habitats, may strongly influence lynx persistence in some parts of this unit.

Lynx Status: There are no reliable estimates of the historic or current number of resident lynx in this unit. As described in section 2.3.2.2 above, the historic record and recent research show that the GYA has supported resident lynx, but it is unclear whether the area consistently supported a persistent resident population over time or whether it naturally supported resident lynx only intermittently. Most historic and recent verified lynx records are from the southern portion of this unit in the Gros Ventre, Salt River, Wind River, and Wyoming mountain ranges in the Bridger-Teton National Forest. Eighteen lynx were reported to have been trapped from a small area in the Wyoming Range in 1971-72 (Squires and Laurion 2000, p. 338), but it is unknown whether any of those lynx were residents (and if so, how many) or if some or all of them were dispersers associated with the "explosion" (irruption) of lynx documented in several places in the contiguous U.S. in the early 1970s (McKelvey *et al.* 2000, pp. 235-242). However, two resident lynx, a male and a female, were trapped, radio-marked, and monitored in the Wyoming Range over several years beginning in 1996. The female produced four kittens in 1998 and two in 1999, though none of the kittens survived to independence, and the female died of starvation in March 2000 (Squires and Laurion 2000, p. 346; Squires *et al.* 2001, pp. 9, 26). The female's home range averaged 50 km^2 (19 mi^2) over the 3 years she was monitored, and the male's averaged 824 km^2 (318 mi^2) over five years (Squires *et al.* 2003, pp. 12-13). The male also made multiple long-distance exploratory movements (up to 728 km [452 mi], including multiple highway crossings) over 3 successive years (Squires *et al.* 2003, pp. 13-16; Squires and Oakleaf 2005, entire).

Other surveys also detected lynx in the southern portion of this unit from 1999-2009, with records most consistent in the Wyoming Range, Togwotee Pass, Union Pass, the Bondurant Corridor, and in the Gros Ventre Range (Squires *et al.* 2001, pp. 9-14; Squires *et al.* 2003, pp. 9-11, 29-31; Endeavor Wildlife Research 2008, 2009, entire; Berg 2016 pers. comm.; Squires *in* Lynx SSA Team 2016, pp. 20-21). Additionally, 10 radio-marked lynx released in Colorado subsequently moved into or through this portion of the GYA unit from 2004-2010, with locations concentrated in areas used previously by native Wyoming lynx (Devineau *et al.* 2010, p. 526; Hanvey 2016, pers. comm.). Several of the Colorado-released lynx occupied home ranges (including overlapping male and female home ranges) in areas of the Wyoming Range previously occupied by "native" resident lynx (Squires *in* Lynx SSA Team 2016, p. 21), but there is no evidence of reproduction among these lynx. On the Shoshone National Forest in the northeastern part of this unit, seven lynx snow tracks were confirmed by DNA analysis in winter 2005/06, and a single track was verified the following winter (Endeavor Wildlife Research 2008, p. 2; Berg 2016, pers. comm.). During the winters of 2004-05 through 2007-08, 26 snow tracks on the Bridger-Teton and Shoshone national forests were confirmed by DNA analyses to be from five individual lynx (3 males, 2 females). One of the males had previously been documented in Yellowstone National Park (see below). The other two males and both females were lynx that had been released in Colorado (Pilgrim 2016, pers. comm.).

Verified records of lynx are less common elsewhere in this unit, including in Yellowstone and Grand Teton national parks and the Custer-Gallatin National Forest. There were no verified records of lynx in Yellowstone National Park from 1920-1999 (McKelvey *et al.* 2000, p. 230); however, surveys in 2001-2004 documented at least 3 individual lynx, including two kittens, in

the eastern part of the park (Murphy *et al.* 2006, entire). Several Colorado-released lynx also traveled through the park (Devineau *et al.* 2010, p. 526), and two possible (unconfirmed) lynx tracks were recorded in the park during winter 2008/2009 (Endeavor Wildlife Research 2009, pp. 4, 12). On the Custer-Gallatin National Forest in Montana in the northern part of the unit, a single female was detected over six consecutive winters (2003/2004 - 2008/2009) but not subsequently (Gehman *et al.* 2010, pp. 2-4), and it appears that she did not encounter a male or produce kittens during the six years she was detected (Gehman *et al.* 2010, p. 4).

Recent surveys and research-related trapping efforts have failed to detect lynx in this unit after 2010 (79 FR 54791; Squires *in* Lynx SSA Team 2016, pp. 20-21, 45; Hanvey 2016, pers. comm.). As discussed above and in section 2.3.2.2, it is uncertain whether this unit historically supported a small but persistent resident population that was recently extirpated, or if it historically and recently has supported resident lynx only intermittently. Given the protected conservation status of millions of acres in this unit, its apparent recent inability to support resident lynx may be a reflection of naturally marginal and patchy habitats and relatively low hare abundance in much of the unit, resulting in only an intermittent ability of this unit to support resident lynx (Lynx SSA Team 2016, p. 57). Conversely, the characteristics described above suggest that relatively small impacts could tip this unit from just barely able to support a persistent resident population to incapable of doing so. Further, the available evidence suggests that if this unit did support a persistent population, it was very likely a very small one, which would be more vulnerable to extirpation due to demographic, environmental, and genetic stochasticity, and to catastrophic events (McKelvey *et al.* 2000b, pp. 23-29), or to a combination of these factors.

Factors Affecting Current Conditions: *Regulatory Mechanisms* - As described above for Unit 3, federal management activities (e.g., timber harvest and precommercial thinning, perhaps fire suppression) that occurred prior to listing and before implementation of current federal regulatory mechanisms likely impacted some lynx and habitats by altering the distribution and quality of hare and lynx habitats. However, because these activities occurred in low proportions of lynx habitat on federal lands and impacts appear to have been localized, they were deemed a low-level to threat to lynx at the time of listing (65 FR 16072-16076; 68 FR 40091-40095). Nonetheless, past federal management activities may continue to influence the current quality and distribution of lynx habitats in some parts of this unit. Current regulatory mechanisms and conservation measures associated with recently amended or revised federal management plans are intended to conserve and restore lynx and hare habitats across large landscapes. Although their effectiveness has not been quantitatively evaluated, they have almost certainly reduced significantly the potential for adverse management-related impacts to lynx habitats in this unit.

Lynx trapping has been prohibited in Wyoming since 1973 (79 FR 54794) and in Montana since 1999 (MTFWP 2016, p. 7) and, as described in section 3.1.2, above, both states require measures to reduce the likelihood of trapping lynx incidentally when legally trapping other species. Since the DPS was listed in 2000, no lynx are documented to have been incidentally trapped in the Montana portion of this unit (MTFWP 2016, pp. 5-10) and we are aware of no incidental captures in northwestern Wyoming since listing.

Climate Change - As elsewhere, increased temperatures, reduced snowpack, earlier snowmelt, and increased drought leading to increased fire all have been documented in this geographic unit (e.g., Mote *et al.* 2005, entire; Pederson *et al.* 2013; Riley *et al.* 2013; Dennison *et al.* 2014, entire; USEPA 2015, entire; Harvey *et al.* 2016, entire; Siren *in* Lynx SSA Team 2016, pp. 14-15; Westerling 2016, entire). A number of potential impacts to lynx have been described, and climate projections suggest these impacts are likely to result in future loss and increased fragmentation and isolation of lynx and hare habitats and declining lynx populations in the DPS (Carroll 2007, entire; Gonzalez *et al.* 2007, entire; ILBT 2013, pp. 69-71; 79 FR 54810-54811; Lawler and Wilsey *in* Lynx SSA Team 2016, pp. 15-16; Siren *in* Lynx SSA Team 2016, p. 15; see also section 3.2, above, and 5.1.3, below). Although climate change has probably already had some impact on lynx habitats in this geographic unit, and such impacts are likely to continue to occur, there currently is no evidence that climate change has had population-level effects or has reduced the ability of this unit to support persistent resident lynx populations. However, such impacts would be difficult to document and, as described under *Habitat Status*, above, because lynx habitats in this unit are naturally highly-fragmented and hare densities low in some places, relatively minor impacts, especially to hare and lynx foraging habitats, may strongly influence lynx persistence in some parts of this unit. However, modeling vegetation and snow suitability for lynx across North America, Gonzalez *et al.* (2007, pp. 12, 15) indicated that boreal and temperate conifer forest biomes were broadly distributed across this geographic unit and that snow conditions suitable for lynx occurred with 95 percent probability from 1961-1990. (Future conditions based on this modeling are described in section 5.1.3, below). As described in section 3.2, above, climate change has also been implicated in recent increases in the frequency and intensity of outbreaks of boreal forest insect pests, with warmer winters resulting in increased insect survival and drought increasing conifer vulnerability to insects. This trend is expected to continue through the end of the century with continued climate warming (Bentz *et al.* 2010. pp. 607, 609).

Vegetation Management - The influence of vegetation management on the current condition of lynx and habitats in this unit is described above under Habitat Status and *Regulatory Mechanisms*.

Wildland Fire Management - As described above in section 3.4, wildfire suppression in this unit, as elsewhere in the West, has likely had little impact on lynx habitats (65 FR 16074; 68 FR 40093-94; USFS 2007, pp. 18, 20; USFS 2008, p. 11; ILBT 2013, p. 76). Also as described in that section, wildfire frequency, size, and intensity have increased in this geographic unit, likely in response to climate warming and related increases in drought conditions (e.g., Dennison *et al.* 2014, entire; Harvey *et al.* 2016, entire; Westerling 2016, entire), with most large, stand-replacing fires having occurred in the northern part of the unit, in Yellowstone National Park (see Harvey *et al.* 2016, Fig. 1). Despite this increase, we are aware of no evidence that increased fire activity in the unit has thus far impacted resident lynx populations or reduced this unit's ability to continue to support resident lynx.

Habitat Loss and Fragmentation - As described above, the dominant land use in this unit, and that most likely to result in habitat loss and fragmentation, is timber harvest and associated vegetation management (e.g., precommercial thinning) and road construction on lands with

developmental allocations. Much of this unit occurs in national parks, designated wilderness and roadless areas, or other nondevelopmental allocations. Even in areas with developmental allocations, the moist subalpine forests important to lynx have had less timber harvest, road construction, and have been modified much less than other drier forests (65 FR 16073), and these activities appear not to have had population-level impacts on lynx or to have measurably reduced the ability of this geographic unit to support resident lynx. Few highways intersect lynx habitats in the Northern Rockies (ILBT 2013, p. 63) and there are few records of lynx killed by vehicle collisions in Montana (5) and Wyoming (1; a Colorado-released lynx) (Broderdorp, unpubl. data; MTFWP unpubl. data). Other potential sources of habitat loss and fragmentation include recreation, minerals/energy development, and forest/ backcountry roads and trails; these are all considered second tier anthropogenic influences (ILBT 2013, pp. 78-85) that are unlikely to exert population-level influences, despite potential impacts to individual lynx.

Other Factors - Connectivity/Immigration - As elsewhere in the range of the DPS, resident lynx populations in this geographic unit are thought to be influenced by connectivity with, and immigration of lynx from, populations in Canada (see section 2.2, above). However, whether and, if so, to what the extent the persistence of populations in this geographic unit may depend on regular or intermittent immigration of lynx from Canada remains uncertain, and historic, recent, and current immigration rates of are unknown. Although this unit is not directly connected to lynx habitats and populations in Canada or elsewhere in the contiguous U.S., no barriers to lynx dispersal from the north have been identified, and 10 lynx released in Colorado are known to have dispersed northward into and through this unit (Devineau *et al.* 2010, p. 526; Hanvey 2016, pers. comm.), demonstrating that dispersal between the southern and northern Rockies is possible. As described above in Lynx Status, the large number of lynx reportedly trapped from a small area of the Wyoming Range in the early 1970s (Squires and Laurion 2000, p. 338) may suggest dispersers associated with the irruption of many lynx from Canada into the northern contiguous U.S. documented at that time (McKelvey *et al.* 2000, pp. 235-242). No subsequent pulses of lynx dispersing from the north have been documented, and lynx trapping records suggest that the magnitude of lynx populations cycles in Alberta and British Columbia, the most likely source of lynx dispersing southward into this unit, dampened dramatically after the early 1980s (McKelvey *et al.* 2000a, p. 226; Bowman *in* Lynx SSA Team 2016, p. 13; also see Appendix 5, 2015 10 13 - 5, pp. 4-5 [https://www.fws.gov/mountain-prairie/es/species/mammals/lynx/SSA2016/Appendices/Appendix%205%20Presentation%20PDFs/2015%2010%2013%20-%205%20-%20Bowman%20Lynx%20Southern%20Canada.pdf]).

As described in section 3.2, above, a number of climate-mediated factors have been suggested as contributing to changes in the periodicity and amplitude of northern lynx and hare population cycles, which could alter the timing and magnitude of irruptions of lynx from Canada into the contiguous U.S. If lynx populations in this geographic unit are reliant on immigration from Canada which is no longer occurring or has been substantially reduced relative to historic conditions, population declines and a reduced probability of persistence among resident populations would be expected. Although the extent to which this factor has influenced the current condition of lynx populations in this unit is unknown, it is possible that it has contributed to the recent apparent loss of resident lynx from this unit.

4.2.6 Unit 6 - Southern Rockies Geographic Area

Unit Description - The overall geographic unit includes Colorado, south-central Wyoming, and north-central New Mexico. However, within the southern Rockies, since we currently have no evidence of resident lynx in southern Wyoming or northern New Mexico, and we question the ability of these two areas to support breeding populations we are not including these two areas in the unit description. Lynx habitat in Colorado totals approximately 25,294 km^2 (9,766 mi^2), and is distributed west of US Interstate-25. We excluded the northwest part of the state bounded on the south by US Interstate-70 and the east by Colorado State Highway 13, because this area lacks sufficient habitat to support lynx. Lynx habitat in Colorado falls within the following land ownerships, USFS 21,555 km^2 (8,322 mi^2), BLM 772 km^2, (298 mi^2), NPS 452 km^2 (174 mi^2), Private 2,350 km^2 (907 mi^2), State 164 km^2 (63 mi^2).

The southern Rockies are separated from the rest of the Rocky Mountain chain, and thus lynx habitat in northern and western Wyoming, by sagebrush and desert shrub communities in the Wyoming Basin and the Red Desert of southern and central Wyoming, and the arid Green and Colorado River plateaus of western Colorado and eastern Utah. Connectivity of lynx habitat has been identified as an important consideration for the southern Rockies, because of the extreme topographic relief juxtaposed with human developments such as highways and residential communities.

Habitat Description - Lynx habitat in the southern Rockies is found within the subalpine and upper montane forest zones, generally above 2,900 m (9,514 ft) elevation (Shenk 2009 page 10). In the upper elevations of the subalpine zone, forests are typically dominated by subalpine fir and Engelmann spruce. As the subalpine zone transitions to the upper montane, spruce-fir forests begin to give way to lodgepole pine and aspen. On cooler, mesic mid-elevation sites, Engelmann spruce may retain dominance, intermixed with aspen, lodgepole pine, and Douglas-fir. Lodgepole pine reaches its southern limits in the central part of the geographic unit, while southwestern white fir occurs only in the San Juan Mountains. The lower montane zone is dominated by ponderosa pine and Douglas-fir, with pines typically dominating on lower, drier, more exposed sites, and Douglas-fir occurring on the more sheltered sites. Lower montane forests do not support snowshoe hares and seldom would be used by lynx.

Mature Engelmann spruce/subalpine fir forests with total canopy cover of 42–65 percent, of which 15–20 percent was contributed by conifer understory tree canopies, were the most commonly used areas, followed by mixed forests of Engelmann spruce/subalpine fir/aspen (Shenk 2008, page 15). Riparian and riparian-mix was the third most-used cover type, with a pattern of increasing use beginning in July, peaking in November, and dropping off in December. Large or medium willow/alder carrs and willow riparian communities provided important habitat for snowshoe hare, grouse, ptarmigan (winter), and other prey species that could be utilized by lynx.

Ivan *et al.* (2012 page 5) confirmed some relationships that were already known (e.g., lynx are strongly associated with high-elevation spruce/fir and mixed spruce/fir forests but avoid lower-

elevation montane forests and montane shrublands). We recognize that all spruce-fir forest does not support lynx equally based on the low detection rate (28 percent) reported during the ongoing lynx study in the San Juan Mountains within predominantly spruce-fir forest (Ivan, Workshop presentation 2015, p. 14), thus not all areas of spruce-fir forest are used by lynx.

Dolbeer and Clark (1975 page 539) estimated a density of 0.73 hares/ha (0.3 hares/ac) within their study site in Colorado, with the highest densities of snowshoe hare in mature and late-successional spruce-fir forests. However, this study was conducted in a very limited area and did not sample younger sapling-stage stands (15-40 years post-disturbance) to compare hare densities with those reported for mature and late-successional spruce-fir forests (USFWS 2008, p. 32).

Habitat that supports snowshoe hares is patchily distributed in the Southern Rocky Mountains Geographic Unit, which limits their abundance. Zahratka and Shenk (2008 entire) found densities of snowshoe hares to be greatest in mature Engelmann spruce-subalpine fir stands when compared to mature lodgepole pine stands in Taylor Park, Colorado. Their density estimates were 0.08±0.03 to 1.32±0.15 hares/ha (0.03–0.5 hares/ac) in Engelmann spruce-subalpine fir habitats, and 0.06±0.01 to 0.34±0.06 hares/ha (0.02–0.14 hares/ac) in lodgepole pine habitats (Zahratka and Shenk 2008 entire).

Ivan (2011*a in ILBT 2013*) compared snowshoe hare density, survival, and recruitment in mature uneven-aged spruce/fir stands, small-diameter lodgepole pine (2.54–12.7 cm [1–5 in]) stands (20–25 years old), and medium-diameter (12.7–22.9 cm [5–9 in]) previously-thinned lodgepole pine stands (40–60 years old) in Colorado. During summer, Ivan (2011*a* in *ILBT 2013*) recorded densities of 0.2+0.01 to 0.66+0.07 hares/ha (0.08–0.27 hares/ac) in small lodgepole pine forest, 0.01+0.04 to 0.03+0.03 hares/ha (0.004–0.01 hares/ac) in medium lodgepole forest, and 0.01±0.002 to 0.26±0.08 hares/ha (0.004–0.1 hares/ac) in spruce/fir forest; densities were more similar across the 3 forest types during the winter months. He concluded that “hares reached their highest densities and recruited juveniles most consistently in stands of small lodgepole, followed closely by spruce/fir, but survival was highest in spruce/fir stands.”

Habitat Status - At the time of the 2000 listing, we identified 26,305 km^2 (10,156 mi^2) of potential lynx habitat in the Southern Rockies (i.e., Colorado and southern Wyoming) [65 FR 16052). In 2003, we estimated 31,027 km^2 (12,419 mi^2) of potential habitat within the southern Rockies (68 FR 40076). As stated above, our focus here is limited to the state of Colorado. In 2008, the USFS reported that most of their LAUs in the southern Rockies fell within a range of 3-8 percent in a currently unsuitable condition, with only one LAU exceeding 30 percent unsuitable (USFS 2008, p. 19). Currently, the USFS reports 51 out of 202 (25%) LAUs currently exceed the 30 percent unsuitable condition (P. McDonald 2016, pers. comm.). These changes are mostly in response to the ongoing bark beetle infestations, as well as wildfire events that have occurred since 2008.

Ivan *et al.* (2012, p. 6), developed a predictive map of lynx habitat use by using lynx location data collected during CPWs reintroduction monitoring, then estimated the amount of habitat associated with a high probability of detecting lynx. Our review of the vegetative characteristics of CPW's predictive map detected large areas of spruce-fir habitats that were excluded by their presentation of the habitat associated the top 20 percent of predicted use. Therefore, we selected the top 30 percent of the Ivan *et al.* (2012, entire) predictions and the associated habitat to represent the amount of potential lynx habitat in Colorado totaling 25,294 km^2 (9,766 mi^2). This habitat estimate falls between the Ivan *et al.* (2012, p. 6) estimate and the USFS's habitat estimate of 30,664 km^2 [11,839 mi^2] (USFS 2008, p. 18), while retaining a greater than 60 percent probability of detecting lynx as described by Ivan *et al.* (2012).

Regulatory mechanisms in Colorado are largely provided through Forest Service planning documents. All USFS land management plans within the unit were amended in 2008 to provide for the conservation of lynx. Three BLM plans in Colorado have been amended or revised to conserve lynx following the 2013 LCAS, totaling approximately 126 km^2 (49 mi^2). One additional plan provides conservation measures for timber management actions only, but the FO contains only about 1 km^2 (0.39 mi^2). The remaining FOs currently have not amended or revised their plans specifically to provide conservation for lynx (approximately 645 km^2 (298 mi^2), Since the 2000 listing however, all BLM Field Offices in Colorado have been conserving lynx discretionarily through application of conservation measures provided in the Lynx Conservation Assessment and Strategy (Ruediger *et al.* 2000, entire; ILBT 2013, entire). Rocky Mountain National Park has a fire management plan that includes conservation measures for lynx. We are not aware of any specific conservation planning guiding activities on non-federal lands (M. Wrigley 2016, pers. comm. ; M.K. Watry 2016, pers. comm.).

Lynx Status - As of 2016, the current distribution of lynx is somewhat uncertain within Colorado. However, we believe it is reasonable that lynx continue to occupy all National Forests within the state of Colorado (Odell 2016, undocumented pers. comm.), and Rocky Mountain National Park (Shenk 2008, p. 3). The CPW is developing a minimally-invasive, long-term, statewide monitoring program to track the distribution, stability, and persistence of lynx in Colorado (Ivan 2012, entire).

As of 2015, evidence of recent lynx reproduction is provided through kittens captured on game cameras accompanying adult females at three locations during 2014-2015 monitoring effort (Ivan presentation 2015 page 17). In addition 38 percent of lynx captured during recent (2010-2015) USFS Rocky Mountain Research Station research projects in Colorado have been young and/or unmarked cats (Ivan *in* Lynx SSA Team 2016, p. 17), suggesting continued reproduction within Colorado. However, reproductive rates are currently unknown.

As of 2007, the average probability of survival for reintroduced lynx was 0.9315±0.0325 within the study area in the San Juan Mountains and 0.8219±0.0744 outside the study area boundary (Devineau *et al.* 2010, page 5). Although 30 percent of known mortalities were due to human causes (being shot or hit by a vehicle), the estimate of survival within the study area was higher than those reported for natural, lightly trapped populations of Canada lynx in the Yukon (0.75–

0.90; Slough and Mowat 1996 entire, O'Donoghue *et al.* 1997, page 155) or in the Northwest Territories (~0.90; Poole 1994, page 612). Successful reproduction, including by females born in Colorado, has been documented (Shenk 2008, page 2), and kitten survival was 0.2260 (Jake Ivan, pers comm. March 9, 2016).

Factors Affecting Current Conditions - Colorado is currently experiencing major bark beetle epidemics in lodgepole pine and spruce-fir forests. Although bark beetles are native insects, and forests in the western U.S. have experienced regular insect infestations throughout their history, the current bark beetle epidemic is notable for its intensity and extensive geographic range. The causes of this epidemic include: relatively even-aged, dense, and homogenous forest conditions, which are highly susceptible to beetle attack, and which were created by large-scale logging in the late 1800s and subsequent fire suppression efforts; warmer winters due to climate change (cold winters typically reduce beetle populations); and a multi-year drought that occurred in the mid-1990s through early 2000s, stressing the trees and making them more susceptible to beetle attack (USFS 2011, pp. 4).

In lodgepole pine forests, a mountain pine beetle (*Dendroctonus ponderosae*) epidemic typically kills the entire overstory and results in a stand-replacing disturbance event. In Colorado, more than 1,375,931 ha (3,400,000 ac) has been affected by mountain pine beetle, and 639,000 ha (1,579,000 acres) affected by spruce beetle since 1996 (USFS 2015, p. 3), a portion of which overlaps with lynx habitat.

Even-aged mature and "dry" lodgepole pine stands characteristically have depauperate understory vegetation and are not capable of supporting dense populations of snowshoe hares. On moist sites, regeneration of beetle-killed lodgepole pine stands is expected to be relatively rapid 20-30 years, and the new stands will be dominated by resprouting aspen or by a new cohort of lodgepole pine. If these newly-established stands grow tall and dense enough to provide horizontal cover above the snow layer, they may produce excellent habitat for snowshoe hares and lynx for several decades, until the crowns again lift above the reach of snowshoe hares.

A spruce beetle epidemic kills the larger-diameter trees and can also result in a stand-replacing disturbance event. Because of the importance of spruce-fir forests for production and survival of snowshoe hares (Ivan 2011a in ILBT 2013), widespread mortality of mature spruce/fir forests could impact lynx habitat for a long duration. By 2015, the spruce beetle outbreak influenced approximately 95 percent of the mature spruce component of the subalpine cover types on the Rio Grande National Forest (Squires *et al.* unpublished report 2016, page 1). Despite the large scale, and almost complete mortality of the mature spruce component within their study area, lynx continue to use and reproduce in the beetle-infested forests (Squires *et al.* unpublished report 2016, page 2). Since the majority of lynx habitat in Colorado is under federal land management (88 Percent), actions occurring on other ownerships are unlikely to result in significant losses of lynx habitat within Colorado. However, habitat connectivity may be negatively affected by intense recreational use or development within strategic areas that are important for habitat connectivity.

ILBT (2013 p. 57; 61-62) states:

> *Plague, a flea-borne disease caused by the bacterium Yersinia pestis, which is not native to North America, was reported for the first time in lynx in Colorado (Wild et al. 2006). Pneumonic plague appeared to be the direct or indirect cause of death of 6 reintroduced lynx between 2000 and 2003. When translocated from Canada and Alaska, none of the lynx had antibody titers to Y. pestis; it appears likely that lynx were exposed to plague by infected prey after their release in Colorado.*
>
> *Vehicular collisions are a potentially important cause of mortality for lynx in portions of the southern Rockies. Thirteen of 102 mortalities documented for lynx translocated into Colorado were from vehicle collisions (Devineau et al. 2010). Brocke et al. (1990) suggested that translocated animals might be more vulnerable to highway mortality than resident lynx and this could have been a factor in Colorado at the time of listing. Currently, the majority of lynx mortalities caused by vehicle collision (13 of 16) occurred during the reintroduction period (1999-2006). Since early 2007, one year after the final reintroductions occurred, only 3 hit by vehicle mortalities have been reported, and only two of those occurred in Colorado (Broderdorp unpublished data 2016). A number of highways with high speed and high traffic volume pass through lynx habitat, such as I-70, I-80, US 50, US 550 and US 160. These highways are not a barrier to lynx movement, as repeated successful crossings by radio-telemetered lynx have been documented on I-70 and Highways 9, 40, 50, 91, and 114 (Ivan 2011b, c, 2012; J. Squires, personal communication 2012). At this time, it appears that hit by vehicle mortality may be a less significant mortality factor for lynx in Colorado.*
>
> *As compared with other portions of the range of lynx, in Colorado more winter recreation and associated development overlaps with lynx habitat. Preliminary information from a study in Colorado indicates that some winter recreation uses may be compatible, but lynx may avoid some developed ski areas (J. Squires, personal communication 2012). It is possible that ski areas and 4-season resorts may reduce the amount and availability of lynx habitat within localized areas, in part by influencing the distribution or abundance of prey resources within the developed area. However, there is also considerable anecdotal evidence of lynx using ski areas.*
>
> *Leg-hold trapping is currently prohibited under the state constitution of Colorado as a means of predator control or for commercial and recreational trapping. If a landowner can prove that all other non-lethal methods have been ineffective, a 30-day exemption may be granted for depredation cases. Incidental trapping mortality of lynx may be a minor risk during trapping seasons in southern Wyoming and surrounding states.*
>
> *Predator control activities on federal lands, including coyote shooting or trapping, are common throughout most of this geographic area, mostly related to the grazing of domestic sheep. The majority of sheep grazing occurs on arid rangelands, but some*

grazing does occur during summer at the higher elevations, especially in south-central Colorado. Incidental capture of lynx is possible, but unlikely.

Chapter 5: Future Conditions

In this chapter, we present our assessment, based on the best available scientific information, ncluding the professional judgment and opinions of lynx experts, of the ~~potential~~ future ~~status~~condition of the lynx DPS in terms of redundancy, representation, and resiliency. We then provide brief summaries of the likely future conditions in each geographic unit, followed by a more detailed evaluation of the factors likely to influence lynx populations and habitats in each unit. We present and summarize the professional judgments and opinions of a panel of 10 lynx experts regarding the factors likely to influence the persistence of resident lynx populations in the DPS as a whole and in each of the ~~six~~6 geographic units. We also present and summarize the experts' projections, based on consideration of those influencing factors, of the probability that each of the geographic units will continue to support resident breeding populations of lynx into the future (at years 2025, 2050, and 2100). We then provide additional Service review of the influencing factors described in Chapter 3, above, and their potential effects on the ability of each geographic unit to support lynx populations in the future.

5.1 Summary of Future Conditions DPS-wide

Given the irresolvable uncertainty about the historical distribution of resident lynx in the contiguous U.S. and the current lack of reliable estimates of the sizes, trends, and many demographic parameters for most DPS populations, it is difficult to confidently predict the future ~~status~~condition of the DPS or the likelihood that any given geographic unit will support resident lynx in the future. We lack data to build rigorous empirical population models for lynx in the DPS, and uncertainty regarding the timing and magnitude of potential impacts to lynx from continued climate warming also limits our ability to predict the future condition~~s for~~of the DPS. Therefore, our assessment of the future condition of the DPS is based on the best professional judgments and opinions of lynx experts and our evaluation of the available scientific information regarding the factors identified by the ILBT as the most likely to have population-level impact to lynx in the DPS (ILBT 2013, pp. 68-78).

Overall, expert opinion and our evaluations suggest that resident lynx populations in each of the geographic units are likely to be smaller and their distributions reduced in the future. These anticipated declines are most likely to be influenced by projected loss and increasing fragmentation and isolation of boreal forests and favorable snow conditions resulting from continued climate warming and related impacts (e.g., increased wildfire and forest insect activity, diminished hare populations) (Lynx SSA Team 2016, p. 58). This outcome seems likely

Comment [MJM31]: We need to explain the context for this analysis of future conditions. This context includes the absence of ESA listing and the protections it provides (no section 9 prohibitions, no section 7 consultation, etc.). This context is important to avoid the circular outcome that ESA listing is unwarranted because the species is sufficiently protected from threats due to its listing under the ESA.

Was this context explained to the experts who provided input?

Comment [MJM32]: This assessment of future condi ions focuses on the "likely" outcome of he threats acting on the species. This focus on only the likely outcome is essentially a single future scenario analysis. Our SSA Guidance directs us to look at a range of future scenarios so as to capture he full risk to the species. A risk analysis requires an assessment of the full range of plausible futures and their probabilities. Even when a "good" future for the species is likely, lower likelihood "bad" future scenarios can individually or cumulatively cons itute sufficient risk to the species to warrant listing.

Comment [MJM33]: This sounds like we consider expert opinion as constituting the best available science/information. Opinions, by hemselves, can never constitute best available information. We should never simply refer to expert opinion as the basis of our conclusions. We must draw our own independent conclusions. Our conclusions can be informed by expert opinion, but we must explain the reasons the experts hold their opinions, explain why we agree or disagree with this reasoning, and then arrive at our own conclusions (making it clear that these are our conclusions). We can hen say "Based on the best available ...

Comment [MJM34]: Use "future condition" or "population status" to avoid confusion with lis ing status (E/T).

Comment [MJM35]: This is an example of where we incorrectly refer to expert opinion as something we consider "in addition to" he best available science. We can consider ONLY the best available science. Our understanding/analysis of the best available science is informed by expert opinion.

Comment [MJM36]: We need to also consider the risks posed by factors that may be of a lower likelihood but still meaningful.

Comment [MJM37]: This paragraph seems to be describing "our" overall conclusions. But it's confusing when it refers to the experts' opinions. We don't need to refer to the experts' opinions when we are presenting our conclusions. We should clearly establish in the introduction to his sec ion where our conclusions come from.

Comment [MJM38]: We need to also consider the risk posed by the less-than-likely probability that he sizes and distributions of populations will be reduced even more.

regardless of which climate emissions scenario is used to model future conditions, although the timing, extent, and magnitude of impacts is uncertain and will likely vary by scenario.

In addition to climate change, forest management also has the potential to influence (negatively or positively) hare and lynx habitats in the DPS range. Forest management on private lands that lack lynx conservation commitments may contribute to future declines in the amount and quality of lynx habitats, particularly in Maine and perhaps also in Minnesota (private lands contribute minimally to lynx habitats in the other geographic units – see ~~T~~table 1, above). Uncertain future forest ownership and markets for forest products, shifts in silvicultural practices, and development pressures on private lands all may affect the resiliency of future lynx populations and thus the units. The lack of evaluation of the effectiveness of forest management plans for lynx on ~~f~~Federal lands is of concern for western units.

In each geographic unit, the probability that resident lynx populations will persist is expected to decline in the future, although uncertainty about persistence probability increases with time from the present (Lynx SSA Team 2016, pp. 36-49; also see 5.2, below). Although all five geographic units that currently support resident populations (all units except the GYA) are expected by lynx experts to continue to do so through mid-century, only one (Northwestern Montana/ Northeastern Idaho) has an estimated probability of persistence greater than 50 percent (i.e., persistence more likely than not) by the end of the century. All other geographic units have a 50-percent or greater probability of functional extirpation (i.e., no longer capable of supporting resident lynx populations) by the end of the century (Lynx SSA Team 2016, pp. 36-49; also see 5.2, below), with a moderate to high likelihood that resident lynx will be lost from two to four units by then (~~F~~figure 7).

Comment [MJM39]: I don't understand what his is saying. Is it trying to say the probability of persistence declines as we look further out into the future? If so, this is a meaningless statement because it could be said of every species on earth. We need to convey the magnitude of the decline.

Comment [MJM40]: What do we expect?

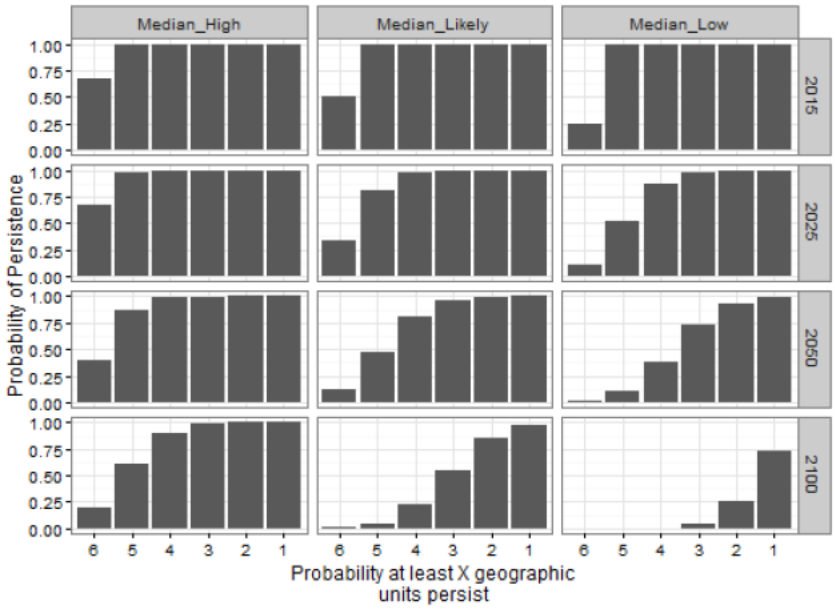

Figure 7. Summarized probability of persistence of at least a given number of geographic units given the probability of persistence for each individual geographic unit. The y axis of each grid in ~~F~~figure 7 is the probability that at least the number of geographic units indicated by the x axis of the grid persist. The probability in a bar reaches 1 when there is no probability of fewer geographic units persisting. Moving from top to bottom the grids show the probabilities by time period (2015, 2025, 2050, and 2100). Moving from left to right the grids show the range of expert responses by summary selection type and probability response. Therefore, looking down a column of grids provides a view of the trend in persistence through time and looking across a row of grids provides a view of the range of uncertainty in persistence for a given time period.

The loss of all resident lynx from one or more geographic units would represent reduced future redundancy, representation, and resiliency within the lynx DPS. With regard to redundancy, however, neither the scientific literature nor expert input provide a basis for concluding that any single future catastrophic event could cause extirpation in any one geographic unit. It is even less likely that a single future catastrophic event (other than climate change, which we considered as a separate stressor) will eliminate all populations in the DPS. A sequence of catastrophic events over a short time could increase the potential for functional extirpation in one or more of the individual geographic units (e.g., additional large wildfires in north-central Washington), thereby reducing redundancy within the DPS. However, as long as resident lynx remain geographically well-distributed in one or more units within the DPS, extirpation from a single catastrophic event is very unlikely.

With regard to representation, although some lynx populations in the DPS units are demographically isolated from each other and the level of interaction between others is

Comment [MJM41]: The title of the figure and he text should make clear that this is a summary of expert opinions.

Presenting the experts' opinions as line graphs and bar graphs makes it seem as if we are treating these opinions as data – as the best available science. They are only opinions. These opinions can inform our conclusions about how we interpret the science, but only after we have analyzed the reasoning behind hem.

Comment [MJM42]: This better portrays that we are drawing our own conclusions. Using the word "input" rather than "opinions" is a better way to get across the idea that it is the reasoning behind the opinions that matters. "Input" seems to capture both the opinions and he reasoning behind them.

Comment [MJM43]: What about climate change? Shouldn't we qualify his as we do below for the statement about extirpation of the whole DPS?

Comment [MJM44]: Recommend stating his as a probability. "Could" means "possible." I suspect the intended meaning is that it's highly unlikely, not that it's impossible.

Comment [MJM45]: But we didn't say how likely the first claim is that this claim is being compared to.

Comment [MJM46]: What is he likelihood of such a series of events? This statement has no benefit to the analysis without stating the likelihood.

Comment [MJM47]: Of what? A geographic unit or the whole DPS?

uncertain, there seems to be little risk of significant genetic drift. This is because of the currently- observed and likely future high level of gene flow across most of the lynx's continental range, the species' well-documented dispersal capability, the current and likely future absence of significant barriers to dispersal between Canada and the DPS, and continued connectivity between most parts of the DPS and lynx populations in Canada. Based on expert input, there is no indication that the relatively low level of genetic diversity currently observed among lynx populations is likely to reduce DPS viability in the future (USFWS 2016, p. 51). This information suggests the current and likely future relative genetic health of the DPS.

How the potential loss of resident lynx from one or more geographic units may affect representation within the DPS in terms of ecological diversity is uncertain. Despite similarities in the fundamental components (vegetation, snow conditions, and hares) that define the ecological niche of lynx DPS-wide, differences in habitats and how lynx use them are apparent. For example, snow depth that seems to demarcate a boundary between lynx and bobcat occupancy in Maine (270 cm/yr) is almost twice that observed in Minnesota (140 cm/yr]), and lynx in some parts of the West select mature forest stands, particularly in winter, while in other parts of the DPS, young regenerating stands are most important. The loss of resident lynx from any of the geographic units could result in the loss of behavioral and potential future genetic adaptations to the climate-mediated changes now occurring and likely to continue into the future at the southern edge of the lynx range. Such potential adaptability to diminished snow conditions, increasingly patchy and isolated boreal forests, and reduced hare abundance may be important to the taxon as a whole faced with a rapidly changing climate.

In terms of resiliency, expert opinion and our analyses suggest a declining probability of persistence (loss of resiliency) for each of the geographic units within the DPS throughout the rest of this century (the analysis did not extend beyond 2100). Projected climate warming is expected to exert the greatest influence on the resiliency of individual populations, and thus continued presence of resident lynx in each geographic unit. Climate models project that boreal forests and snow conditions favorable for lynx at the southern periphery of the range will retreat northward and upslope with continued warming, further fragmenting and diminishing the quality of lynx and hare habitat within the DPS. Although uncertainty remains regarding the timing, extent, and biological consequences of such impacts, as habitat conditions decline, hare populations will decline and lynx mortality rates are likely to increase and reproductive rates decrease. As snow conditions become less favorable, competitors (e.g., bobcats) are likely to outcompete and displace lynx. This in turn will reduce lynx abundance and density within populations, making populations more susceptible (i.e., less resilient) to stochastic events.

5.1.1 Summaries of Future Conditions in Each Geographic I Unit

Unit 1 – Northern Maine: Although the Northern Maine geographic unit currently has extensive lynx habitat, it may be one of the units in the DPS at greater risk. Forestry practices and climate change will be the greatest future drivers of hare and lynx habitat. Lynx habitat and numbers are expected to decline by 50 to 60 percent by 2032 in response to aging of the budworm-era clearcuts and the effects of 27 years of extensive partial harvesting. In the next few decades,

Comment [MJM48]: But what is he likelihood hat the level of gene flow will not be high? To say there is little risk of genetic drift, we need to be able to say the likelihood is very low hat gene flow will be reduced to a level that would cause his problem. It's apparent that the likelihood is something less than likely, but "less han likely" is not necessarily "very low."

Comment [MJM49]: This better portrays that we are drawing our own conclusions. Using the word "input" rather than "opinions" is a better way to get across the idea that it is the reasoning behind the opinions that matters. "Input" seems to capture both the opinions and he reasoning behind them.

Comment [MJM50]: Again, we don't need to keep referring to expert opinion when presenting "our" conclusions.

Comment [MJM51]: This is a meaningless statement. We need to describe the magnitude of this decline in probability.

high quality hare habitat will drop from about 10 percent to 5 percent of the landscape. High quality habitat patches will become more fragmented, smaller, and more isolated, thus making the landscape less suitable for lynx. For the next few decades the best habitat will occur in the southern portion of the range where effects of climate change and competition with bobcats are likely to be greatest. Absent long-term lynx management agreements, the future of lynx habitat is uncertain. Wood products markets will continue to change, and could be affected by interest in carbon sequestration in response to climate change. Rapid changes in private forest land ownership are likely to continue resulting in subdivision of large ownerships. Changing land uses (wind energy development, transmission line corridors, residential land development, national monument) will compete with forest management as the primary land use. Conservation easements will help reduce development pressures and keep some lands as working forest. Climate change is expected to affect the Maine unit more than others in the DPS because snow depth and duration already seem to be at thresholds for lynx and there are few potential elevational refugia. In the near term and to mid-century, snow quantity and quality will continue to deteriorate, likely causing the range of lynx to begin contracting northward. In the long term (to 2100), some believe lynx could become extirpated from the unit. Climate change, increasing demand for hardwood forest products, a pending spruce-budworm outbreak, and frequent disturbance of the forest all will contribute toward the trend in the loss of spruce-fir forest and expansion of northern hardwoods, although the timeframe for conversion is uncertain. Lynx experts indicate the probability of persistence will decline to about 50% by the end of the century. After reviewing the scientific literature concerning climate change projections (diminishing snow conditions, lack of elevational refugia), some members of the Service's SSA team were more pessimistic about the future of lynx in Maine than the lynx expert panel. There is great uncertainty about the future of forest management and future development on private forest lands. There are no long-term management plans in place, State forest regulations have greatly influenced harvesting practices that have (and will continue to) reduce landscape hare densities, markets for forest products are depressed, and projections (under current harvest scenarios) are that habitat will diminish and shift southward in the near term because of post-harvest succession and recede northward over the longer-term because of continued climate warming.

Comment [MJM52]: This is exactly what we need to do with all he experts' opinions – explain why we agree or disagree. Where is his analysis?

Unit 2 - Northeastern Minnesota: The direct and indirect effects of climate change are expected to affect lynx into the future in Minnesota. Specifically, there is an expected decline in the quantity, quality, and duration of snow; increased competition and hybridization with bobcats; northward contraction of boreal conifer forest; and increased isolation due to diminishing forest conditions in Ontario. The probability of persistence of the lynx population in Minnesota is projected to decrease over time with increasing uncertainty through the end of the century, driven in the near term by the quality, quantity and persistence of snow, competition, disease, and forest insects, and over the long term from the some of the same reasons with the addition of climate change, loss of spruce-fir forests, and wildfires. If the SNF in Minnesota continues to follow vegetation management and other recommendations under the LCAS in their Forest Plan, we expect that several risk factors will continue to be minimized and managed to promote the conservation of lynx within the SNF into the future. It is expected that the MFRC guidelines will remain in place into the future and that voluntary actions will continue on State and private

lands. Taking all factors into consideration (i.e., loss of boreal forest, increased competition, potential disease and insect outbreaks, loss of snow), lynx experts projected the mean probability persistence of lynx in Minnesota to the year 2025 was greater than 90 percent, to 2050 was 80 percent, and would decline to approximately 35 percent by 2100.

Comment [MJM53]: What do WE project and why?

Unit 3 - Northwestern Montana/Northeastern Idaho: As in other units, climate change is projected to reduce the future amount, distribution, and quality of lynx habitats in this unit via northward and upslope contractions in favorable snow and forest vegetation conditions. This will result in increased fragmentation and isolation of habitats and smaller and more isolated lynx populations. Increased wildfire frequency and extent and perhaps other climate-mediated factors (forest insect outbreaks, changes in northern hare/lynx cycles that may influence immigration into this unit) could also reduce future lynx habitats and populations in this unit. Fire- and insect-related habitat losses would likely be temporary, resulting subsequently in improved habitat conditions when impacted areas regenerate the dense vegetative structure conducive to hare abundance. Continued forest management to conserve and maintain the vast majority of lynx habitats in this unit will benefit resident lynx in the future, though it is unlikely to offset the projected adverse consequences of continued climate warming. Lynx experts felt that future extirpation of lynx from this unit due to reduced genetic health or a catastrophic event is unlikely. However, the extent to which the future demographic and genetic health of lynx populations in this unit may be influenced by immigration is unknown. Considering the factors above, lynx experts felt this geographic unit has the highest likelihood of continuing to support resident lynx into the future in the near term (year 2025; median probability of persistence > 0.95), at mid-century (median = 0.90), and end-of-century (median = 0.78), despite a declining probability of persistence and greater uncertainty with increasing time from present, as in all units.

Comment [MJM54]: What do WE conclude?

Comment [MJM55]: What do WE conclude and why?

Unit 4 - North-central Washington: Recent wildfires have temporarily eliminated or reduced the quality of greater than 50 percent of lynx habitat within north Cascades, which has significantly affected the status of and current viability of the lynx population within this geographic unit. Similar to the other geographic units, climate change is anticipated to reduce the future quality and distribution of lynx habitat in Washington, potentially further exacerbating the recent temporary losses of lynx habitat from wildfires. Climate change may increase wildfire frequency and severity, which may result in further temporary losses of lynx habitat. Climate change may also decrease the quantity and quality of snow resulting in permanent reductions in the quantity and distribution of lynx habitat in Washington State. These potential climate change driven reductions of lynx habitat may serve to further isolate lynx populations within Washington State as well as between neighboring lynx populations in the other geographic units and Canada. Continued forest management on both federal and State lands will benefit lynx populations in Washington, but this may not completely ameliorate the potential negative effects related to climate change. Considering the recent reduction in lynx habitat and the projected impacts of climate change, experts predicted near-term (year 2025) persistence probabilities of 60% to 90% (median = 80%), mid-century persistence at 30% to 80% (median = 70%), and end-of century (year 2100) persistence probabilities less than 50% (median = 38%) for lynx populations within this geographic unit.

Comment [MJM56]: What do WE predict and why?

Unit 5 - Greater Yellowstone Area (GYA): As elsewhere, climate change is projected to reduce the future amount, distribution, and quality of lynx habitats in this unit via northward and upslope contractions in favorable snow and forest vegetation conditions. This will result in increased fragmentation and isolation of habitats and smaller and more isolated lynx populations. Because potential habitats in much of this unit already are naturally highly fragmented and perhaps only marginally capable of supporting resident lynx, and because it appears to have never supported more than a small number of residents, its ability to do so in the future is tenuous. Lynx experts felt that the small number of lynx this unit appears capable of supporting and its relative isolation from other lynx populations make it more vulnerable to genetic drift and extirpation due to catastrophic events or demographic or environmental stochasticity. However, the extent to which the future demographic and genetic health of lynx populations in this unit may be influenced by immigration is unknown. Increased wildfire frequency and extent and perhaps other climate-mediated factors (forest insect outbreaks, changes in northern hare/lynx cycles that may influence immigration into this unit) could also reduce future lynx habitats and populations in this unit. Continued forest management to conserve and maintain the vast majority of lynx habitats in this unit will benefit resident lynx in the future, though it is unlikely to offset the projected adverse consequences of continued climate warming. Considering the factors above, lynx experts felt this geographic unit has the lowest likelihood of supporting resident lynx into the future in the near term (year 2025; median probability of persistence = 0.52), at mid-century (median = 0.35), and end-of-century (median = 0.15), with a declining probability of persistence and greater uncertainty with increasing time from present, as in all units.

Unit 6 - Western Colorado: Climate change is expected to affect vegetation and influence snow conditions within the Western Colorado unit. The elevation gradient in Colorado may provide refugia from deteriorating snow quality, depth, and duration throughout the period. Climate models suggest a 40 percent decline in snow persistence, but large areas of snow persistence will remain through the end of the century. Experts suggest that beetle kill and fire will result in unsuitable habitat conditions. However, these areas are likely to regenerate and provide excellent habitat conditions to support hares and lynx. A caveat to future habitat conditions in light of climate warming is that some areas that currently support snowshoe hare populations may experience vegetation type conversion that may not support snowshoe hares. The majority of the experts predicted the persistence of a viable lynx population in the unit by 2100, but further discussion revealed uncertainty about persistence in the unit, and genetic connectivity across ski areas in the unit.

Table 4, below, summarizes factors thought likely to influence the future resiliency of lynx populations in each geographic unit.

Table 4. Predicted ~~F~~future (2050 to 2100) resiliency of individual units of the Canada lynx DPS

Lynx population	Lynx expert probability of	Key evidence	Uncertainties

Comment [MJM57]: What do WE conclude and why?

Comment [MJM58]: What do WE conclude and why?

Comment [MJM59]: Is this our thought or the experts'?

Comment [MJM60]: To he point of retracting he prediction? Need to explain he magnitude of the uncertainty.

Comment [MJM61]: By whom? The experts or us? The ti le of the table needs to make this clear.

Comment [MJM62]: See above comment. Need to make it clear if this represents our hinking or the experts' hinking.

	persistence		
Unit 1 Maine	2050 median 80% (range 20 to 100%) 2100 median 50% (range 0 to 100%)	• 50% decline in habitat expected by 2032, habitat will occur in south edge of range • Slight recovery of habitat by end of century depending on forestry trends • Continued demographic and genetic connectivity to southern Quebec, New Brunswick populations • Climate models predict deteriorating snow quality, depth and duration below thresholds for lynx; more severe than other units • Little elevation refugia	• Future forest management trends and habitat conditions on private forest lands in Maine and Canada • Future shifts in land ownership, forest products markets, and development • Extent and pace of deteriorating snow conditions • Response of hares (pelage mismatch), bobcat and fisher to changing snow regime • Extent and pace of loss of spruce-fir • Future trends in hare populations • Disease and parasites in lynx • Effects of lynx trapping in Quebec
Unit 2 Minnesota	2050 median 80% (range 35 to 100%) 2100 median 35% (range 0 to 100%)	• Smaller population could be susceptible to stochastic effects • Habitat conditions on national forests will remain stable or improve if managed for softwoods • Continued demographic and genetic connectivity to southern Ontario populations • Climate models predict deteriorating snow quality, depth and duration below thresholds for lynx • Little elevation gradient: lake-effect snow may retain refugia to 2050 but not 2100	• Future forest management trends and habitat conditions on private forest lands in Minnesota and Ontario • Extent and pace of deteriorating snow conditions • Response of bobcat and fisher to changing snow regime • Rate of decline of spruce-fir • Future trends in hare populations • Disease and parasites in lynx
Unit 3 Northwestern Montana	2050 median 90% (range 40 to 100%) 2100 median ~78% (range 10 to 100%)	• Some habitat loss from increased wildfire, otherwise habitat will remain stable with USFS management • Continued demographic and genetic connectivity to southern British Columbia populations • Potential high elevation buffer against climate change • Recent loss of small sub-metapopulation in Garnet Range • Increasing fire frequency	• Extent and frequency of fire in hare-lynx habitat • Extent and frequency of insect outbreaks • Extent and pace of deteriorating snow conditions • Response of bobcat, pumas, coyotes to changing snow regime • Extent and pace of elevational migration of spruce-fir • Mismatch in elevation between appropriate snow regime for lynx and spruce-fir • Future trends in hare populations
Unit 4 North-central Washington	2050 median 70% (range 10 to 100%)	• Habitat and population low because of recent fires; could be susceptible to stochastic effects • Continued demographic and genetic	• Extent and frequency of fire in hare-lynx habitat • Extent and frequency of insect outbreaks

	2100 median ~38% (range 0 to 90%)	connectivity to southern British Columbia populations ● Elevation is not sufficient to provide long-term refugia from deteriorating snow quality, depth, and dura ion	● Extent and pace of deteriorating snow conditions ● Response of bobcat, pumas, coyotes to changing snow regime ● Extent and pace of elevational migration of spruce-fir ● Future trends in hare populations
Unit 5 Greater Yellowstone	2050 median 35% (range 0 to 90%) 2100 median 15% (range 0 to 90%)	● Habitat loss from 1980s wildfire, otherwise habitat will remain stable with USFS and NPS management ● No connectivity with Canada populations; little immigration from DPS populations ● Elevation may provide refugia from deteriorating snow quality, depth and duration ● Low quality habitat; dry; low hare populations ● Smaller population could be susceptible to stochastic effects	● Will habitat support adequate landscape hare densities to support lynx? ● Extent to which GYA remains demographically isolated from other DPS populations; immigration from Colorado population ● Extent and frequency of insect outbreaks ● Extent and pace of deteriorating snow conditions ● Response of bobcat, pumas, coyotes to changing snow regime ● Extent and pace of elevational migration of spruce-fir ● Future trends in hare populations ● Extent to which high elevation may provide climate and snow refugia ● Extent to which area will be repopulated by the north and/or the south
Unit 6 Western Colorado	2050 median 80% (range 20 to 100%) 2100 median 50% (range 0 to 100%)	● Habitat loss from increased wildfire and insect outbreaks, otherwise habitat will remain stable with USFS management ● Isolation from other lynx populations ● Elevation may provide refugia from deteriorating snow quality, depth and duration ● Uncertainty about stability of recently-reintroduced lynx population	● Demographic and genetic effects of isolated population ● Extent and frequency of fire in hare-lynx habitat ● Extent and frequency of future insect outbreaks ● Extent and pace of deteriorating snow conditions ● Response of bobcat, pumas, coyotes to changing snow regime ● Extent and pace of elevational migration of spruce-fir ● Mismatch in elevation between appropriate snow regime for lynx and spruce-fir ● Future trends in hare populations

5.2 Future Conditions - Detailed Descriptions by Geographic Unit

5.2.1 Unit 1 - Northern Maine

Expert Projections of Future Lynx Status

Most experts indicated an initially high and subsequently declining probability of persistence of resident lynx in Maine through the end of the century, with uncertainty (range between lowest and highest probabilities) also increasing over time (Lynx SSA Team 2016, pp. 33-36 and Fig. XX below). Climate change was an overriding near- and long-term stressor.

Increased winter precipitation in the form of rain, reduced snow depth, and reduced snow durations were discussed. Changes in snow conditions will favor bobcats and fisher (a predator of lynx that is limited by deep snow). Experts believed that the effects of climate change would continue to increase as a stressor by mid- to the end of the century (2050, 2100). Snow conditions would continue to deteriorate (especially in the northern Maine unit compared to other areas in the DPS) resulting in increased competition with bobcats and predation by fisher. Climate-induced loss of spruce-fir forest will occur slowly, and an increase in northern hardwood composition of the forest is already occurring. Loss of spruce-fir could be accelerated by forest disturbance (budworm outbreak, forest management affecting large acreages of lynx habitat annually).

Experts expressed a number of near-term stressors (in the next 15 years) related to forest management in northern Maine. Land management objectives were uncertain because of changes in private forest land ownership. Changes in forestry management because of the Maine Forest Practices Act (shift to partial harvesting, increasing acreage harvest, habitat shifting to south) would result in increased fragmentation and declining lynx and snowshoe hare habitat (succession of previous clearcuts from young, dense regenerating stands to mature stands less conducive to high hare densities).

There was uncertainty concerning the severity and response by new landowners to the next spruce budworm outbreak. Experts were concerned that investment landowners would not respond to the pending spruce budworm outbreak like they did in the 1970s (extensive clearcuts, herbicide application). Experts also acknowledged concerns about the effects of the current clearcuts aging past conditions that support hares and lynx.

Hare populations have declined by about half across all stand types (and in adjacent Quebec) since 2006 and apparently have not rebounded. In response, lynx initially had lower reproduction (lower proportion of females breeding, slightly lower litter sizes), but this has not affected home range sizes. Lower landscape hare densities are likely to support lower lynx populations. It is uncertain how hare numbers will cycle or fluctuate in the future.

Comment [MJM63]: See earlier comment. Need to explain what we think about he experts' opinions and heir rationale and draw our own conclusions – and own those conclusions. Where do we do this?

Comment [MJM64]: To avoid confusion with lis ing status (i.e., E/T), refer to "population status" or "persistence."

Comment [MJM65]: Didn't hey all indicate his? Can't this be said of every species on earth?

Although uncertainty increases with time from the present, experts generally agreed that climate-related loss of favorable snow conditions (amount, consistency, and duration), loss of spruce-fir, and bobcat competition are likely to reduce the probability of lynx persistence in this unit. Modeling of current lynx habitat and future habitat trends was more advanced for the Northern Maine Unit than other units. Models indicate that aging of past clearcuts and changes in forest practices to partial harvesting will diminish the current lynx habitat by half in coming decades. Experts and the core team expressed uncertainty about the severity of a pending spruce budworm outbreak, forestry response by investment company landowners, and how this will affect future lynx habitat. More is known about long-term trends in snowshoe hare populations in this unit than others. Hares seem to have declined by half since about 2006 and have remained low. Experts and the core team were uncertain about whether hare numbers would rebound or remain at this lower level, but lower hare densities are affecting demographics (especially percentage of females breeding), which could contribute to population declines. Taking all of these factors into consideration, the experts projected the mean probability of persistence to the years 2025 was greater than 95 percent, to 2050 was about 80 percent (range from 20 to 100 percent), and to 2100 was about 50 percent (range from 0 to 100%)(Lynx SSA Team 2016, pp. 33-34, Fig. 8). The USFWS lynx core team generally agreed with this prognosis with the exception that some were less optimistic about the persistence of this population, especially after reviewing the literature pertaining to climate change in this region.

Comment [MJM66]: These ranges encompass the full range of responses. For the other units, hese ranges encompass just he "most likely" points. Why the difference for the Maine unit?

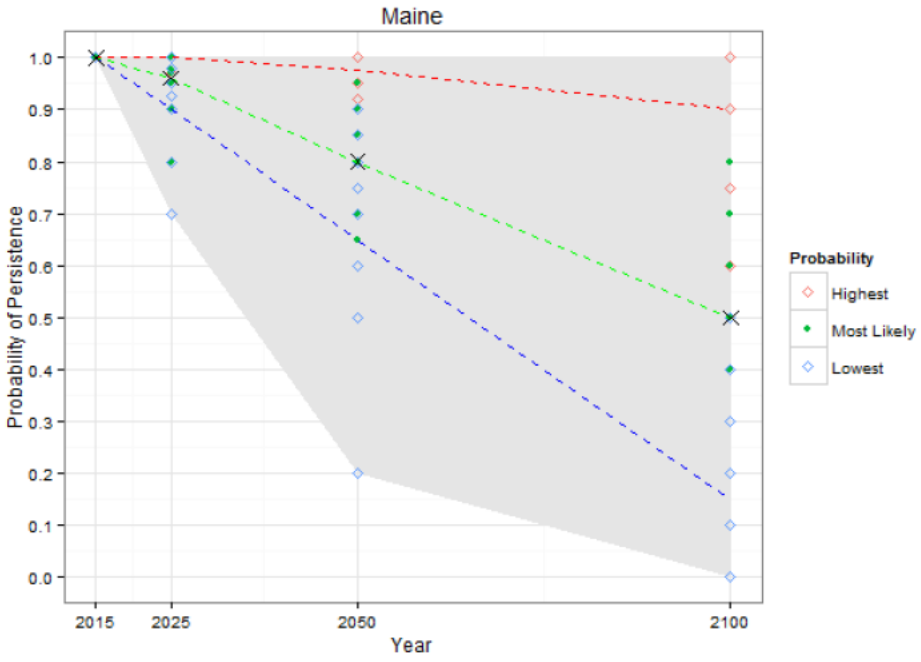

Figure 8. Lynx expert estimates of the probability that the Northern Maine Geographic Unit will continue to support resident lynx in the future (at years 2025, 2050, and 2100).

Note: In Figure 8, above, and similar figures for the other geographic units, below, points for each of the 10 expert responses, for each of the three probability-of-persistence levels, i.e., highest, most likely, and lowest probabilities of persistence, are represented by the hollow red, filled green, and hollow blue points respectively. The black x mark is the median of the most likely responses across the experts in each response year. The red, green, and blue dashed lines connect the median of the highest, most likely, and lowest probability of persistence responses across the experts in each response year. The edges of the grey area were defined by the extreme responses, i.e., the range from the largest of the highest probability of persistence responses to the smallest of the lowest probability of persistence responses. The median lines and grey area are provided as a summarizing visualization to aid comprehension of the experts' responses and their range, and should not be viewed as a substitute for individual responses or presented outside the context of the accompanying discussion.

Service Evaluation of Factors Influencing Future Conditions

Comment [MJM67]: Where do we explain whether we agree or disagree with the experts' opinions and why? The "Service evaluation" for each unit seems to be independent of he discussions about the preceding "Expert Projections" for each unit I was expecting this explanation to be in he Service evaluations.

Regulatory Mechanisms - In response to public concern about widespread clearcutting in northern Maine, in 1989 the Maine Legislature passed the Maine Forest Practices Act (MFPA). The MFPA regulates maximum size of clearcuts (250 acres), separation zones between clearcuts, harvest plans, and notification to the Maine Forest Service. Clearcuts are not banned, but require varying levels of state permits depending on their size. As a result, the number and acreage of clearcuts completed annually has declined substantially and have been replaced by various forms of partial harvesting (Sader *et al.* 2003, p. 349-350, McWilliams *et al.* 2003, p. 35). In the first decade following passage of the MFPA, the percentage of acreage clearcut in Maine annually declined from 40 percent to 4 percent (Simons 2009, pp. 45-46). The average size of clearcuts has been reduced from >125 acres (Maine Forest Service 1995) to <25 acres (Maine Forest Service 2003, 2005, 2007). Currently, partial harvesting comprises about 94 percent of acres cut annually in Maine (Simons 2009, p. 50). The total volume harvested, however, changed relatively little. The partial harvest that replaced clearcuts include a variety of silvicultural treatments, including both even-aged (e.g., shelterwood) and uneven-aged (e.g., selection) management that result in a wide range of residual stand conditions (Robinson 2006), which have important implications for lynx conservation. Foremost, snowshoe hare densities in partially harvested forests are on average about 50 percent lower (but range from 20 to 90 percent lower) than in regenerating conifer stands created by clearcutting (Robinson 2006, entire; Scott 2009, p. 109, Simons 2009 p. 83), thus reducing landscape hare density and presenting a challenge for future lynx conservation (Simons 2009, pp. 206, 209, 217; Simons-Legaard *et al.* 2016, p. 7-8; Simons-Legaard 2016, entire).

To harvest the same volume of wood annually, landowners must partial harvest many more acres than they would under former clearcutting silvicultural systems. The acres of forest harvested annually in Maine have increased from about 250,000 acres pre-MFPA to 550,000 acres post-MFPA (McWilliams *et al.* 2003, p. 35). Currently, 27 years after implementing the

MFPA, much of the 10 million-acre northern Maine landscape has been influenced by partial harvesting. Extensive partial harvesting and aging of the spruce budworm-era clearcuts will reduce landscape hare densities (Simons-Legaard *et al.* 2016, 9-10). If the current landowners continue to harvest using similar methods at and similar rates, habitat for lynx will diminish by about 50 percent by 2030 (Simons-Legaard 2016, pp. 9-10). After 2030, projected outcomes for lynx habitat become more uncertain and depend on assumptions about habitat definitions and harvest rates. Lynx in Maine selected for regenerating, conifer-dominated forest (>75 percent conifer, Vashon *et al.* 2008, pp. 1490, 1492-1494). If one defines lynx habitat as stands having greater than 75 percent spruce-fir, then habitat will decline by about 50 percent by 2030 and remain at about at this level through 2060 (Simons-Legaard 2016, pp. 9,16).

These projections do not consider the next outbreak of spruce budworm. After being low for the last 20 years, spruce budworm numbers are again building toward epidemic levels in Maine, southern Quebec, and northern New Brunswick. Significant defoliation in Maine is expected to begin between 2018 and 2021 (Wagner *et al.* 2014). Although Maine research has clearly demonstrated that landowner response to the last outbreak resulted in unintended, positive benefits for lynx from one to three decades later, our ability to project what effects the next outbreak will have on lynx habitat is still limited. Land ownership has changed dramatically since the last outbreak. To reduce risk from spruce budworm, some financial investment owners may cut younger spruce-fir stands that still support elevated hare populations. Some may be less inclined to intensively manage for spruce-fir. It is unlikely that current landowners will use widespread use of pesticides to control spruce budworm and herbicides to promote spruce-fir regeneration after stands are defoliated. The MFPA may serve as an additional constraint on motivation to clearcut infested stands, even with recently-enacted changes intended to reduce the regulatory burden for landowners. Landowner response to the pending outbreak will have important implications for the short- and long-term persistence of lynx habitat in the northern Maine unit (Simons-Legaard 2016, pp. 16-17).

Nor do these projections consider a substantial decline in snowshoe hare densities that has occurred in Maine. Snowshoe hare density declined by 69.3 percent from a period of high hare density in 2001-2006 (average of 2.1 hares/ha in regenerating conifer) to a period of lower hare density 2007-2009 (average of 1.0 hares/ha). This decline occurred across all forest stand types and across a broad geographic area of Maine (Scott 2009 p. 36) and the adjacent Gaspe region of southern Quebec (Assells *et al.* 2007, Scott 2009, p. 41-42). Hares remained at these lower numbers through 2013 (D. Harrison, University of Maine, unpublished data). If future hare populations remain low, then Maine habitats will have a lower capacity for supporting lynx.

Climate Change - The northern Maine unit is more vulnerable to snowpack loss because of the lack of elevational refugia (Siren *in* Lynx SSA Team 2016, pp. 15 and experts p. 37) and changes in snow conditions could further restrict their range (Hoving 2002, Hoving *et al.* 2005, Carroll 2007). Wildlife experts in Maine ranked lynx as highly vulnerable to climate change (>66 percent loss in species range/population and extirpation within 50 to 100 years) (Whitman *et al.* 2013, p. 19, 74). Similarly, Carroll (2007, entire) modeled Maine lynx population assuming non-cycling hare populations and snow conditions expected under intermediate to high emissions

Comment [MJM68]: Lynx in Maine, or lynx everywhere?

climate models (Kiehl and Gent 2004, entire). He predicted a 59 percent decline in the lynx population (the non-cycling hare population model) by mid-century because of climate change alone. Maine lacks elevational refugia for lynx under reduced snow scenarios (Carroll 2007, p. 1102), except for the mountains in western Maine where snow refugia may only persist as very small, isolated “sky islands” that would be unlikely to support lynx.

Climate change is affecting the Northeast, and the rate of change is faster than expected (Rustad *et al.* 2014). Rapid winter warming in recent decades is believed to be caused by reduced albedo feedback caused by the reduced persistence of snow in winter (Hayhoe *et al.* 2006). Average winter temperatures are increasing 0.42-0.46^{o} C/decade with the greatest warming occurring in the coldest months of winter (January, February)(Burakowski *et al.* 2008). Northeast climate models predict average winter temperature increasing 2.0^{o}C (low emission) to 2.9^{o}C (high emission) by mid-century and 3.1^{o}C (low emissions) to 5.3^{o}C (high emissions) by late century (Notaro *et al.* 2014). Largest increases in temperature are expected in northern Maine (A. Siren, Workshop Notes 2016, Rawlins *et al.* 2012) where temperatures may increase 4.5 to 5.0^{o} F by 2050 (Fernandez *et al.* 2015, p. 3). In response to climate change, interest in wind development has escalated in northern and western Maine increasing threats to high elevation and potential spruce-fir refugia (Whitman *et al.* 2013). Climate conditions are currently at or falling below threshold values needed to support lynx in Maine.

If future trends in increasing temperature and decreasing snow occur, then lynx are unlikely to persist in Maine. Gonzales *et al.* (2007, entire) modeled distribution of boreal forest and future snow conditions under nine different low, medium, and high emission scenarios (IPCC 2007) and predicted loss of forest and snow conditions able to support lynx in Maine by the end of the century. Although there are uncertainties about future climate warming, lynx populations in Maine are expected to recede northward and decline substantially this century (Vashon *et al.* (2012, p. 60).

Snow Duration. The current average snow duration in Maine is at or below the 4-month snow persistence thresholds believed needed to support lynx (section 4.1.1, Gonzales *et al.* 2007) and is projected to decline. Snow duration is projected to continue to deteriorate. Snow duration declined by 16 days in the Northeast from 1970 to 2001 (Wake 2005) and is expected to diminish another ~~two~~2 weeks in Maine by mid-century (Fernandez *et al.* 2015). Snow duration is expected to diminish by 25 percent (low emissions) to 50 percent (high emissions) from current conditions by the end of the century (Hayhoe *et al.* 2006). Similarly, Notaro *et al.* (2014) projected an average decrease of 28 days (low emission) to 47 days of snow cover (high emissions) by the end of the century.

Snow Depth. The current average snow depth in northern Maine is at or below the 270 cm/yr. (106 in/yr) thresholds believed needed to support lynx (section 4.1.1; Hoving *et al.* 2005) and is expected to decline. By the end of the century, large areas of the Northeast will experience 15-percent (low emission) to 25-percent (high emissions) reduced snowfall (Ning and Bradley 2015). Similarly, by the end of the century Notaro *et al.* (2014) projected average snow declines in the North Atlantic Landscape Conservation Cooperative of 59 cm (31 percent) (low

emissions) to 92 cm (48 percent) (high emissions) because a higher proportion of winter precipitation will fall in the form of rain rather than snow. Winter precipitation in Maine is likely to increase by 10 to 15 percent by the end of the century (Hayhoe *et al.* 2006) with a greater proportion of winter precipitation falling as rain (Huntington *et al.* 2004, Hayhoe *et al.* 2007, Ning and Bradley 2015).

Snow Quality. Winter precipitation in Maine is likely to increase by 10 to 15 percent by the end of the century (Hayhoe *et al.* 2006) with a greater proportion of winter precipitation falling as rain (Huntington *et al.* 2004, Hayhoe *et al.* 2007, Ning and Bradley 2015). Snow density and compaction (caused by wet, heavy snow or rain on snow events in winter) will continue to increase in the region in the future (Dudley and Hodgkins 2002, Huntington *et al.* 2004, Huntington 2005, Hodgkins and Dudley 2006, Karl *et al.* 1993).

Loss of Boreal Forest. Climate change is projected to cause a northward contraction of spruce-fir forest in the Northeast with potential negative consequences for both lynx and snowshoe hares (Gonzales *et al.* 2007, entire). Spruce-fir forest is expected to decline substantially in Maine and the Northeast (Ollinger *et al.* 2007 Beckage *et al.* 2008, Tang and Beckage 2010, Whitman *et al.* 2010, p. 12, Jacobson *et al.* 2009, p. 27) or disappear (Iverson and Prasad 2001, pp. 192-193, Prasad *et al.* 2007) because of climate change. Climate change is anticipated to increasingly fragment the boreal forest in northern New England (Iverson *et al.* 2008, Ollinger *et al.* 2008, Whitman *et al.* 2013). Lynx habitat will decline as boreal forest diminishes (Simons 2009). Even under the lowest emissions scenarios, spruce-fir forest would be greatly reduced by 2100 (Williams and Liebhold 1997, Prasad *et al.* 2007), although some spruce-fir may persist at highest elevations (Tang and Beckage 2010) and along the eastern coast (Jacobson *et al.* 2009) where cooler conditions will prevail.

The spruce-fir forest type has come and gone from New England during the post-glacial period. It nearly disappeared from the Northeast during interglacial warming period 1000 years ago, then moved south into New England only in the past few centuries during the “Little Ice Age” (Schauffler and Jacobson 2002, DeHayes *et al.* 2000). Because of its sensitivity to climate and mobile nature, Iverson *et al.* (2008, p. 403) predicted a significant decline (low emissions) or the disappearance (high emissions) of the spruce-fir forest type in northern Maine in response to climate change.

Spruce (red, black, white) and balsam fir are the most important boreal forest conifer tree species in the Northeast and will be affected by climate change in different ways. Mechanisms of injury to spruce-fir include winter injury from freeze-thaw cycles, spring drought (because of reduced snowpack), and reduced seed germination (Perfect *et al.* 1987, Auclair *et al.* 2010). Thus, the range of spruce-fir is limited by summer heat and drought. Mohan *et al.* 2009 projected that suitable area for balsam fir would decline by 80 percent in 2100 under an average to high emissions scenario. In contrast, Ollinger *et al.* (2008) projected increasing growth rates for balsam fir and red spruce to mid-century, after which they would decline.

The timescale of the spruce-fir decline in the Northeast is difficult to predict because of the many variables that influence shifting of the forest species composition (emissions scenarios, the long lifespan of trees, slowness of tree dispersal, frequency of disturbance, competition from advancing hardwoods and invasive tree species, complex interactions with moisture, and synergistic effects with other pollutants). Arguments in favor of an accelerated decline include evidence that spruce-fir is already in decline (Seymour 1992, Simons 2009) and is being replaced in Maine by northern hardwoods (oak, pine, red maple). The decline of the spruce-fir forest type is accelerated by forest disturbances. A pending spruce budworm outbreak and frequent disturbance from forest management could accelerate conversion to northern hardwoods in northern Maine and eastern Canada (Flannigan *et al.* 2001, Gauthier *et al.* 2015). Other climate-related forest disturbances (forest pests, diseases) could further accelerate conversion to northern hardwoods (Iverson *et al.* 2008, p. 404).

In contrast, some authors note that trees migrate slowly and are long-lived. Therefore, a time lag may occur in shifting forest composition from spruce-fir to northern hardwoods (Mohan *et al.* 2009, Zhu *et al.* 2012). Some northern Maine industrial forest landowners could "adapt" to climate change by intentionally favoring spruce-fir (e.g., by plantations and use of herbicides). McWilliams *et al.* 2005 (p. 8) noted that balsam fir increased in Maine's forest inventory in the 2000s. Forest models projected increases in spruce-fir biomass over the next century because of partial harvesting and periodic budworm outbreaks, but did not take climate change into consideration (Simons-Legaard *et al.* 2013).

Finally, there is uncertainty concerning the influence of climate change on balsam fir, a short-lived, shade-tolerant, conifer that dominates much of the understory in the Acadian forest and is an important component of lynx habitat in the Northern Maine Unit. Climate change will influence precipitation and temperature, forest management strategies, and forest disturbance (fire frequency and spruce budworm), all of which will interact in complex ways to influence the spruce-fir forest at the southern edge of its range. Carter (1996), Iverson *et al.* (1999), and Goldblum and Rigg (2005) documented balsam fir growth rates and growth potential would decline under likely climate warming scenarios (~4 to 5 F degree temperature increase by the end of the century and reduced snow conditions). Some have projected the extirpation of spruce-fir forest types in the Great Lakes States (Scheller and Mladenoff 2005) and New England (Iverson and Prasad 2000). In contrast, balsam fir has prolific seed production following forest disturbance such as harvesting (Seymour 1992), and has proliferated under the current climate and forest management regime dominated by partial harvesting (Olson *et al.* 2013, entire). Balsam fir is a relatively short-lived tree (~100 years), and is unlikely to persist long if climate change affects seed and germinations rates. Given, anticipated climate changes, especially early snow melt and low spring precipitation, fir may increase for the next few decades but is unlikely to regenerate in a the future Maine forest (E. Simons-Legaard, University of Maine, pers. comm. May 31, 2015).

Vegetation Management - Habitat suitable for lynx is expected to decline in the future (see Regulatory Mechanisms section above). By 2020, all of the extensive areas that were clearcut in the 1970s and 1980s will be greater than 35 years of age and no longer support high hare

densities. For the foreseeable future, partial harvesting will continue as the primary means of forest management. Although partially harvested forests with well-developed understory structure may provide foraging opportunities via increased prey access (Fuller *et al.* 2007), snowshoe hare densities are approximately 50 percent less in landscapes dominated by partially harvested stands (Robinson 2006, entire; Fuller and Harrison 2010). Thus changing forest management practices will continue to reduce landscape hare density below levels that can support lynx.

Sources of uncertainty concerning future habitat conditions in northern Maine include changes in forest policy, timber harvesting methods, changing timberland ownership, response to budworm outbreaks, and timber markets - all of which have occurred in the recent past and will undoubtedly shape forest management in the future (Simons-Legaard *et al.* 2016, p. 8). Currently, the landscape is owned primarily by financial investors who may be less inclined to intensively manage for spruce and fir after the next outbreak of the spruce budworm (Wagner *et al.* 2014).

The dramatic shift from clearcutting to partial harvesting presents a challenge for lynx conservation in this unit for the next several decades. Lynx, habitat is expected to peak and remain stable through about 2020 (Simons 2009, Simons-Legaard *et al.* 2016 p. 6). After 2020, aging of the former clearcuts and extensive partial harvesting are projected to result in a 50 to 65 percent decline in lynx habitat by 2032. Lynx habitat will decline from about 9.5 percent of the landscape (current condition) to about 4.5 percent of the landscape (Simons-Legaard 2016). By 2032, the Northern Maine Unit may support less than half the lynx population as it does today (Simons 2009, p. 209, 217).

In the future, lynx habitat will be fragmented into smaller, isolated parcels, and will shift southward into areas occupied by bobcats and fishers where snow conditions are unlikely to support lynx (Simons 2009, Simons-Legaard *et al.* 2016, Simons-Legaard 2016). By 2022, the number of patches of high quality hare habitat will increase by 57 percent, but the average size of patches will be diminished by 87 percent, and patches will become more isolated (Simons-Legaard *et al.* 2016, pp. 5-6). The proximity index of high quality habitat patches will decline by 78 percent within lynx home ranges. Although lynx habitat is peaking, fragmentation is diminishing its ability to support lynx (Simons-Legaard *et al.* 2016).

Beyond 2030 assumptions concerning future climate change, land ownership, and harvest rates introduce greater uncertainty. The most optimistic forest management models (greatest harvest rates, no climate change, no spruce budworm) project that lynx habitat will decline over the next few decades then gradually increase to about 10 percent of the landscape by 2060. The most most pessimistic models (lowest harvest rates, no climate change, no spruce budworm) project about 5 percent of northern Maine will have high quality hare habitat (Simons-Legaard 2016, entire), although the habitat will be much more fragmented and smaller patch size (Simons-Legaard *et al.* 2016).

Softwood plantations could offset losses in spruce-fir and become a form of adaptation to climate change. Jack pine plantations are extensive in adjacent New Brunswick (Etheridge *et al.* 2005, p. 1966). A forest company that has planted extensive spruce plantations in New Brunswick and recently purchased nearly 1 million acres of forestland in northern Maine where they are doing the same. Spruce plantations are becoming more common on this ownership in Maine, but not others. Stand structure and intensive management of plantations are highly variable (e.g., pruning, thinning, herbicide treatments), thus hare density and use by lynx vary (Roy *et al.*) Hares can achieved higher densities in plantations depending on the amount of lateral cover, but for shorter periods of time; ~10 to 17 years after cutting and planting in New Brunswick (Parker 1984, p. 163) and 15 to 25 years in Quebec (Roy *et al.* 2010, p. 585). This is in contrast to ~15 to 35 years in naturally regenerating spruce-fir stands after harvest (Simons-Legaard *et al.* 2016, p. 4). The future of plantations in the northern Maine unit is uncertain. Most investment landowners have short-term investment horizons and are unlikely to invest in plantations.

Natural stand-replacing disturbances are rare and infrequent and, other than spruce budworm outbreaks, are unlikely to significantly affect future habitat conditions (Hoving *et al.* 2004). A spruce budworm outbreak is projected to reach epidemic proportions in 2018 to 2021. The epidemic has already affected 10 million acres of spruce-fir in southern Quebec, immediately north of Maine (Wagner *et al.* 2014, entire). The last outbreak in the 1970s and 1980s killed millions of acres of spruce and fir forests in the northern Maine unit. Maine's 5.8 million acres of spruce-fir stands across the state are at risk of some level of defoliation. The intensity of the next outbreak is uncertain, although some project a weaker outbreak because spruce and fir trees are younger and less susceptible and there is a higher hardwood component in northern Maine forests (Wagner *et al.* 2014, p. 21-27). A typical outbreak lasts for a decade.

Forest management strategies for addressing the coming outbreak vary and include applying insecticides (although land area sprayed is expected to be small compared to the previous outbreak), pre-emptive cutting of mature spruce-fir before defoliation, stop precommercial and commercial thinning, and salvaging dead and diseased trees (Wagner *et al.* 2014, pp. 5-6). An aggressive forest management response (or not) will greatly affect future outcomes for lynx habitat (see section 5.2.1). The next budworm outbreak and subsequent forestry response is a disturbance agent that may accelerate changes in forest composition influenced by climate change, especially toward increased northern hardwood and reduced spruce-fir. The nature of landownership is greatly changed from the 1970s and 1980s, and landowner response is expected to be diverse depending on their objectives and investment horizons. The pending budworm outbreak cast additional uncertainty on the status of lynx habitat beyond 2030.

Climate change, forest management and budworm outbreaks will interact to influence the future trajectory of spruce-fir forest in Maine. All three variables have yet to be modeled simultaneously (K. Legaard, UMaine, personal communication). Assuming current forest management trends persist to the end of the century, spruce-fir dominated forest is expected to continue to decline (Legaard *et al.* 2013, entire). The combination of budworm-induced mortality and salvage harvesting will have a negative effect on spruce-fir (Legaard *et al.* 2013, entire).

However, after a budworm outbreak the biomass and area of mixed-hardwood/softwood forest would be expected to increase through this century primarily because of regenerating balsam fir (see discussion above) (Legaard *et al.* 2013). Mixed forests having a high hardwood component are not believed to support high hare densities (Scott 2009, p. 109) or be preferred by lynx (Vashon *et al.* 2008, pp. 1492-1493). It is uncertain whether lynx can adapt to lower landscape hare densities associated with mixed hardwood-softwood forest. They may persist, but at lower densities as they currently do in the western units of the DPS. However, the probability of persistence is further diminished by deteriorating snow conditions and increased populations of bobcats and other competitors.

Fire Management - Susceptibility of the northern Maine unit to fire may be enhanced by a severe spruce budworm outbreak because of the amount of dead and dying spruce-fir (Stocks 1987), although there were no large fires after the last outbreak. Fire risk is currently very low in this unit and a continuous decrease in fire frequency is predicted with climate change in eastern Canada because of increased precipitation and decreased drought (Bergeron and Flannigan 1995, Flannigan *et al.* 1998). Climate is expected to become more variable during the next century (Gregory & Mitchell 1995; Gregory *et al.* 1997), which could create fire conditions in unusually dry years (Flannigan *et al.* 1998, p. 475). Maine's policy is to immediately suppress wildfire, thus large, stand-replacing fires are expected to be infrequent in this region. Notable large fires in Maine include a 3 million-acre fire in 1825 and a 200,000-acre fire in 1947.

Habitat Fragmentation - The future of the 10 million-acre, sparsely populated "North Woods" of Maine is highly uncertain and has been the subject of intense public debate (Baldwin *et al.* 2007). Land use and zoning in the state's "unorganized townships" are the responsibility of the Land Use Planning Commission (LUPC) in the Maine Department of Conservation. The LUPC revised its Comprehensive Land Use Plan (De2010), and described principal values in guiding future land management decisions: maintaining working forests, provide for traditional recreational opportunities, protect high-value natural resources, and encourage long-term conservation. The North Woods has long been considered a public resource or "commons," even though privately owned (Judd 2007, p. 9). This land was traditionally owned by a few large timber companies, but since the 1980s there has been rapid turnover in ownership largely by investments companies and subdivision of large parcels (Hagan *et al.* 2005). Financial investors, such as REITS and TIMOs focus on maximizing the asset value of timberlands and are increasingly likely to seek revenue from non-timber resources if they will generate a higher return. These new owners operate over relatively short time horizons (e.g., 5 to 15 years) and are willing to consider multiple means of monetizing their asset, including development and real estate sales (Legaard 2013, entire). If left unchecked, these pressures may continue to promote dispersed residential development throughout this region. Parcelization and subdivision has increased, particularly in the southern third of the jurisdiction (Maine Department of Conservation 2010, p. 72-73). The LUPC has limited ability to address stressors on Maine's North Woods, including resale and subdivision trend. This trend is likely to continue into the foreseeable future and will make management of large, forested landscapes for Canada lynx even more difficult.

Historically, development has stayed mostly on the edges of the North Woods jurisdiction with exception of scattered seasonal dwellings and sporting camps in the interior, but this could change in the future. Between 1971 and 2005, the LUPC permitted 8,136 new dwellings in unorganized townships — an increase of 66 percent in the number of residences during this time period (Maine Department of Conservation 2010, p.80). Between 1971 and 2005, the LUPC issued 1,353 development permits for new uses scattered throughout the unorganized townships (Maine Department of Conservation 2010, pp. 97-99); most (42 percent) being recreational facilities (boat launches, campsites, gatehouses, recreational lodges). Most development has occurred in areas that abut organized communities and near public roads. Within the interior most development has occurred on long lakeshores and waterfront. However, the amount of hillside and ridge development is growing and this trend is likely to continue (Maine Department of Conservation 2010, p. 136), which will further fragment lynx habitat.

We have an incomplete understanding of the effects of outdoor recreation on lynx and their habitat (ILBT 2013, p. 80). Future trends in outdoor recreation in northern Maine are also uncertain (Vail 2007, entire). A portion of the North Maine Woods is a gated road system that encompasses about 3.5 million acres. Visitation by outdoor recreationists is currently about 175,000 per year and declining. Likewise, visitors to Baxter State Park and the Allagash Wilderness Waterway have declined (Vail 2007, p. 107). Aside from a vigorous discussion of a proposed national park or monument, national heritage area, or a master tourism plan for the area (Vail 2007, pp. 112-113), there is likely to be stagnant or declining participation in traditional outdoor recreational activities in the future (Vail 2007, p. 107). Snowmobiling may be an exception because of declining snow (see climate change section). The effects of new or expanded downhill ski development on fragmentation of lynx habitat are expected to be minimal. Three alpine ski resorts occur within the unit on the southern margin of lynx habitat: Saddleback Mountain Ski Area in Sandy River Plantation near Rangeley, Sugarloaf Mountain Ski Area in Carrabassett Valley, and Sunday River Skiway in Newry and Riley Township. Further development of ski areas is unlikely in the western Maine mountains. Future trends in outdoor recreation and associated effects on lynx, hares, and their habitat are uncertain in the northern Maine unit

Within the last ~~five~~5 years, two landowners developed concept plans for rezoning for large-scale development hundreds of house lots and resort development within the lynx critical habitat. One concept plan would construct 975 houses and ~~two~~2 resorts on about 3,500 acres and establish a 363,000-acre conservation easement. A second concept plan would allow development on about 1900 acres of land and establish a 14,600-~~-~~acre conservation easement. Although these developments have not been built, they may portend future trends in land use.

Energy production is emerging as a potentially significant economic factor in this unit, with grid-scale industrial wind power, biomass, biofuels, and other energy sources offering new opportunities to utilize natural resources. Wind energy resources are high within the lynx critical habitat (National Renewable Energy Laboratory 2010, http://apps2.eere.energy.gov/wind/windexchange/wind_resource_maps.asp?stateab=mecitation; last accessed 5/25/2016), and wind development in the lynx critical habitat are likely to

accelerate in the foreseeable future. Mining is not a traditional land use, but a large operation is being considered at one location in the lynx critical habitat. Extraction operations for gravel (for road building) are widely scattered throughout the unit.

The lynx critical habitat is heavily roaded, particularly with forestry roads. While accurate numbers are difficult to obtain, approximately 1,500 miles of public roads and over 20,000 miles of private roads exist within unorganized areas of Maine (Maine Department of Conservation 2010). There has been discussion of an east-west limited access highway through northern Maine and extending Interstate 95 north from Houlton to Presque Isle, which, if constructed, would further fragment habitat (Maine Department of Transportation 1999, Beck *et al.* 2012, p. 38).

An increasing area of the lynx critical habitat area is likely to be placed under conservation easements that will limit future development and fragmentation of lynx habitat. Maine has the largest amount of land under easement of any state, and there are about 2 million acres of conservation easements in lynx habitat in northern Maine (Pidot 2011). Continued expansion of areas under conservation easement is uncertain and will depend on willing landowners and funding available for purchase of easements

All of development trends portend increased fragmentation of lynx habitat in the northern Maine unit. As habitat is fragmented, it will become increasingly difficult to influence landscape-scale forest management that could benefit lynx.

5.2.2 Unit 2 - Northeastern Minnesota

Expert Projections of Lynx Status

The probability of persistence of the lynx population in Minnesota is projected to decrease over time with increasing uncertainty through the end of the century (Lynx SSA Team 2016, pp. 37-38 and Figure 9, below). Near term drivers of the projected decline were reduced quality, quantity, and persistence of snow, competition from bobcats, disease (*e.g.*, lungworm, liver fluke, feline leukemia), and forest insects. Long term drivers of the projected decline were reduced the quality, quantity, and persistence of snow, competition from bobcats, loss of spruce-fir forests, wildfires, and climate change. Climate change was primarily associated with loss of boreal forest but could potentially also increase disease or insect outbreaks, and is likely to affect the amount of precipitation falling as good quality snow in the area of the state supporting lynx habitat. The connection to lynx in Ontario reduces the likelihood of local extirpation in this geographic unit, but the likelihood would increase if connectivity was compromised. Taking all factors into consideration (i.e., loss of boreal forest, competitions, disease and insect outbreaks, loss of snow), the experts projected the mean probability persistence to the year 2025 was greater than 90 percent, to 2050 was 80 percent (ranging from 60 to 90 percent), and would decline to approximately 35 percent (ranging from 10 to 60 percent) by 2100 (Lynx SSA Team 2016, pp. 37- 38).

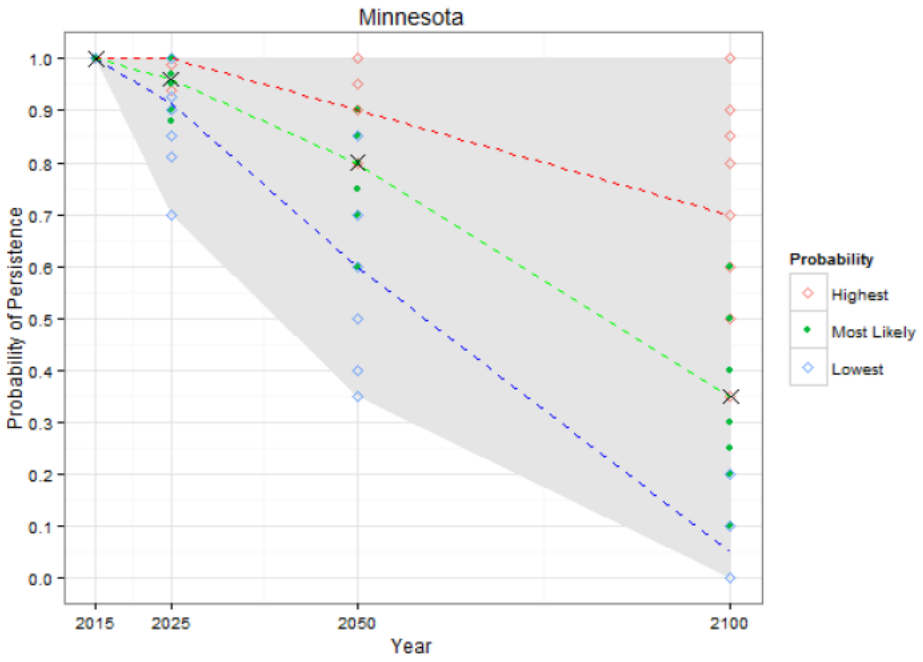

Figure 9. Lynx expert estimates of the probability that the Northeastern Minnesota Geographic Unit will continue to support resident lynx in the future (at years 2025, 2050, and 2100).

Service Evaluation of Factors Influencing Future Conditions

Regulatory Mechanisms - In Minnesota, the vast majority of lynx habitat that supports long-term persistent lynx breeding population is administered by the Superior National Forest. This area includes designated critical habitat (79 FR 54782). The SNF is currently implementing the 2004 SNF Plan (USDA 2004a), which has direction based on the LCAS and Canada Lynx Conservation Agreement (CA) between the Forest Service and the Service (LCAS 2000, entire), for all forest activities that occur within LAUs. Active management of forest lands can produce lynx habitat, and the Superior National Forest has a long-term commitment for doing so. If the SNF continues to follow vegetation and wildland fire management and other applicable recommendations under the 2000 LCAS (or the updated 2013 LCAS or subsequent updates) in their Forest Plan, we expect that several risk factors will continue to be minimized and managed to promote the conservation of lynx within the SNF into the future. Management of lynx and its habitat on SNF land will remain in place until the forest amends or revises ~~their~~its individual LRMPs. We expect that management direction for lynx addressing vegetation management, wildland fire management, and habitat fragmentation on national forest system lands will be incorporated into the revised or amended Forest Plans (LPMPs).

Comment [MJM69]: See comments about establishing proper context (lynx not listed) for evalua ing future conditions.

Although outside of areas considered to be core lynx area (i.e., where lynx are persistent and are reproducing) in the Great Lakes, the Chippewa National Forest and the Chequamegon-Nicolet National Forest Forest Plans also include direction based on the LCAS and Canada Lynx Conservation Agreement (CA) between the Forest Service and the Service (LCAS 2000, entire), for all forest activities that occur within LAUs (USDA CNF 2004, USDA CNNF 2004).

Additionally, the Minnesota Department of Natural Resources (MN DNR) manages approximately 36 percent of the lynx habitat in this unit, and private landowners make up about 16 percent of the unit. Under the Sustainable Forest Resource Act of 1995 (revised in 2014), the Minnesota Forest Resources Council (MFRC) has developed guidelines for site-level timber harvesting and forest management (MFRC 2013, entire; MFRC 2014, entire) - these voluntary guidelines are intended for private and state landowners and include some general recommendations for wildlife including lynx (MFRC 2014, pp. 4-5). It is expected that the MFRC guidelines will remain in place into the future and that voluntary actions will continue. Private landowners, however, do not have an official commitment to land management. We cannot say with any certainty what proportion of privately owned land will follow those guidelines into the future, because following the guidelines is voluntary.

Comment [MJM70]: But two sentences before we say we expect voluntary ac ions will continue. This makes it sound like we have no clue whether anyone will follow the guidelines. Surely we can say with some certainty that at least some minimal number of landowners will continue to follow he guidelines.

The NPS manages Voyageurs National Park, which is also within the Minnesota unit. Voyageurs National Park protects an area of 882 km^2, of which 534 km^2 (62 percent) is covered by forests and other uplands (Moen *et al.* 2012, p. 348), but does not have lynx specific direction in its management plan (NPS 2002, entire). The National Park consults with the FWS to consider the effects of any projects to lynx (NPS 2002, p. 26) and is anticipated to do so as long as the species is listed under the ESA. Lynx documented on and near Voyageurs National Park are probably transient animals (Moen *et al.* 2012, p. 348).

Approximately 1 percent of the Minnesota unit is managed by the Grand Portage Band of Chippewa, who has been actively working on lynx conservation since 2004. On-reservation timber sales and harvest practices follow an integrated management plan for priority wildlife management, sustainable economic development, and recreational uses. The Band's timber management practices benefit populations of snowshoe hares, the lynx's primary prey (Deschampe 2008, entire) and are expected to continue into the future.

In response to a 2008 court ruling, the MN DNR began to draft a plan to address incidental take of lynx that may result from otherwise legal trapping in Minnesota. This plan is still under development by the MN DNR and will be designed to reduce the likelihood of incidental take from trapping (LCAS 2013, p. 49).

Comment [MJM71]: But what do we think will happen if lynx were not listed?

Climate Change - The direct and indirect effects of climate warming are expected to affect lynx in Minnesota (Siren *in* Lynx SSA Team 2016, pp. 15 and Moen *in* Lynx SSA Team 2016, p. 19) and could further restrict their range. Since the time of listing, new information on regional climate changes and potential effects to lynx habitat has been developed (e.g., Danby & Hik 2007; Gonzalez *et al.* 2007; Knowles *et al.* 2006, Notaro *et al.* 2015), and this new information

suggests that climate change may be an issue of concern for the future conservation of lynx because lynx distribution and habitat is likely to shift upward in elevation within its currently occupied range as temperatures increase (Gonzalez *et al.* 2007, entire). Greatest stressors of climate change include diminishing snow depth, quality and duration; competition from bobcats and other carnivores, hybridization with bobcat (Schwartz *et al.* 2002); loss of spruce-fir to northern hardwoods; and future isolation of the metapopulation because of diminishing forest conditions in Ontario.

Gonzales *et al.* (2007, entire) modeled distribution of boreal forest and future snow conditions under nine different low, medium, and high emission scenarios (IPCC 2007, pp. 44-47) and predicted loss of forest and snow conditions able to support lynx in Minnesota by the end of the century. Notaro *et al.* (2015, pp. 1668-1669) projected changes in lake effect snowfall using downscaled climate models (Abdus Salam International Centre for Theoretical Physics (ICTP) Regional Climate Model version 4 (RegCM4; Elguindi *et al.* 2011 and Giorgi *et al.* 2012 as cited in Notaro *et al.* 2015) for the Great Lakes Basin. Siren (*in* Lynx SSA Team 2016, p. 15) stated that climate models show an increase in lake effect snow in the eastern Great Lakes until 2050, with a decline later in the century, with an overall decline in the amount and duration of pack in the Midwest. Although there are uncertainties about future climate warming, lynx populations in Minnesota are expected to recede northward and decline over the next century (Lynx SSA Team 2016, pp. 37-38).

Lynx require at least ~~four~~4 months (120 days) of continuous snow coverage (Gonzales *et al.* 2007, p. 7). Snow cover days of 1 inch or greater in northern Minnesota (1959 -1979) ranged from 130-160 days, of 6 inches or greater ranged from 85 to 130 days, of 12 inches or greater ranged from 50 to 100 days, of 24 inches or greater ranged from 10 to 30 days (Kuehnast *et al.* 1982, pp. 7-9). In the future, Notaro *et al.* (2015, p. 1675) projected a general reduction in the frequency of heavy lake-effect snowstorms during the twenty-first century, with the exception of projected mid-century increases around Lake Superior when local air temperatures are expected to remain low enough for precipitation to largely fall in the form of snow. The snow season in the Great Lakes basin is likely to become substantially compressed during the twenty-first century with dramatic increases in rainfall (Notaro *et al.* 2015, pp. 1676-1678). The Minnesota unit may be more vulnerable to snowpack loss due to lack of elevational refugia (Siren *in* Lynx SSA Team 2016, p. 15).

Normal annual snowfall from 1981-2010 in northeastern Minnesota ranged from 140 to 241 cm per year (55 to 95 in/yr.) http://www.dnr.state.mn.us/climate/summaries_and_publications/normals_snow_1981_2010.html, accessed 24May2016) and is projected to decline across the Great Lakes Basin (Notaro *et al.* 2015, p. 1675). Snow quality ('fluffiness") is projected to deteriorate in the Great Lakes. Notaro *et al.* (2015, pp. 1671-1674) projected a dramatic decline of Great Lakes ice cover that will become confined to the northern shallow lakeshores during mid-to-late winter by the end of the century. Ultimately, this leads to increased rainfall, not snowfall, as these projected reductions in ice cover and greater dynamically induced wind fetch lead to enhanced lake evaporation and total lake-effect precipitation (Notaro *et al.* 2015, pp. 1674-1678).

Climate change is projected to cause some northward contraction of boreal conifer forest in Minnesota (Gonzales *et al.* 2007, p. 16, 18) with some potential loss of habitat at the southern portion of lynx habitat in the state (Gonzales *et al.* p. 2007, p. 19). According to Frelich (*in* Lynx SSA 2016, p. 14) Minnesota is likely to lose boreal biome, potentially within the next 60 to 70 years, with unmitigated climate change. According to Gonzales *et al.* (2007, p. 8), the Superior National Forest is a potential refugia for lynx in the lower 48 states, however, when compared to other regions.

Vegetation Management - Vegetation management conducted under the Forest Plan currently will likely continue into the future on Forest Service lands in Minnesota. These activities include timber harvest, such as thinning, clear-cutting, shelterwood, partial cut, and uneven-aged cutting; wildlife restoration projects that involve tree cutting, shearing, burning, seeding, and planting; prescribed burning for ecological purposes, hazardous fuel reduction, and site preparation; mechanical site preparation.

Vegetation, timber, and minerals management authorized under the Forest Plan has the potential to adversely affect lynx and lynx critical habitat by reducing habitat quality for denning, foraging, and dispersal; disrupting travel, resting, and foraging patterns; disturbing denning females and reducing habitat quality for lynx prey species, especially snowshoe hare. Depending on the timing, frequency, intensity, extent, amount, or other conditions, impacts may be variable among similar projects. Using the LCAS as a basis, the Forest Plan has incorporated a number of components that would reduce the risk of those impacts into the future. We expect that management direction for lynx addressing vegetation management on national forest system lands will be incorporated into the revised or amended future plans, using LCAS as a basis.

Future Forest Plan revisions will likely maintain broad direction to design and implement vegetation management projects to maintain or restore conditions for lynx foraging and denning habitat and to maintain or improve juxtaposition of required habitat types and connectivity.

Over the long term, the Forest Plan will alter vegetation patterns on the landscape. Suitable hare habitat was predicted to decrease over time with implementation of the Forest Plan, but has actually increased since 2004 (USFWS 2011, p. 51). Management activities that create unsuitable conditions for hare generally include clear-cut and seed tree harvest, and might include management-ignited fire, mechanical site preparation, salvage harvest, and shelterwood and commercially-thinned harvest, depending on unit size and remaining stand composition and structure. Suitable hare habitat is predicted to remain above the range of natural variation, which is essentially a description of conditions that existed prior to European settlement (1600 – 1900 A.D.) of the area (USDA 2004b, p. 105). Further, unsuitable habitat for lynx would vary only slightly with continued implementation of the Forest Plan and would remain distinctly below the maximum of 15 percent unsuitable in a decade prescribed in the LCAS and incorporated into the Forest Plan. Current (2010) unsuitable habitat levels are below what was predicted in the 2004 (USFWS 2011, pp. 51-52). Because suitable habitat on National Forest lands alone is

such a high percentage within LAUs and the Superior National Forest is the majority landowner within most LAUs, we expect that in the future, the Forest would not approach the LCAS maximum of 30 percent of lynx habitat on all ownerships in an unsuitable condition within an LAU at any time, which would be ensured by corresponding guidance in the Forest Plan.

Wildland Fire Management - Unlike the Maine unit, the susceptibility of the Minnesota unit to fire may be reduced by periodic spruce budworm outbreaks. Measurable defoliation due to spruce budworm has occurred in Northeastern Minnesota continuously since 1954 (MN DNR http://www.dnr.state.mn.us/fid/july2014/articles.html) and is expected to continue into the future. Modeling to evaluate the relative strength of interactions between spruce budworm outbreaks and fire disturbances in the BWCA showed that budworm disturbance can partially mitigate long-term future fire risk by periodically reducing live ladder fuel within the forest types of the BWCA but will do little to reverse the compositional trends caused in part by reduced fire rotations there (Sturtevant *et al.* 2012, pp. 1286-1292).

The Superior National Forest manages for wildfires through preventative measures such as fuels reductions, but does not manage for wildfires in the BWCAW. Natural successional changes and those associated with natural phenomena, such as wildfire or windstorms, are and are expected to continue to be the dominant force in ecosystems on the BWCAW.

Habitat Fragmentation - Ravenscroft *et al.* (2010, p. 329) considers northeastern Minnesota forest landscape as largely un-fragmented. The BWCAW remains intact and contiguous with Canada. Within the SNF, natural disturbances and vegetation management activities make up most of the annual human-caused fragmentation in actively managed portions of the Forest. These areas typically re-vegetate within ~~three~~3 to ~~five~~5 years, depending on the forest type and number and type of activities (USDA 2011, p. 119). The Forest Plan (USDA 2004a, ~~A~~appendix E) provides direction on limiting lynx habitat fragmentation, and the Forest actively consolidates habitat through land acquisitions and exchanges.

5.2.3 Unit 3 - Northwestern Montana/Northeastern Idaho

Expert Projections of Future Lynx Status

Because of its connectivity to lynx populations and habitats in Canada, its large geographic extent, and the relatively large number and broad distribution of resident lynx it is thought to support, future extirpation of lynx from this unit due to reduced genetic health or a catastrophic event is unlikely (Lynx SSA Team 2016, pp. 25-34). When considering the probability that this unit would continue to support resident lynx in the future, experts noted that despite projected losses of favorable forest and snow conditions, climate models project that some boreal forest will persist in this unit and that it will maintain some areas of suitable snow into the future. Experts also noted that lynx in this unit primarily occupy public lands, which are actively managed for lynx into the future. Experts also considered recent and projected future increases in wildfire frequency, size and intensity.

As for most other geographic units, all experts indicated an initially high and subsequently decreasing probability of the persistence of resident lynx in this unit, with increasing uncertainty over time, but a higher probability of persistence at all time frames than other units. All experts predicted near-term (year 2025) persistence probability >= 95%, mid-century persistence at 70% to 100% (median = 90%), and end-of-century persistence probabilities >= 50% (median = 78%) (Figure 10, below).

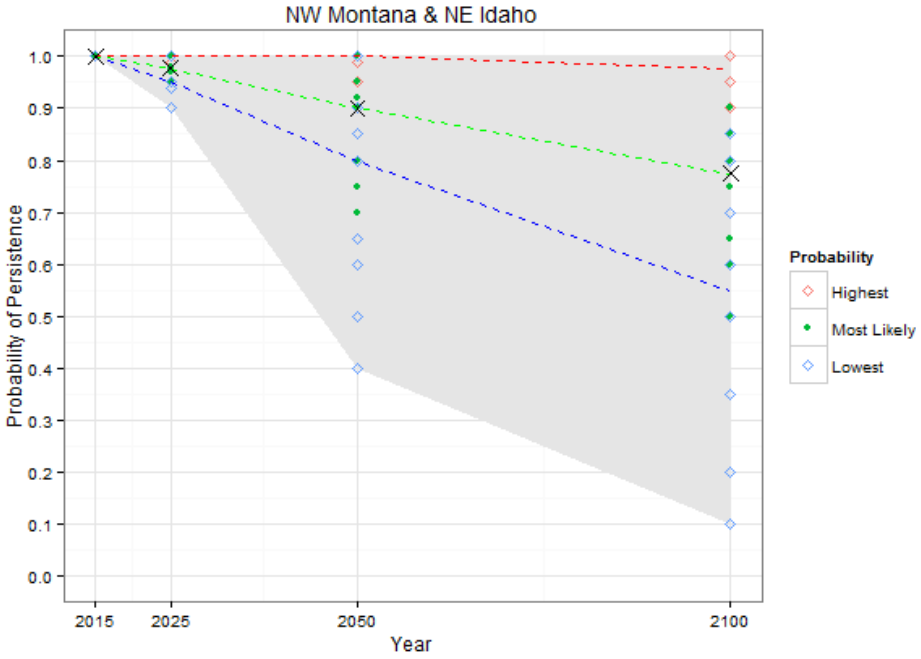

Figure 10. Lynx expert estimates of the probability that the Northwestern Montana/Northeastern Idaho Geographic Unit will continue to support resident lynx in the future (at years 2025, 2050, and 2100).

Overall, experts assigned a higher probability of persistence in this unit compared to the other geographic units. Most lynx habitats in this unit occur on federal lands that are managed for lynx conservation, but one expert noted that little has been done to document whether lynx are responding to this management. The recent sale of large tracts of private commercial timberlands in the central part of this unit to The Nature Conservancy has increased protection for lynx via conservation easements managed for lynx. Habitats in some areas should improve in the near future as previously cut or burned areas mature into dense stands. Unlike the Maine and Minnesota geographic units (but similar to most other western units), high elevations in this unit could buffer the effects of climate change by providing for the upslope migration of lynx habitats and snow conditions that climate models predict. However, this would result in even patchier and more isolated islands of habitat in high elevation areas that would be more prone

to extirpation due to catastrophic or stochastic events. Competition from coyotes and bobcats seem to be less of a concern for this unit.

This unit has unimpeded connectivity with Canada, but some experts questioned whether this geographic unit depends on intermittent immigration of lynx from Canada, and whether the historic lynx population cycles in Canada believed to have fueled such immigration are still occurring or will into the future. There doesn't appear to be much demographic input from recent cycles. There is evidence of lynx from this unit moving north into Canada, but little evidence of demographic interactions among the three subpopulations (Purcell Mountains, Seeley Lake, and Garnet Mountains) in this unit. Experts noted that the Garnets Mountains subpopulation at the southern end of this unit may have recently become extirpated.

Discussion among experts indicated that fire was more of a concern for this area. Increased fire extent and severity or other catastrophic events and small subpopulation effects in separated mountain ranges could affect lynx persistence in the future in some parts of this unit. Fire exclusion in this area for the last 100 years likely resulted in the accumulation of fuels; however, this unit may have a reduced probability of a catastrophic fire over time because of recent changes in management and recent fires that may have reduced fuels. Out to the year 2050 and beyond, some experts felt there may be more pressure on lynx populations in this unit from continued increases in fire extent and severity. Other experts expressed a different opinion of the overall effect of fire in this unit, indicating that it may actually improve habitat over time, and that whether fires improve or degrade habitat depends on the frequency, intensity, size and spatial extent of future fires.

Experts discussed the possibility for increased precipitation and warmer temperatures in this unit because of climate change, and how this might affect lynx habitats. Boreal/subalpine forest may move up in elevation as described above; however, experts expected a shift in forest composition and diminished lynx habitat quality in future with climate change. It is unknown how much the distribution of dry ponderosa pine (non-habitat for lynx) will increase with climate change, but it is likely to happen at some level. One expert cautioned that some climate modelers estimated that vegetation will lag about 50 years behind the projected changes in temperature and precipitation. Snow levels in lower elevation areas are already decreasing in some areas, which could lead to smaller areas for lynx to use in winter in the future.

Service Evaluation of Factors Influencing Future Conditions

Regulatory Mechanisms - Federal, State, and Tribal regulations and land management direction could change in the future, but such changes and their potential impacts on lynx populations and habitats are difficult to predict. Because most (84 percent) of this geographic unit consists of ~~f~~Federal lands, the regulations and guidance that govern management of those lands have the greatest potential to influence future lynx habitats and populations in this unit. When Forest Service, Park Service, and BLM management plans are revised or amended, they require opportunities for public participation in accordance with several statutes (e.g., the National Environmental Policy Act [NEPA], National Forest Management Act [NFMA], National Parks and

Recreation Act, Federal Land Policy and Management Act [FLPMA]) (USFWS 2014 pp. 26-34, also see 3.1, above). If plan amendments or revisions may affect listed species, management agencies must consult with the Service in accordance with section 7 of the ESA. If in the future the lynx DPS is determined by the Service to be recovered and the protections of the ESA no longer necessary (i.e., if the DPS is removed from the *Federal Lists of Endangered and Threatened Wildlife and Plants*), the ESA requires the Service, in cooperation with the States, to monitor the DPS for a minimum of ~~five~~5 years to assess its ability to sustain itself without the ESA's protective measures. If, within the designated monitoring period, threats to the DPS change or unforeseen events affect its stability, then the DPS may be relisted or the monitoring period extended. Given these requirements, we expect that future ~~f~~Federal management direction will continue to include regulations and guidance protective of lynx, although specific measures may change as new information becomes available.

We anticipate that future federal management direction will include continued management of national parks, designated wilderness and roadless areas, and other areas with nondevelopmental land-use allocations to maintain natural ecological processes, which should maintain natural disturbance regimes and landscape-level habitat mosaics to which lynx are adapted (although continued climate warming [see below] may preclude maintenance of historic disturbance and landscape patterns). Regardless of the future listing status of the DPS, these lands will continue to be managed in accordance with the acts described above, as well as the National Park Service Organic Act and the Wilderness Act.

We also expect that federal management into the future will include continued management of lands with developmental allocations to avoid or minimize potential impacts of vegetation management (timber harvest, thinning, salvage logging, other silvicultural prescriptions), wildland fire management (fire suppression, fuels reduction, prescribed fires), energy exploration and development, recreation, or other management activities with the potential to affect lynx. Current and likely future objectives include (1) managing vegetation to mimic or approximate natural disturbance and succession processes while maintaining habitat components necessary for lynx conservation; (2) providing a mosaic of habitat conditions through time that supports dense horizontal cover, high hare densities, and winter hare habitat in both young regenerating and mature multistoried forest stands; (3) using fire (natural and prescribed) to restore ecological process and maintain or improve lynx habitat, and (4) focusing vegetation management in areas with potential for improving winter hare habitat (BLM 2004a, pp. 2-3; USFS 2007, Attachment 1, p. 2). Although specific standards and guidelines may change as new scientific information and management techniques become available, we anticipate continued federal management designed to conserve or restore the capacity of the areas that historically or recently supported resident lynx populations, including the Northwestern Montana/Northeastern Idaho Geographic Unit, to continue to do so in the future.

On non-~~f~~Federal lands (about 16 percent of this unit), as described above (sections 3.1.1 and 4.2.3, Habitat Status), recent acquisitions and conservation easements on some of the private lands in this unit will also reduce the likelihood of future adverse impacts to important lynx habitats. Similarly, the MTDNRC HCP includes a 50-year commitment to manage most (64

Comment [MJM72]: See my comment at beginning of Chapter 5 about establishing the proper context for evaluation of status. That context requires we evaluate status assuming he lynx is not currently listed. Our assessment would take into account everything that would be different if the lynx were not listed, not just Federal management.

Also, if this correct context is established, it's not appropriate or necessary to describe what will happen if we were to delist the DPS – we' will have already established a context of the lynx not being listed. We don't need to envision how the world will change as a consequence of going through the delisting process (and initiating postdelisting monitoring); we simply need to envision he world without the lynx being listed.

In envisioning the world without the lynx being listed, we can and should still assess how Federal agencies, states, landowners, etc. will act in a world where future lis ing of the lynx is a possibility. So, the prediction here that Federal management will continue to be protec ive of lynx (so as to avoid a possible future listing) is OK, but the way we get to his conclusion needs to be revised.

This kind of analysis needs to be done for all units and for all actors (Federal agencies, states, landowners, etc.) and for all consequences, not just regulatory mechanisms.

percent) State lands in this unit to conserve lynx foraging, denning, and connectivity habitats. Additionally, the Confederated Salish and Kootenai Tribe's objective to manage wildlife and habitats on the Flathead Reservation for future generations (section 3.1.2, Tribal Management, above) suggests continued management to conserve lynx habitats on Tribal lands.

Given the commitments and management objectives and practices described above, implementation of current and future regulatory mechanisms will likely continue to support conservation and restoration of lynx habitats in this unit and improve the likelihood that it will continue to support resident lynx into the future.

If the DPS ~~were to be delisted in the future~~was not listed, it is possible that State-managed trapping could resume in this and perhaps other geographic units. We expect that would only occur if scientific evidence strongly suggested the presence of a harvestable surplus of lynx and that harvest quotas would be carefully managed to ensure that the viability of resident lynx populations would not be diminished or that potential recovery objectives were not otherwise compromised.

Comment [MJM73]: Suggest addressing this in each unit analysis.

Comment [MJM74]: Why? Have the states expressed this reasoning as part of their operating principles? If so, cite this evidence.

Climate Change - The recent evidence of climate change and the numerous mechanisms by which continued warming may affect future conditions for lynx and the potential consequences for the DPS and specific geographic areas are described in detail in section 3.2, above. Also, as noted above in section 4.2.3, evidence of warming and related impacts (increased temperatures, reduced snowpack, earlier snowmelt, and increased drought leading to increased fire) have already been documented in the Northern Rocky Mountains, including this geographic unit. Climate projections suggest these impacts are likely to continue and to result in future northward and upslope contractions in the snow conditions and boreal/ subalpine vegetation communities that support lynx. This is expected to cause loss and increased fragmentation and isolation of lynx and hare habitats and, therefore, declining and more vulnerable lynx populations in the DPS and in this geographic unit (Carroll 2007, entire; Gonzalez *et al.* 2007, entire; ILBT 2013, pp. 69-71; 79 FR 54810-54811; Lawler and Wilsey *in* Lynx SSA Team 2016, pp. 15-16; Siren *in* Lynx SSA Team 2016, p. 15).

Snow conditions in this unit are projected to become less favorable, with an overall decrease in snowpack after mid-century as a result of a shorter snowfall season, fewer days with snowfall, and a lower proportion of winter precipitation in the form of snow (more as rain; Siren *in* Lynx SSA Team 2016, p. 15). In this unit, the probability of suitable snow conditions is modeled to decline from 90-95 percent from 1961-1990 to 50 percent across much of the unit by the end of this century (years 2071-2100), though some parts of this unit are projected to retain adequate snow (Gonzalez *et al.* 2007, pp. 12-14; Lynx SSA Team 2016, pp. 15, 41). There will likely be a lag time between the loss of favorable snow conditions and an eventual shift/ contraction in vegetative communities (Lynx SSA Team 2016, pp. 43, 59; also see 3.2, above), but continued warming is projected to convert much of the boreal forest in this unit to temperate conifer forest by the end of the century (Gonzalez *et al.* 2007, pp. 15-17). The ability of lynx and hare populations to persist during this lag and to adjust to future habitat distributions is uncertain, but

habitat quality, quantity, distribution, and connectivity are expected to decline, likely compromising this unit's continued ability to support resident lynx populations.

Climate change has also been linked to increased wildfire size, frequency, and intensity in this geographic unit, and to increased frequency and extent of forest insect outbreaks in other parts of the DPS. These factors are likely to have temporary impacts on future lynx habitat, with regeneration to hare and lynx foraging habitat 20-40 years post-disturbance, depending on local climate, elevation, and topography. However, if extensive areas are affected, the ability of these landscapes to continue supporting resident lynx may be compromised, and lynx populations may be unable to persist until favorable vegetation conditions return. This is especially true where habitats and populations are naturally fragmented and patchily-distributed, and where landscape-level hare densities are already marginal, which appears to be the case for much if not all of this geographic unit.

Climate change has also been implicated in observed declines in the amplitude of northern hare and lynx population cycles (Yan *et al.* 2013, p. 3269). If lynx populations in this geographic unit are influenced (as is suspected) by intermittent immigration from the north, and if climate change diminishes the likelihood of future immigration via muted northern lynx population cycles, the future persistence of resident lynx in this unit is uncertain (see also Other Factors, below).

Given the factors described above, recent and projected future climate warming will reduce this geographic unit's ability to continue to support resident lynx into the future. The timing and magnitude of climate-driven impacts are uncertain; however, all are anticipated to adversely affect, and none are expected to benefit, lynx populations in this geographic unit. Climate model uncertainties and resolution limits, combined with our imperfect understanding of historic and current lynx numbers and habitat distributions, preclude quantifying future habitat quality/ distribution or lynx population dynamics in this unit. Nonetheless, it appears likely that continued climate warming will reduce future habitat quality and quantity and, therefore, the likelihood that this geographic unit will support resident lynx in the future.

Vegetation Management - Future vegetation management and, therefore, its implications for future lynx habitats and populations in this unit, are closely linked to the current and future regulatory mechanisms described above. As noted, we expect future vegetation management on all federal and most non-federal lands in this unit to continue to focus on maintaining and restoring lynx habitats by implementing standards, guidelines, and BMPs based on the best available scientific information. We expect these measures to continue to benefit lynx by limiting detrimental effects of timber harvest, thinning, fuels management, etc., and encouraging the use of these activities to restore, improve, or create high quality hare and lynx foraging habitats where feasible.

Wildland Fire Management - As noted in sections 3.4 and 4.2.3, above, past wildfire management, including fire suppression, does not appear to have altered the historic fire regime in lynx habitats in the western contiguous U.S., including this geographic unit. Also as noted

there and in sections 3.1.1 and the Regulatory Mechanisms section of this chapter, current federal management restricts, with few exceptions, fire management (fuels reductions, prescribed fires, etc.) impacts to lynx habitats, and it promotes the use of such activities and wildfire response to conserve and restore lynx and hare habitats. We expect such conservation-focused fire management to continue and, therefore, to benefit lynx rather than to affect them detrimentally in the future.

However, as also noted in section 4.2.3, increased wildfire frequency, size, and intensity have been documented in this geographic unit, and that pattern is anticipated to continue in the future with continued climate warming. Although this increased wildfire activity does not appear to have diminished this unit's current ability to support resident lynx, it could do so in the future depending on the timing and extent of future fires. As described in section 3.4, increases in fire frequency and size could rapidly convert large areas to the temporarily unsuitable stand-initiation successional stage, thus reducing the amount and altering the distribution of higher-quality habitats and potentially compromising this unit's ability to support a resident lynx population until burned habitats recover. Because lynx habitats are naturally patchily-distributed and landscape-level hare densities already marginal in many parts of this unit, it is possible that very large wildfires or many over a short time period could tip some parts of this unit from just barely capable of supporting resident lynx to incapable of doing so in the future. Although fire suppression was considered a potential risk factor for lynx in the DPS range, given the trends discussed above and the likely continued increase in future fire activity due to climate change, it may be necessary to reconsider whether fire suppression in some lynx habitats could benefit lynx by reducing the potential for extirpation of resident populations, especially in places already apparently only marginally capable of supporting them.

Habitat Loss/Fragmentation - As described above in section 4.2.3, lynx habitats in this unit are naturally fragmented but otherwise appear to be largely intact relative to historical conditions in most of this geographic unit. Although some localized impacts of past timber harvest and related activities have likely occurred, anthropogenic habitat loss or fragmentation does not appear to have broadly diminished this unit's ability to support resident lynx. Current and probable future management for conservation of lynx habitats suggests that broad-scale habitat loss or fragmentation due to timber harvest and other development activities are unlikely. The most likely sources of future habitat loss and fragmentation in this unit are the climate-mediated influences discussed above: increased wildfire activity and the projected contraction in vegetation and snow conditions favorable for lynx. Increased frequency, size, and severity of forest insect outbreaks, also driven by climate warming, has been documented in other geographic units and could occur in this unit in the future, too, resulting in temporary habitat loss and increased (though also temporary) fragmentation.

Additional highway construction and other transportation developments are likely in this unit, but the future locations, size, and potential impacts of such projects are difficult to predict. We are not currently aware of plans for specific major highway/road projects in this unit that would potentially impact lynx habitats and increase future habitat loss or fragmentation. Other potential sources of future habitat loss and fragmentation include recreation, minerals/energy

development, and forest/ backcountry roads and trails; these are all considered second tier anthropogenic influences (ILBT 2013, pp. 78-85) that are unlikely to exert population-level influences, despite potential impacts to individual lynx.

Other Factors: *Connectivity/immigration* – As described above and in section 4.2.3, maintaining connectivity between this geographic unit and lynx populations in Canada is thought to be important, although it is uncertain if or to what degree immigration of lynx from Canada is essential to the persistence of lynx in this unit. A number of climate-mediated factors have been suggested as contributing to changes in the periodicity and amplitude of northern lynx and hare population cycles (see section 3.2, above), which could alter the timing and magnitude of irruptions of lynx from Canada into the contiguous U.S. If lynx populations in this unit rely on immigration from Canada which is no longer occurring or has been substantially reduced relative to historic conditions, population declines and a reduced probability of persistence among resident populations would be expected.

Although the extent to which this factor may influence lynx populations in this unit is unknown, the population growth rate estimated for the Seeley Lake area ($\lambda = 0.92$, declining trend 1999-2007; Squires *in* Lynx SSA Team 2016, p. 20) may reflect a gradual decline of a resident lynx population that needs but is not receiving adequate immigration. If this growth rate was applied continuously to a hypothetical resident population of 250 lynx (the midpoint of the range in the number of resident lynx this geographic may support based on expert opinion [Lynx SSA Team 2016, p. 41]), the population would decline to 100 lynx after 11 years, about 50 lynx after 20 years, and roughly 20 individuals after 30 years. Vulnerability to demographic, environmental, and genetic stochasticity would increase as lynx numbers decreased, resulting in an increased likelihood of functional extirpation of lynx from this unit. However, as noted above, the lynx population in the Purcell Mountains in the northwestern part of this unit was estimated to be increasing ($\lambda = 1.16$, 2003-2007; Squires *in* Lynx SSA Team 2016, p. 20) over the last four years of the period for which the Seeley lake population was estimated to be declining. In the absence of information on historic, recent, and likely future rates of immigration and its contribution to the persistence of lynx populations in this geographic unit, impacts of potentially reduced future immigration are difficult to project and are largely speculative at this time.

5.2.4 Unit 4 - North-central Washington

Expert Projections of Future Lynx Status

Compared to the previous units, most expert graphs showed a lower probability of persistence for this unit over the short term, and then lower probability of persistence along with increasing uncertainty by 2100, reflecting a more pessimistic outcome for this unit compared to previous units (Figure 11). Experts predicted near-term (year 2025) persistence probabilities of 60% to 90% (median = 80%), and mid-century persistence at 30% to 80% (median = 70%). All experts predicted end-of-century persistence probabilities less than 50%, with a median of 38%, by 2100 (Figure 11). However, one expert predicted an increase in persistence probability by mid-

century as habitats impacted by recent large-scale fires regenerate into optimal hare-lynx habitat.

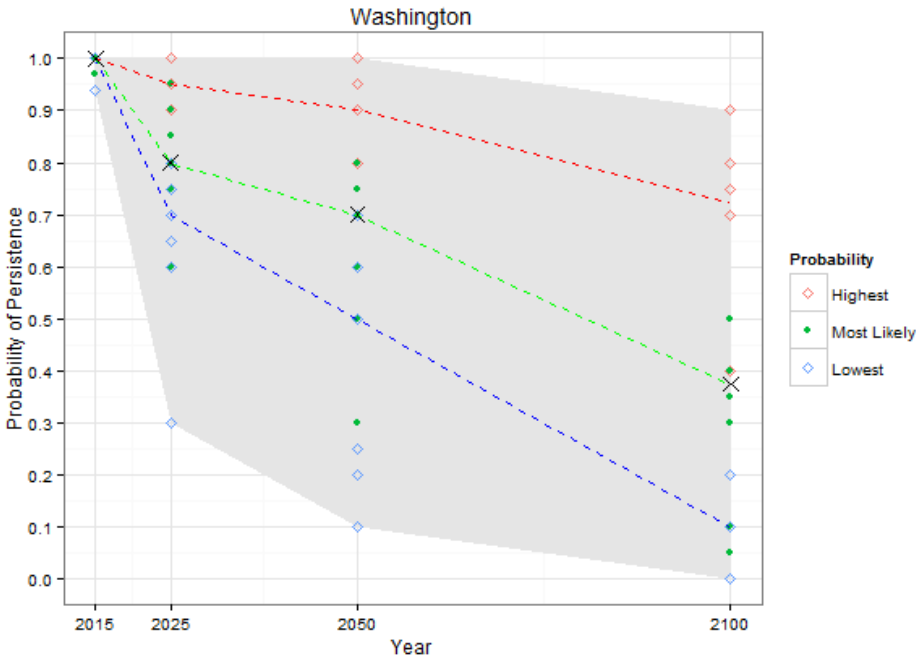

Figure 11. Lynx expert estimates of the probability that the North-central Washington Geographic Unit will continue to support resident lynx in the future (at years 2025, 2050, and 2100).

The probability of lynx persistence in this unit could decrease sharply over the next 10-20 years because of extensive recent fires in lynx habitats and the time needed for these areas to regenerate back to good hare/lynx habitat. After that, the probability could rebound (or decline more slowly) over the longer term as these large areas return to prime habitat providing high hare densities. The current small population is likely at greater risk of extirpation because of stochastic events, particularly if large fires in lynx habitat continue to occur in the near future as they have in the recent past. A small population also could be more susceptible to disease, though none has been documented among lynx in this unit. Experts discussed the extent to which small lynx populations could be reduced before they would become highly susceptible to stochastic demographic effects. It was suggested that 15-20 breeding individuals might be the minimum needed to avoid such susceptibility. Unimpeded connectivity between Canada and the Okanogan area of this unit could allow lynx to repopulate currently-unsuitable areas after the habitat recovers. Lynx in this unit are likely the southern portion of a larger population in

Canada, not really a separate, isolated small population. Factors that influenced expert persistence probabilities for this unit included fire, habitat loss, and the future loss of favorable snow conditions predicted by climate change models.

Service Evaluation of Factors Influencing Future Conditions

Regulatory Mechanisms - As stated previously, it appears that, currently, adequate protective regulatory mechanisms are in place in this geographic unit. Looking to the future, relative to the regulatory risks to lynx, we do not anticipate the existing regulatory protections for lynx to diminish. We anticipate that either the CA will remain in place (and/or be extended), or the OWNF and CNF will revise or amend their respective LRMPS incorporating direction for lynx management similar to what has occurred with other 18 National Forests in Idaho, Montana, Utah, and Wyoming. These 18 National Forests amended their respective LRMPs with lynx management direction known as the Northern Rockies Lynx Amendment (NRLA) in 2007. The NRLA incorporated management recommendations from the LCAS, with modifications based on the advent of new information pertaining to the management of lynx. Currently, both the OWNF and CNF are in the process of amending or revising their LRMPs. We expect that management direction for lynx addressing vegetation management, wildland fire management, and habitat fragmentation on national forest system lands will be incorporated into the revised or amended LRMP. Also, as discussed previously, the WADNR has developed and is implementing its 2006 Lynx Plan. The WADNR commits to implementing the 2006 Lynx Plan until lynx are delisted or until 2076, whichever is shorter (WADNR 2006, p. 6). Thus, it appears the regulatory future of lynx management, and thus, lynx habitat management, is largely secure on both federal and state managed lands within Washington State.

Comment [MJM75]: Need to specifically what we expect if lynx were not listed.

Climate Warming - The one risk factor identified by the LCAS over which the Forest Service, or the WADNR for that matter, has little ability to control or influence is climate change. Climate change was identified by the panel of lynx experts convened during development of the Canada Lynx Expert Elicitation Workshop Report to potentially represent the greatest threat to the long-term persistence of lynx (Lynx Workshop Report 2016, p. 56).

Potentially further exacerbating the recent losses of lynx habitat from fires is climate change. Climate change may affect fire return intervals and severity as well as the quality and depth of snow within lynx habitat. Westerling *et al.* (2006, pp. 942-943) compiled information on large wildfires in the western U.S. from 1970-2004 and found that large wildfire activity has increased significantly from the mid-1980s with large-wildfire frequency, longer wildfire duration, and longer wildfire seasons. The greatest increases occurred in high elevation forest types including lodgepole pine and spruce fir in the northern Rockies (i.e., lynx habitat). They also found that fire exclusion had little impact on natural fire regimes. Rather, climate appeared to be the primary driver of increasing wildfire risk. As stated previously, Koehler's (1990, p. 847) estimated adult lynx density of 2.3 lynx/100 km^2 was obtained in an area supporting high quality lynx habitat in the Meadows area of north central Washington (at least relative to other lynx habitat in Washington). Much of the lynx habitat in the Meadows was impacted by the recent large, stand replacing fires in the Cascades, resulting in further fragmentation of lynx habitat in

the northern Cascades. Thus, the lynx densities Koehler observed in his study area may not be currently supported, because as habitat becomes more fragmented and isolated (i.e., marginal), the carrying capacity for a particular species declines.

Additionally, relative to the persistence of Washington's lynx population, during the lynx expert elicitation workshop several of the lynx experts expressed concern that should more wildfires occur within the next 10 years and result in losses of lynx habitat similar to the impacts caused by the recent wildfires, such wildfires could result in the functional extirpation of lynx in Washington. The experts expressed heightened concern of functional extirpation of lynx in this geographic unit from wildfires due to its small size and current lynx population (Lynx Workshop Report 2016, p. 27). However, the experts felt the potential extirpation of lynx, should it occur from a large catastrophic wildfire(s) (or other mechanisms such as insect outbreaks), may be ameliorated to some extent due to Washington's juxtaposition and connectivity to Canadian lynx populations. The experts felt that lynx immigration from Canada may rapidly recolonize Washington as the habitat recovers from fires or other impacts (Lynx Workshop Report 2016, p. 43). Climate change, in addition to potentially affecting fire return intervals, fire severity (intensity, size), and insect outbreaks, is likely to affect the amount of precipitation falling as snow at elevations typically supporting lynx habitat in this geographic unit.

Lynx survive in areas with cold, snowy winters providing deep, fluffy snow (78 FR 59443) that gives lynx competitive advantages over other competitors and predators of lynx, as well as providing the conditions supporting the lynx's main prey, the snowshoe hare, which can comprise as much as 97 percent of their winter diet (Koehler and Aubry 1994, p. 75). Snowshoe hares are limited to environments with snowy climates (Ruggiero *et al.* 2000b, p. 448).

Climate change may impact the quantity, quality, and temporality of snow in the Cascades. Mote (2003, pp. 272, 274), who evaluated temperature trends in the Pacific Northwest using data collected by weather stations from 1930 to 1995, determined that the temperature increased in the Pacific Northwest, and more precipitation fell in the spring and summer months, especially at elevations below 1,800 m (5,900 ft). Additionally, Mote (2003, pp. 2-3) determined that an increasing temperature and precipitation trend from 1950 to 2000 is correlated with a 40 percent decrease in the snow water equivalent in the Cascades. Mote *et al.* (2005, p.45) determined that the Cascades are very sensitive to temperature changes, with large increases in temperature potentially resulting in significant declines in snowpack. Corroborating Mote's speculation, Stoelinga *et al.* (2010, p. 2474) determined that the Cascade snowpack has declined by up to 40 percent in the latter half of the twentieth century, which resulted from increased temperatures. Furthermore, predicted continued increasing temperature changes of 2° C to 5° C over the next century are expected to cause further and accelerated losses in snowpack in the Cascades (Mote *et al.* 2005, p. 48). Continued declines of snowpack in the Cascades through 2025 are predicted to range from 9 percent (Stoelinga *et al.* 2010, p. 2486) to 29 percent (Elsner *et al.* 2010 *cited in* Stoelinga *et al.* 2010, p. 2486), which may also affect lynx densities supported in the Cascades. Finally, some of the best lynx habitat in this geographic unit occurs on plateaus that may be more vulnerable to impacts of climate change because of the absence of higher elevation areas to which habitats and lynx could migrate in response to

climate warming (Lynx Workshop Report 2016, p. 42). Thus, in addition to the recent losses of lynx habitat to large wildfires, coupled with increasing wildfire risk, the potential for the Cascades to support a viable lynx population may be further reduced due to decreasing quantity and quality of snow.

Similar to the potential effects of wildfires on the persistence of the lynx population in this geographic unit, the lynx experts identified climate change relating to loss of favorable snow conditions as a significant factor potentially affecting the long-term persistence of this population (Lynx Workshop Report 2016, pp. 43-44). Taking all factors into consideration (i.e., catastrophic wildfire, insect outbreaks, loss of snow), the experts felt the probability of this population persisting to the year 2050 most likely ranged between approximately 60 percent to 80 percent, declining by the year 2100 to approximately 30 percent to 50 percent (Lynx Workshop Report 2016, p. 43).

5.2.5 Unit 5 - Greater Yellowstone Area

Expert Projections of Future Lynx Status

The expert graphs for this unit were widely variable and had different outcomes and high uncertainty at all time frames. Experts predicted near-term (year 2025) persistence probabilities of 10% to 70% (median = 52%), and mid-century persistence at 15% to 60% (median = 35%). All experts predicted end-of-century persistence probabilities less than 50% for this unit, with a median of 15%, by 2100 (Figure 12). This was the only unit for which most experts believed the present probability of persistence is low (i.e., that it is uncertain whether this area currently supports a resident lynx population). Some experts increased probability of persistence into mid-century as the 1980s-era fires regenerate into hare/lynx habitat, and with the possibility of continued immigration of lynx from Colorado. Other experts project a 10% to 20% probability of persistence by 2100. One reason given for wide variability in responses is because of the uncertainty whether a population currently exists. There were wide confidence intervals around the probabilities for all time periods for this area.

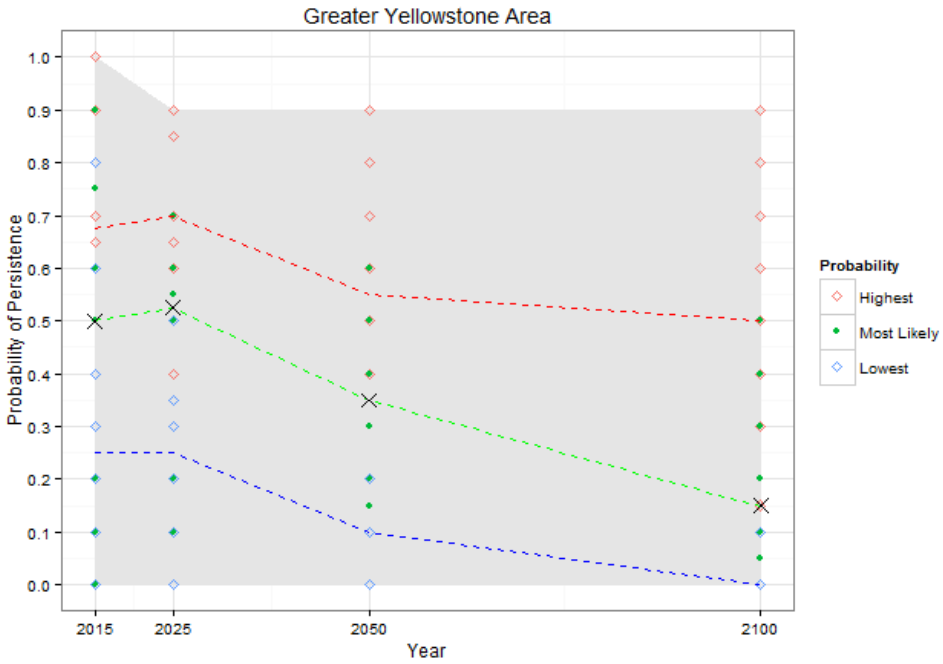

Figure 12. Lynx expert estimates of the probability that the Greater Yellowstone Area Geographic Unit will continue to support resident lynx in the future (at years 2025, 2050, and 2100).

Current and future factors expressed by experts as influencing probability of persistence for this unit included small population size, forest disease and insect pests, and fire. Some experts doubt that the GYA unit currently supports a resident breeding population of lynx. Experts indicated that climate models predict that some parts of the GYA unit could provide refuge from climate change impacts because of their high elevations and potential to maintain winter snow levels into the future. Summer conditions in this unit, however, could be drier in the future, resulting in increased fire frequency, extent and intensity, and additional temporary habitat loss. However, regeneration of these areas and the extensive areas that have burned in the recent past may provide good habitat over the next several decades. Lynx immigrating to this unit from Colorado could occupy such improved habitats in the near future. Colorado lynx have made exploratory movements into the GYA in summer months, and analysis of available data could improve our understanding of Colorado lynx movement into and use of the GYA. It is possible that lynx from Colorado are maintaining or could maintain lynx in GYA.

Service Evaluation of Influencing Factors

Regulatory Mechanisms - As noted above in section 5.2.3, federal, State, and Tribal regulations and land management direction could change in the future, but such changes and their potential impacts on lynx populations and habitats are difficult to predict. Federal lands account for over 97 percent of this geographic unit; therefore, regulations and guidance that govern management of those lands have the greatest potential to influence future lynx habitats and populations. Also as described above, revisions or amendments to federal management plans require opportunities for public participation in accordance with NEPA, NFMA, National Parks and Recreation Act, and FLPMA (USFWS 2014 pp. 26-34; also see 3.1, above) and consultation with the Service in accordance with section 7 of the ESA. If the DPS were to be recovered and delisted in the future, the ESA requires a minimum of five years of monitoring to assess its ability to sustain itself without the ESA's protective measures. If, during that time, threats to the DPS change or unforeseen events affect its stability, then the DPS may be relisted or the monitoring period extended. Given these requirements, we expect that future federal management direction will continue to include regulations and guidance protective of lynx, although specific measures may change as new information becomes available.

We anticipate that future federal management direction will include continued management of national parks, designated wilderness and roadless areas, and other areas with nondevelopmental land-use allocations to maintain natural ecological processes, which should maintain natural disturbance regimes and landscape-level habitat mosaics to which lynx are adapted (although continued climate warming [see below] may preclude maintenance of historic disturbance and landscape patterns). Regardless of the future listing status of the DPS, these lands will continue to be managed in accordance with the acts described above, as well as the National Park Service Organic Act and the Wilderness Act.

We also expect that federal management into the future will include continued management of lands with developmental allocations to avoid or minimize potential impacts of vegetation management (timber harvest, thinning, salvage logging, other silvicultural prescriptions), wildland fire management (fire suppression, fuels reduction, prescribed fires), energy exploration and development, recreation, or other management activities with the potential to affect lynx. Current and likely future objectives include (1) managing vegetation to mimic or approximate natural disturbance and succession processes while maintaining habitat components necessary for lynx conservation; (2) providing a mosaic of habitat conditions through time that supports dense horizontal cover, high hare densities, and winter hare habitat in both young regenerating and mature multistoried forest stands; (3) using fire (natural and prescribed) to restore ecological process and maintain or improve lynx habitat, and (4) focusing vegetation management in areas with potential for improving winter hare habitat (USFS 2007, Attachment 1, p. 2; BLM 2008, pp. A18-10 - A18-15; BLM 2010, pp. A-9 - A-12). Although specific standards and guidelines may change as new scientific information and management techniques become available, we anticipate continued federal management designed to conserve or restore potential lynx habitats in this geographic unit in the future.

Given the commitments and management objectives and practices described above, implementation of current and future regulatory mechanisms will likely continue to support

conservation and restoration of lynx habitats in this unit and improve the likelihood that it will support resident lynx into the future. Because non-federal lands make up such a small proportion of this geographic unit, we believe it is unlikely that regulatory mechanisms on those lands will influence this unit's future ability to support resident lynx.

If the DPS ~~were to be delisted in the future~~was not listed, State-managed trapping could resume in this geographic unit. We expect that would occur only if scientific evidence strongly suggested the presence of a harvestable surplus of lynx and that harvest quotas would be carefully managed to ensure that the viability of resident lynx populations would not be diminished or that potential recovery objectives were not otherwise compromised.

Comment [MJM76]: See previous related comment.

Climate Change - The recent evidence of climate change and the numerous mechanisms by which continued warming may affect future conditions for lynx and the potential consequences for the DPS and specific geographic areas are described in detail in section 3.2, above. Also, as noted above in section 4.2.5, evidence of warming and related impacts (increased temperatures, reduced snowpack, earlier snowmelt, and increased drought leading to increased fire) have already been documented in the Northern Rocky Mountains, including this geographic unit. Climate projections suggest these impacts are likely to continue and to result in future northward and upslope contractions in the snow conditions and boreal/ subalpine vegetation communities that support lynx. This is expected to cause loss and increased fragmentation and isolation of lynx and hare habitats and, therefore, declining and more vulnerable lynx populations in the DPS and in this geographic unit (Carroll 2007, entire; Gonzalez *et al.* 2007, entire; ILBT 2013, pp. 69-71; 79 FR 54810-54811; Lawler and Wilsey *in* Lynx SSA Team 2016, pp. 15-16; Siren *in* Lynx SSA Team 2016, p. 15).

Snow conditions in this unit are projected to become less favorable, with an overall decrease in snowpack after mid-century as a result of a shorter snowfall season, fewer days with snowfall, and a lower proportion of winter precipitation in the form of snow (more as rain; Siren *in* Lynx SSA Team 2016, p. 15). In this unit, the probability of suitable snow conditions is modeled to decline from 90-95 percent from 1961-1990 to 50 percent across much of the unit by the end of this century (years 2071-2100), though some parts of this unit are projected to retain adequate snow (Gonzalez *et al.* 2007, pp. 12-14; Lynx SSA Team 2016, pp. 15, 46). There will likely be a lag time between the loss of favorable snow conditions and an eventual shift/ contraction in vegetative communities (Lynx SSA Team 2016, pp. 43, 59; also see 3.2, above), but continued warming is projected to convert much of the boreal forest in this unit to temperate conifer forest by the end of the century (Gonzalez *et al.* 2007, pp. 15-17). The ability of lynx and hare populations to persist during this lag and to adjust to future habitat distributions is uncertain, but habitat quality, quantity, distribution, and connectivity are expected to decline, likely further compromising this unit's ability to support resident lynx populations, which is already questionable.

Climate change has also been linked to increased wildfire size, frequency, and intensity in this geographic unit, including the extensive fires in Yellowstone National Park in 1988, which burned over one-third of the park. Climate warming has also been linked to increased frequency

and extent of forest insect outbreaks in other parts of the DPS. These factors are likely to have temporary impacts on lynx habitat, with regeneration to hare and lynx foraging habitat 20-40 years post-disturbance, depending on local climate, elevation, and topography. However, if extensive areas are affected, the ability of landscapes in the GYA to support resident lynx may be further compromised, and resident lynx may be unable to persist until favorable vegetation conditions return. This is especially true where potential habitats are naturally fragmented and patchily-distributed, and where landscape-level hare densities are already marginal, which appears to be the case for much of this geographic unit.

Climate change has also been implicated in observed declines in the amplitude of northern hare and lynx population cycles (Yan *et al.* 2013, p. 3269). If lynx populations in this geographic unit are influenced by intermittent immigration from the north, and if climate change diminishes the likelihood of future immigration via muted northern lynx population cycles, the future persistence of resident lynx in this unit is uncertain (see also Other Factors, below).

Given the factors described above, recent and projected future climate warming will further reduce this geographic unit's ability to support resident lynx into the future. The timing and magnitude of climate-driven impacts are uncertain; however, all are anticipated to adversely affect, and none are expected to benefit, lynx and habitats in this geographic unit. Climate model uncertainties and resolution limits, combined with our imperfect understanding of historic and current lynx numbers and habitat distributions, preclude quantifying future habitat quality/ distribution or lynx population dynamics in this unit. Nonetheless, it appears likely that continued climate warming will further reduce habitat quality and quantity and, therefore, the likelihood that this geographic unit will support resident lynx in the future.

Vegetation Management - Future vegetation management and, therefore, its implications for future lynx habitats and populations in this unit, are closely linked to the current and future regulatory mechanisms described above. As noted, we expect future vegetation management on all federal lands in this unit to continue to focus on maintaining and restoring lynx habitats by implementing standards, guidelines, and BMPs based on the best available scientific information. We expect these measures to continue to benefit lynx by limiting detrimental effects of timber harvest, thinning, fuels management, etc., and encouraging the use of these activities to restore, improve, or create high quality hare and lynx foraging habitats where feasible.

Wildland Fire Management - As noted in sections 3.4 and 4.2.5, above, past wildfire management, including fire suppression, does not appear to have altered the historic fire regime in lynx habitats in the western contiguous U.S., including this geographic unit. Also as noted there and in sections 3.1.1 and the Regulatory Mechanisms section of this chapter, current Ffederal management restricts, with few exceptions, fire management (fuels reductions, prescribed fires, etc.) impacts to lynx habitats, and it promotes the use of such activities and wildfire response to conserve and restore lynx and hare habitats. We expect such conservation-focused fire management to continue and, therefore, to benefit lynx rather than to affect them detrimentally in the future.

However, as also noted in section 4.2.5, increased wildfire frequency, size, and intensity have been documented in this geographic unit, and that pattern is anticipated to continue in the future with continued climate warming. Although the extent to which increased wildfire activity has impacted this unit's current ability to support resident lynx is uncertain, such impacts may become more likely in the future depending on the timing and extent of future fires. As described in section 3.4, increases in fire frequency and size could rapidly convert large areas to the temporarily unsuitable stand- initiation successional stage, thus reducing the amount and altering the distribution of higher-quality habitats and potentially compromising this unit's ability to support resident lynx until burned habitats recover. Because lynx habitats are naturally patchily-distributed and landscape-level hare densities already marginal in many parts of this unit, it is possible that very large wildfires or many over a short time period could tip some parts of this unit from just barely capable of supporting resident lynx to incapable of doing so in the future. Although fire suppression was considered a potential risk factor for lynx in the DPS range, given the trends discussed above and the likely continued increase in future fire activity due to climate change, it may be necessary to reconsider whether fire suppression in some lynx habitats could benefit lynx by reducing the potential for extirpation of resident populations, especially in places already apparently only marginally capable of supporting them.

Habitat Loss/Fragmentation - As described above in section 4.2.5, lynx habitats in this unit are naturally fragmented but otherwise appear to be largely intact relative to historical conditions in most of this geographic unit. Although some localized impacts of past timber harvest and related activities have likely occurred, anthropogenic habitat loss or fragmentation does not appear to have broadly diminished this unit's ability to support resident lynx. Current and probable future management for conservation of lynx habitats suggests that broad-scale habitat loss or fragmentation due to timber harvest and other development activities are unlikely. The most likely sources of future habitat loss and fragmentation in this unit are the climate-mediated influences discussed above: increased wildfire activity and the projected contraction in vegetation and snow conditions favorable for lynx. Increased frequency, size, and severity of forest insect outbreaks, also driven by climate warming, has been documented in other geographic units and could occur in this unit in the future, too, resulting in temporary habitat loss and increased (though also temporary) fragmentation.

Additional highway construction and other transportation developments are likely in this unit, but the future locations, size, and potential impacts of such projects are difficult to predict. We are not currently aware of plans for specific major highway/road projects in this unit that would potentially impact lynx habitats and increase future habitat loss or fragmentation. Other potential sources of future habitat loss and fragmentation include recreation, minerals/energy development, and forest/ backcountry roads and trails; these are all considered second tier anthropogenic influences (ILBT 2013, pp. 78-85) that are unlikely to exert population-level influences, despite potential impacts to individual lynx.

Other Factors: *Connectivity/immigration* – This geographic unit is not directly connected to lynx populations in Canada or elsewhere in the DPS range, although lynx released into Colorado have dispersed northward into and through this unit. There is little evidence of intermittent

immigration into this unit during past irruptions of lynx from Canada, as has been documented in other parts of the contiguous U.S. Nonetheless, as elsewhere in the DPS, immigration may influence the persistence of resident lynx in this unit. If continued climate warming or other factors further reduce the chances that dispersing lynx will reach this unit and contribute to its demographic and genetic health, either through habitat loss and fragmentation in potential dispersal corridors or declines in the amplitude of northern hare and lynx population cycles, the likelihood that the unit will support resident lynx in the future may also decline. However, as in Unit 3 above, because we lack information of historic, recent, and likely future rates of immigration and its contribution to the persistence of lynx populations in this geographic unit, impacts of potentially reduced future immigration are difficult to project and are largely speculative at this time.

5.2.6 Unit 6 - Western Colorado

Expert Projections of Future Lynx Status

The majority of the experts suggested an initially high probability of persistence in Colorado, declining gradually with increasing uncertainty through the end of the century. Experts predicted near-term (year 2025) persistence probabilities of 60 percent to 100 percent (median = 90 percent), and mid-century persistence at 50 percent to 85 percent (median = 80 percent). Experts predicted end-of-century persistence probabilities of 20 percent to 70 percent for this unit, with a median of 50 percent, by 2100 (Figure 13).

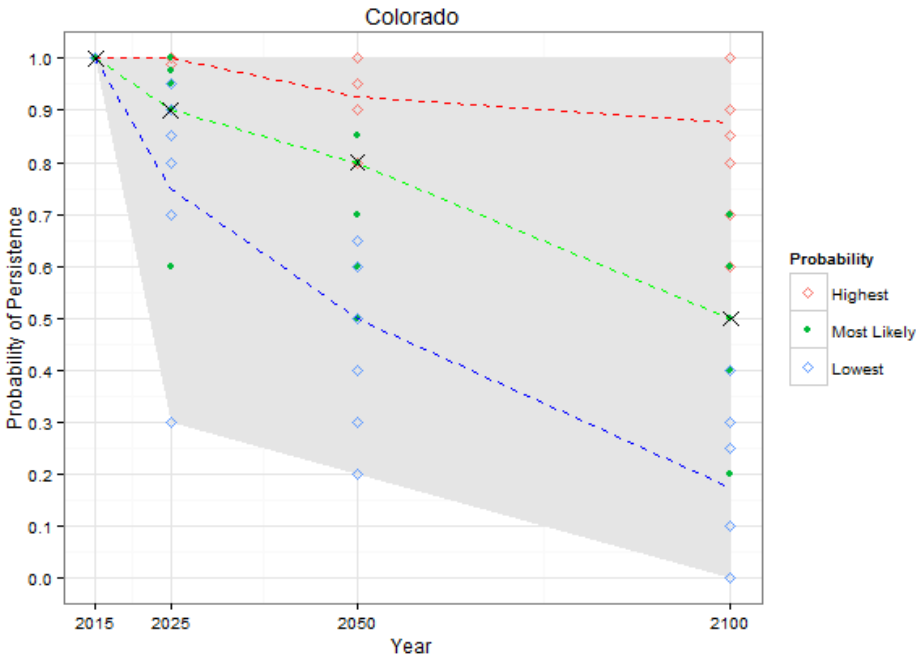

Figure 13. Expected probability of persistence for the Western Colorado Geographic Unit at present, 2015, and in 2025, 2050 and 2100.

Some experts indicated that beetle kill and fire could potentially create poor habitat conditions in large areas of this unit by mid-century, but that regeneration after these impacts could result in good lynx/hare habitats. Others expressed uncertainty about whether fire and insect impacts would be temporary or permanent, especially considering climate change and the potential for conversion from boreal/subalpine forests to other forest types. Although 8 of 10 experts graphed 50 percent to 70 percent probability of persistence at 2100, during subsequent discussions, several expressed greater uncertainty about whether resident lynx will persist in the unit at the end of the century. Higher-quality lynx habitat occurs primarily in two areas and is patchily-distributed. Lynx in this unit may occur as several smaller, relatively isolated subpopulations, which are likely more vulnerable to stochastic events. This unit's relative isolation may limit exchange with other lynx populations, increasing the likelihood of genetic drift and reducing the chance of demographic rescue or recolonization if lynx in the unit become extirpated. There was discussion about whether ski areas may affect daily movements of lynx, and hares may be declining in ski areas. Ski areas tend to expand and may, therefore, have larger impacts on lynx in future. There is some evidence of lynx using ski areas in summer months but avoiding them during the ski season. It is uncertain whether ski areas may affect genetic connectivity within the Western Colorado geographic unit. Two-thirds to three-quarters of the lynx in this unit are in the southern portion of the range in the San Juan Mountains. There is a large area (Weminuche

Wilderness) in Colorado that has not been well surveyed for lynx, so it is possible that lynx also could be using that area.

Service Evaluation of Influencing Factors

Regulatory Mechanisms - Regulatory mechanisms for the conservation of lynx in the Southern Rockies consist of seven amended USFS management plans in south-central Wyoming, and Colorado. We concluded that the Southern Rockies Lynx Amendment substantively reduced the inadequate regulatory mechanisms by addressing the major adverse impacts of Forest Service land management on lynx (Service 2008, p 70-71). Lynx habitat on all other ownerships makes up the remaining 15 percent of lynx habitat in Colorado, of which, only five percent is in federal ownership. Other ownerships include state, county, municipal, etc., and private lands. The BLM resource management plans have not been amended to include conservation specifically for lynx and, with a few exceptions. Lynx habitat on BLM ownership mostly consists of narrow forest extensions connected to larger blocks of habitat on adjacent USFS lands. Generally these extensions are insufficient on their own to support a lynx home range. However, the Gunnison Field Office is the only BLM unit that contains sufficient habitat to map and identify LAUs.

The State of Colorado manages lynx as a state endangered species C.R.S. 33-2-105, prohibiting take of the species with exceptions for protection of human life (C.R.S. 33-6-205 and incidentally during depredation management (not caused by lynx) [C.R.S. 33-6-207].

Climate Change - ILBT (2013 p. 61) – “Climate change generally is expected to result in warmer winters, earlier spring snowmelt, and a reduction in the extent of snow cover in the southern Rockies. McKelvey *et al.* (2011 entire in ILBT 2013) used a variety of climate models to predict snow depth and the persistence of spring snow across the western United States. The models predicted an overall decline in persistent snow of 40 percent, but large areas of persistent snow would continue to be retained late in the 21st century, including the high elevations of Colorado.”

“All of the climate models under all representative concentration pathway (RCP) project that Colorado’s climate will warm substantially by 2050. Under RCP 4.5 (medium-low emissions scenario), Colorado’s annual temperatures are projected to warm by +2.5°F to +5°F by mid-century relative to 1971–2000 observed baseline. Under RCP 8.5 (high emissions scenario), Colorado’s annual temperatures are projected to warm by +3.5°F to +6.5°F by mid-century. Summers are projected to warm slightly more than winters under both RCPs. Looking beyond the 2050-centered analysis period, the warming trend is projected to continue into the late-21st century under all RCPs except RCP 2.6. By the period centered on 2070 (2055–2084), the projected warming in Colorado annual temperatures under RCP 4.5 is +2.5°F to +6.5°F relative to the 1971–2000 baseline. Under RCP 8.5, the projected warming is +5.5°F to +9.5°F relative to the 1971–2000 baseline.” [Lukas *et al.* 2014 page 61]

An analysis of projected 21st century temperature trends as a function of elevation in the Northern Hemisphere mid-latitudes from CMIP5 models shows more warming at higher

elevations during winter, particularly in the daily minimum temperature (Rangwala *et al.* 2013 [cited in Lukas *et al.* 2014 page 63]). “However, as discussed in Section 3, the global climate models do not represent the topography of Colorado very well, so it is difficult to discern whether the warming projected for the higher elevation regions (>10,000’) in the state is substantially different from that projected for lower elevations” (Lukas *et al.* 2014 page 63).

On average, the climate models indicate a seasonal shift in precipitation for Colorado, with increasing winter precipitation, and in some areas a decrease in late spring precipitation (Lukas *et al.* 2014, page 65).

Vegetation Management - In the past decade, vegetation management within lynx habitat has been predominantly salvage of dead and dying timber caused by a mountain pine beetle infestation in the northern part of the state (generally north of Interstate 70), and a spruce bark beetle infestation south of the interstate. Salvage operations may temporarily impact understory regeneration, if present, reducing the capacity of the stand to support higher snowshoe hare densities. Assuming the existing US Forest Service plans retain their current conservation framework, USFS lands should continue to provide sufficient habitat for lynx through the end of the century.

Vegetation management on non-federal ownerships within lynx habitat is unlikely to cause significant concern for lynx conservation in Colorado through the remainder of the century.

Wildland Fire Management - “It is generally acknowledged that in the Southern Rocky Mountains fire suppression has altered historic vegetative patterns. This effect has been most pronounced within vegetation communities where fire regimes are of low intensity or mixed severity. It is generally agreed that spruce-fir habitats have been little affected by fire suppression because the fire regimes within this type tend to be stand-replacing events occurring at long intervals (100+ years). Depending on the moisture regime, large stand-replacing fires within lynx habitat may produce young age class snowshoe hare habitat after approximately 10-30 years. Although this vegetative condition may provide some high quality snowshoe hare habitat, mature forests are also very important as winter foraging habitat.” (USFS 2008 page 36)

Habitat Fragmentation - Sources of current habitat fragmentation include high-speed high-volume highways, high mountain valley developments, vegetation management, ski/recreation area development, and wildland fire. Currently, only vegetation management on USFS lands is managed to limit lynx habitat fragmentation. Highways are likely to be expanded to accommodate increasing traffic volume as mountain valley communities continue to be developed and expended. While these linear features already exist on the landscape, widening of the cleared right-of-way, as well as behavioral avoidance of highway rights-of-way due to traffic reduces available habitat. Many ski areas in Colorado are located within lynx habitat and will likely be expanded in the future through permanent removal of vegetation to create conventional ski runs, reducing tree density and clearing understory vegetation to create glade conditions, reduces lynx habitat. The magnitude of fragmentation caused by these sources of

has not been quantified, but is unlikely to remove enough habitat to eliminate the possibility of lynx persistence in Colorado.

Chapter 6: Synthesis

This section synthesizes the needs, current condition, and likely future condition of the Canada lynx in the contiguous U.S. DPS with respect to the conservation biology principles of representation, redundancy, and resiliency. Its purpose is to provide an understanding of the range-wide status of this DPS that is as clear as possible given the unavoidable uncertainties involving demography and long-term threats.

Comment [MJM77]: See my comments on executive summary, which pulls many of the conclusions form this chapter. I did not repeat hose comments here.

Comment [MJM78]: Where do we explain whether we agree or disagree with the experts' opinions and why? The "Service evaluation" for each unit seems to be independent of he discussions about the preceding "Expert Projections" for each unit I was expecting this explanation to be in he Service evaluations or here.

Needs

Throughout the species' range, the lynx is a habitat and prey specialist requiring boreal forests with dense horizontal cover, long winters, and deep, fluffy snow, which gives it a competitive advantage for exploiting its primary prey, the snowshoe hare. Lynx in the contiguous U.S. have ecological requirements similar to those of lynx in Canada and Alaska, and throughout the species' range hare abundance is the primary driver of lynx population dynamics. However, the DPS is at the southernmost margin of the species' range, where boreal forests transition to temperate conifer and hardwood forests, and where snow conditions and hare abundance generally become less favorable with decreasing latitude. Because of this, habitat is less extensive and generally more fragmented within the DPS range than in the core of the species' range in Canada and Alaska. As a result, lynx in the contiguous U.S. are naturally less abundant and more patchily distributed than in the core of the range. Maintaining connectivity between lynx populations in Canada and the DPS is thought to be important; however, whether and if so to what extent the demographic and/or genetic health of DPS populations relies on periodic immigration from Canadian populations remains uncertain.

Current Conditions and Threats

Resiliency, the ability to withstand stochastic disturbance events, and redundancy, the ability to withstand catastrophic events, are currently exhibited in the lynx DPS by the persistence of individual lynx populations and their broad distribution across the geographic scope of the DPS. Available information indicates that five out of six geographic units in the DPS contain resident breeding lynx populations. Although we have no reliable population-size estimates for any of the geographic units, Northern Maine (Unit 1) is believed to currently support the largest resident population in the DPS. In Northeastern Minnesota (Unit 2), a resident population occupies the Arrowhead Region of the State. Northwestern Montana and northeastern Idaho (Unit 3) continue to support resident lynx, although a small subpopulation in the Garnet Mountains on the southern periphery of this unit may have been extirpated recently. In North-central Washington (Unit 4), recent extensive wildfires have temporarily reduced the amount of high-quality lynx habitat and may have caused a decline in lynx numbers there. Since the release of Canadian and Alaskan lynx in 1999-2006, resident lynx currently occupy western Colorado (Unit 6). The Greater Yellowstone Area (GYA, Unit 5) is thought to have historically supported a small

resident population; however, resident lynx have not been documented recently in this unit. The apparent long-term (historic and current) persistence of resident lynx populations in at least four of the six geographic units (Units 1-4) and the absence of reliable information indicating that the current distribution and relative abundance of resident lynx are substantially reduced from historic conditions suggest the historical and recent resiliency of lynx populations in the DPS. The large sizes and broad geographic distributions of the areas occupied by resident lynx populations likewise indicate adequate historical and current redundancy in the DPS to preclude its extirpation because of catastrophic events.

Representation, the ability of a species to adapt to changing environmental conditions over time, is characterized by the breadth of genetic and ecological diversity within and among populations (Lynx SSA Team 2016, p. 25). Information provided by lynx experts and geneticists indicates high rates of dispersal and gene flow and, therefore, generally low levels of genetic differentiation across most of the species' range, including the DPS (Lynx SSA Team 2016, pp. 12-14, 55-56). Hybridization with bobcats has been documented but is not considered a substantial current threat to the DPS (Lynx SSA Team 2016, p. 13). Despite differences in forest community types and topographic/elevation settings, lynx across the range of the DPS occupy a similarly narrow and specialized ecological niche defined by specific vegetation structure, snow conditions, and the abundance of a single prey species. Thus, lynx naturally have little ability to adapt to changing environmental conditions (i.e., shift to other forest habitats, snow conditions, or prey species). However, although some small populations may have become extirpated recently, resident lynx in the DPS remain broadly distributed across the range of ecological settings that seems to have supported them historically in the contiguous U.S. There are no indications of current threats to the genetic health or adaptive capacity of lynx populations in the DPS, and the current level of representation does not appear to represent a decrease from historic conditions.

The primary threat identified at the time of listing, lack of regulations protecting lynx habitat on federal lands, has been largely addressed by formal and binding amendments or revisions to most federal land management plans within the DPS range. Although questions remain about the efficacy of this improved regulatory framework, federal lands are now being managed specifically to protect and restore lynx habitats, with the goal of supporting continued lynx presence on these lands. Most federal lands, which constitute 64 percent of lynx habitat evaluated in this SSA, are found in the western U.S.

Other stressors affect lynx in one or more geographic units. For example, in northern Maine, where most high-quality lynx habitat occurs on private commercial timber lands and is the result of past timber harvest, changes in State forestry regulations (the Maine Forest Practices Act of 1989) that govern private forest management may currently be causing decreases in habitat quantity, quality, and distribution, and in lynx numbers (also see *Future Conditions and Threats*, below). The lack of binding lynx conservation commitments on private lands may exacerbate this risk to current lynx habitats in Maine. In North-central Washington, recent large-scale wildfires have resulted in the temporary loss of nearly 50 percent of lynx habitat, likely reducing this unit's current lynx population and potentially compromising its current ability to support a

resident population until habitats recover. Increased wildfire activity also has impacted lynx habitats in the other western geographic units (Northwestern Montana/Northeastern Idaho, the GYA, and Western Colorado), but the extent to which it has influenced the current condition of lynx populations in those units is uncertain.

Climate change is occurring at a global and, thus, a DPS-wide scale. Climate warming has reduced snow amount, duration, and quality (in terms of conditions favorable for lynx), it has been linked to increased frequency, size, and severity of wildfires and forest insect outbreaks, and it likely has already resulted in some changes in forest vegetative communities. Climate warming has also been linked to changes in the amplitude, periodicity, and synchronicity of northern hare population cycles, which could alter the timing and magnitude of irruptions of lynx from Canada into the contiguous U.S. If lynx populations in the DPS depend on immigration from Canada which is no longer occurring or has been substantially reduced relative to historic conditions, population declines and an increased likelihood of extirpation among resident populations would be expected. However, whether, and if so to what extent, these climate-mediated factors have influenced current lynx numbers, other demographic parameters, and/or habitat quality and distribution is uncertain and has not been quantified across the range of the DPS or in individual geographic units. Despite uncertainty regarding its influence over current conditions for lynx, climate modeling and expert opinion concur that continued climate warming will adversely impact lynx in the DPS in the future (see below).

Future Conditions and Threats

Overall, ~~expert opinion and~~ our evaluations suggest that resident lynx populations in each of the geographic units are likely to be smaller and their distributions reduced in the future. These anticipated declines are most likely to be influenced by projected loss and increasing fragmentation and isolation of boreal forests and favorable snow conditions resulting from continued climate warming and related impacts (e.g., increased wildfire and forest insect activity, diminished hare populations) (Lynx SSA Team 2016, p. 58). Forest management on private lands that lack lynx conservation commitments may also contribute to future declines, particularly in northern Maine. In each geographic unit, the probability that resident lynx populations will persist is expected to decline. The loss of resident lynx from one or more geographic unit would represent reduced future resiliency, redundancy, and representation within the lynx DPS.

The resiliency of lynx populations in individual geographic units is the primary determinant of the future viability of the lynx DPS. ~~Expert opinion and o~~Our analyses suggest a declining probability of persistence (loss of resiliency) for each of the geographic units within the DPS throughout the rest of this century (the analysis did not extend beyond 2100). Projected climate warming is expected to exert the greatest influence on the resiliency of individual populations, and thus continued presence of resident lynx in each geographic unit. Climate models project that boreal forests and snow conditions favorable for lynx at the southern periphery of the range will retreat northward and upslope with continued warming, further fragmenting and diminishing the quality of lynx and hare habitat within the DPS. Although uncertainty remains regarding the

timing, extent, and biological consequences of such impacts, as habitat conditions decline, hare populations will decline and lynx mortality rates are likely to increase and reproductive rates decrease. As snow conditions become less favorable, competitors (e.g., bobcats) are likely to outcompete and displace lynx. This in turn will reduce lynx abundance and density within populations, making populations more susceptible to stochastic events.

The loss of any geographic units would also reduce the level of redundancy and could diminish representation within the DPS. With regard to redundancy, however, neither the scientific literature nor expert input provide a basis for concluding that any single future catastrophic event could cause extirpation in any one geographic unit. It is even less likely that a single future catastrophic event (other than climate change, which we considered as a separate stressor) will eliminate all populations in the DPS. A sequence of catastrophic events over a short time could increase the potential for functional extirpation of one or more of the individual geographic units (e.g., fires in north-central Washington, as described above), thereby reducing redundancy within the DPS. However, as long as resident lynx remain geographically well-distributed in one or more units within the DPS, extirpation from a catastrophic event is very unlikely.

With regard to representation, although some lynx populations in the DPS units are demographically isolated from each other and the level of interaction between others is uncertain, there seems to be little risk of significant genetic drift. This is because of the currently-observed and likely future high level of gene flow across most of the lynx's continental range, the species' well-documented dispersal capability, the current and likely future absence of significant barriers to dispersal between Canada and the DPS, and continued connectivity between most parts of the DPS and lynx populations in Canada. Furthermore, based on expert input, we conclude that there is no indication that the relatively low level of genetic diversity currently observed among lynx populations is likely to reduce DPS viability in the future (USFWS 2016, p. 51). This information suggests the current and likely future relative genetic health of the DPS. How the potential loss of resident lynx from one or more geographic unit may affect representation within the DPS in terms of ecological diversity is uncertain. Despite similarities in the fundamental components (vegetation, snow conditions, and hares) that define the ecological niche of lynx DPS-wide, differences in habitats and how lynx use them are apparent. For example, snow depth that seems to demarcate a boundary between lynx and bobcat occupancy in Maine (270 cm/yr) is almost twice that observed in Minnesota (140 cm/yr]), and lynx in some parts of the West select mature forest stands, particularly in winter, while in other parts of the DPS, young regenerating stands are most important. The loss of resident lynx from any of the geographic units could result in the loss of behavioral and potential future genetic adaptations to the climate-mediated changes now occurring and likely to continue into the future at the southern edge of the lynx range. Such potential adaptability to diminished snow conditions, increasingly patchy and isolated boreal forests, and reduced hare abundance may be important to the taxon as a whole faced with a rapidly changing climate.

Given the high percentage of federal land ownership in the West, regulatory commitments that these lands will continue to be managed in accordance with lynx conservation principles, and

Comment [MJM79]: Does this document explain how we arrive at this conclusion? If so, summarize it here. And do this for every conclusion.

the existence of potential high-elevation climate refugia to which lynx habitats and some lynx might move, the western geographic units (Units 3-6) may be more likely to support resident lynx longer under projected continued climate warming. Nonetheless, it is unlikely that any management actions can abate the long-term retreat of boreal forests and diminished snow conditions projected by climate models. Further, the size, frequency, and intensity of wildfires and forest insect outbreaks are expected to increase with continued climate warming, particularly in the western portion of the DPS, although we do not anticipate such events in-and-of-themselves are likely to cause the permanent loss of breeding lynx populations in any geographic unit.

Although projections of climate-mediated losses of boreal forests and favorable snow conditions suggest impacts to lynx and hare populations throughout the DPS, persistence of resident lynx in Maine and Minnesota may be relatively lower than the western geographic units given the smaller percent of federal lands and the absence of associated regulatory commitments to lynx conservation, and the lack of potential elevational refugia. Additionally, as noted above, changes to regulations governing timber harvest on private forest lands in Maine are unlikely to maintain the current historically-high amount and distribution of good lynx habitat or the current large population of resident lynx. These changes, which may affect over 90 percent of lynx habitats in northern Maine, are projected to result in substantial declines in habitat quality and distribution, and lynx numbers, over the next 10-30 years, primarily through restrictions on clearcutting and the proliferation of partial harvesting, which are detrimental to snowshoe hare and lynx needs. On private forest lands, energy development (wind energy, mining), rapid turnover in ownership and parcelization of forest land, and uncertain forest markets may also reduce the future quality and quantity of lynx habitat.

DPS viability

Although all five geographic units that currently support populations (all units except the GYA) are expected by lynx experts to continue to do so through mid-century, only one (Northwestern Montana/ Northeastern Idaho) has an estimated probability of persistence greater than 50 percent (i.e., persistence more likely than not) by the end of the century (Lynx SSA Team 2016, pp. 36-49, 58). All other geographic units have a 50 percent or greater expert-estimated probability of functional extirpation (i.e., no longer capable of supporting resident lynx populations) by the end of the century, with a moderate to high likelihood that resident lynx will be lost from two to four units by then. Potential elevational refugia may increase the likelihood of persistence in western units, although uncertainty remains about the timing of warming-driven upslope movements of habitats and snow conditions and the extent to which hare and lynx populations may follow them. Regardless, future lynx habitats throughout the DPS range are likely to be smaller and more fragmented, and geographic units that are already relatively isolated from other lynx populations are likely to become even more isolated in the future. Despite the lack of elevational refugia, lynx may also persist at the end of the century in Maine and Minnesota, depending on the timing and severity of climate change effects and, in Maine, on trends in development and private forest management. Uncertainty increases at mid- to late-century concerning the timing and extent of various stressors that will affect lynx and hare habitat and snow regimes, especially those related to climate change. However, review of the

Comment [MJM80]: We never say whether we agree or disagree with hese specific experts' opinions and explain why. We make a meaningless statements in the end about probability of persistence, and that doesn't tell he reader whether we agree or disagree with hese specific opinions of the experts.

best available science in concert with input from lynx experts suggests that the probability of the persistence of resident breeding populations will decline in all geographic units beginning as early as 2025, with the negative DPS-wide trajectory continuing to the end of the century, and (with no evidence to the contrary) beyond that time frame.

We conclude that the ~~potential~~ functional extirpation of resident lynx populations from one or more geographic units would demonstrate a loss of resiliency, reduced redundancy, and, possibly, reduced representation within the DPS. The~~se~~ probability of losses in resiliency, redundancy, and representation ~~will~~ puts the Canada lynx DPS at increasing risk of extirpation through the end of this century.

Comment [MJM81]: It actually starts now. All species have decreasing probability of persistence over time. That probability begins to decline immediately and never stays the same or increases.

Comment [MJM82]: It's not the potential but rather the actual extirpa ion that would demonstrate a loss of the 3Rs.

Comment [MJM83]: None of he overall conclusions helps decisionmakers understand how big the risk is. Recommend presenting our conclusions about the probabili ies of persistence.

Mark - Here are my comments on the lynx SSA. I focused on the Future Conditions and Synthesis chapters. I have three major comments:

1. Establishing the proper context for the future: This is a future with lynx not being listed. The document presents a delisting scenario in its evaluation of the Federal management future of the MT/ID Unit. I explain in my comments that, while the conclusions about what the future will look like may be OK, the way we get there needs to be revised. And this context needs to be established for evaluation across all units, actors (Federal agencies, states, landowners, etc.), and consequences (not just regulatory mechanisms).

2. Explaining how the experts' opinions inform our conclusions: The document does not explain what we think about the experts' opinions (agree or disagree and why). I was expecting this explanation for each unit in Chapter 5 in the "Service Evaluation" section, which follows the "Expert Projections,' but these two discussion appear to be independent. We continue to refer to the experts' opinions about persistence to the very end without ever saying whether we agree with them (and explaining why).

3. Drawing meaningful conclusions: The ultimate conclusions we make (the DPS has a decreasing probability of persistence into the future) is meaningless as it can be said of every species on earth. I recommend we present "our" conclusions on persistence. If we thought it was valuable to know what the experts think about persistence, we need to at least present our conclusions on persistence. I understand we are advised not to present our conclusions in a manner that too closely resembles a conclusion about listing being warranted or not. But we're too far down the "probability of persistence" road to avoid presenting our conclusions on this. And we need to do it in a way that describes the magnitude of the risk, not statements that are generalized to the point of being meaningless.

Many of the comments I made on the Executive Summary I did not bother repeating in the Chapters.

Let me know if you have any questions.

Attached is the version that Kate sent me at about 11:30, with much strike-through from Lesley at DOJ.

In the second attachment, I've added my comments/edits/recommendations and tried to respond to the questions/comments that were already there. I also added the last numbered item in an attempt to include the direction Mike asked me to try to incorporate - not sure if that works.

Seth was not on the call earlier, though he had provided comments on an earlier draft of the declaration. We should forward the next version to him once you've reviewed/edited this one.

Let me know if you have questions or needed anything else.

Need to get this to Marj, Seth, Kate, Dana, and Lesley by COB today so Lesley can submit final to court by about 1 PM Eastern Time tomorrow.....

FRIENDS OF THE WILD SWAN, ROCKY MOUNTAIN WILD, et al.,	)	No. 13-cv-57-DWM
Plaintiffs, v.	)	DEFENDANTS' STATUS REPORT
DANIEL ASHE, U.S. FISH & WILDLIFE SERVICE, et al.,	)	
Defendants.	)	

Pursuant to the Court's order of June 25, 2014, Federal Defendants hereby submit the following status report on the United States Fish and Wildlife Service's ("Service") recovery planning for the Canada lynx under 16 U.S.C. § 1533(f) for

the period of July 1, 2016 to January 1, 2017. *See* ECF No. 30.

1. In March, 2015, the Service determined that a Species Status Assessment ("SSA") was necessary to guide recovery planning direction for the lynx DPS. From July, 2016 through December, 2016, the Service continued weekly calls with the SSA Framework Implementation Team (which oversees development and completion of the SSA report); biweekly calls with the SSA Core Team (which drafts the SSA report and associated documents); and monthly calls with both Service field offices and State agency partners.
2. In August, 2016, the Service awarded a contract to Atkins North America to coordinate and compile the administrative record for peer review of the Draft SSA Report.
3. In October, 2016, the Service completed the Draft SSA Report and circulated it for internal agency review.
4. In November, 2016, the Service conducted a webinar to update State and Federal agency partners on the status of the SSA and provide time lines for the statutorily-required 5-year status review and subsequent recovery planning efforts.
5. In December, 2016, the Service provided the revised Draft SSA Report to the peer review contractor and to State, Federal, and Tribal partners for their

reviews and comments.

DATED: {date}.

Respectfully submitted,

2. In August, 2016, the Service awarded a contract to Atkins North America to coordinate peer review of the Draft SSA Report and compile the decision file for the peer review.
3. In October, 2016, the Service completed the Draft SSA Report and circulated it for internal agency review.
4. In November, 2016, the Service conducted a webinar to update State and Federal agency biologists on the status of the SSA and provide time lines for the statutorily-required 5-year status review and associated recovery planning efforts.
5. In December, 2016, the Service provided the revised Draft SSA Report to the peer review contractor and to State, Federal, and Tribal partners for their

reviews and comments.

---

This needs to go through Dana J. then DOJ and then gets submitted by latter to the court by July 1; wanted to get an early jump on it.

This is my first stab at the Jan.- June 2017 reporting period. Some questions about how to present Decision Team meetings (if at all). Let me know what you think.

Used the last report I had from DOJ as a template. TRACK and CLEAN versions attached.

Let me know if we need to discuss and what changes are necessary before we send this to Dana.

Thanks.

Hey Justin,

Jodi will be out of the office most of next several working days and won't have time to review this semi-annual court update on the recovery plan lawsuit, so I'm sending it to you for your review. I discussed the issue of whether or not to include the Decision/Recommendation Team meeting and follow-up webinar (items 3 and 5 in attached), and her take was that those items should not be included in this update.

I've left them in the attached draft for now in case you, based on your experience with these and with working with Dana, feel differently (strongly).

Also, the technical editor Jodi had lined up to review the draft FINAL SSA Report has left the Service for another position and won't be able to do it. How do you feel about doing a close technical review of it when I have finished responding to peer and partner review comments and completed other edits? I hope to have that done in the next couple weeks, with the plan to send it to you, Jodi and the Core team for review, while I work on lit cited (along with Mark), and trying to get the final done by end of June as per Jodi.

Let me know if you'd like to discuss any of this.

Thanks,

Jim

Attorneys for Federal Defendants

IN THE UNITED STATES DISTRICT COURT
FOR THE DISTRICT OF MONTANA
MISSOULA DIVISION

FRIENDS OF THE WILD SWAN, ROCKY MOUNTAIN WILD, et al., Plaintiffs, v. DANIEL ASHE, U.S. FISH & WILDLIFE SERVICE, et al., Defendants.	No. 13-cv-57-DWM DEFENDANTS' STATUS REPORT

Pursuant to the Court's order of June 25, 2014, Federal Defendants hereby submit the following status report on the United States Fish and Wildlife Service's ("Service") recovery planning for the Canada lynx under 16 U.S.C. § 1533(f) for

the period from January 1, 2017 to July 1, 2017. *See* ECF No. 30.

1. In March, 2015, the Service determined that a Species Status Assessment ("SSA") was necessary to guide recovery planning direction for the lynx Distinct Population Segment ("DPS"). From January, 2017 through June, 2017, the Service continued regular calls with the SSA Framework Implementation Team (which oversees development and completion of the SSA report) and with the SSA Core Team (which drafts the SSA report and associated documents). The Service has organized monthly calls or updates via electronic mail with Service field offices and with State and other Federal wildlife agency personnel.
2. In late February, 2017, the Service received comments on the Draft SSA Report from the wildlife agencies of 11 States within the DPS range. The Association of Fish and Wildlife Agencies consolidated and provided these comments to the Service, which also received comments from the Bureau of Land Management, the U.S. Forest Service, and the National Park Service.
3. In early March, 2017, the SSA Team convened a meeting with Service Leadership (*i.e.*, Assistant Regional Directors from Service regions 1, 3, 5, and 6; and the Regional Director from Region 6) in Denver, at which the SSA Core Team summarized the findings of the Draft SSA Report and the peer and State and Federal agency reviews to-date.

4. By mid-March, 2017, the Service received reviews of the Draft SSA Report from all five peer reviewers selected by the Service's peer review contractor, Atkins North America.
5. In mid-May, 2017, the SSA Team reconvened with Service leadership via webinar to review the findings of the Draft SSA Report and to consider recent peer and State and Federal reviews.
6. In February, 2017 through June, 2017, the SSA Core Team responded to peer and State and Federal review comments and revised the Draft SSA Report, with the intent to complete the Final SSA Report in summer, 2017.

DATED: July 1, 2017

Respectfully submitted,

JEFFREY H. WOOD

Cc:	Peter Lamothe; Dave Rothstein
Subject:	Follow up from Lynx SSA - Attorney/Client Privalege - Do Not Release
Date:	Tuesday, August 08, 2017 11:00:25 AM

Hi Anna - OK, we'll wait to hear what Jodi says. We'll especially want to check to see if they dealt with the issues that MDIFW weighed in on. We need to make sure we have a good basis for disagreeing with MDIFW in our projections for how they would manage lynx and lynx habitat (incidental trapping and otherwise) in the absence of ESA protection. We'll also want to check to see if they've fixed the problems relating to conclusions not being adequately supported. Our job is to arrive at rational conclusions and persuasively explain why our conclusions are the most rational - Dave's comments zero in on where we should do this better. Marty

Looks good. I like the characterization of what we identified as the threat (potential) in the original listing as well as that of the 5 year review.

One thing we might want to change. Not all of the federal mgmt plans have been revised. so on page 5 we could say: Nearly all Federal Land Management Plans....

thanks for your work Justin. JB

Subject: Canada lynx 4(f)(1) determination
To: Marjorie Nelson <marjorie_nelson@fws.gov>, Jodi Bush <jodi_bush@fws.gov>

After talking w/ Maricela at HQ, it appears we need to do a 4(f)(1) determination (see attached draft) to be square w/ our Recovery Planning guidance and the Act. The Service has done very few of these over the years, and to our knowledge, never in a situation like we have for lynx. The attached determination memo has in the past been signed at the Director level, and I have it drafted as such.

I know we're waiting to hear from Dana and DOJ on the necessity for some kind of memo to the court regarding the 2014 Order, but if we have to do this determination memo anyway, maybe this can serve that purpose as well?

Please take a look. And let me know if I should share w/ RSOL now.

And if a call to discuss is desired, I can try and set that up, but availability for everyone is tight this week.

Memorandum

To: Director (AES)

From: Regional Director, Region 6

Subject: 4(f)(1) Determination Regarding Recovery Planning for the Canada Lynx (*Lynx Canadensis*)

Region 6 is currently the lead Region for the contiguous United States (U.S.) distinct population segment (DPS) of the Canada lynx under the Endangered Species Act (Act). By this memorandum, I am requesting that the U.S. Fish and Wildlife Service (Service) make a determination under 16 USC § 1533(f)(1) that development of a formal recovery plan at this time would not promote the conservation of the lynx DPS. Your approval signature is requested at the end of this memorandum.

The Service listed the lynx DPS as a threatened species under the Act in 2000 (65 FR 16052-16086). On May 8, 2014, the United States District Court for the District of Montana ordered the Service to complete recovery planning for the lynx DPS (U.S. District Court MT 2014a, p. 8). On June 25, 2014, the same court ordered the Service to complete a recovery plan by January 15, 2018 "…unless the Service finds that such a plan will not promote the conservation of the [lynx]" (i.e., the DPS is recovered or no longer warrants ESA protections; U.S. District Court MT 2014b, p. 2).

The Service listed the lynx DPS as threatened in 2000 because of the *potential for impacts* to lynx habitat conditions and the availability of prey populations within the lynx DPS and existing regulatory mechanisms on Federal lands, *at that time*, did not provide sufficient guidance for the conservation of lynx habitats and populations or prey habitat in light of *potential threats* (65 FR 16052-16086). Federal lands management plans, at that time, allowed for forest management practices that could potentially reduce lynx habitat on a population level scale, thereby creating a future risk to the species existence in the DPS. Nearly all Federal land management plans throughout the DPS have since been revised to include science- and research-based measures and management practices consistent with lynx conservation, thereby greatly reducing the risk of future population scale habitat deterioration on Federal lands (Service 2017, p. 5).

We recently completed a 5-year status review that recommends delisting the lynx DPS (Canada Lynx 5-Year Review 2017, entire). Our status review was informed by a comprehensive Species

Status Assessment (SSA) Report that summarizes the best available scientific information on the current status and likely future viability of the DPS (SSA Report, entire). The peer and partner reviewed SSA Report provides the scientific basis for the 5-year review.

Under the ESA, a threatened species is any species that is "likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range." The foreseeable future refers to the extent to which the Secretary can reasonably rely on predictions about the future in making determinations about the future conservation status of the species (U.S. Department of Interior, Solicitor's Memorandum, M-37021, and January 16, 2009). The key statutory difference between a threatened species and an endangered species is the timing of when a species may be in danger of extinction, either now (endangered species) or in the foreseeable future (threatened species). In the SSA, we considered the future condition of the lynx DPS out to 2025, 2050, and 2100 (SSA Report, chapter 5). It became apparent through discussions with lynx experts, in peer and partner reviews of the draft SSA Report, and among Service biologists and management that any future projections of lynx status beyond mid-century were complicated by a very high degree of uncertainty concerning the timing and extent of various stressors that may affect lynx and hare habitat and snow regimes, especially those related to projected future climate change (SSA Report, chapter 5.1). Therefore, in our 5-year review evaluation, we identified mid-century (2050) as the foreseeable future because this time horizon gives us a higher degree of certainty in reasonably projecting the future condition of the lynx DPS (Canada Lynx 5-Year Review 2017, p. 6).

As discussed in the SSA Report, resident lynx populations in all geographic units that currently support them are expected to be smaller and more fragmented and isolated in the future, and each geographic unit and the DPS as a whole will be less resilient in the future (SSA Report, pp. 173, 236). However, all five geographic units that currently support resident lynx populations (all units except the Greater Yellowstone Area) are expected to continue to do so through mid-century (2050) (SSA Report, p. 236). Our analyses, as informed by expert input, suggest that resiliency will likely be sufficient to foster persistence (i.e., preclude extirpation) of resident lynx through mid-century in all or most of the five geographic units that currently support them (SSA Report, p. 236). At mid-century, we expect lynx to retain a wide geographical distribution of populations, maintaining redundancy within the DPS (SSA Report, p. 236). Should lynx populations in each geographic unit become smaller and more patchily distributed, reduced genetic health and/or adaptive capacity would be expected; however, we have no information to suggest reduced representation would be a DPS-level concern at mid-century (SSA Report, chapter 6). Therefore, we conclude that the risk of extinction (extirpation of the DPS) by 2050 is sufficiently low that the lynx DPS is not likely to become endangered throughout all of its range within the foreseeable future and therefore does not meet the definition of a threatened species (Canada Lynx 5-Year Review 2017, p. 6).

Section 4(f)(l) of the Act requires the Service to develop and implement recovery plans for species listed as endangered or threatened, "unless [the Service] finds such a plan will not promote the conservation of the species. " The definition of conservation, in Section 3(3) of the

Act means" ... all methods and procedures which are necessary to bring any endangered or threatened species to the point at which the measures provided pursuant to the Act are no longer necessary".

According to the 2004 draft revised Recovery Planning Guidance jointly developed by the Service and the National Marine Fisheries Service, acceptable justifications for an exemption from having a recovery plan include: (1) delisting is anticipated due to extinction or listing error; (2) the species historic and current ranges occur entirely under the jurisdiction of other countries; and, (3) "other circumstances not easily foreseen, but in which the species would not benefit from a recovery plan." We believe that preparation of a recovery plan will not contribute to the conservation of the lynx DPS as defined by the Act, and that exemption from recovery planning efforts for the lynx DPS is warranted under reasons (3) above. The “other circumstance” in this case is our recommendation to delist the lynx DPS due to recovery as described in the lynx DPS 5-year review (Canada Lynx 5-Year Review 2017, entire). The lynx DPS no longer meets the definition of a threatened species; therefore, I am requesting that the Service make a determination under 16 USC § 1533(f)(1) that development of a formal recovery plan at this time would not promote the conservation of the lynx DPS. This determination will fulfill the Service’s obligations under the 2014 Court Order (U.S. District Court MT 2014b, p. 2).

Memorandum

To: Director (AES)

From: Regional Director, Region 6

Subject: 4(f)(1) Determination Regarding Recovery Planning for the Canada Lynx (*Lynx ~~C~~canadensis*)

Region 6 is currently the lead Region for the contiguous United States (U.S.) distinct population segment (DPS) of the Canada lynx under the Endangered Species Act (Act). By this memorandum, I am requesting that the U.S. Fish and Wildlife Service (Service) make a determination under 16 USC § 1533(f)(1) that development of a formal recovery plan at this time would not promote the conservation of the lynx DPS. Your approval signature is requested at the end of this memorandum.

The Service listed the lynx DPS as ~~a~~ threatened ~~species~~ under the Act in 2000 (65 FR 16052-16086). On May 8, 2014, the United States District Court for the District of Montana ordered the Service to complete recovery planning for the lynx DPS (U.S. District Court MT 2014a, p. 8). On June 25, 2014, the same court ordered the Service to complete a recovery plan by January 15, 2018 "…unless the Service finds that such a plan will not promote the conservation of the [lynx]" (~~i.e., the DPS is recovered or no longer warrants ESA protections;~~ U.S. District Court MT 2014b, p. 2).

The Service listed the lynx DPS as threatened in 2000 because of the *potential for impacts* to lynx habitat conditions and the availability of prey populations within the lynx DPS and because existing regulatory mechanisms on Federal lands, *at that time*, did not provide sufficient guidance for the conservation of lynx habitats and populations or prey habitat in light of *potential threats* (65 FR 16052-16086). Federal lands management plans, at that time, allowed for forest management practices that could potentially reduce lynx habitat on a population level scale, thereby creating a future risk to the species existence in the DPS. Nearly all Federal land management plans throughout the DPS have since been revised to include science- and research-based measures and management practices consistent with lynx conservation, thereby greatly reducing the risk of future population scale habitat deterioration on Federal lands (Service 2017, p. 5).

Commented [ZJ1]: The segment was listed; not the species

Commented [ZJ2]: This is my parenthetical clarifying language I used in the SSA report (& it perhaps got carried over into other memos); it is not part of the quote from the from the court order

Commented [ZJ3]: Should we note that even in the few instances where management plans have yet to be formally revised or amended (only one National Forest - the Okanogan-Wenatchee in Washington, and several BLM districts in CO with minimal lynx habitat), the mgmt agency (USFS or BLM) did adopt and implement conservations measures based on best available science as provided in the interagency Lynx Conservation Assessment and Strategy (LCAS) and in accordance with signed conservation agreements (CAs) between the agencies and the Service?

We recently completed a 5-year status review that recommends delisting the lynx DPS (Canada Lynx 5-Year Review 2017, entire). Our status review was informed by a comprehensive Species Status Assessment (SSA) Report that summarizes the best available scientific information on the current status and likely future viability of the DPS (SSA Report, entire). The peer and partner reviewed SSA Report provides the scientific basis for the 5-year review.

Under the ESA, a threatened species is any species that is "likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range." The foreseeable future refers to the extent to which the Secretary can reasonably rely on predictions about the future in making determinations about the future conservation status of the species (U.S. Department of Interior, Solicitor's Memorandum, M-37021, and January 16, 2009). The key statutory difference between a threatened species and an endangered species is the timing of when a species may be in danger of extinction, either now (endangered species) or in the foreseeable future (threatened species). In the SSA, we considered the future condition of the lynx DPS out to 2025, 2050, and 2100 (SSA Report, chapter 5). It became apparent through discussions with lynx experts, in peer and partner reviews of the draft SSA Report, and among Service biologists and management that any future projections of lynx status beyond mid-century were complicated by a very high degree of uncertainty concerning the timing and extent of various stressors that may affect lynx and hare habitat and snow regimes, especially those related to projected future climate change (SSA Report, chapter 5.1). Therefore, in our 5-year review evaluation, we identified mid-century (2050) as the foreseeable future because this time horizon gives us a higher degree of certainty in reasonably projecting the future condition of the lynx DPS (Canada Lynx 5-Year Review 2017, p. 6).

As discussed in the SSA Report, resident lynx populations in all geographic units that currently support them are expected to be smaller and more fragmented and isolated in the future, and each geographic unit and the DPS as a whole will be less resilient in the future (SSA Report, pp. 173, 236). However, all five geographic units that currently support resident lynx populations (all units except the Greater Yellowstone Area) are expected to continue to do so through mid-century (2050) (SSA Report, p. 236). Our analyses, as informed by expert input, suggest that resiliency will likely be sufficient to foster persistence (i.e., preclude extirpation) of resident lynx through mid-century in all or most of the five geographic units that currently support them (SSA Report, p. 236). At mid-century, we expect lynx to retain a wide geographical distribution of populations, maintaining redundancy within the DPS (SSA Report, p. 236). Should lynx populations in each geographic unit become smaller and more patchily distributed, reduced genetic health and/or adaptive capacity would be expected; however, we have no information to suggest reduced representation would be a DPS-level concern at mid-century (SSA Report, chapter 6). Therefore, we conclude that the risk of extinction (extirpation of the DPS) by 2050 is sufficiently low that the lynx DPS is not likely to become endangered throughout all of its range within the foreseeable future and therefore does not meet the definition of a threatened species (Canada Lynx 5-Year Review 2017, p. 6).

Section 4(f)(l) of the Act requires the Service to develop and implement recovery plans for species listed as endangered or threatened, "unless [the Service] finds such a plan will not promote the conservation of the species. " The definition of conservation, in Section 3(3) of the Act means" ... all methods and procedures which are necessary to bring any endangered or threatened species to the point at which the measures provided pursuant to the Act are no longer necessary".

According to the 2004 draft revised Recovery Planning Guidance jointly developed by the Service and the National Marine Fisheries Service, acceptable justifications for an exemption from having a recovery plan include: (1) delisting is anticipated due to extinction or listing error; (2) the species historic and current ranges occur entirely under the jurisdiction of other countries; and, (3) "other circumstances not easily foreseen, but in which the species would not benefit from a recovery plan." We believe that preparation of a recovery plan will not contribute to the conservation of the lynx DPS as defined by the Act, and that exemption from recovery planning efforts for the lynx DPS is warranted under reason~~s~~ (3) above. The “other circumstance” in this case is our recommendation to delist the lynx DPS due to recovery as described in the lynx DPS 5-year review (Canada Lynx 5-Year Review 2017, entire). The lynx DPS no longer meets the definition of a threatened species; therefore, I am requesting that the Service make a determination under 16 USC § 1533(f)(1) that development of a formal recovery plan at this time would not promote the conservation of the lynx DPS. This determination will fulfill the Service’s obligations under the 2014 Court Order (U.S. District Court MT 2014b, p. 2).

Memorandum

To: Director (AES)

From: Regional Director, Region 6

Subject: 4(f)(1) Determination Regarding Recovery Planning for the Canada Lynx (*Lynx ~~C~~canadensis*)

Region 6 is currently the lead Region for the contiguous United States (U.S.) distinct population segment (DPS) of the Canada lynx under the Endangered Species Act (Act). By this memorandum, I am requesting that the U.S. Fish and Wildlife Service (Service) make a determination under 16 USC § 1533(f)(1) that development of a formal recovery plan at this time would not promote the conservation of the lynx DPS. Your approval signature is requested at the end of this memorandum.

The Service listed the lynx DPS as ~~a~~ threatened ~~species~~ under the Act in 2000 (65 FR 16052-16086). On May 8, 2014, the United States District Court for the District of Montana ordered the Service to complete recovery planning for the lynx DPS (U.S. District Court MT 2014a, p. 8). On June 25, 2014, the same court ordered the Service to complete a recovery plan by January 15, 2018 "…unless the Service finds that such a plan will not promote the conservation of the [lynx]" (~~i.e., the DPS is recovered or no longer warrants ESA protections;~~ U.S. District Court MT 2014b, p. 2).

The Service listed the lynx DPS as threatened in 2000 because of the *potential for impacts* to lynx habitat conditions and the availability of prey populations within the lynx DPS and because existing regulatory mechanisms on Federal lands, *at that time*, did not provide sufficient guidance for the conservation of lynx habitats and populations or prey habitat in light of these *potential threats* (65 FR 16052-16086). Federal lands management plans, at that time, allowed for forest management practices that could potentially reduce lynx habitat on a population level scale, thereby creating a future risk to the species existence in the DPS. Nearly all Federal land management plans throughout the DPS have since been revised to include science- and research-based measures and management practices consistent with lynx conservation, thereby greatly reducing the risk of future population scale habitat deterioration on Federal lands (Service 2017, p. 5).

Commented [ZJ1]: The segment was listed; not the species

Commented [ZJ2]: This is my parenthetical clarifying language I used in the SSA report (& it perhaps got carried over into other memos); it is not part of the quote from the from the court order

Commented [ZJ3]: Should we note that even in the few instances where management plans have yet to be formally revised or amended (only one National Forest - the Okanogan-Wenatchee in Washington, and several BLM districts in CO with minimal lynx habitat), the mgmt agency (USFS or BLM) did adopt and implement conservations measures based on best available science as provided in the interagency Lynx Conservation Assessment and Strategy (LCAS) and in accordance with signed conservation agreements (CAs) between the agencies and the Service?

I think Yes JB

We recently completed a 5-year status review that recommends delisting the lynx DPS (Canada Lynx 5-Year Review 2017, entire). Our status review was informed by a comprehensive Species Status Assessment (SSA) Report that summarizes the best available scientific information on the current status and likely future viability of the DPS (SSA Report, entire). The peer and partner reviewed SSA Report provides the scientific basis for the 5-year review.

Under the ESA, a threatened species is any species that is "likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range." The foreseeable future refers to the extent to which the Secretary can reasonably rely on predictions about the future in making determinations about the future conservation status of the species (U.S. Department of Interior, Solicitor's Memorandum, M-37021, and January 16, 2009). The key statutory difference between a threatened species and an endangered species is the timing of when a species may be in danger of extinction, either now (endangered species) or in the foreseeable future (threatened species). In the SSA, we considered the future condition of the lynx DPS out to 2025, 2050, and 2100 (SSA Report, chapter 5). It became apparent through discussions with lynx experts, in peer and partner reviews of the draft SSA Report, and among Service biologists and management that any future projections of lynx status beyond mid-century were complicated by a very high degree of uncertainty concerning the timing and extent of various stressors that may affect lynx and hare habitat and snow regimes, especially those related to projected future climate change (SSA Report, chapter 5.1). Therefore, in our 5-year review evaluation, we identified mid-century (2050) as the foreseeable future because this time horizon gives us a higher degree of certainty in reasonably projecting the future condition of the lynx DPS (Canada Lynx 5-Year Review 2017, p. 6).

As discussed in the SSA Report, resident lynx populations in all geographic units that currently support them are expected to be smaller and more fragmented and isolated in the future, and each geographic unit and the DPS as a whole will be less resilient in the future (SSA Report, pp. 173, 236). However, all five geographic units that currently support resident lynx populations (all units except the Greater Yellowstone Area) are expected to continue to do so through mid-century (2050) (SSA Report, p. 236). Our analyses, as informed by expert input, suggest that resiliency will likely be sufficient to foster persistence (i.e., preclude extirpation) of resident lynx through mid-century in all or most of the five geographic units that currently support them (SSA Report, p. 236). At mid-century, we expect lynx to retain a wide geographical distribution of populations, maintaining redundancy within the DPS (SSA Report, p. 236). Should lynx populations in each geographic unit become smaller and more patchily distributed, reduced genetic health and/or adaptive capacity would be expected; however, we have no information to suggest reduced representation would be a DPS-level concern at mid-century (SSA Report, chapter 6). Therefore, we conclude that the risk of extinction (extirpation of the DPS) by 2050 is sufficiently low that the lynx DPS is not likely to become endangered throughout all of its range within the foreseeable future and therefore does not meet the definition of a threatened species (Canada Lynx 5-Year Review 2017, p. 6).

Section 4(f)(l) of the Act requires the Service to develop and implement recovery plans for species listed as endangered or threatened, "unless [the Service] finds such a plan will not promote the conservation of the species. " The definition of conservation, in Section 3(3) of the Act means" ... all methods and procedures which are necessary to bring any endangered or threatened species to the point at which the measures provided pursuant to the Act are no longer necessary".

According to the 2004 draft revised Recovery Planning Guidance jointly developed by the Service and the National Marine Fisheries Service, acceptable justifications for an exemption from having a recovery plan include: (1) delisting is anticipated due to extinction or listing error; (2) the species historic and current ranges occur entirely under the jurisdiction of other countries; and, (3) "other circumstances not easily foreseen, but in which the species would not benefit from a recovery plan." We believe that preparation of a recovery plan will not contribute to the conservation of the lynx DPS as defined by the Act, and that exemption from recovery planning efforts for the lynx DPS is warranted under reason~~s~~ (3) above. The “other circumstance” in this case is our recommendation to delist the lynx DPS due to recovery as described in the lynx DPS 5-year review (Canada Lynx 5-Year Review 2017, entire). The lynx DPS no longer meets the definition of a threatened species; therefore, I am requesting that the Service make a determination under 16 USC § 1533(f)(1) that development of a formal recovery plan at this time would not promote the conservation of the lynx DPS. This determination will fulfill the Service’s obligations under the 2014 Court Order (U.S. District Court MT 2014b, p. 2).

Subject:	DRAFT Lynx Update to the Court
Date:	Thursday, November 30, 2017 3:28:21 PM
Attachments:	2017 12 01 DOJ Draft WILDLIFE-#298505-v1- Lynx RP 7 17 Status Report CLEAN.doc

Although I'm a little out of the loop with what's going on with the 4(f)(1) and the RSOL's/HQ's review of the final SSA report and the 5-year review, we do have a 6-month update to the court due by the end of December. Given the above and the upcoming holiday, I've drafted the attached update based on my understanding of how things may unfold, using the last court update as a template.

Because of my uncertainty about this process, I thought I'd run this by you three before sending a draft to Dana.

Please edit as you see fit in TRACK CHANGES and send me your thoughts/concerns at your earliest convenience so I can get a draft to Dana allowing plenty of time for her to coordinate with DOJ and get the final update to the court by the Dec. 31 deadline.

Also wanted to let you know that I will be on annual leave after Christmas, returning to the office on Jan. 15 - the same day, coincidentally, that our determination (or formal recovery plan) is due to the court...

Cheers!

Jim

Attorneys for Federal Defendants

IN THE UNITED STATES DISTRICT COURT
FOR THE DISTRICT OF MONTANA
MISSOULA DIVISION

FRIENDS OF THE WILD SWAN, ROCKY MOUNTAIN WILD, et al.,	)	No. 13-cv-57-DWM
Plaintiffs, v.	)	DEFENDANTS' STATUS REPORT
DANIEL ASHE, U.S. FISH & WILDLIFE SERVICE, et al.,	)	
Defendants.	)	

Pursuant to the Court's order of June 25, 2014, Federal Defendants hereby submit the following status report on the United States Fish and Wildlife Service's ("Service") recovery planning for the Canada lynx under 16 U.S.C. § 1533(f) for

the period from July 1, 2017 to January 1, 2018. *See* ECF No. 30.

1. In March, 2015, the Service determined that a Species Status Assessment ("SSA") was necessary to guide recovery planning direction for the lynx Distinct Population Segment ("DPS"). From July, 2017 through December, 2017, the Service continued monthly calls or updates via electronic mail with Service field offices and with State and other Federal wildlife agency personnel. During this time period, the SSA Core Team continued work to finalize the SSA report based on peer and partner reviews and comments.
2. In October, 2017, the Core Team completed the Final SSA Report. The Final Report was submitted to the Service's Species Assessment Team, which relied on the report to draft the Canada Lynx (*Lynx canadensis*) 5-Year Review: Summary and Evaluation (5-year review).
3. On November 13, 2017, after internal Service and Solicitor review and concurrence from the other Regional Directors within the DPS range, the Regional Director for Region 6 signed the 5-year review (attached), which recommends delisting the Canada lynx DPS due to recovery.
4. On December XX, 2017, the Service's Acting Director signed the 4(f)(1) Determination Regarding Recovery Planning for the Canada Lynx (*Lynx canadensis*) (4(f)(1) determination; attached), indicating that development of a formal recovery plan at this time would not promote the conservation of

the lynx DPS.

5. On December XX, 2017, RSOL/DOJ briefed the Court on the Service's 5-year review recommendation and provided the Court copies of the Final SSA Report, the signed 5-year review, and the signed 4(f)(1) determination.

6. On December XX, 2017, the Service made the Final SSA Report, the signed 5-year review, and the signed 4(f)(1) determination available to the public via a news release and posting of the documents on its Canada lynx web page (https://www.fws.gov/mountain-prairie/es/canadaLynx.php).

DATED: {date}.

Respectfully submitted,

I agree with Justin's edits but want to remind everyone that we have a court mandated timeline for a Final Lynx recovery plan of January 15, 2018. That is just over 4 weeks away. Has that been briefed up the chain ? Cause I can foresee a huge problem if we don't meet that timeline. JB

Memorandum

To: Director

From: Regional Director, Mountain-Prairie Region Noreen E. Walsh

Subject: 4(f)(1) Determination Regarding Recovery Planning for the Canada Lynx (*Lynx canadensis*)

The purpose of this memorandum is to make a determination under 16 U.S.C. § 1533(f)(1) that the development of a recovery plan for the contiguous United States distinct population segment (DPS) of the Canada lynx would not promote the conservation of the species. A recent multi-region 5-year review determined that the lynx DPS should be proposed for delisting pursuant to the Endangered Species Act (Act). The Service is required, by court order, to complete a recovery plan for the lynx DPS by January 15, 2018 unless the agency finds that such a plan will not promote conservation for the species.

Background

The Service listed the lynx DPS as a threatened species under the Act in 2000 (65 FR 16052-16086). We originally designated critical habitat for the lynx on November 9, 2006 (71 FR 66008), revised critical habitat on February 25, 2009 (74 FR 8616), then revised critical habitat again on September 12, 2014 (79 FR 54782). On May 8, 2014, the United States District Court for the District of Montana ordered the Service to complete recovery planning for the lynx DPS (U.S. District Court Montana 2014a, p. 8). On June 25, 2014, that court ordered the Service to complete a recovery plan by January 15, 2018 "...unless the Service finds that such a plan will not promote the conservation of the [lynx]" (U.S. District Court Montana 2014b, p. 2).

The Service listed the lynx DPS as threatened in 2000 because of the potential for impacts to lynx habitat conditions and prey populations due to regulatory mechanisms on Federal lands that did not provide sufficient certainty that lynx habitats, lynx populations, and prey populations would be adequately conserved in light of potential threats (65 FR 16052-16086). Federal land management plans, at that time, allowed for forest management practices that could potentially reduce lynx habitat on a population level scale, thereby creating a future risk to the species' existence in the DPS.

In coordination with Regions 1, 3, 5, and 6, the Service recently completed a 5-year status review that recommends delisting the lynx DPS (Canada Lynx 5-Year Review 2017, entire). Our status review was informed by a comprehensive Species Status Assessment (SSA) Report that summarizes the best available scientific information on the current status and likely future viability of the DPS (SSA Report, entire). The peer and partner reviewed SSA Report provides the scientific basis for the 5-year review.

As we stated in the 5-year review, "In light of potential threats considered at the time of listing, lynx conservation measures and habitat management guidance adopted by the U. S. Forest Service (USFS) and the Bureau of Land Management (BLM), via formally amended or revised management plans or conservation agreements with the Service, have substantially addressed the conservation of lynx habitats and populations and snowshoe hare habitat (SSA Report, p. 4)." (Canada Lynx 5-Year Review 2017, p. 5). All five geographic units that currently support resident lynx populations are expected to continue to do so through mid-century (2050) (SSA Report, p. 236). Our analyses, as informed by expert input, suggest that resiliency will likely be sufficient to sustain species persistence of resident lynx through mid-century in all or most of the five geographic units that currently support them (SSA Report, p. 236). At mid-century, we expect lynx to retain a wide geographical distribution of populations, maintaining redundancy within the DPS (SSA Report, p. 236). Should lynx populations in each geographic unit become smaller and more patchily distributed, reduced genetic health and/or adaptive capacity would be expected; however, we have no information to suggest reduced representation would be a DPS-level concern at mid-century (SSA Report, chapter 6). Therefore, we concluded in the 5-year review that the lynx DPS may not meet the definition of a threatened species (Canada Lynx 5-Year Review 2017, p. 6).

Recommendation

Section 4(f)(l) of the Act requires the Service to develop and implement recovery plans for species listed as endangered or threatened, "unless [the Service] finds such a plan will not promote the conservation of the species." According to the 2004 draft revised Recovery Planning Guidance jointly developed by the Service and the National Marine Fisheries Service, acceptable justifications for an exemption from having a recovery plan include: (1) delisting is anticipated due to extinction or listing error; (2) the species' historic and current ranges occur entirely under the jurisdiction of other countries; and, (3) other circumstances not easily foreseen, but in which the species would not benefit from a recovery plan.

For the lynx DPS, we are seeking concurrence that preparation of a recovery plan will not contribute to the conservation of the lynx DPS as defined by the Act, and that exemption from recovery planning efforts for the lynx DPS is warranted under reason (3) above. The "other circumstance" in this case is our recommendation to delist the lynx DPS due to recovery as described in the lynx DPS 5-year review (Canada Lynx 5-Year Review 2017, entire). The lynx DPS may no longer meet the definition of a threatened species. A proposed delisting rule should be prepared by the Service.

If, during the rulemaking process on the recommendation to delist the DPS, the Service determines that lynx should remain listed, the Service would reconsider the need to complete a recovery plan. Presently, the Service determines under 16 U.S.C. § 1533(f)(1) that a recovery plan would not promote conservation of the species and this determination will fulfill the Service's obligations under the 2014 Court Order.

Canada Lynx
(Lynx canadensis)

5-Year Review:
Summary and Evaluation

U.S. Fish and Wildlife Service
Mountain-Prairie Region
Lakewood, Colorado

5-YEAR REVIEW
Canada lynx (*Lynx canadensis*) – Contiguous U.S. Distinct Population Segment (DPS)

GENERAL INFORMATION

Methodology Used to Complete the Review:

In accordance with section 4(c)(2) of the Endangered Species Act (ESA), the purpose of a 5-year review is to assess each threatened and endangered species to determine whether its status has changed since the time of its listing, or its last status review and whether it should be classified differently or removed from the list of threatened and endangered species. The U.S. Fish and Wildlife Service (Service) evaluated the biology and status of the contiguous United States (U.S.) distinct population segment (DPS) of the Canada lynx as part of a Species Status Assessment (SSA) to inform this 5-year review and, if needed, recovery planning. The SSA Report was written by the Canada Lynx Species Status Assessment Team (Lynx SSA Team), which consists of a Core Team of Service biologists who work on lynx issues across the DPS range and an SSA Framework Implementation Team of Service and U.S. Geological Survey staff who have developed and advanced the SSA framework. The SSA Report represents the Service's evaluation of the best available scientific information, including the formally-elicited professional judgments and opinions of recognized lynx experts. The SSA Report underwent independent peer and partner review before being used as the scientific basis to support a decision making process involving Service Regions 1, 3, 5, and 6 regarding the recommendation presented in this 5-year review.

Region 6 is the lead region for this action in coordination with Regions 1, 2, 3, and 5. The lead field office (FO) is the Montana Ecological Services FO, with support from the Maine, Minnesota, Northern Idaho and Western Colorado Ecological Services FOs.

Background:

Listing History

The Service listed the lynx DPS as a threatened species under the ESA in 2000 because of the potential for impacts to lynx habitat conditions and the availability of snowshoe hare and other prey populations within the lynx DPS and existing regulatory mechanisms on Federal lands, at that time, did not provide sufficient guidance for the conservation of lynx habitats and populations or snowshoe hare habitat in light of potential threats (65 FR 16052-16086). On May 8, 2014, the United States District Court for the District of Montana ordered the Service to complete recovery planning for the lynx DPS (U.S. District Court MT 2014a, p. 8). On June 25, 2014, the same court ordered the Service to complete a recovery plan by January 15, 2018 "…unless the Service finds that such a plan will not promote the conservation of the [lynx]" (i.e., the DPS is recovered or no longer warrants ESA protections; U.S. District Court MT 2014b, p. 2). We published the initiation of the 5-year review in the Federal Register on April 18, 2007

(72 FR 19549), and additionally published a news release announcing initiation of a 5-yr review on January 13, 2015.

We completed the SSA Report to summarize the best available scientific information on the current status and likely future viability of the DPS. The SSA provides the scientific basis for this 5-year review.

REVIEW ANALYSIS

Application of the 1996 Distinct Population Segment (DPS) Policy in the 2000 Listing

The Service listed lynx in the contiguous United States as a DPS because of differences in the management of lynx and lynx habitats across the international boundary with Canada (meeting discreteness criteria in the DPS policy) and because of the climatic, vegetative, and ecological differences in lynx habitat compared to the northern parts of the species' range in Canada and Alaska (meeting significance criteria) (65 FR 16052; 68 FR 40076; 72 FR 1186).

Updated Information and Current Species Status

Summary of SSA Results:

In the SSA, we describe the current and future viability of the lynx DPS in terms of resiliency, redundancy, and representation. Resident lynx populations persisted historically and continued to persist in four of the six geographic units evaluated in the SSA (Unit 1 (Northern Maine), Unit 2 (Northeastern Minnesota), Unit 3 (Northwestern Montana/Northeastern Idaho), and Unit 4 (North-central Washington)) (SSA Report, p. 235). Based on verified records, it is uncertain if the Greater Yellowstone Area (Unit 5) historically supported a persistent resident lynx population and it currently appears not to support resident lynx (SSA Report, p. 235). Available information also suggests that Colorado (Unit 6) did not historically support persistent lynx presence; however, a resident population has persisted there for more than a decade since the 1999-2006 release of 218 Canadian and Alaskan lynx in the San Juan Mountains (SSA Report, p. 235).

Considering the available information, we found no reliable information that the current distribution and abundance of resident lynx in the contiguous United States are substantially reduced from historical conditions (SSA Report, p. 235). In fact, because of the introduction of lynx in Colorado and anthropogenically influenced lynx abundance in Maine, there may be more resident lynx currently in the DPS range than occurred historically (SSA Report, pp. 228, 229). This suggests historical and current resiliency among lynx populations in the DPS. The current broad distribution of resident lynx in large, geographically discrete areas (redundancy) makes the DPS invulnerable to extirpation caused by a single catastrophic event (SSA Report, pp. 106, 235). Because we lack information that formerly persistent lynx populations have been lost from any large areas, it also seems that redundancy in the DPS has not been meaningfully diminished from historical levels (SSA Report, pp. 106, 235). As a result of the current population in Colorado, redundancy in the DPS is likely greater, at least temporarily, now than it was historically (SSA Report, p. 235). Similarly, resident lynx remain broadly distributed across the

range of habitats that have supported them historically, suggesting maintenance of the breadth and diversity of ecological settings occupied within the DPS range (representation) (SSA Report, p. 235).

Additionally, observed high rates of dispersal and gene flow and therefore generally low levels of genetic differentiation across most of the lynx's range, including the DPS, suggest the past and recent genetic health of lynx populations in the DPS (representation) (SSA Report, section 2.1). Because there are no indications of significant loss of, or current stressors to, the genetic health or adaptive capacity of lynx populations in the DPS, we find that the current level of representation within the DPS does not appear to indicate a decrease from historical conditions (SSA Report, pp. 107, 230).

We conclude that resident lynx populations are very likely to persist in all five units that currently support them (Units 1 to 4 and 6) in the near term (2025) and likely to persist in those five units at mid-century (2050) (SSA Report, p. 236). We have low confidence in assessing the risk to DPS populations beyond 2050 (SSA Report, p. 236). Therefore, we consider 2050 as the foreseeable future for this 5-year review. Nonetheless, we expect lynx populations in each geographic unit to become smaller and more patchily distributed in the future (2050 and beyond) due largely to projected climate-driven losses in habitat quality and quantity and related factors (SSA Report, p. 236). However, the timing, rate, and extent of habitat decline due to projected climate warming and corresponding effects to lynx populations all are highly uncertain (SSA Report, p. 236). That said, smaller, more isolated populations would be less resilient and more vulnerable to demographic and environmental stochasticity and genetic drift and therefore at higher risk of extirpation (SSA Report, p. 236). Despite some reduced resiliency, we conclude that resident lynx populations are likely to persist through mid-century in the geographic units that supported them historically (Units 1 to 4); with the corresponding maintenance of redundancy and representation in the DPS over that time span (SSA Report, p. 236). Although the SSA report also discusses the future out to 2100, predictions that far into the future are highly uncertain (SSA Report, p. 236), and beyond what we consider to be reasonably foreseeable.

Consideration of the Five 4(a)(1) Factors:

Through our SSA analysis, we have evaluated the effects of all factors identified in section 4(a)(1) of the ESA. In the SSA we focused on the influences identified as having the potential to exert population and DPS-level impacts on lynx and lynx habitats (SSA Report, chapter 3). Those anthropogenic influences include climate change (Factor E), vegetation management (Factor A), wildland fire management (Factor A), and habitat loss and fragmentation (Factor A). We also considered other potential stressors such as trapping (Factor B), and disease and predation (Factor C). Additionally, we considered how each of the above influences is ameliorated or exacerbated by existing regulatory mechanisms (Factor D).

In using the SSA framework to analyze the scientific information, as documented in the SSA Report, we fully assess not only individual effects on the Canada lynx, but also their potential cumulative impacts. Specifically, we incorporate cumulative effects into our analysis when we characterize the current and future conditions for each population, which we do both individually and cumulatively. Our analysis described the ways in which anthropogenic and natural factors

singly and collectively affect the habitat and/or demographics needed by individuals and populations. Because the SSA framework considers not just the presence of the factors but also the degree to which they collectively influence the species' viability, our assessment integrates the cumulative impacts of stressors.

In light of potential threats considered at the time of listing, lynx conservation measures and habitat management guidance adopted by the U. S. Forest Service (USFS) and the Bureau of Land Management (BLM), via formally amended or revised management plans or conservation agreements with the Service, have substantially addressed the conservation of lynx habitats and populations and snowshoe hare habitat (SSA Report, p. 4).

Synthesis (Application of SSA Results to ESA Classification)

As defined by the ESA, an endangered species is any species that is "in danger of extinction throughout all or a significant portion of its range." In the SSA Report, we evaluated the best available scientific information regarding the current and predicted future condition of the lynx DPS to describe its viability and how it may change over time (2025, 2050, and 2100). We assess the viability of the lynx DPS by evaluating its ability to maintain a sufficient number and distribution of viable populations to withstand environmental stochasticity (resiliency), catastrophes (redundancy), and changes in its environment (representation) into the future. Ultimately, we compare our evaluation of the DPS' risk of extinction against the definitions of an endangered or threatened species as defined by the ESA.

As stated above. the Service listed the lynx DPS as threatened in 2000 because of the *potential for impacts* to lynx habitat conditions and the availability of prey populations within the lynx DPS and existing regulatory mechanisms on Federal lands, *at that time*, did not provide sufficient guidance for the conservation of lynx habitats and populations or prey habitat in light of *potential threats* (65 FR 16052-16086). Federal lands management plans, at that time, allowed for forest management practices that could potentially reduce lynx habitat on a population level scale, thereby creating a future risk to the species existence in the DPS. Nearly all Federal land management plans throughout the DPS have since been revised to include science- and research-based measures and management practices consistent with lynx conservation, thereby greatly reducing the risk of future population scale habitat deterioration on Federal lands.

The apparent long-term (historical and current) persistence of resident lynx populations in at least four of the six geographic units (Units 1 to 4), the current persistence of lynx in one of the units (Unit 6), and the absence of reliable information indicating that the current distribution and relative abundance of resident lynx are substantially reduced from historical conditions suggest the historical and recent resiliency to stochastic events of lynx populations in the DPS (SSA Report, pp. 107, 230). The large sizes and broad distributions of the geographic units occupied by resident lynx populations likewise indicate historical and current redundancy in the DPS sufficient to reduce the possibility of extirpation from catastrophic events (SSA Report, pp. 230, 235). There are no indications of current threats to the genetic health or adaptive capacity of lynx populations in the DPS, and the current level of representation does not suggest a decrease from historical conditions (SSA Report, p. 230). Due to the current resiliency, redundancy, and

representation of the lynx DPS, we conclude that the risk of extinction (in this case, extirpation of all resident lynx populations in the DPS) is low, such that the DPS currently is not in danger of extinction throughout all of its range and, therefore, does not meet the definition of an endangered species.

Having determined that the lynx DPS is not endangered, we next compare the status of the DPS to the definition of a threatened species. Under the ESA, a threatened species is any species that is "likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range." The foreseeable future refers to the extent to which the Secretary can reasonably rely on predictions about the future in making determinations about the future conservation status of the species (U.S. Department of Interior, Solicitor's Memorandum, M-37021, and January 16, 2009). The key statutory difference between a threatened species and an endangered species is the timing of when a species may be in danger of extinction, either now (endangered species) or in the foreseeable future (threatened species). In the SSA, we considered the future condition of the lynx DPS out to 2025, 2050, and 2100 (SSA Report, chapter 5). It became apparent through discussions with lynx experts, in peer and partner reviews of the draft SSA Report, and among Service biologists and management that any future projections of lynx status beyond mid-century were complicated by a very high degree of uncertainty concerning the timing and extent of various stressors that may affect lynx and hare habitat and snow regimes, especially those related to projected future climate change (SSA Report, chapter 5.1). Therefore, in this evaluation, we identified mid-century (2050) as the foreseeable future because this time horizon gives us a higher degree of certainty in reasonably projecting the future condition of the lynx DPS.

As discussed in the SSA Report, resident lynx populations in all geographic units that currently support them are expected to be smaller and more fragmented and isolated in the future, and each geographic unit and the DPS as a whole will be less resilient in the future (SSA Report, pp. 173, 236). However, all five geographic units that currently support resident lynx populations (all units except the GYA) are expected to continue to do so through mid-century (2050) (SSA Report, p. 236). Our analyses, as informed by expert input, suggest that resiliency will likely be sufficient to foster persistence (i.e., preclude extirpation) of resident lynx through mid-century in all or most of the five geographic units that currently support them (SSA Report, p. 236). At mid-century, we expect lynx to retain a wide geographical distribution of populations, maintaining redundancy within the DPS (SSA Report, p. 236). Should lynx populations in each geographic unit become smaller and more patchily distributed, reduced genetic health and/or adaptive capacity would be expected; however, we have no information to suggest reduced representation would be a DPS-level concern at mid-century (SSA Report, chapter 6). Therefore, we conclude that the risk of extinction (extirpation of the DPS) by 2050 is sufficiently low that the lynx DPS is not likely to become endangered throughout all of its range within the foreseeable future and therefore does not meet the definition of a threatened species.

Recovery Criteria

Recovery Plan or Outline: There is no recovery plan for the Canada lynx DPS, and therefore recovery criteria have not been developed. The Service completed a Recovery Outline on September 14, 2005, which provided preliminary recovery objectives and actions based on our

understanding, at that time, of current and historical lynx occurrence and lynx population dynamics in the contiguous United States DPS. Lynx conservation measures and habitat management guidance adopted by the USFS and the BLM have substantially addressed the potential threats considered at the time of listing (and the time of the recovery outline) to the maintenance of lynx DPS habitat conditions and the availability of snowshoe hare and other prey populations (SSA Report, p. 4). Additionally, our understanding of lynx biology, ecology, effects of stressors into the foreseeable future, and historic and current occupancy in the contiguous United States has improved in the 12 years since the Recovery Outline was drafted, rendering some of the preliminary recovery objectives and actions in the 2005 Recovery Outline obsolete. Finally, as described above, the lynx DPS no longer meets the definition of a threatened species; therefore, recovery criteria are not necessary.

RESULTS

Recommended Classification: After assessing the best available information, we conclude that the Canada lynx DPS is not in danger of extinction throughout all of its range or likely to become so in the foreseeable future; that is, it is not an endangered species throughout all of its range or a threatened species throughout all of its range. We recommend removing the Canada lynx DPS, currently listed as threatened, from the list of threatened and endangered species.

____ **Downlist to Threatened**
____ **Uplist to Endangered**
__x_ **Delist** (*Indicate reasons for delisting per 50 CFR 424.11):*
____ *Extinction*
__x_ *Recovery*
____ *Original data for classification in error*

Brief Rationale:

RECOMMENDATIONS FOR FUTURE ACTIONS – Proceed with a proposed rule to remove the Canada lynx DPS from the list of threatened and endangered species.

REFERENCES – A large part of the lynx SSA involved seeking expert input on lynx biology, stressors, and current and future condition of the DPS. We describe the expert elicitation process and the experts involved in our Canada Lynx Expert Elicitation Workshop Final Report (Service 2016, entire). A draft SSA Report went through an extensive review process with peer reviewers, tribes, State agencies, and Federal agencies within the range of the lynx DPS. The final SSA Report has been revised in response to the reviews, comments, and suggestions of 5 independent peer reviewers, 11 State wildlife and natural resources management agencies, and 3 other Federal agencies.

This SSA report was produced by the Canada Lynx Species Status Assessment Team (Lynx SSA Team), which consists of a Core Team of Service biologists who work on lynx conservation across the DPS range and an SSA Framework Implementation Team of Service and U.S. Geological Survey staff who have developed and advanced the SSA framework.

U.S. Fish and Wildlife Service Lynx SSA Core Team

Jim Zelenak (Lead), Region 6, Montana Ecological Services Field Office: Chapters/sections - Executive Summary, 1, 2, 3.1, 3.4, 6, and Units 3 and 5
Mark McCollough (Co-lead), Region 5, Maine Ecological Services Field Office: Sections - 3.2, 3.3, 3.5, and Unit 1
Kurt Broderdorp, Region 6, Western Colorado Ecological Services Field Office: Unit 6
Bryon Holt, Region 1, Northern Idaho Ecological Services Field Office: Unit 4
Tamara Smith, Region 3, Minnesota-Wisconsin Ecological Services Field Office: Unit 2

All Core Team members participated in development of conceptual models and reviewed and provided comments/edits on other sections of the SSA report. All members also helped identify and contact lynx expert panelist candidates and other subject matter experts and contributed to expert elicitation and the report of the Expert Elicitation Workshop (see Acknowledgments).

SSA Framework Implementation Team

Heather Bell, USFWS Headquarters, Ecological Services, Division of Restoration and Recovery
Mary Parkin, USFWS Region 5, Endangered Species Recovery Coordinator
Justin Shoemaker, USFWS Region 6, Classification and Recovery Biologist
Jonathan Cummings, USGS - Patuxent Wildlife Research Center, Research Ecologist

The Framework Implementation Team (FIT) developed and facilitated the expert elicitation process. J. Cummings compiled, analyzed, graphed, and summarized the information generated via expert elicitation and created, with Core and FIT input, conceptual models presented in section 1.3. All FIT members contributed to the Executive Summary and sections 1.2 and 1.3, and all provided technical review and editing of other parts of the report.

Administrative and Technical Support: Marigaye Bissell, Barbara Chavez, Kaimy Marks, and Karen Newlon, Montana Ecological Services Field Office.

Acknowledgments

This report relies heavily on the input and professional opinions provided by a panel of 10 recognized lynx experts and captured during a formal Expert Elicitation Workshop held in Bloomington, Minnesota, October 13-15, 2015. Several other recognized lynx experts from Canada and the contiguous United States were invited but unable to participate. The workshop also was supported by and benefitted from the participation and presentations of other recognized experts in the fields of snowshoe hare ecology, lynx genetics, forest ecology, climate change modeling, and Federal lynx habitat management.

Figure 8. Generalized relationship between habitat conditions and hare and lynx population dynamics and their influence on lynx population resiliency. 26

Figure 9. Summary of lynx experts' predictions regarding the probability of persistence of at least a given number of geographic units given the probability of persistence for each individual geographic unit. The y axis of each grid in figure 9 is the probability that at least the number of geographic units indicated by the x axis of the grid persist. The probability in a bar reaches 1 when there is no probability of fewer geographic units persisting. Moving from top to bottom, the grids show the probabilities by time period (2015 [current at time of expert elicitation], 2025, 2050, and 2100). Moving from left to right the grids show the range of expert responses by summary selection type and probability response. Therefore, looking down a column of grids provides a view of the trend in persistence through time and looking across a row of grids provides a view of the range of uncertainty in expert projections of persistence for a given time period. 170

Executive Summary

This report presents the results of a species status assessment (SSA) for the contiguous United States distinct population segment (DPS) of Canada lynx (*Lynx canadensis*). The report represents the U.S. Fish and Wildlife Service's (Service's) evaluation of the best available scientific information, including the formally elicited professional judgments and opinions of recognized lynx experts. Based on this information, we (1) describe the ecological requirements and population dynamics of the species; (2) evaluate the historical and current condition of lynx populations in the DPS and the factors that appear to have influenced them; and (3) assess the DPS's near-term (at year 2025), mid-term (year 2050), and longer-term (year 2100) viability. This final SSA has been revised in response to the reviews, comments, and suggestions of 5 independent peer reviewers, 11 State wildlife and natural resources management agencies, and 3 other Federal agencies.

Background

The Canada lynx is a North American boreal forest carnivore whose populations are strongly tied to its primary prey, the snowshoe hare (*Lepus americanus*). Both species occur primarily in the extensive boreal spruce-fir forests of Canada and Alaskan; however, the southern margins of both their ranges extend into the northern contiguous United States. The Service designated lynx in the Lower 48 States as a DPS because of differences in the management of lynx and lynx habitats across the international boundary with Canada and because of the climatic, vegetative, and ecological differences between lynx habitat at the southern extent of its range in the contiguous United States compared to the northern range in Canada and Alaska. The Service listed the DPS as threatened under the Endangered Species Act (ESA) in 2000 because of the inadequacy, at that time, of regulatory mechanisms on some Federal lands to provide for the conservation of lynx habitats and populations (see section 3.1.1). This SSA does not reconsider the designation of the DPS or its listing status under the ESA, which are Service policy decisions. Instead, it provides the scientific basis for the statutorily required 5-year status review for the DPS and other decisions the Service is required to make in accordance with the ESA.

In this SSA, we evaluate the current and possible future conditions for lynx in 6 geographic units within the DPS range that currently support or recently supported resident lynx. The units are distributed from Maine to Washington and south along the Rocky Mountains to western Colorado (fig. 1). Units 1 (Northern Maine), 2 (Northeastern Minnesota), 3 (Northwestern Montana/Northeastern Idaho), and 4 (North-central Washington) historically supported and currently support resident lynx populations. Based on verified records, it is uncertain whether Units 5 (Greater Yellowstone Area [GYA]) and 6 (Western Colorado) historically supported persistent populations or if they supported resident lynx only ephemerally (see section 2.3.2.2). Combined, the 6 units encompass over 131,000 km^2 (about 50,640 mi^2) of occupied or potential lynx habitat and represent roughly the southern 2 percent of the species' breeding distribution (98 percent occurs in Canada and Alaska). Land ownership varies among the units, with private

lands accounting for most of Unit 1; a mix of Federal, State and private lands in Unit 2; and predominantly Federal lands in the 4 western units (see table 2, chapter 1 for additional details on unit sizes and land ownership).

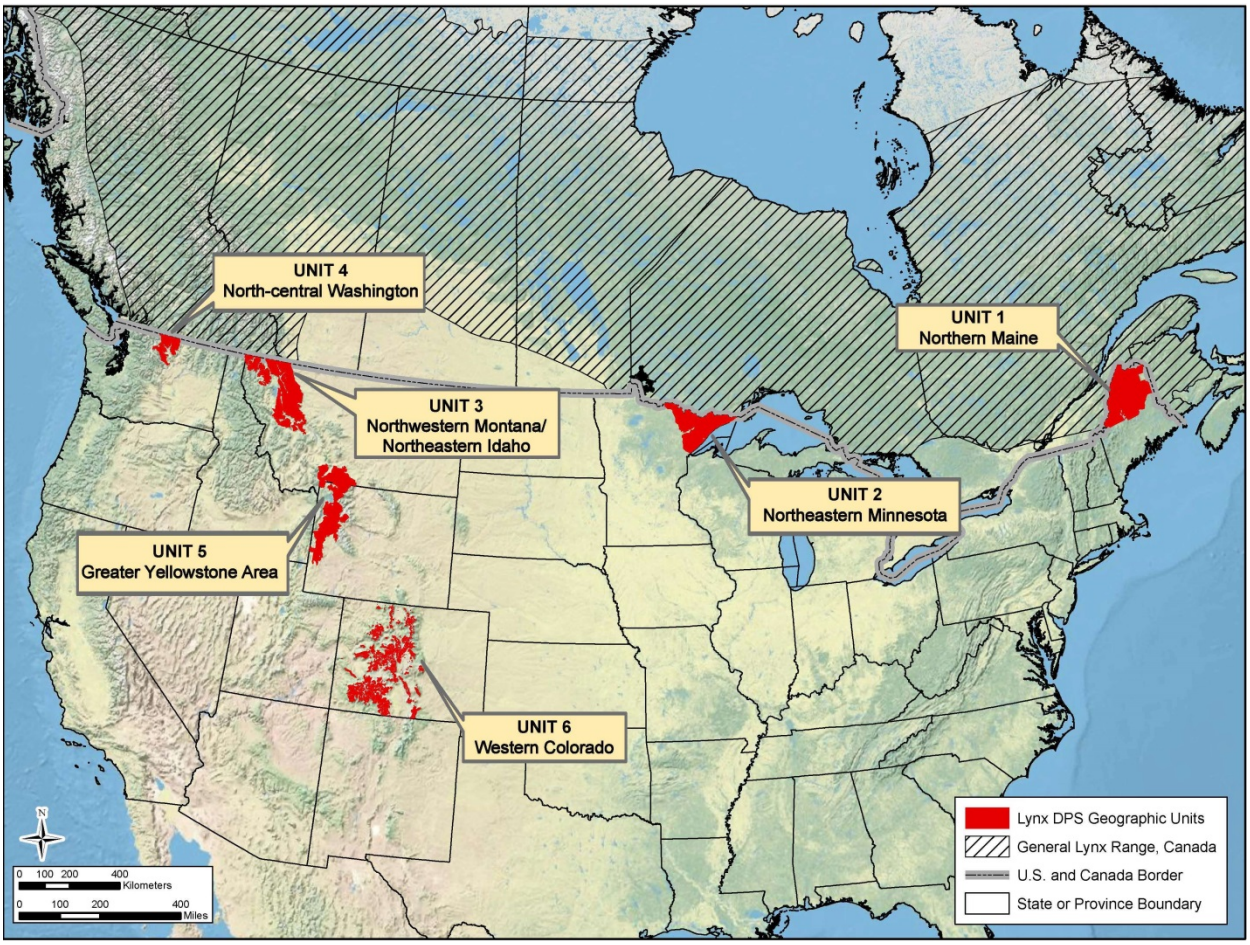

Figure 1. Six geographic units within the range of the contiguous United States distinct population segment of Canada lynx (*Lynx canadensis*).

The lynx is a habitat and prey specialist that requires dense boreal and subalpine forests that support abundant snowshoe hares, which typically constitute greater than 90 percent of the lynx's year-round diet. Lynx and hares are most abundant in areas with long winters and persistent deep, powdery snow. The lynx has evolved morphological adaptions - long legs and exceptionally large paws - which in snowy conditions are thought to confer a competitive advantage over other terrestrial hare predators and allow lynx to occupy habitats that are unavailable, at least seasonally, to some of its potential competitors. The DPS occurs at the southern margin of the species' range, where boreal forest habitats and thus lynx are, in most places, naturally less abundant and generally more patchily-distributed than in the core of the species' range in Canada and Alaska. Maintaining connectivity between the DPS and lynx populations in Canada is thought to be important. However, the extent to which DPS populations may depend on immigration of lynx from Canada remains uncertain.

Our understanding of lynx biology has improved substantially since the DPS was proposed for listing in 1998. For example, analysis of historical trapping data indicated that many lynx records in the contiguous United States coincided with the intermittent (roughly decadal) mass dispersal ("irruptions") of lynx from Canada into the northern United States when hare populations in Canada underwent steep cyclic declines. During these events, particularly the unprecedentedly large irruptions of the early 1960s and early 1970s, hundreds to thousands of lynx dispersed south into both suitable and unsuitable habitats in the northern United States. In suitable habitats, immigrants may have contributed to the demographic and genetic health of resident populations; in unsuitable habitats, dispersing lynx occurred only temporarily and disappeared relatively quickly from areas that are not capable of supporting resident populations over the long-term. Research and monitoring conducted by State, Federal, and Tribal agency partners and academic institutions also have refined our understanding of lynx habitat requirements and associations, distributions, demography, and potential stressors throughout the DPS range (see Summary of Findings, below, and chapters 2-4).

SSA Framework

The SSA framework considers a species' life history and ecological requirements to understand how the species maintains itself over time. Therefore, we evaluated the ecological requirements of individual lynx and populations and the current and possible future conditions for resident lynx populations in each geographic unit to assess the viability of the DPS. The SSA uses the conservation biology principles of resiliency, redundancy, and representation (the "3 Rs") as the framework for assessing current and future conditions. Resiliency describes the ability of populations and species to withstand stochastic events, redundancy describes a species' ability to withstand catastrophic events, and representation describes a species' ability to adapt to long-term changes in the environment (see sections 1.2 and 1.3). For lynx, the factors capable of influencing the 3 Rs that we evaluate in this SSA include the adequacy of existing regulatory mechanisms (the factor for which the DPS was listed); climate change, vegetation management, wildland fire management, and habitat loss and fragmentation (the factors considered by the Interagency Lynx Biology Team [ILBT] to have the potential to exert population-level effects on the DPS); and other factors that could influence the continued ability of particular geographic units to support resident lynx.

Uncertainties and Assumptions

Several sources of uncertainty had to be accounted for in our analysis, including limited data on lynx population sizes, trends, and other important demographic parameters in the DPS; the influence of lynx immigration from Canada on the persistence of the DPS; the effectiveness of habitat management efforts; and the potential effects of competition. We similarly lack consistent habitat and demographic information for snowshoe hares throughout much of the DPS range. Given the emerging role of climate change as a stressor, uncertainties about the timing, rate, and magnitude of projected future impacts to hares; boreal, subalpine, and montane forests; and snow quality, depth, and persistence constrain our ability to precisely predict effects on lynx populations and habitats. To account for these uncertainties in our

analysis, we identified a number of critical assumptions based on the scientific literature and input provided by the lynx experts we consulted (see section 1.4).

As part of our evaluation of the DPS's viability, we asked a panel of 10 lynx experts to provide their opinions on the likelihoods that each geographic unit would support resident lynx populations in the short-term (at year 2025), mid-term (at year 2050) and longer-term (at year 2100). The level of uncertainty regarding the viability of the DPS and each of the factors that may influence it increases the farther into the future we (and the experts we consulted) try to look, and this uncertainty greatly reduces confidence in projections, particularly beyond mid-century. The output from this expert elicitation process (summarized below and presented in detail in chapter 5) remains the experts' best professional judgment, and readers should consider the inherent limitations and substantial uncertainties in expert responses, particularly over longer time periods (see also section 1.4 and chapter 5).

Summary of Findings

Much irresolvable uncertainty remains regarding the historical distributions and sizes of resident lynx populations in the contiguous United States. Several small populations may have been extirpated from some areas within or adjacent or peripheral to the geographic units we assess and a recent fire-driven decline in lynx numbers in Unit 4 seems likely. However, we find no compelling evidence, based on verified historical records, of major range contraction or dramatic declines in the number of resident lynx in the DPS as a whole (see section 2.3.2). In fact, there are currently more resident lynx in some parts of the DPS (Maine and Colorado) than likely occurred historically and, in those areas and in Minnesota, there are more resident lynx now than was suspected when the DPS was listed. Further, some areas suspected to have lost historical lynx populations may have been (and perhaps are now) naturally capable of supporting resident lynx only ephemerally or intermittently, as would be expected in marginal habitats at the southern periphery of the species' range under a metapopulation structure like that thought to govern DPS lynx populations (see sections 2.2 and 4.1).

Lynx conservation measures and habitat management guidance adopted by the U.S. Forest Service (USFS) and the Bureau of Land Management (BLM) via formally amended or revised management plans or conservation agreements with the Service have substantially addressed the singular threat for which the DPS was listed (the inadequacy of regulatory mechanisms when the DPS was listed; see section 3.1). Conservation efforts by State, Tribal, and other Federal agencies; conservation organizations; and some private landowners also have secured protection of lynx habitats and reduced a number of other potential stressors to lynx populations and habitats throughout the DPS range. Nonetheless, we and the experts we consulted expect that resident population sizes and distributions in the DPS will likely decline largely as a result of projected continued climate warming and associated impacts, which are likely to exacerbate the potential adverse effects of other stressors.

Although the timing and extent of climate-mediated impacts are uncertain, continued warming is expected to cause a northward and upslope contraction of the boreal forest, snow conditions,

and hare populations that support lynx, along with several other potential impacts (see section 3.2). This, in turn, will likely result in smaller, more fragmented, and increasingly isolated patches of habitat and smaller, more isolated lynx populations in the DPS that would be more vulnerable to stochastic demographic and catastrophic events and genetic drift. It also may improve conditions for other terrestrial hare predators, potentially resulting in increased competition and displacement of lynx from areas that currently support resident populations. Climate-driven increases in the frequency, size, and intensity of wildfires and forest insect outbreaks are also expected to continue, although we do not anticipate that such events alone would cause the permanent loss of breeding lynx populations in any geographic unit. We are aware of no management actions that could be expected to abate the projected long-term retreat of boreal forests, declining hare populations, and diminished snow conditions expected under continued climate warming.

Despite the anticipated long-term effects of climate warming and the effects of other potential stressors (see chapter 3), we and the experts we consulted expect that each of the 5 geographic units that currently supports resident populations (Units 1-4 and 6) individually has a high likelihood (80 to 98 percent based on median "most likely" expert projections; see table 1, below, and section 5.2, figs. 10-13 and 15) of continuing to do so at year 2025. Experts similarly indicated high likelihoods (70 to 90 percent) that those units will continue to support resident populations through 2050, albeit in reduced numbers and distributions. Experts projected that only Unit 3 has a high (78 percent) likelihood of supporting resident lynx by 2100; all other geographic units individually were deemed to have a 50 percent or greater likelihood of functional extirpation (i.e., no longer capable of supporting resident lynx populations) by the end of the century; however, all experts expressed great uncertainty in their projections for that time period (see section 1.4 and the introduction to chapter 5).

Table 1. Summary of expert opinion regarding the likelihood that individual geographic units will continue to support resident lynx populations in the future[1].

Geographic Unit	Year					
	2025		2050		2100	
	Probability of Persistence (%)[2]	Range (%)[3]	Probability of Persistence (%)	Range (%)	Probability of Persistence (%)	Range (%)
1	96	80-100	80	65-95	50	40-80
2	96	88-100	80	60-90	35	10-60
3	98	95-100	90	70-100	78	50-90
4	80	60-95	70	30-80	38	5-50
5	52	10-70	35	15-60	15	5-50
6	90	60-100	80	50-85	50	20-70

[1]We asked 10 recognized lynx experts to provide their estimates of the probability that resident lynx populations or subpopulations would persist in each geographic unit, even if reductions in lynx numbers and distributions were anticipated (i.e., the probability that resident lynx would *not* be functionally extirpated from the unit).
[2]Median "most likely" probabilities of persistence provided by 10 lynx experts for each geographic unit considering the current status of lynx populations and current and likely future stressors to those populations. Green = 68–100% median probability of persistence; Yellow = 34–67% median probability of persistence; Red = 0–33% median probability of persistence.
[3]The full range of "most likely" probabilities of persistence provided by the 10 lynx experts.

Cumulatively, expert median “most likely” responses suggest a high (80 percent) likelihood that resident lynx populations will persist in all 5 units that currently support them at year 2025 and in at least 4 of the 5 units at 2050, and a moderate (just under 50 percent) likelihood that they will persist in all 5 units at 2050 (fig. 2, middle column; also see section 5.1). Over the longer-term, expert responses suggest a high (about 85 percent) likelihood that resident populations will persist in at least 2 of the 5 units at 2100 and a more than 50 percent likelihood they will persist in 3 units, but also a high (> 75 percent) likelihood that resident populations will be functionally extirpated from 2 of the 5 units by the end of the century (fig. 2).

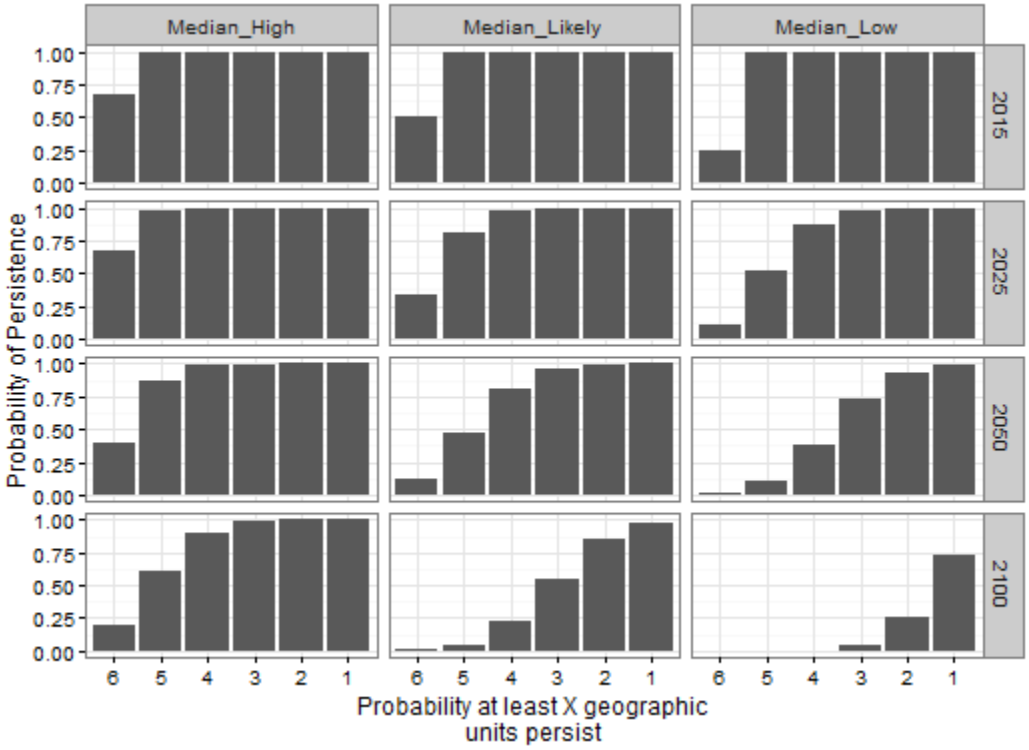

Figure 2. Cumulative probabilities that resident lynx populations will persist in at least a given number of geographic units over time (at years 2015 [current at time of expert elicitation], 2025, 2050, and 2100) based on experts’ predictions for individual geographic units. Experts’ “most likely” probabilities are summarized in the middle column; their highest (“better case”) and lowest (“worse case”) probabilities, representing uncertainty in their predictions, are summarized in the left and right columns, respectively. See section 5.1 for additional details on graph construction and interpretation.

Below we summarize lynx status in each geographic unit based on our understanding of conditions historically, at the time the DPS was listed, and currently, and considering expert opinions regarding potential population sizes and future persistence. See section 2.3.2 for a detailed assessment of historical and current lynx distribution across the DPS range and chapters 4 and 5, respectively, for detailed evaluations of current and possible future conditions in each geographic unit.

Unit 1 - Currently, northern Maine is thought to support many more resident lynx than likely occurred historically and many more than was known or suspected at the time the DPS was

listed, and recent information suggests that resident lynx may be expanding to the south of the core population area. This is due to the large amount and broad distribution of high-quality lynx and hare habitat that currently exists as a result of landscape-level clearcutting on private commercial timber lands in response to a major spruce budworm (*Choristoneura fumiferana*) outbreak in the 1970s and 1980s. These dense regenerating conifer stands are much more extensive than they are thought to have been historically under natural disturbance regimes. The State of Maine suggests that this unit currently may support 750-1,000 or more resident lynx. However, the extent of these high-quality stands probably peaked by 2010, and habitat quality is projected to decline in these stands over the next few decades as they age beyond 35-40 years post-harvest. Because a shift in forest management from clearcutting to partial harvesting that began in 1989 appears unlikely to maintain or recreate this extensive high-quality habitat, we expect lynx habitat and numbers to decline in this unit over the next several decades, perhaps to levels more consistent with likely historical conditions. We concur with the expert panel that the resident lynx population in this unit is very likely to persist at 2025 and at 2050. Over the longer-term (at 2100), we expect continued climate warming to reduce the amount and quality of lynx habitat in this unit and exacerbate other potential stressors (commercial and energy developments, changing forestry practices and land ownership patterns, etc.), further reducing lynx numbers and likely decreasing the population's resilience. Some climate models indicate substantial loss of boreal forest and favorable snow conditions under higher emissions scenarios, and this unit generally lacks potential elevational refugia that would support upslope movement of lynx habitats and populations. Therefore, we suggest that the likelihood that this unit will support a resident lynx population at 2100 may be somewhat lower than expert projections, although the timing and extent of climate-mediated habitat decline is highly uncertain. This geographic unit also may be the source of dispersing lynx that recently recolonized northern New Hampshire as well as several that temporarily established residency in northern Vermont. Some reproduction has been verified recently in both states, although neither was occupied when the DPS was listed, and resident lynx were thought to have been extirpated from New Hampshire.

Unit 2 - Northeastern Minnesota similarly supports many more resident lynx than was suspected when the DPS was listed (when it was unknown whether a resident population occurred there at all), although how the current population compares to historical conditions is uncertain. Trapping records indicate strongly cyclic increases in lynx abundance in this unit in the 1930s through 1970s in association with decadal irruptions of lynx dispersing south from Canada. Currently, Minnesota lynx experts suggest that the population in this unit likely fluctuates from 50 to 200 resident lynx, and we find no evidence that it historically supported a larger resident population or a more extensive distribution of habitat capable of doing so. We concur with the expert panel that the resident lynx population in this unit is very likely to persist at 2025 and at 2050. Over the longer-term (at 2100), we expect continued climate warming to reduce the amount and quality of lynx habitat in this unit, reducing lynx numbers and likely decreasing the population's resilience. Under higher emissions scenarios, some climate models project substantial loss of boreal forest and favorable snow conditions in this unit before the end of the century. Like Maine, this unit also lacks potential elevational refugia that would support upslope movement of lynx habitats and populations. Therefore, we suggest that the likelihood that resident lynx will persist in this

unit at 2100 may be somewhat lower than expert projections, although the timing and extent of climate-mediated habitat decline is highly uncertain.

Unit 3 - Recent research, monitoring, and habitat mapping refinements indicate that habitats capable of supporting resident lynx in this and other western geographic units are naturally less abundant and more patchily-distributed than was thought when the DPS was listed. For example, earlier estimates that western Montana supported 1,000 or more lynx were based on broad assumptions regarding habitat suitability and lynx distribution that are not supported by current understanding of lynx habitat requirements (see section 4.2.3). Currently, this unit is thought to be capable of supporting 200-300 resident lynx. How the current population compares to historical conditions is uncertain, but we find no evidence that this unit historically supported a larger resident population or a substantially broader distribution of habitat capable of doing so. Lynx habitats in this unit are naturally patchy and fragmented due to topography and elevational and moisture (aspect) constraints. We concur with the expert panel that resident lynx are very likely to persist in this unit at years 2025 and 2050, and likely to do so at 2100. Over the longer-term, we expect continued climate warming and associated impacts, perhaps especially increased wildfire activity, to reduce the amount and quality of lynx habitat in this unit, reducing lynx numbers and likely decreasing the population's resilience. Although the timing and extent of climate-mediated habitat decline is highly uncertain and fire-driven habitat loss typically would be temporary, wildfire size, frequency, and intensity have increased in this unit over the past few decades, and this pattern is expected to continue with projected climate warming.

Unit 4 - Atypically large, frequent, and intense wildfires over the past few decades have impacted over a third of the lynx habitat in north-central Washington, perhaps substantially more after additional fires in 2017. Because of this, the number of resident lynx in this unit is likely lower than it was historically and when the DPS was listed. Based on estimates of lynx carrying capacity, this unit may have been capable of supporting roughly 50-60 resident lynx prior to large fires beginning in the early 1990s. Recent habitat evaluations suggest it currently may be capable of supporting only about 30-35 lynx, with the decline due to fire-driven habitat losses. Although these losses are expected to be temporary, additional fires in this unit before previously burned areas recover (10-40 years post-burn) would further reduce lynx numbers and make this geographic unit more vulnerable to extirpation. Because of these habitat impacts, limited demographic information, and remaining uncertainties (e.g., immigration/emigration rates, changes in snowpack, disease, lynx population status and impacts of trapping in southern British Columbia, and habitat corridor stability between British Columbia and this unit), the Washington Department of Fish and Wildlife recently submitted, and the State Fish and Wildlife Commission adopted, a proposal to uplist lynx from threatened to endangered within the State. Nonetheless, we concur with the expert panel that the resident lynx population in this unit is very likely to persist at years 2025 and 2050. Over the longer-term (2100), we expect continued climate warming to reduce the amount and quality of lynx habitat in this unit, further reducing lynx numbers and likely decreasing the population's resilience. Therefore, we concur with experts that this unit has a relatively lower likelihood of supporting a resident population at 2100, although the timing and extent of climate-mediated habitat decline is highly uncertain.

Unit 5 – Based on evaluation of verified historic records, it is uncertain whether this geographic unit historically supported a small but persistent resident population or supported resident lynx only ephemerally. There are very few verified lynx records in the GYA from 1920-1999, but several resident lynx and evidence of reproduction were verified in the late 1990s and early 2000s (around the time the DPS was listed). In addition, at least 9 radio-marked lynx released in Colorado (see below) dispersed northward into or through this unit from 2003-2010, but no lynx have been detected in the GYA since 2010. Most places surveyed in Yellowstone National Park had hare densities clearly too low to support resident lynx. However, parts of the Wyoming Range south of the park, where many historical and most recent occurrences in this unit have been concentrated, had hare densities among the highest documented in the DPS range. No population estimates are available, but expert opinion suggests that this unit may only support 0-10 lynx, and we find no reliable evidence that it once supported a larger or persistent resident population. Therefore, given the uncertainty whether this unit historically or recently supported a persistent resident population and the lack of evidence that it is currently occupied by resident lynx, we concur with experts that it is very unlikely to support a resident population in the future.

Unit 6 – There are currently many more resident lynx in this unit than likely occurred historically, and many more than were known or suspected at the time the DPS was listed. There were even fewer verified records in this unit during the last century than in the GYA, and no reliable evidence of a resident breeding population. However, from 1999-2006, 218 Canadian and Alaskan lynx were released into the San Juan Mountains of southwestern Colorado. As a result of the subsequent reproduction of some of the released lynx and some of their offspring over several generations, resident lynx currently occupy this unit. When the DPS was listed in 2000, 27 of 41 lynx released in 1999 were still alive. The State of Colorado has concluded that its efforts have established a viable lynx population, and the State's lynx experts suggest this unit may currently support 100-250 resident lynx. Recent snow-tracking and camera surveys in the San Juan Mountains in the southern part of the unit documented evidence of continued lynx residency and reproduction. We concur with the expert panel that resident lynx in this unit are likely to persist at year 2025. However, given this unit's apparent historical inability to support a persistent resident population, its relative isolation from other lynx populations, its naturally fragmented habitat and generally very low hare densities, and its generally lower proportion of females producing kittens and low kitten survival, we believe it is less likely than expert projections to support a resident population at 2050 or at 2100. It is possible that hare densities will increase over the next several decades as large areas of forest regenerate from recent extensive insect and fire impacts. However, we expect any increase in hares to be temporary and accompanied by a longer-term insect- and fire-driven decrease in red squirrel (*Tamiasciurus hudsonicus*) abundance.

DPS Viability

In this SSA, we describe the current and future viability of the DPS in terms of resiliency, redundancy, and representation. Resident lynx populations persisted historically and continue to persist in 4 geographic units (Units 1-4). It is uncertain whether Unit 5 (the GYA) historically

supported a small persistent population or if lynx residency was ephemeral; currently, it appears not to support resident lynx. Available evidence suggests that Unit 6 (Colorado) did not historically support persistent lynx presence; however, a resident population has persisted there for more than a decade since the 1999-2006 releases described above. Considering the available information, we find no reliable evidence that the current distribution and relative abundance of resident lynx in the contiguous United States are substantially reduced from historical conditions. This suggests historical and current resiliency among lynx populations in the DPS.

The current broad distribution of resident lynx in large, geographically discrete areas (redundancy) makes the DPS invulnerable to extirpation caused by a single catastrophic event. Because we lack evidence that formerly persistent lynx populations have been lost from any large areas, it also seems that redundancy in the DPS has not been meaningfully diminished from historical levels. In fact, as a result of the current population in Colorado, redundancy in the DPS is likely greater, at least temporarily, now than it was historically.

Similarly, resident lynx remain broadly distributed across the range of habitats that has supported them historically, suggesting maintenance of the breadth and diversity of ecological settings occupied within the DPS range (representation). Additionally, observed high rates of dispersal and gene flow and, therefore, generally low levels of genetic differentiation across most of the lynx's range, including the DPS, suggest the past and recent genetic health of lynx populations in the DPS (representation; but see section 2.1). Because there are no indications of significant loss of or current stressors to the genetic health or adaptive capacity of lynx populations in the DPS, we find that the current level of representation within the DPS does not appear to indicate a decrease from historical conditions.

We expect lynx populations in each geographic unit to become smaller and more patchily-distributed due largely to projected climate-driven losses in habitat quality and quantity and related factors. However, the timing, rate, and extent of habitat decline due to projected climate warming and corresponding effects to lynx populations is highly uncertain. Despite some reduced resiliency, we conclude that resident lynx populations are very likely to persist in all 5 units that currently support them (Units 1-4 and 6) in the near-term (2025) and in all or most of those units at 2050, with corresponding maintenance of redundancy and representation in the DPS over that time span. We and the experts we consulted have low confidence in predicting the likely conditions of DPS populations beyond 2050. That said, smaller, more isolated populations would be less resilient and more vulnerable to demographic and environmental stochasticity and genetic drift and, therefore, at higher risk of extirpation. Although predictions out to 2100 are highly uncertain, it is possible that resident lynx populations could be functionally extirpated from some units by the end of the century. Should extirpations occur, this would indicate a loss of resiliency, reduced redundancy and representation, and an increased risk of extirpation of the DPS.

Chapter 1: Introduction

The Service designated Canada lynx in the contiguous United States as a DPS because of differences in the management of lynx and lynx habitats across the international boundary with Canada and because of the climatic, vegetative, and ecological differences in lynx habitat compared to the northern parts of the species' range in Canada and Alaska (62 FR 28654-28655). The Service listed the DPS as threatened under the ESA in 2000 because of the inadequacy, at that time, of existing regulatory mechanisms on some Federal lands to provide for the conservation of lynx habitats and populations (65 FR 16052-16086). On May 8, 2014, the United States District Court for the District of Montana ordered the Service to complete recovery planning for the lynx DPS (U.S. District Court MT 2014a, p. 8). On June 25, 2014, the same court ordered the Service to complete a recovery plan by January 15, 2018 "…unless the Service finds that such a plan will not promote the conservation of the [lynx]" (i.e., the DPS is recovered or no longer warrants ESA protections; U.S. District Court MT 2014b, p. 2). We completed this SSA (version 1.0) to summarize the best available scientific information on the current status and likely future viability of the DPS. This SSA will inform a determination by Service decision makers of whether (1) the DPS continues to warrant protection under the ESA and (2) a recovery plan is needed to guide conservation and recovery of the lynx DPS.

1.1 Background

The Canada lynx is a North American wild cat that is most strongly associated with northern-latitude boreal forests (taiga) of Canada and Alaska (McCord and Cardoza 1982, p. 729; Agee 2000, pp. 39-41; Aubry *et al*. 2000, pp. 373-374; Mowat *et al*. 2000, p. 272). It is a prey specialist and relies heavily on its primary prey, the snowshoe hare (*Lepus americanus*), to support survival, reproduction, recruitment, and, therefore, population persistence (Ruggiero *et al*. 2000a, p. 110; Mowat *et al*. 2000, p. 270; Steury and Murray 2004, pp. 128, 136-138; USFWS 2005, p. 2; Interagency Lynx Biology Team [ILBT] 2013, pp. 30-34; 79 FR 54808-54809). Lynx distribution and population persistence are also influenced by snow conditions (e.g., Peers *et al.* 2012, pp. 4-9). It is generally restricted to areas that receive deep and persistent unconsolidated ("fluffy") snow, which is thought to allow lynx, with their proportionately longer limbs and very large feet, to outcompete other terrestrial hare predators that are less efficient in such conditions (McCord and Cardoza 1982, pp. 748-749; Quinn and Parker 1987, p. 684; Buskirk *et al*. 2000a, pp. 89-94; Buskirk *et al*. 2000b, pp. 400-401; Ruggiero *et al*. 2000b, pp. 445–449; Hoving 2001, p. 75; Hoving *et al*. 2005, p. 744-749; Carroll 2007, entire; Gonzalez *et al*. 2007, entire; ILBT 2013, pp. 25-26; 79 FR 54809).

The lynx is generally considered secure, widespread, abundant, and distributed throughout most of its historical ranges in Canada and Alaska, which, combined, account for roughly 98 percent of the species' distribution. Lynx are distributed across approximately 5.5 million km^2 (2.1 million mi^2) in Canada (Environment Canada 2014, p. 2) and 534,454 km^2 (206,354 mi^2) in Alaska (Univ. of Alaska Center for Conservation Science 2016, entire; Reimer 2016, *pers. comm.*). The southern peripheries of the boreal forest and the distributions of snowshoe hares and lynx extend into the northern contiguous United States (Bittner and Rongstad 1982, p. 146;

McCord and Cardoza 1982, p. 729; Agee 2000, pp. 39-41; Aubry *et al*. 2000, pp. 379-382; Hodges 2000a, pp. 163-173; McKelvey *et al*. 2000a, pp. 242-253), where the 6 geographic units evaluated in this SSA represent the other 2 percent of the species' breeding distribution (approximately 131,168 km^2 [50,644 mi^2]; see fig. 1, above, and table 2, below).

We consider "southern" lynx populations to include all those in the contiguous United States and in the southern parts of the adjacent Canadian provinces of (east to west) Nova Scotia, New Brunswick, Quebec (south of the Saint Lawrence Seaway and River), Ontario (north of the Great Lakes and Minnesota), Manitoba, Saskatchewan, Alberta, and British Columbia (e.g., see Ivan and Shenk 2016, p. 1051, fig. 1). Lynx populations in the DPS and on the margin of the range in adjacent Canadian provinces seem to function as peripheral subpopulations of a larger metapopulation that is broadly distributed across Canada and Alaska (McKelvey *et al*. 2000b, p. 25; 68 FR 40077; also see 2.2 below). The demographic and genetic health and persistence of DPS populations are thought to be influenced by connectivity with, and immigration of lynx from, larger populations in Canada (McKelvey *et al.* 2000b, pp. 21, 33; Schwartz *et al.* 2002, entire; 78 FR 59434, 59447; 79 FR 54815).

Lynx were documented historically in 24 of the Lower 48 States (McKelvey *et al.* 2000a, pp. 207-232), but records in many places are associated with cyclic "irruptions" of large numbers of lynx dispersing from southern Canada during the decline/low phase of snowshoe hare population cycles, roughly every 10 years. Many of these occurrences were in anomalous habitats, and lynx were unable to persist and establish populations in most of these areas (Gunderson 1978, entire; Thiel 1987, entire; McKelvey *et al.* 2000a, pp. 242, 253; Aubry 2006, pp. 1-2; ILBT 2013, p. 23; see also section 2.3.2). Habitats capable of supporting persistent resident lynx populations in the contiguous United States occur over a much smaller geographic area that includes parts of the Northeast (primarily northern Maine), western Great Lakes (northeastern Minnesota), Rocky Mountains (northern Idaho, northwestern Montana; perhaps also parts of northeastern Washington, the Greater Yellowstone Area (GYA) of southwestern Montana and northwestern Wyoming, and parts of western Colorado), and the eastern Cascade Mountains of northern Washington (68 FR 40077-40080; USFWS 2005, p. 3; 79 FR 54806-54807; Lynx SSA Team 2016a, pp. 6-7). Although uncertainty remains regarding the historical distribution of resident lynx in the contiguous United States, and small breeding populations may have been lost from some places, neither broad-scale breeding range contraction nor substantial changes in population status in the contiguous United States has been documented based on verified occurrence data (68 FR 40099; 72 FR 1187; 79 FR 54798, 54815; McKelvey *in* Lynx SSA Team 2016a, p. 11; also see section 2.3.2).

The Service designated lynx in the contiguous United States as a DPS and listed it as threatened under the ESA in 14 states in 2000 because of the inadequacy, at that time, of existing regulatory mechanisms on U.S. Forest Service (USFS) and Bureau of Land Management (BLM) lands in those states (65 FR 16052). In 2003, in response to a court memorandum opinion on the 2000 listing rule, the Service reaffirmed its determination of the lynx DPS and its status as threatened under the ESA (68 FR 40076). The Service completed a recovery outline in 2005 (USFWS 2005, entire), designated critical habitat for the DPS in 2006

(71 FR 66008) and, in 2007, again in response to a court order, clarified its determinations of "significant portion of the range" and that all lynx in the contiguous United States constitute a single DPS (72 FR 1186). Also in 2007, the Service announced that it would initiate a 5-year status review of the DPS (72 FR 19549). The Service revised the critical habitat designation for the DPS in 2009 (74 FR 8616) and 2014 (79 FR 54782) and, concurrent with the latter, rescinded the state-based definition of the DPS boundary to formally extend ESA protection to lynx "where found" in the contiguous United States, including New Mexico and other states that were not included in the original DPS range (79 FR 54804). Also in 2014 and as described above, the U.S. District Court for the District of Montana ordered the Service to complete a recovery plan for the lynx DPS by January, 2018, unless it finds that such a plan is not necessary. The Service reinitiated the 5-year status review in 2015 (USFWS 2015a, entire), and that review and potential recovery planning pursuant to it will be informed by this SSA report. On September 7, 2016, the U.S. District Court for the District of Montana remanded the 2014 critical habitat designation to the Service for further consideration (U.S. District Court MT 2016, entire).

The 6 geographic units evaluated in this SSA encompass all areas of the contiguous United States that currently support or are believed to have recently (since the DPS was listed in 2000) supported persistent resident lynx populations (fig. 1, above). Five of the 6 geographic units were designated as "Core Areas" in the Recovery Outline, and western Colorado was designated a "Provisional Core Area" (USFWS 2005, pp. 4-6, 21, 23). With the exception of western Colorado, the SSA units reflect the areas the Service designated as critical habitat in 2014 (79 FR 54782). Some areas adjacent to these geographic units are known or suspected to intermittently support resident lynx and occasional reproduction. Uncertainty remains as to whether resident lynx populations occurred historically in other areas not encompassed by the geographic units evaluated here.

The 6 geographic units include Federal, private, State, and Tribal lands, and proportions vary among the units, with private lands predominating in Maine, a mix of ownerships present in Minnesota, and Federal lands predominating in the western units (table 2).

Table 2. Lynx SSA Unit Sizes and Percent Ownership.

Unit[1]	Unit Size (km^2)	Percent of SSA Area	Land Ownership/Management (Percent)[2]						
			Federal[3]				Private	State	Tribal
			All Federal	USFS	NPS	BLM			
1	28,909	22.0	1.2	0	1.2	0	90.4	7.3	0.9
2	21,101	16.1	47.4	44.9	2.5	0.01	15.5	36.2	1.0
3	26,997	20.6	84.3	69.3	13.6	1.5	8.0	4.1	3.5
4	5,176	3.9	91.5	84.6	6.7	0.1	0.3	8.2	0
5	23,687	18.1	97.6	79.7	16.7	1.1	2.2	0.3	0
6	25,294	19.3	90.1	85.2	1.8	3.1	9.3	0.6	0
All Units	131,164	100	63.8	55.6	7.1	1.1	26.3	8.8	1.1

[1] Unit 1 - Northern Maine; Unit 2 - Northeastern Minnesota, Unit 3 - Northwestern Montana/Northeastern Idaho, Unit 4 - North-central Washington, Unit 5 - the Greater Yellowstone Area (Southwestern Montana/Northwestern Wyoming), Unit 6 - Western Colorado.

[2] Unit sizes and ownership for units 1-5 are those calculated for the areas designated in 2014 as lynx critical habitat, including some Tribal, State and private lands that met the criteria for critical habitat but which were excluded from the designation in accordance with section 4(b)(2) of the Endangered Species Act. Unit 6 size and ownership were calculated by the Service's Western Colorado Field Office in coordination with Colorado Parks and Wildlife based on telemetry data from radio-marked lynx.

[3] USFS = U.S. Forest Service; NPS = National Park Service; BLM = Bureau of Land Management.

1.2 SSA Framework and Report

The Service is engaged in a number of efforts to improve the implementation of the ESA[1]. As part of this effort, our Endangered Species Program has developed the Species Status Assessment (SSA) Framework to guide how we assess the best scientific and commercial data available when evaluating the biological status of species. The purpose of the SSA Framework is to provide a consistent, integrated, conservation-focused, and scientifically robust approach to assessing a species' biological status such that the information and analysis are useful to all decisions and activities under the ESA. The SSA does not result in a decision document; rather, it provides the biological information and scientific analysis in support of ESA decisions.
The SSA Framework entails 3 iterative assessment stages (fig. 3; USFWS 2016a):

[1] See: http://www.fws.gov/endangered/improving_ESA/.

1. **Species' Needs**. An SSA begins with a compilation of the best available biological information on the species (taxonomy, life history, and habitat) and its ecological needs at the individual, population, and species levels based on how environmental factors are understood to act on the species and its habitat.

2. **Current Species' Condition**. Next, an SSA describes the current condition of the species' habitat and demographics, and the probable explanations for past and ongoing changes in abundance and distribution within the species' ecological settings (i.e., areas representative of the geographic, genetic, or life history variation across the species' range).

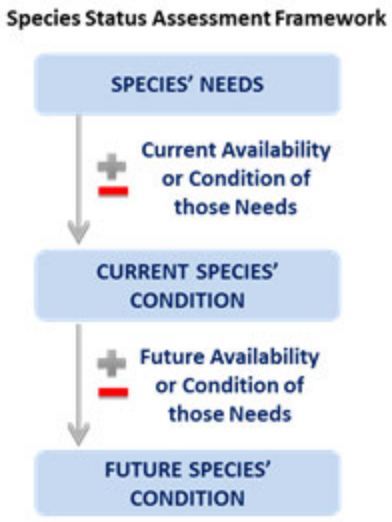

Figure 3. SSA Framework stages.

3. **Future Species' Condition**. Lastly, an SSA forecasts the species' response to probable future scenarios of environmental conditions and conservation efforts. As a result, the SSA characterizes species' ability to sustain populations in the wild over time (viability) based on the best scientific understanding of current and future abundance and distribution within the species' ecological settings.

Throughout the assessment, the SSA uses the conservation biology principles of resiliency, redundancy, and representation (collectively known as the "3 Rs") as a lens to evaluate the current and future condition of the species. Resiliency describes the ability of the species to withstand stochastic disturbance events, which is associated with population size, growth rate, and habitat quality. Redundancy describes the ability of a species to withstand catastrophic events, which is related to the number, distribution, and resilience of populations. Representation describes the ability of a species to adapt to changing environmental conditions, which is related to distribution within the species' ecological settings. Together, the 3 Rs, and their core autecological parameters of abundance, distribution and diversity, comprise the key characteristics that contribute to a species' ability to sustain populations in the wild over time. When combined across populations, they measure the health of the species as a whole.

The Species Status Assessment Report (SSA Report) is a summary of the information assembled, reviewed, and assessed by the Service and is based on the best scientific and commercial data available at the time of the assessment. Completed SSA Reports and supporting material can be found at the collaborative repository of the National Park Service and the USFWS called "ServCat"[2].

1.3 Analytical Approach and Methods

We used the SSA Framework described above to evaluate the current status of resident lynx in the contiguous United States as well as the likelihood that the geographic areas supporting resident lynx in the DPS would continue to do so in the near-term and at mid- and end-of-century (years 2025, 2050, and 2100). We framed our evaluation in terms of the 3 Rs using conceptual modeling (figs. 4-7) based on available published literature, other information on the historical and current status of and threats to lynx in the DPS and, where empirical data are lacking, on formally-elicited expert opinion and best professional judgment (Lynx SSA Team 2016a, entire). The conceptual models below are intended to broadly highlight important relationships thought to influence lynx in the DPS in terms of representation, redundancy, and resiliency. They are not meant to capture every nuance of all possible relationships between lynx and their environments or to illustrate all factors potentially capable of affecting individual lynx or populations.

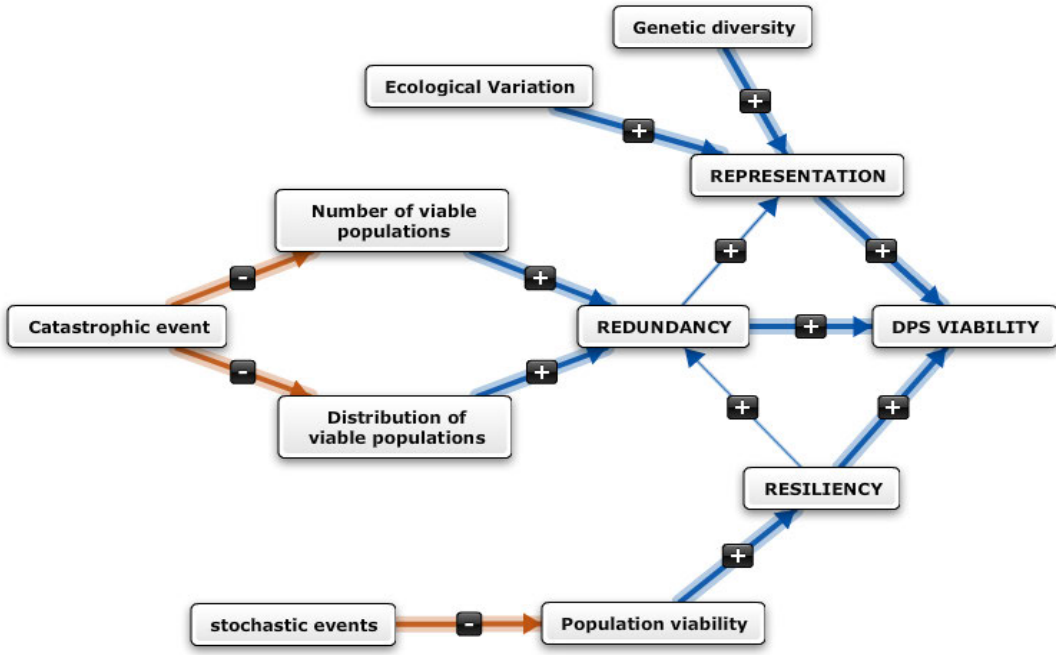

Figure 4. Conceptual model of the factors thought to influence the 3 Rs as they pertain to lynx viability.

We applied the definitions from the SSA Framework for the principles of redundancy, representation, and resiliency, provided in section 1.2, to Canada lynx as described below. We evaluated redundancy and representation at the scale of the DPS as a whole, and resiliency at the scale of lynx populations within each of the 6 geographic units and at the scale of the DPS as a whole.

To evaluate **redundancy** for the lynx DPS, we considered the current and likely future geographic distributions of resident breeding populations and whether the DPS is currently vulnerable to extirpation from a catastrophic event or would be vulnerable in the future. We

consider catastrophic events to be relatively discrete in both time and geographic extent (e.g., wildfires, storms, floods, volcanic eruptions, etc.) and, therefore, we do not consider anthropogenic climate warming as a catastrophic event (see below). Figure 5 shows examples of relationships among factors that may influence redundancy within the lynx DPS.

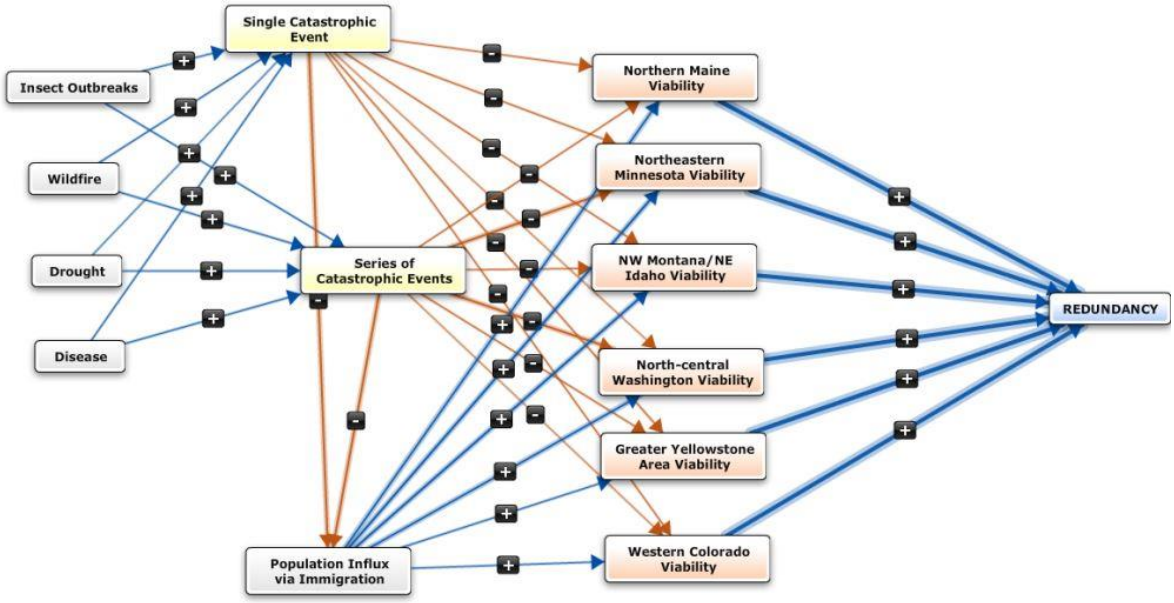

Figure 5. Conceptual model of factors thought to influence redundancy within the lynx DPS.

To evaluate **representation** for the lynx DPS, we considered measures of genetic diversity and heterozygosity, the current and likely future ecological diversity (breadth) of geographic areas occupied by resident breeding populations, and the documented dispersal capabilities of the species, as shown in figure 6 below.

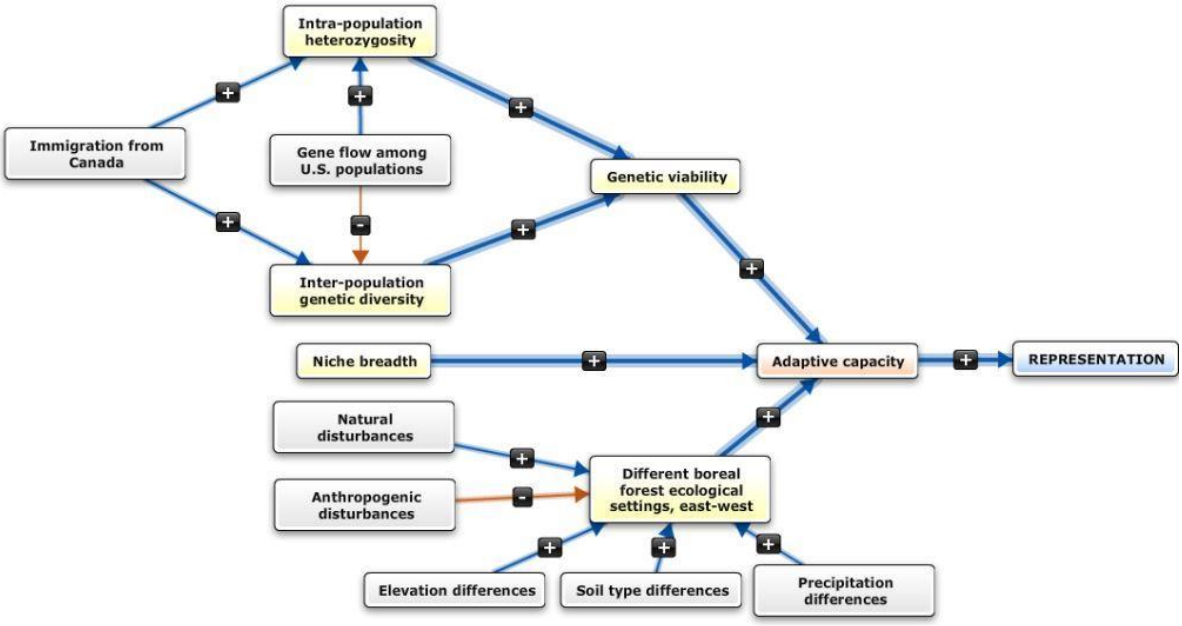

Figure 6. Conceptual model of factors thought to influence representation within the lynx DPS.

Because we lack reliable estimates of the sizes and trends of lynx populations in the DPS and existing demographic data are inadequate to construct empirical models to project population sizes, trends, and viability into the future, our evaluation of the **resiliency** of lynx populations in the DPS was based largely on consideration of recent status updates and formally-elicited expert opinion regarding the likelihood that DPS populations will remain viable into the future. The relationships among factors that influence DPS resiliency are shown in figure 7 below.

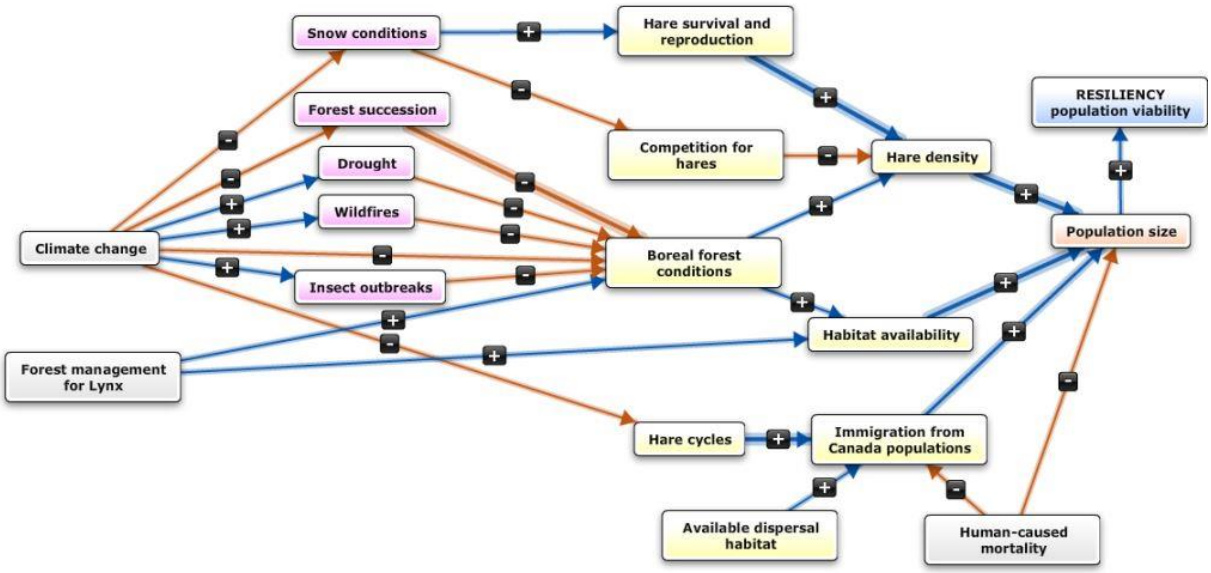

Figure 7. Conceptual model of factors thought to influence the resiliency of lynx populations within the DPS.

We elicited expert input on the current status of resident lynx populations in each geographic unit and the likelihood that each unit would continue to support them in the future (i.e., that resident populations would not be functionally extirpated [reduced to the point that a viable breeding population could no longer be sustained]). To assess both current and future conditions for lynx in the DPS, we considered the adequacy of existing regulatory mechanisms (the factor for which the DPS was originally listed) as well as the anthropogenic influences considered by the Interagency Lynx Biology Team (ILBT) to have the potential to exert population-level (3 Rs) effects on the DPS (climate change, vegetation management, wildland fire management, and habitat loss and fragmentation; ILBT 2013, pp. 68-78).

In Chapter 4, we present our assessment of current conditions based on expert input and our evaluation of the available scientific information regarding lynx populations and habitats and the influencing factors described above for each geographic area. In Chapter 5, we present summaries of experts' predictions regarding the probability of lynx persistence in each geographic unit; the factors they thought would most likely influence those probabilities; and the sources of uncertainty that influenced their confidence in their predictions. We then present our evaluation of the scientific literature regarding how certain anthropogenic factors may influence future conditions for resident lynx in each geographic unit. Other factors were also evaluated for some geographic units if the SSA Core Team member most familiar with that unit felt those factors could pose meaningful, even if less likely, risks to the unit's continued ability to support resident lynx. After considering all of the above, we present our conclusions regarding the future conditions for resident lynx in each geographic unit and we discuss the extent to which our conclusions agree with or differ from the projections provided by the lynx expert panel we consulted, and if they differed, why.

Implicit in our evaluation of the future for lynx in the contiguous United States is our recognition and consideration of a possible future in which the DPS is not listed under the ESA. However, we do not evaluate the unlikely hypothetical future in which all protections and conservation efforts would disappear if the DPS was not listed given (1) the history of lynx management, research, monitoring, and habitat conservation efforts by State wildlife and natural resource agencies in most states throughout the DPS range; (2) similar efforts by Federal land managers and related formal amendments or revisions to most of their land management plans to address the threat for which the DPS was listed (the inadequacy of previous Federal regulatory mechanisms); (3) Tribal lynx conservation efforts and wildlife management philosophies; and (4) the DPS's listing and consultation history. Rather, we assume that although some protections could be relaxed (e.g., less stringent analyses of Federal project-related impacts, potential for some states to reinstitute limited lynx trapping/hunting harvest, reduced incentives for lynx conservation efforts on some private lands), Federal, State, Tribal and some private land managers would continue efforts to conserve lynx and its habitats and to assure persistence of resident lynx populations in those places that can support them in the DPS range. Our evaluation, therefore, considers the possibility of the future relaxing of some lynx conservation measures and efforts should the DPS be delisted, but not the complete absence of all protections for lynx.

Additionally, we do not define and evaluate specific and explicit climate change or greenhouse gas emissions scenarios or attempt to quantify differences in DPS viability or the persistence of resident lynx populations in individual geographic units based on differences in the rate and extent of potential impacts associated with projected continued climate warming. This is because of the limited resolution and inherent uncertainty of available climate models and the inadequacy of existing demographic data for projecting lynx populations in the DPS over time, including their potential responses to a range of climate-mediated potential future habitat conditions. Therefore, this SSA does not constitute or include a formal climate change vulnerability assessment (Glick *et al*., editors, 2011, entire) for the lynx DPS. Instead, underlying our evaluation in this SSA is the recognition that the lynx, as a boreal forest- and snow-associated specialist predator, is probably broadly exposed and highly sensitive to the projected impacts of continued climate warming and has limited capacity to adapt to it (see sections 1.4 and 3.2 below). Therefore, we (along with the experts we consulted and the ILBT) consider lynx populations in the DPS vulnerable (predisposed to be adversely affected; IPCC 2014a, p. 5) to the projected impacts climate change. While we recognize that the pace and extent of impacts would be expected to differ under specific emissions or modeling scenarios, the limitations described above preclude us from quantifying those differences and their potential influence on the likelihood that resident lynx populations will persist in the DPS or in individual geographic units. Finally, in our analyses we do not consider anthropogenic climate warming a catastrophic effect because it is not temporally- and spatially-discrete; characteristics of events traditionally considered catastrophic (e.g., wildfires, floods, storms, volcanic eruptions, etc.). Rather, we consider climate change as an ongoing, pervasive, and cumulative stressor of lynx and their habitats, particularly at the southern margin of the species' distribution, including all geographic areas of the DPS.

1.4 Uncertainties and Assumptions

Several sources of uncertainty had to be accounted for in our analysis, including the paucity of empirical data on lynx population sizes, trends, and other important demographic parameters in the DPS; the influence of immigration of lynx from Canada on the persistence of DPS populations; the effectiveness of habitat management efforts; and the effects of competition on lynx populations. We similarly lack demographic information for snowshoe hares throughout much of the DPS range, and consistent methods to monitor hare and lynx habitats and populations have not been implemented throughout most of the range. And importantly, given the emerging role of climate change as a stressor, uncertainties about the rate and extent of projected future impacts to boreal, subalpine, and montane forests and snow quality, depth, and persistence constrain our ability to precisely predict effects on lynx and hare populations and habitats, including to what degree these changes may affect interactions between lynx and their potential competitors.

To account for these uncertainties in our analysis, we identified a number of critical assumptions based on the scientific literature and input provided by the lynx experts we consulted. We treated the following assumptions as constants in the analysis.

- We assume that, in general, habitat quality and contiguity and hare densities are naturally lower at the southern margin of the lynx's range (in both the contiguous United States and the southern portions of adjacent Canadian provinces) compared to the core of the species' range in Canada and Alaska. Hare populations in the DPS range are noncyclic or weakly cyclic and, although they do not exhibit the dramatic cyclic declines of their northern counterparts, they typically occur at densities on the lower end of those in the northern range. Because of this, lynx densities in most of the DPS range are typically similar to those in the north during hare cycle lows.

- We assume that, as a consequence of generally lower habitat quality and hare densities, only some places within the DPS range are capable of supporting persistent resident lynx populations, while others may naturally support resident lynx only ephemerally, and yet other areas are naturally incapable of supporting resident lynx despite boreal-forest-like vegetation, the presence of some hares, and the occasional or intermittent presence of dispersing or transient lynx.

- We assume that the statuses of lynx populations in individual SSA geographic units are largely independent of those in the other geographic units. This is clearly true for Units 1 and 2, and it is probably true of the western geographic units (3 – 6), despite likely historical north-to-south connectivity and dispersal from or through Unit 3 to Unit 5 and possibly Unit 6, and recent evidence of south-to-north connectivity and dispersal from Unit 6 to and through Units 5 and 3. We are aware of no evidence of east-west connectivity or dispersal between Units 3 and 4.

- We assume that lynx populations in the DPS occur as the southern extensions of larger, cross-border populations or as relatively isolated subpopulations of the larger Canadian populations.

- We assume that lynx exhibit a metapopulation structure in which populations at the southern periphery of the species' range (including all DPS populations and some in southern Canada) receive periodic immigration of lynx dispersing from populations in the core of the Canadian range.

- We assume that connectivity with lynx populations in Canada is important, and that periodic immigration of lynx into the DPS from Canada contributes to the persistence of DPS populations, although the extent to which the demographic and genetic health of DPS populations may depend on immigration remains uncertain.

- We assume that (1) the lynx's morphology confers a competitive advantage in snowy conditions over other terrestrial hare predators, (2) snow conditions (depth, consistency, and persistence) influence the distribution of lynx and its potential terrestrial competitors, and (3) in the absence or loss of these conditions, lynx could be displaced by other terrestrial hare predators.

- We assume that the lynx, as a boreal forest- and snow-associated predator that relies heavily on a single, similarly-specialized prey species, and whose habitats are influenced by climate-mediated disturbance factors (e.g., wildfire, forest insects, wind/ice storms), is highly sensitive and broadly exposed to the impacts of climate warming and has limited adaptive capacity to respond to it. That is, despite some level of behavioral plasticity suggested by differences in snow conditions and specific vegetation communities and stand conditions across the DPS range, we expect that lynx lack the adaptive capacity to shift to non-boreal (e.g., temperate coniferous or deciduous) forests, non-snow-domintated climates, or to persist on alternate prey species where hare densities are or become inadequate. Therefore, we assume lynx populations in the DPS are vulnerable (sensitive, exposed, and with little capacity to adapt; therefore, predisposed to be adversely affected; IPCC 2014a, p. 5) to the projected impacts of continued climate warming.

- We assume that lynx conservation measures and habitat management guidance adopted by the USFS and the BLM via formally amended or revised management plans or conservation agreements with the Service have had a positive influence on DPS lynx populations that occur on Federal lands and will continue to provide benefits as long as those measures and guidance are implemented.

- We assume that the DPS could be delisted in the future and that some of the current protections afforded by the ESA could be lost and/or relaxed. However, we assume that Federal, State, and Tribal agencies and some private landowners would continue to manage for the conservation of resident lynx populations in those places that can support them in the DPS range.

For purposes of the SSA, we forecast potential future conditions for lynx in the DPS through the end of this century, and we asked a panel of 10 lynx experts to provide their opinions on the likelihoods that each geographic unit would support resident lynx populations over the short-term (year 2025), mid-term (2050) and longer-term (2100). As expected, the level of uncertainty regarding the viability of the DPS and each of the factors that may influence it increases the farther into the future we (and the lynx experts we consulted) try to look, and this uncertainty greatly reduces confidence in future projections, particularly beyond mid-century. Beyond that time frame, uncertainty regarding the potential impacts of climate change and other potential stressors to lynx populations in the DPS becomes so great that it precludes meaningful analysis or reliable predictions regarding viability.

Finally, although formal elicitation of expert opinion where empirical information is unavailable or inadequate is an appropriate and scientifically supported approach, we remind readers that the output remains the experts' best professional judgment, which is subjective and, therefore, inherently different than experimentally collected data subjected to rigorous statistical analyses. For purposes of useful and meaningful presentation and comparison among geographic units, it was necessary to combine, quantify, graph, and summarize the qualitative information provided by experts. However, we caution that the results we present, graph, and describe in chapter 5 should not be interpreted as precise, statistically robust estimates of the probability that resident lynx will persist in the DPS or in any individual geographic unit in the future, and readers should consider the inherent limitations and substantial uncertainties in expert responses, particularly over longer time periods.

Chapter 2: Lynx Ecology

In this chapter, we describe the physical characteristics, taxonomy, and genetics of the Canada lynx, its life history and population dynamics, and its taxon-wide and DPS distributions. We rely heavily on recent summaries of this information provided in the revised *Canada Lynx Conservation Assessment and Strategy* (LCAS; ILBT 2013, entire), the Service's recent proposed (2013) and final (2014) rules to revise the designation of critical habitat for the DPS (78 FR 59430-59474; 79 FR 54782-54846), and the results of the October 2015 Canada Lynx Expert Elicitation Workshop (Lynx SSA Team 2016a, entire). We also provide a summary of the pertinent ecological requirements of lynx at the individual, population, and DPS levels. These ecological requirements form the basis of our analyses conducted in Chapters 3 through 5.

2.1 Species Taxonomy, Description, and Genetics

The Canada lynx (order Carnivora; family Felidae) is 1 of 4 species within the genus *Lynx* (Kerr 1792), which also includes the bobcat (*L. rufus*, Schreber 1777), the Eurasian lynx (*L. lynx*, Linnaeus 1758), and the Iberian or Spanish lynx (*L. pardinus*, Temminck 1827). There are 3 recognized subspecies of Canada lynx: *Lynx canadensis canadensis* (Kerr 1792), *L. c. mollipilosus* ("Arctic lynx," Stone 1900), and *L. c. subsolanus* ("Newfoundland lynx," Bangs

1897; Integrated Taxonomic Information System online database[3], retrieved April 14, 2016). The Canada lynx is believed to have evolved from the Eurasian lynx in the last 200,000 years in North America as a snowshoe hare specialist (Werdelin 1981, p. 69).

The Canada lynx is a medium-sized cat with long legs and large, well-furred paws. In winter, the lynx's fur is dense and has a grizzled appearance with a grayish-brown mix of buff or pale brown fur on the back, and a grayish-white or buff-white fur on the belly, legs, and feet. In summer, its fur is more reddish to gray-brown (McCord and Cardoza 1982, p. 730). It has long tufts of black hairs extending from the tips of its ears, a short, completely black-tipped tail, and often a distinct dish-like facial ruff of pale hairs tipped black. Lynx generally measure 75 to 90 cm (30 to 35 in) long and weigh 6 to 14 kg (14 to 31 lb; Quinn and Parker 1987, table 1; Moen *et al.* 2010a, fig. 2; MDIFW 2012, *unpubl. data*), and males are 13-25 percent larger than females (Mowat *et al.* 2000, p. 267). The lynx's large feet and long legs make it well-adapted for traversing and hunting in deep, powdery snow, where its low foot-loading (weight per surface area of foot) is thought to provide a competitive advantage (Buskirk *et al.* 2000a, p. 90; 2000b, p. 400; ILBT 2013, pp. 26, 36, 81) over other terrestrial predators of snowshoe hares, the lynx's primary prey. In southern Canada and the northern contiguous United States, where the southern edge of the lynx range overlaps the northern edge of the bobcat range, the 2 species are easily confused because of their similar size and appearance. However, the lynx's longer ear-tufts, larger feet, and black-tipped tail distinguish it from the bobcat, which has shorter ear tufts, small feet, and white on the underside of the tail. Bobcats are much more common, widespread, and abundant than lynx in most of the contiguous United States.

Overall, genetics research suggests high gene flow across most of the continental range of lynx, likely because of high dispersal rates, large dispersal distances, and the absence of significant barriers to genetic interchange throughout much of the lynx range, including the DPS (Schwartz *in* Lynx SSA Team 2016a, pp. 11-12). Genetic evidence also indicates interactions between lynx populations even where physical barriers appear most likely to restrict gene flow. For example, although *L. c. subsolanus* on Newfoundland Island is genetically (Row *et al.* 2012, pp. 1262-1266; Koen *et al.* 2015, p. 528) and morphologically (Khidas *et al.* 2013, pp. 597-601) distinct from mainland lynx (*L. c. canadensis*), there is evidence of genetic exchange between the 2 areas, indicating that some lynx are able to cross the 15-60 km- (9-37 mi-) wide Strait of Belle Isle that separates them (Koen *et al.* 2015, p. 527). Similarly, despite some differences in functional genetic markers (unique alleles) in lynx south versus north of the St. Lawrence Seaway/River in eastern Canada, which suggest the potential for evolutionarily significant differences in those areas (Bowman *in* Lynx SSA Team 2016a, p. 14), recent analyses reveal genetic exchange among lynx on either side, indicating that some lynx successfully navigate this barrier (Koen *et al.* 2015, pp. 524-528; Bowman *in* Lynx SSA Team 2016a, p. 12-13). However, Prentice *et al*. (2017, entire) documented natural selection for unique alleles in relatively isolated island populations of lynx in eastern Canada.

Schwartz *et al.* (2003, entire) documented reduced genetic variation (lower mean number of alleles per population and lower expected heterozygosity) among peripheral lynx populations

[3] http://www.itis.gov.

compared to populations in the core of the lynx geographical range in Canada and Alaska. While recognizing that small changes in genetic variation can lead to large changes in population fitness, the authors noted that the differences between core and peripheral populations in their study were small enough to suggest a lack of significant population subdivision (i.e., no indication of genetic isolation, substantial genetic drift, or potential genetic ''bottlenecks'' among DPS populations; Schwartz *et al.* 2003, p. 1814; 79 FR 54793). This finding is consistent with their earlier work, which documented high levels of gene flow (the highest yet documented for any carnivore) between core and peripheral lynx populations despite large separation distances (Schwartz *et al.* 2002, entire). Their results did not suggest that reduced genetic variation among peripheral populations was because of human disturbance (i.e., habitat loss/fragmentation on the southern periphery of the geographic range; Schwartz *et al.* 2003, p. 1814), but the authors concluded that the persistence of lynx populations in the contiguous United States depends on dispersal from larger (core) populations (Schwartz *et al.* 2002, p. 522).

Within the contiguous United States, minor genetic sub-structuring has been documented among lynx subpopulations in western Montana (Schwartz *in* Lynx SSA Team 2016a, p. 12 and Appendix 5). Genetic diversity may be somewhat greater among lynx in western Colorado than elsewhere in the DPS range because of the broad geographic distribution of the source populations that contributed to the lynx releases in Colorado (45 lynx from Quebec, 4 from Manitoba, 91 from British Columbia, 48 from The Yukon Territory, and 30 from Alaska). Additionally, lynx-bobcat hybridization has been documented in Minnesota, Maine, and New Brunswick (Schwartz *et al.* 2004, entire; Homyack *et al.* 2008, entire), where male bobcats bred with female lynx to produce fertile offspring with lynx-like ear tufts, intermediate foot-size, and bobcat-like fur (ILBT 2013, p. 35). In Minnesota from 2000 to 2015, DNA analyses documented 13 distinct hybrid individuals (Moen and Catton *in* Lynx SSA Team 2016a, pp. 13, 19); hybrids have yet to be documented in the western portion of the lynx's range (Schwartz *in* Lynx SSA Team 2016a, p. 12). At a continental scale, Koen *et al*. (2014b, pp. 111-113) found a low level of bobcat-lynx genetic introgression (i.e., hybridization) but suggested it could increase if bobcat distribution shifts northward in the future as a result of continued climate warming (also see section 3.2 below).

Currently, there is no indication that the levels of connectivity and gene flow between lynx populations in the DPS and those in the core of the lynx's range are inadequate to maintain the genetic health of DPS populations. Given the connectivity of most DPS units with lynx populations and habitats in Canada (particularly Units 1-4, which have the strongest evidence of historically persistent resident lynx populations), the noted dispersal capabilities of lynx, evidence of dispersal in both directions across the Canada-United States border (Aubry *et al.* 2000, pp. 386-387; Squires *et al.* 2006a, p. 38; Moen *et al.* 2010b, pp. ii, 17, 19; Vashon *et al.* 2012, p. 22), and the small number of immigrants thought necessary to maintain genetic variability in peripheral populations (McKelvey *et al.* 2000b, pp. 23-24), genetic isolation, biologically meaningful genetic drift, or potential genetic ''bottlenecks'' appear unlikely among most DPS populations in the near future (79 FR 54793). However, the potential for genetic drift would be expected to increase at some point in the future if lynx and hare habitats shift

northward and upslope, as projected with continued climate warming, resulting in reduced connectivity and gene flow among smaller and more isolated lynx populations at the periphery of the range (Schwartz 2017, pp. 4-5; also see section 3.2).

2.2 Life History and Population Dynamics

All aspects of lynx life history are inextricably tied to its primary prey, the snowshoe hare (fig. 8), which comprises most of the lynx diet throughout its range (Nellis *et al.* 1972, pp. 323–325; Brand *et al.* 1976, pp. 422–425; Koehler and Aubry 1994, pp. 75, 85; Apps 2000, pp. 358–359, 363; Aubry *et al.* 2000, pp. 375–378; Mowat *et al.* 2000, pp. 267–268), including the DPS (Koehler 1990a, p. 848; von Kienast 2003, pp. 37–38; Squires *et al.* 2004a, p. 15, table 8; Moen 2009, p. 7; Vashon *et al.* 2012, p. 11; Olson 2015, pp. 60-69; Ivan and Shenk 2016, p. 1053). Lynx are highly specialized hare predators and require landscapes that consistently support relatively high hare densities (McCord and Cardoza 1982, p. 744; Quinn and Parker 1987, pp. 684-685; Aubry *et al.* 2000, pp. 375-378).

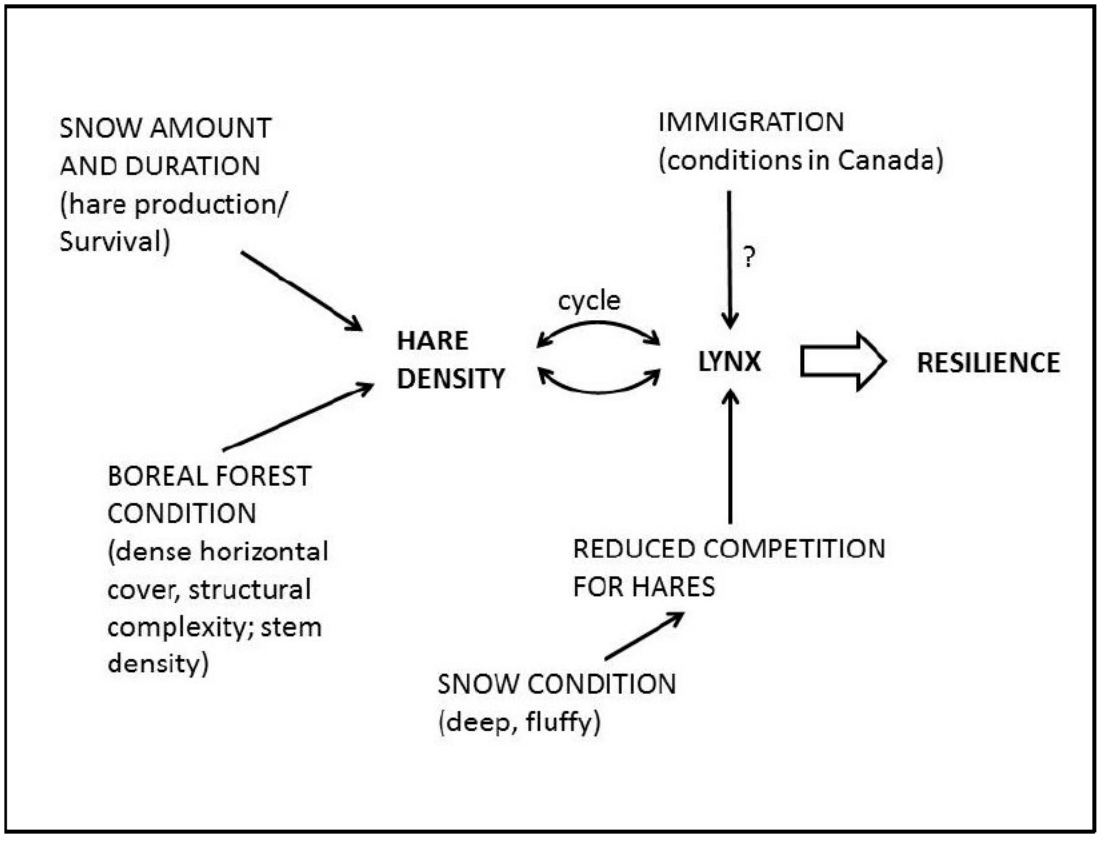

Figure 8. Generalized relationship between habitat conditions and hare and lynx population dynamics and their influence on lynx population resiliency.

Although lynx take a variety of alternate prey species, especially red squirrels (*Tamiasciurus hudsonicus*), which may be important when hare numbers are low (O'Donoghue *et al.* 1997, pp. 154-155; 1998, pp. 1198-1205; Ivan and Shenk 2016, pp. 1054-1056), hare abundance is the major driver of lynx population dynamics. Lynx denning area selection, pregnancy rates and

litter sizes, as well as survival (kitten, subadult, and adult), recruitment, and dispersal rates, and population age structure, home range sizes, density, and distribution are all strongly influenced by hare abundance (Koehler and Aubry 1994, pp. 75-76, 80-83; Apps 2000, entire; Aubry *et al.* 2000, pp. 375-390; Mowat *et al.* 2000, pp. 270-294; Moen *et al.* 2008a, p. 1507; Organ et al. 2008, p. 1516; Vashon *et al.* 2012, p. 16; ILBT 2013, pp. 18, 22-24, 26-34).

Lynx and snowshoe hares are strongly associated with moist boreal forests, where winters are long, cold, and snowy (Bittner and Rongstad 1982, p. 154; McCord and Cardoza 1982, p. 743; Quinn and Parker 1987, p. 684-685; Agee 2000, p. 39-47; Aubry *et al.* 2000, pp. 373-382; Hodges 2000a, pp. 183-191; 2000b, pp. 136-140; McKelvey *et al.* 2000a, pp. 211-232). The predominant vegetation of boreal forest is conifer trees, primarily species of spruce (*Picea* spp.) and fir (*Abies* spp; Elliot-Fisk 1988, pp. 34-35, 37-42). Snowshoe hares feed on conifers, deciduous trees, and shrubs (Hodges 2000a, pp. 181-183) and are most abundant in forests with dense understories that provide forage, cover to escape from predators, and protection during extreme weather (Wolfe *et al.* 1982, pp. 665-669; Litvaitis *et al.* 1985, pp. 869-872; Hodges 2000a, pp. 183-195; 2000b, pp. 136-140). Lynx population dynamics, survival, and reproduction are closely tied to snowshoe hare availability, making snowshoe hare habitat the primary component of lynx habitat. However, lynx do not occur everywhere within the range of snowshoe hares in the contiguous United States (Bittner and Rongstad 1982, p. 146; McCord and Cardoza 1982, p. 729). This may be due to inadequate abundance, density, or spatial distribution of hares in some places, or the absence of snow conditions that would provide lynx a competitive advantage over other terrestrial hare predators (see below), or a combination of these factors (79 FR 54809).

The boreal forest landscapes lynx and hares occupy are naturally dynamic. Forest stands within the landscape may experience abrupt changes after natural or human-caused disturbances such as fire, insect outbreaks, wind, ice, disease, and forest management (e.g., timber harvest or thinning) and more gradual changes as they undergo succession and regenerate after such events (Elliot-Fisk 1988, pp. 47-48; Agee 2000, pp. 47-69). As a result, lynx habitat is a shifting mosaic of forest patches of variable ages and changing quality (68 FR 40077). These stands of differing ages and conditions provide lynx foraging or denning habitat (or may provide these in the future depending on patterns of disturbance and forest succession), and some serve as travel routes for lynx moving between foraging and denning habitats (McKelvey *et al.* 2000c, pp. 427-434; Hoving *et al.* 2004, pp. 290-292).

Over much of the lynx's range, hare densities are higher in regenerating, earlier successional forest stages because they often have greater understory structure (dense horizontal cover) than mature forests (Buehler and Keith 1982, p. 24; Wolfe *et al.* 1982, pp. 665-669; Koehler 1990a, pp. 847-848; Hodges 2000a, pp. 183-195; Homyack 2003, pp. 63, 141; Griffin 2004, pp. 84-88). However, snowshoe hares also can be abundant in mature forests with dense horizontal cover, particularly in the Northern Rocky Mountains (Griffin 2004, pp. 53-54; Griffin and Mills 2009, pp. 1492-1496; Hodges *et al.* 2009, p. 876; Squires *et al.* 2010, pp. 1653-1657; Berg *et al.* 2012, pp. 1483-1487). These mature forests may be a source of hares for other adjacent forest types (Griffin and Mills 2009, pp. 1492, 1495-1496), and they may provide especially important

winter foraging habitats (Squires *et al.* 2010, pp. 1655-1657), which may be the most limiting habitat for lynx (Squires *et al.* 2010, pp. 1655-1657; ILBT 2013, pp. 17, 27). They also are more temporally-stable (i.e., they provide high-quality hare habitat for a longer period of time) than regenerating stands, which may foster high hare densities for a variable window of time between stand-initiation and stem-exclusion stages of succession, after which older regenerating stands may persist, in the absence of disturbance, for many years as lower-quality hare habitat (ILBT 2013, pp. 62, 71, 127).

Lynx generally concentrate hunting activities in areas where snowshoe hare densities are high (Koehler *et al.* 1979, p. 442; Ward and Krebs 1985, pp. 2821-2823; Murray *et al.* 1994, p. 1450; O'Donoghue *et al.* 1997, pp. 155, 159-160 and 1998, pp. 178-181), but several studies showed that lynx focused foraging efforts in stands with intermediate hare densities and forest structural complexity that occurred at the edges of the highest density habitat, suggesting that lynx must balance between hare abundance and accessibility (Fuller and Harrison 2010, pp. 1276–1277; Simons-Legaard *et al.* 2013, p. 574). Because understory density within a forest stand changes over time, hare habitat quality and corresponding hare densities also shift over time across boreal forest landscapes.

Hare populations in the core of the lynx range in Canada and Alaska undergo well-documented dramatic 8 to 11 year cycles during which hare numbers may fluctuate 10 to 25 fold or more, with peak densities as high as 23 hares/hectare (ha; 9.3 hares/acre [ac]) and lows of 0.1 hares/ha (0.04 hares/ac; Hodges 2000b, pp. 117-121; Vashon 2015, p. 4). Hare densities are generally lower at the southern periphery of lynx distribution, and hare population cycles are generally much less pronounced or absent entirely among some hare populations in southern Canada and in the contiguous United States (Hodges 2000a, pp. 163–173; Hodges *et al.* 2009, pp. 870, 875–876; Scott 2009, pp. 1–44; Environment Canada 2014, p. 1; Hodges *in* Lynx SSA Team 2016a, pp. 16-17). In the contiguous United States, average stand-level hare densities may exceed 2 hares/ha (0.8 hares/ac; Walker 2005, pp. 20, 85; McCann 2006, p. 15; Robinson 2006, pp. 26-36, 62-75; Homyack *et al.* 2007, pp. 10-11; Griffin and Mills 2009, p. 1492; Vashon *et al.* 2012, p. 14), but in many parts of the DPS, landscape-level densities are lower, ranging from just above to well below the 0.5 hares/ha (0.2 hares/ac) density thought necessary to sustain lynx home ranges and populations (Hodges 2000a, pp. 168-169, 185; Ruggiero *et al.* 2000b, pp. 446–447; Squires and Ruggiero 2007, pp. 313-314; Maletzke *et al.* 2008, pp. 1476-1477; Zahratka and Shenk 2008, pp. 910-911; Hodges *et al.* 2009, pp. 873-877; Ivan 2011a, pp. 91-92, 95-102; Berg *et al.* 2012, p. 1483; ILBT 2013, pp. 24, 26, 90; Ivan *et al.* 2014, entire).

Lynx prey opportunistically on other small mammals and birds, especially red squirrels, grouse (*Bonasa umbellus, Dendragapus* spp., *Falcipennis canadensis*) and ptarmigan (*Lagopus* spp.), but alternate prey species do not sufficiently compensate for low availability of snowshoe hares, and lynx populations likely cannot persist over time in areas with consistently low hare densities (Brand *et al.* 1976, pp. 422–427; Brand and Keith 1979, pp. 833–834; Koehler 1990a, pp. 848–849; Mowat *et al.* 2000, pp. 267–268). Hares constitute the majority of the biomass in lynx diets even in areas with relatively low or marginal hare densities (Koehler and Aubry 1994, p. 85; Apps 2000, pp. 362-363; Aubry *et al.* 2000, pp. 375-378; Roth *et al.* 2007, pp. 2740-2741;

Squires and Ruggiero 2007, pp. 310-313; Hanson and Moen 2008, p. 9; Maletzke *et al.* 2008, pp. 1475-1477; Shenk 2009, pp. 13, 16). This remains true in years when hare abundance is low and proportionally more alternate prey items are taken (Brand *et al*. 1976, pp. 424-427; O'Donoghue *et al*. 1998, pp. 1198-1200; Ivan and Shenk 2016, p. 1053). Nonetheless, alternate prey, particularly red squirrels, may contribute to lynx persistence through cyclic hare population lows in the core of the range (O'Donoghue *et al*. 1997, pp. 156-160; 1998, pp.1204-1205) and may be important at the southern periphery of lynx range where hare numbers may be chronically marginal or low and where red squirrels may be less vulnerable than hares to projected impacts of continued climate warming (Roth *et al*. 2007, pp. 2740-2741*;* Peers *et* al. 2014, entire; Ivan and Shenk 2016, pp. 1050, 1054-1056).

Lynx typically mate in March and April, and kittens are born from late April to mid-June after a 60- to 70-day gestation period (Koehler and Aubry 1994, p. 81; Mowat *et al.* 2000, p. 285). Female lynx typically reach reproductive maturity in their second year (at 22 months of age); however, when hares are abundant, females may breed at 10 months of age and produce kittens as 1-year-olds (Koehler and Aubry 1994, p. 81; Mowat *et al.* 2000, p. 285). Males do not seem to breed as yearlings, and they do not contribute to rearing of young (ILBT 2013, p. 30). Lynx dens are typically located in areas of dense cover, where coarse woody debris, such as downed logs and windfalls, provides security and thermal cover for lynx kittens (McCord and Cardoza 1982, pp. 743-744; Koehler 1990a, pp. 847-849; Slough 1999, p. 607; Squires and Laurion 2000, pp. 346-347; Organ *et al.* 2008, entire; Squires *et al.* 2008, pp. 1497, 1501-1505; Moen and Burdett 2009, pp. 5-8). Dens have been documented in both mature and younger boreal forest stands (Mowat *et al.* 2000, pp. 274-275; Squires *et al.* 2008, p. 1497; ILBT 2013, pp. 29-30; 78 FR 59441-59442; 79 FR 54809-54810; Organ *et al.* 2008, entire), and the amount of structure (e.g., downed trees; large, woody debris; tip-up mounds) seems to be more important than the age of the forest stand for lynx denning habitat (Mowat *et al.* 2000, pp. 274-275, Organ *et al.* 2008, p. 1516; Moen and Burdett 2009, p. 5). Denning habitat is not thought to be a limiting factor for lynx in the DPS (Moen *et al.* 2008a, p. 1512; Organ *et al.* 2008, pp. 1514, 1516–1517; Squires *et al.* 2008, p. 1505; ILBT 2013, p. 30; 79 FR 54790). Dens must be near foraging habitat to allow females to adequately provision dependent kittens, and females seem to select den sites near prey sources to minimize time spent away from kittens while foraging (Moen *et al.* 2008a, p. 1507; Vashon *et al.* 2012, p. 16; ILBT 2013, p. 29). Females attend kittens at the natal den site and 1 or more (up to 5) alternate or maternal dens until kittens are about 6-10 weeks old (Squires *et al.* 2008, p. 1502; Olson *et al.* 2011, pp. 458-460; Vashon *et al.* 2012, p. 17; ILBT 2013, p. 29).

Thereafter, kittens remain with their mothers through their first winter, apparently learning from her how to hunt and capture prey, initially on a small portion of her home range, but by fall on the larger area the female used before kittens were born (Mowat *et al.* 2000, pp. 269, 278). Juveniles remain closely associated with their mothers until February or March, when family groups begin to break up, with young typically dispersing in April and May (Mowat *et al.* 2000, pp. 278-279) to establish their own home ranges. Female offspring may establish home ranges overlapping or adjacent to their mother's home range and maintain mother-daughter bonds throughout their lives (Mowat *et al.* 2000, pp. 279-280). Male home ranges may slightly overlap

adjacent male home ranges. While male home ranges typically overlap 1 to 3 female home ranges, and female home ranges are partially or completely encompassed by a male's home range, core areas within home ranges appear to be exclusive except during the breeding season (Koehler and Aubry 1994, pp. 90-91; Mowat *et al.* 2000, pp. 276-280; Vashon *et al.* 2012, pp. 17, 22-23). Fidelity to home ranges over several years has been documented for both sexes, but shifts and abandonment of home ranges have also been documented (Koehler and Aubry 1994, p. 91; Mowat *et al.* 2000, p. 277). Lynx have been documented to live up to 16 years in the wild (Kolbe and Squires 2006, entire).

Lynx populations in Canada fluctuate in response to the cycling of hare populations (Elton and Nicholson 1942, pp. 241–243; Hodges 2000b, pp. 118–123; Mowat *et al.* 2000, pp. 265–272), with synchronous fluctuations in lynx numbers emanating from the core of the Canadian population and spreading over vast areas, generally lagging hare numbers by 1 year (McKelvey *et al.* 2000a, pp. 232, 239; Mowat *et al.* 2000, pp. 266, 270). When hares are abundant, lynx have higher pregnancy rates and larger litter sizes, higher kitten survival, and lower adult mortality, resulting in rapid population growth during the increase phase of the hare cycle (Slough and Mowat 1996, pp. 955–956; Mowat *et al.* 2000, pp. 266, 270–272, 281–289). When hare populations are low, female lynx produce few or no kittens that survive to independence (Nellis *et al.* 1972, pp. 326–328; Brand *et al.* 1976, pp. 420, 427; Brand and Keith 1979, pp. 837–838, 847; Poole 1994, pp. 612–616; Slough and Mowat 1996, pp. 953–958; O'Donoghue *et al.* 1997, pp. 158–159; Aubry *et al.* 2000, pp. 388–389; Mowat *et al.* 2000, pp. 285–287). When hares decline, lynx mortality rates increase, largely because of starvation, and home range sizes and dispersal/emigration rates also increase (Ward and Krebs 1985, pp. 2821–2823; O'Donoghue *et al.* 1997, pp. 156, 159; Poole 1997, pp. 499–503; Mowat *et al.* 2000, pp. 265–272, 278, 281–294). Lynx numbers decline dramatically during the ''crash'' phase of the hare cycle (Slough and Mowat 1996, p. 956; Mowat *et al.* 2000, pp. 283-285), when many lynx starve and many others abandon home ranges and disperse in search of food, with many dispersers also dying, often soon after initiating dispersal (Mowat *et al.* 2000, p. 293).

In Canada, lynx abundance may be 3 to 17 times higher at the peak versus the low of the hare cycle, with lynx densities reaching 30-45/100 km^2 (78-117/100 mi^2) in optimal dense regenerating forests 15-40 years post-fire, 8-20/100 km^2 (21-52/100 mi^2) in older forests or further south, and < 3/100 km^2 (< 8/100 mi^2) at the hare cycle low (Slough and Mowat 1996, pp. 952, 955; Mowat *et al.* 2000, p. 283; Hatler and Beal 2003, pp. 2, 5; Environment Canada 2014, p. 1). In southern Canada, where hares are less abundant and hare population cycles are muted or absent, lynx populations may be stable at 2-3/100 km^2 (5-8/100 mi^2; Environment Canada 2014, p. 1). Lynx densities estimated in the contiguous United States have ranged from 9.2-13/100 km^2 (24-34/100 mi^2), including kittens, in Maine's highest-quality habitat when hares were abundant (Vashon *et al.* 2008a, pp. 1483-1484; Vashon *et al.* 2012, pp. 14-15) to 2.3/100 km^2 (6/100 mi^2) in Washington when hare abundance was low (Koehler 1990a, pp. 847-850).

Correspondingly, hare abundance may also influence lynx home range size. Ward and Krebs (1985, pp. 2819-2820) documented a 3-fold increase in home range size in southwestern Yukon, from 13 km^2 (5 mi^2) on average when hares were abundant and increasing to 39 km^2 (15

mi^2) when hare density was low (90 percent MCP method). Poole (1994, pp. 613-614) documented a similar trend in the Northwest Territories, where lynx home range size increased from 17 km^2 (7 mi^2; males and females combined) when hares were abundant, to 44 km^2 (17 mi^2) and 62 km^2 (24 mi^2) for males and females, respectively, when hare numbers declined (95 percent MCP method). In contrast, Breitenmoser *et al.* (1993, p. 552) reported no change in lynx home range size despite a 10-15 fold increase in lynx density as hare abundance increased in the southern Yukon (home range estimation method not provided). Similarly, in Maine, lynx home range size did not increase when hare densities in the best habitats declined by half from 2 hares/ha (0.8 hares/ac) to 1 hare/ha (0.4 hares/ac; Mallett 2014, pp. 53-93; 90 percent fixed kernel method). In general, hare and lynx densities are lower and lynx home ranges larger at the southern periphery of the lynx's range, including most of the DPS range, and lynx densities are similar to those of northern populations during the low phase of the hare population cycle (Koehler and Aubry 1994, p. 93; Aubry *et al.* 2000, pp 382-385; Apps 2000, pp. 362-367; Burdett *et al*. 2007, pp. 463-465).

Although empirical data are lacking and would be difficult to acquire (ILBT 2013, p. 82), the lynx's physical adaptations (described above) are thought to provide lynx a seasonal advantage over potential terrestrial competitors and predators, which generally have higher foot-loading, causing them to sink into the snow more than lynx (McCord and Cardoza 1982, p. 748; Murray and Boutin 1991, entire; Buskirk *et al.* 2000a, pp. 86-95; Ruediger *et al.* 2000, pp. 1-11; Ruggiero *et al.* 2000b, pp. 445, 450). Buskirk *et al.* (2000a, entire) described potential exploitation (for food) and interference (avoidance) competition between lynx and several other terrestrial and avian predators of hares, several of which have also been documented to prey on lynx. Documented lynx predators include cougar (*Puma concolor*; also mountain lion), coyote (*Canis latrans*), wolverine (*Gulo gulo*), gray wolf (*Canis lupus*), fisher (*Pekania pennant*), and other lynx (ILBT 2013, pp. 33, 35). Bobcats are also likely capable of killing lynx in some circumstances. Although lynx have co-evolved with other predators, the influence of predation on lynx populations is unknown (ILBT 2013, pp. 35-36). Coyotes are now more widespread and abundant in the southern periphery of the lynx distribution than they were historically (Gompper 2002, entire), while cougars have been extirpated from the eastern half of the United States (except Florida; USFWS 2011a, entire) but are more abundant and widespread in the western United States now than in the mid-1900s (Buskirk *et al.* 2000a, p. 89).

The species above, along with red fox (*Vulpes vulpes*), American marten (*Martes americana*), mink (*Mustela vison*), as well as a suite of avian predators (e.g., northern goshawk [*Accipiter gentilis*], northern hawk-owl [*Surnia ulula*], great gray owl [*Strix nebulosi*], and great-horned owl [*Bubo virginianus*]) may compete with lynx for hares (Buskirk *et al.* 2000a, pp. 86-95; ILBT 2013, p. 16). Of these, coyotes are the most likely to exert local or regionally important exploitation competition impacts to lynx, and coyotes, bobcats, and cougars are capable of imparting interference competition effects on lynx (Buskirk *et al.* 2000a, p. 89). Interference would be most likely during summer but also during winter in areas lacking deep, unconsolidated snow (ILBT 2013, p. 36). Except for fisher and marten, lynx predators and potential terrestrial competitors all have higher foot-loading, making them less efficient at traveling and hunting in the snow conditions favorable for lynx (Murray and Boutin 1991, entire; Buskirk *et al.* 2000a, pp 86-95;

Krohn *et al.* 2005, entire) and, therefore, likely limiting, at least seasonally, interactions between lynx and these species. The fisher has foot-loading similar to lynx, and the marten's is even lower (Buskirk *et al.* 2000a, p. 90), but both species have much shorter legs, which likely limits their mobility in deep, unconsolidated snow compared to lynx. The extent to which predation and competition may influence lynx populations in the DPS remains uncertain.

Lynx populations in the contiguous United States seem to function as subpopulations or southern extensions of larger populations in southern and eastern Canada (McKelvey *et al.* 2000b, pp. 21, 25, 33; 65 FR 16052–16082; 68 FR 40077–40099; 71 FR 66025–66035; 74 FR 8616–8641; Koen *et al.* 2015, pp. 527-528). Populations in the DPS are relatively isolated from one another, though most are directly connected via dispersal to lynx populations in Canada (McKelvey *et al.* 2000b, pp. 25-34; U.S Fish and Wildlife Service 2005, p. 2). DPS populations are at the periphery of the species' range and some, particularly in the West (geographic units 3-6), may behave as islands in a mainland-island metapopulation construct. In such a system, larger islands with higher habitat quality and in closer proximity to the mainland would be more likely to support persistent resident populations and to sometimes act as "sources" that produce surplus animals that may disperse to other islands. Smaller islands with lower habitat quality or at greater distance from the mainland may, in contrast, act as "sinks" that depend on immigration from source populations (McKelvey *et al.* 2000b, p. 30), and which may support resident lynx only occasionally, intermittently, or temporarily.

Although lynx habitats are more contiguous in units 1 and 2 than in the western units, and units 1 and 2 are connected to larger contiguous habitats and lynx populations in Canada, they remain peripheral populations, and a metapopulation structure in which they receive intermittent immigration from the larger population may still exist, even if the mainland-island contruct does not apply. Lynx disperse in both directions across the Canada–United States border (Aubry *et al.* 2000, pp. 386-387; Moen *et al.* 2010b, pp. ii, 17, 19; Vashon *et al.* 2012, p. 22), and this connectivity and interchange with lynx populations in Canada is thought to be important to the conservation of lynx populations in the DPS. (McKelvey *et al.* 2000b, p. 33; Schwartz *et al.* 2002, p. 522; U.S Fish and Wildlife Service 2005, p. 2; ILBT 2013, p. 34, 42, 47, 54, 60, 65; Squires *et al.* 2013, p. 187). However, it remains uncertain whether the demographic and genetic health and persistence of populations in the DPS depend on regular or intermittent immigration of lynx from Canada and if so to what extent (McKelvey *et al.* 2000a, pp. 241-242; 79 FR 54793).

2.2.1 Ecological Requirements of Individuals

From birth through recruitment of at least one of it's progeny into the breeding population, the ecological requirements of an individual lynx are met if:

1) its mother occupies a home range containing
    a) secure denning habitat,
    b) adequate prey abundance (especially snowshoe hares) to support lactation during the early kitten stage and later provisioning of the kitten with meat,

c) habitat (boreal forest and snow) conditions that reduce the likelihood and effect of competition from other hare predators, and
d) a low likelihood of encounters with lynx mortality agents (predators, traps, vehicles, etc.);

2) its mother's home range occurs within a larger landscape that also contains adequate hare abundance and available habitat into which the yearling lynx may disperse and establish its own home range after the period of maternal dependence, with low likelihood of adverse competition or mortality; and

3) the larger landscape also supports other secure lynx home ranges and ensures the opportunity to encounter a lynx of the opposite sex, breed successfully, and contribute to the recruitment of at least 1 offspring into the breeding population during its lifetime.

In cyclic lynx populations in the core of the species' range (northern Canada and Alaska), there is a strong element of timing that determines whether these individual needs will be met. During the decline and low phases of the hare population cycle, few or no kittens are born, very few survive until their first winter, and recruitment may collapse completely or nearly so for several successive years (Slough and Mowat 1996, entire; Mowat *et al.* 2000, pp. 266, 285-287). Therefore, even in the core of the species' range, a kitten born during a period of declining or low hare abundance is very unlikely to survive to independence, breed successfully, and replace itself within the breeding population in its lifetime. Conversely, a kitten born during the increase or high phase of the hare population cycle is much more likely to survive and, therefore, have an opportunity to breed successfully and replace itself via recruitment of 1 or more of its offspring into the breeding population.

At the southern periphery of the lynx's range (southern Canada and the contiguous United States), hare population cycles are of lower amplitude or absent (Hodges 2000a, pp. 163–173; Hodges *et al.* 2009, pp. 870, 875–876; Scott 2009, pp. 1–44; Environment Canada 2014, p. 1; Hodges *in* Lynx SSA Team 2016a, pp. 16-17), hare densities are typically on the lower end of densities reported for northern populations, and lynx abundances and demographic rates in the south are typically like those of northern lynx populations during hare lows (Koehler and Aubry 1994, p. 93; Aubry *et al.* 2000, pp 382-385; Apps 2000, pp. 362-367). Therefore, in southern populations the likelihood is probably relatively low that an individual lynx will have its ecological requirements met sufficiently to replace itself in the breeding population. Also in the south, there are more diverse assemblages of potential competitors and predators, more natural patchiness and anthropogenic fragmentation of lynx habitat (fewer areas with adequate hare densities and favorable snow conditions distributed broadly across large landscapes), and higher road densities and, thus, greater potential for lynx-vehicle collisions (Wolff 1980, p. 128; Buskirk *et al.* 2000a, entire). These factors probably further reduce the likelihood that an individual lynx in the southern periphery of the range will survive, reproduce successfully, and have 1 or more offspring recruited into the resident breeding population.

Individual lynx require large areas (tens to hundreds of square kilometers) of boreal forest landscapes to support their home ranges, provide hares in adequate abundance to meet their

nutritional needs, provide breeding opportunities, and facilitate dispersal and exploratory travel. Female home ranges must also provide secure denning habitat in close proximity to foraging areas with high hare densities to allow females to adequately provide for dependent kittens (Moen *et al.* 2008a, p. 1507; Vashon *et al.* 2012, p. 16; ILBT 2013, p. 29). The size of lynx home ranges is strongly influenced by the quality of the habitat, particularly the abundance of snowshoe hares, in addition to other factors such as gender, age, season, and density of the lynx population (Aubry *et al.* 2000, pp. 382–385; Mowat *et al.* 2000, pp. 276–280). Generally, females with kittens have the smallest home ranges, likely related to their need to stay close to dens and dependent kittens, and males have the largest home ranges (Moen *et al.* 2005, p. 11; Burdett *et al.* 2007, p. 463; ILBT 2013, p. 24).

The increased natural patchiness and fragmentation of high-quality hare habitat where boreal forest conditions transition to temperate forest types require individual lynx in many parts of the DPS to maintain relatively large home ranges that include patches of higher hare densities within a matrix of lower-quality habitats with lower hare densities (ILBT 2013, p. 126; 78 FR 59434; also see 2.3.3). Larger home ranges likely require more energy output associated with greater foraging effort (Apps 2000, p. 364) and possibly increased exposure to predation and other mortality factors than lynx face in the core of their range (78 FR 59438). Annual home range sizes reported for lynx in the contiguous United States (table 3) vary greatly across the DPS but are generally larger in the west than the east; however, differences should be interpreted with caution because different methods, sample sizes, and estimators were used to generate them (ILBT 2013, pp. 23-24; also see footnotes to table 3, below).

Table 3. Reported annual home range sizes for Canada lynx in the contiguous United States.

Juvenile and adult lynx require about 400 and 600 grams (14 and 21 ounces) of food per day (for adults, 0.4-0.5 hares/day, 170-200 hares/year), respectively, to meet their basic nutritional requirements (Saunders 1963, p. 390; Nellis *et al.* 1972, pp. 324-325). Several sources (Ruggiero *et al.* 2000b, pp. 446-447; ILBT 2013, pp. 26, 125) have suggested that landscape-level hare densities ≥ 0.5 hares/ha (0.2 hares/ac) are necessary to support lynx home ranges and resident breeding populations. Lynx home range abandonment, dispersal, and mortality increase when hare densities are lower, and lynx may be unable to survive where landscape hare densities are below 0.3 hares/ha (0.12 hares/ac; Ward and Krebs 1985, pp. 2819-2822; Slough and Mowat 1996, entire). Recent research in the contiguous United States generally supports the 0.5 hares/ha threshold. For example, in northern Maine, areas with average landscape hare densities of 0.74 hares/ha (0.30 hares/ac) supported resident breeding lynx, but areas with hare densities below 0.5 hares/ha (0.2 hares/ac) were not occupied by lynx (Simons-Legaard *et al.* 2013, pp. 567, 574-575). In northeastern Minnesota, resident lynx maintained home ranges where landscape hare densities were 0.64 hares/ha (0.26 hares/ac), but nearby Voyageurs National Park, where hare density was estimated at 0.35 hares/ha (0.14 hares/ac), did not support resident breeding lynx (Moen *et al.* 2012, pp. 352–354). Similarly, in western Montana, resident lynx used dense young forest stands with mean summer and winter hare densities of 0.64 hares/ha (0.26 hares/ac) and 0.47hares/ha (0.19 hares/ac), respectively, and dense mature multi-story stands in winter when mean hare density was 0.53 hares/ha (0.21 hares/ac), but they did not use more open young or mature stands where hare densities ranged from 0.12 - 0.20 hares/ha (0.05 - 0.08 hares/ac; Squires and Ruggiero 2007, pp. 313-314).

Steury and Murray (2004, p. 137) suggested minimum hare densties of 1.1 - 1.8 hares/ha (0.45 - 0.73 hares/ac) would be necessary to support lynx reintroduction efforts in the southern portion of the range, but Murray *et al*. 2008 (p. 1468) acknowledged that threshold could be overly conservative if southern lynx are less reliant on hares (i.e., more reliant on alternate prey) or if southern hare numbers are more stationary so that resident lynx numbers in the south do not fluctuate as dramatically as is typical in northern populations. Indeed, more than 10 years after translocations of Canadian and Alaskan lynx ceased, resident lynx continue to occupy parts of western Colorado, where hare densities are generally much lower, and lynx there rely heavily on red squirrels, which accounted for 23 ± 6 percent (annual range = 0.1 to 66 percent) of prey items identified over 11 winters (Shenk 2009, pp. 16, 24).

In addition to adequate hare density, individual lynx require landscapes in which they are unlikely to encounter animals that may prey on them or suffer reduced fitness from competition with other hare predators. As described above, the lynx has a much lower foot-loading than most of its potential predators and competitors, and this is believed to provide an advantage in places that receive deep and persistent unconsolidated snow. Although specific snow requirements for lynx (amount/depth, quality, persistence) have not been quantified throughout the DPS range, historical lynx occurrence records in the contiguous United States were correlated with areas that received at least 4 months (December through March) of continuous snow coverage (Gonzalez *et al.* 2007, p. 7). Where snow conditions do not consistently favor

lynx, increased potential for predation and competition would be expected (Peers *et al.* 2013, p. 8). Finally, individual lynx are more likely to survive, breed, and replace themselves in the breeding population if they occupy home ranges where trapping is prohibited or trapping pressure is low (Slough and Mowat 1996, entire), high-speed/high-volume roadways are absent (ILBT 2013, pp. 77-78), and other potential anthropogenic causes of lynx mortality are absent or minimal.

In summary, individual lynx require large landscapes with hare densities that maximize their chances of (1) surviving to independence, (2) establishing and maintaining a home range, (3) breeding successfully, and (4) contributing genes to future generations (Breitenmoser *et al.* 1993, p. 552). These landscapes also must provide conditions that allow lynx to compete sufficiently for hares and minimize the likelihood of predation and other sources of lynx mortality. The available science, including recent research in the DPS range, suggests that landscape-level hare densities consistently ≥ 0.5 hares/ha (0.2 hares/ac) and favorable snow depth and conditions for about 4 months are needed to support lynx occupancy, reproduction, and recruitment. At the southern periphery of lynx distribution, some places, including within the range of the DPS, seem to be at minimum thresholds to meet these requirements or do so inconsistently.

2.2.2 Ecological Requirements of Populations and the DPS

Lynx populations require essentially the same things that individual lynx do, but on a larger landscape with hare densities and habitat conditions capable of consistently supporting multiple home ranges, breeding and dispersal opportunities, and reproductive and survival rates such that recruitment and immigration will, on average over the long term, equal or exceed mortality and emigration (Pulliam 1988, pp. 652-654). To support persistent lynx populations, such landscapes must provide for the survival of at least some resident lynx even when hares are least abundant and/or other habitat features (e.g., snow conditions) are least favorable so that the lynx population can recover, perhaps aided by immigration, when hare numbers and/or other habitat conditions improve. As with individual lynx, populations are more likely to persist in landscapes where the effects of competition, predation, and human-caused mortality (e.g., trapping, vehicle collisions) are relatively lower.

In a metapopulation structure like that thought to govern lynx population dynamics, the persistence of peripheral populations is determined by colonization and extinction rates (McKelvey *et al.* 2000b, p. 25). Colonization is driven by the number of populations, the distances between them, and the species' dispersal capabilities and timing. Extinction rates are determined by population size and demographic and environmental stochasticity, with extinction more likely in smaller and more isolated populations (McKelvey *et al.* 2000b, pp. 25-31). Formal population viability analyses (PVAs) have not been published for most lynx populations in the DPS and may not be possible for some populations given limited data and natural temporal variation in demographic rates (McKelvey *et al.* 2000b, pp. 22, 30). Although some demographic data are available for most lynx populations in the DPS, most are limited to relatively few, small study areas or relatively short durations. There remains uncertainty about whether, and if so to

what extent, the demographic health of DPS populations relies on immigration from northern (Canadian) populations; and immigration rates are not known for DPS populations (McKelvey *et al.* 2000b, pp. 24-34). These factors likely preclude development of meaningful DPS-wide or unit-specific empirical population viability models (McKelvey *et al.* 2000b, p. 22).

In the core of the species' range in the southern Yukon, Slough and Mowat (1996, p. 952, table 4) calculated a lynx population growth rate (lambda, λ) = 2.03 (annual doubling) during the 4-year increase-to-peak phase of the hare cycle. This period of rapid growth was followed by a rate of λ = 1.01 (stable) during the first year of a hare decline, and λ = 0.10 and λ = 0.46 (rapid decline) during the first 2 years of the lynx population decline when hares were scarce. However, the natural range in λ that would be expected among peripheral, isolated, or semi-isolated lynx populations where hares are non-cyclic or weakly-cyclic (i.e., in DPS and some southern Canadian populations; Murray 2000, pp. 1210-1215; Murray 2003, pp 152-155), versus those that would signal long-term population decline or instability is unknown. Despite this, and the limitations noted above, Squires (*unpubl. data in* Lynx SSA Team 2016a, p. 20) calculated population growth rates in northwestern Montana of λ = 0.92 for lynx in the Seeley Lake area (i.e., declining population trend, 1999-2007) and λ = 1.16 for lynx in the Purcell Mountains (increasing trend, 2003-2007). Likewise, MDIFW in 2012 calculated an intrinsic rate of growth of 0.05 (λ = 1.05) for Maine's lynx population based on demographic data from a radiotelemetry study collected over a 12-year period (Vashon *et al*. 2012, Appendix VI). Neither the Montana nor Maine estimates incorporated rates of immigration/emigration (i.e., both assumed immigration and emigration rates of zero, which is very unlikely and contradicted by historical and recent evidence of lynx dispersal in both directions across the Canada-Unites States border across the DPS range). Schwartz (2017, p. 4) noted that very low immigration rates (less than 1 female/year on average for a theoretical population of 100 lynx) could provide population stability or even growth, suggesting that the Seeley Lake population and perhaps other DPS populations are probably being bolstered by low levels of immigration, which may go undetected. Other efforts to model lynx population dynamics in the DPS range include those of Lyons *et al*. (2016, entire), who developed spatially-explicit, individual-based population models to estimate reductions in potential lynx carrying capacity in Washington associated with recent large wildfires, and Licht *et al*. (2017, *in press*, entire), who conducted a PVA of a potential lynx reintroduction to Isle Royale in Lake Superior, about 22 km (14 mi) east of Unit 2.

Although minimum viable population sizes have not been derived for lynx populations in the DPS, the Service's Recovery Outline (USFWS 2005, p. 5) suggested landscapes of at least 1,250 km^2 (483 mi^2) with sufficient boreal/subalpine habitat, hare densities, and snow conditions favorable for lynx. These are the minimum landscape size and habitat conditions thought necessary to support a minimum lynx population of at least 25 adults based on a density of 1 lynx per 50 km^2 (USFWS 2005, p. 5). McKelvey *et al.* (2000b, p. 29) noted that extinction (extirpation) risk should decrease with increasing population size, and that extinction resulting from demographic stochasticity is very unlikely even for a population (generally; not specific to lynx) with as few as 20 reproducing females. Kramer-Schadt *et al.* (2005, entire) developed a spatially explicit population model for Eurasian lynx in Germany which they combined with demographic scenarios to evaluate the likely success of potential reintroduction efforts; they

concluded that at least 10 females and 5 males would be required to establish a population with an extinction probability less than 5 percent over 50 years. Rodriguez and Delibes (2003, entire) evaluated extinction among populations of Iberian lynx; they found that extinction occurred only in small populations that occupied habitats of less than 500 km^2 and that extinction within 35 years was unlikely among populations occupying areas of at least 500 km^2 of adequate habitat quality.

In summary, lynx populations need large (thousands of square kilometers) boreal forest landscapes with hare densities capable of supporting (1) multiple lynx home ranges, (2) reproduction and recruitment most years, and (3) at least some survival even during years when hare numbers are low. These landscapes also must have snow conditions (consistency, depth, and duration) that allow lynx to outcompete other terrestrial hare predators. To persist, lynx populations must exhibit recruitment and immigration rates that exceed mortality and emigration rates on average over the long-term. Immigration may be particularly important to the persistence and stability of lynx populations at the southern periphery of the range, including those within the DPS, where hare densities are generally low and hare populations are either non-cyclic or weakly-cyclic compared to northern populations. Low hare densities reduce the likelihood that lynx recruitment will consistently equal or exceed mortality, and non-cyclic or weakly-cyclic hare populations are unlikely to allow the rapid lynx population recovery observed in northern lynx populations when hare numbers increase dramatically after cyclic population crashes. Conversely, more stable hare populations, even at lower landscape-level densities, likely provide stability (i.e., prevent periodic steep declines) among lynx populations on the periphery of the range in the DPS and in southern Canada. Although immigration rates for DPS populations are unknown, as is the rate and periodicity of immigration needed to provide demographic stability among them, connectivity with and immigration from lynx populations in Canada are believed to be important to the persistence of lynx populations in the DPS (McKelvey *et al.* 2000a, pp. 232-242; 2000b, pp. 32-34; Schwartz *et al.* 2002, entire; USFWS 2005, p. 2; ILBT 2013, pp. 34, 42, 47, 54, 60, 65; Squires *et al.* 2013, p. 187; 79 FR 54789).

2.3 Historical and Current Lynx Distribution

2.3.1 Lynx Distribution and Status in Canada and Alaska

The Canada lynx is broadly distributed across northern North America from eastern Canada to Alaska (McCord and Cardoza 1982, p. 729; Poole 2003, p. 361; Vashon 2015, p. 4; Univ. of Alaska Center for Conservation Science 2016, p. 1). It is strongly associated with the expansive, continuous boreal forests of those areas, and its range largely overlaps that of its primary prey, the snowshoe hare, also a boreal forest specialist (Bittner and Rongstad 1982, p. 146; Mowat *et al.* 2000, pp. 268-269; Aubry *et al.* 2000, p. 375). In Canada, lynx are thought to occupy about 5.5 million km^2 (over 2.1 million mi^2), which represents 95 percent of their historical range in that country (Environment Canada 2014, p. 2), and over 89 percent of the species' entire distribution. Nationally in Canada, lynx are classified as secure, widespread, and abundant; they are managed for long-term population stability, with a conservative estimate of 110,000

individuals during cyclic lows; and no acute, widespread threats to lynx have been identified (Environment Canada 2014, entire; Vashon 2015, pp. 1-6). Provincially, lynx status is considered secure in British Columbia, Manitoba, Ontario, Quebec, Newfoundland and Labrador, Northwest Territories, and the Yukon; sensitive in Alberta and Saskatchewan; at risk/endangered in New Brunswick and Nova Scotia; and undetermined in Nunavut (Environment Canada 2014, pp. 3-4; Vashon 2015, p. 1). Lynx were extirpated from Prince Edward Island (0.1 percent of lynx range in Canada) by the late 1800s, and on the mainland the southern margin of assumed lynx range has contracted northward in Quebec, southeastern Ontario, Manitoba, Saskatchewan, and Alberta (Poole 2003, p. 361; Bayne *et al.* 2008, pp. 1192-1195; Koen *et al.* 2014a, pp. 757-760).

In Alaska, lynx are distributed across roughly 534,454 km^2 (206,354 mi^2) of boreal forest (Univ. of Alaska Center for Conservation Science, 2016, entire; Reimer 2016, *pers. comm.*), which represents about 8.7 percent of the species' breeding distribution. Lynx in Alaska are apparently secure, with low to moderate threats, and populations appear stable statewide, although total abundance is unknown (Alaska Natural Heritage Program 2008, pp. 2-4).

In both Alaska and Canada, lynx trapping is managed through regulated seasons and harvest levels, which are adjusted to avoid overexploitation, especially during the low phase of the lynx-hare population cycle (Alaska Natural Heritage Program 2008, pp. 2-6; Vashon 2015, pp. 5-6). Along the Canada-United States border in provinces adjacent to DPS lynx populations, lynx trapping is prohibited in New Brunswick (adjacent to northeastern Maine) but regulated trapping is permitted in Quebec (adjacent to northwestern Maine, northern New Hampshire, and northern Vermont), Ontario (adjacent to northeastern Minnesota), Alberta (adjacent to northwestern Montana), and British Columbia (adjacent to northwestern Montana, northern Idaho, and northern Washington). Because after 2 centuries of being legally harvested for the international fur trade it remains widespread and abundant over most of its range, and because managed harvest in recent decades does not appear to have caused significant range loss or population decline, the lynx has been designated a "species of least concern" in accordance with the IUCN Red List of Threatened Species (Vashon 2015, entire).

2.3.2 Lynx Distribution in the Contiguous United States

2.3.2.1 Defining Lynx Distribution at the Periphery of the Range

Several aspects of lynx population dynamics and dispersal patterns have resulted in inconsistent approaches and difficulty in defining the range and/or distribution of the species, especially at the margins (74 FR 66942). There also is uncertainty and ambiguity in some historical lynx occurrence records, with early assessments based largely on trapping harvest records of questionable accuracy, particularly where lynx and bobcats overlap, and a reliance on anecdotal or unverified occurrence information (McKelvey *et al.* 2000a, pp. 208-210; 65 FR 16054). These issues confound efforts to accurately portray the species' historical distribution in the contiguous United States and to assess the current distribution relative to historical conditions (McKelvey *et al.* 2008, pp. 553-554; 79 FR 54814-54815; McKelvey *in* Lynx SSA

Team 2016a, p.11). This has resulted in inaccurate portrayals of lynx distribution and misperceptions that the historical range of lynx in the contiguous United States was once much more extensive than is ecologically possible (68 FR 40080; 74 FR 66942).

The boreal forest reaches its southern extent in the northern contiguous United States and it becomes naturally patchy and marginal for hares and lynx in places where it transitions to temperate forest types. Many areas of boreal or boreal-like (spruce-fir) forest (e.g., the Appalachian Mountains from New York southward in the East, most of northern Michigan and northern Wisconsin in the Midwest, and the Southern Rocky Mountains and Southern Cascade Mountains in the West) probably never supported persistent native lynx populations despite the presence of snowshoe hares. Hare densities in these areas are generally low and appear insufficient to support resident lynx populations over time. Only a relatively few areas in the contiguous United States historically supported an adequate quantity, quality, and spatial arrangement of habitat to support resident lynx populations continuously over time, and many historical lynx occurrences across a large area of the contiguous United States were likely dispersers. The occurrence of dispersing lynx is unpredictable, and dispersing lynx will probably continue to move periodically and temporarily into areas that cannot support persistent populations (68 FR 40077).

Because the lynx is highly mobile and has, throughout most of its range, cyclic population dynamics that are closely tied to cyclic snowshoe hare populations, numbers of lynx naturally fluctuate and become extremely low during lows in decadal hare cycles. The dramatic, cyclic fluctuations in lynx populations across much of the range as they track cyclic hare populations and the mass synchronous dispersals (irruptions) of large numbers of lynx into the contiguous United States when northern hare populations crashed are well-documented (Elton and Nicholson 1942, entire; Gunderson 1978, entire; Thiel 1987, entire; McKelvey *et al.* 2000a, pp. 219, 232-242; Mowat *et al.* 2000, pp. 281-294; ILBT 2013, p. 33). These events have resulted in records of lynx occurrence, in some cases very rarely, in other cases sometimes in large numbers and with intermittent (cyclic) regularity, in places that otherwise lack evidence of persistent lynx presence or the habitats and hare densities necessary to support a resident lynx population (USFWS 2005, pp. 3-4; 79 FR 54787-54789, 54793-54795, 54812-54823).

Many records of lynx in the contiguous United States appear to be related to such events, including the unprecedented ‘‘explosions’’ of lynx observed in the early 1960s and 1970s (Gunderson 1978, entire; McKelvey *et al.* 2000a, pp. 232-242). During these events, many lynx occurred in anomalous habitats, exhibited unusual behavior, suffered high mortality, and numbers declined dramatically within a few years of irruptive peaks (Gunderson 1978, entire; Thiel 1987, entire; McKelvey *et al.* 2000a, p. 242). Because dispersing lynx typically do not persist in these areas of temporary range expansion, disappearing fairly quickly after irruptions, van Zyll de Jong (1971, p. 16) suggested that only areas that support lynx populations throughout both the low and the high phases of the “10-year cycle” (i.e., across the natural range of hare densities) should be considered to constitute the species’ range. In its 2003 remanded determination, the Service determined that lynx in the contiguous United States exist either as resident populations or as dispersers, that dispersing lynx are often found repeatedly

and for variable amounts of time in habitats that cannot sustain breeding populations over time (though some breeding may occur occasionally in some of these areas), and that such areas probably contribute little (if at all) to the persistence of lynx in the DPS (68 FR 40077, 40079-80). This repeated dispersal into habitats that ultimately cannot support the species (‘‘sink’’ habitats) often leads to confusion about where lynx populations may be viable (74 FR 66938).

The metapopulation structure thought to govern lynx populations in the DPS (McKelvey *et al.* 2000b, pp. 25-31; see Section 2.2) and the transitional (and, therefore, increasingly fragmented and isolated) and spatially- and temporally-shifting nature of lynx habitat at the southern periphery of the range (Koehler and Aubry 1994, pp. 78-79; McKelvey *et al.* 2000b, pp. 29-30; 74 FR 66940; 79 FR 54814) also present challenges in defining the distribution of lynx. Both factors suggest that some areas may naturally support resident lynx only temporarily or occasionally when habitat conditions (both boreal forest vegetation supporting abundant hares and snow conditions favoring lynx) are adequate and/or when immigration is sufficient to offset the lower productivity and recruitment rates expected among lynx populations in marginal or suboptimal habitats. McKelvey *et al.* (2000b, pp. 21, 29-31) described such habitats as “... source-sink mosaics that shift with disturbance and succession,” and the contribution, if any, of these places (especially those that act more often as “sinks” than “sources”) to the maintenance and persistence of lynx populations in the DPS remains questionable (74 FR 66938).

Finally, the southern periphery of the lynx’s range, where lynx are rare in many places, overlaps with the northern distribution of the much more common bobcat (Peers *et al.* 2012, pp. 4-5). The 2 species are difficult to distinguish in the field, they often were not reliably differentiated in historical trapping records (McKelvey *et al.* 2000a, pp. 208-209), and errors in early accounts of lynx distribution based on anecdotal information seem likely (Halfpenny and Miller 1980, pp. 1, 3-8; Meaney 2002, pp. 3-5, Hoving *et al.* 2003, pp. 366-367). Because of the large effect that relatively few errors in identification can have on assessments of the distribution of rare animals, McKelvey *et al.* (2000a, p. 209; 2008, pp. 553-554) suggest that anecdotal information should be interpreted with caution, and only verified occurrence data should be used to assess historical and current lynx distributions.

These complexities of lynx population dynamics and our incomplete understanding of the limited lynx occurrence data, combined with a naturally dynamic and transitional habitat, make it difficult, if not impossible, to precisely delineate the historical or current distribution of resident lynx populations in the contiguous United States (Koehler and Aubry 1994, p. 79; 68 FR 40084). While recognizing these limitations, we use our best professional judgment of the best scientific and commercial data available to make conclusions about the range of the lynx for the purposes of this SSA. In the following section, we describe the types and distributions of potential lynx habitats in the contiguous United States, and our current understanding of the historical and current distributions of resident lynx populations in the DPS considering the factors discussed above.

2.3.2.2 Lynx Distribution within the DPS Range

The southern periphery of boreal forest vegetation extends into parts of the northern contiguous United States, where it transitions to the Acadian forest in the Northeast (Seymour and Hunter 1992, pp. 1, 3), deciduous temperate forest in the Great Lakes region, and subalpine forest in the Rocky Mountains and Cascade Mountains in the west (Agee 2000, pp. 40-41). In much of the DPS range, these boreal forest landscapes become naturally patchy and transitional because they are at the southern edge of the boreal forest range, and they are limited, particularly in the west, by elevation and/or aspect (Ruediger *et al.* 2000, p. 4-16; 68 FR 40090). Non-forested land uses (e.g., agriculture, development) become increasingly prevalent in these areas. These factors generally limit snowshoe hare populations in the contiguous United States from achieving landscape densities similar to those of the expansive northern boreal forest in Alaska and Canada, where hares are generally more evenly distributed across the landscape and more abundant except during cyclic population lows (Wolff 1980, pp. 123-128; Buehler and Keith 1982, pp. 24, 28; Koehler 1990a, p. 849; Koehler and Aubry 1994, p. 84; Aubry *et al.* 2000, pp. 373-375, 382, 394). Consequently, important foraging habitat for lynx is often more limited and fragmented in the contiguous United States than in boreal forests of northern Canada and Alaska (Berg and Inman 2010, p. 6), and overall habitat quality is typically lower.

The habitats that lynx use in the contiguous United States are characterized by patchily-distributed moist forest types with relatively higher hare densities in a matrix of other habitats (e.g., hardwoods, dry forest, non-forest) with lower landscape hare densities (ILBT 2013, p.126; 78 FR 59434). In these areas, lynx incorporate the matrix habitat (non-boreal forest habitat elements) into their home ranges and use it for traveling between patches of boreal forest that support higher hare densities where most lynx foraging occurs. In some areas, patches of habitat containing snowshoe hares become so small and fragmented that the landscape cannot support lynx home ranges (ILBT 2013, p. 77) or populations over time (68 FR 40077). Additionally, the presence of more snowshoe hare predators and potential lynx competitors at southern latitudes may inhibit the potential for high-density hare populations (Wolff 1980, p. 128). Wirsing *et al*. (2002, entire) concluded that high predation rates on hares in fragmented habitats may explain the relative stability (i.e., lack of cyclicity) in southern hare populations. As a result, lynx in the DPS generally occur at relatively low densities compared to lynx in the core of the Canadian and Alaskan range when hares are abundant (Aubry *et al.* 2000, pp. 375, 393-394). Because the lynx is a habitat and prey specialist, its densities in the DPS range are also typically lower than those of the bobcat, which is a habitat and prey generalist (Peers *et al*. 2012, pp. 4-9).

Snow conditions also are thought to influence lynx distribution (Ruggiero *et al.* 2000b, pp. 445-449; Peers *et al.* 2012, pp. 4-9) because they are morphologically and physiologically well-adapted for hunting snowshoe hares and surviving in areas that have cold winters with deep and persistent unconsolidated snow (Murray and Boutin 1991, p. 463). Long-term snow conditions also presumably limit the winter distribution of potential lynx competitors and

predators (Buskirk *et al.* 2000a, p. 90; Krohn *et al.* 2005, p. 123; Peers *et al.* 2012, entire; also see section 2.2 above), although behavioral adaptations may offset morphological differences to some degree (e.g., Murray *et al*. 1994, entire; 1995, entire).

Based on verified data, lynx were documented historically in 24 of the contiguous United States (McKelvey *et al.* 2000a, 207-232). More recently, lynx have been documented in 3 other states after some of the lynx released into southwestern Colorado (see below) dispersed into northern New Mexico, Arizona, and Kansas (Colorado Division of Wildlife 2000, p. 3; Devineau *et al.* 2010, p. 526; 74 FR 66938), which had previously lacked verified evidence of lynx occurrence (McKelvey *et* al. 2000a, p. 210; USFS 2009, entire; 74 FR 66940-66943). However, in many states, lynx occurred very rarely as dispersers and often in anomalous habitats – usually (as described above) in association with “irruptions” (mass dispersal events) of lynx from Canada when northern snowshoe hare populations underwent dramatic cyclic declines roughly every decade. Based on our current understanding of lynx and hare habitat requirements, the Service concludes that records in at least 13 states (Arizona, Connecticut, Illinois, Indiana, Iowa, Kansas, Massachusetts, Nebraska, Nevada, New Mexico, North Dakota, Pennsylvania, and South Dakota) represent occasional dispersing lynx that arrived in places with no historical or recent evidence of the habitat quality, quantity, or distribution necessary to support resident lynx (68 FR 40099; 74 FR 66940-66942; 79 FR 54807, 54817). These states are not within the distribution of resident lynx in the DPS, and we conclude that they naturally lack the necessary habitat, hare densities, and snow conditions and that they were not capable historically, and are not capable now, of supporting resident lynx populations over time.

When it listed the DPS under the ESA, the Service defined its range as the forested portions of the remaining 14 states; 4 in the Northeast (Maine, New Hampshire, New York, Vermont), 3 in the Great Lakes Region (Michigan, Minnesota, Wisconsin), and 7 in the West (Colorado, Idaho, Montana, Oregon, Utah, Washington, Wyoming; 65 FR 16052, 16085). Some of these states, and parts of others, are thought to have historically supported only dispersing lynx or to have only occasionally supported resident breeding lynx (68 FR 40099; 74 FR 66940). Such areas were included within the range of the DPS because of the possibility that lynx could establish small, local populations in them and perhaps contribute to the persistence of the DPS, though evidence of this was (and remains) lacking (68 FR 40080; 74 FR 66938).

Based on a comprenhensive, peer-reviewed analysis of verified historical lynx records that was published at about the time the DPS was listed (McKelvey *et al.* 2000a, entire) and on research and monitoring that have occurred since then, it seems likely that lynx occurred historically in some states (New York, Vermont, Wisconsin, Oregon, and Utah) only intermittently as dispersers or as small, naturally ephemeral populations; not as persistent resident breeding populations. In other states (New Hampshire, Michigan, Colorado, and Wyoming), it remains uncertain whether resident lynx occurred historically as small but persistent breeding populations or only ephemerally. Parts of the remaining states (Idaho, Maine, Minnesota, Montana, and Washington) show the strongest evidence of historical and recent (at the time of listing and since then) persistent resident populations.

In its 2003 remanded determination for the lynx DPS, the Service concluded that (1) potential lynx and hare habitats in Michigan, Oregon, Utah, Vermont, and Wisconsin were relatively small, isolated, and of marginal quality, and that available information suggested that these states did not historically or recently support resident lynx populations; (2) it was uncertain whether Colorado, New York, and Wyoming historically supported resident populations or only occasional dispersers; (3) New Hampshire probably supported a small resident population that had been extirpated; and (4) the remaining states (Idaho, Maine, Minnesota, Montana, and Washington) had the best historical and recent evidence of resident breeding populations (68 FR 40082, 40086-40095, 40097-40101). Below we provide our current understanding of these state groupings and the information available since the 2003 remand that informs this understanding.

Michigan, Oregon, Utah, Vermont, and Wisconsin - Additional information and analyses available since 2003 support the determination that Michigan (except for Isle Royale in Lake Superior) and Oregon did not historically or recently support resident lynx populations (Aubry 2006, pp. 1-2; Linden 2006, pp. 83-90), and no evidence has emerged to suggest that resident populations occurred historically or recently in Utah or Wisconsin (ILBT 2013, pp. 45, 58). Isle Royale, a 535-km^2 (206-mi^2) island in northwestern Lake Superior that is closer to northeastern Minnesota and southern Ontario than to the rest of Michigan, is thought to have historically supported a small (perhaps 30 lynx) population that was extirpated in the 1930s due to overtrapping (Licht *et al.* 2015, p. 139; 2017, p. 505). The best available information continues to suggest that the rest of Michigan, as well as Oregon, Utah, and Wisconsin, did not historically, and do not currently, support resident lynx populations. We conclude that (1) habitats in these states are naturally incapable of supporting persistent resident populations; (2) historical and potential future occurrences of lynx in these states most likely represent occasional dispersing lynx; and (3) these states (with the possible except of Isle Royale, MI) have not historically or recently contributed to the persistence and conservation of lynx in the DPS and are unlikely to do so in the future.

In contrast, 9 lynx occurrences were confirmed in the 530-km^2 (205-mi^2) Nulhegan Basin of northeastern Vermont from 2003 to 2014, and breeding was confirmed in 2012; intensified surveys since then have resulted in only a single photograph of a lynx in 2014 (Bernier 2015, pp. 1-3; Bernier 2016, *pers. comm.*). This new information indicates that this small area of northernmost Vermont is at least occasionally capable of supporting a small number of resident breeding lynx. However, assessments of the amount and quality of potential lynx and hare habitat, snow conditions, and the presence and distribution of lynx competitors and predators (Hoving *et al.* 2005, pp. 746-749; Bernier 2015, entire) indicate it is unlikely that northern Vermont can support a persistent resident lynx population (79 FR 54820-54821). We conclude that this small area of Vermont only occasionally supports lynx reproduction when hare abundance and snow conditions are temporarily adequate; that it most likely represents a “sink” rather than a “source” for the regional lynx population; and that this likely represents its natural historical condition.

Colorado, New York, and Wyoming - When the Service listed the DPS in 2000, it believed that a resident lynx population occurred historically in the Southern Rocky Mountains of western Colorado and southeastern Wyoming, that lynx were also historically resident in northwestern Wyoming (part of the Northern Rocky Mountains), and that the Adirondack Mountains of northern New York may historically have supported a resident population that was extirpated by the latter half of the 1900s (65 FR 16055-16056; 16058-16059). In the 2003 remand, the Service noted inconsistencies and likely errors in historical lynx reports for the Southern Rockies, questioned its original conclusion that Colorado historically supported an isolated resident population, and concluded that it was uncertain whether a resident population occurred historically in Colorado or if historical records were of periodic dispersing lynx during "extremely high population cycles" and that a resident population never existed in southeastern Wyoming (68 FR 40081, 40091). In that rule, the Service also concluded that, despite evidence of reproduction in northwestern Wyoming (part of the GYA), potential habitat there is naturally marginal (patchier and composed of drier forest types), may be incapable of supporting a resident lynx population, and that lynx in northern Wyoming are most likely dispersers (68 FR 40090). Also in 2003, the Service concluded that it was possible resident lynx occurred in northern New York prior to 1900 but the potential habitat there is small, marginal, isolated and likely has only supported dispersing lynx since then (68 FR 40086-40087).

In Colorado, after the initial release of 96 lynx in 1999 and 2000, none were released in 2001 or 2002 (Shenk 2010, pp. 1, 4; Ivan *in* Lynx SSA Team 2016a, p. 22). From 2003-2006, another 122 lynx were released, bringing the total to 218 (Devineau *et al.* 2010, p. 526). Reproduction was documented in 2003-2006 and 2009-2010, with 48 dens documented in that time, including a third generation of Colorado-born lynx (Shenk 2010, p. 5; Ivan *in* Lynx SSA Team 2016a, p. 22). In 2010, CPW determined that all benchmarks for its lynx program had been met and had resulted in the establishment of a viable, self-sustaining lynx population (Ivan 2011b, pp. 11, 12). Intensive monitoring of the population ceased in 2010 and was replaced by an effort to develop a minimally-invasive long-term monitoring program (Ivan 2011b, entire), which used snow-tracking surveys and camera traps to document continued lynx presence in the core release area of the San Juan Mountains in 2010-11, 2014-15, and 2015-16, with evidence of reproduction also documented during that time (Ivan *et al*. 2015, p.1; Odell *et al*. 2016, entire). In its 2014 revised critical habitat designation for the DPS, the Service concluded that the historical record of verified lynx occurrence in Colorado combined with naturally highly-fragmented and isolated potential habitat and generally low snowshoe hare densities suggest that Colorado and the Southern Rockies were unlikely to have historically supported a persistent resident lynx population and that the long-term persistence of the introduced population is uncertain (79 FR 54787-54789, 54793-54795, 54816-54817). The current size of the resident lynx population in Colorado is unknown but thought to number between 100 and 250 (Ivan *in* Lynx SSA Team 2016a, p. 47). We continue to believe that available information suggests Colorado did not historically support a persistent resident lynx population and that the long-term persistence of the introduced population remains uncertain.

In northern New York, 83 lynx were released into the Adirondack Mountains in 1988-1990 (Brocke et al. 1993, p. 1); however, that effort failed to establish a resident breeding population

(65 FR 16055), suggesting that potential habitat there may be (and historically may have been) inadequate to support lynx persistence (68 FR 40086-40087). Information and analyses since the 2003 remand support the conclusion that New York has inadequate habitat quantity and quality (both vegetation and snow conditions) to support a resident lynx population (Hoving *et al.* 2005, pp. 746, 749). We have no information that resident lynx presently occur in New York, and our evaluation of historical records suggests that the timing of most (19; 83 percent) of the 23 verified records in the state after 1900 (McKelvey *et al.* 2000a, p. 216, table 8.2) were consistent with expected decadal irruptions of lynx from the north. The work of Hoving *et al.* (2005, entire), our evaluation of verified records of historical occurrence, and the rapid failure of the 1988-1990 lynx translocations to establish a resident population all suggest that New York has not recently and likely did not historically support a persistent resident lynx population. We conclude that (1) habitat in the Adirondack Mountains is incapable of supporting a resident lynx population, (2) verified historical records were most likely of dispersing lynx, and (3) dispersing lynx may currently and in the future continue to occur rarely and temporarily in northern New York.

In northwestern Wyoming, 18 lynx were reported to have been trapped from a small area in the Wyoming Range in winter 1971-72 (Squires and Laurion 2000, p. 338), and other sources[4] claim that 13 lynx were trapped in the Wyoming Range in winter 1972-73. However, Reeve *et al*. (1986a, Appendix A, pp. 67-69) reported no verified ("certain") records of lynx trapped from 1970-1982 and unverified ("probable") accounts that included no lynx trapped in 1971, 5 trapped in 1972, and 1 trapped in 1973. These conflicting anecdotal reports of lynx occurrence/trapping records illustrate compellingly why only verified records are appropriate for consideration of lynx historical distribution, especially given evidence of historical misidentification of bobcats as lynx (McKelvey *et al.* 2000a, pp. 208-210, 227; 2008, pp. 553-554). Even if some of these anecdotal records were correct, the large numbers of lynx reported in the early 1970s correspond to the second of 2 well-documented and unprecedentedly large irruptions of lynx from Canada into the northern contiguous United States, when dispersing/transient lynx occurred temporarily in many places with little or no evidence of the historical presence of resident lynx (McKelvey *et al.* 2000a, pp. 232-242). It is more plausible that the sudden increase in lynx reportedly trapped in the Wyoming Range suggested by some of these anecdotal records would have reflected a pulse of dispersing lynx associated with that large irruption rather than a previously undocumented resident lynx population that suddenly and simultaneously became vulnerable to trapping in only a handful of winters.

However, verified information available since 2003 has documented continued presence of a small number of lynx in northwestern Wyoming as recently as 2010, including some evidence of reproduction (Squires *et al.* 2003, entire; Squires and Oakleaf 2005, entire; Murphy *et al.* 2006, entire; Endeavor Wildlife Research 2008 and 2009, entire). Additionally, at least 9 radio-marked lynx released in Colorado subsequently moved into or through the area from 1999-2010, with several settling temporarily into parts of the Wyoming Range previously occupied by native lynx (Ivan 2017, entire; see section 4.2.5, below). More recent surveys and research-related trapping

[4] http://www.sublettecountyjournal.com/v4n16/v4n16s7.htm.

efforts have failed to detect lynx in this area or elsewhere in Wyoming since 2010 (79 FR 54791; Squires *in* Lynx SSA Team 2016a, pp. 20-21, 45).

The historical record and recent evidence of lynx occupancy and reproduction indicate that the GYA of northwestern Wyoming and southwestern Montana at least occasionally supports a small number of resident lynx. However, the consistency of lynx occupancy in the GYA over time remains uncertain (Lynx SSA Team 2016a, pp. 11, 45, 57). Uncertainty about whether this area consistently or only intermittently supported resident lynx historically makes it difficult to interpret their recent apparent absence from the area (Lynx SSA Team 2016a, p. 57). If residency was intermittent historically, the current apparent absence of resident lynx might be a natural condition related to the area's largely marginal or suboptimal habitat conditions - i.e., it may naturally be capable of supporting resident lynx only intermittently when habitat conditions and hare densities are optimal. In that case, future intermittent residency would be expected, but only if lynx dispersing from a source population immigrate to the GYA when habitat conditions and hare densities return to more favorable levels. Conversely, if the GYA always historically supported a small number of resident lynx but no longer does, it may suggest that some factor or factors have acted to shift the quality of the area's habitat from just barely capable of supporting a small resident population to no longer capable of doing so, potentially resulting in extirpation.

We conclude that this uncertainty cannot be resolved based on the available information but, given the protected conservation status of large areas of the GYA unit (Yellowstone and Grand Teton national parks; all or parts of the Absaroka-Beartooth, Bridger, Gros Ventre, Lee Metcalf, Northern Absaroka, Teton, and Washakie wilderness areas), its historical inability to support a robust, persistent resident population and its apparent recent inability to support any resident lynx may be a reflection of naturally marginal and patchy habitats and relatively low hare abundance in much of the unit, resulting in only an intermittent ability of this unit to support resident lynx. We note that some of the best potential habitat and highest hare densities have been documented in areas with developmental land use designations (see 4.2.3 and 4.2.5) outside parks and wilderness (e.g., the Wyoming Range/Union Pass/Togwotee Pass areas; Squires 2017, p. 2). However, most of those areas have been managed by the USFS to conserve lynx and habitats in accordance first with the recommendations in the LCAS (Reudiger *et al*. 2000, entire) and the associated conservation agreement (CA) between the USFS and the Service (USFS and USFWS 2000, entire) and subsequently with the NRLMD (USFS 2007, entire). Nonetheless, despite active management for lynx conservation and the passage, presumably, of adequate time for some previously impacted areas to regenerate back into higher-quality hare and lynx habitats, lynx apparently have failed to naturally recolonize this unit, and released lynx dispersing from Colorado have failed to maintain long-term home ranges or produce kittens in these areas. We also note, however, that extensive areas of the GYA were burned by the large, intense wildfires of 1988, and that some of those areas may soon (perhaps in the next 5-15 years) regenerate to a stage containing the dense horizontal conifer structure favorable for hares and, therefore, lynx foraging habitat, perhaps increasing the likelihood that the GYA may support resident lynx again in the near future (Lynx SSA Team 2016a, p. 46).

In southern Wyoming, all recent lynx records are of Colorado-released lynx that moved into or through the area (Devineau *et al.* 2010, fig. 1, p. 526; Ivan 2017, entire), including 1 female that in 2004 established a den on the west side of the Medicine Bow Mountains and produced 3 kittens that did not survive (Bjornlie 2016, *pers. comm*.; Ivan 2016a, *pers. comm.;* 2017, p. 3). Based on the available information, we conclude that southern Wyoming did not historically or recently support a resident lynx population and is not now capable of doing so.

New Hampshire - There were 87 confirmed lynx records in northern New Hampshire from 2006 to 2016 (though these do not represent 87 different individual lynx), with evidence of reproduction in 2010 and 2011 (79 FR 54820; NHFGD 2017, entire). Most of these records were documented during snow-track surveys in 2012-2015, with an additional 30 lynx detections recorded in 2014-2016 by remote cameras (NHFGD 2017, entire). Most records since 2006 are in the vicinity of Pittsburg in the northernmost reaches of the state, though lynx detections in 2015 and 2016 suggest a southern expansion from the area where they had been documented in 2006 through 2014 (Siren 2016a, p. 1; Siren 2016b, *pers. comm.*). Despite recent evidence of lynx residency and reproduction, the Service concluded in the 2014 revised critical habitat designation that, based on modeling of the amount of potentially suitable habitat and favorable snow conditions (Hoving *et al.* 2005, pp. 739, 749; Litvaitis and Tash 2005, p. A-298), it is unlikely that northern New Hampshire will support a resident breeding population over the long-term (79 FR 54820-54821). Siren (2014a, p. 10) suspected that the relatively few lynx detections documented in 2012-2014 may be related to the presence and abundance of bobcat, coyote, and fisher populations in much of northern New Hampshire. We conclude that northern and central New Hampshire likely supported a small resident lynx population historically that was extirpated during the latter half of the 20th century. We are uncertain whether lynx detections in northernmost New Hampshire over the past decade may represent the natural reestablishment of a small resident breeding population in the state or if it is a temporary phenomenon related to an expanding source population in neighboring northern Maine (79 FR 54821). Although bobcat populations have increased and expanded their range in this region in recent decades (Lavoie *et al.* 2009, pp. 873-874), severe winters and deep snow can substantially limit their populations (Reed 2013, pp. 29-33; McCord, 1974, pp. 433-434). Maine's bobcat harvest declined substantially after 2 deep-snow winters in 2008 and 2009 (MDIFW 2015a, p. 37). It is possible that these anomalous deep-snow winters provided a temporary competitive advantage to lynx in northern New Hampshire.

Idaho, Maine, Minnesota, Montana, and Washington - These states (along with New Hampshire, above) have the strongest historical evidence of continuous lynx presence and recent evidence of resident lynx populations (McKelvey *et al.* 2000a, pp. 211-228; 68 FR 40086-40095, 40097-40101; McKelvey *in* Lynx SSA Team 2016a, p. 11). Historical lynx records exist for much of Idaho, but many, especially in the central and southern part of the state, occurred in anomalous habitats or were associated with large irruptions of lynx from Canada to the northern contiguous United States in the early 1960s and early 1970s (McKelvey *et al.* 2000a, pp. 225-227). The historical record and recent surveys (summarized at 79 FR 54818-54820) suggest that (1) only dispersing lynx occur throughout most of Idaho, (2) habitats in many parts of the state are drier forest types that support lower densities of hares, and (3) resident lynx seem to

be confined to the Purcell, Selkirk, and Cabinet mountain ranges in the State's northern panhandle. The number of individual lynx with home ranges occurring in the northeast corner of the Idaho Panhandle is unknown but small based on the amount of potential habitat and results of recent surveys (Lucid 2016, pp. 7-11; Lucid *et al*. 2016, pp. 158-160, 180), and lynx in Idaho are part of a larger population that occurs primarily in northwestern Montana and southeastern British Columbia. In the Selkirks, a single lynx was detected in 2010 and there were multiple detections in 2015-2016. Over the last several years, radio-collar data and remote camera images have documented a single lynx with a home range in the west Cabinet Mountains and there have been detections of multiple lynx in the Purcell Mountains in or immediately adjacent to designated critical habitat (i.e., within 16 km [10 mi] of the Canada border). Detections in the Purcells in 2015-2016 included a photo of an adult lynx accompanied by juvenile lynx, the only recent evidence of lynx reproduction in Idaho, which otherwise lacks evidence of a long-term, persistent resident population (IDFG 2017a, pp. 2-3).

Maine has a long history of continual lynx presence, with evidence of a persistent resident population in much of the northern half of the state (McKelvey *et al.* 2000a, pp. 211-212; Hoving *et al.* 2003, entire;), which currently is believed to support the largest lynx population in the DPS (Vashon *et al.* 2012, pp. 50-60; 79 FR 54784-54785, 54792, 54822-54824; Vashon *in* Lynx SSA Team 2016a, p. 18). The current amount and distribution of high-quality lynx and hare habitat and the numbers of hares and resident lynx in Maine are all much larger than was suspected at the time of listing or the 2003 remand, and all are probably substantially larger now than under likely typical historical conditions. Based on habitat distribution and lynx home range data, the MDIFW estimated that this geographic unit may have supported roughly 250-320 adult lynx in 1995 and 750-1,000+ by 2003-06 (Vashon *et al.* 2012, p. 58; Vashon *in* Lynx SSA Team 2016a, p. 18]), and recent information suggests that resident lynx may be expanding to the south of the core population area (Vashon 2017, *pers. comm.*). The current lynx population in Maine is supported by the broad distribution of high-quality hare habitat that resulted from extensive, large-scale clearcutting in the 1970s and 1980s in response to a massive spruce budworm (*Choristoneura fumiferana*) outbreak (68 FR 40087; 79 FR 54792; also see section 4.2.1). As these regenerating clearcuts, which currently provide the dense horizontal structure preferred by hares, mature beyond about 35-40 years post-harvest, hare densities are expected to decline as cover and forage are reduced as a result of forest succession (Simons 2009, p. 217; Simons-Legaard *in* Lynx SSA Team 2016a, p. 16). The current lynx population in Maine is probably substantially larger than typically occurred historically under the natural disturbance regime, when relatively small amounts of the spruce-fir forests in the state are thought to have been composed of the dense young stands that provode optimal hare (and, therefore, lynx foraging) habitat (Lorimer 1977, entire; 68 FR 40094; Vashon *et al.* 2012, pp. 45, 56; 79 FR 54792). With the reduction in clearcutting and the proliferation of partial harvesting following enactment of the Maine Forest Practices Act of 1989, lynx densities in Maine are projected to decline by 55 to 65 percent by 2032 (Simons 2009, p. 217; Simons-Legaard *in* Lynx SSA Team 2016a, p. 16), perhaps to levels more consistent with likely historical conditions. Lynx in Maine likely represent the southern periphery of a larger population that occurs in northern New Brunswick and southern Quebec south of the St. Lawrence Seaway/River, which appears to partially isolate lynx in this region, demographically and genetically, from populations in the core of the species'

range (Koen *et al.* 2015, entire). Whether lynx persistence in Maine relies on immigration from Canada, and if so to what extent, is unknown.

In Minnesota, research conducted since the 2003 remand has demonstrated the continuous presence of a resident lynx population in the northeastern part of the state that seems to be the southern periphery of a larger population in southwestern Ontario (Moen *et* al. 2008b, entire; Moen *in* Lynx SSA Team 2016a, pp. 19, 39). The number of resident lynx in Minnesota is unknown but believed to be between 50 and 200 (Moen *in* Lynx SSA Team 2016a, pp. 19, 39). Hare densities and snow conditions consistently favorable for lynx appear to be restricted to the northeastern "Arrowhead" region of the state. Lynx are occasionally detected to the south and west of this region; however, those areas are dominated by bobcats. Although there are currently more lynx in Minnesota than was suspected when the DPS was listed, it is unclear whether current numbers and distribution are similar to the historical condition. The extent to which lynx persistence in Minnesota may rely on immigration from Canada is also unknown.

In Montana, research conducted since the DPS was proposed for listing has documented the continued presence and broad distribution of resident lynx in much of the northwestern portion of the state (Squires *in* Lynx SSA Team 2016a, p. 20). The number of resident lynx in northwest Montana is unknown but the area is thought to be capable of supporting between 200 and 300 resident lynx (Squires *in* Lynx SSA Team 2016a, p. 41). In this area, resident lynx occur in 3 subpopulations - the Purcell Mountains, Seeley Lake/Central, and Garnet Mountains (Squires *in* Lynx SSA Team 2016a, p. 20). No lynx were detected in the Garnet Range from 2011 to 2015, prompting concerns about the potential loss of the small resident population (perhaps 7-10 lynx) documented there in the mid-1980s and again recently from 2002 to 2010. However, whether this absence indicates the extirpation of a previously persistent resident population or the temporary loss of an historically ephemeral population is uncertain. A single lynx was verified in the Garnet Range in February 2016, indicating that natural recolonization of the area is possible; however, no other detections of that lynx or other lynx have been verified since then, and there currently remains no evidence of lynx residency in this mountain range (Lieberg 2017, *pers. comm.*). Lynx in northwestern Montana (and northern Idaho) likely represent the southern periphery of a larger population in southwestern Alberta and southeastern British Columbia. The extent to which lynx persistence in this area relies on immigration from Canada is unknown, and trapping harvest data suggest declining immigration after the mid-1980s (McKelvey *et al.* 2000a, p. 225; Squires *in* Lynx SSA Team 2016a, p. 20). In southwest Montana, few lynx and no recent evidence of reproduction have been documented in the Montana portion of the GYA where, as with the northwestern Wyoming part of the GYA (discussed above), uncertainty about whether this area consistently or only intermittently supported resident lynx historically makes it difficult to interpret their recent apparent absence from the area (Lynx SSA Team 2016a, p. 57). As elsewhere in the West, recent research and habitat assessments suggest that habitats capable of supporting resident lynx in Montana are, and historically were, naturally patchier and less-broadly distributed (Squires *et al.* 2006a, pp. 46-47; Squires *et al.* 2013, p. 191), and lynx therefore naturally rarer, than was thought when the DPS was listed (ILBT 2013, p. 23; Jackson *in* Lynx SSA Team 2016a, p. 12).

In Washington, research and monitoring conducted since the 2003 remand has continued to document a resident lynx population in the Okanogan region of the eastern Cascade Mountains in the north-central part of the state (von Kienast 2003, entire; Maletzke 2004, entire; Koehler *et al.* 2008, entire; Maletzke *et al.* 2008, entire; Maletzke *in* Lynx SSA 2016, pp. 21-22). Since at least 1985, this is the only area of the state with evidence of a resident breeding population (Koehler and Maletzke 2006, p. 4; Koehler *et al.* 2008, p. 1518; ILBT 2013, p. 58; Maletzke *in* Lynx SSA 2016, p. 21), although the Kettle Mountains in the northeastern part of the state are thought to have historically supported a small breeding population (possibly 10-20 resident lynx), and lynx are detected there occasionally (Stinson 2001, pp. 13–14; Koehler *et al.* 2008, p. 1523; USFWS 2008a, p. 2). Multiple large wildfires in this area over the last 25 years have burned about 34-37 percent of the Okanogan Lynx Management Zone (LMZ), resulting in a more than doubling of estimated female lynx home range size and a commensurate decline in the LMZ's potential lynx carrying capacity (Lewis 2016, pp. 4, 6; Maletzke *in* Lynx SSA 2016, p. 21). Although these areas should regenerate into lynx and hare habitat, it may take 35-40 years (Maletzke *in* Lynx SSA 2016, p. 21), during which time additional fire impacts could further diminish habitat availability and the likelihood that the lynx population will persist (Lynx SSA Team 2016a, p. 44; see also sections 3.4, 4.2.4, and 5.2.4).

In summary, although uncertainty remains regarding the historical distribution of resident lynx in the DPS and small breeding populations may have been lost from some places, neither broad-scale breeding range contraction nor substantial population declines in the contiguous United States from historical conditions until the DPS was listed have been documented based on verified occurrence data (68 FR 40099; 72 FR 1187; 79 FR 54798, 54815; McKelvey *in* Lynx SSA Team 2016a, p. 11). New information summarized above indicates that there are currently many more lynx in Maine and Colorado than likely occurred historically, and many more in those places and in Minnesota than was suspected when the DPS was listed. Likewise, resident lynx and some reproduction have also been documented recently in northern New Hampshire, where lynx were previously thought to have been extirpated, and in northern Vermont, which previously lacked evidence of historical lynx residency. Neither of these areas was occupied by lynx when the DPS was listed, and the expanding population in northern Maine was likely the source of lynx recolonizing northern New Hampshire and colonizing northern Vermont. Conversely, there are naturally fewer lynx and a more limited distribution of suitable habitats in most of the western United States than was previously thought (68 FR 40085, 40091-40092; ILBT 2013, p. 23), and lynx numbers in Washington have likely declined (perhaps temporarily) in response to extensive wildfire impacts to habitats over the past several decades. The geographic units evaluated in this SSA include all areas in the contiguous United States with strong historical or recent evidence of resident lynx populations. Detailed assessments of the current status and future viability of resident lynx populations and habitats in these areas are presented in chapters 4 and 5 below.

Chapter 3: Factors Influencing Viability of the DPS

In this chapter we discuss factors thought to influence the historical and current distribution and status of lynx populations in the contiguous United States, how these factors would likely

influence the future viability of the DPS, and we describe the cause-and-effects pathways of impacts associated with particular factors. We focus on the factor for which the DPS was listed under the ESA (the inadequacy of regulatory mechanisms in Federal land management plans when the DPS was listed) and on the anthropogenic influences identified by the ILBT in the revised LCAS as having the potential to exert population-level impacts on lynx and lynx habitats (ILBT 2013, pp. 68-78). Those anthropogenic influences - climate change, vegetation management, wildland fire management, and habitat loss and fragmentation - are considered the most influential factors in the future viability of the lynx DPS.

3.1 Regulatory Mechanisms

A number of activities with the potential to affect lynx habitat suitability, productivity, mortality, and movements via habitat loss or fragmentation, creation of barriers, or that otherwise alter the vegetation mosaics and prey abundances maintained historically by natural disturbance processes may occur in lynx habitats regardless of land ownership and management. The extent to which regulations guide such activities to avoid, reduce, or mitigate impacts to lynx influences the current and future likelihoods that those habitats will provide the ecological requirements to support resident lynx populations. As described in more detail below, the lynx DPS was listed as threatened because of the lack of specific conservation direction and associated regulations on some Federal lands. At that time, the available information indicated that most lynx habitat in the DPS occurred on Federal lands, predominantly in the western United States (65 FR 16061). Since then, research and monitoring have revealed that non-Federal lands contribute more to the conservation of the DPS than was known at the time of listing, particularly in the Northern Maine and Northeastern Minnesota geographic areas. Therefore, in the following sections we describe and compare the Federal regulatory environment for lynx in the DPS at the time of listing and currently, and we describe other regulatory mechanisms as they pertain to lynx on private as well as State and Tribal lands.

3.1.1 Federal Regulatory Mechanisms

Since it was listed in 2000, the DPS has been protected by the ESA's prohibition on take (under section 9), which applies to lynx wherever they occur in the DPS, regardless of land ownership. The DPS has also been protected since listing by section 7 of the ESA, which requires Federal agencies to use their authorities to conserve listed species and to consult with the Service for any actions they implement, fund, or permit (i.e., for which a "Federal nexus" exists) and which may affect lynx or lynx habitats within the DPS, again regardless of land ownership. Additionally, section 4 of the ESA requires that critical habitat, defined as the specific geographic areas containing the physical and biological features essential for the conservation of a listed species and that may require special management and protection, be designated for listed species, and section 7 prohibits the destruction or adverse modification of such designated habitats. Critical habitat was designated for the lynx DPS in 2007 and was revised in 2009 and 2014; in accordance with a September, 2016 court order (U.S. District Court MT 2016, entire), it may be revised again in the future. Section 4 of the ESA requires recovery planning for listed species; a

recovery plan for the lynx DPS has not yet been completed, but part of the purpose of this SSA is to inform near-term recovery planning direction.

Federal lands make up approximately 64 percent of the lands encompassed by the 6 geographic units evaluated in this SSA. Of those Federal lands, roughly 87 percent is managed by the U.S. Forest Service (USFS), 11 percent by the National Park Service (NPS), and 2 percent by the Bureau of Land Management (BLM). The amount of Federal land varies by unit, ranging from 1 percent in the Northern Maine Unit to over 97 percent in the GYA Unit (see table 2 and Chapter 4 for ownership in each geographic unit). Federal lands management is guided by a number of statutes and associated regulations, policies, standards, guidelines, and best management practices (BMPs) applied by managing agencies to meet legislative mandates and achieve agency missions (for a summary of relevant Acts and associated regulations and guidance, see USFWS 2014, pp. 24-34). Many of these regulatory mechanisms provide some benefits to lynx and protect lynx habitats. For example, the conservation priority in the management of NPS lands in accordance with the National Park Service Organic Act (16 USC 1 *et seq*. as amended), the National Parks and Recreation Act (Public Law 95-625), and the Wilderness Act (16 USC 1131-1136, 78 Stat. 890) likely provides an adequate regulatory framework for the conservation of lynx populations and habitats in the NPS units in which they occur (USFWS 2014, pp. 28-29, 31-33). However, it was the absence of specific management direction and conservation measures for lynx and lynx habitats in USFS and BLM land management plans that led the Service to conclude that the regulatory mechanisms in those plans at the time of listing were inadequate to ensure the conservation of the DPS. Therefore, the evaluation below focuses on the efforts of USFS and BLM, in collaboration with the Service, to address the regulatory inadequacy for which the DPS was listed.

The Service designated lynx in the contiguous United States as a DPS and listed it as threatened under the ESA in 2000 because of the inadequacy, at that time, of existing regulatory mechanisms. Specifically, at that time the Service believed that most lynx populations and potential lynx habitats (broad forest vegetation classes defined as “lynx forest types” [65 FR 16071]) in the contiguous United States occurred on Federal (USFS, NPS, and BLM) lands in the western states, and that the plans that guided management of those lands (particularly USFS and BLM lands) included “...programs, practices, and activities within the authority and jurisdiction of Federal land management agencies that may threaten lynx or lynx habitat. The lack of protection for lynx in these Plans render them inadequate to protect the species” (65 FR 16052, 16082). At that time, the Service found that USFS and BLM management plans did not adequately address risks to lynx and, as identified in the LCAS (Ruediger *et al.* 2000, pp. 2-1 through 6-3), those plans allowed actions that cumulatively could result in significant detrimental effects to lynx in the contiguous United States. As a result, the Service concluded in the final rule that the lack of Federal land management plan guidance for the conservation of lynx and the potential for those plans to allow or direct actions that could adversely affect lynx constituted a significant threat to the DPS (68 FR 40096).

In 1998, in anticipation of the DPS’s listing under the ESA, regional and state directors of the Service, USFS, BLM, and NPS approved preparation of the interagency LCAS to provide a

consistent and effective approach to conserve lynx and to assist with section 7 consultation on Federal lands. An interagency Steering Committee selected a Science Team to assemble the best available scientific information on lynx and appointed the ILBT to prepare a lynx conservation strategy applicable to Federal land management in the contiguous United States (USFWS 2014, p. 15). The first edition of the LCAS was completed in January, 2000 and revised in August, 2000 (Ruediger *et al.* 2000, entire). The Steering Committee subsequently issued several amendments and clarifications, and the most recent revision of the LCAS was completed in August, 2013 (ILBT 2013, entire). The LCAS initially identified and evaluated 17 risk factors (e.g., timber and fire management, recreation, roads, livestock grazing, trapping, etc.) thought to have the potential to affect lynx habitat suitability, productivity, mortality, and movements and that may be addressed under programs, practices, and activities within the authority and jurisdiction of Federal land management agencies. These risk factors included programs or practices with the potential to result in habitat conversion, habitat fragmentation, or obstruction to lynx movement; roads or winter recreation trails that may facilitate access to historical lynx habitat by competitors; and fire suppression, which changes the vegetation mosaic maintained by natural disturbance processes. The risks identified in the 2000 LCAS were based on potential effects to lynx habitats and to individual lynx, lynx populations, or both; therefore, not all of the risks initially identified in the LCAS were thought to threaten lynx populations in the DPS (68 FR 40096). In the 2013 revised LCAS, risk factors were redefined as "Anthropogenic Influences on Lynx and Lynx Habitat," and grouped into 2 tiers based on the potential magnitude of effects (ILBT 2013, pp. 1, 68). First tier influences (climate change, vegetation management, wildland fire management, and habitat fragmentation - discussed in the remainder of this chapter) are those with potential to negatively affect lynx populations and habitats, while second tier influences are those that may affect individual lynx but are not expected to substantially impact populations or habitats (ILBT 2013, pp. 68-85).

In addition to identifying risks, the LCAS also directed Federal agencies to map potential lynx habitat and identify lynx analysis units (LAUs) to evaluate potential impacts of management actions on lynx and snowshoe hare habitats. Finally, the LCAS developed recommended conservation measures, standards, and guidelines to be applied to lynx habitats on Federal lands that were designed to mimic historical conditions and landscape-scale disturbance patterns and to maintain or improve lynx and hare habitats at both local (project-level) and landscape scales (USFWS 2014, p. 16). After its initial completion in 2000, USFS and BLM managers within the range of the DPS agreed to implement the standards and guidelines identified in the LCAS until management plans could be formally amended to specifically address lynx conservation. In 2000, the Service, USFS, and BLM developed and adopted Canada Lynx Conservation Agreements (CAs; BLM and USFWS 2000, entire; USFS and USFWS 2000, entire) in which the BLM and USFS agreed to coordinate assessment and planning efforts with the Service to assure a comprehensive approach to lynx conservation and to use the LCAS, supporting science, and locally specific information as the basis for the approach and to streamline consultation under section 7 of the ESA. The USFS further committed to deferring any actions not involving third parties that would adversely affect lynx until such time as the Forest Plans were amended or revised to adequately conserve lynx (USFS and USFWS 2000, p. 8; 68 FR 40083).

Concurrent with development of the LCAS and interagency CAs, the USFS and BLM in 1999 completed the *Biological Assessment* (BA) *of the Effects of National Forest Land and Resource Management Plans and Bureau of Land Management Land Use Plans on Canada Lynx* (USFS and BLM 1999, entire). The BA identified and evaluated the potential effects on lynx of implementation of 57 USFS Land and Resource Management Plans and 56 BLM Land Use Plans throughout the 14 states in which the lynx DPS was proposed for listing. The BA concluded that the potential for adverse effects to lynx existed on each administrative unit in each geographic area and that, cumulatively, implementation of the existing plans was likely to adversely affect the DPS. It recommended that all of the plans be amended or revised to incorporate conservation measures to reduce or eliminate adverse effects to lynx (USFS and BLM 1999, p. 14). In its 2000 biological opinion on the BA, the Service evaluated the USFS and BLM plans in conjunction with the CAs described above (USFWS 2000, p. 15). The Service concluded that implementation of the existing plans in accordance with the CAs until plans could be formally amended or revised was not likely to jeopardize the DPS, but that amendments or revisions to those plans were needed to further reduce or avoid the potential for adverse effects to lynx (USFWS 2000, pp. 48-50).

In the 2003 remanded rule, the Service similarly determined that adherence to the CAs, the biological opinion, and the LCAS in assessing the impacts of Federal actions on lynx alleviated the potentially-adverse effects of Federal land management activities on lynx, but that amendment of USFS and BLM land management plans to conserve lynx would be the strongest mechanism to ensure long-term conservation of lynx and lynx habitat on Federal lands (68 FR 40096-97). It concluded that although Federal, State, and Tribal regulations and plans had reduced threats to the DPS, the inadequacy of existing regulatory mechanisms still posed a moderate, albeit lower-level threat, and would continue to do so until Federal land management plans were specifically amended to address lynx conservation (68 FR 40097).

Since the 2003 remand, most Forest Service units with lynx forest types (actual and “potential” lynx habitats) have formally amended or revised their land management plans to incorporate the conservation measures, standards, and guidelines identified in the LCAS. Because these amended and revised plans apply to secondary areas and other potential lynx habitats (i.e., all mapped habitat in all LAUs), the USFS had applied the conservation measures to many areas outside the geographic units evaluated in this SSA, including many areas that lack evidence of lynx occupancy and some with no verified lynx records. From 2004-2006, forest plans for 7 national forests with potential lynx habitat in Maine, New Hampshire, Vermont, Michigan, Minnesota, and Wisconsin were revised to include recommendations from the LCAS and the CAs (Jackson 2015, p. 6; USFWS 2014, p. 33). In 2007, the USFS completed the Northern Rockies Lynx Management Direction (NRLMD), which formally amended management plans to include lynx conservation measures, standards, and guidelines for 18 national forests covering over 150,000 km^2 (57,915 mi^2) in Idaho, Montana, Wyoming and Utah, including over 72,000 km^2 (27,800 mi^2) of potential lynx habitat (USFS 2007, entire; USFWS 2014, pp. 16-19; 79 FR 54813; Jackson 2015 *in* Lynx SSA Team 2016b, Appendix 3, p. 11). In 2008, the USFS similarly completed the Southern Rockies Lynx Amendment (SRLA), which formally amended forest

plans covering about 59,000 km^2 (22,780 mi^2), including over 30,000 km^2 (11,583 mi^2) of mapped (potential) lynx habitat on 7 national forests or national forest complexes in western Colorado and southern Wyoming (USFS 2008a, entire; Jackson 2015 *in* Lynx SSA Team 2016b, Appendix 3, p. 11). The management direction adopted in the NRLMD and SRLA was developed in accordance with the National Forest Management Act of 1976 (16 USC 1600) and the regulations that implement the statute (36 CFR 219.22), which requires public review and comment as part of the decision making process. Among national forests within the geographic units evaluated in this SSA, only those in Washington (the Okanogan-Wenatchee and Colville national forests) have not formally amended or revised their land and resource management plans. However, the plan revision process has been initiated for both forests, and both continue to manage for lynx habitats in accordance with the LCAS and the CA. Overall, the USFS manages nearly 56 percent (72,927 km^2 [28,157 mi^2]) of the lands within the 6 geographic units evaluated in this SSA (see table 2, above), and all USFS lands are managed to support lynx conservation in accordance with formally revised or amended Forest Plans or binding conservation agreements with the Service.

The BLM manages a much smaller proportion of the lands within the SSA geographic units, nearly all of which occur in Colorado, Montana, and Wyoming. In Western Colorado (Unit 6), 10 BLM Field Offices (FOs; Colorado River Valley, Grand Junction, Gunnison, Kremmling, Little Snake, Royal Gorge, San Luis Valley, Tres Rios, Uncompahgre, and White River) contain 784 km^2 (303 mi^2) of potential lynx habitat. These BLM areas were subject to the 2000 interagency CA; however, that CA expired in 2004 (BLM and USFWS 2000, p. 8) and was not renewed. Since then, BLM Resource Management Plans (RMPs) have been revised for 5 of the 10 FOs (Colorado River Valley, Grand Junction, Kremmling, Little Snake, and Tres Rios). RMPs for the Gunnison, Royal Gorge, San Luis Valley, Uncompahgre, and White River FOs have not been revised and do not contain specific measures for the conservation of lynx; however, these areas constitute a very small proportion of lynx habitat this unit. In western Montana (Unit 3), BLM lands in the Garnet Resource Area include 405 km^2 (156 mi^2) of designated lynx critical habitat. In western Wyoming (Unit 5), 261 km^2 (101 mi^2) of BLM lands on the Kemmerer and Pinedale districts are also designated as lynx critical habitat. The RMP for the Garnet area was amended in 2004 to formally adopt the conservation measures of the LCAS (BLM 2004a, 2004b, entire), and the RMPs for the Pinedale and Kemmerer districts were revised in 2008 and 2010, respectively, to adopt conservation measures and BMPs for lynx (BLM 2008, pp. A18-10 - A18-16; BLM 2010, pp. A-9 - A-12). Overall, the BLM manages just over 1 percent (1,443 km^2 [557 mi^2]) of the lands within the 6 geographic units evaluated in this SSA (see table 2, above), most of which is actively managed to support lynx conservation.

The completion and implementation of the LCAS and its subsequent revisions, the interagency CAs, and the subsequent formal management plan revisions and amendments adopted under the NRLMD and SRLA all were undertaken to address the inadequacy of regulatory mechanisms on USFS and BLM lands for which the DPS was listed. Each incorporated the best available scientific information to develop goals, objectives, conservation measures, standards, and BMPs to guide USFS and BLM management activities at both project- and landscape-level scales to reduce or eliminate the potential for adverse effects to lynx or lynx habitats and thus

promote the conservation of the DPS (Ruediger *et al.* 2000, pp. 7-1 - 7-18; BLM and USFWS 2000, entire; USFS and USFWS 2000, entire; USFS 2007, pp. 8-30, USFS 2008a, pp. 6-19, Attachment 1-1 - 1-9). Standards and guidelines developed and implemented in accordance with the NRLMD and the SRLA were designed to promote beneficial effects and limit potentially adverse effects of management activities (vegetation management [e.g., timber harvest, precommercial thinning], wildland fire and fuels management, grazing, recreation, road/access management, energy development, etc.) on important lynx habitats including winter snowshoe hare habitat (high-quality lynx foraging habitat), denning habitat, and linkage/connectivity corridors (USFS 2007, pp. 8-30, USFS 2008a, pp. 6-19, Attachment 1-1 - 1-9). The USFS concluded that the vegetation standards adopted in the NRLMD that limit the total amount and the rate at which lynx habitat can be converted to temporarily unsuitable habitat (stand-initiation seral stage following timber harvest) ensure that the agency's timber management program is beneficial to lynx and will provide sufficient lynx habitat through time at both LAU and landscape-level scales (USFS 2007, p. 35). In its biological opinion on the NRLMD, the Service concluded that its application "...would substantially reduce or eliminate adverse effects to lynx from Forest Service land management activities on at least 94 percent of this area (National Forest System lands in the Northern Rockies), and more likely nearer to 98 percent" (USFWS 2007, p. 76). Similarly, in its 2008 biological opinion on the SRLA, the Service concluded that vegetation management standards in the SRLA would prohibit treatments that could adversely affect essential components of lynx habitat on 95.5 percent of the mapped (potential) lynx habitat in the SRLA area (National Forest System lands in the Southern Rockies; USFWS 2008b, p. 52).

In summary, all USFS and most BLM lands with known or potential lynx habitat within the range of the DPS, including all SSA geographic units that encompass USFS and BLM lands, are currently managed in accordance with the specific conservation measures and considerations identified in the LCAS and implemented via the CAs or formally revised and amended management plans described above. These agreements and revised/amended plans constitute the regulatory framework and specific regulatory mechanisms adopted to conserve lynx habitats and populations on USFS and BLM lands that support or are potentially capable of supporting them. They represent the agencies' efforts, in collaboration with the Service, to address and ameliorate the singular threat for which the lynx DPS was listed under the ESA. Although formal effectiveness monitoring has not been completed, it is clear that implementation of the CAs and revised/amended plans, and the associated programmatic and project-specific consultations between BLM/USFS and the Service in accordance with section 7 of the ESA, have resulted in avoidance/minimization of impacts to important lynx and hare habitats on Federal lands and have reduced the likelihood that management activities on these lands may adversely affect lynx in the contiguous United States. Overall, Federal lands managed by the USFS, BLM, and NPS constitute nearly 64 percent 83,683 km^2 [32,310 mi^2]) of the area evaluated in this SSA, and all but a tiny fraction of these lands are actively managed for lynx conservation.

3.1.2 State Regulations and Tribal Management

Private, State, and Tribal lands make up the remaining 36 percent of the lands encompassed by the 6 geographic units evaluated in this SSA, accounting for almost 27 percent, almost 9 percent, and 1 percent of the total, respectively (table 2). The amount of private land varies by unit, ranging from 0.3 percent in the North-central Washington Unit to over 90 percent in the Northern Maine Unit. Likewise, State ownership varies from less than 1 percent in the GYA and Western Colorado units to 36 percent in the Northeastern Minnesota Unit. Tribal lands account for about 4 percent of the Northwestern Montana/Northeastern Idaho Unit and roughly 1 percent of the Northern Maine and Northeastern Minnesota units; there are no Tribal lands in the North-central Washington, GYA, or Western Colorado units. Private, State, and Tribal lands, combined, constitute 99 percent of the lands in the Northern Maine Geographic Unit and over half of those in the Northeastern Minnesota Unit. Because both of these units support larger resident lynx populations than was suspected when the DPS was listed and, therefore, may contribute more substantially to the conservation of the DPS than was understood at the time of listing, we must evaluate the regulatory mechanisms that pertain to lynx on these lands (Lynx SSA Team 2016a, p. 54). Although private, State, and Tribal lands constitute much smaller proportions of the other 4 (western) geographic units (from about 3 percent to 16 percent, combined), important lynx habitats occur on some of those lands, and regulatory mechanisms may influence their contributions to the conservation and persistence of DPS populations or parts of them. Therefore, in this section, we summarize the relevant regulatory frameworks and mechanisms that may affect lynx on private, State, and Tribal lands within the 6 geographic units of the DPS, but with a focus on those units with the greatest proportions of these lands and on activities on these lands with the greatest potential to impact lynx.

State Wildlife Management Regulations - The following information is derived largely from the Service's 2014 Incremental Effects Memorandum prepared in support of the revised designation of critical habitat for the lynx DPS (USFWS 2014, pp. 35-38) and updated as warranted by new information. State furbearer and other wildlife management regulations benefit lynx populations in the states where they occur. In addition to State and private lands, State wildlife regulations govern hunting and trapping activities on many Federal lands where those activities are permitted. Most states within the range of the lynx prohibited trapping and hunting of lynx prior to the Service's1998 proposal to list the DPS under the ESA, and those activities were prohibited in all states by the time the DPS was listed in 2000. All states within the lynx DPS range that allow legal bobcat harvest (1) manage in accordance with the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) Export Program for Appendix II Furbearer Species (USFWS 2014, pp. 25-26), (2) have distributed information to bobcat trappers and hunters on how to avoid incidental take of lynx, and (3) report all known incidental take of lynx associated with bobcat harvest to the Service's Division of Management Authority to assure that take does not exceed the amount permitted under the intra-agency section 7 consultation for the CITES Export Program (USFWS 2001, entire). Most states have also adopted special regulations in areas where lynx occur to minimize the potential for incidental take (including injury) of lynx during legal trapping of other furbearers. These efforts benefit lynx and are expected to do so in the future with continued implementation and

enforcement. Most reported incidentally-trapped lynx are released unharmed (see below), and there is no evidence that incidental trapping has had population-level impacts on lynx in the DPS range.

Unit 1: Northern Maine - In 1967, a bounty on lynx in Maine was repealed, and lynx were given complete protection from trapping and hunting. In Wildlife Management Districts where lynx may occur, the Maine Department of Inland Fisheries and Wildlife (MDIFW) has adopted special trapping regulations intended to minimize the incidental capture, injury, and death of lynx. These restrictions have varied over the past two decades, becoming mored restrictive with time following a consent decree in 2008. Some of the requirements developed over time include specification of trap sizes and sets that may be used to legally harvest other furbearers and that are intended to minimize the likelihood of incidentally trapping lynx[5] (MDIFW 2016a, pp. 8, 13). MDIFW has also prohibited the use of visual baits and visual attractants and reqires mandatory reporting of incidental lynx captures. MDIFW also adopted and made available for download on its web page the interagency brochure *How to Avoid Incidental Take of Lynx while Trapping or Hunting Bobcats and other Furbearers*, modified it to be more specific to Maine, and updated it in 2015 (MDIFW 2015b, entire). MDIFW also set-up an incidental lynx capture hotline and has staff on stand-by to help immobilize, evaluate, collect tissue and/or hair samples, and release, if appropriate, any lynx reported to the hotline. From 2000 to 2016, this program has resulted in the release of 106 lynx that were reported incidentally trapped in northern Maine; during this time, 12 lynx died from traps or being illegally shot while in traps (MDIFW 2014, p. 75; MDIFW 2016b, pp. 5-10).

After preparing a habitat conservation plan (Incidental Take Plan), the MDIFW in 2014 obtained an incidental take permit from the Service for lynx trapped incidental to predator management and animal damage control activities, and the recreational furbearer trapping program in Maine. The permit allows incidental trapping of 195 lynx over a 15-year period, including 3 mortalities. After 2 lynx were killed in leaning-pole trap sets in 2014, MDIFW imposed additional trapping restrictions to further reduce mortality and injury of incidentally-trapped lynx, as required by the permit (also see Other Factors in section 4.2.1 below). In addition to prohibiting the type of leaning-pole sets that resulted in the 2 mortalities, the regulations now require exclusion devices on most killer-type traps and multiple swivels on chains, and they prohibit the use of drag sets on foothold traps.

The MDIFW also is responsible for implementing the Maine Endangered Species Act[6] (MDIFW 2009, p. 9). Although the lynx is not State-listed as threatened or endangered because its population is believed to exceed the State's listing threshold, it is considered a species of special concern (MDIFW 2011, p 2). The MDIFW works collaboratively with the Service to conduct research and monitor lynx populations and habitats, and it recommends voluntary forest management activities to promote a sustainable supply of large, connected, and widely-distributed blocks of dense, young spruce-fir stands and to conserve large blocks of unfragmented forestland in northern and western Maine (MDIFW 2011, p. 3).

[5] http://www.maine.gov/ifw/hunting_trapping/trapping/avoid_lynx.htm, last accessed 8.08.2016.
[6] http://www.mainelegislature.org/legis/statutes/12/title12sec12803.html.

Unit 2: Northeastern Minnesota - Although lynx were unprotected and had a bounty placed on them in Minnesota prior to 1965, lynx trapping and hunting have been prohibited in Minnesota since 1984 (65 FR 16077; Moen *in* Lynx SSA Team 2016a, p. 19). Overlapping the Northeastern Minnesota SSA unit, the Minnesota Department of Natural Resources (MNDNR) has identified a specific "Lynx Management Zone" (LMZ) for which it has promulgated and enforces special trapping regulations for other furbearers in lynx habitat (MNDNR 2016a, p. 53). The MNDNR has modified trapping regulations within the LMZ to minimize the incidental take of lynx during the legal trapping of other furbearers. The regulations address specific trap types and sets, prohibit the use of certain baits and visual attractants, and require reporting of any incidentally trapped lynx to DNR conservation officers within 24 hours (MNDNR 2016a, pp. 53-55). The MNDNR also distributed to trappers the interagency brochure *How to Avoid Incidental Take of Lynx while Trapping or Hunting Bobcats and other Furbearers*. In response to a Federal court order, MDNR developed an incidental take plan designed to minimize the potential for lynx to be incidentally trapped during other legal furbearer trapping; the plan is currently under review by the Service. Like Maine, Minnesota has a State Endangered Species Statute (84.0895) which requires the MNDNR to adopt rules designating species meeting the statutory definitions of endangered, threatened, or species of special concern (State of Minnesota 2016, entire). The Statute also authorizes the MNDNR to adopt rules that regulate treatment of species designated as endangered and threatened. Also like Maine, however, Minnesota has not designated lynx as threatened or endangered under the statute. Instead it has designated the lynx a species of special concern, a designation for species that are extremely uncommon, have unique or highly specific habitat requirements, or occur on the periphery of their range in Minnesota and, therefore, deserve careful monitoring (MNDNR 2013, pp. 1-2). Thus, the MNDNR coordinates with the Service and other agencies to conduct research and monitor lynx populations and habitats.

Unit 3: Northwestern Montana/Northeastern Idaho - Lynx are designated as a species of greatest conservation need (S3; "potentially at risk") by the State of Montana (MTFWP 2015, pp. 12, 435) and were previously considered a species of greatest conservation need (S1) by the State of Idaho (ILBT 2013, p. 57). However, in its recently revised State Wildlife Action Plan, Idaho did not retain that designation for lynx because of the lack of evidence of a persistent lynx presence in the state (IDFG 2017a, p. 4). The harvest of lynx was prohibited in Idaho and Montana beginning in 1996 and 1999, respectively. Both States participate in the CITES Export Program for bobcats, and both have promulgated and enforce special regulations for the legal trapping of other furbearers in areas occupied by lynx. In its trapping regulations, Idaho Fish and Game (IDFG) provides information on how to distinguish between bobcats and lynx and provides guidelines to reduce injury and minimize non-target catches, including lynx (IDFG 2017b, pp. 36-37). Guidelines recommend (1) a minimum 8-pound pan tension on foothold traps set for wolves, (2) specific trap types and sets for other furbearers, and (3) bait and habitat considerations when making sets. Trappers are also required to contact IDFG or local sheriff's offices to assist with the safe release of incidentally trapped lynx. Three of 4 lynx incidentally trapped in Idaho recently were released unharmed; the other was illegally shot (IDFG 2017a, p. 3). To minimize and track the incidental capture of lynx, Montana Fish, Wildlife, and Parks

(MTFWP) has promulgated an evolving set of trapping regulations and reporting requirements since the DPS was listed (MTFWP 2016, pp. 7-10), including significant changes in 2008 that reduced the reported rate of incidental lynx captures from 1.6 per year in 2000-2007 to 0.4/year in 2008-2015 (MTFWP 2016, p. 5). In 2015, the Federal District Court of Montana approved a settlement agreement reached between the State of Montana and conservation groups aimed at protecting lynx from trapping. The case is now dismissed in accordance with the agreement, under which Montana has implemented a set of restrictions on trapping in lynx habitat. Currently, these regulations identify designated lynx protection zones (LPZs) and define acceptable trapping methods for public lands within them, which (1) prohibit the use of lethal (non-relaxing) snares for bobcats, (2) specifies the types of sets and baits or attractants that may be used for marten, fisher, and other furbearers where lynx occur, (3) requires a minimum 10-pound pan tension on foothold traps set for wolves, and (4) requires that any incidentally trapped lynx must be released unharmed if possible and reported to MTFWP (MTFWP 2016, pp. 7-10).

Unit 4: North-central Washington - Lynx harvest has been prohibited in Washington since 1991, and the lynx was listed as a State threatened species in 1993 and uplisted to endangered in 2016 (Lewis 2016, pp. *iii*, 1; WAFWC 2016, p. 3). Under the State's Endangered Species Program, the Washington Department of Fish and Wildlife (WADFW) developed a Lynx Recovery Plan[7] and a Status Report[8], and it prepares annual reports to update population and habitat information for the species. The WADFW also coordinates with the Service and other agencies to conduct research and monitor lynx populations and habitats. Additionally, the use of body-gripping traps (foothold, conibear, snares, etc.) for trapping other furbearers is prohibited in Washington (except for damage control or nuisance wildlife, which requires special permits). This avoids the potential for lynx to be incidentally captured in traps set legally for other animals.

Unit 5: GYA (Southwestern Montana and Northwestern Wyoming) - See Unit 3, above, for summary of Montana's special trapping regulations to minimize incidental take of lynx, which apply to the northern part of this unit. Lynx in Wyoming are classified as nongame wildlife, a Species of Greatest Conservation Need, and a Protected Animal by Wyoming State Statute. A classification of "State Protected" status prohibits trapping or any intentional take in the state, and lynx in Wyoming were offered full protection from trapping and hunting beginning in 1973 (ILBT 2013, p. 57). The Wyoming Game and Fish Department (WGFD) also participates in the CITES Export Program for bobcats.

Unit 6: Western Colorado - Lynx harvest has been prohibited in Colorado since 1970 and the lynx was listed as endangered in the State in 1973. Colorado participates in the CITES Export Program for bobcats, provides information to trappers and hunters on how to distinguish between lynx and bobcats, and requires immediate release of uninjured incidentally trapped lynx as well as reporting of any (uninjured, injured, or killed) incidentally trapped lynx (CPW 2015, pp. 6-7). Colorado law prohibits the use of foothold or conibear traps and snares for

[7] http://wdfw.wa.gov/publications/00394/.
[8] http://wdfw.wa.gov/publications/01521/.

trapping, which avoids the potential for lynx to be incidentally captured in traps set legally for other animals.

State Forest Management Regulations - Timber harvest and other forest management activities on State and private lands are governed by State regulations. Because these activities have the potential for beneficial, benign, or adverse impacts to lynx habitat depending on methods, implementation, and conservation measures, State forestry regulations may influence lynx populations, particularly where substantial amounts of lynx habitat occur on State and private lands. Below, we provide an overview of the forest management regulations in the SSA geographic units and briefly discuss their potential influences on lynx habitat. Additional details on the current and likely future influences of these regulations on lynx populations are provided below in chapters 4 and 5, particularly for the Maine and Minnesota units, where State and private lands constitute the majority of lynx habitats.

Unit 1: Northern Maine - State and private lands constitute 7 percent and 90 percent, respectively, of this SSA unit, with the vast majority of private lands managed for commercial timber production. As described above in section 2.3.2.2 and in more detail below in sections 4.2.1 and 5.2.1, the current abundance of lynx in northern Maine is attributable to the landscape-scale clear-cutting that occurred on private timber lands in the 1970s and 1980s in response to an extensive spruce budworm outbreak, which resulted in the recent unnaturally large amount of young (15 to 35 years post-harvest) regenerating forest in prime hare (lynx foraging) habitat condition. The amount and distribution of this post-clear-cut high-quality hare habitat likely peaked in the late 1990s to early 2000s, when 20-25 percent of the forest in Maine was in an early regeneration stage. The amount of young, regenerating forest at that time was 3 to 8 times higher than typical historical conditions under the natural disturbance regime, when only 3 to 7 percent of stands were likely in such condition at any given time (68 FR 40094). Current timber harvest and management on State and private lands in Maine are governed by the Maine Forest Practices Act of 1989 and administered by the Maine Forest Service within the Department of Agriculture, Conservation & Forestry to regulate, among other things, the size, arrangement, regeneration, and management of clearcuts (MEDACF 2014, pp. 42-45). Under the Act, small (up to 101 ha [250 ac]) clear-cuts are still permitted but require special permits and review and have, therefore, been replaced by various forms of partial harvest techniques; many of which are unlikely to maintain the current unnaturally high amount and distribution of high-quality hare and lynx habitat. The consequences of this large-scale shift in forest management on Maine's current lynx population, which is likely much larger than was possible under the natural historical disturbance regime, and on future conditions for lynx in this unit are discussed below in sections 4.2.1 and 5.2.1, respectively, along with other programs and factors that may influence private lands forest management in this unit.

In Maine, most private lands lack long-term management agreements to assure lynx conservation. However, in 2006 and 2007, the Natural Resource Conservation Service (NRCS) provided funds to Maine for a pilot Healthy Forest Reserve Program (HFRP) specifically to manage for Canada lynx and American marten. Under this program, 4 landowners have developed and implemented lynx management plans covering about 652 km^2 (252 mi^2; 2.3

percent of Unit 1). All 4 landowners completed lynx plans using guidelines in the Service's *Canada lynx management guidelines for Maine* (McCollough 2007, entire). NRCS contracts with the landowners last for 10 years and these contracts expired in 2016 and 2017. The HFRP described an opportunity for enrollees to apply for Safe Harbor Agreements when their contracts expired, although none have yet indicated an interest in doing so. Management plans were written for a 70-year period; therefore, some landowners may continue voluntary lynx management activities. Many private landowners in Maine are enrolled in forest certification programs; the Sustainable Forestry Initiative (SFI) and Forest Stewardship Council (FSC). Both programs require landowners to protect endangered species and their habitats. Maine has more than 40,500 km^2 (15,625 mi^2) of certified forestland; more than any other state[9]. It is uncertain how certified landowners address lynx management. About 10,117 km^2 (3,906 mi^2; 35 percent of Unit 1) of private lands in northern Maine are under "working woodland" conservation easements[10]; although these covenants do not require specific management practices or outcomes beyond sustainable forestry, they do ensure that conversions to other land uses will never occur (MDIFW 2017, p. 2). In the past Maine private forest landowners have expressed interest in long-term commitments to lynx management plans, but to our knowledge, there are no private landowners in Maine who have committed to long-term or permanent protection and creation of lynx habitat according to the Service's lynx management guidelines or the LCAS.

State lands include Baxter State Park (809 km^2 [312 mi^2; about 3 percent of Unit 1]) and the various lots owned and managed by the Maine Bureau of Parks and Lands (MBPL). Most of Baxter State Park is managed as wilderness area, and lynx sightings in the Park are rare, probably because most of the park is mature forest that does not support high hare densities. MBPL integrated resource policy requires that it promote the conservation of Federally-listed species. To our knowledge, with one exception, MBPL has not developed any lynx-specific management plans. However, the mitigation for the MDIFW's incidental take permit for trapping requires the maintenance, enhancement and creation of lynx habitat on about 28 percent of the MBPL's 89-km^2 (34-mi^2) Seboomook habitat management unit during a 15-year period, with those habitats likely available to lynx beyond that time.

Unit 2: Northeastern Minnesota - State and private lands constitute about 36 percent and 16 percent, respectively, of this SSA unit. The MNDNR Division of Forestry regulates timber harvest and management on State and private lands. Under the Sustainable Forest Resources Act of 1995 (revised most recently in 2014 [MNFRC 2014, p. 1]), the Minnesota Forest Resources Council (MNFRC) has developed voluntary guidelines for site-level timber harvesting and forest management (MNFRC 2012, p. 1) that are intended for private and State landowners and include some general recommendations for wildlife including lynx. However, because they are voluntary, the extent to which these guidelines benefit lynx is uncertain (see sections 4.2.2 and 5.2.2 below).

[10] http://web.colby.edu/stateofmaine2012/state-of-large-landscape-conservation-in-maine/, accessed 8.18.2016.

Unit 3: Northwestern Montana/Northeastern Idaho - State and private lands constitute about 4 percent and 8 percent, respectively, of this SSA unit and almost all are in the Montana portion of the unit. The Montana Department of Natural Resources and Conservation (MTDNRC) administers several laws pertaining to forest practices on State and private lands. These laws are intended to protect streamside management zones, reduce fire hazards, and provide BMPs to minimize non-point source water pollution[11]. Although these laws may provide indirect benefits to lynx and other wildlife, they do not include specific measures to conserve or avoid impacts to lynx habitats. However, the MTDNRC and the Service collaborated on a multi-species habitat conservation plan (HCP) for forested State Trust lands that includes a Lynx Conservation Strategy to minimize impacts of forest management activities on lynx and describes conservation commitments that are based on recent information from lynx research in Montana (USFWS 2104, pp. 22-23; 79 FR 54835-54837). This HCP covers about 64 percent of the State lands in this SSA unit, regulates activities primarily associated with commercial forest management to conserve lynx foraging, denning, and connectivity habitats, and includes a 50-year commitment (79 FR 54835-54836). Additional details on this HCP and other programs for conserving lynx habitats on State and private lands in this unit are provided in section 4.2.3 below.

Unit 4: North-central Washington - State and private lands constitute about 8 percent and 0.3 percent, respectively, of this SSA unit and most are State Trust lands in the Loomis State Forest, which accounts for all 426 km^2 (164 mi^2) of State lands in this unit. The Washington Department of Natural Resources (WADNR) administers rules guiding forest practices, such as timber harvests and road building, on State, private, and tribal forests in Washington. The Forest Practices Board, an independent State agency, adopts forest practices rules to protect water quality, fish habitat, other public resources and guide DNR's permitting process for timber harvests and other forest practices statewide. The WADNR developed a Lynx Habitat Management Plan (LHMP) for WDNR-managed lands distributed throughout north-central and northeastern Washington in areas delineated as Lynx Management Zones in the Washington State Lynx Recovery Plan (Stinson 2001, entire; Washington DNR 2006, entire). The WADNR LHMP guides timber harvest and other vegetation management on these lands, including the part of the Loomis State Forest that occurs in this unit, with the goal of creating and preserving quality lynx habitat through its forest management activities. Additional information on the LHMP is provided in sections 4.2.4 and 5.2.4 below.

Unit 5: GYA - State and private lands constitute about 0.3 percent and just over 2 percent, respectively, of this SSA unit and, combined, likely have little influence on lynx population persistence. Forestry regulations for the Montana portion of this unit are described above. In the Wyoming portion, the Wyoming State Forestry Division is responsible for the management of forested trust land across the state, including timber management and harvest, for long term forest health and productivity. Although the Division's programs may provide some indirect benefits to lynx, they do not include species- or habitat-specific regulations or conservation measures.

[11] http://dnrc.mt.gov/divisions/forestry/forestry-assistance/forest-practices, accessed 7.18.2016.

Unit 6: Western Colorado - State and private lands constitute about 0.6 percent and over 9 percent, respectively, of this SSA unit. The Colorado Department of Natural Resources and the State Division of Forestry oversee forest management activities on State and private lands in Colorado.

Tribal Management: Tribal lands contribute 1,408 km^2 (544 mi^2; just over 1 percent) of lynx habitat to the geographic units evaluated in this SSA. This includes lands of the Passamaquoddy Tribe and the Penobscot Indian Nation in Maine (248 km^2 [96 mi^2] in Unit 1), Grand Portage Band of Lake Superior Chippewa in Minnesota (202 km^2 [78 mi^2] in Unit 2), and the Confederated Salish and Kootenai Tribes of the Flathead Nation - Flathead Reservation in Montana (958 km^2 [370 mi^2] in Unit 3). Tribal management of these lands is expected to benefit lynx and lynx habitats. No tribal lands occur within SSA units 4, 5, or 6.

Unit 1: Northern Maine - Tribal lands represent less than 1 percent of this unit. The Passamaquoddy Tribe has lands enrolled in the Healthy Forest Reserve Program, described above. The Passamaquoddy Tribe's stated environmental mission is "...to protect the environment and conserve natural resources within all Passamaquoddy lands, waters, and the air we share" (Passamaquoddy Tribe 2014, entire). That of the Penobscot Indian Nation Department of Natural Resources is "...to manage, develop and protect the Penobscot Nation's natural resources in a sustainable manner that protects and enhances the cultural integrity of the Tribe" (Penobscot Indian Nation 2014, entire). Hunting, trapping or possessing lynx are prohibited in accordance with the Penobscot Indian Nation Chapter VII Inland Fish and Game Regulations – Section 204 (Penobscot Indian Nation 2012, p. 15). Tribal lands of the Aroostook Band of Micmac Indians and Houlton Band of Maliseet Indians occur immediately adjacent to this unit and lynx are thought to occupy both areas occasionally.

Unit 2: Northeastern Minnesota - Tribal lands of the Grand Portage Indian Reservation and the Bois Forte Indian Reservation—Vermillion Lake District represent 1 percent of this SSA unit. The Grand Portage Band of Chippewa has been actively working on lynx conservation since 2004. In October 2007, the Band hosted an international conference on lynx research and conservation where more than 50 researchers from the United States and Canada presented results of research on lynx diet, habitat, and management. Additionally, on-reservation timber sales and harvest practices follow an integrated management plan for priority wildlife management, sustainable economic development, and recreational uses. The Band's timber management practices benefit populations of snowshoe hares, the lynx's primary prey (Deschampe 2008, entire).

Unit 3: Northwestern Montana/Northeastern Idaho - Tribal lands of the Confederated Salish and Kootenai Tribes of the Flathead Nation, Flathead Reservation represent nearly 4 percent of this SSA unit. The mission statement of the Tribes' Fish, Wildlife, Recreation and Conservation Division is "...to protect and enhance the fish, wildlife, and wildland resources of the Tribes for continued use by the generations of today and tomorrow" (Confederated Salish and Kootenai Tribes 2014a, entire). An objective of the Tribes' Tribal Wildlife Management Program Plan is to ". . . develop and implement habitat management guidelines for Canadian lynx in coordination

with the Forestry Department as specified in the Forest Management Plan'' (Confederated Salish and Kootenai Tribes. 2014b, p. 5). The Forest Management Plan states that ''Standards for lynx management and habitat protection are set forth in the Canada Lynx Conservation Assessment and Strategy. This strategy guides land management activity in lynx foraging and denning habitat. Lynx occurrence and populations will continue to be monitored on the Reservation'' (Confederated Salish and Kootenai Tribes 2000, p. 285).

In summary, a variety of State wildlife and forestry regulations and conservation efforts, along with Tribal resource management objectives, influence activities in lynx habitats across the range of the DPS. While many of these clearly benefit lynx habitats and likely contribute to the persistence of resident populations, uncertainty remains regarding the effectiveness of some regulations and voluntary programs or measures in maintaining or restoring lynx habitats. This may be especially important with regard to timber management regulations and programs on private lands, which constitute the majority of lands in the Northern Maine geographic unit and a substantial amount of the Northeastern Minnesota unit.

3.2 Climate Change

''Climate'' refers to the mean and variability of different types of weather conditions over time, with 30 years being a typical period for such measurements (IPCC 2007, p. 78; IPCC 2014b, pp. 119-120). The term ''climate change'' thus refers to a change in climate that can be identified statistically by changes in the mean and/or variability of 1 or more measures of climate (e.g., temperature or precipitation) that persists for decades or longer, whether the change is a result of natural variability, human activity, or both (IPCC 2014a, p. 5). Various types of changes in climate can have direct or indirect effects on species. These effects may be positive, neutral, or negative, and they may change over time, depending on the species and other relevant considerations, such as the effects of interactions of climate with other variables (e.g., habitat fragmentation; IPCC 2007, pp. 8–14, 18–19; Melillo *et al*. 2014, p. 12).

In 2014, the International Panel on Climate Change (IPCC) released its Fifth Assessment Report (AR5), which represents the current scientific consensus on global and regional climate change and the best synthesis of scientific data available in this rapidly changing field. The AR5 largely reaffirms the conclusions of previous reports that the global climate is warming at an accelerating rate and that this warming is largely the result of human activities and the associated release of carbon dioxide and other greenhouse gases into the atmosphere (IPCC 2014a, entire). The report concludes that the strongest and most comprehensive evidence of the impacts of climate change is in natural systems, where many species have responded by shifting their geographic ranges, seasonal activities, migration patterns, abundances, and species interactions (IPCC 2014a, p. 4). It also concludes that projected climate change during and beyond the 21st Century will likely increase extinction risk for many terrestrial and freshwater species (IPCC 2014a, pp. 14–15).

Globally, annual average temperature increased by 0.61°C (1.1°F; range = -0.53° to +2.50°C [-0.95° to +4.5°F]) from 1850-1900 to 1986-2005 (IPCC 2014a, pp. 10-11). Greenhouse gas

emissions are increasing and tracking levels predicted by models for high emissions scenarios (e.g., RCP 8.5; Hartmann *et al*. 2013, p. 180, 187-189; Peters *et al.* 2013, entire; Friedlingstein *et al.* 2014, p. 709, 712; Fuss *et al.* 2014, p. 851). Analysis of paleoclimate data indicates 20th century warming is likely to have been the largest of any century within the last 1,000 years (Folland *et al.* 2001, pp. 99-101). These changes are predicted to continue and accelerate under future climate scenarios (Hall and Fagre 2003, fig. 7; Peters *et al*. 2013, entire, fig. 1). The IPCC projects that mean surface temperature will likely increase globally by 0.4° - 2.6°C (0.7° - 4.7°F) by mid-century and 0.3° - 4.8°C (0.5° - 8.6°F) by the end of this century relative to the 1986-2005 period (IPCC 2104b, p. 60). Rogelj *et al*. (2012, entire, table 1) concluded that the change in global mean surface temperature at equilibrium by 2100 has a greater than 95 percent probability of increasing more than 1.5°C (2.7°F), a 76 percent probability of increasing 2° - 4.5°C (3.6° - 8°F), and a 14 percent probability of exceeding 4.5°C (8°F).

In North America, climate history and projections from regional climate models corroborate global models, and indicate that both eastern and western North America, including all portions of the lynx DPS, have warmed in the last century and are likely to warm by 1° to 3°C (1.8° to 5.4°F) by the year 2050 (Christensen *et al*. 2007, p. 889; IPCC 2014a, pp. 23, 31; Romero-Lankao *et al*. 2014, pp. 1452-1454) and by 1.7° to 5.6°C (3° to 10°F) by the end of this century (Melillo *et al*. 2014, p. 8). The greatest increases in winter surface air temperatures in North American are projected in the interior of Canada, but large increases (in the range of 3.9°C [7°F]) are also expected in the northern contiguous United States by 2051 to 2060 (NOAA 2007[12], entire). To date, the observed and predicted increases in surface temperatures have been greater in the Northern Rocky Mountains and the Northeast (much of the lynx DPS) than elsewhere in the contiguous United States (Romero-Lankao *et al*. 2014, pp. 1453-1454; Lynx SSA Team 2016a, pp. 14-15). For example, in the Northern Rockies at Glacier National Park, mean summer temperatures increased 1.7°C (3.0°F) between 1910 and 1980, resulting in lower snowpack, earlier spring melt, and distributional shifts in vegetation (Hall and Fagre 2003, pp. 134–139; Fagre 2005, pp. 4–9). Observed impacts attributable to climate change that may affect lynx habitats and populations include upslope and northward shifts in species distributions across multiple taxa, decreases in snow cover and duration, and increased wildfire and insect activity in boreal and subarctic conifer forests of Canada and the western United States (Vaughan *et al*. 2013, pp. 358-360; Georgakakos *et al*. 2014, p. 72; Groffman *et al*. 2014, pp. 200-205; IPCC 2014a, p. 31; Joyce *et al*. 2014, pp. 176-179; Melillo *et al*. 2014, p. 17; Romero-Lankao *et al*. 2014, pp. 1456, 1458-1461).

When we listed the DPS in 2000, the Service determined there was no evidence that global warming was a threat to lynx (65 FR 16068-16069). In 2003, we concluded that the information available regarding the potential impact of climate change on lynx was speculative and did not demonstrate a threat to lynx (68 FR 40083, 40098). In the 2005 recovery outline, we acknowledged that continued climate warming was likely to negatively affect the boreal forest ecosystem for which lynx are highly adapted, eventually causing it to recede north and/or to higher, colder elevations, potentially resulting in a substantial future reduction or even

[12] https://www.gfdl.noaa.gov/wp-content/uploads/files/research/climate-change/gfdlhighlight_vol1n6.pdf last accessed 7.27.2017.

elimination of lynx habitats from the contiguous United States (USFWS 2005, pp. 11, 14). In the 2009 and 2014 revised critical habitat designations, the Service acknowledged that new science suggested that climate change may pose a significant risk to the future conservation of the lynx DPS (74 FR 8617, 8621; 79 FR 54811).

There is growing scientific evidence of accelerated athropogenically-influneced global climate warming during the 20th and early 21st centuries and little doubt among climatologists that this warming will continue and may increase in the future (Hansen *et al.* 2006, entire; IPCC 2014a, entire). Because the lynx is a cold-climate and snow-adapted habitat and prey specialist, there is general agreement that the species is vulnerable (highly sensitive, broadly exposed, and with limited adaptive capacity to respond favorably; therefore, predisposed to be adversely affected [IPCC 2014a, p. 5]) to climate warming and that the anticipated effects of continued warming will be adverse (not beneficial) for lynx, especially at the southern periphery of its range. Therefore, lynx biologists now identify climate change as the factor most likely to influence long-term resiliency of the DPS (Lynx SSA Team 2016a, pp. 14, 17, 19, 21-22, 35-47, 50, 53-57; ILBT 2013, pp. 43, 48, 53, 55, 63, 66, 69-71, 98).

Continued climate warming is expected to diminish boreal forest habitats and snow conditions at the southern edge of the range (all of the DPS range) that are, in some places, already patchily-distributed and perhaps only marginally capable of supporting resident lynx. Climate models project reductions in the extent of boreal forest habitats and snow conditions thought necessary to support lynx throughout the DPS, with both features predicted to migrate northward in latitude and to higher elevations (where possible; Sturm *et al.* 2001, pp. 342-342; Carroll 2007, pp. 1099-1102; Danby and Hik 2007, pp. 360-362; Gonzalez *et al.* 2007, entire; Gonzalez *et al.* 2010, pp. 761-766; McKelvey *et al*. 2011, entire; Johnston *et al*. 2012, pp. 8-11; ILBT 2013, p. 69; Koen *et al.* 2015. p. 528;). This would result in fewer, smaller, and more fragmented and isolated areas capable of supporting resident lynx and therefore smaller and more isolated lynx populations that would be more vulnerable to stochastic environmental and demographic events and genetic drift (Carroll 2007, pp. 1099–1100; Johnston *et al.* 2012, p. 11; 79 FR 54811; Schwartz 2017, pp. 4-5). Climate change has also been linked to increases in wildfire and forest insect activities in North America (Joyce *et al*. 2014, pp. 177-179; Romero-Lankao *et al*. 2014, pp. 1459-1461); two important components of boreal forest disturbance and, therefore, lynx habitat quality, quantity, and distribution. It also may affect other factors that could influence the future health of lynx populations in the DPS, such as hare/lynx cycles in Canada, disease transmission, and parasites.

Although projected climate warming is expected to reduce the future distribution and number of lynx in the DPS, there remains substantial uncertainty about the timing, rate, magnitude, and extent of potential impacts that may affect lynx populations in the DPS and how (and when) those populations may respond to increasing tempreatures and altered precipation patterns and disturbance regimes. Despite these uncertainties, specific effects of climate warming on lynx, hares, and their habitats in the DPS range that are occurring or can be reasonably anticipated include: 1) northward and upslope contraction of boreal spruce-fir forest types, 2) northward and upslope contraction of snow conditions believed to favor lynx over other terrestrial hare

predators, 3) reduced hare populations and densities, and 4) changes in the frequency, pattern, and intensity of forest disturbance events. Other potential effects of projected warming include: 5) reduced gene flow between Canadian and DPS lynx populations, 6) changes in the periodicity and amplitude of northern hare cycles, which could result in reduced lynx immigration to the DPS from Canada, and 7) increased or novel diseases and parasites. Each of these factors is discussed in more detail below.

Northward and Upslope Contraction of Boreal Spruce-fir Forest Types – Historically, boreal forest (lynx habitat) distribution in the contiguous United States has changed dramatically in response to changes in climatic conditions. It nearly disappeared from the Northeast 1,000 years ago during the interglacial warming period, then returned south into New England only in the past few centuries during the "Little Ice Age" (DeHayes *et al.* 2000, entire; Schauffler and Jacobson 2002, entire; also see 5.2.1). In the West during prehistorical periods of warmer climate, the alpine treeline ecotone (upper elevation of lynx boreal habitat) and deciduous-boreal forest ecotone (lower elevation of lynx boreal habitat) readily moved upslope in both the Northern and Southern Rockies (Legg and Baker 1980, pp. 331-332; Kearney and Luckman 1983, pp. 783-784). Boreal forest was likely continuous from the Canadian border south through the Southern Rockies of Colorado and northern New Mexico until the climate began warming and drying beginning about 15,000 years ago. That warming caused a northward and upslope retreat of the boreal zone to its current distribution, which has resulted in a naturally patchy distribution of boreal forest in the western United States that has remained relatively stable for the past 3,000 years (ILBT 2013, p. 50), with some patches largely isolated from more contiguous areas of boreal forest to the north.

Now, projected temperature increases and changes in precipitation patterns are expected to again shift the distribution of northern hemisphere ecosystems northward and up mountain slopes (McDonald and Brown 1992, pp. 411–412; Danby and Hik 2007, pp. 358–359; IPCC 2014a, pp. 3, 24-29; Groffman *et al*. 2014, p. 200). On a global or continental scale, there is general agreement that temperature is a primary determinant of treeline (Decker and Fink 2014, p. 122). Based on historical evidence, treeline is generally expected to migrate to higher elevations as temperatures warm, as permitted by local microsite conditions, although there may be a lag time in some mountain ranges (Smith *et al*. 2003, entire; Richardson and Friedland 2009, pp. 7-8, 15-16; Grafius *et al*. 2012, entire; Decker and Fink 2014, p. 67). McKenney *et al.* (2007, entire) predicted that the ranges of North American tree species will likely decrease, on average, by 12 percent and will shift northward by 700 km (435 mi) during this century. Several authors have also suggested that grasslands, aspen (*Populus* spp.) parklands, and temperate forest will expand northward, resulting in decreases in some areas that are currently boreal forest (Rizzo and Wiken 1992, p. 50; Starfield and Chapin 1996, entire; Rupp *et al.* 2000, entire; Galatowitsch *et al*. 2009, pp. 2015-2018), which could further fragment spruce-fir habitat (Iverson *et al.* 2008, p. 404; Tang and Beckage 2010, pp. 152-156; Rustad *et al.* 2012, p. 15; Simons-Legaard *et al.* 2016, p. 5). Thus, projected future warming is expected to cause another northward and upslope contraction of boreal forest in some parts of the contiguous United States (and in Canada; Groffman *et al*. 2014, p. 200), likely with negative

consequences for both lynx and snowshoe hare populations in the DPS and in southern Canada (Gonzalez *et al.* 2007, entire).

Some predicted changes to the boreal forest are already occurring, and much of the climate-induced change is occurring faster than originally predicted, suggesting rapid change as opposed to slow linear change (Soja *et al.* 2007, pp. 5-6; Settele *et al*. 2014, pp. 303-305). Globally, temperatures are increasing and snowfall is declining at the fastest rates in the high-latitude boreal forests of Canada and Eurasia (IPCC 2007, pp. 9, 52, 72), and climate models agree that winter warming across the circumboreal region will likely exceed 40 percent above the global mean winter warming (Soja *et al.* 2007, p. 4). Higher summer temperatures are thought to limit the distribution of boreal spruce-fir forests, which also are believed to be more sensitive to drought than other forests (Iverson and Prasad 2001, pp.192–196; Lenton *et al.* 2008, pp. 1788, 1791). In fact, over the past century, northward and upward (in elevation) biome shifts (the replacement at a location of one suite of species by another) in boreal ecosystems have been detected in numerous locations (Settele *et al*. 2014, pp. 278-279). Several studies (Joos *et al.* 2001, entire; Lucht *et al.* 2006, entire) suggest a temperature-increase threshold for boreal forest dieback of about 3°C (5.4°F), and some boreal forests are experiencing increases in tree mortality (Peng *et al.* 2011, entire). For example, widespread mortality and reduced growth in red spruce (*Picea rubens*; a component of lynx habitat in Unit 1) in the Northeastern United States in the 1960s to 1980s were believed to be linked to climate stress (McLaughlin *et al.* 1987, p. 501; Johnson *et al.* 1988, p. 5373).

Although increased precipitation is expected in the boreal region of Canada, particularly during the winter, it may be offset by increases in summer drought, heat stress, and evapotranspiration (Stocks *et al.* 1998, entire). Lienard *et al.* (2016, p. 7) conclude that spruce-fir forest types in New England, the Northern Great Plains, and higher elevations in the Rockies are vulnerable to drought-related stress from climate change during the next century. Nonetheless, Decker and Fink (2014, pp. 66-69) concluded that spruce-fir habitats in Colorado are only moderately vulnerable to the effects of climate change by mid-century under a moderate emissions scenario. Similarly, Keane *et al*. (*in press*, p. 209) concluded that while subalpine fir (*Abies lasiocarpa*; a major component of lynx habitats in western geographic units [3, 4, 5, and 6]) is likely to shift in distribution in the Northern Rockies, gains (expansion) will likely balance losses (contraction). They also concluded that Engelmann spruce (*Picea engelmanii*; also a major component of the 4 western geographic units), though highly sensitive to climate warming, will likely persist on the Northern Rockies landscape (Keane *et al*. *in press*, p. 213).

Upslope migration of boreal forest could occur either gradually or as a series of scattered, rapid advances as climate thresholds are crossed (Kupfer and Cairns 1996, p. 259-261) and may be limited by high winds, desiccation, and soil depths not conducive to conifer colonization. At lower elevations, the upslope movement of the deciduous-boreal ecotone is limited by excessively cold winter temperatures (generally -40°C [-40°F]), moisture (cloud, fog line), and acidic soils (Kupfer and Cairns 1996, p. 263-264). Boreal treelines in Scandinavia moved upslope an average of 40 meters (m; 131 feet [ft]), but in some locations up to 100 m (328 ft), during a recent 50-year period of warming (Kullman 1990, entire). In the Yukon, upslope

migration of spruce-fir seemed to be triggered by climate thresholds and was characterized by slow, gradual change followed by rapid advances (Danby and Hik 2007, p. 361). In Vermont, the northern hardwood-boreal ecotone moved upslope 91-119 m (299-390 ft) between 1962 and 2005 consistent with rapidly increasing cloud ceilings in the Northeast, which is believed to be closely associated with this ecotone transition (Beckage *et al.* 2008, pp. 4200-4201). Overall, the rate at which boreal forest could retreat upslope is highly speculative depending on how climate change may affect complex moisture and temperature regimes, and there could be a lag time before these community types shift (Kupfer and Cairns 1996, p. 268).

In summary, climate change is expected to further fragment boreal forest in southern Canada (Hogg 1994, entire) and in the contiguous United States, potentially reducing connectivity between lynx populations at the southern periphery of the species' range. As temperatures increase, lynx and hare habitats and, therefore, lynx distribution, are likely to recede northward and shift upward in elevation within its currently occupied range (Gonzalez *et al.* 2007, pp. 7, 13–14, 19; Beckage *et al.* 2008, entire; Jacobson *et al.* 2009, pp. 26–27, 30–31; Vashon *et al.* 2012, pp. 60, 64; ILBT 2013, p. 69). In the contiguous United States, researchers expect that lynx in mountainous habitat will, to some extent, track climate changes by using higher elevations on mountain slopes, assuming that vegetation communities supportive of lynx and hare habitats also move upslope with temperature and precipitation shifts (Gonzalez *et al.* 2007, p. 7). However, some areas of the DPS (e.g., Maine, Minnesota) lack such potential elevational refugia (Carroll 2007, pp. 1098-1102). Under a suite of emissions and climate change scenarios, boreal spruce-fir forests (lynx habitats) are projected to diminish dramatically and, under higher emissions scenarios, could largely or completely disappear from much of the DPS range by the end of this century (e.g., in Maine and Minnesota [Iverson and Prasad 2001, pp. 186, 195-196; Iverson *et al.* 2008, pp. 400, 403; Galatowitsch *et al*. 2009, pp. 2015-2016] and in the Rocky and Cascade Mountains in the west [Gonzalez *et al.* 2007, pp. 15-18; Johnston *et al.* 2012, pp. 6–13]). Under these scenarios and combined with projected impacts to snow conditions (see below), lynx populations would be anticipated to decline accordingly, with the potential loss of some DPS populations by the end of the century (Carroll 2007, pp. 1098–1102; Johnston *et al.* 2012, pp. 7-13). Although there remains much uncertainty regarding the timing, rate, and extent of modeled changes, ultimately, future northward and upslope contraction of lynx habitat in the DPS would likely result in fewer, smaller, and more isolated lynx populations that would be at increasing risk of extirpation resulting from demographic or environmental stochasiticty or genetic drift.

Northward and Upslope Contraction of Snow - As described above (section 2.2), the lynx's long limbs, large feet, and low foot-loading are believed to give it an advantage in snowy conditions over terrestrial competitors and predators. Although specific snow requirements for lynx (amount/depth, quality, persistence) have not been quantified throughout the DPS range, climate warming is diminishing snow conditions in the contiguous United States. Warmer winter temperatures are reducing snow cover extent and duration and altering snow structure via a combination of a higher proportion of precipitation falling as rain, more winter thaw-freeze events, higher rates of snowmelt during winter, and earlier spring melt and runoff (Hamlet and Lettenmaier 1999, p. 1609; Brown 2000, p. 2347; Hoving 2001, pp. 73–75; Mote 2003a, p. 3–1;

Christensen *et al.* 2004, p.347; Knowles *et al.* 2006, pp. 4548–4549; Mote *et al*. 2008, entire; Pierce *et al*. 2008, entire; Abatzoglou 2011, entire; Vaughn *et al*. 2013, pp. 358-359; Georgakakos *et al*. 2014, pp. 71-85). These trends are expected to continue with projected future climate warming (Hamlet and Lettenmaier 1999, p. 1611; Christensen *et al.* 2004, p. 347; Mote *et al.* 2005, p. 48; Christensen *et al*. 2007, p. 850; McKelvey *et al*. 2011, pp. 2887-2896; IPCC 2014b, p. 62). The IPCC projects that spring snow cover in the Northern Hemisphere is likely to decrease by 7-25 percent by the end of this century (IPCC 2014b, p. 62) and that ''snow season length and snow depth are very likely to decrease in most of North America except in the northernmost part of Canada where maximum snow depth is likely to increase'' (Christensen *et al*. 2007, p. 850). Because lynx occurrence is correlated with prolonged periods of deep, fluffy snow, current lynx habitats would be expected to decline in value for lynx with decreases in snow condition and duration (Hoving 2001, p. 73; Carroll 2007, pp. 1100-1103; Gonzalez *et al.* 2007, entire).

Warming in recent decades corresponded to a substantial decline in snow cover duration in North America, particularly in the mountains of the western United States (Mote *et al.* 2005, pp. 47-48; Kapnick and Hall 2012, entire). These areas have historically been snow-covered from November through March, but the length of snowfall-conducive temperatures over many western mountain ranges could be reduced from about 5 months to about 3 months (December-February) by mid-century (Klos *et al.* 2014, p. 4566). Spring snowpack has already declined in many parts of the Rockies, especially since the mid-20th century, despite overall increases in winter precipitation in many places (Mote *et al.* 2005, entire; Scalzitti *et al.* 2016, pp. 5367-5368). The recent rate of decline in the snowpack of the Northern Rockies is unprecedented in the last 1,000 years (Pederson *et al.* 2011, entire), and some mountainous regions appear to be warming faster than global land averages (Rangwalla and Miller 2012, entire). However, Oyler *et al*. (2015, entire) showed that systematic errors in temperature measurements at some Snow Telemetry (SNOTEL) sites resulted in the artificial amplification of mountain climate trends. In particular, during late spring the commonly used climate datasets (PRISM and Daymet) show elevation increases of 274 m (899 ft) and 487 m (1,598 ft), respectively, in minimum (snow-inducing) temperatures, while data with the systematic errors corrected show a statistically nonsignificant change of 66 m (217 ft; IDFG 2017a, p. 6). Nonetheless, the western United States has clearly warmed over the latter half of the 20th century, and this trend is very likely to continue into the future.

Estimating trends in snowpack is challenging because the high variability in snowpack dynamics and microsite variations due to canopy cover, aspect, and elevation are not well-reflected in observation records (Hubbart *et al*. 2015, pp. 885-892; Rasouli *et al*. 2015, pp. 3937-3938; Painter *et al*. 2016, p. 149; IDFG 2017a, p. 7). Nonetheless, snowpack losses have been documented and will likely continue and could even accelerate in the future (Hamlet and Lettenmaier 1999, entire; Payne *et al.* 2004, entire; McKelvey *et al*. 2011, entire; Kapnick and Hall 2012, pp. 14-16; Ashfaq *et al*. 2013, entire; Lute *et al*. 2015, 969-971), with faster losses likely in milder climates like the Cascades and the slowest losses in the high peaks of the Northern Rockies and Southern Sierras. For every 1°C (1.8°F) increase in temperature, snowline is projected to retreat upslope about 150 m (492 ft) in elevation (Beniston 2016, p.

106). In the West, areas of contiguous spring snow cover are projected to become smaller and more isolated throughout the Columbia, Upper Missouri, and Upper Colorado Basins, with greatest losses at the southern periphery (McKelvey *et al.* 2011, pp. 2892-2896). Snow accumulation and duration are also expected to continue to decline generally in the central and eastern portion of the lynx DPS range (Christensen *et al*. 2007, p. 891; Burns *et al.* 2009, p. 31; Moen *in* Lynx SSA Team 2016, p. 19). Similarly, because of diminishing snow resources, potential lynx habitat is diminishing in the northern Appalachians and small areas in the Canadian Maritime Provinces (Carroll 2007, p. 1093). An analysis of recent and potential future snow cover under a range of IPCC climate scenarios suggests that snow conditions correlated with historical lynx occurrence records could decline by 10-20 percent across the continental United States and Canada and by 46-84 percent in the contiguous United States by the end of the century (Gonzalez *et al.* 2007, pp. 4, 7, 12-14).

Across North America, a significant increase in the proportion of winter precipitation falling as rain rather than snow has also contributed to reduced depth and persistence of winter snowpack (Brown 2000, pp. 2347-2354; Dyer and Mote 2006, entire; Georgakakos *et al*. 2014, pp. 71-72) and increased snow density (Hodgkins and Dudley 2006, entire). Because winter temperatures have increased disproportionately, especially in the coldest northern tier states (Tebaldi *et al*. 2013, entire), the amount of winter precipitation falling as rain instead of snow has also increased throughout the DPS (Huntington *et al.* 2004, entire; Knowles *et al.* 2006, entire; Feng and Hu 2007, entire). If greenhouse gas emissions continue at the current rate, by 2100, the elevation above which it snows and below which it rains could climb as much as 244 m (800 ft) in the Colorado Rockies and by 423 m (1,400 ft) in the Rockies of Idaho and Wyoming, with the snow line projected to rise by an average of 290 m (950 ft) across 6 Western mountain regions (Scalzitti *et al.* 2016, p. 1564).

Shifts in the timing of the initiation of spring runoff toward earlier dates in western North America are also well documented (Hamlet and Lettenmaier 1999, p. 1609; Brown 2000, p. 2347; Cayan *et al.* 2001, pp. 409–410; Christensen *et al.* 2004, p. 347; Mote *et al.* 2005, p. 41; Knowles *et al.* 2006, p. 4554). In addition, a feedback (albedo) effect is likely to amplify regional warming and accelerate the rate of loss of snow cover because of the reflective nature of snow and the relative heat-absorbing properties of non-snow-covered ground (Vaughan *et al*. 2013, pp. 321, 358-361). This feedback effect causes the greatest warming to occur at the interface of snow-covered and exposed areas, increasing the rate at which melting occurs in spring (Groisman *et al.* 1994a, pp. 1637–1648; Groisman *et al.* 1994b, pp. 198–200). This effect has shifted the average date of peak snowmelt 3 weeks earlier in spring in the Intermountain West (Fagre 2005, p. 4). This albedo effect is further exacerbated by atmospheric soot and desert dust on the snow surface (Painter *et al.* 2007, entire; Qian *et al.* 2009, entire) and fire-darkened landscapes (Amiro *et al.* 2006, pp. 47-49).

Warming and more frequent winter rains and thaws are also contributing to changes in snowpack structure; namely replacing deep, unconsolidated snow with harder, crustier snow. These snow conditions are expected to occur at higher latitudes (Callaghan *et al.* 2011, entire) and higher elevations in the Rockies (Abatzoglou 2011, pp. 1138-1141). As winter temperatures

rise above freezing more often, rain on snow events and winter thaws become more common, causing changes in snowpack structure, including larger grain size, basal ice layers, depth hoar (weak layers in the snowpack), and slip planes (crusts and ice layers within the snowpack; Callaghan *et al.* 2011, p. 23). The frequency of winter warm spells is correlated to the hardness of the snow surface and sinking depth, which may influence the hunting efficiency of terrestrial hare predators (Murray and Boutin 1991, entire; Murray *et al*. 1994, p. 1450; 1995, p. 1209; Stenseth *et al.* 2004, p. 10633), potentially reducing the competitive advantage lynx are believed to have over some potential competitors (Pozzanghera *et al*. 2016, pp. 698, 703). These various forms of snow compaction and structure within the snowpack could give a competitive advantage to other terrestrial predators/competitors with higher foot-loading that would normally have difficulty traveling and hunting efficiently in deep, unconsolidated snow (Murray and Boutin 1991, entire; Murray *et al.* 1994, p. 1450; Kolbe *et al.* 2007, p. 1409).

The bobcat is the closest related species to lynx in North America, and bobcats occur within or immediately adjacent to all areas occupied by resident lynx populations in the DPS. Bobcats may outcompete or displaces lynx in some areas where the 2 species overlap, at both broad (Peers *et al.* 2013, entire) and local (Parker *et al.* 1983; Robinson 2006, pp. 120-129) geographic scales. In some areas of sympatry, lynx may be displaced to habitats of inferior quality, which could limit survival and productivity at the southern edge of their range (Robinson 2006, pp. 120; Peers *et al.* 2013, entire). Snow depth, consistency, and persistence likely mediate competition between the 2 species (Peers *et al*. 2012, pp. 4-9). Because of their higher foot-loading, bobcats likely hunt less efficiently than lynx in deep, unconsolidated snows (Hoving *et al.* 2005, entire; Krohn *et al.* 2005, pp. 122-129), which appear to limit bobcat mobility and distribution (Litvaitis *et al.* 1986, p. 116). Considering recent and projected future changes in snow conditions described above, stable or increasing bobcat populations in the DPS range (Roberts and Crimmins 2010, p. 170), and the predicted northward expansion of bobcats into areas currently occupied by lynx (Anderson and Lovallo 2003, p. 758; Lavoie *et al.* 2009, pp. 873-874; Roberts and Crimmins 2010, p. 172), lynx may experience increased competition and displacement by bobcats, which could influence lynx distribution and persistence at the southern edge of their range (in all DPS geographic units and in southern Canada).

Loss of favorable snow conditions could also result in increased lynx-bobcat hybridization. Thus far, hybridization has been documented in places (Minnesota, Maine, and New Brunswick) where low topographic relief and variability in winter severity may allow more interaction between the 2 species during the breeding season (Schwartz *et al.* 2004, entire; Homyack *et al.* 2008, entire; ILBT 2013, p. 34). The effects of hybridization on lynx populations in the DPS are uncertain, but it is not currently thought to be a substantial threat (Schwartz *in* Lynx SSA Team 2016a, p. 13). The hybridization rate is currently low (0.24 percent) but it could increase as bobcat populations are expected to move north with continued climate warming and related loss of snow conditions favoring lynx (Murray *et al.* 2008, p. 1465; Koen *et al.* 2015, p. 528). However, because lynx also are expected to shift northward with receding habitat conditions, it is possible that the zone of overlap between lynx and bobcats will shift northward but not increase in size, in which case an increase in hybridization rate would not be expected.

Although high-elevation areas in the western part of the DPS range (geographic units 3-6) may provide future snow refugia for lynx (Lynx SSA Team 2016a, p. 45), these areas will likely also be affected by continued climate warming, with lynx habitat distribution decreasing and isolation increasing as it moves upslope. Because recent and current rates of climate warming are much faster than occurred historically, it is possible that in these areas snow conditions favorable for lynx may move upslope at a faster rate than boreal forest vegetation, creating a mismatch of these lynx habitat elements. Thus, although it is possible that boreal forest vegetation may persist for some time, snow conditions thought to favor lynx could retreat upslope, potentially precluding lynx use of those boreal habitats and instead favoring potential competitors such as bobcats and coyotes.

Reduced Hare Populations and Densities – Climate change has also been linked to changes in the distribution of snowshoe hares in some parts of the southern edge of their range (Diefenbach *et al*. 2016, entire; Sultaire *et al.* 2016a, entire; 2016b, pp. 900-904). In Wisconsin, snowshoe hare range has contracted northward an average of 8.7 km (5.4 mi) per decade (1980-2014) and is projected to continue to recede northward with continued climate warming (Sultaire *et al.* 2016a, pp. 6-7). The authors concluded that loss of snow now contributes more than loss of habitat in determining the range of snowshoe hares in central Wisconsin (Sultaire *et al.* 2016a, entire). In Pennsylvania from 1983 to 2011, hare range contracted toward the coldest and snowiest areas in the northeastern and northwestern parts of the state, and continued warming may threaten the species' viability there (Diefenbach *et al*. 2016, entire). These 2 studies were of hare populations that do not now and apparently have not historically supported resident lynx populations, but similar contractions could occur in the future among hare populations within the range of resident lynx in the DPS.

Climate change also may affect hare populations in other ways, especially at the southern extent of its range in the DPS and in parts of southern Canada. As described above, changing snow conditions may influence lynx hunting behavior and effectiveness. For example, hard-packed snow is reported to be associated with a higher kill rate of hares by lynx and coyotes compared to soft snow (Buskirk *et al.* 2000a, p. 94; Stenseth *et al.* 2004, p. 10633). Consistently higher kill rates could generate numeric responses (population increases) by lynx and other hare predators (Hone *et al.* 2011, p. 420) that could drive hare populations to lower levels (Stenseth *et al.* 2004, p. 10633). Terrestrial hare predators are generally more diverse at the southern edge of the lynx range than in its core (Murray *et al.* 2008, pp. 1464-1465), and snow conditions that are projected to decreasingly favor lynx and increasingly favor less specialized predators (i.e., those with lower foot-loading) would be expected to result in increased predation on hares in some parts of their southern range.

Climate change is also projected to cause increases in annual precipitation and extreme precitpitation events as well as hotter summers and increasing drought across most of North America (Romero-Lankao 2014, pp. 1452-1456). Because the second litters of snowshoe hares have lower survival in wet summers (Meslow and Keith 1971, entire), increased precipitation may reduce hare numbers. However, because hares have 2 to 4 litters per summer, there is opportunity for compensatory survival of later litters if one is affected by weather (Krebs *et al.*

2014, p. 1043). Decreased hare survival may also be expected during prolonged hot, dry summer conditions. Conversely, in dry western forests, increased precipitation may result in more herbaceous forage and cover, which may promote hare survival and reproduction (Ivan *et al.* 2014, p. 590). Thus, climate change may have both positive and negative effects on hares.

The shorter duration and diminished snow cover in the DPS range is also causing an increasingly pronounced mismatch in the timing of hare color change that may reduce hare survival and result in population declines by the end of the century (Mills *et al.* 2013, entire; Zimova *et al.* 2014, entire; 2016, entire). Under a high emissions scenario, projected decreases in snowpack duration by as much as 4 weeks at mid-century and 8 weeks by the end of the century (Mills *et al*. 2013, p. 7362; Zimova *et al*. 2016, p. 304) could have population-level effects on hares at the southern edge of their range (Zimova *et al*. 2016, pp. 304-305). Hares exhibit plasticity in the rate at which they can molt from white to brown in the spring, but not in the initiation date of color change or the fall transition from brown to white (Mills *et al.* 2013, pp. 7362-7363). Hares do not seem to compensate for mismatched color by changing their behavior related to concealment, thus predisposing them to predation (Zimova *et al.* 2014, pp. 5-7). There is wide variability in the timing of pelage change by individual hares within populations, and "mismatched" hares experience increased mortality rates (Zimova *et al.* 2016, p. 302). Under high emission scenarios, hare survival could decline by 11 percent by mid-century and by 23 percent by late century (Zimova *et al*. 2016, p. 304). Lower survival could result in moderate (under a medium-low emissions scenario) to steep (high emissions scenario) declines in hare populations by late century (Zimova *et al.* 2016, p. 304).

This phenotypic color mismatch resulting in reduced hare survival, in conjunction with warming temperatures and decreased snow cover duration, is suspected of contributing to northward contractions of the snowshoe hare range in Wisconsin (Sultaire *et al*. 2016a, entire; 2016b, p. 902) and Pennsylvania (Diefenbach *et al*. 2016, p. 245). It is also possible that this phenological mismatch may affect hare cycles (Zimova *et al.* 2016, p. 305). The northward contraction of hares in Wisconsin over the past 3 decades occurred concurrently with a dampening of hare population cycles (Sultaire *et al.* 2016a, p. 7).

Although increased color mismatch and associated reduced survival have the potential to result in hare population declines as described above, natural selection acting on the wide individual variation in molt phenology might enable evolutionary adaptation/rescue (Zimova *et al*. 2016, p. 305) and the color mismatch should be corrected over time by strong natural selection pressure (ILBT 2013, p. 71; Moen 2017, p. 5). Such selection pressure may explain why snowshoe hares in some parts of the southern periphery of the range do not undergo pelage change in areas with no or little snow cover (e.g., in the Pacific Northwest; Dalquest 1942, pp. 167, 174-175; Nagorsen 1983, entire) or undergo only partial change to white in winter (in Pennsylvania; Gigliotti 2016, pp. 72, 89). However, with projected accelerated climate warming, it is uncertain whether adaptation via natural selection will be able to keep pace with rapid declines in snow cover duration at the southern edge of the snowshoe hare range (Sultaire *et al*. 2016a, p. 6).

Changes in the Frequency, Pattern, and Intensity of Disturbance Events - The distribution, amount, and composition of lynx habitat could be rapidly and dramatically altered by an increasing occurrence and persistence of drought, along with associated outbreaks of insects and pathogens, wind and ice storms, and wildfires (ILBT 2013, p. 70). All of these factors are potentially interrelated with multiple feedback mechanisms, and some have a cascading effect (Dale *et al.* 2001, p. 729). For example, drought can weaken trees, increasing their vulnerability to insects and pathogens. Insects and pathogens can create dead trees or increase fuel loads, potentially increasing the risk and intensity of fire. The boreal forest is a complex and variable system, and these effects are expected to vary in time and space and may interact. These interactions may appear slowly and be difficult to detect because of the typically long life spans of trees, or they may be manifested quickly after a catastrophic perturbation to the forest.

Drought and heat stress have already affected temperate and boreal forests (Allen *et al.* 2010, entire; Settele *et al*. 2014, p. 6), particularly in the West (geographic units 3-6), where tree mortality rates have increased rapidly in recent decades (van Mantgem *et al.* 2009, entire; Garfin *et al*. 2014, p. 464, 484; Joyce *et al*. 2014, p. 177-179; Mote *et al*. 2014, p. 495-496; Wade *et al*. 2017, p. 166). Increasing growing-season temperature is expected to increase episodic drought duration and/or intensity, which could increase evaporative demand, triggering moisture stress and increased forest vulnerability to periodic widespread regional mortality events (Joye *et al*. 2014, p. 179). Although much of the United States has experienced an increase in prolonged periods of excessively high temperatures and more severe droughts over the past 50 years (Melillo *et al*. 2014, p. 15), thus far it is not possible to attribute changes in North American drought frequency to anthropogenic climate change (Romero-Lankao *et al*. 2014, p. 1456). Nonetheless, some regional trends are apparent. For example, the drought over the last decade in the western United States suggests the driest conditions in 800 years based on tree ring data (Walsh *et al*. 2014, p. 38). Drought is projected to increase in much of the West by the middle and end of this century, including lynx geographic units 5 (GYA) and 6 (Western Colorado; Walsh *et al*. 2014, p. 41, fig. 2.22). Drought conditions are also expected to increase in the Northeast (which includes Unit 1 in Maine; Horton *et al*. 2014, p. 374), Midwest (which includes Unit 2 in Minnesota; Pryor *et al*. 2014, p. 425-426), Great Plains (which includes Unit 3 in western Montana; Shafer *et al*. 2014, p. 442); Northwest (which includes Unit 4 in Washington; Mote *et al*. 2014, p. 495), and Southwest (which includes Unit 6 in Colorado; Garfin *et al*. 2014, pp. 464-465, 468), with drought severity also expected in increase in Montana (Wade *et al*. 2017, pp. 155, 158-164). Increasing drought frequency and intensity are related to increased wildfire and forest insect activity in North America, including throughout much of the DPS range, with these trends expected to continue into the future (Groffman *et al*. 2014, pp. 203, 218; Joyce *et al*. 2014, pp. 176-178, 182; Melillo *et al*. 2014, pp. 9, 17; Romero-Lankao *et al*. 2014, pp. 1448, 1460-1461, 1477).

Wildfire frequency is increasing in boreal forests of North America, and extended fire seasons and increases in the total area burned are anticipated to continue in the western United States with continued climate warming (McKenzie *et al.* 2004, entire; Westerling *et al.* 2006, entire; Romero-Lankao *et al*. 2014, pp. 1447, 1461; Westerling 2016, entire). Evaluating wildfire patterns in the western United States from 1970-2012, Westerling (2016, pp. 5-10) found rapid

and dramatic increases in the frequency of large fires, wildfire durations, and the length of the wildfire season beginning in the mid-1980s. Mesic middle- and high-elevation forest types (such as lodgepole pine [*Pinus contorta*] and spruce-fir; i.e., lynx habitats) in the Northern Rockies experienced the greatest increases. Increased spring and summer temperatures and an earlier spring snowmelt strongly influenced large wildfires, suggesting that climate is the primary driver of these changes rather than fire exclusion (suppression), which appears to have had little impact on natural fire regimes of these higher-elevation forest types in this area (ILBT 2013, p. 70). Montana and Wyoming may be acutely sensitive to climate change and, even for a very mild climate-warming scenario, the area burned in the West could roughly double by the end of the century (McKenzie et al. 2004, p. 897). Increases are most likely in dry forests with high-frequency and low-intensity fire regimes (which typically do not provide lynx habitat); in areas of moderate fire frequency and intensity and areas of low frequency and high intensity fires regimes, habitat conditions for lynx may improve (McKenzie *et al*. 2004, p. 899). In contrast, climate change is increasing precipitation in boreal forest regions of eastern North America, which has reduced wildfire frequency (Bergeron *et al.* 2001, p. 388).

Under multiple climate scenarios, large increases in fire frequency are expected for boreal forests in central and western Canada, and reduced frequency in eastern Canada - a situation that reflects past Paleoclimates that were warmer than the present (Flannigan *et al.* 2001, pp. 860-862). Increased fire frequency at the grassland – aspen parkland – boreal forest transition in western Canada may hasten the conversion of boreal forest to aspen parkland and aspen parkland to grassland (Flannigan *et al.* 2001, p. 860-861), which could affect connectivity and gene flow in lynx populations. In the DPS range, large wildifres in north-central Washington (Unit 4) have reduced lynx habitat by 35-40 percent over the past 25 years (see section 4.2.4 below). Large wildfires have also occurred recently in lynx habitats in Units 2, 3, 5 and 6, though impacts to resident populations in those units have not been documented, estimated, or modeled.

Warming and drought are also likely affecting the frequency and intensity of some eruptive boreal forest insect pests and pathogens that affect disturbance patterns in spruce-fir forests (Volney and Fleming 2000, entire; Gray 2008, entire; Groffman *et al*. 2014, p. 203; Joyce *et al*. 2014, pp. 176-178; Melillo *et al*. 2014, p. 17). For example, native bark beetles, such as the spruce beetle (*Dendroctonus rufipennis*) and mountain pine beetle (*Dendroctonus ponderosae*), are key agents of change in coniferous forest ecosystems in western North America and have recently defoliated millions of hectares – among the largest and most severe outbreaks in recorded history (Bentz 2009, entire; USFS 2014, entire; Ivan *in* Lynx SSA Team 2016a, p. 23). Drought-stressed conifers have increased vulnerability to insect attack. Warmer springs also could increase the frequency and duration of wildfires, which in turn could increase vulnerability of surviving trees to bark beetle attack (Westerling *et al.* 2006; Bentz *et al*. 2010, p. 611; ILBT 2013, p. 70). Increasing temperatures and forest homogeneity could create conditions favorable for bark beetle outbreaks that exceed natural disturbance thresholds, perhaps increasing the likelihood of additional outbreaks in the resulting large areas of even-aged forests (Raffa *et al.* 2008, p. 512; ILBT 2013, p. 70). By the end of the century, changes in temperatures across the boreal forests of western North America may cause markedly high probability of outbreak of

these species (Bentz *et al.* 2010. pp. 607, 609). In contrast, the range of the spruce budworm, a major pest of spruce-fir ecosystems in eastern North America, is expected to shift northward, potentially reducing vulnerability of spruce-fir forests in Maine and Minnesota (Regniere *et al.* 2012, entire).

Climate change has also been implicated in increases in severe weather events. For example, in January, 1998 a severe ice storm extensively damaged the canopy of many northeastern United States and eastern Canadian forests, causing moderate to severe forest damage to over 40,000 km^2 (15,444 mi^2) in the Northeast United States and southern Quebec (Jones and Mulhern 1998, p. 19; Irland 2000, entire; Millward and Kraft 2004, entire). Ice storm damage to stands can range from light and patchy to total breakage of all mature stems over extensive areas (Irland 2000, entire). Similarly, in 1999, a derecho (severe wind-and hail-producing thunderstorm; Frelich *in* Lynx SSA Team 2016, p. 14) uprooted and snapped off trees in a 48 km- (30 mi-) long by 6-19 km- (4-12 mi-) wide swath of boreal forest in Unit 2 that impacted over 1,930 km^2 (745 mi^2)[13] of lynx habitat. It is uncertain how climate change may affect the frequency, intensity, location, and extent of ice storms and derechos; however, atmospheric warming will most likely shift the locations of prevailing ice storms northward.

In summary, natural disturbances (wildfire, forest insect outbreaks, and storms) are essential components of lynx habitats that historically have maintained the mosaic of forest stand seral stages and distriubutions that benefit lynx. Although these events may diminish lynx and hare habitats by removing forest cover, these impacts are typically temporary, and affected areas typically regenerate into the dense, young conifer stands that are associated with high hare and lynx densities throughout both species' ranges, including in the DPS. However, climate-mediated increases in the frequency, size, and intensity of these events may result in larger proportions of lynx habitats in a temporarily-unfavorable condition that occurs immediately post-disturbance and which may last for 10-40 years or more, depending on the nature of the disturbance and a suite of local climatic, topographical, and soil conditions. Such changes to historical disturbance regimes could affect a number of lynx demographic variables (e.g., distribution, density, survival, productivity) that influence population resiliency and, therefore, the likelihood that populations will persist on the landscape. For example, increased wildfire frequency, size, and intensity has affected over a third of the lynx habitat in Unit 4 over the past 25 years, resulting in increased lynx home ranges size and, therefore, lower density, likely reducing the population's resiliency compared to historical conditions (see sections 4.2.4 and 5.2.4, below).

Reduced Gene Flow between Canadian and DPS Lynx Populations - Koen *et al.* (2014a, entire) found that relatively lower neutral genetic diversity, lower allelic richness, and higher genetic differentiation among lynx at the trailing (southern) range edge in Ontario were correlated with high winter temperatures, low snow depth, and a low proportion of suitable habitat since the 1970s. The authors hypothesized that continued climate warming would increasingly create these unsuitable environmental conditions for lynx (e.g., milder winters with reduced snow quality, declining and fragmented boreal forest), at the trailing (southern) edge of the range. The

[13] https://en.wikipedia.org/wiki/Boundary_Waters%E2%80%93Canadian_derecho

authors surmised that genetic structuring in southern lynx populations could be caused by a northward shift in optimal conditions, potentially resulting in isolation and extirpation of lynx populations at the trailing edge of their range or climate-induced changes in the distributions of snowshoe hare or bobcats causing lynx to shift northward. Lynx with the greatest allelic richness were found in areas with the deepest snow in the core of their range in northern Ontario (Koen *et al.* 2014a, p. 758). The authors concluded that climate warming has reduced gene flow at the receding (southern) edge of the lynx's range, and that southward gene flow from Canada into threatened United States (DPS) populations is unlikely (Koen *et al.* 2014a, p. 760). Stenseth *et al.* (2004, entire) documented population and genetic structuring in the lynx populations east and west of Hudson Bay based on differences in snow conditions on either side of this divide. This may be explained by the reluctance of lynx to disperse between areas having different snow regimes and snow quality. Snow conditions may be the key factor in the spatial, ecological, and genetic structuring of Canada lynx (Stenseth *et al.* 2004, pp. 10633-10644).

Climate warming is expected to cause increased isolation of southern lynx populations, which could reduce gene flow by reducing connectivity between populations. For example, gene flow between lynx populations in Maine, New Brunswick, and eastern Quebec and more northern populations in Canada depends on an ice bridge for dispersal across the St. Lawrence River. Although some lynx currently cross the river, Koen *et al.* (2014a, entire) found genetic structuring on either side of the river. Thus, the river already restricts gene flow. Climate-induced deteriorating ice conditions on the St. Lawrence River could further restrict gene flow between lynx populations north and south of the river (Koen *et al.* 2015, p. 528). Between 1969 and 2002 there was a 20 to 40 percent reduction in sea-ice cover during the spring thaw in the Gulf of the St. Lawrence (Johnston *et al.* 2005, pp. 214-215). Conversely, reduced ice on the St. Lawrence may prevent bobcats from dispersing northward into lynx areas in central Quebec (Koen *et al.* 2015, p. 528).

The potential for genetic drift among DPS populations would be expected to increase at some point in the future if lynx and hare habitats shift northward and upslope, as projected with continued climate warming, resulting in reduced connectivity and gene flow among smaller and more isolated lynx populations at the periphery of the range. This would result in (1) smaller and more distant potential source populations in the southern Canadian provinces, reducing the likelihood and number of immigrant lynx reaching DPS populations, and (2) smaller effective population sizes (the size of an ideal population [i.e., one that meets all the Hardy-Weinberg assumptions] that would lose heterozygosity at a rate equal to that of the observed population) among DPS populations, making them more vulnerable to drift, the consequences of which could include lower survival and reproduction rates and loss of adaptive potential (Schwartz 2017, pp. 4-5).

Changes in the Periodicity and Amplitude of Northern Hare Cycles - Climate change is altering large-scale climate systems such as the North Atlantic Oscillation (NAO), Southern Oscillation, Pacific North American Index, and North Pacific Index which, in turn, affect patterns of temperature and snow in North America (Stenseth *et al.* 2003, entire). Climate change-induced disruptions are believed to have caused or contributed to the collapse of cycles in some voles

(*Microtus* and *Myodes* spp.) in northern Europe (Cornulier *et al*. 2013, entire) and lemmings in northern Finland (Ims *et al.* 2008, pp. 81, 84). The collapse of cycles in some herbivores with high-amplitude population cycles also would imply collapses of important ecosystem functions such as pulsed flows of resources and disturbances throughout the ecosystem, including declines in predator communities (Schmitz *et al.* 2003, p. 1202; Ims *et al.* 2008, p. 85).

A common denominator of cycles that exhibit spatial gradients, such as the more pronounced snowshoe hare cycles in the northern part of its North American range, is that the cycles seem to fade as winters become shorter (Ims *et al.* 2008, p. 81). Therefore, climate has also been hypothesized to influence snowshoe hare and lynx population cycles and synchrony (Hone *et al*. 2011, entire; Krebs 2011, pp. 484-488; Yan *et al*. 2013, entire). Hone *et al.* (2011, pp. 423-424) concluded that the NAO influenced both hare and lynx numbers and could dampen cycle oscillations. Yan *et al*. (2013 ,p. 3269) concluded that climate forcing is not only essential in producing sustained cycles, but also in modifying cycle intervals, and that greatly reduced lynx fur harvests in Canada beginning in the mid-1980s may be linked to climate warming. However, climate data analyzed by Krebs *et al.* (2013, pp. 566-572; 2014, pp. 1042-1043, 1046-1047) failed to explain changes in hare cycle synchrony documented in Alaska and western Canada beginning in about 1995. The authors rejected the hypothesis that climatic variation was correlated with hare-cycle amplitude in their study areas (Krebs *et al*. 2014, p. 1047), and their analyses did not support concern about collapsing population cycles hypothesized by Ims *et al*. (2008, entire).

Nonetheless, changes in large-scale climate systems have already influenced the climate and snow conditions throughout the geographic range of the lynx in North America (Stenseth *et al.* 1999, entire; Brown 2000, pp. 2347-2354; Krebs *et al.* 2001, p. 34; Stenseth *et al.* 2004, entire). If climate warming produces more pronounced troughs in hare abundance cycles in the interior of Canada, lynx populations would be expected to decline, though local extinction seems unlikely (Hone *et al.* 2011, p. 424). The potential for diminished lynx populations in Canada is a concern because periodic emigration from Canada is believed to influence the demographic and genetic health of lynx populations in the DPS (McKelvey *et al.* 2000a, pp. 232-242; 2000b, pp. 32-34; Schwartz *et al.* 2002, entire; USFWS 2005, p. 2; ILBT 2013, pp. 34, 42, 47, 54, 60, 65; Squires *et al.* 2013, p. 187; 79 FR 54789, 68 FR 40091, 40097-40100). Recent lower-amplitude hare cycles in southern Canada likely resulted in lower-amplitude lynx cycles as well, possibly resulting in muted irruptions with fewer dispersing lynx emigrating from Canada into the DPS. If these reduced cycles persist, they could result in reduced demographic support and gene flow into the DPS, both of which could influence the health and persistence of resident lynx populations in the DPS.

Increased or Novel Diseases and Parasites - Climate change can increase the distribution and transmission of parasites and pathogens and alter vectors, hosts, and host-susceptibility to disease. With continued warming, some species are predicted to experience more frequent or severe disease impacts with warming while others may be relieved of pathogens (Daszak *et al*. 2000, p. 444; Harvell *et al.* 2002, entire; Brooks and Hoberg 2007, entire; Harvell *et al.* 2009, entire). Climate change is likely to cause changes to the geographic range and incidence of

insect and tick-borne diseases (Daszak *et al.* 2000, entire). No apparent climate-influenced parasites or diseases have been identified that would be expected to broadly affect lynx or snowshoe hare populations, but several lynx experts believed this is difficult to predict and remains a possibility (Lynx SSA Team 2016a, pp. 27, 37-39). A few pathogens have been documented in lynx in the DPS. For example, plague, a flea-borne disease caused by the bacterium *Yersinia pestis*, which is not native to North America, was reported for the first time in lynx in Colorado (Wild *et al.* 2006, entire). Pneumonic plague appeared to be the direct or indirect cause of death of 6 lynx released in Colorado between 2000 and 2003. When translocated from Canada and Alaska, none of the lynx had antibody titers to *Y. pestis*; it appears likely that lynx were exposed to plague by infected prey after their release in Colorado. Exposure of some lynx to feline parvovirus was detected in 6 areas in western North America (Montana-Alaska; Biek *et al.* 2002, entire). *Troglostongylus wilsoni* is a nematode that infects the lungs of lynx and bobcats (Sarmiento and Stough 1956, entire; Van Zyll de Jong 1966, entire; Kumar 1974, entire; and Reichard *et al*. 2004, entire) and was detected in Maine lynx (Vashon *et al.* 2012, p. 24). Lynx with heavy infestations have difficulty breathing and succumb to starvation, as occurred with several Maine lynx (Vashon *et al.* 2012, p. 24). Davidson *et al*. (2011, p. 242) hypothesized that toxoplasmosis could spread northward into lynx populations with changing climate and expanding ranges of humans and feral cats, cougars, and bobcats.

Summary – Well-documented climate warming over the past half-century has probably already had some impacts on lynx habitats in the DPS range, and such impacts are likely to continue and perhaps increase in the future. However, there currently is no clear evidence that climate change has had population-level effects within the DPS range or reduced the ability of habitats within the DPS range to support persistent resident lynx populations. However, such impacts would be difficult to detect and document, and lynx habitats in much of the DPS range are naturally highly-fragmented and many appear to support hare densities only marginally capable of supporting persistent lynx populations. Therefore, even relatively minor climate-mediated impacts to boreal forest habitats and snow conditions, especially to winter hare and lynx foraging habitats, may strongly influence lynx persistence in some parts of the DPS range.

Although the rates of change and magnitudes of effects of climate warming are difficult to predict, climate models agree that lynx habitat and populations are likely to decline in the future, particularly at the southern margin of the range (Carroll 2007, pp. 1098–1102; Gonzalez *et al*. 2007, entire; Peers *et al*. 2014, pp. 1129-1134) and may disappear completely or nearly so from parts of the DPS range by the end of this century or sooner, depending on the intensity of greenhouse gas emissions (Galatowitsch *et al*. 2009, pp. 2015-2017; Johnston *et al.* 2012, pp. 6–13). Remaining lynx populations in the DPS range will likely be smaller than at present and, because of small population size and increased isolation, they will likely be more vulnerable to stochastic environmental and demographic events (Carroll 2007, pp. 1100–1103) and to genetic drift (Schwartz 2017, pp. 4-5).

In addition to the factors discussed above, synergistic effects between them and other stressors (e.g., forest management, trapping, development) may intensify their impacts (Carroll 2007, entire) and could further reduce and isolate lynx populations within the DPS and reduce

connectivity between Canadian and DPS lynx populations and habitats. Declining boreal forests and snow conditions, increasing drought and fire, and increasing scale of forest insect outbreaks are currently believed to be the most important stressors for lynx in the DPS, but it is possible that other pathways are, or may also become, important. Potential climate-mediated changes in habitat, prey base, and competitor guild, along with ongoing habitat loss and fragmentation, has led some authors to question whether lynx will be able to adapt to such changes and persist at the southern periphery of the species' range (Murray *et al.* 2008, p. 1469). Largely because of the likely consequences of projected continued climate warming, lynx experts expect a decreasing likelihood that resident lynx populations will continue to persist in the future in the 5 geographic units that currently support them (Lynx SSA Team 2016a, pp. 35-47; see ch. 5, below). However, despite concerns about the long-term persistence of DPS populations, experts projected that resident lynx populations are very likely to persist in all 5 geographic units that currently support them in the near-term (year 2025) and mid-term (2050), and uncertainty was great regarding predicitons beyond that time frame.

3.3 Vegetation Management

Vegetation (i.e., timber) management is the most prevalent land use throughout the lynx DPS range and can have beneficial, neutral, or adverse effects on lynx and snowshoe hare habitats and populations (65 FR 16071; 68 FR 40083; ILBT 2013, p. 71). Vegetation management affects stand age, structure, composition, and arrangement on the landscape, which are important elements of lynx and hare habitat (ILBT 2013, p. 71). Timber harvest can create, restore, and maintain lynx and hare habitats, but it and related silvicultural activites (e.g., precommercial and commercial thinning, fuels management, fire suppression) can also diminish (often temporarily) habitat quality, quantity, and distribution; alter natural disturbance regimes; and preclude attainment of the dense horizontal cover that provides high-quality hare and lynx habitat (see section 2.2). The Service listed the lynx DPS under the ESA because of the potential for such activities to adversely affect lynx habitats and populations and the absence of measures to guide them for lynx conservation on Federal lands (68 FR 40076-40101).

At the home range scale, lynx throughout the DPS range consistently occupy landscapes having the greatest snowshoe hare densities. Although forest types and the effects of forest (vegetation) management vary geographically, hare abundance throughout the DPS range is strongly correlated with a single common denominator - dense horizontal cover at ground and snow level. Such cover provides hares with a source of browse, protects them from predation, and is the most important forest structural characteristics for hares throughout their range (Ferron and Ouellet 1992, pp. 2180-2182; Wolfe *et al.* 1982, pp. 665-670; Litvaitis *et al.* 1985, entire). Hare density is directly and positively correlated with stem density (Litvaitis *et al*. 1985, p. 870; Sullivan and Sullivan 1988, pp. 803-804; Koehler 1990b, entire; Thomas *et al.* 1997, pp. 24-50; Homyack *et al.* 2006, pp. 76-79; Robinson 2006, pp. 5-37, 67-75; Scott 2009, pp. 58-93; Fuller and Harrison 2013, pp.4-6), and softwood (e.g., spruce-fir) has about 3 times more cover value than hardwoods (Litvaitis *et al.* 1985, p. 870). Young (10-40 years post-disturbance) regenerating spruce-fir forests provide optimal cover and high hare densities throughtout the DPS range, and seral lodgepole pine and mature multi-storied spruce-fir stands may also

provide such conditions in the western part of the DPS range (Koehler and Brittell 1990, p. 10; Hoving *et al.* 2004, p. 290; Maletzke *et al*. 2008 p. 1477; Squires *et al.* 2010, pp. 1648, 1653–1656; McCann and Moen 2011, pp. 513-515; Berg *et al.* 2012, pp. 1483-1487; Holbrook *et al*. 2017, entire). Therefore, vegetation management practices that promote high stem density and dense horizontal cover can increase snowshoe hare densities (Conroy *et al.* 1979 pp. 684-689; Wolff 1980, pp. 115-128; Parker *et al.* 1983, pp. 783-785; Livaitis *et al.* 1985, p. 872; Monthey 1986, entire; Koehler 1990a, pp. 848-850, 1990b, entire; Robinson 2006, pp. 31-36, 62-75, 119-129; Fuller *et al.* 2007, entire; Homyack *et al.* 2007, entire; Scott 2009, pp. 8--92; McCann and Moen 2011, pp. 513-515), while forest practices that reduce dense understory generally reduce habitat quality for hares and lynx.

Historically, the dominant natural disturbance processes that created young, regenerating conifer forest conducive to hares and lynx were wildfire, insect and disease outbreaks, and wind events (Kilgore and Heinselman 1990, entire; Heinselman 1996, entire; Veblen *et al.* 1998, entire; Agee 2000, entire; Seymour *et al.* 2002, entire; Lorimer and White 2003, entire). After disturbances, forests generally develop through several stages described by Oliver (1980, pp. 155-161) as “stand initiation,” “stem exclusion,” “understory reinitiation,” and “old growth.” Stand dynamics, particularly within-stand competition for light, nutrients, and space, determine how forests grow and respond to intentional manipulations and natural disturbances (Oliver and Larson 1996, entire). The frequency and severity of disturbances have a large role in determining which tree species will dominate in a stand after the disturbance event. Snowshoe hare and lynx habitat are created during the stand initiation stage, after the young trees have established and grown tall enough (1-3 m (3-10 ft) to protrude above the snow and provide adequate horizontal cover. During the stem exclusion stage (when trees reach about 10 m [33 ft], depending on tree species) the tree crowns lift and lower branches self-prune, thus reducing the live horizontal branches providing food and cover for snowshoe hares. In the old growth stage, understory may re-develop (e.g., in forest gaps where mature trees die or fall down) and food and cover may again become available to support snowshoe hares.

Traditionally, commercial timber management of conifer forests has used a variety of silvicultural techniques (plantations, herbicide application, precommercial and commercial thinning, group selection, fuels management, and salvage and regeneration harvest) to (1) reduce tree density, promote tree growth, and select for desired species in young regenerating forests; (2) improve growth and vigor of mature trees; (3) reduce vulnerability of commercially-valuable trees to insects, disease, and fire; and (4) harvest forest products (ILBT 2013, p. 71). Just as the timing and intensity of a natural disturbance event affects the composition of the succeeding forest, the season, climate, machinery, and type of final harvest (e.g., clearcut v. partial harvest) all have a role in determining the species composition and health of the next crop of trees following management activities. Although some timber management practices may mimic natural disturbance processes, others, such as herbicide use and plantations, do not have natural analogues. Timber harvest may differ from natural disturbances in ways that may affect lynx and hare habitats, including (ILBT 2013, pp. 71-72):

- Removing most standing biomass, especially larger size classes of trees, and downed logs, which alters microsite conditions and nutrient cycling;
- Creating smaller, more dispersed patches and concentrating harvest at lower elevations in mountainous regions and on more nutrient rich soils, resulting in habitat fragmentation;
- Causing soil disturbance and compaction by heavy equipment, which may result in increased water runoff and slower tree growth at the site; or
- Giving a competitive advantage to commercially-valuable tree species and reducing the structural complexity of the forest through the application of harvest, planting, thinning, and herbicide treatments.

Therefore, vegetation management may or may not be compatible with creating, maintaining, or restoring habitats capable of supporting hares and lynx, depending on the extent to which conservation awareness and measures guide management. Vegetation management can provide snowshoe hare habitat by creating additional early-successional forest conditions in areas that are capable of, but not currently providing, dense horizontal cover; designing the appropriate size, shape and temporal pattern of treatment units (mimicking patterns created and maintained by natural disturbance regimes); retaining coarse woody debris; maintaining high stem densities in regenerated forests; and maintaining connectivity and dispersal habitat (Koehler and Brittell 1990, pp. 11-12; Homyack *et al.* 2004, pp. 141-142; Bull *et al.* 2005, entire; Fuller and Harrison 2005, p. 719). However, forest management can also diminish lynx and hare habitats by removing cover, altering natural disturbance patterns and regimes, creating unnaturally large or continuous openings, fragmenting habitat, and eliminating connectivity/dispersal habitats. Roads associated with forest management also fragment habitat and can increase access by competing predators and humans, both potentially affecting lynx habitats and populations.

Forest Products Markets - North America is the world's leading producer and consumer of wood products. Therefore, worldwide trends in forest products markets greatly affect forest management decisions, which may influence the amount and quality of lynx habitat in the DPS. Globalization of manufacturing and expanded use of electronic media have reduced demand in pulp and paper since the late 1990s, and the collapse of housing construction, which deepened with the recession of 2007-2009, has contributed to declines in United States wood products output. In recent years, the nation's forest products industry experienced a downturn in output levels not seen in decades, with considerable declines in timber harvest, mill numbers, and wood consumption since 2000, and employment losses in the hundreds of thousands (Woodall *et al.* 2011, p. 595).

Forest management decisions (e.g., to focus on hardwood or softwood production) can change dramatically in response to unpredictable and changing forest products markets. Lynx occur in forests dominated by softwood conifers; therefore, management related to softwood production and harvest has the greatest potential to affect lynx populations in the DPS range. Because they depend on demand for paper and housing, markets for softwood products are affected by economic factors that are difficult to predict and are therefore particularly volatile. For example,

the western United States, a major softwood lumber producing region, was particularly hard hit by the recession and housing collapse - forest industry employment dropped by 30 percent (nearly 80,000 workers) and annual output value fell by more than 25 percent (Keegan *et al.* 2011). Under depressed markets, landowners may reduce harvests, which may be to the detriment of lynx in some parts of the DPS (e.g., Maine and Minnesota), but to their benefit in others (the western part of the range). Likewise, rapidly expanding (recovering) softwood markets could lead to rapid and extensive harvest, with potential benefits or detriment to DPS populations, depending on local cicumstances and landscape habitat conditions.

Despite depressed markets, one area of increasing interest is bioenergy production. Rising energy costs and growing concerns over global climate change have increased interest in bioenergy production, and the United States Energy Independence and Security Act (2007) mandates a 5-fold increase in biofuel production (Benjamin *et al.* 2009, p. 125). The wood pellet sector is expected to grow, although woody biomass is typically the lowest value wood commodity sold from the forest. Thus, it is questionable whether wood energy revenues would be enough to sustain forest investments and forest management into the future (Woodall *et al.* 2011, p. 601) and, therefore, potential impacts or benefits to lynx habitats and populations are uncertain.

Although management of State and Federal forest lands has been relatively stable in recent decades, management and ownership of private forest lands have been comparatively unstable. This has resulted in substantial shifts in forest management strategies, outcomes, and products. For example, in the last 2 decades in Maine, where nearly all the lynx critical habitat is on private land, about 96,315 km^2 (37,187 mi^2; 80 percent) of commercial timber lands in the "northern forest" (Adirondacks to northern Maine) were sold to many different kinds of financial groups (Hagan *et al.* 2005). These groups have short-term investment goals and their management objectives differ from traditional commercial timber operations, resulting in changes to traditional harvest practices. Whereas the previous large commercial timber landowners focused on the forest land base as a supply for their manufacturing facilities, the new Timber Investment Management Organizations (TIMOs) and Real Estate Investment Trusts (REITs) focus on maximizing return on their investment (Jin and Sader 2006, p. 178). Initially, the effects of ownership changes were uncertain (McWilliams *et al.* 2005), but an evaluation of harvesting in the last decade indicates these landowners increased harvest rates, shortened rotation times, and shifted to managing and harvesting hardwood tree species (Jin and Sader 2006, p. 183-185). On one hand, these trends in private lands management in Maine may make lynx conservation more difficult to achieve because short-term landowners may be less interested in long-term commitments. On the other hand, some easement owners may have an incentive to manage for lynx to meet forest certification requirements.

The extensive sale of private forestlands initiated the growth of conservation easements in this region (deGooyer and Capen 2004; Lilieholm *et al.* 2010). Conservation land as a percentage of Maine's State area increased from less than 5 percent in 1987 to approximately 19 percent by 2012 (Beck *et al.* 2012, p. 15). Conservation easements restrict development but usually do not affect forest management; neither do they typically require management for lynx and other rare

species. Some private forestlands were sold to State and Federal agencies and conservation interests. For example, in recent years The Nature Conservancy purchased over 125,000 ha (310,000 ac) of private forestland in Montana and nearly 75,000 ha (185,000 ac) of private forestland in northern Maine. Lands in conservation ownership are more likely to be managed to benefit hares and lynx.

Finally, future trends in forest management will likely be affected by climate change (Irland *et al.* 2001, entire). Many models have been developed to project how United States timber production and markets may adapt to climate change (e.g., Joyce *et al.* 1995; Burton *et al.* 1998; Sohngen and Mendelsohn 1998; Perez-Garcia *et al.* 2002). Economic models predict that with continued climate warming, total United States timber inventories will increase, timber harvest will increase, and product prices will decrease relative to an assumed stable climate. Some models predict that consumers will gain from climate change while landowners in some regions will lose. The forest industry will likely adapt to climate change in many ways including using alternate tree species in manufacturing, shifts to geographic regions of the country with economic advantages in timber growth, and increasing forest plantations with new species that are favorably adapted to the new climate and markets. Many strategies have been evaluated to increase the quantity of carbon stored in North American forests (Irland *et al.* 2001) including discontinuing or greatly reducing harvest in some forests to build carbon reserves, increased recycling to reduce use of forest products, converting agricultural lands to forests, and substituting wood products for more energy-intensive products. Increased atmospheric carbon will increase forest growth slightly, except for softwood (Irland *et al.* 2001, p. 757-758). Sawtimber production, which sequesters more carbon, is expected to increase (Irland *et al.* 2001, p. 758). Expanding landscapes with older growth conifer forest to sequester carbon could benefit lynx in the West and be to the detriment of lynx in the East.

Reduced Quality of Hare Habitat - Throughout the lynx DPS, some vegetation management practices, especially thinning in young, dense regeneration; reducing overstory canopy in mature multi-story spruce-fir forests (in the West); and partial harvesting (in northern Maine) reduce the quality of boreal forest habitats for snowshoe hares and lynx. The probability of lynx occupancy of a potential home range is sensitive to small changes in average hare density (Simons 2009, pp. 89-110; Simons-Legaard *et al*. 2013, pp. 572-576). Below a threshold of about 0.5 hares/ha (0.2 hares/ac), declines in hare abundcance, whether from natural population fluctuations (hare cycles) or habitat loss or fragmentation from detrimental forest practices, development, or other anthropogenic incluences could be sufficient to diminish landscape carrying capacity for lynx (Scott 2009, p. 118). Such declines could result in reduced productivity (Slough and Mowat 1996, pp. 953-956), cause lynx to increase home range sizes (Scott 2009, p. 120; Ward and Krebs 1985, entire; Mowat *et al*. 2000, pp. 276-280) or, in extreme cases, to abandon their home range or cause mortality (Ward and Krebs 1985, p. 2819; Slough and Mowat 1996, pp. 956-957).

Thinning of young, dense sapling stage conifers (precommercial thinning) is a forest management practice used widely throughout the DPS to increase the growth and value of selected trees and to reduce the time to maturity of a stand of trees. Precommercial thinning

removes competing trees of the same species or shrubs and trees of other species (Daniel *et al.* 1979; Homyack *et al.* 2005, 2007). The effects of precommercial thinning are summarized in the revised Lynx Conservation Assessment and Strategy (ILBT 2013, pp. 72-73):

> *Reducing the density of sapling-sized conifers in young regenerating forests to increase the growth of certain selected trees promotes more homogeneous patches and reduces the amount and density of horizontal cover, which is needed to sustain snowshoe hares (Sullivan and Sullivan 1988, Hodges 2000b, Griffin and Mills 2004, Ausband and Baty 2005, Griffin and Mills 2007, Homyack et al. 2007, Ellsworth 2009). Hares reach highest densities in stands with stem densities ranging from 4,600–33,210 stems/ha (1,862–13,445 stems/ac)(Wolff 1980, Parker 1984, Litvaitis et al. 1985, Monthey 1986, Parker 1986, Koehler 1990a, Griffin 2004, Fuller and Harrison 2005, Robinson 2006, Scott 2009), whereas thinned stands have densities of 2990 (6-foot spacing) to 1,682 (8-foot spacing) stems/ha (Pitt and Lanteigne 2008, p. 593). Precommercial thinning has been shown to reduce hare numbers by as much as 2- and 3-fold (Griffin and Mills 2004, 2007; Homyack et al. 2007) because of reduced cover and decreased availability of browse. Griffin and Mills (2007) reported that, if their results were representative, the practice of precommercial thinning could significantly reduce snowshoe hare populations across the range of lynx.*
>
> *There are anecdotal examples of precommercially thinned stands that subsequently "filled in" with understory trees. Some have suggested this could be a technique to extend the time that understory trees and low limbs provide the dense horizontal cover that constitutes snowshoe hare habitat. The duration between time of thinning and regrowth to a height providing winter snowshoe hare habitat would likely vary by tree species, each having different regenerative capacities that could be influenced by a variety of local factors (e.g., topographic relief, moisture, and mineral and organic content of the soil; Baumgartner et al. 1984, Koch 1996). Bull et al. (2005) reported that the slash and coarse woody debris remaining after precommercial thinning provided both forage and cover for snowshoe hares up to a year following treatment. However, Homyack et al. (2007) found that snowshoe hare densities were reduced following precommercial thinning for 1–11 years post-thinning. They further suggested that after precommercial thinning, the stands did not regain the structural complexity in the understory that would be needed to support pre-treatment snowshoe hare densities. At this time, no other data are available to quantify the re-establishment of snowshoe hare habitat and over what time period, or the response by snowshoe hares, as compared with sites that were not precommercially thinned, so this remains an unproven management technique. As an alternative to standard precommercial thinning (i.e., complete thinning resulting in a homogeneous patch), Griffin and Mills (2007) suggested retaining at least 20 percent of the patch in untreated clumps of about ¼ ha (½ ac), which would maintain hare habitat in the short term. However, Lewis et al. (2011) found that landscapes with patches of high-quality habitat surrounded by similar vegetation supported more hares than did more fragmented landscapes composed of high-quality*

patches in a matrix of poorer-quality habitat. Further long-term studies of modified thinning methods are needed.

Abele *et al*. (2013, entire) also found that precommercial thinning reduced hare abundance in western Oregon but did not affect individual hare survival or activity patterns. Because of documented adverse effects of precommercial thinning to snowshoe hares and lynx, in 2007 and 2008 the USFS amended Forest Plans to incorporate management that would conserve lynx, including direction that prohibited precommercial thinning in most lynx foraging habitat (USFS 2007, pp. 8, 11-14, 36; USFS 2008a, pp. 6-9, 23-26). However, precommercial thinning is not regulated on private forest lands throughout the remainder of the DPS.

Particularly in western forest systems, uneven-aged management (single tree, partial harvest, and small group selection) can be used in stands with poorly developed understories, but which have the potential to develop dense horizontal cover. In such stands, removing some large trees can create openings in the canopy that mimic natural gap dynamics and maintain or stimulate multi-story attributes (ILBT 2013, p. 73). However, creation of large openings may discourage use by lynx (Koehler 1990a; von Kienast 2003; Maletzke 2004; Squires *et al.* 2010; ILBT 2013, p. 73), at least temporarily. Removing larger trees from mature multi-story stands to reduce competition and increase tree growth or resistance to forest insects may degrade lynx winter habitat by reducing horizontal cover (Robinson 2006; Koehler *et al.* 2008, Squires *et al.* 2010). Similarly, removing understory trees from mature multi-story stands also reduces dense horizontal cover, reducing winter habitat quality for both hares and lynx (ILBT 2013, p. 73).

In eastern forests, partial harvesting practices diminish (compared to regeneration following large-scale clear-cutting) the development of large patches of dense horizontal cover for snowshoe hares (Simons-Legaard *et al*. 2016, pp. 7-8). Partial harvesting broadly describes many methods of removing a portion of the overstory trees from a forest stand. Partial harvesting includes selective cuts, shelterwood cuts, and uneven-aged management. Partial harvest may be “light” (e.g., < 10 percent of trees removed) to “heavy” (e.g., 90 percent of trees removed). Since passage of the Maine Forest Practices Act in 1989, various forms of partial harvesting have replaced clearcutting as the predominant form of forest management in northern Maine (Sader *et al.* 2003, entire). In recent years, almost 172,000 ha (425,000 ac) of Maine forest are harvested annually and 96 percent of this land is partially harvested (Maine Forest Service 2016). After 28 years of extensive partial harvests, much of the northern Maine landscape has been influenced by this form of forestry, and will continue to be into the future. The popularity of this form of harvesting extends beyond Maine. From the mid-1980s to mid-1990s, partial harvesting comprised 62 percent of the harvest in the United States, and clearcuts comprised the other 38 percent. Partially harvested stands result in a wide range of residual stand conditions, but many have lower conifer stem densities and higher hardwood density than regenerating clearcuts (Robinson 2006). On average, partially harvested stands in Maine supported about 50 percent of the hare densities observed in regenerating clearcuts (Robinson 2006; Harrison *et al*. 2016 p. 55; also see sections 4.2.1 and 5.2.1, below).

Shelterwood harvesting (sometimes referred to as overstory removal) is a form of even-aged management most frequently used in hardwood and mixedwood stands in Maine (Rolek 2016, *unpubl. data*, Maine Cooperative Fish and Wildlife Research Unit), but also in spruce and fir stands (Pothier and Prevost 2008, entire). Shelterwood harvests that occur in predominantly softwood stands contribute to landscape hare densities to support lynx; however, hare density in regenerating shelterwood stands was only about half that of regenerating clearcut and herbicide-treated stands (D. Harrison, Univ. Maine, *pers. comm.* and *unpubl. data*; Harrison *et al*. 2016, p. 55). Regenerating shelterwood harvests in softwood stands are less likely to support higher landscape hare densities because they are most often done in small patches to avoid problems with windthrow, especially in wet soils (D. Harrison, Univ. Maine, *pers. comm*.). As much as 30 to 40 percent of the advanced regeneration may be damaged from repeated entries by machinery to remove the overstory (R. Seymour, Univ.Maine, *pers. comm.*). Finally, because subsequent overstory removal occurs about 15 years after the initial entry, some of the dense understory is damaged just as the stand develops conditions to support higher hare densities. The damage to the understory not only reduces the quality of the habitat for hares, but also cuts short the duration that the stand produces high-quality hare habitat.

Fuels treatment and biomass removal projects also may reduce hare and lynx habitat quality. Fuels treatment projects are typically designed to remove understory biomass and reduce stem density in forests that are outside their historical range of variability, and to clear fuels adjacent to human developments for safety or to protect investments (ILBT 2013, p. 74). Removing or reducing the understory and ladder fuels to meet those objectives reduces horizontal cover important to snowshoe hares and thus diminishes lynx habitat quality (ILBT 2013, p. 74). In the West, most of these projects occur in dry, lower-elevation forests where past fire suppression has resulted in unnatural fuel build-ups; however, these are not lynx habitat. In the Great Lakes Region, prescribed burning to reduce fuels and mimic a more natural fire regime in lynx habitat causes a short-term (10–30 years) impact on snowshoe hare habitat (ILBT 2013, p. 75). Biomass removal for energy production targets the removal of dead trees, logging slash, and small-diameter trees and shrubs. Biomass removal is similar to fuels treatments in reducing cover and habitat for snowshoe hares (ILBT 2013, p. 75).

Loss, Degradation, and Fragmentation of Boreal Forest Habitat - Forest management rarely results in conversion of lands to non-forest. In fact, forested landscapes have increased in some parts of the DPS (especially in the Northeast) because of farm abandonment and recolonization by second-growth forest. However, some forms of forest management such as selective harvesting and fire suppression can (intentionally or unintentionally) alter tree species composition away from boreal forest types that support snowshoe hares and lynx. Similarly, lack of forest management can alter tree species composition (Trani *et al.* 2001, pp. 415-417). Other stressors, such as insect outbreaks and climate change, can work in synergy with forest management to reduce boreal forest. For example, in northern New England clearcutting sometimes leads to drying of the forest floor and consequent heavy mortality in spruce and fir regeneration and increased light levels that increase hardwood competition (White and Cogbill *in* Eagar and Adams 2012, p. 32).

Plantations can convert native forest communities into monocultures of a native or exotic tree species that may lack hardwood browse for snowshoe hare. Cutting rotations can be reduced by half through mechanical site preparation, planting, and suppression of hardwood competition. Conifer stem densities in plantations range from 800-5,000 stems/ha and may support relatively low populations of snowshoe hares because of the initial wide spacing of trees (Bellefeuille *et al.* 2001, p. 44). Hare densities in plantations may increase after trees reach the sapling stage and branches intermingle at the ground level, creating horizontal cover if the lateral branches are not pruned (Parker 1984, p. 163; Parker 1986 p. 160; Roy *et al.* 2010, p. 285). However, the period of time that spruce plantations may support high hare densities in Maine and eastern Canada may be relatively short (10 to 17 years post-harvest) compared to regenerating softwood clearcuts (15-35 years post-harvest; Simons-Legaard *et al.* 2013, p. 569).

Under certain forest stand conditions, herbicide treatment may have long-term effects on stand composition and structure (MacLean and Morgan 1983; Daggett 2003), thus potentially reducing food, cover, and habitat for hares (Borrecco 1976; Bellefeuille *et al.* 2001, p. 43; Thompson *et al.* 2003 p. 462). Understory deciduous stems were lacking in stands treated with herbicide (Homyack *et al.* 2004). Although herbicide treatments reportedly do not directly affect survival, fecundity, or other demographic parameters of snowshoe hares (Sullivan 1996), treatments have indirect effects on hares via changes in vegetative cover and browse (Homyack *et al.* 2005, p. 10). In Norway, hare use of plantations was reduced up to 10 years after herbicide application (Hjeljord *et al.* 1988).

Forest management can fragment and isolate patches of high-quality hare habitat (Simons-Legaard *et al.* 2016). Fragmentation of the already naturally patchy pattern of lynx habitat in much of the contiguous United States can affect lynx by reducing their prey base and increasing the energetic costs of using habitat within their home ranges. Buskirk *et al.* (2000a) identified direct effects of fragmentation on lynx to include creation of openings that potentially increase access by competing carnivores, increasing the edge between early-successional habitat and other habitats, and changes in the structural complexities and amounts of seral forests within the landscape. At some point, landscape-scale fragmentation from forest management can make patches of foraging habitat too small and too distant from each other to be effectively accessed by lynx as part of their home range. For example, in Maine the proliferation of partial harvesting will actually increase the patches of high-quality hare habitat by 57 percent, but the average size of patches will be diminished by 87 percent, and patches will become more isolated (Simons-Legaard *et al.* 2016, pp. 5-6).

Changes in Frequency and Pattern of Disturbance Events - Prior to European settlement, the dominant natural disturbance processes that created early-successional stages within the range of the lynx were wildfire, insect and disease outbreaks, and wind events (Kilgore and Heinselman 1990; Veblen *et al.* 1994; Heinselman 1996; Agee 2000; Seymour *et al.* 2002; Lorimer and White 2003). In the DPS range, fire was more important in the West and Great Lakes areas and less a factor in the Northeast, where insects and wind events predominated. Today, natural disturbances, especially fire and insect outbreaks, remain the predominant forms of disturbance in boreal forests throughout much of the lynx's range, including the western

contiguous United States, where they also influence and interact with forest management. However, forest management (i.e., timber harvest) is an important disturbance agent in some boreal forest types in the DPS range and, in some instances has greatly altered the natural disturbance regime. For example, prior to logging, the Acadian forest in Maine and eastern Canada likely exhibited forest gap dynamics similar to some parts of the West today, and true stand-replacing disturbances were quite uncommon with recurrence intervals of hundreds to thousands of years. After several centuries of forest management, stand age structures in the Acadian forest have become simplified, and commercial timber rotations (harvesting schedules) are a fraction (15 to 40 percent) of the lifespan of boreal tree species (Seymour 2002). Although the prevalence of these younger even-aged forest stands on the landscape may benefit hares and lynx in Maine, forestry has shifted the species composition of Maine's forest to tree species favored by frequent harvest disturbance, such as red maple (*Acer rubrum*), paper birch (*Betula papyrifera*), aspen (big-toothed [*Populus grandidentata*] and quaking [*P. tremuloides*]), and balsam fir (*Abies balsamea*).

3.4 Wildland Fire Management

Wildfire is a natural and essential component of boreal and montane forests that plays an important role, along with forest insects and other disturbance factors, in creating and maintaining the shifting mosaic of stand ages and forest structure across large boreal landscapes that provide snowshoe hare and lynx habitats (Agee 2000, p. 47; Ruediger *et al.* 2000, pp. 1-3, 2-5, 7-6; ILBT 2013, p. 75). Wildfire creates and maintains lynx habitats by providing periodic vegetation disturbances that result in the spatial and temporal distribution of early-successional forest stands or patches within older stands featuring dense horizontal cover at ground and snow level. These stands/patches provide high-quality hare foraging habitat and typically support high hare densities, which in turn provide high-quality lynx foraging habitat. They are generated by (1) high-intensity, stand-replacing fires that result initially in removal of all or most vegetation, followed by regeneration of dense horizontal cover, or (2) low- or moderate-intensity fires that stimulate understory development in older stands without killing all the overstory, resulting in patches of dense horizontal cover within multi-story stands (Agee 2000, p. 53; Ruediger *et al.* 2000, p. 7-6). These habitats become most favorable for hares and lynx when regenerating conifers grow tall enough to protrude above the snow, providing cover and food for hares throughout the winter (ILBT 2013, pp. 10-12). They remain important as winter foraging habitat, which may be the most limiting habitat for lynx (Squires *et al.* 2010, p. 1656; ILBT 2013, pp. 17, 27), until they reach the stem-exclusion structural stage and self-pruning results in the loss of dense horizontal cover above the snow, or until another disturbance resets them to the stand-initiation structural stage (Agee 2000, pp. 62-71; Ruediger *et al.* 2000, p. 1-3; ILBT 2013, p. 27). The length of time to achieve favorable hare and lynx habitat after fire (or other vegetation disturbance) and the duration for which those conditions persist vary across the lynx range depending on soil and vegetation potential, temperature and precipitation patterns, topography, fire intensity, and perhaps other local conditions (Agee 2000, pp. 62-71; Ruediger *et al.* 2000, p. 2-5; ILBT 2013, pp. 27-29, 75). Generally, regenerating forests in the DPS range may begin providing winter hare habitat within 10-20 years after fire or other disturbance, with favorable conditions persisting for 20-30 years after that (Koehler and Aubry 1994, pp. 86-87;

Agee 2000, pp. 67-71; Fuller *et al.* 2007, p. 1985; McCann and Moen 2011, p. 515; Vashon *et al.* 2012, p. 15; ILBT 2013, pp. 28-29), although it may take longer, perhaps 35-40 years, for lynx habitat to recover in some parts of the range (e.g., Maletzke *in* Lynx SSA 2016a, p. 21).

Fire frequencies, sizes, intensities, and return intervals also vary across the range of the lynx and depend on local vegetation communities, climatic conditions, and topography (Agee 2000, pp. 47-56; Ruediger *et al.* 2000, p. 4-8; ILBT 2013, pp. 75-76). In lynx habitats, fire intensity is typically high and fire return intervals long but variable, with large areas affected by infrequent stand-replacing fires and, in mixed fire regimes, moderate- or low-intensity fires in the intervals between stand-replacing events (Agee 2000, pp. 49-54; Ruediger *et al.* 2000, pp. 4-8, 7-6). Within the DPS range, fire return intervals in the Great Lakes Region appear similar to those in the core of the lynx's range in the Canadian and Alaskan taiga (roughly 50-150 years), with longer return intervals in Western (150-300 years) and Northeastern (up to 500 years) forests (Agee 2000, pp. 52-53; ILBT 2013, pp. 75-76). Despite these long intervals, fire is the dominant natural disturbance mechanism in lynx habitats in the DPS range except in the Northeast, where insects and wind are more important (Agee 2000, p. 53).

Current Federal wildland fire management policy recognizes fire as a natural ecological process essential to the health and resilience of some forest systems, and it attempts to balance the ecological, social, and legal aspects of wildfire (USDA and USDI 2009, p. 6). However, the prior history of fire response was largely one of active suppression for most of the last century (Zimmerman and Bunnell 2000, p. 288; USDI *et al.* 2001, p. 1-1; USDA and USDI 2003, p. 3; 68 FR 40092; Calkin *et al.* 2015, pp. 1-3) which, combined with other land-use practices, dramatically altered fire regimes in some places and created conditions prone to larger and more severe fires (USDI *et al.* 2001, p. 1-2). Because of (1) fire's important role in creating and maintaining high-quality early-successional hare habitat in most lynx habitats in the contiguous United States, (2) the potential for fire suppression to alter this dynamic to the detriment of hares and lynx, and (3) the limited ability of land managers (at that time) to use fire to benefit hares and lynx, wildland fire management was identified as a "Lynx Risk Factor Affecting Lynx Productivity" (Ruediger *et al.* 2000, pp. 2-5, 5-2). To address these concerns, the authors developed objectives, standards, and guidelines for Federal land managers to restore fire's role in maintaining lynx habitats, attempt to mimic historical natural fire regimes, and integrate lynx habitat objectives into fire management plans (Ruediger *et al.* 2000, pp. 7-6 - 7-8). They also directed Federal land managers to evaluate whether fire suppression or other management practices had altered fire regimes and ecosystem function in potential lynx habitats and, where so, to use fire (naturally ignited fires or prescribed burns) as a tool to restore and maintain lynx habitat by creating or regenerating snowshoe hare habitat (Ruediger *et al.* 2000, p. 7-7).

In its 2000 listing rule and 2003 remanded determination, the Service recognized the potential for fire suppression to adversely affect lynx and hare habitats at local and regional scales, particularly in the Great Lakes Region, where fire suppression policies across land ownerships likely prevented fire from assuming its natural role in creating a landscape mosaic of vegetation communities and age classes (65 FR 16076; 68 FR 40095). In the Northeast, the Service concluded that the very long fire return intervals and maritime influence in lynx forest types

indicated that fire did not historically play a significant role in creating or maintaining lynx and hare habitats and thus fire suppression was unlikely to have affected lynx habitat (68 FR 40094). In the West, the Service concluded that the effects of fire suppression were likely lower in lynx forest types because of their typically long fire return intervals compared to lower and drier forest types (65 FR 16074; 68 FR 40093-94). Overall, the Service concluded that fire suppression did not represent a threat to lynx in the Northeast and was a low-magnitude threat in the Great Lakes, Southern Rockies, and Northern Rockies/Cascades (65 FR 16075-16076; 68 FR 40093-40098).

In response to the guidance provided in the LCAS, the USFS, when developing the NRLMD and the SRLA to amend forest plans to address lynx conservation (see 3.1.1), evaluated whether fire suppression had adversely affected potential lynx habitats on national forests in the Northern and Southern Rockies. The USFS concluded that many forests in potential lynx habitat are in Condition Class 1, which means they have not missed a fire cycle because large, stand-replacing fire only occurs every 100 to 200 years; the long fire return interval has not been affected to any large degree by more recent fire suppression as is the case in drier forests with short fire return intervals; and they are close to historical conditions (USFS 2007, pp. 18, 20; USFS 2008a, p. 11). In addition to the national forests covered by the NRLMD and SRLA (all national forests in the Northwestern Montana/Northeastern Idaho, GYA, and Western Colorado geographical units), the Superior National Forest, which accounts for 45 percent of the Northeastern Minnesota unit, revised its forest plan to adopt lynx conservation measures consistent with the LCAS (USFS 2004a, Appendix E). The Okanogan-Wenatchee National Forest in the North- central Washington unit is currently revising its management plan and continues to manage for lynx conservation in accordance with the LCAS, including direction to restore fire to its natural ecological role and to use it as a tool to restore and maintain hare and lynx habitats.

As described above in section 3.1.1, current Federal management on most USFS and BLM lands, in accordance with formally revised or amended management plans, includes limits on the proportion of lynx habitat within LAUs that can be in an unsuitable condition at any given time, including such conditions, usually temporary, created by wildfire. Although some exemptions and exceptions to these limits are permitted for activities to reduce fire risks to communities and infrastructure in the wildland-urban interface (WUI) or to achieve other resource benefits, even these potential impacts are limited on the larger landscape scale (USFWS 2007, p. 7). These conservation measures and the direction to use fire management (as well as timber harvest/vegetation management) as a tool to restore hare and lynx habitats and return to natural temporal and spatial patterns of fire disturbance, which were not in place when the DPS was listed, likely further reduce what was even then considered the low potential threat to lynx of past fire suppression activities. Based on the information above, we conclude that fire suppression and other fire management activities have not substantially impacted lynx and hare habitats in the DPS range and are unlikely to do so in the future.

However, warming temperatures attributed to climate change are reducing snowpack, causing earlier snowmelt and longer and more extensive droughts, resulting in longer wildfire seasons

and increased fire frequency, size, and intensity in boreal forests of the north and in boreal and montane forests in some parts of the DPS range (Weber and Flannigan 1997, entire; Stocks *et al.* 1998, entire; Gillett *et al.* 2004, entire; Kasischke and Turetsky 2006, entire; Soja *et al.* 2007, entire; Pierce *et al.* 2008, entire; Flannigan *et al.* 2009, entire; Krawchuk *et al.* 2009, entire; Le Goff *et al.* 2009, entire; Bergeron *et al.* 2010, entire; Salathe *et al.* 2010, entire; Abatzoglou 2011, entire; McKelvey *et al.* 2011, entire; Abatzoglou and Kolden 2013, entire; Pederson *et al.* 2013, p. 1815; Price *et al.* 2013, pp. 342-343, 352-354; Barbero *et al.* 2014, entire; Trenberth *et al.* 2014, entire; Barbero *et al.* 2015, entire; Jolly *et al.* 2015, entire; Lute *et al.* 2015, entire; USEPA 2015, entire; Lienard *et al.* 2016, entire; Littell *et al.* 2016, entire; Westerling 2016, entire; see also section 3.2 above). Increases in fire frequency and size have the potential to adversely affect lynx and hare habitats in the DPS range by rapidly converting large areas to the temporarily unsuitable stand-initiation successional stage, thus reducing the amount and altering the distribution of higher-quality habitats (ILBT 2013, p. 70). Although this would likely be a temporary impact, with burned areas subsequently regenerating into higher-quality habitat, it would likely reduce landscape-level hare densities and therefore lynx numbers, potentially compromising an area's ability to support a resident lynx population until burned habitats recover.

Because lynx habitats are naturally patchily-distributed and landscape-level hare densities already naturally marginal in many parts of the DPS range, it is possible that very large wildfires or many fires over a short time period could, perhaps in concert with other influencing factors, cause a shift in habitats in a given area from just barely capable of supporting a resident lynx population to no longer capable of doing so, resulting in extirpation. For example, as described in sections 2.3.2.2 and 4.2.4, large fires in Unit 4 during the past few decades have burned over a third of lynx habitat (Lewis 2016, pp. 4-6), increasing lynx home range size and reducing carrying capacity (Maletzke *in* Lynx SSA 2016, p. 21). If additional large fires occur in this unit before previously burned areas recover (10-40 years post-burn), carrying capacity and the lynx population would likely decline, further reducing the likelihood that resident lynx will persist (Lewis 2016, pp. 5-6; Lynx SSA Team 2016a, p. 44; also see sections 4.2.4 and 5.2.4). The loss of habitat resulting from these fires and its potential demographic impacts on the State's only resident lynx population contributed substantially to the WADFW's recent recommendation, and the State Fish and Wildlife Commission's decision, to uplist lynx from threatened to endangered under its State Endangered Species Program (Lewis 2016, entire; WAFWC 2016, p.3).

Wildfire frequency, size, and intensity have also increased in the Northwestern Montana/ Northeastern Idaho geographic unit, where about 4,172 km^2 (1,611 mi^2; over 15 percent of the unit) have burned in western Montana from 2000-2013 (Squires *in* Lynx SSA Team 2016a, p. 20). Large fires have also impacted lynx habitat in the Western Colorado geographic unit, where fire size, frequency, and intensity are expected to increase with climate change (Ivan *in* Lynx SSA Team 2016a, p. 23). As mentioned in section 2.3.2.2, large areas of the GYA unit were burned by the extensive wildfires of 1988. The extent to which those fires may have diminished lynx and hare habitats and contributed to the recent absence of resident lynx is uncertain, as is the potential for those burned areas to support high hare densities and resident lynx in the future. However, some burned areas may soon develop the dense horizontal conifer structure

favorable for hares and therefore for lynx foraging habitat, perhaps increasing the likelihood that they may support resident lynx in the near future.

Fire suppression was in the past thought to be a potential risk factor for lynx in the DPS range. However, given the trends discussed above and the likely continued increase in future fire activity related to projected continued climate warming, it may be necessary to reconsider whether fire suppression in some lynx habitats could benefit lynx by reducing the potential for extirpation of lynx populations, especially in places already affected by increased fire activity and those that are naturally only marginally capable of supporting resident lynx.

3.5 Habitat Loss and Fragmentation

Habitat loss for lynx is, generally, the conversion of boreal forest to another land use or vegetative cover. Fragmentation, which may involve permanent or temporary habitat loss, has been variously defined to describe a reduction of total area, increased isolation of patches, and reduced connectedness among patches of natural vegetation (Rolstad 1991; ILBT 2013, p. 76). "Patchiness" is sometimes used to refer to natural processes (Buskirk *et al.* 2000a, p. 85), whereas "fragmentation" refers to anthropogenic disruption of natural patterns. Boreal forest habitats in most parts of the DPS range are naturally patchy (ILBT 2013, p. 76) and marginal for both snowshoe hares and lynx compared to the northern cores of both species' ranges. In the northern contiguous United States, boreal forest transitions to various types of northern hardwood forest in the Northeast and Great Lakes Region and to drier, more temperate montane forests in the West. The transitional nature of the boreal forest at its southern extent is believed (along with competition from other hare predators) to limit the numbers of both hares and lynx, preventing either from achieving densities comparable to those regularly achieved (except during the low of the hare population cycle) in the classic boreal forests in the cores of both species' ranges in Canada and Alaska (Wolff 1980, pp. 123–128; Buehler and Keith 1982, pp. 24, 28; Koehler 1990a, p. 849; Koehler and Aubry 1994, p. 84; 79 FR 54790).

Forest loss and fragmentation are relatively low in the DPS range compared to other forested regions in the United States (Heilman *et al.* 2002, p. 416). Since 2000 in the western United States, land uses associated with residential development, roads, and highway traffic have resulted in a 4.5 percent (20,000 km^2 [7,722 mi^2]) loss in forest area, and continued expansion of residential development will likely reduce forested patches by another 1.2 percent percent by 2030 (Theobold *et al.* 2011, entire). Human-caused fragmentation in the forested western landscape resulted in a decline of weighted mean patch size from roughly 35,000 km^2 (13,514 mi^2) to 3,200 km^2 (1,236 mi^2) from natural to current conditions, but models predict relatively small declines in the size of forested patches over the next 30 years (Theobold *et al.* 2011, p. 2451). In the eastern United States, nearly half or more of the natural forest was cleared in the past 3 centuries, but as agriculture and settlement relocated westward and some eastern farmlands were abandoned, eastern forest cover rebounded (Williams 1989; Smith *et al.* 2005). Similarly, a large portion of Minnesota's forests was cleared in the last century and, although overall forest cover has rebounded, the forested area in northern Minnesota has decreased 4 percent since 1977 (Miles *et al.* 2007, p. 22). Future trends portend increased human population

and declining forestland in the United States (Haynes 2003), but whether and to what extent forest conversion will affect boreal forest habitat in the DPS is uncertain.

Effects of Fragmentation - Canada lynx seem to be flexible in their response to habitat fragmentation, whereas closely related species, such as bobcats and Iberian lynx, are sensitive to habitat fragmentation (Ferreras 2001; Crooks 2002). In southern Ontario, Hornseth *et al.* (2014, pp. 8-9) demonstrated that lynx exhibited a wide range of responses to habitat alteration. In general, lynx responded most positively to areas having greater than 50 percent suitable habitat and generally avoided areas having less than 30 percent suitable habitat. However, lynx showed no sensitivity to the degree of forest fragmentation in areas of high or low suitable habitat.

In the DPS range, lynx achieve highest densities in landscapes having a high percentage of large, contiguous patches of high-quality hare habitat (Simons 2009; Simons-Legaard *et al.* 2013). Throughout the DPS range, landscapes with more contiguous boreal forest habitat support more snowshoe hares than fragmented landscapes, and lynx select habitats that improve their foraging opportunities (Moen *et al.* 2008; Vashon *et al.* 2008a; Simons 2009; Fuller and Harrison 2010; Squires *et al.* 2010; Lewis *et al.* 2011, p. 565; ILBT 2013, p. 77). During winter, coarse-scale habitat selection by lynx in Maine maximized their access to snowshoe hares (Fuller and Harrison 2010; ILBT 2013, p. 77). In Montana, lynx similarly selected habitat patches that supported snowshoe hares and in winter avoided recent clearcuts or other open patches (Squires *et al.* 2010; ILBT 2013, p. 77). Several other studies documented lynx avoidance of large openings, especially during winter, probably because such habitats are rarely used by hares and would not, therefore, attract foraging lynx (Koehler 1990a; Mowat *et al.* 2000; von Kienast 2003; Maletzke 2004; Squires and Ruggiero 2007; ILBT 2013, p. 77). Koehler (1990a) suggested that lynx movements and habitat use patterns could be altered temporarily by vegetation management that creates large distances (> 100 m [328 ft]) to forested cover (ILBT 2013, p. 77).

Throughout the northern part of their range, snowshoe hares are found in vast areas of boreal forest interspersed with occasional bogs and fens and water that are less preferred. Conversely, southern hare populations (including most in the DPS range) occur primarily in insular patches of suitable habitat set amidst large areas of less-preferred habitats (Wolff 1980; Keith *et al.* 1993). This disparity has led a number of biologists to speculate that habitat fragmentation ultimately may be responsible for the non-cycling nature of snowshoe hare populations in southern Canada and the northern contiguous United States (Dolbeer and Clark 1975; Buehler and Keith 1982; Keith *et al.* 1993; Strohm and Tyson 2009). Wolff (1980, 1981) described the mechanism by which a fragmented habitat might dampen or eliminate cyclic population fluctuations. The patchy distribution and generally lower densities of hares in many parts of the contiguous United States require lynx in most areas of the DPS range to maintain larger home ranges than lynx in the core of the species' range (Mowat *et al.* 2000, pp. 265, 277–278). Larger home ranges likely require more energy output associated with greater foraging effort to acquire adequate food (Apps 2000, p. 364) and may expose lynx to increased risk of predation and

other mortality factors such as roads and trapping. At some point, landscape hare densities become too low, making some areas incapable of supporting lynx.

Snow, also an important component of lynx habitat (79 FR 54809), can be patchily-distributed, variable and unpredictable from year to year, and affected by local topography, water bodies, and climate gradients. Snow depth (Hoving *et al.* 2005; Peers *et al.* 2013, entire) and persistence (Gonzalez *et al.* 2007) are believed to give lynx a competitive advantage over generalist predators in the contiguous United States. The snow environment in much of the DPS range is patchy and marginal in both space and time for snowshoe hares and lynx. Too little snow or crusting conditions may favor potential competitors and predators like bobcat, fisher, and coyotes. High elevations may provide snow conditions that favor lynx, whereas lower elevations may favor conditions for competitors. Snow conditions that provide lynx a competitive advantage over other terrestrial hare predators are most consistent in the high-elevation regions of the western United States, although snow alone does not constitute lynx habitat (i.e., many places receive sufficient snow but lack other features lynx need, typically adequate hare densities). Lynx likely have a competitive advantage at higher elevations in the DPS in the winter, but not in summer months when potential competitors have increased access to all habitats. Snow conditions are less consistent in the East. For example, lake-effect snow from Lake Superior can increase snow depth and duration in northeastern Minnesota in some years but not in others. The Gulf of Maine has the reverse effect, and its warming influence reduces snow depth and duration inland. Distribution models by Hoving (2001, p. 74) indicate that eastern Maine has extensive areas of boreal forest, but they do not achieve snowfall conditions associated with lynx presence in other parts of the state, and lynx are rarely found there.

Naturally patchy forests and those fragmented by humans may exacerbate competition between lynx and other predators (Buskirk *et al.* 2000a, entire). Forest patchiness, fragmentation, and competition are strongly linked because vegetation mosaics in landscapes provide high-quality environments for generalist species such as the bobcat, red fox, and coyote (Goodrich and Buskirk 1995; Buskirk *et al.* 2000a, p. 84), and generalist predators tend to dominate the predator guild in patchy or fragmented landscapes (Oehler and Litvaitis 1996). Hares fluctuate less dramatically in the southern part of the lynx range, thus there is more competition for a limited resource and exploitation competition could be inflicted by generalists (e.g., coyotes) and other predators (Buskirk *et al.* 2000a, p. 95). Snowshoe hares in the south are concentrated in isolated patches of suitable habitat and subject to predation by a suite of generalist predators (e.g., Litvaitis *et al.* 1985; Sievert and Keith 1985; Keith *et al.* 1993; Cox *et al.* 1997). Keith *et al.* (1993) found that an extremely high predation rate on hares living in high-quality habitats seemed to be driving the changes in distribution and abundance in a snowshoe hare population in Wisconsin, rather than predation on naturally dispersing individuals. In that study, predation pressure on hare populations occupying small (< 7 ha [< 17 ac]) patches of preferred habitat was so severe that 3 of the 5 populations under investigation were extirpated in the course of the 3-year study. Fragmentation exacerbates the effect of predation by allowing carnivores to concentrate their hunting efforts on small patches of habitat used by their preferred prey instead of preying disproportionately on dispersing individuals (Wirsing *et al.* 2002, p. 170). In predator-

rich landscapes characteristic of the DPS, this can result in intense predation and competition for a limited prey resource.

Landscape features further fragment hare and lynx habitat. In the western geographic units, potentially suitable boreal forests and appropriate snow conditions occur in relatively narrow elevational bands in the Cascade and Northern and Southern Rocky Mountains (McKelvey *et al*. 2000a, pp. 243-246). Thus, lynx habitats are naturally fragmented by topography and vegetation gradients. These "islands" of habitat can be extensive (e.g., the Okanagan in Washington or most of northwestern Montana) or smaller and relatively isolated (e.g., the Garnet Range in western Montana) depending on topography and precipitation patterns. Some of these areas of boreal forest are separated by unsuitable habitats in the low valleys (e.g., sage flats, urban corridors, agricultural lands) or by snow regimes (e.g. snow shadows) that may discourage lynx dispersal between habitat patches (although verifed records of lynx in many parts of the contiguous United States and long-distance dispersal of lynx released in Colorado demonstrate that lynx at least occasionally navigate such habitats). In some western parts of the DPS range, lynx habitat is also fragmented by rugged, high elevation terrain (Carroll *et al.* 2001, p. 976). In most areas of the DPS, including Maine and Minnesota where there is little topography, lynx travel through a "matrix" of less suitable forested areas as they move between areas of higher-quality habitat. Large rivers are unlikely to fragment habitat as lynx readily swim across large bodies of water (Feierabend and Kielland 2014, entire) or cross them on ice in the winter (Koen *et al.* 2015).

As described above, both lynx and hares are influenced by the spatial arrangement of preferred habitat. Lynx populations are clearly most viable in areas having extensive and relatively unfragmented boreal forest habitats with large patches of high-quality foraging (hare) habitat and persistent deep, unconsolidated snow. Similarly, individual lynx have the smallest home ranges and greatest survival and productivity in landscapes that have extensive, large patches of habitat in combination with deep, fluffy snow. The factors described above create a naturally patchy distribution of high-quality lynx habitat thoughout much of the DPS range, resulting in generally lower reproductive output and a more tenuous conservation status for lynx in many parts of the DPS relative to those in Canada and Alaska (Buskirk *et al.* 2000a, p. 95). Thus, human activities, described below, that increase boreal forest fragmentation may further reduce the quality of lynx habitat that is already naturally marginal thoughout much of the DPS range, perhaps reducing the likelihood that resident lynx populations will persist.

Anthropogenic Sources of Fragmentation - Human activities can exacerbate the naturally-patchy habitat that is typical throughout much of the DPS range. Anthropogenic activities such as forest management, development, and highways alter natural landscape patterns. They cumulatively can reduce the total area of habitat, diminish the quality of habitat, increase the isolation of habitat patches, and impair the ability of lynx and other wildlife to effectively move between patches of habitat. Anthropogenic fragmentation may be permanent, for example by converting forest habitat to residential, industrial, or agricultural purposes, or temporary, for example by conducting forest management but allowing trees and shrubs to regrow. Habitat

fragmentation (both natural and anthropogenic) increases the risk of extirpation of small lynx populations.

Human-caused fragmentation of the already naturally patchy pattern of lynx habitat in the contiguous United States can affect lynx by reducing their prey base and increasing the energetic costs of using habitat within their home ranges. Buskirk *et al.* (2000a) identified direct effects of fragmentation on lynx to include creation of openings that potentially increase access by competing carnivores, increasing the edge between early-successional habitat and other habitats, and changes in the structural complexities and amounts of seral forests within the landscape. At some point, landscape-scale fragmentation can make patches of foraging habitat too small and too distant from each other to be effectively accessed by lynx as part of their home range. Maintaining a mosaic of large (> 40 ha [100 ac]) patches of young to old stands in patterns that are representative of natural ecological processes and disturbance regimes would be conducive to long-term conservation of lynx (ILBT 2013, p. 77).

Roads, development, climate change, and forest management fragment snowshoe hare and lynx habitat in the DPS. We know little about how hare and lynx respond to these anthropomorphic changes to their habitat, which requires additional research (Murray *et al.* 2008, p. 1464; Squires *et al.* 2013, p. 194). In the next decades, southern lynx populations will likely incur further habitat loss and fragmentation from these and other factors. Changes in habitat, prey base, and perhaps competitor guild will likely impact lynx populations in the DPS and in southern Canada.

Roads - Paved highways fragment lynx habitat. They surround large areas of lynx habitat in Minnesota and northern Maine. In the West, they typically follow natural features such as rivers, valleys, and mountain passes that may have high value for lynx in providing habitat or connectivity. Nonetheless, the density of paved roads is generally low in most lynx habitat in the DPS range. Various studies have documented lynx crossing highways. A male lynx in western Wyoming was documented to have successfully crossed several 2-lane highways during exploratory movements (Squires and Oakleaf 2005). However, in Alberta, Canada, high road densities, human activity, and associated developments appeared to reduce the habitat quality based on decreased occupancy by lynx (Bayne *et al.* 2008). Apps *et al.* (2007) found lynx were 13 times less likely to cross the Trans-Canada Highway (a 4-lane highway) relative to random expectation, but only 2.2 and 3.1 times less likely to cross smaller 2-lane highways (93 and 1A, respectively). In southeastern British Columbia, lynx avoided crossing highways within their home ranges (Apps, 2000). Squires *et al.* 2013 (p. 194) documented 44 radio-collared lynx with home ranges within an 8 km buffer of 2-lane highways; however, only 12 of these individuals crossed the highway. Paved highways also pose a risk of direct mortality to lynx and may inhibit lynx movement between previously connected habitats. If lynx avoid crossing some highways, this could lead to a loss of effective habitat within a home range and reduced interaction within a local population (Apps *et al.* 2007). Lynx and other carnivores may avoid using habitat adjacent to highways, or become intimidated by highway traffic when attempting to cross (Gibeau and Heuer 1996; Forman and Alexander 1998).

Carnivores are especially vulnerable to highway-caused mortality in areas with dense and high traffic volume roadways (Clevenger *et al.* 2001). As the standard of roads increases from single-lane gravel to 2-lane or 4-lane highways, traffic volumes and the degree of impact are expected to increase. Walpole *et al.* (2012, p. 770) found that small logging roads with low traffic volume had no effect on lynx distribution, and lynx in Nova Scotia followed road edges for considerable distances (Parker 1981, p. 229). In Maine, lynx occasionally travel on unplowed logging roads during winter, but these roads and their associated edge habitat were selected against within home ranges (Fuller *et al*. 2007, p. 1983). Lynx killed fewer hares near logging roads in Maine likely because hare density was lower there than in adjacent un-roaded habitats (Fuller *et al*. 2007, p. 1985; Fuller and Harrison 2010, p. 1274) or possibly because of increased potential for interactions with generalist competitors suchs as coyotes (Fuller *et al*. 2007, p. 1985). In Minnesota, Moen *et al*. (2010b) found that lynx selected for roads during long-distance movements. Although roads may not be essential to these movements, lynx appeared to benefit energetically from the use of these linear features. Squires *et al*. (2008) reported that lynx denned farther from all roads compared to random expectation.

Four-lane highways, such as the interstate highway system, commonly have fences on both sides, service roads, parallel railroads or power lines, and impediments like "Jersey barriers" that make successful crossing more difficult, or impossible, for wildlife (ILBT 2013, p. 78). Alexander *et al.* (2005) suggested traffic volumes between 3,000 and 5,000 vehicles per day may be the threshold above which successful crossings by carnivores are impeded. In Colorado, lynx successfully and repeatedly crossed major highways, including I-70 (Ivan 2011c; 2011d; 2012). Colorado lynx crossed 2-lane highways an average of 0.6 times per day and more frequently during dusk and at night when traffic volume was lower (Baigas *et al.* 2017, p. 204). They also crossed 4-lane highways (I-70), especially in forested areas under large, elevated bridges that spanned streams (Baigas *et al.* 2017, p. 204).

Between 2000 and 2015, 54 lynx were reported to have been killed on roads (both paved and unpaved) in Maine (Vashon, MDIFW, *unpubl. data*), 9 in Minnesota (and 2 hit by trains; USFWS 2016b, *unpubl. data*), 1 in Idaho, and 5 in Montana (USFWS 2016c, *unpubl. data*). Between 1995 and 2011, 15 lynx were reported killed on British Columbia highways (British Columbia Wildlife Accident Reporting System 2012, as cited in ILBT 2013, p. 78). Most of these mortalities are on higher-speed paved highways. However, in Maine, about 41 percent (22 of 54) were killed on dirt logging roads with low traffic volumes and lower speed limits. In Minnesota, 2 lynx were killed on backcountry railroads and 2 on unpaved forest roads. Backcountry roads also provide human access into lynx habitat where incidental trapping or illegal shooting can occur.

Translocated lynx may be more vulnerable to road mortality than resident lynx (Brocke *et al.* 1991, p. 308), because they often move extensively after their release and are unfamiliar with their surroundings (ILBT 2013, p. 78). In the Adirondack Mountains of New York, an attempt to reintroduce lynx failed and 18 of 37 documented mortalities (among 83 lynx released over 3 years; Brocke *et al*. 1993, p. 1) were attributed to road kills (Brocke *et al.* 1991, p. 308; ILBT 2013, p. 78). Over a 7-year period in Colorado, 13 of 102 documented mortalities of translocated lynx were the result of vehicle collisions on highways (Devineau *et al.* 2010, p.

528). Traffic volumes on those Colorado highways were estimated to range from about 2,300 to > 25,000 vehicles per day (USFWS 2016c, *unpubl. data*, p. 1).

In summary, roads of all sizes may have direct (e.g., habitat loss and fragmentation, vehicle collisions) as well as indirect effects to lynx. The latter may include increasing human access, potentially resulting in increased incidental trapping and illegal shooting; creating edge habitats that may promote co-occurrence with potential competitors like coyotes and bobcats (Bayne *et al.* 2008, p. 1195); reducing prey densities; and influencing lynx behavior, both detrimentally (avoidance) and beneficially (energetic savings during long-distance movements). Although potential adverse impacts of roads in lynx habitats likely outweigh any potential benefits, thus far population-level impacts of roads have not been demonstrated among DPS lynx populations.

Vegetation Management - As described above in section 3.3, forest management can further fragment boreal forest in the northern contiguous United States, potentially affecting habitat suitability for both snowshoe hares and lynx. Large-scale forest fragmentation or maturation can be detrimental to snowshoe hares because both can cause hares to become increasingly restricted to remaining small patches with adequate cover, where higher predation rates from a variety of carnivores tend to increase local hare extinction risk (Wolff 1981; Keith *et al.* 1993; Wirsing *et al.* 2002; see also Barbour and Litvaitis 1993, entire). Although forest management can benefit lynx if it creates, maintains, or restores a shifting mosaic of high-quality habitat, it can also be detrimental if it fragments habitat into small, widely-spaced parcels. Changes to vegetation structure can influence lynx movements; in Montana, fragmentation from forest thinning decreased the probability of lynx movements across the forested landscape (Squires *et al.* 2013, p. 192). Lynx in the Northern Rockies also seem sensitive to changes in forest structure and avoid large forest openings like recent clearcuts and thinned areas, particularly in winter (Koehler, 1990a; Squires *et al.* 2010). Modeling in Maine suggests that the shift from clear-cutting to partial harvesting will likely increase the number of patches of high-quality hare habitat but greatly reduce the size of patches and increase their isolation (Simons-Legaard *et al.* 2016, pp. 5-6), thus diminishing landscape habitat quality for lynx. See section 3.3 for further discussion of vegetation management as a potential source of habitat fragmentation.

Residential and Commercial Development - Residential and commercial development is increasing on private forest lands. Increased traffic and urbanization are projected for the Northern Rockies (Hansen *et al.* 2002) and Maine (also see section 5.2.1). It is uncertain to what degree lynx can tolerate habitat fragmentation from roads and clearing forest for development, and how human and pet activity associated with development may affect lynx use of habitats. Some anecdotal information suggests that lynx are quite tolerant of humans, although given differences in individuals and contexts, a variety of behavioral responses to human presence may be expected (Staples 1995, Mowat *et al.* 2000). The degree to which residential development and associated roads reduce connectivity of mesocarnivore populations (including lynx) likely depends on the physical design of highway improvements, the surrounding environmental features, the density of increased urbanization, and the increased traffic volume (Clevenger and Waltho, 2005; Grilo *et al.* 2009).

Ski area development also results in permanent habitat loss and fragmentation. One ski run is often separated from the next only by small inter-trail forest islands. Ski runs often are intermixed with other open areas such as open or gladed bowls, rock outcrops, or barren tundra ridges. Ski resorts that are built or expanded in lynx habitat may impact lynx by removing forest cover, reducing the snowshoe hare prey base, and creating or increasing human disturbance in or near linkage areas. There is limited information on lynx behavior and habitat use in and around ski areas. Lynx have been known to incorporate smaller ski resorts within their home ranges, but may not utilize the large resorts. Preliminary information from an ongoing study in Colorado suggests that some recreational use may be compatible, but lynx may avoid some areas with concentrated recreation use. In some areas, lynx habitat may be limited and concentrated in the ski area development footprint (ILBT 2013, p. 55). More than 50 ski areas exist throughout the range of the lynx in the contiguous United States (ILBT 2013, pp. 82-83). Most ski areas are located on north-facing slopes, where ample snow conditions provide for extended ski/snowboard recreational seasons. In the western states, many of these landscapes feature spruce-fir forests. While ski resorts occupy a small proportion of the landscape, spruce-fir forests provide important habitat for snowshoe hares and lynx at the southern extent of their range. In winter, alpine and Nordic skiing and snowboarding are the primary uses. Most of these resorts offer year-round recreation, with summer activities typically including hiking and mountain biking. Despite concerns regarding ski-area impacts to lynx, they have affected only a tiny fraction of potential lynx habitats in the DPS range, and no population-level effects of ski areas or related recreation activities have been demonstrated for DPS lynx populations.

Mineral Extraction – Mining and oil and gas exploration and production activities occur primarily within the western units of the DPS although there is increased interest in mining in the Minnesota and Maine units. Lynx habitats may be lost and fragmented as a result of mining, similar to other development: loss of boreal forest; construction of roads, railroads, and transmission lines; and increased human access and disturbance where lynx occur. In the West, for example in the Wyoming Range (Unit 5), extensive oil and coal bed methane development can affect large areas of landscape (e.g., 1 well per 2-4 ha (5-10 ac) and could diminish potential lynx habitat in some areas. Open pit and subsurface mines can affect from tens to thousands of hectares of habitat. To reduce effects of mineral development, land exchanges are sometimes implemented to consolidate private land ownership of the surface above a deposit to be mined. Depending on the lands exchanged, this could retain lynx habitat in public ownership. Surface deposits of minerals and gravel for forest road construction are excavated within some lynx areas and vary from a single truck load to tens of acres. Although mining and oil and gas development can result in loss and fragmentation of lynx habitats, thus far, effects to DPS lynx populations have not been demonstrated.

Wind Energy - Wind energy development and associated transmission lines are increasing across the nation and could affect lynx habitats. Facilities are often located on ridge tops or other areas exposed to consistent wind. Construction of wind facilities, including access roads, clearing for turbines, and transmission lines, may result in loss of lynx habitat and increased fragmentation from permanent forest clearings. Noise and human activity associated with the construction and operation of wind facilities could disturb or displace lynx from important

habitats. Effects would likely continue through the life of the project, which may exceed 20 years. Wind energy development has occured in some areas of the lynx DPS but has effected relatively small amounts of lynx habitat. Despite being a potential source of additional habitat loss and fragmentation, there is no information to suggest that wind energy development has had population-level effects on lynx in the DPS range.

Utility Corridors - Utility corridors contain developments such as overhead or buried powerlines and gas pipelines, and often are located within or adjacent to existing road rights-of-way. Utility corridors potentially could have short- or long-term impacts to lynx habitats, depending on location, type, vegetation clearing standards, and frequency of maintenance. Those that are extensively cleared of vegetation and maintained in grass or herbaceous vegetation likely equate to a permanent habitat loss. When associated with highways and railroads, utility corridors may further widen rights-of-way. Utility corridors can facilitate human access into previously remote areas potentially exposing lynx to increased trapping, illegal shooting, or other human disturbance. In most instances, naturally-vegetated utility corridors are less than 300 m (984 ft) wide and would not be expected to block lynx movements. Despite being a potential source of additional habitat loss and fragmentation, there is no information to suggest that impacts from utilitiy corridors have had population-level effects on lynx in the DPS range.

Agriculture - Agricultural activity currently is not expanding in lynx habitat areas and has decreased in some parts of the DPS range. For example, the amount of farmland in northern Maine has declined by over 75 percent, from over 1.2 million ha (3 million ac) in the late 1800s, to about 283,000 ha (700,000 ac) early this century (Ahn *et al.* 2002, p. 8). Most of the current farming is in northeastern Maine, where it fragments the forested landscape corridor between core habitats in northern Maine and western New Brunswick. However, lynx have been documented dispersing through this landscape (J. Vashon, Maine Department of Inland Fisheries and Wildlife, *unpubl. data*). Forest clearing for agriculture also may have contributed (along with increasing road densities and an expansion in coyote distribution) to the recent contraction in the southern part of lynx range in eastern Alberta (Bayne *et al.* 2008, p. 1195). Overall, agricultural activities occur at very low levels within potential lynx habitats in the DPS range, and no impacts to DPS lynx populations have been demonstrated.

Habitat Loss and Fragmentation in Corridor Areas Connecting Lynx Populations in the DPS with Adjacent Populations in Canada - Lynx conservation in the contiguous United States is thought to depend in part on maintaining connectivity with habitat areas and lynx populations in Canada. Maintaining connectivity for lynx may become increasingly difficult because of climate change and other anthropogenic influences, as evidenced by reduced connectivity for other boreal species (van Oort *et al.* 2011). Potential corridors have been identified in the northern Rockies (Squires *et al.* 2013, entire). There are likely broad forested corridors with suitable dispersal habitat connecting core habitats in Maine to southern Quebec and northern New Brunswick, and northern Minnesota to southern Ontario. Given the perceived importance of lynx immigration from Canada to the persistence of the DPS (FR 68 40076– 40101; Squires *et al.* 2013, p. 187), roads and other forms of habitat loss and fragmentation that may impede lynx movements in the border regions of Canada and the United States are of concern.

Summary - Although lynx responses to forest management and forest roads are relatively well understood (e.g., Simons-Legaard *et al*. 2016, entire; sections above), their response to other human activity and types of development remain poorly understood. Nearly all studies of lynx in North America occurred in remote areas where human activity and development are minimal. In more developed areas of the DPS range, lynx may have to balance selection for prey density against mortality risk from humans. For example, in a developed landscape in Norway, Eurasian lynx demonstrated a trade-off in habitat selection, avoiding areas near human development despite high prey (roe deer, *Capreolus capreolus*) densities, and instead selecting areas with intermediate prey abundance and lower levels of human disturbance (Basille *et al*. 2009, pp. 687-690). Their occurrence in areas having intermediate human occupancy (Basille *et al*. 2009, p. 687) confirms their ability to live in relatively human-modified habitats. Because lynx and snowshoe hares in North America are not typically associated with human development, it is uncertain whether Canada lynx would make similar trade-offs between prey density and risks associated human activity.

Overall, most lynx habitats in the DPS range are naturally fragmented, which limits the abundance and density of both hares and lynx. The largest source of anthropogenic fragmentation throughout the DPS range is vegetation management (timber harvest and related silvicultural treatments), which has thus far benefitted lynx in northern Maine by creating optimal hare (and thus lynx foraging) habitat. In other geographic units, there have likely been localized adverse (and potentially some beneficial) impacts of vegetation management to lynx habitats and perhaps individual lynx. However, we find no evidence that habitat loss and fragmentation from forest management or other anthropogenic activites have had population-level negative consequences for resident lynx in the DPS range or resulted in extirpation of lynx from areas that previously supported persistent resident populations. That said, many parts of the DPS range seem naturally only marginally capable of supporting resident lynx populations, and it is possible that relatively low levels of anthropogenic habitat loss and fragmentation, in addition to natural fragmentation, could diminish landscape-level hare densities to the point that resident lynx populations may be unable to persist.

Chapter 4: Current Conditions

In this chapter, we present our understanding, based on the best available scientific information, including the professional judgment and opinions of lynx experts, of the current status of the lynx DPS in terms of redundancy, representation, and resiliency. We then provide brief summaries of the current conditions in each geographic unit, followed by a more detailed evaluation of the status of lynx populations and habitats and the factors currently believed to influence them in each unit. Where appropriate, we compare our current understanding to what was known or believed when the DPS was listed under the ESA in 2000 and to our understanding of historical conditions.

4.1 Summary of Current Conditions DPS-wide

Because of the limitations and uncertainty in the historical records of lynx occurrence in the contiguous United States (described above in section 2.3.2.1), it is difficult to compare the current distribution and status of resident lynx populations in the DPS with what may have been the historical condition (but see evaluation in section 2.3.2.2). However, research and surveys over the last 2 decades have significantly improved our understanding of the current distribution, habitats, and the status of resident populations compared to what was known when the DPS was listed in 2000. For example, although we knew there were some resident lynx in Maine (Unit 1), we lacked information on the quality and distribution of lynx and hare habitats and the potential number of lynx. We now know this unit currently has large areas of high-quality habitat created by the regeneration of areas of extensive clear-cutting in the 1970s and 1980s in response to a large spruce budworm outbreak, that there are probably more lynx in Maine now than was likely under historical natural disturbance regimes and habitat distributions, and that currently this unit probably supports the largest resident lynx population in the DPS. Similarly, when the DPS was listed, we were uncertain whether Minnesota (Unit 2) supported a resident population. We now know that a persistent population occupies the northeastern corner of the state. Research also suggests that lynx and habitats in the western United States (Units 3, 4, 5, and 6) are naturally less abundant and more patchily-distributed than was thought at the time of listing, and several areas thought to have historically supported small resident populations currently do not (the GYA [Unit 5], the Garnet Mountains in western Montana [Unit 3], and the Kettle Mountains of northeastern Washington). We also know that recent extensive wildfires in north-central Washington (Unit 4) have substantially reduced (probably temporarily) the amount of high-quality lynx habitat and likely caused a decline in lynx numbers there. Finally, as a result of the release of 218 Canadian and Alaskan lynx from 1999-2006 and the subsequent survival and reproduction of some of these lynx and some of their offspring, resident lynx currently occupy parts of western Colorado (Unit 6), although the current number of lynx there is uncertain.

With regard to redundancy, defined as the ability of the DPS to withstand catastrophic events, we find that the current broad distribution of resident lynx populations in large, geographically discrete areas makes the DPS invulnerable to extirpation caused by a single catastrophic event. The DPS range currently spans the northern contiguous states from Maine to Washington and south along the Rocky Mountains to southern Colorado. Resident breeding lynx populations currently occupy 5 of the 6 geographic units (all but the GYA; fig. 1). Of the 5 occupied units, 4 are larger than 20,000 km^2 (7,722 mi^2), and the other (North-central Washington) is over 5,000 km^2 (1,931 mi^2; see tables 2 and 3). Our analyses and lynx expert imput indicate no single catastrophic event that could result in the functional extirpation (loss of the ability to support resident lynx populations) of the entire DPS and, further, no or a very low likelihood of functional extirpation of any of the individual geographic units caused by a single catastrophic event (Lynx SSA Team 2016a, p. 56).

Because we lack evidence that resident lynx populations have been lost from any other large geographic areas in the contiguous United States, it also seems that redundancy in the DPS

has not been meaningfully diminished from historical levels. That is, the loss of resident lynx populations in the DPS, to the extent suggested by verified historical records, was likely in areas peripheral to the geographic units that currently support resident lynx (e.g., northern New Hampshire [McKelvey *et al*. 2000a, pp. 212-214], the Kettle/Wedge area of northeastern Washington [Koehler et al. 2008, p. 1523; Lewis 2016, pp. 1-2], Isle Royale in Lake Superior [Licht *et al*. 2015, entire]). Any small populations that were lost were not in large, discrete geographic units that would have represented substantially greater redundancy in the contiguous United States. The implications of the potential recent loss of resident lynx in the GYA for the redundancy of the DPS are unclear. The historical record and recent research show that the GYA has supported resident lynx. However, it is unclear whether the area consistently supported a resident breeding population over time or whether it naturally supported resident lynx only some of the time ("winked on" in a metapopulation sense) when habitat conditions and hare densities were favorable, and at other times, when habitats and hare densities were less favorable, it did not support resident lynx ("winked off" in a metapopulation sense). Given the protected conservation status of millions of acres in the GYA unit (Yellowstone and Grand Teton national parks; all or parts of the Absaroka-Beartooth, Bridger, Gros Ventre, Lee Metcalf, Northern Absaroka, Teton, and Washakie Wildernesses), its apparent recent inability to support resident lynx may be a reflection of naturally marginal and patchy habitats and relatively low hare abundance in much of the unit, resulting in only an intermittent ability of this unit to support resident lynx. If so, the contribution of the GYA to redundancy within the DPS is questionable.

Representation, defined as the ability of the DPS to adapt to changing environmental conditions, is characterized by the breadth of genetic and ecological diversity within and among populations (Lynx SSA Team 2016a, p. 25). Lynx experts and geneticists indicated high rates of dispersal and gene flow and, therefore, generally low levels of genetic differentiation across most of the species' range, including the DPS (Lynx SSA Team 2016a, pp. 12-14, 55-56). Although hybridization with bobcats has been documented in the DPS (in Maine and Minnesota), it is not considered a substantial current threat to the DPS (Lynx SSA Team 2016a, p. 13). Further, despite differences in forest community types and other habitat parameters (e.g., topography and elevations) lynx across the range of the DPS occupy a similarly narrow and specialized ecological niche defined by specific vegetation structure, snow conditions, and the abundance of a single prey species. Therefore, lynx likely have little ability to adapt to changing environmental conditions (i.e., shift to other forest habitats, snow conditions, or primary prey species). However, although some small populations may have become extirpated recently, resident lynx in the DPS remain broadly distributed across the range of ecological settings that seems to have supported them historically in the contiguous United States. Because there are no indications of current threats to the genetic health or adaptive capacity of lynx populations in the DPS, we find that the current level of representation does not appear to represent a decrease from historical conditions.

Resiliency, the ability to withstand stochastic disturbance events, is currently exhibited in the lynx DPS by the persistence of individual lynx populations and their broad distribution across the geographic scope of the DPS. However, because we lack reliable estimates of the sizes and trends of most lynx populations in the DPS, we are unable to use these parameters to evaluate

the current resiliency of individual populations or geographic units. Although some demographic data (survival, reproductive rates) are available for each geographic unit (see table 4), they were collected using different methods, at different times, and for different intervals, and possibly at different points in hare population cycles or fluctuations and, therefore, do not provide a consistent measure of resiliency. Efforts to understand resiliency within the DPS are also confounded by the metapopulation structure thought to govern lynx populations at the southern margin of their continental range, which suggests that some populations may be naturally ephemeral (i.e., “winked on” when conditions are favorable; “winked off” when conditions are not favorable). The related uncertainty about the extent to which DPS populations may rely on cyclic immigration of lynx from Canada during population irruptions and the ambiguity in the historical record that limits our understanding of the relative persistence of lynx in various geographical areas also limit our ability to characterize, rank, or model the relative contribution of each geographic area to the resiliency of the DPS.

Despite uncertainties and data deficiencies, qualitative factors provide some hints about current relative resiliency among some geographic areas or parts of them. For example, in Maine, lynx have demonstrated resiliency by responding positively to substantial anthropogenic increases in the amount and distribution of high-quality foraging habitat. Conversely, the current apparent absence of resident lynx in the GYA (Unit 5) and in the Garnet Mountains of Unit 3 may indicate the lower level of resiliency expected among small and relatively more isolated populations. The persistence of lynx in north-central Washington (Unit 4) despite the substantial recent wildfire-mediated loss of habitat suggests resiliency in that population; however, the post-fires increase in home range size and likely decrease in lynx numbers may indicate the population is currently less resilient (less able to persist if additional or similar habitat losses occur) than it was previously. Overall, the apparent long-term (historical and current) persistence of resident lynx populations in at least 4 of the 6 geographic units (Units 1-4), and the absence of reliable information indicating that the current distribution and relative abundance of resident lynx are substantially reduced from historical conditions, suggest historical and recent resiliency of lynx populations in the DPS.

In summary, the lynx DPS currently exhibits redundancy sufficient to preclude extirpation as a result of catastrophic events. The genetic health and ecological diversity expressed across the DPS range likewise suggest the recent and current maintenance of representation. The long-term persistence and broad geographical distribution of lynx populations in 4 of the 6 geographic units also suggests historical and recent resiliency in the DPS, although the potential recent extirpation of several small populations may be an indication of declining resiliency in those places.

4.1.1 Summaries of Current Conditions in Each Geographic Unit

Unit 1 - Northern Maine: This geographic unit encompasses the northern hardwood and spruce-fir (Acadian) forest in roughly the northern half of Maine. Resident lynx in this unit represent the southern periphery of a larger and highly resilient population (Harrison 2017, p. 3) that also occupies southern Quebec (where trapping is legal) and northern New Brunswick

(where lynx are a provincially-endangered species and harvest is prohibited). Although the actual number of resident lynx in this unit is unknown, the MDIFW believes this unit currently may be capable of supporting 750-1,000 lynx based on estimates of habitat distribution and lynx home range sizes (Vashon *et al*. 2012, pp. 87-91), which would make it the largest population in the DPS. This is many more resident lynx than likely occurred historically and many more than were suspected to occur in this unit when the DPS was listed, and it is the result of extensive clearcutting and herbicide application to salvage spruce-fir and encourage softwood regeneration following a severe spruce budworm outbreak in the 1970s and 1980s (Hoving *et al.* 2004; Vashon *et al.* 2008b; Simons 2009, pp. 122-165). Those past treatments have created the current extensive distribution of young, regenerating softwood stands that provide optimal hare foraging habitat. Lynx responded to these conditions with high survival and reproduction, small home ranges, and the highest densities documented in the DPS. Historically, under a more natural disturbance regime, Maine typically had a greater proportion of mature forest and, therefore a patchier distribution of high-quality habitat that likely supported a smaller lynx population that may have been more dependent on immigration from Canada. State forestry regulations passed in 1989 caused landowners to shift to various forms of partial harvesting that have resulted in lower landscape hare densities across much of the unit. Hare populations do not seem to cycle in this region, but hare density estimates from 2008-2015 declined by over 50 percent compared to estimates from 2001-2006. Reproduction and adult survival declined in the low-hare environment after 2006, although kitten survival remained high. Unlike other DPS units, lynx habitat in northern Maine occurs nearly entirely on private, industrial forest lands, most of which lack long-term commitments to lynx management. The majority of private lands in this unit are now owned by investment companies seeking to diversify income from their investments, which could result in forest practices less likely to maintain or conserve hare and lynx habitat. Other potential stressors to lynx in this unit include incidental trapping, road mortality, large-scale wind energy development, residential and resort development, and parcelization of forestlands from rapid turnover in investment company landowners. Another spruce budworm outbreak may be imminent, and forestry response by investment landowners is uncertain. Climate change is a concern because average annual snowfall and duration are currently at the minimum thresholds believed necessary to give lynx a competitive advantage over bobcats and other mesocarnivores. Although lynx regularly occur outside this unit in southeastern and southwestern Maine, and small numbers of reproducing lynx have also been documented recently in northern New Hampshire and northern Vermont, the ability of some of these peripheral areas to support persistent breeding populations is questionable. However, recent telemetry data in Maine suggest that resident lynx are expanding both east and south of the Northern Maine Geographic Unit, with home range maintenance and reproduction documented in both areas, which previously were considered outside the area capable of supporting resident lynx (Vashon 2017, *pers. comm*.).

Unit 2 - Northeastern Minnesota: This geographic unit contains a mix of upland conifer and hardwood interspersed with lowland conifer, alder (*Alnus* spp.) or willow (*Salix* spp.) shrub swamps, and black spruce (*Picea mariana*) or tamarack (*Larix laricina*) bogs. Despite uncertainty when the DPS was listed, it has become apparent that a reproducing resident population of roughly 50 to 200 lynx exists in northeastern Minnesota. This unit is directly

connected to lynx habitats and populations in Canada, and lynx in this unit likely represent the southern extent of a larger cross-border population, most of which occurs in Ontario, where trapping of lynx is legal. Lynx in Minnesota select regenerating forest dominated by conifer with extensive forest edge; lynx beds (resting and hunting) and kill sites are associated with regenerating and mixed forest (Burdett 2008, p. 57). Hare densities in parts of northeastern Minnesota appear to be sufficient to support a viable lynx population and are highest in regenerating forests (McCann and Moen 2011, p. 513). The Superior National Forest continues to manage lynx habitats in accordance with its 2004 Forest Plan, which includes measures to minimize several risk factors and promote lynx conservation on the forest. Management of lynx habitat on State and private lands is voluntary and lacks long-term commitments to lynx management. Factors affecting current conditions in this unit primarily include forestry management, roads, and incidental trapping; other factors that could potentially impact resident lynx in this unit include mining development, snow compaction related to winter recreation, competition with bobcats, and lynx-bobcat hybridization. Since 2000, 45 lynx mortalities have been documented in Minnesota from unknown causes (16), incidental trapping (11), vehicle collisions (9 on roads and 2 on railroads), and illegal shooting (7). Six lynx radio-collared in Minnesota died after traveling north into Ontario, 4 from legal trapping/hunting, and 2 from unknown causes; some of these mortalities occurred years after the lynx was last located in Minnesota, indicating survival of Minnesota lynx in Ontario for extended periods is possible.

Unit 3 - Northwestern Montana/Northeastern Idaho: The historical and current sizes of the resident lynx population in this unit are unknown, but it is thought currently to be capable of supporting 200-300 lynx home ranges. Habitats capable of supporting resident lynx in this unit are naturally patchier and less-broadly distributed (Squires *et al.* 2006a, pp. 46-47; Squires *et al.* 2013, p. 191), and lynx therefore naturally rarer, than was thought when the DPS was listed (ILBT 2013, p. 23; Jackson *in* Lynx SSA Team 2016a, p. 12). Minor genetic differences suggest 3 subpopulations in the northwest (Purcell Mountains), central (Seeley Lake), and southern (Garnet Mountains) parts of the unit. No lynx were detected in the Garnet Range from 2011 to 2015, prompting concerns about the potential loss of the small resident population (perhaps 7-10 lynx) documented there in the mid-1980s and again recently from 2002 to 2010. However, whether this absence indicates the extirpation of a previously persistent resident population or the temporary loss of an historically ephemeral population is uncertain. A single lynx was verified in the Garnet Range in February 2016, indicating that natural recolonization of the area is possible; however, subsequent surveys have failed to detect that lynx or other lynx, and there currently remains no evidence of lynx residency in this mountain range (Lieberg 2017, *pers. comm.*). Most (about 90 percent) of this unit is managed to conserve and restore lynx and hare habitats, including on Federal, State, Tribal, and some private lands. Past timber harvest and associated management (e.g., thinning, road construction, fire suppression) appear to have had localized impacts but not to have diminished the unit's ability to support resident lynx, with habitats in the Garnet Range being a possible exception (see 4.2.3 below). The size, frequency, and intensity of wildfires in this unit have increased over the past several decades, likely in response to climate warming, but population-level impacts to lynx have not been documented. Whether (and if so to what extent) other climate-mediated factors have influenced the current condition of lynx populations or habitats in this unit are also unknown. Regulations prohibit lynx

trapping and require measures to reduce the likelihood of trapping lynx incidentally when legally trapping other species. Hare densities have not been estimated broadly throughout the unit but appear to be low or marginal even in what is considered the highest-quality habitat, suggesting that even small decreases in habitat quality/hare densities could influence its continued ability to support resident lynx. The role of past and recent immigration in maintaining the demographic and genetic health of current lynx populations in this unit is unknown, but peaks in cyclic lynx numbers in Canada have declined, especially when compared to the unprecedented irruptions of the early 1960s and 1970s, and there is no evidence of significant immigration into this unit since then.

Unit 4 – North-central Washington: This geographic unit encompasses extensive boreal forest vegetation types and is directly connected to lynx habitats and populations in British Columbia. It represents about 58 percent of the Okanogan Lynx Mangagement Zone (LMZ) designated by the WADNR. Historical and current resident lynx numbers in northern Washington are unknown, but recent habitat and home range analyses for the larger Okanogan LMZ (summarized in Lewis 2016) suggest that this geographic unit may have been capable of supporting about 50 lynx prior to extensive wildfires over the past 2-3 decades (85-90 lynx in the entire LMZ). Those fires affected over a third of the LMZ, led to increased home range size, and may have reduced the carrying capacity of this unit to perhaps 30 lynx currently (50-55 in the entire LMZ). Additional extensive wildfire activity in the northern part of this unit in 2017 may result in further reduction of carrying capacity. The recent increases in wildfire frequency, size, and intensity in lynx habitat in this unit may have been influenced by climate change (Westerling *et al.* 2006, pp. 942-943). Burned habitats are expected to regenerate back into suitable lynx habitat, but this may take 10-40 years. However, additional wildfire activity in this unit before previously burned areas recover could substantially reduce the viability of the lynx population in this geographic unit (see section 5.2.4). Because of these habitat impacts and remaining stressors to lynx, the Washington Department of Fish and Wildlife recently submitted, and the State Fish and Wildlife Commission adopted, a proposal to uplist lynx from threatened to endangered within the State. Hare densities in Washington are generally at the low end of the range thought necessary to support lynx persistence. The Okanogan-Wenatchee and Colville National Forests, which administer more than 90 percent of lynx habitat in Washington, continue to manage in accordance with the LCAS. Additionally, the WADNR, which manages approximately 4 percent of lynx habitat in Washington, developed a Lynx Habitat Management Plan in 1996, which was updated in 2006 and is also largely based on the LCAS. The Kettle Range to the east of this unit was suspected to have supported a small (likely fewer than 20 individuals) resident population until about 30 years ago when over-trapping compounded by habitat changes may have resulted in its extirpation (Stinson 2001, p. 13; Koehler *et al.* 2008, p.1523). Potential impediments to lynx movement between the Kettle Range and the Cascades and British Columbia may make natural recolonization of the Kettle Range unlikely.

Unit 5 - Greater Yellowstone Area (GYA): There are no reliable estimates of current or historical lynx numbers in this unit but, given its naturally-fragmented potential habitat, generally low hare densities, and the paucity of verified records, it appears unlikely this unit ever supported a large resident population, and it is possible that this unit historically supported resident lynx only

ephemerally. No lynx have been verified in this unit since 2010, but whether this indicates the extirpation of a small but previously persistent resident population or the temporary loss of an historically ephemeral population is uncertain. Over 97 percent of this unit consists of Federal lands that are currently managed to conserve and restore lynx and hare habitats. Past timber harvest and associated management (thinning, road construction, fire suppression) appear to have had localized impacts but not to have diminished the unit's ability to support resident lynx. The size and intensity of wildfires have increased over the past several decades, predominantly in the northern half of the unit (including the large fires of 1988 in Yellowstone National Park) and likely in response to climate warming, but impacts to lynx are uncertain. Whether (and if so to what extent) other climate-mediated factors have influenced the current condition of lynx populations or habitats in this unit are also unknown. Snow conditions currently appear to be adequate, with most of this geographic unit modeled to have a 95 percent probability of providing snow cover conditions supportive of lynx presence (Gonzalez *et al.* 2007, p. 12). Hare densities were very low in most of Yellowstone National Park but high in parts of the Bridger-Teton National Forest in the southern half of the unit. The role of past and recent immigration in maintaining the demographic and genetic health of lynx populations in this unit is unknown. This unit lacks direct connectivity to other lynx populations, and there is only anecdotal evidence that irruptions of lynx from Canada resulted historically in immigration into this unit. At least 9 lynx released in Colorado dispersed northward into this unit and some temporarily occupied home ranges in areas used previously by native resident lynx, but there is no evidence of long-term occupancy or reproduction by these lynx.

Unit 6 - Western Colorado: The current and historical numbers of resident lynx numbers in this unit are unknown, but CPW lynx biologists believe it currently could support 100-250 lynx as a result of the 1999-2006 release of 218 lynx from Canada and Alaska. Released lynx had high survival but the proportion of females producing kittens and kitten survival were low. This unit is not directly connected to lynx populations in Canada, and it does not appear to have received immigrant lynx during the historicaly large irruptions of the early 1960s and early 1970s. Since 1996, 2 unprecedentledly large bark beetle epidemics have affected about 16,200 km^2 (6,255 mi^2) of spruce-fir and lodgepole pine forests in Colorado, including much of the lynx habitat in this unit. Additionally, the 2013 West Fork Complex fire impacted more than 400 km^2 (154 mi^2) of lynx habitat in the San Juan Mountains. Beetle outbreaks do not appear to have negatively impacted hares, and hare numbers may increase in affected areas as succession progresses; however, they have negatively impacted red squirrels, an important alternate prey species for lynx in this unit. Areas affected by beetles that contained multi-story stand conditions likely continue to provide habitat to support snowshoe hares and lynx. Areas affected by fire may require 20 years or more, and in some areas considerably longer, to recover to a point where the stands will again support snowshoe hares. Large-scale monitoring efforts in the San Juans documented continued lynx occupancy during 2010-11, 2014-15, and 2015-2016, and it is reasonably likely that lynx continue to occur in all national forests within the State of Colorado. Snowshoe hare habitat is naturally patchily-distributed in this geographic unit, which limits hare abundance. Because the majority (90 percent) of potential lynx habitat in Colorado is under Federal land management, actions occurring on other ownerships are unlikely to result in significant impacts to lynx habitat within this unit. The USFS manages over 85 percent of the

lynx habitat in this unit, providing conservation through the SRLA. However, regulatory mechanisms for the conservation of lynx are lacking on approximately 3,159 km^2 (1,220 mi^2; over 12 percent) of this unit, including lynx habitats on some BLM and some non-Federal lands.

Table 4. Summary of current conditions in 6 geographic units within the DPS range[1].

	Unit 1 - Northern ME	Unit 2 - Northeastern MN	Unit 3 - Northwestern MT, Northeastern ID	Unit 4 - North-central WA	Unit 5 - Greater Yellowstone Area	Unit 6 - Western CO
Unit Size (km^2)	28,909	21,101	26,997	5,176	23,687	25,294
Percent of Unit in Conservation Ownership (i.e., Federal, State, Tribal, Other Conservation Org.)	10 - 15	75 - 90	> 95	> 90	> 95	> 90
Connectivity to Lynx Populations/ Habitats in Canada	Directly connected to lynx habitats/ populations in s. Quebec and n. New Brunswick; evidence of natural movement, but rates of immigration/ emigra ion unknown	Directly connected to lynx habitats/ populations in s. Ontario; evidence of natural movement, but rates of immigra ion/ emigration unknown	Directly connected to lynx habitats/ popula ions in s. Alberta and s. Bri ish Columbia; evidence of natural movement, but rates of immigration/ emigration unknown	Direc ly connected to lynx habitats/ populations in s. British Columbia; evidence of natural movement, but rates of immigration/ emigration unknown	No direct connec ion; rates of immigration/ emigra ion unknown	No direct connection; rates of immigration/ emigration unknown; long-distance dispersal (emigration) documented to many western states and to Canada
Home Range Size (Adult Female, km^2)	25-33	17 - 21	43 - 115	37 - 91	50 (1 female, 3 years)	75
Productivity – Percent Females with Kittens	89% (high hares); 30% (low hares);	100%	83% (Purcells); 61% (Seeley Lake)	100% (2 females)	Few data	24%
Productivity - Litter Size	2.74 (high hares); 2 25 (low hares)	3.3	2.95 (Purcells); 2.24 (Seeley Lake)	2 25 (2 females)	3.0 (1 female, 2 years)	2.75
Average Annual Adult Survival Rate	0.80 (high hares); 0.71 (low hares)	0.75 - 1.00	0.85 (Purcells); 0.75 (Seeley Lake)	0 86	Few data	0 93 (in Core Release Area [CRA]); 0.82 (out of CRA)
Kitten Survival Rate	0.78 (high hares); 0 89 (low hares)	No estimate; recruitment thought low	0.58 (Seeley Lake)	0.12 (7 of 8 kittens died in 1st year)	No estimate; no evidence of kitten survival to independence	0.23
Lambda (Annual Rate of Population Change)	1.05 (1.16, high hares, 6 yrs; 0.88,low hares, 4 yrs)	No estimate	1.16 (Purcells, 4 yrs); 0.92 (Seeley Lake, 8 yrs)	No estimate	No es imate	0.93 - 1.08

[1]Estimators used to calculate home range size are provided in table 3.

4.2 Current Conditions - Detailed Descriptions by Geographic Unit

4.2.1 Unit 1 - Northern Maine

Unit Description: This geographic unit encompasses approximately 28,909 km^2 (11,162 mi^2) of northern hardwood and spruce-fir forest (the Acadian forest) in northern Maine that has been designated as critical habitat for lynx (79 FR 54823-54828). Land ownership in this unit is about 90 percent private, 7 percent State (primarily Baxter State Park), 1 percent Federal (the newly-designated Katahdin Woods and Waters National Monument and Appalachian Trail Corridor), and 1 percent Tribal (Passamaquoddy Tribe, Penobscot Indian Nation). Almost all private lands are intensively managed for commercial forest (timber and pulp) products. This unit is directly connected to lynx habitats and populations in southern Quebec and northern New Brunswick. Lynx in this unit represent the southern extent of a larger cross-border population, most of which

occurs in the Gaspe region of southern Quebec and northern New Brunswick (Ray *et al.* 2002, pp. 17-20) and which is geographically isolated by the St. Lawrence River from lynx populations in central Quebec (120 km [75 mi] north of Maine). Lynx populations in Maine and eastern Canada are also geographically isolated from other lynx populations on the island of Newfoundland (900 km [559 mi] northeast of Maine), and on Cape Breton Island, Nova Scotia (650 km [404 mi] east of Maine; Koen *et al.* 2015, entire; Prentice *et al*. 2017, entire). Lynx in Maine are also isolated from other DPS populations, the closest of which is in northeastern Minnesota, about 1,610 km (1,000 mi) west of this unit.

Lynx regularly occur outside this unit and recently have been documented in smaller areas of similar habitat in southeastern and southwestern Maine, northern New Hampshire, and the northeastern corner of Vermont (see below). Occasional lynx reproduction has been documented recently in New Hampshire and Vermont, but these areas are not thought to support persistent breeding populations and are likely incapable of doing so (see below). Climate in this region is characterized by warm summers and some of the coldest temperatures and highest snowfalls in the eastern United States; a function of latitude, elevation, and distance from the ocean. The average terrain rises in northern Maine to 305-457 m (1,000-1,500 ft) with mountain peaks, particularly in western Maine, northern New Hampshire, and Vermont, from 914-1,524 m (3,000-5,000 ft). Average annual precipitation is currently 104 cm (41 in), with greatest precipitation in winter in the form of snow (average total snowfall is 228-280 cm (90 - 110 in), with higher amounts at the highest elevations. Snow duration is about 5 months (mid-November through mid-April).

New Hampshire - Potential habitat in northern New Hampshire is limited (Hoving 2001, p. 59), and the few habitat patches that support lynx in New Hampshire are much smaller than those in northern Maine (Litvaitis and Tash 2005, fig. 2 and p. A–298; Robinson 2006, fig. 3.3, p. 99). Hoving estimated approximately 1,000 km^2 (386 mi^2) of potential habitat having a greater than 50 percent probability of being occupied by lynx (68 FR 40086). Litvaitis and Tash (2005, p. A–298) estimated that New Hampshire contains about 888 km^2 (343 mi^2) of potential Canada lynx habitat. Historical lynx occurrence in New Hampshire included Coos and northern Carroll and Grafton counties (i.e., White Mountain National Forest; Siegler and Jorgensen 1971: Silver 1974: Hoving *et al.* 2003). The majority of lynx records in northern New Hampshire over the past 10 years have occurred in the vicinity of Pittsburg on the 101-km^2 (39-mi^2) Connecticut Lakes Natural Area (CLNA), which is owned and managed by New Hampshire Fish and Game, and on surrounding habitat owned and managed by the Connecticut Lakes Timber Company under a conservation easement held by the State (Kilborn 2015, App. A, pp. 42-43). The CLNA, under a conservation easement, includes a 61-km^2 (23-mi^2) area that will be allowed to mature to a climax forest type which is contained within what is considered core lynx habitat. The area will potentially provide good denning habitat but will likely restrict the amount of snowshoe hare habitat in the foreseeable future. Current conditions are in a transition state, and portions of the core area currently support higher densities of snowshoe hare because of past forest management (Kilborn 2015, App. A pp. 42-43). Regional-scale modeling suggests that a high component of deciduous forest and insufficient snow conditions in New Hampshire make it

unlikely to support a persistent, viable lynx population over time (Hoving *et al.* 2005, pp. 739, 749).

Vermont – Recent modeling indicates that the Nulhegan River Basin contains Vermont's best lynx habitat (Farrell 2012). The 530-km^2 (205-mi^2) area is approximately 20 percent Federal (Nulhegan National Wildlife Refuge), 17 percent State (Vermont Department of Natural Resources), and 63 percent private commercial timber lands (with conservation easement). Vermont does not appear to have historically supported a persistent resident lynx population and, despite several recent verified records of lynx presence and evidence of limited reproduction (see section 2.3.2.2), it is unlikely to do so in the future because of the patchy and limited amount of potential habitat, climate change (decreasing snow), trends toward hardwood management, and increasing human disturbance (Vermont Fish and Wildlife 2015, Appendix A5 p. 127).

Habitat Description: Most lynx occurrence records in this unit are found within the broadly described ''Mixed Forest-Coniferous Forest-Tundra'' cover type (68 FR 40086). This habitat type occurs along the northern Appalachian Mountain range from southeastern Quebec, northern New Brunswick, and northern and western Maine, south through northern New Hampshire. This area is part of the Acadian Forest Region (Rowe 1972, p. 112-129) representing a transition between northern boreal spruce and balsam fir and southern temperate deciduous forests (Seymour and Hunter 1992, pp. 3-4). This forest type becomes naturally fragmented and begins to diminish to the south and west, with a disjunct segment running north-south through Vermont and a patch in the Adirondacks of northern New York (McKelvey *et al.* 2000a, pp. 248-250). Patches of boreal forest in New Hampshire, Vermont, and New York are more highly fragmented and smaller than in northern Maine. These more southerly forests also contain a higher proportion of northern hardwood and are believed to lack an adequate conifer component needed to produce sufficient snowshoe hare densities to consistently support resident lynx populations (Hoving *et al.* 2005, p. 749; Carroll 2007, p. 1100). Northern Maine is characterized by low-relief, hilly terrain, but with some higher elevations in the Katahdin Highlands and in western Maine. Higher elevations support a predominantly coniferous forest (white, red, and black spruce; balsam fir; eastern white pine [*Pinus strobus*]) intermixed with northern hardwoods (red maple, aspen, paper [white] birch, sugar maple [*Acer saccharum*], beech [*Fagus* spp.], and yellow birch [*Betula alleghaniensis*]). Lowland areas include spruce-fir flats interspersed with peatlands (black spruce, tamarack).

In this unit, lynx are most strongly associated with stands of regenerating sapling spruce-fir forest supporting high hare densities (Homyack 2003, p. 53; Fuller and Harrison 2005, p. 716, Vashon *et al.* 2008b, p. 1492; Scott 2009, pp. 24, 32, 36-44). Most current high-quality stands in this unit are the result of landscape-level clearcutting in the 1970s and 1980s (see Habitat Status, below). Regenerating stands used by lynx typically develop 15-30 years after timber harvest (Hoving *et al.* 2004, p. 291) or other disturbance (e.g., periodic spruce budworm defoliation), are characterized by high stem density and dense horizontal cover within 1 m (3 ft) of the ground (Robinson 2006 pp. 26-36, Scott 2009, pp. 81-93; Fuller and Harrison 2010, p.

1276-1278; Vashon *et al.* 2012, p. 15), and support the highest snowshoe hare densities (Homyack 2003, p. 63; Fuller and Harrison 2005, pp. 716, 719; Vashon *et al.* 2005a, pp. 10–11).

At the stand scale, lynx in northwestern Maine selected older (11- to 26-year-old), tall (4.6- to 7.3-m [15- to 24-ft]) softwood-dominated (spruce and fir) regenerating clearcut stands, adjacent older (11- to 21-year-old) partially harvested stands in close proximity to clearcut stands (Fuller *et al.* 2007, pp. 1980, 1983–1985), and mature conifer stands (Simons-Legaard *et al.* 2013, p. 568) where hares are more accessible. During winter, lynx primarily selected tall (4.4–7.3 m [15–24 ft]) regenerating clearcuts and established partially harvested stands that were 11–21 years post-harvest (Fuller *et al.* 2007, pp. 1984-1985). Lynx selected against mature second-growth stands (> 40 years old), short (3.4–4.3 m [11–14 ft]) regenerating clear-cut or partially harvested stands < 10 years post-harvest, and roads and road edges (Fuller *et al.* 2007, pp. 1980, 1983-1985). Research of year-round habitat use yielded similar results, with lynx preferentially using conifer-dominated sapling stands that were 3.4–7.3 m (11–24 ft) in height and supported high densities of snowshoe hares (Vashon *et al.* 2008b, pp. 1492-1495). At the home range scale, lynx select landscapes having extensive regenerating conifer forest, but also with some mature conifer forest (Simons-Legaard *et al.* 2013, pp. 572–573). Lynx tended to forage in areas with intermediate to high hare densities, where hares were more accessible to lynx compared to the densest (short regenerating) stands (Fuller and Harrison 2010, pp. 1276-1278). Lynx may select partially harvested and mature conifer stands in close proximity to clearcut stands because of increased ease of travel and access to hares along the extensive edges of the densest, high-quality (regenerating clear-cut) hare habitats (Simons-Legaard *et al.* 2013, p. 574). Lynx are more likely to occur in large landscapes having a high percentage (> 27 percent) of regenerating forest, and less likely to occur in landscapes with very recent clearcuts or extensive partial harvest (Hoving *et al.* 2004, pp. 291–292; Simons-Legaard *et al.* 2013, entire).

Denning habitat included various types of coarse woody debris including blowdown, deadfalls, and root wads. In northern Maine, nearly half (12 of 26) of natal dens occurred in conifer-dominated sapling stands, and 6 dens were found in mature or mixed multi-story forest stands dominated by conifers (Organ *et al.* 2008, pp. 1515-1517).

In general, landscape scale and home range scale habitat selection by lynx on commercial forest lands reinforces the importance of dense regenerating conifer forest along with a component of mature conifers (Hoving *et al.* 2004, p. 286; Vashon *et al.* 2008b, pp. 1494-1495; Simons 2009, pp. 64-110; Simons-Legaard *et al.* 2013, p. 568). Simons-Legaard *et al.* (2013, p. 573) found the probability of lynx occurrence was > 50 percent where landscape hare densities were > 0.74 hares/ha (0.39 hares/ac) and there was > 10 percent mature conifer forest. No lynx maintained home ranges in landscapes with hare densities < 0.5 hares/ha (0.2 hares/ac). At a landscape scale, lynx habitat selection did not differ between sexes; however, at a home range scale, males tended to use more mature forest dominated by conifers than females, and both male and female lynx tended to avoid mature forests that had a high deciduous component (Vashon *et al.* 2008b, pp. 1492-1493). Based on these observations, Simons-Legaard *et al.* (2013, pp. 574-576) recommended maintaining landscape hare densities of > 0.5 hares/ha (0.2

hares/ac) and a minimum of 27 percent high-quality hare habitat within 100-km^2 areas to conserve lynx.

Habitat Status: As elsewhere in the DPS, boreal spruce-fir forest habitats in the Northern Maine Unit are naturally patchily-distributed and intermixed with northern hardwoods, riparian areas, and peatlands. USFS forest inventory data indicate that over 16,000 km^2 (6,178 mi^2) of forestland are classified as spruce-fir in Aroostook, Penobscot, Piscataquis, and Somerset Counties in northern Maine (McWilliams *et al.* 2005, p. 122), although not all of this forest type is in areas occupied by lynx. Currently, most of the high-quality hare and lynx habitat in northern Maine is the result of extensive landscape-scale clearcut timber harvesting in response to a spruce budworm outbreak in the 1970s–1980s (Hoving *et al.* 2004, p. 291; Simons 2009, pp. 64, 218). Many of these clearcuts were also treated with herbicides to promote conifer regeneration by suppressing deciduous tree species. After salvage harvest of the affected trees, a portion of the area was sprayed with herbicide to reduce deciduous competition (Scott 2009, pp. 7, 14). The resulting vegetation was dominated by balsam fir and red or black spruce (Scott 2009, p. 60). This created favorable habitat conditions for snowshoe hares and lynx. Habitat conditions for hares and lynx in the unit improved from the late-1980s to present, benefitting from stand-replacing salvage harvests during the last budworm outbreak (Simons 2009, pp. 122-229; Simons-Legaard *et al.* 2016, entire). During this time period, the percentage of forestland with an average landscape hare density greater than 0.5 hares/ha (0.2 hares/ac) increased 400 percent (Simons-Legaard *et al.* 2016, p. 7). Both the current amount of high-quality habitat and the lynx population in Maine are likely larger than occurred prior to European settlement, when a relatively smaller proportion of the forest was typically in an early successional stage (Lorimer 1977, entire; Vashon *et al.* 2012, pp. 45, 56).

In the Northeast prior to European settlement, lynx habitat was created and maintained by frequent, small-scale forest gap dynamic events and infrequent, large-scale stand-replacing forest disturbances (Seymour *et al.* 2002, pp. 359-365; Lorimer and White 2003, pp. 54-58). Historically, the natural disturbance regime (fires, windthrow, insect outbreaks) resulted in smaller, more frequent disturbances and long intervals between larger disturbances; thus, high-quality lynx foraging habitat in northern Maine was probably typically much less abundant and less broadly-distributed than it is today. Large, stand-replacing events (fire, wind and ice storms, insect outbreaks) are rare (intervals of several hundred to several thousand years) and highly variable in size (Seymour *et al.* 2002, entire; Lorimer and White 2003, pp. 50, 54, 59). Spruce budworm, spruce beetle, beech bark disease, and sugar maple defoliators have been important influences affecting forest landscape patterns (McNab and Avers 1994, Chapter 14). The frequency and intensity of spruce budworm outbreaks, the most likely insect to affect lynx habitat, have been highly variable in Maine and eastern Canada in recent centuries (Blais 1983, entire). Although, high-elevation boreal forests often exhibit dense, regenerating conifer (resulting from a wind-throw phenomenon known as fir-waves [Sprugel 1976, entire]), hare densities are believed to be low in these areas (Siren *et al.* 2015, entire). In this geographic area, wildfire is less significant as a natural agent of disturbance. The typical fire regime is infrequent surface fires in the dormant season in the hardwood forests, and slightly more frequent but long-interval fires in conifer forests (Kilgore and Heinselman 1990, entire; Seymour

et al. 2002, pp. 359-365, Lorimer and White 2003, p. 59). For the past several decades, early successional forests and lynx habitat in northern Maine, New Brunswick, and southern Quebec have been created almost exclusively by forest management (Lorimer and White 2003, pp. 42-43).

In a roughly 14,500-km^2 (5,598-mi^2) area in northern Maine (about half of the Northern Maine geographic unit), Simons-Legaard (2016, p. 9-10) estimated that 3,845 km^2 (1,485 mi^2; nearly 27 percent) of the forested landscape was comprised of spruce-fir in a young, regenerating stand condition that provide high-quality hare habitat. This habitat is similar to, and contiguous with, forested areas in Quebec and New Brunswick that support lynx (Hoving *et al.* 2005, pp. 740-741). The current range of lynx in this unit is associated with areas of deep snowfall, extensive forested landscapes, and areas having a high proportion of regenerating conifer-dominated forest that had previously been clearcut and treated with herbicides to suppress hardwoods (Homyack 2003, p. 2; Hoving *et al.* 2004, p. 287).

Snowshoe hare populations in Maine do not seem to cycle at 10-year intervals, but they have experienced a period of higher (1995-2005) and lower (2006 to present) densities (Scott 2009, pp. 1-44; Vashon *et al.* 2012, p. 14; Harrison *et al.* 2016, entire). Prior to 2006, several estimates of hare densities in the highest-quality regenerating conifer or mixed forest averaged 1.9 to 2.1 hares/ha (0.8 to 0.9 hares/ac; Homyack *et al.* 2007, p. 8; Robinson 2006, p. 26). After 2006, hare densities declined by about half in all stand types and have remained at these lower levels (Scott 2009, p. 109; D. Harrison, Univ. Maine, *unpubl. data*). Similar trends were observed in the Gaspe Region of Quebec (Assells *et al.* 2007, entire). In New Hampshire in 1990, hare densities in dense, regenerating spruce-fir stands were about 0.5 hares/ha (0.2 hares/ac) at low and high elevations (Brocke *et al.* 1993, p. 61). More recently, Siren *et al.* (2015) reported lower densities in New Hampshire (0.25 to 0.36 hares/ha [0.1 to 0.15 hares/ac]) that are unlikely to support lynx persistence in both montane and lowland spruce-fir. Densities in high elevation areas (krumholtz, stunted spruce-fir) were only 0.19 to 0.28 hares/ha (0.08 to 0.11 hares/ac), also unlikely to support lynx persistence. Comparable hare density data are not available for Vermont.

Currently, the amount and distribution of high-quality habitat are likely at historically high levels, but this habitat has peaked and high-quality lynx habitat is projected to decline in the near future (Simons-Legaard *et al.* 2016, pp. 140-163, 202-218). In response to the widespread clearcutting in the 1970s and 1980s, Maine passed the Forest Practices Act in 1989, which regulated clearcutting. Since then, various forms of partial harvesting have replaced clearcutting as the predominant form of forest management in northern Maine. Partially harvested stands (e.g., selection harvest, shelterwood harvest, overstory removal) have a wide range of residual stand conditions, but many have lower conifer stem densities and higher hardwood density than regenerating clearcuts (Robinson 2006, p. 29). On average, partially harvested stands support about 50 percent of the hare densities observed in regenerating clearcuts (Robinson 2006, p. 26-27). Over 95 percent of cutting that occurs now in northern Maine is partial harvesting compared to 59 percent in 1988 (Scott 2009, p. 8; Simons 2009, pp.45-47, 69-71; Simons-Legaard *et al.* 2013). This new cutting regime results in lower landscape densities of snowshoe

hares (Fuller 1999; Homyack 2003; Robinson 2006; Scott 2009). Another consequence of partial harvesting is that a much greater acreage needs to be cut annually to attain similar harvest volume (as compared to clearcutting). Annual harvest rates have increased from about 40,000 ha (100,000 acres) per year (before the Forest Practices Act) to over 200,000 ha (500,000 acres) per year (after the Act). Thus, 28 years after the Maine Forest Practices Act, much of the forested landscape in northern Maine has been partially harvested.

Unlike Federal lands, there is no requirement that private landowners comply with lynx management guidelines, and a Federal nexus for review of forestry projects rarely exists. Furthermore, there continues to be high turnover in forest land ownership (Hagan *et al.* 2005; Ippoliti and Nadeau-Drillen 2006) and little funding to provide incentives or to work with private landowners. As of 2005, there were 23 landowners in northern Maine with land holdings in excess of 40,000 ha (100,000 ac) including the State, Federal government (White Mountain National Forest south of lynx range), a conservation group (The Nature Conservancy), 2 tribes (Penobscot Indian Nation and Passamaquoddy Tribe with much land south of lynx range) and 18 private forest landowners (Ippoliti and Nadeau-Drillen 2006, p. 13).

Although long-term, binding land management commitments are generally lacking in the northern Maine unit, several landowners have made short-term commitments to conserving lynx habitat. In 2003, Congress passed the Healthy Forest Restoration Act. Title V of this Act designates a Healthy Forest Reserve Program (HFRP) with objectives to: (1) promote the recovery of threatened and endangered species, (2) improve biodiversity, and (3) enhance carbon sequestration. In 2006, Congress provided the first funding for the HFRP, and Maine, was 1 of several pilot States to receive funding through its Natural Resources Conservation Service (NRCS) State office. Based on a successful pilot program, in 2008, the HFRP was reauthorized as part of the Farm Bill, and in 2010, NRCS published a final rule in the Federal Register (75 FR 6539) amending regulations for the HFRP based on provisions amended by the bill. In 2006 and 2007, the NRCS offered the HFRP to landowners in the proposed Canada lynx critical habitat unit in Maine to promote development of Canada lynx forest management plans. Since that time 4 private landowners, The Nature Conservancy, the Passamaquoddy Tribe, Merriweather LLC, and Katahdin Forestlands successfully enrolled in the program. Collectively, these land ownerships comprised 2,443 km^2 (943 mi^2), or 9.3 percent of the total designated critical habitat in northern Maine in 2014 (79 FR 54828).

The NRCS required that lynx forest management plans must be based on the Service's ''Canada Lynx Habitat Management Guidelines for Maine'' (McCollough 2007, entire). These guidelines were developed from the best available science on lynx management for Maine. The guidelines required maintenance of landscapes having hare densities that support reproducing lynx populations. Notably, HFRP forest management plans provided a net conservation benefit for lynx, which was achieved by employing the lynx guidelines, identifying baseline habitat conditions, and meeting NRCS standards for forest plans. Plans met NRCS HFRP criteria and guidelines and complied with numerous environmental standards. Plans were reviewed and approved by the NRCS with assistance from the Service.

Unlike lynx forest plans on Federal lands, HFRP plans lack long term commitments beyond an initial 10-year contract period, after which longer-term commitments to lynx management are voluntary. Plans were prepared for a forest rotation (70 years) and include a decade-by-decade assessment of the location and anticipated condition of lynx habitat on the ownership. Some landowners developed plans exclusively for lynx, and others combined lynx management (umbrella species for young forest) with American marten (umbrella species for mature forest) and other biodiversity objectives. All 4 plans have been completed although contracts with NRCS expired as of 2017. Landowners have the option to convert HFRP contracts into Safe Harbor Agreements or other agreements to provide regulatory assurances, however, at this time this option has not been explored with landowners.

Many large private forest landowners in the northern Maine unit could potentially include lynx management as part of endangered species management required by forest certification programs. For example, The Nature Conservancy land enrolled in the HFRP is also enrolled in the Forest Stewardship Council (FSC) forest certification program. Other landowners are certified under the Sustainable Forestry Initiative (SFI). Both certification programs require protection of threatened and endangered species (FSC 2010, pp. 24, 27; SFI 2015, pp. 6-7). However, certification programs are also voluntary and may not include long-term commitments. Few certified landowners have consulted with the Service on forest management for lynx. In addition, "working woodland" easements now encompass > 10,000 km^2 (3,861 mi^2) across northern Maine; although these covenants do not require specific management practices or outcomes beyond sustainable forestry, they do ensure that conversions to other land uses will never occur (MDIFW 2017, p. 2).

Lynx Status: Historically, Maine seems to have consistently had a breeding population of lynx. Early written accounts did not consistently distinguish bobcats from lynx (Hoving 2001). Prior to 1939, lynx observations were based largely on written accounts of lynx from museum records, journals, and periodicals (Vashon *et al*. 2012, p. 56). Hoving *et al*. (2003, pp. 368-369) compiled 118 lynx occurrence records (509 individual lynx) from 1833-1999, which suggest that lynx were widespread throughout the state except for the coastal areas. These records included 39 kittens representing at least 21 litters, primarily in northern and western Maine, from 1864-1999 (Hoving *et al*. 2003, p. 371). Populations apparently fluctuated, and in some years 200-300 lynx were harvested in Maine (Hoving *et al*. 2003, pp. 373-374). Lynx were later documented in winter snow track surveys conducted by MDIFW during 1994-1998 (Vashon *et al*. 2012, p. 56).

When the DPS was listed, lynx were known to be present in northern Maine but little was known about their distribution, population size and trend, snowshoe hare populations, and relationships to forest management. Since then, research from the MDIFW (Vashon *et al.* 2008a, entire; 2008b, entire; and 2012, entire) and the University of Maine (Hoving *et al.* 2003, entire; Hoving *et al.* 2004, entire; Hoving *et al.* 2005, entire; Homyack *et al.* 2005, entire; Homyack *et al.* 2007, entire; Homyack *et al.* 2006, entire; Fuller *et al.* 2007, entire; Fuller *et al.* 2004, entire; Fuller and Harrison 2005, entire; Simons-Legaard *et al.* 2013, entire; Simons-Legaard *et al.* 2016, entire) have greatly increased our knowledge. Snow track surveys and confirmed occurrence records document that lynx occur throughout northern Maine and in small, isolated pockets in western

and eastern Maine (Vashon *et al.* 2012, pp. 10, 12, 59), and small numbers of lynx have also been documented recently in northern New Hampshire (Siren 2014b, pp. 7-16), and Vermont (Bernier 2015, entire). Population size and trend are still uncertain in northern Maine, and persistence in New Hampshire and Vermont remain questionable.

This geographic unit is part of a larger, contiguous lynx population that extends into northern New Brunswick and the Gaspe region of southern Quebec. Extensive areas of contiguous forestland in this region provide high connectivity between populations in Maine and Canada. Lynx populations in adjacent southern Quebec may exhibit cyclic populations (Ray *et al*. 2002, entire), but obvious immigration of large numbers of lynx into Maine associated with hare cycles (if they occur) has not been documented (Hoving *et al*. 2003, pp. 373-374). Although potential lynx habitat in New Hampshire and Vermont is fragmented, there is near contiguous forest and connectivity for lynx movement between these areas and habitats in northern Maine (Farrell 2013, *pers*. *comm*.; 79 FR 54821). Areas of recent lynx breeding in New Hampshire and Vermont are not directly connected to Canadian populations, but they are connected to the larger population in northern Maine via habitat corridors in western Maine.

Lynx in the Northern Maine Unit and adjacent populations in southern Quebec and northern New Brunswick are separated from lynx populations in the interior of Canada. The St. Lawrence River restricts lynx dispersal and demographically isolates this population from those in northern Quebec, Labrador, and Ontario (Prentice *et al*. 2017, entire). However, sufficient numbers of individuals apparently cross the river on the ice each generation to prevent genetic drift of this population (Koen *et al.* 2015, enitre; Prentice *et al*. 2017, entire).

When the DPS was listed, the Northern Maine Unit was not believed to contribute significantly to its persistence. However, we now believe that the extensive young, regenerating spruce-fir habitat created by large-scale clearcutting in the 1970s and 1980s may currently support the largest lynx population in the DPS (Vashon *et al.* 2012, pp. 58-59, Appendix IV; Vashon *in* Lynx SSA Team 2016a, p. 18). Habitat in northern Maine supported lynx densities in a localized area of high-quality habitat that was substantially greater than densities elsewhere in the DPS (ILBT 2013, p. 23). In 2003 when hare populations were high, lynx density (juveniles and adults) in one of Maine's highest-quality habitats was estimated to be 9.2-13.0 lynx/100 km^2 (Vashon *et al.* 2008a, Vashon *et al.* 2012, p. 15). At about the same time, the density of lynx in nearby Gaspe Peninsula, Quebec was estimated to be 10 lynx/100 km^2 (Ray *et al.* 2002). These densities are intermediate to those in Canada during the high (17-45/100 km^2) and low periods (2.3-3.0/100 km^2) of the lynx-hare cycle (Poole 1994, Slough and Mowat 1996, O'Donaghue *et al.* 1997). Simons (2009, p. 102) estimated that habitat on a 14,407-km^2 (5,563-mi^2) study area (about half of the geographic unit) in northern Maine could potentially support a population of 236 to 355 adult lynx, and Vashon *et al.* (2012, pp. 58-59 and Appendix IV) estimated the potential for a population of 750 to 1,000 adult lynx in all of northern Maine in 2006. The actual number of lynx, however, is unknown because there are no methods available to count individuals over such a large geographic area.

Lynx seem to have maintained a similar distribution throughout northern Maine since the 1970s, and are found primarily north of Moosehead Lake and west of Interstate 95, with scattered pockets in western and eastern Maine (Hoving *et al*. 2003, p. 369; Vashon *et al*. 2012, pp. 10-12.) Resident lynx in small pockets of habitat outside of the core range in Maine (including New Hampshire and Vermont) may occur only ephemerally, winking on an off over time as would be expected at the periphery of the range of a metapopulation structure, and as suspected for other lynx populations at the periphery of the range (McKelvey *et al.* 2000b, pp. 25-31; Apps 2007, pp. 81, 95-104). From 1995-1998 and 2003-2008, the MDIFW conducted snow track surveys in 66 townships to document the distribution of lynx and to inform habitat modeling at the University of Maine (Vashon *et al*. 2012, p. 91). Modeled areas of potential lynx habitat were well-distributed throughout northern Maine in the early 2000s (Simons-Legaard *et al*. 2016, entire).

Lynx populations in New Hampshire and Vermont may consist of only a few animals and they may be ephemeral, although breeding has been documented in both locations in recent years. Most historical lynx records from New Hampshire are from trapping records from the 1930s to the 1960s (Brocke *et al.* 1993, pp. 71-74; McKelvey *et al.* 2000a, pp. 212-214). There were only 2 records in the 1990s. In 2003, the Service determined that, despite a lack of breeding records, a small resident population likely occurred historically in New Hampshire but no longer exists (68 FR 40087). Lynx were detected in northern New Hampshire in 2006 and have occurred there annually since then (Siren 2014b, pp. 53, 55). In 2011, 4 lynx kittens were observed in Pittsburg and were considered evidence of breeding in New Hampshire (Kilborn 2015, Appendix A, p.44). There were only 4 historical records of lynx in Vermont prior to 2003. Since then, 9 lynx sightings have been confirmed, and reproduction was confirmed in 2012 in the Nulhegan Basin when the tracks of 3 lynx, a presumed family group, were observed travelling together in late February (Vermont Fish and Wildlife 2015, Appendix A5, p. 126). Since 2012, more intensive surveys in Vermont have resulted in only a single photograph of a lynx in 2014 (Bernier 2015, pp. 1-3; Bernier 2016, *pers. comm.*). Landscape hare densities are marginal in these areas; 0.52 hares/ha (range 0.12-0.58 hares/ha) in the Nulhegan Basin of Vermont and 0.12-0.23 hares/ha in the White Mountain National Forest (Siren 2017, pp. 13, 23, 24), which may explain why lynx rarely occur.

Maine lynx had spatial and demographic parameters similar to some northern populations during the cyclic high in the snowshoe hare cycle (Brand *et al.* 1976, Parker *et al.* 1983, O'Donaghue *et al.* 1997). From 1999 to 2011, biologists with the MDIFW trapped and radio-marked 85 lynx in northern Maine and documented lynx movements and home range (Vashon *et al*. 2008a, entire; Mallet 2014, pp. 69-93), resource use (Vashon *et al*. 2008b, entire), survival (Vashon *et al*. 2012, pp. 18-21), productivity (Vashon *et al*. 2012, pp. 17-19), and other aspects of their life history (Vashon *et al*. 2012, entire). During the period when snowshoe hare populations were highest (2000-2006), Maine lynx had among the highest reproductive rates in the DPS (89 percent of adult females produced litters, average litter size was 2.74, and kitten survival was 78 percent) (Vashon *et al.* 2012, pp. 18-21). During the current (2006-present) period of lower hare density, only 30 percent of females had litters and average litter size was smaller (2.25), but kitten survival rate remained high, and was actually somewhat higher during the lower hare years (89 percent from 2006-2010, compared to 78 percent from 1999-2005;

Vashon *et al*. 2012, p. 21, table 1.5). Maine lynx have among the smallest home ranges documented in the DPS (Vashon *et al*. 2008a, p. 1482; ILBT 2013, p. 24; also see tables 3 and 4). Home range sizes were similar during periods of higher and lower hare density (Mallett 2014). Lynx populations likely increased during the period of high hare density (lambda [λ] = 1.16) and declined during periods of low hare density (λ = 0.88; USFWS, Vortex 10, deterministic population simulation 2016; demographic data from Vashon *et al.* 2012, pp. 17-21).

In summary, Maine lynx and hare habitats are believed currently to be at historical highs as a result of forest regeneration following widespread clearcutting in the 1970s and 1980s and subsequent use of herbicides to suppress hardwoods in response to a spruce budworm outbreak (Hoving *et al.* 2004; Vashon *et al.* 2008b). In the Northeast prior to European settlement, lynx habitat was created and maintained by small-scale, frequent forest gap dynamic events and large-scale, infrequent (stand-replacing) forest disturbances (Seymour *et al.* 2002; Lorimer and White 2003). Historically, lynx distribution was patchy, and lynx populations likely fluctuated and may have been more dependent on immigration from Canada. At multiple scales, lynx in Maine select extensive areas of regenerating, dense (7,000 – 14,000 stems/ha) spruce-fir stands 15 to 35 years after clearcut, other even-aged harvest, or natural disturbance (Hoving *et al.* 2005; Fuller *et al.* 2007; Vashon *et al.* 2008b; Simons-Legaard *et al.* 2013). The unnaturally high amount of high-quality lynx habitat in this unit is expected to decline by 2030 because of changing forest practices, before stabilizing or increasing again by 2060 (Simons-Legaard 2016, p. 10, fig. 8; Simons-Legaard *et al.* 2016; see 5.2.1, below).

Factors Affecting Current Conditions

Regulatory Mechanisms - In response to public concern about widespread clearcutting in northern Maine (described above), in 1989 the Maine Legislature passed the Maine Forest Practices Act (MFPA). The MFPA regulates maximum size of clearcuts (about 100 ha [250 ac]), separation zones between clearcuts, harvest plans, and notification to the Maine Forest Service. Clearcuts are not banned, but require varying levels of State permits depending on their size. As a result of these regulatory requirements, clearcuts have declined substantially in annual number and acreage and have been replaced by various forms of partial harvesting (Sader *et al.* 2003, p. 349-350; McWilliams *et al.* 2005, p. 35; Legaard *et al*. 2015, pp. 14-21). Following passage of the MFPA, the percentage of acreage clearcut annually in Maine declined from 44 percent of annual harvest in 1989 to < 5 percent in 2004 (Simons 2009, pp. 45-46; Legaard *et al*. 2015, p. 18). The average size of clearcuts has been reduced from > 50 ha (125 ac; Maine Forest Service 1995, entire) to < 10 ha (25 ac; Maine Forest Service 2003, entire; 2005, entire; 2007, entire). Currently, partial harvesting comprises about 94 percent of acres cut annually in Maine (Simons 2009, p. 50). Although total timber volume harvested has changed relatively little, landowners must partial harvest about twice as many acres to harvest the same volume of wood annually that they would with clearcutting (Legaard *et al*. 2016, p. 18). Thus, the annual forest area harvested in Maine has increased from about 100,000 ha (250,000 ac) pre-MFPA to 223,000 ha (550,000 ac) post-MFPA (McWilliams *et al.* 2003, p. 35).

Currently, 28 years after implementing the MFPA, much of the 4 million-ha (10 million-ac) northern Maine landscape has been partially harvested (Legaard *et al*. 2016, p. 16) – some areas on multiple occasions. The partial harvests that replaced clearcuts include a variety of silvicultural treatments, including both even-aged (e.g., shelterwood) and uneven-aged (e.g., selection) management that result in a wide range of residual stand conditions (Robinson 2006, pp. 5-37), which have important implications for lynx conservation. Snowshoe hare densities in partially harvested forests are on average about 50 percent lower (but range from 20 to 90 percent lower) than in regenerating conifer stands created by clearcutting (Robinson 2006, pp. 5-37; Scott 2009, p. 109; Simons 2009, p. 83), thus reducing landscape hare density and, thererofe, lynx habitat quality in this unit (Simons 2009, pp. 206, 209, 217; Simons-Legaard *et al.* 2016, p. 7-8; Simons-Legaard 2016, entire). Landscape level hare densities have declined with extensive partial harvesting and aging of the spruce budworm-era clearcuts, and future declines are anticipated (Simons-Legaard *et al.* 2016, 9-10; also see section 5.2.1).

Climate Change - Climate change is affecting temperature, snow, and precipitation patterns in the Northeast at rates faster than expected (Rustad *et al.* 2012, p. 6). Rapid winter warming in recent decades is believed to be influenced by an albedo effect caused by the reduced persistence of snow in winter (Hayhoe *et al.* 2006). Average winter temperatures are increasing 0.42° - 0.46°C/decade (0.76° - 0.83 °F/decade) with the greatest warming occurring in the winter months, especially January and February (Burakowski *et al.* 2008). Under mid- to high-emissions scenarios, average mean temperatures in northern Maine are projected to increase by 6.7° - 7.8°C (12° - 14°F) by 2080-2099 relative to 1971-2000 (Galbraith *et al*. 2013, p. 43). Under a higher emissions scenario, snow covered days in northern Maine (from December to February) could decrease from 30 days per month observed from 1961-1990 to about 18-20 days per month in 2070-2099 (Galbraith *et al*. 2013, p. 49). Climate warming may have already affected lynx habitat in this unit by reducing the distribution of favorable snow conditions and boreal forest vegetation, and it is likely to continue to do so in the future (see section 5.2.1).

Snow Duration, Depth, and Quality - As noted in chapter 2, records of lynx occurrence are correlated with areas that regularly have at least 4 months (120 days) of continuous snow coverage (Gonzalez *et al.* 2007, p. 7). Snow cover days in northern New England (1965-2005) ranged from 60-121 days and declined an average of 3.6 days/decade from 1965-2005 (Burakowski *et al.* 2008). Snow duration declined by 16 days in the Northeast from 1970 to 2001 (Wake 2005) and is expected to diminish another 2 weeks in Maine by mid-century (Fernandez *et al.* 2015). Thus, average conditions in Maine are currently at or below the snow cover duration correlated with historical lynx occurrence records. Similarly, the largest decreases in snow depth observed in Canada in the last 6 decades have occurred in the lower St. Lawrence Valley, immediately north of Maine (Brown and Braaten 1998, pp. 48-52).

Lynx in the northeastern United States and eastern Canada occur where average annual snowfall typically exceeds 270 cm/yr (106 in/yr; Hoving *et al.* 2005), which defines the distribution of lynx (to the north) and bobcat (to the south) in this region (Hoving *et al.* 2005; Carroll 2007; Peers *et al.* 2013). Average annual snow depth at all 5 NOAA weather stations within the range of the lynx in northern Maine (1981-2010) was below this threshold and ranged

from 228-263 cm (90-104 in; NOAA 2011[14]). In the last 50 years, 18 of 23 snow sampling sites in and near Maine experienced reduced depth of snowpack (Hodgkins and Dudley 2006). Snow depth in New England (1965-2005) declined an average of 4.6 cm/decade (1.8 in/decade; Burakowski *et al.* 2008). Thus, average annual snowfall in Maine is currently at or below depths associated historically with lynx presence, and further declines could reduce the likelihood that resident lynx will persist in this unit (Hoving *et al.* 2005).

As noted in chapter 2, deep, unconsolidated and persistent snow is thought to provide lynx with a competitive advantage over other terrestrial hare predators and gives snowshoe hares the ability to reach winter browse. Snow quality ("fluffiness") has deteriorated and snow density has increased in the Northeast. Unlike other units, annual precipitation in Maine is increasing because of climate change, but primarily as rain (Siren *in* Lynx SSA Team 2016a, p. 15; Fernandez *et al.* 2015), and especially rain on snow events in winter in northern Maine (Huntington *et al*. 2004; Deser *et al.* 2014; Fernandez *et al.* 2015). Snow density and compaction and crust conditions (caused by wet, heavy snow or rain on snow events in winter) have increased in northern New England (Dudley and Hodgkins 2002; Huntington *et al.* 2004; Huntington 2005; Hodgkins and Dudley 2006) and southern Canada (Karl *et al.* 1993).

Vegetation Management - The effects of forest management on foraging and denning habitat for lynx in northern Maine are discussed in the Habitat Description, Habitat Status, and Regulatory Mechanisms sections above. As described there, past vegetation management in the form of landscape-level clearcutting (sometimes followed by herbicide application to promote softwood regeneration) of budworm impacted forests is responsible for the current historically high amount of high-quality hare (and therefore lynx forgaing) habitat in this unit. The amount of high-quality habitat created by these densely-regenerating stands probably peaked in the late 1990s – early 2000s and is expected to decline over the next several decades (see section 5.2.1).

Wildland Fire Management - Although fire is frequent in many boreal forest regions, it is not a stressor for lynx in northern Maine and likely played a minimal role historically in creating and maintaining lynx and hare habitats. Annual precipitation is comparatively greater in this unit than others, and conditions for large fires occur infrequently. The fire regime in this unit is one of infrequent (50- to 200-year interval) and generally small (several acres) surface fires in the dormant season. Large (up to 32,375 ha [about 80,000 ac]) stand-replacing fires are rare and occur at a less frequent interval (800 to 9,000 years; Seymour *et al.* 2002, p. 360). In contrast, spruce budworm outbreaks cause stand-replacement over large areas every 100–250 years (Cogbill, 1985).

Habitat Fragmentation - Habitat fragmentation (smaller and more isolated patches of high-quality hare habitat) caused by current forest practices in northern Maine is discussed in the Habitat Description and Habitat Status sections above.

[14] http://www.ncdc.noaa.gov/oa/climate/normals/usnormals.html, https://www.currentresults.com/Weather/Maine/annual-snowfall.php, last accessed 3.31.2016.

Other Factors: *Trapping* - This unit is directly connected to lynx habitats and populations in southern Quebec, where trapping of lynx is legal. In areas where lynx are trapped for furs (Canada and Alaska), trapping can be additive to other sources of mortality and have population-level effects (Brand and Keith 1979; Koehler and Aubry 1994). Thus, harvest regulations for lynx are modified (e.g., lynx quotas per trapper are reduced) when hare and lynx populations are low (Bailey *et al.* 1986). About 400 lynx are trapped and killed annually in Quebec south of the St. Lawrence River[15]. Several lynx that were captured and radio-marked in northern Maine were subsequently trapped in southern Quebec (Vashon *et al.* 2012).

Lynx trapping and hunting seasons were closed in Maine in 1967 (Vashon *et al*. 2012, p. 28) and also in New Hampshire and Vermont for decades prior to the DPS being listed under the ESA. In 2014, the MDIFW worked with the Service to develop an *Incidental Take Plan for Maine's Trapping Program* (MDIFW 2014, entire; 2015a as amended, entire) and obtained a permit from the Service for lynx trapped incidental to other furbearer trapping in Maine (see section 3.1.2). Trapping injury and mortality are not believed to have a population-level effect on lynx in northern Maine and adjacent Canada when lynx may be at historically high numbers, but increased, targeted lynx trapping in southern Quebec could have a synergistic and negative effect if hare and lynx populations decline, habitat declines, or climate change further stresses lynx (Slough and Mowatt 1996; Carroll 2007, pp. 1099-1103). Carroll (2007, pp. 1099-1103) modeled lynx populations in this unit and demonstrated that increased trapping pressure in Quebec could, combined with projected clmate warming and associated snow loss, have a negative effect on protected lynx populations in Maine and New Brunswick.

Wind Power Development - Interest in wind energy development has increased in northern and western Maine, and such development could impact high- and low-elevation spruce-fir habitats (Whitman *et al.* 2013). Maine has experienced a rapid increase in wind energy development[16], and there is increased interest in placing developments on private lands in unpopulated areas in northern Maine, New Hampshire, and Vermont. Wind energy is an increasingly appealing source of income for investment companies and other landowners who own forestland in the northern Maine unit. As of 2016, at least 11 wind projects have been proposed in northern and western Maine and 5 projects are in operation; 2 have been proposed in northern New Hampshire and 2 are in operation; and 3 have been proposed for northeast Vermont and 2 are in operation or under construction. Maine's 2 largest wind projects (combined over 250 turbines covering 932 km^2 [360 mi^2]) are proposed entirely within Maine's designated lynx critical habitat. Although impacts of wind energy projects on lynx, hares, and their habitats have not been demonstrated, potential effects include loss and fragmentation of habitat from turbines, roads, and transmission lines, and disturbance or displacement of resident lynx. Road construction could further fragment habitat and increase access, potentially increasing vehicle collisions with lynx and other sources of mortality, including incidental trapping or illegal shooting (also see 5.2.1).

[16] http://www.eia.gov/electricity/data/browser, last accessed 8.2.2016.

Changing Land Ownership and Development - Until recently, the northern Maine unit was largely undeveloped and owned primarily by about a dozen large, commercial timber interests, but land ownership patterns have changed dramatically in the last 15 years (Ippoliti and Nadeau-Drillen 2006). Large tracts of land have been sold, lumber and pulp mills shut down, and much of the area has been sold to investment-oriented owners. Some of these new landowners are seeking diversified financial returns on their investment, including developing residential housing, second homes, and resorts. At various times in the past, 2 large residential and resort areas have been proposed on forestlands within designated lynx critical habitat in this unit. Both projects, if eventually built as previously-planned, could result in the development of several thousand acres of potential lynx habitat, but would be mitigated by substantial (100,000s of acres) conservation easements on surrounding forestland. Also, a private landowner recently purchased and donated 354 km^2 (137 mi^2) within designated lynx critical habitat that was subsequently designated as the Katahdin Woods and Waters National Monument. This area currently has a legacy of young regenerating spruce-fir habitat from previous commercial timber harvest, but its new monument designation will limit future forest management activities (timber harvest or other vegetation management) that could benefit lynx. In addition, the Nature Conservancy continues forest management on about half of its 750-km^2 (290-mi^2) ownership in this unit, including managing part of the area for lynx.

Construction or expansion of developed areas such as residential areas and resorts and smaller recreational sites like Nordic ski huts or campgrounds may directly remove forest cover. Such habitat alteration and associated human recreation in lynx habitat could result in a more fragmented landscape and localized decreases in prey availability, and could affect lynx movements within home ranges or displace lynx from high-quality habitats. As with energy development, road and highway construction often associated with residential and recreational development can further fragment habitat and, with associated increases in traffic volumes and/or speeds and human access, can increases the likelihood of lynx mortality and injury from vehicle collisons and incidental or illegal trapping or hunting.

In summary, lynx were historically and are currently widespread throughout northern Maine, and they currently occur (and probably occurred historically) as small resident or ephemeral populations in small patches of habitat outside this geographic unit in eastern and western Maine, northern New Hampshire, and northern Vermont. According to MDIFW, habitat in northern Maine may currently support a potential population of 750 to 1,000 lynx. High-quality habitat created by extensive clearcutting 30 to 40 years ago is peaking and is projected to decline by 50 percent in the next 15 to 20 years (Simons-Legaard 2016, pp. 10-18; also see section 5.2.1). Hare densities declined by 50 percent in this unit starting in about 2006 and have remained at lower levels, and future hare fluctuations or cycles are uncertain. Recent history demonstrates that some forms of forest management have the potential to create or increase lynx habitat. However, forest practices have shifted to partial harvesting, which is less likely to create large areas of lynx habitat or maintain the current historically broad distribution of high-quality habitat generated by previous landscape-level clear-cutting. Additionally, private landowners who previously entered into commitments to manage for lynx conservation have not renewed those commitments (although the habitat will remain viable for lynx for some time).

Land ownership has also changed in northern Maine, and the majority of lands are owned now by investment companies that often wish to diversify income from their investments, which could result in forest practices inconsistent with lynx habitat conservation. Without long-term, binding land management commitments in this unit, there is no guarantee that the current historically high amount of lynx habitat will be maintained by future forest managment practices on private lands. The greatest stressors to resident lynx in this unit are habitat loss (as a result of the shift in forest management from clearcutting to partial harvesting resulting in lower landscape hare densities), lack of forest planning for lynx, and projected continued climate warming (diminishing snow depth, quality and duration; transition from spruce-fir to northern hardwood forests; potential increased competition from bobcats and fishers; and increased future isolation of lynx in this unit and southeastern Canada because of diminishing ice conditions on the St. Lawrence River/Seaway).

4.2.2 Unit 2 - Northeastern Minnesota

Unit Description: This geographic unit encompasses approximately 21,100 km^2 (8,147 mi^2) in northeastern Minnesota. It includes the area designated as critical habitat in 2014 (79 FR 54782) and an additional relatively small area of tribal land that was excluded from critical habitat. Land ownership in this unit is about 47 percent Federal (primarily USFS, with some NPS and BLM land); 36 percent State; 16 percent private; and 1 percent Tribal (Grand Portage Reservation; see table 2). This unit includes most of Superior National Forest (SNF; including the Boundary Waters Canoe Area Wilderness [BWCAW]) and Voyageurs National Park. This unit is directly connected to lynx habitats and populations in Canada, and lynx in this unit likely represent the southern extent of a larger cross-border population, most of which occurs in Ontario. Relative to other DPS lynx populations, this unit is about 1,610 km (1,000 mi) west of the Northern Maine geographic unit and about 1,480 km (920 mi) east of the Northwest Montana/Northeast Idaho Unit.

Habitat Description: In Minnesota, most lynx occurrences are associated with the Mixed Deciduous/Conifer Forest (McKelvey *et al.* 2000a, pp. 246, 248) within the Laurentian Mixed Forest Province (McNab *et al.* 2007, p. 5). Most of this province is characterized by low-relief hilly landscapes with glacial features and an elevation from sea level to 730 m (2,400 ft), including many lakes and rivers. This unit contains a mix of upland conifer and hardwood interspersed with lowland conifer, alder or willow shrub swamps and black spruce or tamarack bogs. Coniferous and mixed-coniferous/deciduous vegetation types are dominated by balsam fir; black and white spruce (*Picea glauca*); northern white cedar (*Thuja occidentalis*); Jack (*Pinus banksiana*), white, and red (*Pinus resinosa*) pine; eastern hemlock (*Tsuga canadensis*); and tamarack; mixed with aspen and paper birch (Burdett 2008, p.5; McCann and Moen 2011, p. 510). Burdett (2008, p. 57) reported that lynx in Minnesota selected regenerating forest, dominated by conifer with extensive forest edge, and that lynx beds (resting and hunting) and kill sites were associated with regenerating and mixed forest. McCann and Moen (2011, p. 513) found snowshoe hare densities were highest in regenerating forests. Female lynx selected large woody debris and dense horizontal cover in lowland conifer cover for denning in northern

Minnesota (Moen *et al.* 2008a, p. 1510), but other cover types were used if recent blowdowns were present (Moen and Burdett 2009, p. 5).

Snowshoe hare habitat in Minnesota primarily consists of conifer forests with dense low-growing understories, lowland shrub, and conifer bogs. Conifer bogs or lowland conifer forests may be especially important during declines in hare abundance by acting as refugia for hares. Early regenerating or pole-sized stands are not used as much as in other portions of their range, although older regeneration stands were used frequently in Minnesota (McCann 2006, p. 45). Sapling-sized aspen adjacent to conifer cover may also provide functional snowshoe hare habitat. In northeastern Minnesota, edge habitats and regenerating conifer stands appeared to be important for snowshoe hare populations (Burdett 2008, p. 58; McCann 2006, p. 45), as were dense habitats containing balsam fir, white spruce, and cedar (Fuller and Heisey 1986, p. 263). Recent research indicates that the red squirrel is not an important prey species for lynx in northeastern Minnesota (Burdett 2008, p. 62; Hanson and Moen 2008, p. 9).

Average annual snowfall in this unit ranges from about 180 cm (71 in) in the northwestern part of the unit near International Falls, to 219 cm (86 in) in Duluth, on the southern end of the unit, to 228 cm (90 in) in Tofte, near the lake shore on the far eastern-central part of the unit and in Isabella, near the center of the unit, to 107 cm (42 in) in Grand Portage, at the northeastern tip of the unit. More snow is produced along Lake Superior, because of the lake effect[17].

Habitat Status: Friedman and Reich (2005, p. 732) conducted a spatially explicit forest composition change analysis on a 3.2 million-ha study area in northeastern Minnesota, which was based on General Land Office Survey records from the late 1800s and the 1990 USFS Inventory and Analysis Survey. The study documents altered forest tree species abundance, proportional basal area, and spatial distribution patterns. The proportionally most abundant species in northeastern Minnesota shifted from the presettlement period (spruce, 21 percent; tamarack, 15 percent; and paper birch, 15 percent) to aspen (30 percent), spruce (16 percent), and balsam fir (16 percent) in 1990. White pine declined from 20 percent to 5 percent basal area dominance, birch from 16 percent to 13 percent, spruce from 14 percent to 9 percent, and tamarack from 12 percent to 2 percent, while aspen increased from 8 percent to 35 percent basal area dominance.

The SNF continues to manage in accordance with its 2004 Forest Land and Resource Management Plan (USFS 2004a, entire). The Forest Plan emphasizes providing sustainable amounts of timber, maintaining or enhancing biodiversity, contributing to economic and social needs of the community, and managing in an environmentally sound manner to produce goods and services that provide for long-term public benefits. The Plan includes many objectives, standards, and guidelines for the protection of lynx and enhancement of lynx habitat (USFS 2004a, Appendix E) that are based on recommendations in the 2000 LCAS (Ruediger *et al*. 2000, entire). LAUs were delineated on the SNF in 2000 as the smallest landscape scale on which to analyze effects to lynx. The boundaries have remained in place since that time to allow for long term analysis of project effects. However, the SNF Plan proposed several changes of

[17] https://snowfall.weatherdb.com/d/a/Minnesota; accessed 4/25/2016.

current LAU boundaries, such as adding LAUs to the Virginia Management Unit of the Laurentian Ranger District, and designating the BWCAW a lynx refugium.

Hare density in parts of northeastern Minnesota appears to be sufficient to support a viable lynx population (Moen *et al.* 2008a, p. 1512), with stand-level densities ranging from 0.3–2.0 hares/ha (0.12–0.8 hares/ac; McCann 2006, p. 17). Hare populations in northeastern Minnesota appear to be patchily-distributed, but are most consistently abundant in 10-30 year old regenerating forests (McCann 2006, p.45). Pellet count data prior to the 1990s show evidence of density fluctuations of snowshoe hare populations occupying Minnesota (Fuller and Heisey 1986, pp. 262-263), but these fluctuations were not observed during the 1990s (Hodges 2000a, p. 172).

This unit is directly connected to lynx habitats and populations in southern Ontario, where trapping of lynx is legal. Habitat connectivity within and between portions of northeastern Minnesota and Canada appears functional based on radio-telemetry data that have documented lynx movements in both directions between Minnesota and Ontario (Burdett *et al.* 2007, p. 458; Moen 2009, pp. 4-6; Moen *et al.* 2010b, p. 5).

Lynx Status: When the DPS was listed, it was uncertain whether a resident lynx population occurred in Minnesota. However, we now know that a reproducing resident population has persisted in Unit 2 since the DPS was listed. Moen *et al.* (2008b, p. 30) estimated a likely maximum (all available habitat occupied) number of 190-250 resident lynx in this unit, and Moen (*in* Lynx SSA Team 2016a, p. 39) recently suggested that the resident population likely fluctuates from about 50 to 200 lynx. A more precise estimate of resident population size is not available.

Average home range sizes in Minnesota were first reported as 194 km^2 (75 mi^2) for males and 87 km^2 (34 mi^2) for females (Mech 1980, p. 263). Later radio-telemetry data showed that males had much larger average home range sizes (267 km^2 [103 mi^2]) than females (21 km^2 [8 mi^2]), and that females with kittens had the smallest home ranges (Burdett *et al.* 2007, pp. 460-461). A study of radio-collared lynx in Minnesota documented approximately 40 percent of male and female lynx making long distance movements outside of their home ranges and into southern Ontario (Moen *et al.* 2010b, p. 17). Among lynx that made long-distance movements, females tended to move 100-200 km (62-124 mi) and did not return to their original home ranges in Minnesota, while males moved 50-80 km (31-49 mi) back and forth between Ontario and Minnesota (Moen *et al.* 2010b, p. 17).

The SNF and others have identified 268 unique individual lynx (48 percent female, 51 percent male) from DNA samples taken since 2000 (Catton *et al.* 2015, p. 1). This study also documented lynx hybridization with bobcat and identified 13 unique individual lynx-bobcat hybrids (5 Female, 8 Male; Catton *et al.* 2015, p. 1). The DNA analyses also showed persistence of individual lynx in Minnesota of 2 years (N = 27 lynx), 3 years (N = 11), 4 years (N = 5), 5 years (N = 6), and 1 female lynx tracked for over 5 years, who produced 7 kittens in Minnesota (Catton *et al.* 2015, pp. 3-5).

Since 2000, the Service has documented 45 lynx mortalities in Minnesota including 16 that died of unknown causes, 11 that died after being incidentally captured in traps set for other species, 9 that were hit by vehicles on roads, 7 that were illegally shot, and 2 that were hit by trains (USFWS 2016b, *unpubl. data*). In addition to the 11 trapping mortalities, another 15 lynx were documented to have been incidentally trapped but released alive. The documented incidents largely occurred during legal trapping that targeted bobcat, coyote, fox, and marten, and involved a variety of traps including foot-holds, body gripping traps, and snares. Other lynx may have been incidentally trapped but not reported. Additionally, lynx emigrating from Minnesota to Ontario are exposed to legal trapping and shooting in accordance with regulated harvest in Canada. At least a third of lynx radio-collared in Minnesota spent time in Ontario; 4 radio-collared lynx were legally harvested (trapped) in Canada between 2003 and 2010, and 2 died in Ontario of unknown causes (USFWS 2016b, *unpubl. data*). Some of these mortalities occurred years after the lynx was last located in Minnesota, indicating, along with evidence of lynx returning to Minnesota after dispersing to Ontario, that survival of Minnesota lynx in Ontario for extended periods is possible (Moen 2009, pp. 2-3, 10-13). Minnesota has relatively high forest road and highway densities that intersect lynx habitat and several radio-collared lynx in Minnesota inhabited home ranges that were bisected by highways.

Factors Affecting Current Conditions

Identified factors potentially affecting current conditions for lynx in Minnesota include reduction in habitat quality or quantity, habitat fragmentation, climate change, increased access for competing hare predators, and human-caused mortality. The SNF is currently implementing the 2004 SNF Plan (USFS 2004a, entire), which has direction based on the LCAS (Ruediger et al. 2000, entire) and the Canada Lynx Conservation Agreement (CA) between the Forest Service and the Service (USFS and USFWS 2000, entire), for all forest activities that occur within LAUs. Active management of forest lands can create, maintain, and restore lynx habitat, and the SNF has a long-term commitment for doing so; however, private landowners do not. Under the Sustainable Forest Resource Act of 1995, the Minnesota Forest Resources Council (MNFRC) has developed guidelines for site-level timber harvesting and forest management (MNFRC 2012, p. 1); these voluntary guidelines are intended for private and State landowners and include some general recommendations for wildlife including lynx. The implementation of the MNFRC guidelines is monitored annually (e.g., MNDNR 2016b, p. 2). Thus, the several risk factors are being minimized and managed to promote the conservation of lynx within the SNF, however implementation of the guidelines on privately owned lands is voluntary.

Activities that change forest structure can affect habitat quantity and quality for lynx and snowshoe hares, their primary prey source. Thinning and other timber management practices that reduce stem density and downed material and promote more open, mature stands can reduce habitat quality and quantity. Throughout the SNF and northern Minnesota, human activities have reduced connectivity between patches of suitable lynx habitat. Development for residential and commercial uses, as well as roads, railroads, and utility corridors have all interrupted linkage corridors. Mineral exploration and development is increasing in portions of

Minnesota, particularly for hard rock (non-ferrous) minerals. Some of the area of interest for minerals overlaps with lynx habitat in northeastern Minnesota. Mineral exploration may result in short-term displacement of lynx. Mining activities and associated development may result in an irreversible loss of habitat or increased mortality risk. The specific effects to lynx and their habitat will depend on the scale and type of each project.

Roads are a factor in human-caused lynx mortality where they provide access to areas where lynx occur, increasing the risk of negative interactions between people and lynx. Throughout the SNF outside the BWCAW, high and low standard roads bisect many areas that provide potential or suitable lynx habitat. Additionally, bobcat harvest in northeastern Minnesota has been increasing over the last decade (Erb 2012, unpaginated), although it is still very rare in the area occupied by resident lynx in this unit. Where lynx and bobcat overlap, there is potential for accidental shooting and increased incidental trapping of lynx.

Winter road use, snowmobiling, cross country skiing, and dog sledding all increase the amount and distribution of compacted snow conditions, which may increase access by potential lynx competitors or predators to snowy areas from which they may otherwise be excluded (ILBT 2013, pp. 80-82). However, results of research on whether these activities result in increased competition or predation are ambiguous (ILBT 2013, p. 81) and impacts, therefore, are uncertain. Outside the BWCAW, snowmobile activity is extensive and increasing significantly. The SNF has 1,135 km (705 mi) of snowmobile trails and 2,514 km (1,562 mi) occur on all ownerships within the National Forest boundary (USFS 2011a, p. 38). Advances in snowmobile capabilities have raised concerns about intrusion and snow compaction in areas previously not vulnerable to high levels of snowmobile use. In addition, new road construction in lynx habitat has made more areas accessible during winter. These routes could be used by snowmobiles even if new roads are designated as closed to motorized public travel during other seasons. The SNF has 3,101 km (1,927 mi) of low standard roads and 254 km (158 mi) of temporary roads (USFS 2011a, p. 38). Increases in these activities have the potential to reduce the competitive advantage lynx are believed to have in areas that typically receive deep, persistent, unconsolidated snows.

As described in Chapter 2, lynx are adapted for surviving in areas that have cold winters with deep, fluffy snow, where they are thought to outcompete potential competitors such as bobcats, coyotes, and wolves. The geographical distribution of bobcat harvest in Minnesota has remained relatively static with a lack of harvest in the Arrowhead Region of Minnesota (the region encompassed by Cook, Lake, and St. Louis counties in northeastern Minnesota; Erb 2009 cited in Kapfer 2012, p. 16; Erb 2012, unpaginated) and annual snow track and scent stations surveys support the conclusion that bobcats are as rare in the Arrowhead Region as harvest indicates (MNDNR, *unpubl. data*, cited in Kapfer 2012, p. 23). However, this may change with decreased snow conditions predicted to result from continued climate warming (Kapfer 2012, p. 25; see section 5.2.2). Bobcat and coyote populations already appear to be increasing in Minnesota (Erb 2014, p. 40). If snow depth and duration decrease in the Arrowhead Region as projected by climate models, deer mortality may be reduced; this could increase bobcat densities and facilitate bobcat expansion into northeastern Minnesota (Kapfer

2012, p. 25), potentially increasing bobcat-lynx hybridization (Koen *et al.* 2014b, p. 113). According to annual track surveys, wolf populations in Minnesota are currently stable (Erb 2014, p. 40); however, similar to bobcat, wolf populations may increase with changing snow conditions and prey availability as influenced by climate change.

In summary, although lynx residency in the unit was uncertain when the DPS was listed, we now understand that it supports a persistent resident population that is thought to fluctuate from 50-200 individuals, likely in response to hare population changes that affect lynx survival, productivity, and recruitment. We have no evidence to suggest that this area historically supported a larger population or a broader distribution of habitat capable of supporting persistent lynx occupany. Although recent research has improved our understanding of lynx distribution, habitat requirements, dispersal, and some demographic parameters in this unit, we still lack information on kitten survival, recruitment, and the influence of immigration and emigration on population persistence.

4.2.3 Unit 3 - Northwestern Montana/Northeastern Idaho

Unit Description: This geographic unit includes the parts of northwestern Montana and northeastern Idaho the Service designated as critical habitat for lynx in 2014 and some Tribal and State lands that were excluded from that designation (79 FR 54825). It encompasses approximately 27,000 km^2 (10,424 mi^2) in portions of Boundary County in Idaho and Flathead, Glacier, Granite, Lake, Lewis and Clark, Lincoln, Missoula, Pondera, Powell and Teton Counties in Montana. Ownership in this unit is 84 percent Federal (USFS, NPS, and BLM); 8 percent private; 4 percent State; and 4 percent Tribal. Most Federal lands in this unit (82 percent) are on national forests managed by the USFS; with NPS (16 percent) and BLM (almost 2 percent) contributing most of the remainder. This unit includes most of Glacier National Park and parts of the Flathead, Helena, Idaho Panhandle, Kootenai, Lewis and Clark, and Lolo National Forests, the BLM's Garnet Resource Area, and the Confederated Salish and Kootenai Tribes Flathead Reservation. It also includes (from northwest to southeast) all or parts of the Purcell, Cabinet, Salish, Whitefish, Lewis, Flathead, Swan, and Garnet mountain ranges. Several areas adjacent to this unit are known or thought to support a small number of resident lynx, at least intermittently, including the southern Selkirk Mountains of northern Idaho and northeastern Washington and the western Cabinet Mountains of northern Idaho (USFS 2015a, pp. 9-10; Lucid 2016, pp. 7-11; Lucid *et al*. 2016, pp. 158-160; IDFG 2017, pp. 2-5), and a small area of the Helena National Forest just south of MacDonald Pass, between Helena and Missoula (Gehman *et al.* 2011, p. 21). This unit is directly connected to lynx habitats and populations in Canada, and lynx in this unit may represent the southern extent of a larger cross-border population that also occurs in southwestern Alberta and southeastern British Columbia. Relative to other DPS lynx populations, this unit is about 200 km (125 mi) east of the north-central Washington unit, about 145 km (90 mi) northwest of the GYA, and about 1,480 km (920 mi) west of the Northeastern Minnesota geographic unit.

Habitat Description: In the Northern Rocky Mountains, most lynx occurrences are associated with the Rocky Mountain Conifer Forest or Western Spruce-Fir Forest vegetative classes

(Kuchler 1964, p. 4; McKelvey *et al.* 2000a, p. 246) at elevations ranging from 1,250 m (4,100 ft) to 2,500 m (8,200 ft; Aubry *et al.* 2000, pp. 378–380; McKelvey *et al.* 2000a, pp. 243–245). The dominant vegetation that constitutes lynx habitat in these areas is subalpine fir, Engelmann spruce and lodgepole pine (Aubry *et al.* 2000, p. 379; Ruediger *et al.* 2000, pp. 4-8 - 4-10). Within these vegetation types, lynx appear to prefer areas of moderate to gentle topographic relief (Koehler and Aubry 1994, p. 86; Apps 2000, p. 352; Squires *et al.* 2013, pp. 187, 191). Lynx use large landscapes that include a temporally- and spatially-shifting mosaic of forest age classes, where natural or anthropogenic disturbances may reset forest succession (ILBT 2013, p. 28). Early successional stages that often provide dense horizontal cover at ground/snow level and support high hare densities (Griffin 2004, pp. 53-54, 70; Squires *et al.* 2010, pp. 1654-1656) may be created and maintained by natural disturbance processes including wildfire, insect infestations, tree diseases, and wind events (ILBT 2013, p. 28). Timber harvest, other silvicultural treatments, wildfire management, or other vegetation management, which may be beneficial, benign, or adverse to lynx and hare habitats depending on prescription, extent, and implementation, can also influence the amount and distribution of early successional stands (Agee 2000, p. 39; ILBT 2013, pp. 28, 71-76). Likewise, natural disturbance regimes and forest management can also influence the amount and distribution of mature multi-story spruce-fir stands, which can include dense horizontal structure, support high hare densities (Griffin 2004, pp. 53-54, 70; Squires and Ruggiero 2007, pp. 313-314; Berg *et al.* 2012, pp. 1483-1485), and provide preferred winter foraging habitat for lynx (Squires *et al.* 2010, pp. 1653-1657).

In northwestern Montana, lynx generally occur in mid-elevation (1,260 – 2,355 m [4,130 – 7,730 ft]) moist subalpine mixed-conifer forests dominated by Engelmann spruce and subalpine fir and including Douglas-fir, western larch (*Larix occidentalis*), and lodgepole pine (Squires *et al.* 2010, pp. 1653-1654). Lynx home ranges occur in areas with low surface roughness (i.e., low topographic relief; gently-sloping to moderately-steep terrain), high canopy cover indices, and little open grassland (Squires *et al.* 2013, p. 191). These lynx habitats occur below the alpine zone and above drier, more open forest types (e.g., ponderosa pine and dry Douglas-fir/western larch/lodgepole pine) that do not provide lynx habitat (Agee 2000, p. 42; Berg 2009, p. 20; Squires *et al.* 2010, p. 1655). As elsewhere in the western portion of the DPS, this elevational pattern contributes, along with the transition from boreal to more temperate forests, to a naturally patchier, more fragmented distribution of lynx habitat than in the continuous boreal forest landscape in the core of the lynx's North American range in northern Canada and interior Alaska (65 FR 16052-53; 68 FR 40089; Squires *et al.* 2006[a], pp. 46-47; ILBT 2013, pp. 76-77; Squires *et al.* 2013, p. 191; 78 FR 59438). Squires *et al.* (2013, pp. 187-189) used telemetry data to model the distribution of probable lynx habitat in a 36,096-km^2 (13,937-mi^2) study area that completely overlaps this geographic unit. Their results indicate that much of the area has a low to moderate probability of selection by lynx, and that the areas with higher selection probabilities are relatively small and patchily- but widely-distributed throughout the unit and are separated by intervening areas of low probability of lynx use (Squires *et al.* 2013; see fig. 1(a), p. 189). Holbrook *et al*. (2017, entire) recently corroborated this result. This patchy distribution of high-quality habitats interspersed with areas of low-quality or non-habitat results in naturally lower densities of both snowshoe hares and lynx than those typical (except durig hare cycle lows) in the continuous boreal forests of northern Canada and Alaska (Wolff 1980, pp. 123–128;

Buehler and Keith 1982, pp. 24, 28; Koehler 1990a, p. 849; Koehler and Aubry 1994, p. 84; Aubry *et al.* 2000, pp. 373–375, 382, 394).

In this unit, female and male lynx exhibit strong selection for advanced (25- to 40-year-old) regenerating spruce-fir stands in both winter and summer and at all levels of proportional availability (ranging from about 5 to 40 percent) of this stand type on the landscape (Holbrook *et al*. 2017, pp. 10-18 and fig. 6). In winter, females and males both preferentially use mature multi-story spruce-fir stands with dense horizontal cover, particularly when it is less available, proportionally, on the landscape, and they avoid clearcuts and large forest openings (Squires *et al.* 2010, pp. 1648, 1653–1656; Holbrook *et al*. 2017, pp. 10-18 and fig. 6). In summer, lynx also select young stands with dense spruce-fir saplings, avoid mature forest, do not appear to avoid openings as in winter, and use slightly higher elevations (Squires *et al.* 2010, pp. 1648, 1653–1656; Holbrook *et al*. 2017, pp. 13, 18). Both mature multi-story and young regenerating stands provide dense horizontal structure at ground/snow level, which supports higher snowshoe hare densities than more open young or mature forests. In the central (Seeley Lake study area) part of this unit, during an apparent regional hare decline in 1999-2001, summer hare densities were highest (up to 1.4 hares/ha [0.6 hares/ac] in 1 study area) in dense young stands, and winter densities were highest (up to 1.8 hares/ha [0.7 hares/ac] in 1 study area) in dense mature stands (Griffin and Mills 2009, pp. 1492-1496). Over a longer interval (1999-2003) when hare populations in this area were thought to be stable, mean summer and winter hare densities, respectively, were 0.34 and 0.53 hares/ha (0.14 and 0.21 hares/ac) in dense mature stands and 0.64 and 0.47 hares/ha (0.26 and 0.19 hares/ac) in dense young stands – habitats selected by lynx, compared to 0.18 and 0.20 hares/ha (0.07 and 0.08 hares/ac) in open mature stands and 0.18 and 0.12 hares/ha (0.07 and 0.05 hares/ac) in open young stands that lynx did not select (Squires and Ruggiero 2007, pp. 313-314). Even the relatively higher hare densities in the dense young and dense mature stands only marginally achieve the threshold density of 0.5 hares/ha (0.2 hares/ac) thought necessary to support lynx within home ranges (Ruggiero *et al.* 2000b, pp. 446–447; ILBT 2013, pp. 24, 26, 90; also see section 2.2.1). Nonetheless, hares accounted for 96 percent of the biomass in lynx diets in this unit based on evidence at kill sites (Squires and Ruggiero 2007, pp. 310-313), suggesting that even small declines in landscape-level hare densities could reduce the ability of habitats in this unit to support resident lynx (Squires *et al.* 2010, p. 1656).

Lynx in this unit generally den in mature spruce-fir forests among downed logs or root wads of wind-thrown trees in areas with abundant coarse woody debris and dense understories with high horizontal cover in the immediate areas around dens (Squires *et al.* 2004a, table 3; Squires *et al.* 2008, pp. 1497, 1501–1505). Dens are located farther from forest edges than random expectation are few occur in young regenerating or thinned stands with discontinuous canopies (Squires *et al.* 2008, p. 1497).

Average annual snowfall in this unit ranges from about 142 cm (56 in) in the Kalispell/Whitefish/ West Glacier area of northwestern Montana to 183 cm (72 in) in Nordman in northern Idaho, to 216 cm (85 in) in Lincoln, Montana, near the southern end of the unit, to 259 cm (102 in) in Rexford, Montana near the Canada-United States border, to 345 cm (136 in) in Seeley Lake,

Montana, in the central part of the unit, with most snow falling from November to March in each place[18].

Habitat Status: Most lynx habitat in this unit is currently designated as critical habitat in accordance with the ESA. Over 84 percent (22,761 km^2 [8,788 mi^2]) of this unit is in Federal ownership, including 18,695 km^2 (7,218 mi^2) in national forests under USFS management, 3,658 km^2 (1,412 mi^2) in Glacier National Park managed by NPS, and 397 km^2 (153 mi^2) managed by BLM in its Garnet Resource Area. As described above, potential lynx habitat in this unit is patchily-distributed and interspersed with areas of non-habitat (matrix). Among the 6 national forests that contribute lands to this geographic unit, potential lynx habitat was mapped on about 54 percent of the total national forest area (both inside and outside this SSA unit; USFWS 2007, pp. 32, 95, 122-123). In Glacier National Park, 2,976 km^2 (1,149 mi^2; about 73 percent of the park) is considered "lynx forest types" (65 FR 16073), but only 1,103 km^2 (426 mi^2; 27 percent of the park, 37 percent of lynx forest types) is estimated to be lynx habitat (68 FR 40086, 40089). In the Garnet Resource Area, the BLM designated 5 LAUs (which approximate a lynx home range) covering 947 km^2 (366 mi^2), of which, 574 km^2 (222 mi^2; about 61 percent) was mapped as lynx habitat (Sparks 2016a, *pers. comm.*).

Federal lands are managed as either ''developmental'' or ''nondevelopmental'' land use allocations (68 FR 40093). Lands in developmental allocations are managed for multiple uses, such as recreation and timber harvest, some of which may conflict with lynx conservation. Management within non-developmental allocations focuses on the maintenance of natural ecological processes, or conservation of rare ecological settings or components, and these areas include wilderness, roadless, and semi-primitive non-motorized areas (USFWS 2007, pp. 33, 77). Timber harvest, road construction, and fire suppression typically do not occur or are very limited in lands managed in non-developmental allocations.

In this SSA unit, almost 46 percent of the Federal land and 40 percent of the entire unit is in designated wilderness or National Park land. This includes (in addition to Glacier National Park) the 6,297-km^2 (2,431-mi^2) Bob Marshall Wilderness Complex (Bob Marshall, Great Bear, and Scapegoat wilderness areas) on the Flathead, Lewis and Clark, Helena and Lolo National Forests; the 302-km^2 (117-mi^2) Mission Mountain Wilderness on the Flathead National Forest; the 139-km^2 (54-mi^2) Rattlesnake Wilderness Area on the Lolo National Forest; and the 371-km^2 (143-mi^2) Mission Mountain Tribal Wilderness on the Flathead Reservation. Management of NPS lands and both national forest and Tribal wilderness areas provides land-use restrictions that are likely beneficial to lynx (65 FR 16073; USFWS 2014, pp. 28-29; 79 FR 54831), and adverse effects of management activities on lynx habitats in these areas are unlikely. Among the 6 national forests that contribute to this unit, 56 percent of potential lynx habitat is in designated wilderness or roadless areas (USFWS 2007, p. 34).

Much of the remaining USFS lands and the BLM lands have developmental land-use allocations where some management activities have the potential to impact lynx or its habitat. However, as described above in section 3.1.1, USFS lands in this unit are managed in accordance with the

[18] https://snowfall.weatherdb.com/d/a/Montana; accessed 4.2.2016.

NRLMD, which formally amended all forest plans to adopt and implement lynx conservation measures (USFS 2007, pp. 8-30 and Attachment 1, pp. 1-9) that were developed based on the scientific findings and recommendations of the LCAS (Ruediger *et al.* 2000, pp. pp. 7-1 - 7-18). Similarly, the BLM in 2004 amended the Resource Management Plan (RMP) for the Garnet Resource Area to incorporate the conservation measures identified in the LCAS (BLM 2004a, 2004b, entire; Sparks 2016b, *pers. comm.*). Both documents provide guidance on the kinds of activities that can and cannot be implemented in important lynx habitats and thresholds for the proportions of lynx habitat in LAUs that can be in an unsuitable state at any given time and how much can be converted from suitable to (temporarily) unsuitable over particular time frames. Implementation of these plans has likely benefitted lynx by providing a consistently applied framework for conserving and restoring important hare and lynx habitats.

Habitat status on private lands, which account for about 8 percent of lands in this unit (2,172 km^2 [839 mi^2]), is governed by some Federal and State regulations and by a number of private-public conservation partnerships and State agency efforts. As described in section 3.1, some Federal and State regulations guide some activities on private lands, including the ESA's prohibition on take of listed species, and State regulations governing trapping and timber management. In addition to these protections, there have been several other notable lynx conservation achievements on private lands in this unit since the DPS was listed. Two of these, the Clearwater-Blackfoot Project and the Montana Legacy Project, are multi-partner and community efforts led by The Nature Conservancy in Montana to purchase large tracts of private commercial timberlands, conveying some to the State of Montana and the USFS for conservation management, and acquiring conservation easements on others (TNC 2016a, 2016b, 2016c, entire). These land acquisitions have resulted in protection of roughly 673 km^2 (260 mi^2) of important lynx habitat within this SSA unit and another 583 km^2 (225 mi^2) just to the south and west that may occasionally or temporarily support lynx or provide dispersal habitat. Additionally, the MTFWP has acquired fee title or conservation agreements on 3,096 km^2 (1,195 mi^2) of private lands in western Montana, including 162 km^2 (63 mi^2) in designated lynx critical habitat in this SSA unit, with ongoing efforts on another 106 km^2 (41 mi^2) in the northwest part of the unit (MTFWP 2016, pp. 1, 3).

In addition to the MTFWP's efforts to acquire private lands and protect them through fee title or conservation agreement, the State of Montana has also worked to protect lynx habitat on State-owned lands, which account for about 4 percent of the lands in this unit (1,106 km^2 [427 mi^2]). As described above in section 3.1.2, the MTDNRC worked closely with the Service to develop the *State of Montana Department of Natural Resources and Conservation Forested State Trust Lands Habitat Conservation Plan* (MTDNRC HCP; MTDNRC and USFWS 2010a, 2010b, 2010c, entire); a multi-species HCP that focuses primarily on commercial forest management. The HCP includes a Lynx Conservation Strategy that minimizes impacts of forest management activities on lynx, describes conservation commitments that are based on recent information from lynx research in Montana, and commits to active lynx monitoring and adaptive management programs. The HCP covers about 2,220 km^2 (857 mi^2) of forested State trust lands in western Montana, including 703 km^2 (271 mi^2) within this SSA geographic unit (about 64 percent of State lands in this unit). The goal of the HCP's Lynx Conservation Strategy is to

support Federal lynx conservation efforts by managing for habitat elements important to lynx and their prey that contribute to the landscape-scale occurrence of lynx. Specific objectives to achieve this goal include protecting den sites and potential denning habitat, mapping and maintaining lynx foraging habitats and limiting the spatial and temporal scope of their conversion to unsuitable conditions from forest management activities, and providing for habitat connectivity (MTDNRC and USFWS 2010b, pp. 2-45 - 2-61). The HCP was finalized and permitted by the Service in 2011, and includes a 50-year commitment by the State to manage for lynx conservation on these lands (79 FR 54835-37).

Tribal lands of the Flathead Reservation account for almost 4 percent of this unit. In addition to the Tribe's approach to lynx management described in section 3.1.2, most lynx and lynx habitat on the reservation occur in areas with formal protective status, including: (1) The long-designated Mission Mountains and Rattlesnake Tribal Wilderness Areas, which are largely roadless and managed for wilderness qualities; (2) the South Fork/Jocko Primitive Area, which is open to use only by Tribe members and in which commercial timber harvest is prohibited; and (3) the Nine-mile Divide country, which is marginal in terms of lynx habitat, but which is also partly roadless (Courville 2014, *pers. comm.*; 79 FR 54831).

As elsewhere in the DPS, winter foraging habitat is thought to be the most limiting habitat for lynx in this unit (Squires *et al.* 2010, p. 1656; ILBT 2013, pp. 20, 27). As described above, lynx selected mature multi-story stands with dense horizontal structure and relatively higher winter hare densities (Squires *et al.* 2010, pp. 1648, 1653–1656). Because of this preference, the Forest Service in the NRLMD adopted a vegetation management standard (VEG S6) that precludes all vegetation management activities that could reduce winter snowshoe hare habitat in multi-story forests, not just precommercial thinning as recommended in the LCAS (USFS 2007, pp. 13-14). Also as elsewhere (Moen *et al.* 2008a, p. 1512; Organ *et al.* 2008, pp. 1514, 1516–1517, ILBT 2013, p. 30; 79 FR 54790), denning habitat is not thought to be a limiting factor for lynx in this unit (Squires *et al.* 2008, p. 1505). Nonetheless, the NRLMD includes guidance to ensure adequate denning habitat remains well distributed in LAUs and, therefore, across the larger landscape and to design projects to create or retain coarse woody debris in areas where denning habitat may be lacking (USFS 2007, p. 17). Snow conditions in this unit also appear to remain suitable to allow lynx to outcompete other terrestrial hare predators. Gonzalez *et al.* (2007, pp. 4-7) compared the highest-precision lynx occurrence data in the contiguous United States from 1966-1998 with snow-cover data available for those locations and concluded that lynx require nearly continuous snow cover from December through March. The authors modeled snow suitability across North America, showing that this geographic unit currently has a 90-95 percent probability of providing snow cover consistent with historical lynx occurrence records (Gonzalez *et al.* 2007, p. 12).

Overall, although naturally fragmented and patchily-distributed, lynx habitat in this geographic unit appears to be largely intact relative to historical conditions and disturbance regimes, with only a small proportion apparently impacted by past management (timber harvest and precommercial thinning) activities (65 FR 16072). Despite some likely localized impacts of past timber management and infrastructure (e.g., highway) development and evidence of minor

genetic differentiation among lynx subpopulations (see *Lynx Status*, below), past management activities do not appear to have diminished this unit's ability to support resident lynx or to have created barriers to lynx movement, or to have had other landscape- or population-level effects.

A possible exception may be in the Garnet Mountains, which are known to have supported a small number of resident lynx in the 1980s and recently from 2002-2010, but where more recent surveys and research trapping efforts failed to detect lynx from 2011 to 2015 before a single lynx was verified in 2016 (Squires *in* Lynx SSA Team 2016a, p. 20; Lieberg 2017, *pers. comm.;* also see Lynx Status, below). This small and relatively isolated island of lynx habitat (Squires 2014, p. 4) at the southern end of this unit is thought to be capable of supporting 7-10 lynx home ranges (Squires 2016, *pers. comm.*). The BLM (2004, pp. 4-5) contrasted current and historical distributions of lynx habitats in the Garnets and found that early-successional stands (future hare and lynx foraging habitats) were at 25-50 percent of the historical condition in lower-elevation (1,370-1,830 m [4,500-6,000 ft]) lynx habitats, and 10-30 percent in higher-elevation (1,675-2,130 m [5,500-7,000 ft]) habitats. Late-successional (mature multi-story) stands (25-75 percent of historical condition) and large (> 100 ha [250 ac]) patches (25-50 percent of historical condition) were also underrepresented at lower elevations, but at higher elevations, these 2 stand types exceeded 200 percent and 100 percent of historical conditions, respectively. Lower elevation habitats were fragmented by roads and past management practices (i.e., timber harvest), while higher-elevation habitat patterns were attributed to the absence of disturbance, including fire (BLM 2004, p. 5), though fire absence was not attributed to suppression.

As discussed for the GYA in section 2.3.2.2, whether the recent absence of resident lynx in the Garnets represents the extirpation of a previously-persistent small population (and, therefore, a contraction in the range of resident lynx in this unit) or a temporary “winking off” of a naturally ephemeral small peripheral population, as might be expected in a mainland-island metapopulation structure, is uncertain and perhaps irresolvable. If residency was intermittent or ephemeral historically, the current absence of resident lynx might be a natural condition related to the area’s naturally fragmented habitats and generally low hare densities - i.e., it may naturally be capable of supporting resident lynx only intermittently when habitat conditions and hare densities are optimal. If so, future intermittent lynx occupancy would be expected, but only if lynx dispersing from a source population immigrate to the Garnets when habitat conditions and hare densities return to more favorable levels. Conversely, if the Garnets historically supported a small but persistent population that was recently extirpated, it may suggest that the alteration of the historical distribution of some habitats in some parts of the range, described above, was enough to shift the quality of the area’s habitat from capable of supporting a small resident population to no longer capable of doing so.

In summary, almost all lands in this unit are managed to conserve lynx and hare habitats in accordance with Federal, State, and Tribal regulations and management direction, conservation easements, and an approved HCP. Much of the area consists of designated Federal and Tribal wilderness areas and other nondevelopmental land use allocations, where management activities with the potential to adversely affect lynx generally do not occur. On lands with development allocations, USFS, BLM, and State management are based on plans that

incorporate the conservation guidance identified in the LCAS as informed by more recently available scientific information. The State and TNC, working with other conservation partners, have bought or acquired conservation easements on large tracts of high-quality private lands in the unit that are known or suspected to be occupied by resident lynx. These efforts and management across multiple ownerships likely preclude landscape-level management-related adverse impacts to the vast majority of existing lynx and hare habitats in this unit. Nonetheless, past management activities that occurred prior to implementation of current regulations and other conservation efforts may exert continuing influence on current habitat quality in some places, as described above for the Garnet Mountains. Because lynx habitats in this unit, like most other areas of the DPS range, are naturally highly-fragmented, and most have hare densities that barely meet the 0.5 hares/ha (0.2 hares/ac) threshold thought necessary to support resident lynx, relatively minor impacts, especially to hare and lynx foraging habitats, may strongly influence lynx persistence in some parts of this unit.

Lynx Status: There are no reliable estimates of the historical or current number of resident lynx in this unit although, as described in section 2.3.2.2 above, it is thought to be capable of supporting perhaps 200-300 lynx (Squires *in* Lynx SSA Team 2016a, p. 41). This is substantially fewer than previous estimates of more than 1,000 lynx, which were based on a habitat area/ density index and broad assumptions regarding habitat suitability and lynx distribution (65 FR 16058) that are not supported by current understanding of lynx habitat requirements and current or historic habitat availability in this unit. That is, based on our understanding of lynx habitat and its current and historical distriubtution, it is very unlikely that this unit and surrounding areas were ever (recently or historically) capable of supporting 1,000 resident lynx. As described above, habitats capable of supporting resident lynx in this unit are (and also were historically) naturally patchier and less-broadly distributed (Squires *et al.* 2006a, pp. 46-47; Squires *et al.* 2013, p. 191), and lynx therefore naturally rarer, than was thought at the time of listing (ILBT 2013, p. 23; Jackson *in* Lynx SSA Team 2016a, p. 12). Although the exact distribution of resident lynx remains uncertain, this unit has a long and continuous history of lynx occurrence and evidence of reproduction (McKelvey *et al.* 2000a, pp. 224-225; Squires and Laurion 2000, pp. 346-348; Squires *et al.* 2008, entire; Squires *et al.* 2013, entire; ILBT 2013, p. 57; 65 FR 16058; 68 FR 40090; 74 FR 8643; 79 FR 54825). Genetic analyses revealed minor fine-scale genetic sub-structuring among lynx subpopulations in the southern (Garnet Mountains), central (Seeley Lake), and northern (Purcell Mountains) parts of this unit, suggesting limited interaction among lynx in those areas (Schwartz *in* Lynx SSA Team 2016a, p. 12 and Appendix 5; Squires *in* Lynx SSA Team 2016a, p. 20). Lynx in this unit likely represent the southern periphery of a larger population in southwestern Alberta and southeastern British Columbia, but the extent to which lynx persistence in this area may rely on immigration from Canada is unknown, and there is no indication of substantial immigration (irruptions) of lynx from Canada into this unit after the 1980s (Squires *in* Lynx SSA Team 2016a, p. 20).

From 1998 to 2007, researchers with the Forest Service's Rocky Mountain Research Station (RMRS) in Missoula trapped and radio-marked 175 lynx in northwestern Montana and collected nearly 170,000 GPS and over 3,000 VHS telemetry locations documenting lynx movements, resource use, survival, and productivity (Squires *in* Lynx SSA Team 2016a, p. 20). From 1999-

2007, litter sizes averaged 2.24 kittens/litter (N = 33) in the Seeley Lake area and from 2003-2007, 2.95 kittens/litter (N = 22) in the Purcell Mountains. In Seeley Lake, 61 percent of breeding-age females (N = 52) produced kittens; in the Purcells, 83 percent of females (N = 28) produced kittens. Recent research (Kosterman 2014, entire) suggests that the probability that a female produces a litter and initial litter size are correlated positively with mature forest connectivity and negatively with fragmentation in female home ranges (Squires *in* Lynx SSA Team 2016a, p. 20 and Appendix A). Annual survival rates for subadult and adult female lynx were 0.52 and 0.75, respectively, in Seeley Lake, and 0.68 and 0.85, respectively, in the Purcells. Kitten survival rate was 0.58 in Seeley Lake (Kosterman 2014, pp. 13, 30). There was no evidence of cyclicity in these vital rates, and no indication of substantial immigration of lynx into these study areas from Canada. Starvation, predation by cougars, and human-caused deaths each accounted for roughly one-third of documented sources of lynx mortality. Population viability analyses yielded population growth rates (λ) of 0.92 for the Seeley Lake area (i.e., declining population trend, 1999-2007) and 1.16 for the Purcells (increasing trend, 2003-2007). However, as described in section 2.2.2, estimates of λ in a cyclic Canadian population of lynx ranged from 2.03 (annual doubling) when hares were abundant to 0.10 (order of magnitude decline) after hare populations crashed (Slough and Mowat 1996, p. 952, table 4), and the natural range in λ that would be expected among peripheral, isolated, or semi-isolated and non-cyclic or weakly-cyclic lynx populations in the DPS versus those that would signal long-term population decline or instability is unknown. Also as noted above, estimates of λ in this unit assumed no immigration, which is a questionable assumption, and only low numbers of immigrants (less than 1 female/yr on average for a hypothetical population of 100 lynx) would be needed to provide population stability or even growth (Schwartz 2017, p. 4).

As described above, lynx distribution in this unit may have contracted with the recent apparent disappearance of resident lynx from the Garnet Mountains in the southern part of the unit. This area is thought to have habitat capable of supporting 7-10 lynx home ranges (Squires 2016, *pers. comm*.). As described in section 2.3.2.2 and above, whether the recent absence of lynx from this part of the unit represents the extirpation of a small but previously persistent population (and, therefore, a permanent contraction of lynx distribution in this unit) or the temporary “winking off” of a peripheral subpopulation that may become “winked on” again in the future is unknown. On February 2, 2016, a single lynx was detected via snow-track survey and verified via DNA analysis in the Garnet Range in the area previously occupied by resident lynx, demonstrating that natural recolonization of this area by dispersing lynx is possible. However, this recent record appears to have been of a dispersing/transient individual because subsequent surveys have not revealed additional detections of that lynx or any other lynx in the area, and there currently remains no evidence of lynx residency in this mountain range (Lieberg 2017, *pers. comm.*).

Snow-tracking, hair-snare, and camera-trap surveys in other parts of this unit since the DPS was listed continued to detect lynx on the Flathead, Helena, Idaho Panhandle, Kootenai, Lewis and Clark, and Lolo National Forests (USFS 2015a, pp. 9-27). On the Flathead, the RMRS trapped and radio-marked 7 lynx (3 females, 4 males) in the Flathead River watershed from 2010-2015, and surveys detected lynx in several other areas including the Salish Mountains, the

area just south of Glacier National Park, and in the vicinity of Hungry Horse Reservoir (USFS 2015a, pp. 10-11). The Swan Lake District in the southern part of the Flathead, along with the Seeley Lake District of the Lolo National Forest and the Lincoln District of the Helena National Forest, is part of the 6,070-km^2 (2,344-mi^2) Southwestern Crown of the Continent, which was intensively surveyed from 2012-2014 by the Southwestern Crown Carnivore Monitoring Team (SCCMT 2014, entire). The SCCMT conducted snow track surveys and used hair snares, bait stations, and camera traps to detect lynx in 36 of the 82, 8 x 8 km (5 x 5 mi) grid cells they surveyed (SCCMT 2014, pp. 3, 17-20). The surveys resulted in collection of DNA that allowed identification of 18 individual lynx (5 females, 13 males), 13 of which were new to regional lynx databases (SCCMT 2014, pp. 3, 17-20), indicating recruitment of new individuals into this population, or immigration, or a combination of the 2.

On the Helena National Forest, few lynx have been detected outside the Lincoln District/ Southwestern Crown area described above. In the south MacDonald Pass area, just south of this SSA unit and south of designated critical habitat, an individual male lynx was verified by DNA evidence over 4 winters (2007-2011), and an individual female was verified in the same area in the winter of 2008-2009 (Gehman *et al.* 2011, p. 21; USFS 2015a, p. 27). Other surveys on the Helena National Forest failed to detect lynx in the disjunct Big Belt and Elkhorn Mountains, although telemetry data indicated that 3 lynx released in Colorado passed through the Big Belts in 2004-2006 (USFS 2015a, pp. 26-27). Likewise, during snow tracking surveys on the Lolo National Forest in 2010-2011 (prior to the Southwestern Crown monitoring described above), lynx were also confirmed on the Seeley Lake District in the eastern part of the forest, but no lynx were documented on the Missoula or Ninemile districts, nor on the Superior and Plains/Thompson Falls districts in the western part of the forest (USFS 2015a, pp. 12-14). The USFS concluded that lynx presence in districts other than Seeley Lake is extremely rare and likely represents occasional dispersing lynx (USFS 2015a, p. 21).

On the Kootenai National Forest, RMRS research trapping and telemetry efforts continued to document the long-term presence of lynx from 2003-2012 (USFS 2015a, p. 10). On the Lewis and Clark National Forest, lynx are considered “still present” in the Rocky Mountain Front portion of the forest, which is within this geographic unit and designated critical habitat, and snow track surveys from 2010-2013 in the disjunct Little Belt and Crazy Mountains documented the continued absence of resident lynx in those ranges (USFS 2015a, pp. 25, 27-34). In Idaho, surveys in 2006-2007 by the Coeur d’Alene Tribe recorded 1 lynx detection in the Coeur d’Alene Mountains and 1 in the Saint Joe Mountains (Albrecht and Heusser 2009, entire). On the Idaho Panhandle National Forest, Multi-species Baseline Initiative (MBI) surveys in 2010-2014 detected 5 individual lynx (2 males, 3 females): 1 male in the Selkirk Mountains; 1 male and 2 females in the Purcell Mountains (and another 18 detections not identifiable to individual), and 1 female in the West Cabinet Mountains (Lucid *et al*. 2016, pp. 158-160). All detections were within 50 km (31 mi) of the Canada border, 3 detections were of incidentally-trapped lynx (2 in the West Cabinets released unharmed [1 with a radio collar] and 1 in the Purcells that died), and no lynx were detected in the Coeur d’Alene or Saint Joe Mountains (Lucid *et al*. 2016, p. 180). MBI follow-up surveys in 2015-2016 targeting areas where lynx were detected in 2010-2014 resulted in 89 lynx detections representing a minimum of 6 individual lynx; 1 in the Selkirks, 4 in

the Purcells (including camera images of an adult traveling with 2 young and later on the same camera an adult traveling with 1 juvenile), and 1 in the West Cabinets (IDFG 2017a, p. 5). No lynx were detected in the Saint Joe Mountains.

In summary, although the number of lynx in this geographic unit is uncertain, resident lynx appear to remain broadly distributed throughout much of the unit as evidenced by continued documentation of lynx in the research surveys described above. Genetic analyses and snow and camera surveys have verified continued reproduction and recruitment among lynx populations in this unit and also suggest some immigration may be occurring. The recent apparent absence of resident lynx in Garnet Mountains may indicate extirpation of a small resident population and a contraction in lynx distribution in the southern part of the unit, or it may reflect natural source-sink dynamics of a naturally ephemeral peripheral population in a mainland-island metapopulation structure. Lynx are rarely detected on surveys on other national forests (or parts of those above) that are outside but adjacent to this geographic unit (Patton 2006, entire; USFS 2105a, pp. 1-9, 25-34), suggesting that these areas lack the habitat features and/or landscape-level hare densities necessary to support resident lynx populations (79 FR 54818-54820).

Factors Affecting Current Conditions

Regulatory Mechanisms - Federal management activities (especially timber harvest and precommercial thinning, perhaps fire suppression) that occurred prior to listing and before implementation of current Federal regulatory mechanisms likely impacted some lynx habitats by altering the distribution and quality of hare habitats. However, because these activities occurred in low proportions of lynx habitat on Federal lands and impacts appear to have been localized, they were deemed a low-level threat to lynx at the time of listing (65 FR 16072-16076; 68 FR 40091-40095). Nonetheless, past Federal management activities may continue to influence the current quality and distribution of lynx habitats in some parts of this unit. For example, as described above in *Habitat Status* and *Lynx Status*, past timber harvest/management and associated road construction may have fragmented, reduced the amount, and altered the distribution of lynx habitats in the Garnet Mountains, perhaps contributing to the apparent recent loss of that area’s ability to support resident lynx.

Currently, as described above and in section 3.1, all Federal and Tribal lands, most State lands, and large blocks of private or formerly-private land in this unit are managed for the conservation of lynx habitats, and much of the unit is in designated wilderness or other nondevelopmental land-use allocations. Regulatory mechanisms and conservation measures associated with these management strategies are intended to conserve and restore lynx and hare habitats across large landscapes and multiple ownerships. Although their effectiveness has not been quantitatively evaluated, and despite the potential extirpation of a small population in the Garnets, lynx habitats and resident lynx appear to remain well distributed throughout most of this unit.

Other regulations prohibit lynx trapping and require measures to reduce the likelihood of trapping lynx incidentally when legally trapping other species. Since the DPS was listed in 2000, 16 lynx are documented to have been incidentally trapped in Montana, with 13 of those occurring before 2008, when more protective regulations (e.g., lethal snares prohibited for bobcat sets, leaning pole sets limited to < 4" pole that must be 48" above ground for marten, fisher, and wolverine) were put in place (MTFWP 2016, pp. 5-10). Of the 16, 8 were released uninjured, 1 was released with an injury, and 7 were killed; all incidences of mortality occurred prior to 2008 and prior to the implementation of the more protective regulations (MTFWP 2016, p. 5). In Idaho, in addition to the 3 lynx incidentally trapped on the Idaho Panhandle National Forest from 2012-2014 (described above under *Lynx Status*), 1 other lynx was incidentally trapped in 2012 on the Salmon-Challis National Forest further south.

Although lynx are legally trapped in Canada adjacent to this unit in southern Alberta and southern British Columbia, trapping there is managed through regulated seasons and harvest levels, which are adjusted to avoid overexploitation, especially during the low phase of the hare-lynx population cycle (Environment Canada 2014, entire; Vashon 2015, pp. 5-6). Lynx harvest in Alberta varied from about 4,000 to 14,000 annually in the late 1970s and early 1980s, but declined to fewer than 2,000 for most years from 1984-2000, and restrictive quotas and season closures were implemented beginning in the late 1980s (Poole and Mowat 2001, pp. 16, 28). Similarly, harvests in British Columbia peaked at over 12,000 in the early 1960s and over 8,000 in the early 1970s, then declined to fewer than 2,000 for most years from the mid-1980s until the year 2000 (Hatler and Beal 2003, p. 2). Whether (and if so to what extent) trapping in Canada may influence lynx dispersal across the border and into this geographic unit is unknown; however, such dispersal was documented historically when harvest levels in Canada were much higher than under current management.

Climate Change - As elsewhere, increased temperatures, reduced snowpack, earlier snowmelt, and increased drought leading to increased fire all have been documented in this geographic unit (e.g., Hall and Fagre 2003, entire; Mote 2003b, entire; Fagre 2005, entire; Knowles *et al.* 2006, entire; Harvey *et al.* 2016, entire; Siren *in* Lynx SSA Team 2016a, pp. 14-15; Squires *in* Lynx SSA 2016, p. 20; Westerling 2016, entire). A number of potential impacts to lynx have been described, and climate projections suggest these impacts are likely to result in future loss and increased fragmentation and isolation of lynx and hare habitats and declining lynx populations in the DPS (Carroll 2007, entire; Gonzalez *et al.* 2007, entire; ILBT 2013, pp. 69-71; 79 FR 54810-54811; Lawler and Wilsey *in* Lynx SSA Team 2016a, pp. 15-16; Siren *in* Lynx SSA Team 2016a, p. 15; see also sections 3.2, and 5.2.3). Although climate change has probably already had some impact on lynx habitats in this geographic unit, and such impacts are likely to continue to occur, there currently is no evidence that climate change has had population-level effects or has reduced the unit's current ability to support persistent resident lynx populations. However, such impacts would be difficult to document and, as described under *Habitat Status*, above, lynx habitats in this unit are naturally highly-fragmented and hare densities, even in areas considered high-quality habitat for this DSP unit, often appear to barely meet the 0.5 hares/ha (0.2 hares/ac) threshold thought necessary to support resident lynx.

Therefore, even relatively minor impacts, especially to hare and lynx foraging habitats, may strongly influence lynx persistence in some parts of this unit.

Modeling vegetation and snow suitability for lynx across North America, Gonzalez *et al.* (2007, pp. 12, 15) indicated that boreal and temperate conifer forest biomes were broadly distributed across this geographic unit and that snow conditions suitable for lynx occurred with 90-95 percent probability from 1961-1990. (Future conditions based on this modeling are described in section 5.2.3). As described in section 3.2, climate change has also been implicated in recent increases in the frequency and intensity of outbreaks of boreal forest insect pests, with warmer winters resulting in increased insect survival and drought increasing conifer vulnerability to insects. This trend is expected to continue through the end of the century with continued climate warming (Bentz *et al.* 2010. pp. 607, 609). Although insect outbreaks have affected some parts of the DPS, no major outbreaks have been documented in lynx habitats in this unit (Lynx SSA Team 2016a, p. 41).

Vegetation Management - As elsewhere in the DPS range, timber harvest and related vegetation management (precommercial thinning and other silvicultural techniques designed to optimize forest products outputs; ILBT 2013, pp. 71-72) are the dominant land uses potentially affecting lynx habitats in this unit (68 FR 40075, 40092; 79 FR 54825). As described in section 3.3, these activities can reduce hare and lynx habitats by reducing horizontal cover and altering natural disturbance regimes and forest successional patterns. In this unit, precommercial thinning was shown to reduce short-term hare abundance (Griffin and Mills 2007, entire) and appeared to influence lynx movements (Squires *et al.* 2013, p. 192-194), and lynx rarely traveled across recent clearcuts or other large openings, especially in winter (Squires *et al.* 2010, p. 1654; ILBT 2013, p. 77). However, as described under *Habitat Status*, above, these activities on Federal lands, which account for most of the lands in this unit, occur only on lands with developmental allocations and historically appear to have impacted only a small proportion of potential lynx habitats in this unit (65 FR 16072; 68 FR 40093). Additionally, timber harvest levels on Federal lands in the West, including the Northern Rockies, and specifically with regard to “lynx forest types,” had declined consistently and dramatically for a decade or longer prior to the DPS being listed (68 FR 40093), and have remained at levels much lower than those from most of the previous century. Despite some likely localized impacts, past vegetation management does not appear to have broadly diminished this unit's ability to support resident lynx, although, as described above, it may have contributed to the current absence of a small number of resident lynx from the Garnet Mountains. Also as described above, current vegetation management in this unit on all Federal, most State and Tribal, and some private lands, is conducted in accordance with formally amended USFS and BLM management plans, an approved State HCP, Tribal regulations, and conservation easements designed to avoid or minimize impacts to lynx habitats, especially important hare and lynx winter foraging habitats.

Wildland Fire Management - As described above in section 3.4, wildfire suppression in this unit, as elsewhere in the West, has likely had little impact on lynx habitats (65 FR 16074; 68 FR 40093-94; USFS 2007, pp. 18, 20; USFS 2008a, p. 11; ILBT 2013, p. 76). Also as described in that section, wildfire frequency, size, and intensity have increased in this geographic unit, where

about 15 percent (4,172 km^2 [1,611 mi^2]) of the forest area in this unit burned from 2000-2013 (Squires *in* Lynx SSA Team 2016a, p. 20), likely in response to climate warming and related increases in drought conditions (e.g., Harvey *et al.* 2016, entire; Westerling 2016, entire). During the 2017 fire season alone, roughly 1,150 km^2 (444 mi^2; over 4 percent of the unit) burned, including the Rice Ridge and Reef fires, which together burned over 690 km^2 (267 mi^2) in the core of the Seeley Lake population's habitat and the site of long-term lynx research by the RMRS.[19] Although these fires likely have reduced or will reduce lynx carrying capacity in some parts of this geographic unit, we expect such impacts to be temporary, with burned areas regenerating into high-quality lynx and hare habitats 20-40 years post-fire. Thus far, we are aware of no evidence that increased fire activity has permanently reduced lynx populations or diminished this geographic unit's ability to support resident lynx. However, with climate-driven elevated wildfire activity projected to continue into the future, such impacts are possible, depending on the location, timing, and extent of future fires (see section 5.2.3, below).

Habitat Loss and Fragmentation - As described above, the dominant land use in this unit, and that most likely to result in habitat loss and fragmentation, is timber harvest and associated vegetation management (e.g., precommercial thinning) and road construction. In the Northern Rocky Mountains, the forests upon which lynx depend have had less timber harvest, road construction, and have been modified much less than other drier forests (65 FR 16073), and these activities appear not to have had population-level impacts on lynx or to have measurably reduced the ability of this geographic unit to support resident lynx (with the possible exception of the Garnet Mountains). Few highways intersect lynx habitats in the Northern Rockies (ILBT 2013, p. 63) and there are few records of lynx killed by vehicle collisions in Montana (5) and Idaho (1; USFWS 2016c; MTFWP *unpubl. data*). Other potential sources of habitat loss and fragmentation include recreation, minerals/energy development, and backcountry roads and trails; these are all considered second tier anthropogenic influences (ILBT 2013, pp. 78-85) that are unlikely to exert population-level influences, despite potential impacts to individual lynx.

Other Factors - Connectivity/Immigration - As elsewhere in the range of the DPS, resident lynx populations in this geographic unit are thought to be influenced by connectivity with, and immigration of lynx from, populations in Canada (see section 2.2). However, whether, and if so to what the extent, the persistence of populations in this geographic unit may depend on regular or intermittent immigration of lynx from Canada remains uncertain, and historic, recent, and current immigration rates are unknown. This unit is directly connected to lynx habitats and populations in southwestern Alberta and southeastern British Columbia, where lynx habitats are also (like Montana and Idaho) patchily-distributed and generally support low hare densities, and where some lynx populations may be ephemeral and the persistence of others reliant on periodic immigration (Apps 2007, pp. 81, 95-104). Additionally, connectivity between this geographic unit and lynx habitats and populations in southern Alberta and southern British Columbia may be facilitated by only a few predicted corridors that extend south from the international border (Squires *et al.* 2013, pp. 187, 191-193).

[19] https://inciweb.nwcg.gov/state/27/0/

Although lynx occurrence and harvest records in this geographic unit reflect the unprecedented irruptions of lynx from Canada into the northern contiguous United States in the early 1960s and early 1970s (McKelvey *et al.* 2000a, pp. 224-226, 232-242), there is no evidence of irruptions of lynx into this unit after the 1980s (Squires *in* Lynx SSA Team 2016a, p. 20). This is supported by lynx trapping records from Canada, which suggest that the magnitude of lynx population cycles in Alberta and British Columbia dampened dramatically after the early 1980s (McKelvey *et al.* 2000a, p. 226; Poole and Mowat 2001, p. 28; Hatler and Beal 2003, p. 2; Bowman *in* Lynx SSA Team 2016a, p. 13; also see Appendix 5, 2015 10 13 - 5, pp. 4-5[20]).

A number of climate-mediated factors have been suggested as contributing to changes in the periodicity and amplitude of northern lynx and hare population cycles (see section 3.2), which would be expected to alter the timing and magnitude of irruptions of lynx from Canada into the contiguous United States. If lynx populations in this unit rely on immigration from Canada which is no longer occurring or has been substantially reduced relative to historical conditions, population declines and a reduced likelihood of persistence among resident populations would be expected. Although the extent to which this factor has influenced the current condition of lynx populations in this unit is unknown, the population growth rate estimated for the Seeley Lake area (λ = 0.92, declining trend 1999-2007; Squires *in* Lynx SSA Team 2016a, p. 20) may reflect a gradual decline of a resident lynx population that needs but is not receiving adequate immigration. In contrast, the growth rate estimated for the lynx population in the Purcell Mountains in the northwestern part of this unit (λ = 1.16, increasing trend 2003-2007; Squires *in* Lynx SSA Team 2016a, p. 20) suggests that the level of immigration, if necessary for demographic stability, has been adequate or that productivity and recruitment have been high enough to offset potentially diminished immigration. It is also possible that, despite the documented historical intermittent (cyclic) influxes of lynx from Canada into lynx populations in this geographic unit, immigration does not contribute meaningfully to the demographic stability of these populations. If that is the case, the estimated growth rates suggest that recruitment has failed to offset mortality in the Seeley Lake population but that it has more than done so in the Purcell Mountains population. However, Schwartz (2017, p. 4) noted that very low immigration rates (less than 1 female/year on average for a theoretical population of 100 lynx) could provide population stability or even growth, suggesting that the Seeley Lake population and perhaps other DPS populations are probably being sustained by low levels of undetected immigration. The growth rate estimates presented above assumed no immigration.

4.2.4 Unit 4 - North-central Washington

Unit Description: This geographic unit is located on the eastern side of the northern Cascade Mountain Range of north-central Washington in portions of Chelan and Okanogan Counties. It includes mostly Okanogan-Wenatchee National Forest lands as well as BLM lands in the Spokane District that were designated as critical habitat for lynx in 2014 (79 FR 54825). The unit also includes State Forest lands (portion of the Loomis State Forest) that were excluded from

[20] https://www.fws.gov/mountain-prairie/es/species/mammals/lynx/SSA2016/Appendices/Appendix%205%20Presentation%20PDFs/2015%2010%2013%20-%205%20-%20Bowman%20Lynx%20Southern%20Canada.pdf.

designation as critical habitat (79 FR 54825). It encompasses approximately 5,176 km^2 (1,988 mi^2), with ownership that is 91.5 percent Federal (USFS, BLM), 8.2 percent State, and 0.3 percent private lands; there are no Tribal lands in this unit. This unit is about 200 km (125 mi) west of the Northern Montana/Northeastern Idaho geographic unit. This area was occupied by resident lynx when the DPS was listed and remains occupied currently. Evidence from recent research and DNA analysis shows lynx distributed within this unit, and breeding has been documented. Although researchers have fewer records in the portion of the unit south of Highway 20, this area contains boreal forest habitat and is thought to support resident lynx. Further, it is contiguous with lynx habitat north of Highway 20, particularly in winter when deep snows close Highway 20. The northern portion of the unit adjacent to the Canada border also appears to support few recent lynx records; however, it is designated wilderness and access to survey this area is difficult. This northern portion contains extensive boreal forest vegetation types and also likely supports resident lynx. Additionally, lynx populations exist in British Columbia directly north of this unit.

This geographic unit represents 58 percent of the 8,923-km^2 (3,445-mi^2) Okanogan Lynx Management Zone (LMZ) identified by the WADFW (Stinson 2001, p. 16). Five smaller and relatively disjunct LMZs to the east of this geographic unit (Vulcan-Tunk, Kettle Range, The Wedge, Little Pend Oreille, and Salmo Priest) combined represent another 3,656 km^2 (1,412 mi^2) of potential lynx habitat known or thought to have historically and perhaps recently supported a small number of lynx, at least intermittently. Among these, the Kettle Range LMZ was thought to support a small (likely fewer than 20 individuals) resident lynx population as recently as the late 1970s that may have been extirpated as a result of overharvest compounded by habitat changes (Stinson 2001, pp. 14-16; Koehler *et al.* 2008, p.1523; see Lynx Status, below).

Habitat Description: In the northern Cascades most lynx occurrences are associated with the Rocky Mountain Conifer Forest (Aubry *et al.* 2000, p. 379; McKelvey *et al.* 2000a, p. 246) at elevations between 1,400 m (4,593 ft) and 2,150 m (7,053 ft; McKelvey *et al.* 2000d, p. 322; Stinson 2001, p. 9). Within this area lynx primarily use forests dominated by Engelmann spruce, subalpine fir, or lodgepole pine on mild to moderate slopes (< 30°), and avoid Douglas-fir and ponderosa pine forests, forest openings, recently burned areas with sparse canopy and understory cover (< 10 percent), low elevations [less than 915 m (3,000 ft)], and steep slopes (> 30°; Koehler *et al.* 2008, pp. 1518, 1521; Maletzke 2004, pp. 16-17). Similar to the Northern Rocky Mountains, lynx habitat in the North Cascades is naturally fragmented (Koehler *et al.* 2008, p. 1523). As in other boreal forest systrems, fires and insect outbreaks are major drivers of disturbance in this unit, but other factors, including wind and tree diseases, also contribute to natural disturbance regimes (Agee 2000, p. 47). Fire return intervals in the North Cascades range between approximately 100 to 250 years (Agee 2000, p. 50). Average annual snowfall is consistent throughout this unit and is approximately 291 cm (115 in)[21].

Walker (2005, p. 20) estimated an average snowshoe hare density of 0.89 hares/ha (0.36 hares/ac) with a range of 0.03 to 4.85 hares/ha (0.01 to 1.94 hares/ac) in the North Cascades.

[21] https://snowfall.weatherdb.com/d/a/Washington; accessed 4.27.2016.

The WADNR estimated snowshoe hare densities between 0.3 and 0.7 hares/ha (0.1 and 0.3 hares/ac) on the Loomis State Forest (WADNR 2006, p. 87). Koehler (1990a, p. 848) found snowshoe hares were the primary prey of lynx in the North Cascades, occurring in 23 of 29 (79 percent) lynx scats examined. The remains of red squirrels were identified in 24 percent of scats, which also included remains of other species including deer and mice. Similarly, Von Kienast (2003, p. 39) found snowshoe hares in 87 percent (40 of 46) of lynx scats in the North Cascades, while red squirrels were identified in 28 percent of scats.

Habitat Status: Lynx habitat in this geographic unit has been reduced and fragmented by multiple large wildifres over the past several decades that have likely caused a reduction, perhaps temporary, in the number of resident lynx in the unit (Lewis 2016, pp. 4-6; Lyons *et al*. 2016, entire; Maletzke *in* Lynx SSA Team 2016a, p. 21; see Lynx Status below). Several wildfires affected lynx habitat in the North Cascades during the middle 1990s and early 2000s: 1994 Whiteface Burn (15.5 km^2 [6 mi^2]); 1994 Thunder Mountain Fire (36.9 km^2 [14.2 mi^2]); 2001 Thirty-Mile Fire (25.7 km^2 [9.9 mi^2]); and 2001 Farewell Fire (323 km^2 [125 mi^2]; Vanbianchi 2015, p. 23). Subsequent to those fires and incorporating research on lynx habitat use, Koehler *et al.* (2008, p. 1522) estimated that the Okanogan LMZ (including this geographic unit) contained approximately 2,411 km^2 (930 mi^2) of suitable lynx habitat, and that the other 5 LMZs in the northeastern corner of the state, combined, contained an additional 1,381 km^2 (533 mi^2) of suitable habitat. More recent wildfires, including the 2006 Tripod Fire (706 km^2 [273 mi^2]; Vanbianchi 2015, p. 23), have affected approximately 1,000 km^2 (386 mi^2) of lynx habitat in the Okanogan LMZ (Maletzke *in* Lynx SSA Team 2016a, p. 21), and the Diamond Creek fire burned another 393 km^2 (152 mi^2) in the northern part of this unit during July-October 2017, along with another 126 km^2 (49 mi^2) across the border in southern British Columbia[22].

Recently, Lewis (2016, pp. 4-6, fig. 3, table 2) estimated that about a third (3,130 km^2 [1,209 mi^2]) of the total forested area in the Okanogan LMZ burned from 1992 to 2015, and that the amount of suitable lynx habitat in the LMZ similarly declined by 37 percent, from 2,581 km^2 (997 mi^2) in 1996 to 1,630 km^2 (629 mi^2) in 2014. In the Kettle Range, Lyons *et al*. (2016, p. 5) estimated that about 11 percent (360 km^2 [139 mi^2]) of the LMZ burned from 2000 to 2015, and Lewis (2016, p. 6) estimated that the amount of suitable lynx habitat in the LMZ declined by about 7 percent, from 404 km^2 (156 mi^2) in 1996 to 376 km^2 (145 mi^2) in 2014. Cumulatively, Lewis (2016, p. 6) estimated that suitable lynx habitat in north-central and northeastern LMZs in Washington declined by 26 percent, from 3,770 km^2 (1,456 mi^2) in 1996 to 2,790 km^2 (1,077 mi^2) in 2014, with 97 percent of the losses occurring in the Okanogan LMZ and attributable to large wildfires over the past 25 years. This estimate does not include impacts of the 2017 Diamond Creek wildfire described above. These burned areas are expected to regenerate back into suitable lynx habitat, but it may take 10 to 40 years for that to occur (Lewis 2016, p. 5; Maletzke *in* Lynx SSA Team 2016a, p. 21), during which time the resident lynx population in this geographic unit will likely be at increased risk of stochastic demographic, genetic, and environmental effects.

[22] https://inciweb.nwcg.gov/incident/5409/, accessed 10/25/2017.

As it is throughout the DPS range, maintaining connectivity with Canada is believed to be important to the conservation of resident lynx in this geographic unit (ILBT 2013, p. 65). Singleton *et al.* (2002, p. 46) reported broad landscape permeability for lynx between the northern Cascades and the Thompson River watershed in British Columbia. With no known barriers and lynx dispersal from this unit into Canada recently documented, connectivity with lynx populations and habitats in Canada currently appears functional (ILBT 2013, p. 65). Outside of this geographic unit, lynx habitat in the Kettle Range and the other northeastern LMZs is limited in size and potentially capable of supporting only a few lynx. Koehler *et al.* (2008, p. 1523) estimated the Kettle Range could support 10 to 23 lynx based upon a lynx density of 2.3 lynx/100km^2 and 400 km^2 (154 mi^2) to 987 km^2 (381 mi^2) of lynx habitat. However, that lynx density estimate was derived from research conducted in the Cascade Range within a large area of contiguous, high-quality habitat (Koehler 1990a, pp. 845, 847). Lynx habitat in the Kettle Range is much smaller and likely more fragmented, and may not be capable of supporting a similar density. The Kettle Range is also somewhat isolated from other lynx habitats in Washington and British Columbia. The Kettle Range is separated from the Cascades in Washington by low elevation valleys dominated by shrub-steppe and Douglas-fir and ponderosa pine forests (Koehler *et al.* 2008, p. 1523), and from British Columbia by the Kettle River Valley (Stinson 2001, p. 20) and a major highway corridor with associated wildlife fencing in British Columbia (Koehler *et al.* 2008, p. 1523). These natural topographic and anthropogenic features may impede lynx movement between the Kettle Range and the Cascades and British Columbia, perhaps reducing the likelihood of natural recolonization and re-establishment of a resident breeding population in the Kettle Range.

Lynx Status: In Washington, there is little information on the status of lynx prior to the early 1960s (Stinson 2001, p. 13) because lynx trapping records were not maintained in Washington prior to 1961. From 1960 to 1991 a total of 234 lynx was harvested in Washington, with the most (35 percent) lynx trapped in Ferry County, followed by Okanogan (23 percent) and Stevens (10 percent) counties (Stinson 2001, p. 13). Lynx were trapped relatively consistently in the Kettle Range in the 1960s, 1970s, and 1980s, with a total of 81 lynx harvested from 1961 through 1986 (Stinson 2001, p. 63). Beginning in 1978, trapping seasons for lynx in Washington were reduced to 1 month. In 1987 a restricted permit system was implemented, and in 1990 a statewide closure on lynx trapping was implemented (USFWS 2008a, p. 2). In 1993, lynx were classified by the Washington Fish and Wildlife Commission as a State threatened species (Stinson 2001, p. 22). In 2001, the WADFW considered lynx to be present in the Okanogan, Kettle Range, Little Pend Oreille, and Salmon-Priest LMZs; at that time lynx had not been detected in the Wedge LMZ since 1987 nor the Vulcan-Tunk LMZ since 1990 (Stinson 2001, p.15). In its October, 2016, *Periodic Status Review for the Lynx*, the WADFW recommended that the Washington Fish and Wildlife Commission uplist the lynx from a State threatened to a State endangered species because of: 1) observed range contraction in Washington following protection efforts; 2) the substantial loss of habitat in the last 20 years; and 3) the ongoing and anticipated threats to lynx population persistence (Lewis 2016, pp. iii; WADFW 2016, entire). In December, 2016, the Commission approved WADFW's review and adopted its recommendation to uplist lynx to endangered (WAFWC 2016, p. 3).

As elsewhere in the DPS, there are no reliable historical or current estimates of the number of resident lynx in this geographic unit. In 2001, based on data collected from lynx telemetry studies conducted in the Cascade Range during the 1980's, the WADFW estimated that Washington contained approximately 12,579 km^2 (4,857 mi^2) of potential lynx habitat which it felt could theoretically support up to 238 lynx, including up to 149 lynx in the Okanogan LMZ (based on a lynx density of 2.5 lynx/100 km^2; Stinson 2001, p. 16). However, based on professional opinions of individuals knowledgeable about lynx and lynx habitat and on surveys conducted as of 2000, the WADFW concluded that the State's lynx population almost certainly numbered fewer than 200 and perhaps fewer than 100 lynx at that time (Stinson 2001, p. 16). Koehler *et al.* (2008, p. 1523) later estimated there was approximately 3,800 km^2 (1,467 mi^2) of suitable lynx habitat in Washington's 6 LMZs, potentially capable of supporting up to 87 resident lynx. This revised estimate of potential carrying capacity was based on a study investigating lynx habitat use in the Okanogan from 2002 to 2004, and used a lynx density estimate of 2.3 lynx/100 km^2 derived from a radio-telemetry study of lynx in the Cascades from 1985-1987 (Koehler 1990a, pp. 845-847). However, the study area from which the 2.3 lynx/100 km^2 density estimate reported by Koehler (1990a, p.847) was derived is located in an area of the northern Cascades known as the "Meadows". During the time of Koehler's study, the Meadows provided some of the best lynx habitat in Washington, whereas most other potential lynx habitat in Washington is lower in elevation and more highly fragmented (Walker 2005, pp. 3, 6). Thus, the lynx densities Koehler observed in his study area in the Meadows may not be applicable to other areas of potential lynx habitat in Washington, because as habitat becomes more fragmented and isolated, the carrying capacity for lynx likely declines. Therefore, applying Koehler's estimated density uniformly throughout Washington would likely overestimate the number of resident lynx potentially supported in Washington.

More recently, Lewis (2016, pp. 5-6) estimated that wildfires over the last several decades (see Habitat Status section above) have reduced the carrying capacity of the Okanogan LMZ by 37 percent, from 43 females (86 total lynx assuming similar numbers of males and females) in 1996 to 27 females (54 total lynx) in 2014. The author estimated a minor decline in carrying capacity in the Kettle Range LMZ from 8 females (16 total lynx) in 1996 to 7 females (14 total lynx) in 2014. Overall, Lewis (2016, p. 6) estimated that suitable lynx habitat in north-central and northeastern LMZs in Washington declined by 26 percent from 1996 to 2014, with most of the losses resulting from large wildfires in the Okanogan LMZ, and that lynx carrying capacity in the State declined by 29 percent from 58 females (116 total lynx) to 41 females (82 total lynx) over that time period. However, considering a dramatic increase in female home range size (from about 39 km^2 [15 mi^2] during 1990-2002 to 91 km^2 [35 mi^2] by 2014), likely a result of fire-driven habitat loss and fragmentation, Maletzke (*in* Lynx SSA Team 2016a, p. 21) suggested that the carrying capacity of the Okanogan LMZ alone, which encompasses this geographic unit, may have declined from 90-115 females (180-230 total resident lynx) to as few as 27 females (54 total resident lynx) currently. Maletzke's estimate suggests a much larger (70 to 77 percent) potential decline in carrying capacity in this LMZ and, therefore, in the North-central Washington geographic unit. Because of these habitat impacts, limited demographic information, and remaining uncertainties (e.g., immigration/emigration rates, changes in snowpack, disease, lynx population status and impacts of trapping in southern British Columbia, and habitat corridor

stability between British Columbia and this unit; WADFW 2017, p. 3),the Washington Department of Fish and Wildlife recently submitted, and the State Fish and Wildlife Commission adopted, a proposal to uplist lynx from threatened to endangered within the State.

From 1985 to 1987, Koehler (1990a, entire) monitored the movements of 5 adult male and 2 adult female radio-collared lynx in the Cascades of north-central Washington. Results of the study indicated average female home range size was 39 km^2 (15 mi^2) and average male home range size was 69 km^2 (27 mi^2). Based on occupancy of the 640 km^2 study area by 15 adult lynx, adult lynx density was estimated to be 2.3 adults/100 km^2. Annual adult survival rates of the radio-collared lynx were 0.73 in 1986 and 1.00 in 1987, and kitten mortality was high at 88 percent with only 1 of 8 known kittens surviving its first year (Koehler 1990a, p. 847).

Factors Affecting Current Condition

Within Washington, the vast majority of lynx habitat is administered by the Okanogan-Wenatchee (OWNF) and Colville (CNF) National Forests. The North Cascades (i.e., the Okanogan LMZ in north-central Washington), which supports the only known, long-term persistent lynx breeding population in Washington, and within which critical habitat was designated for lynx in 2014 (79 FR 54782), is administered by the OWNF. Subsequent to listing lynx under the ESA, the Forest Service entered into a Conservation Agreement (CA) with the Service in 2000 (USFS and USFWS 2000, entire), which was revised and extended in 2006 (USFS and USFWS 2006, entire). The CA committed the OWNF and CNF to use the Lynx Conservation Assessment and Strategy (LCAS) for management of lynx and its habitat on their ownerships, and will remain in place until the forests amend or revise their individual LRMPs.

In Washington, and the north Cascades specifically, it appears that the single threat for which lynx were listed under the ESA (i.e., inadequacy of Federal regulatory mechanisms) has largely been addressed through the development of the LCAS, and CA between the USFS and Service, which commits the USFS, specifically for Washington the OWNF and CNF, to use the LCAS in the management of lynx habitat on National Forest System lands and when designing and implementing projects within LAUs.

The WADNR manages approximately 4 percent of the lynx habitat within portions of each of the delineated LMZs (WADNR 2006, p.9) in Washington State, including the Loomis State Forest that is located in the north Cascades within the Okanogan LMZ. In 1996, the WADNR developed and implemented a Lynx Habitat Management Plan (1996 Lynx Plan) in response to listing of the lynx as a State threatened species by Washington State (WADNR 1996, entire). After the DPS was Federally listed as threatened, the WADNR in 2006 modified its Lynx Habitat Management Plan to incorporate new science and management standards and guidelines to avoid the incidental take of lynx in accordance with the ESA (WADNR 2006, entire). These standards and guidelines address maintenance of lynx denning and foraging habitat, as well as habitat connectivity within and between LAUs and lynx populations within Washington (i.e., LMZs) and Canada.

For example, the WADNR 2006 Lynx Plan includes, among other things: (1) Encouraging genetic integrity at the species level by preventing bottlenecks between British Columbia and Washington by limiting size and shape of temporary non-habitat along the border and maintaining major routes of dispersal between British Columbia and Washington; (2) Maintaining connectivity between subpopulations by maintaining dispersal routes between and within zones and arranging timber harvest activities that result in temporary non-habitat patches among watersheds so that connectivity is maintained within each zone; (3) Maintaining the integrity of requisite habitat types within individual home ranges by maintaining connectivity between and integrity within home ranges used by individuals and/or family groups; and (4) Providing a diversity of successional stages within each LAU and connecting denning sites and foraging sites with forested cover without isolating them with open areas by prolonging the persistence of snowshoe hare habitat and retaining coarse woody debris for denning sites. The 2006 Lynx Plan also describes how WADNR will monitor and evaluate the implementation and effectiveness of the plan. The WADNR has been managing for lynx for almost 2 decades, and the Service has concluded that the management strategies implemented are effective. In the 2014 final revised critical habitat designation, we determined that the benefits of excluding lands managed in accordance with the WADNR 2006 Lynx Plan outweighed the benefits of including them in the designation, and that doing so would not result in extinction of the species (extirpation of the DPS; 79 FR 54834–54835).

In summary, recent wildfires have, perhaps temporarily, eliminated or reduced the quality of over 40 percent of the higher-quality lynx habitat within the North Cascades (Lewis 2016, pp 4-6; Maletzke *in* Lynx SSA Team 2016a, p. 21), which has reduced lynx carrying capacity and significantly affected the status of and current viability of the lynx population within this geographic unit. This geographic unit likely supports fewer resident lynx currently than it did historically, making the current, smaller population more vulnerable to environmental, demographic, and genetic stochasticity and to large catastrophic events (Lewis 2016, p. 5). Recent wildfire severity, extent, and intensity in lynx habitat within this geographic unit may have been influenced by climate change (Westerling *et al.* 2006, pp. 942-943), and as discussed in chapter 5, climate change may similarly affect the future viability of lynx within this geographic unit.

4.2.5 Unit 5 - Greater Yellowstone Area

Unit Description: This geographic unit includes the parts of southwestern Montana and northwestern Wyoming the Service designated as critical habitat (Unit 5) for lynx in 2014 (79 FR 54825-54826). It encompasses approximately 23,691 km^2 (9,147 mi^2) in portions of Carbon, Gallatin, Park, Stillwater, and Sweetgrass Counties in Montana; and Fremont, Lincoln, Park, Sublette, and Teton Counties in Wyoming, with ownership that is 97.5 percent Federal (USFS, NPS, and BLM); 2.2 percent private; and 0.3 percent State. This unit includes parts of Grand Teton and Yellowstone national parks and the Bridger-Teton, Custer-Gallatin, and Shoshone National Forests, and lands managed by the BLM's Kemmerer and Pinedale Districts. It includes parts of the Absaroka, Beartooth, Gallatin, Gros Ventre, Salt River, Teton, Wind River, and Wyoming mountain ranges. This unit is not directly connected to lynx habitats and

populations in Canada or to other DPS populations, although lynx dispersing from the north likely arrived intermittently into the area historically and, more recently, some lynx released into Colorado traveled into and through this unit (Devineau *et al.* 2010, p. 526; Ivan 2017, entire; details below). Relative to other DPS lynx populations, this unit is about 145 km (90 mi) southeast of the Northwestern Montana/Northeastern Idaho unit, and roughly 400 km (250 mi) northwest of the Western Colorado geographic unit.

Habitat Description: In northwestern Wyoming and the GYA, lynx are generally associated with Engelmann spruce-subalpine fir and lodgepole pine of the Rocky Mountain Conifer Forest vegetation class, as described above (Section 4.2.3) for northwestern Montana, although these habitats, and thus lynx, typically occur at higher elevations (2,000-3,000 m [6,550-9,850 ft]) in the GYA (McKelvey *et al.* 2000a, p. 245; ILBT 2013, p. 60). Potential lynx habitat in much of the GYA is naturally marginal (patchier and composed in many places of drier forest types), with fewer shrubs and a more open understory, and generally very low to marginal hare densities, resulting in a spatially-limited distribution of lynx with large home ranges (Squires *et al.* 2003, pp. 5, 12-13; 68 FR 40090; 71 FR 66010, 66029; 74 FR 8624, 8643–8644; Hodges *et al.* 2009, entire; Berg and Gese 2010, p. 1750; 79 FR 54796; Lynx SSA Team 2016a, p. 45). Among the 3 national forests that contribute lands to this geographic unit, potential lynx habitat was mapped on about 42 percent of the total national forest area (both inside and outside this unit; USFWS 2007, pp. 32, 95, 122-123).

In Yellowstone National Park, 7,732 km^2 (2,985 mi^2; about 86 percent of the park) is considered "lynx forest types" (65 FR 16073), but only 2,784 km^2 (1,075 mi^2; 31 percent of the park, 36 percent of lynx forest types) is estimated to be potential lynx habitat (68 FR 40086). However, hares were completely absent from more than 36 percent of surveyed stands in Yellowstone National Park, and 96 percent had estimated hare densities below the 0.5 hare/ha threshold thought necessary to support resident lynx (Hodges *et al.* 2009, pp. 870, 873-877). In contrast, estimated hare densities were ≥ 0.48 hares/ha (0.19 hares/ac) in all surveyed stands on the Bridger-Teton National Forest in the southern portion of the GYA, with highest densities (1.7 hares/ha [0.69 hares/ac]) in 30-70-year-old regenerating lodgepole pine stands with dense horizontal cover, and densities of 1.2-1.6 hares/ha (0.49-0.65 hares/ac) in mature multi-story spruce-fir and mixed spruce-fir (containing aspen or lodgepole pine) stands (Berg *et al.* 2012, p. 1483). In the central Wyoming Range in the southern part of this unit, hare tracks were more abundant in seral aspen stands with a significant spruce-subalpine fir component than in aspen stands with little or no spruce-fir, and hares appeared to be absent from pure aspen stands except where they bordered spruce-fir areas (Endeavor Wildlife Research 2009, p. 4). The only lynx den sites described for this unit (the natal den and a subsequent maternal den of 1 female in 1998) occurred in a mature subalpine fir-lodgepole pine forest in the Wyoming Range, where coarse woody debris and high sapling density provided dense horizontal cover (Squires and Laurion 2000, pp. 346-347).

Average annual snowfall in this unit ranges from about 127 cm (50 in) in Bozeman and 556 cm (219 in) in West Yellowstone, Montana, on the northern and northwestern peripheries of the unit, respectively, to 280-310 cm (110-122 in) in Alpine, Dubois, and Jackson, WY near the central and southern peripheries, with most snow falling from November to March in each

place[23]. In potential lynx habitats on the Bridger-Teton National Forest in the southern half of this unit, deep snow persisted from late October through May (Berg *et al.* 2012, p. 1481).

Habitat Status: Potential lynx habitats in this unit are currently designated as critical habitat in accordance with the ESA. Over 97 percent (23,109 km^2 [8,922 mi^2]) of this unit is in Federal ownership, including 18,877 km^2 (7,292 mi^2) in national forests under USFS management, 3,944 km^2 (1,523 mi^2) in national parks managed by NPS, and 271 km^2 (105 mi^2) managed by BLM. As described above in section 3.1.1, USFS lands in this unit are managed in accordance with the NRLMD, which formally amended all forest plans to adopt and implement lynx conservation measures (USFS 2007, pp. 8-30 and Attachment 1, pp. 1-9) that were developed based on the scientific findings and recommendations of the LCAS (Ruediger *et al.* 2000, pp. pp. 7-1 - 7-18). Similarly, the BLM in 2008 and 2010 revised its RMPs for the Pinedale and Kemmerer districts, respectively, to include conservation measures and BMPs for lynx based on the LCAS (BLM 2008, pp. A18-10 - A18-15; BLM 2010, pp. A-9 - A-12). On lands with developmental land-use allocations, these amended forest plans and the revised BLM RMPs provide guidance on the kinds of activities that can and cannot be implemented in important lynx habitats and thresholds for the proportions of lynx habitat in LAUs that can be in an unsuitable state at any given time and how much can be converted from suitable to (temporarily) unsuitable over particular time frames. Implementation of these plans has likely benefitted lynx by providing a consistently-applied framework for conserving and restoring important hare and lynx habitats.

As elsewhere in the DPS (Squires *et al.* 2010, p. 1656; ILBT 2013, pp. 20, 27), winter foraging habitat is likely the most limiting habitat for lynx in this unit, and denning habitat is not thought to be limiting. Standards, guidelines and BMPs in the NRLMD and in revised BLM plans restrict vegetation management activities that could reduce winter snowshoe hare habitat and direct the creation or retention of coarse woody debris in areas where denning habitat may be lacking (USFS 2007, Attachment 1, pp. 2-5; BLM 2008, pp. A18-10 - A18-15; BLM 2010, pp. A-9 - A-12). Snow conditions in this unit also appear to remain suitable to allow lynx to outcompete other terrestrial hare predators. Gonzalez *et al.* (2007, pp. 4-7) modeled snow suitability across North America, showing that most of this geographic unit has a 95 percent probability of providing snow cover conditions consistent with historical lynx occurrence records (Gonzalez *et al.* 2007, p. 12).

This unit includes substantial areas in nondevelopmental land-use allocations, including (in addition to Yellowstone and Grand Teton national parks) the Absaroka-Beartooth, Bridger, Gros Ventre, Lee Metcalf, Northern Absaroka, Teton, and Washakie designated wilderness areas. Among the 3 national forests that contribute to this unit, 75 percent of potential lynx habitat is in designated wilderness or roadless areas (USFWS 2007, p. 34). Management activities in these areas are unlikely to adversely impact lynx and hare habitats. Large parts of Yellowstone National Park burned in the extensive wildfires of 1988. Although the extent to which those fires may have impacted potential lynx habitats is uncertain, some of the burned areas may soon reach a stage of regeneration capable of supporting increased densities of hares, perhaps

[23] https://snowfall.weatherdb.com/d/a/Montana; accessed 8.17.2016.

increasing the likelihood that lynx could reestablish and maintain home ranges in some parts of the park (Lynx SSA Team 2016a, p. 45). Because non-Federal lands make up less than 3 percent of lynx habitats in this unit, it is unlikely that activities on those lands have impacted lynx populations or meaningfully influenced the unit's current capacity to support resident lynx.

Overall, although naturally fragmented and patchily-distributed, potential lynx habitat in this geographic unit appears to be largely intact relative to historical conditions and disturbance regimes, with only a small proportion apparently impacted by past management (timber harvest and precommercial thinning) activities (65 FR 16072). Despite some likely localized impacts of past timber management and infrastructure (e.g., highway, railroad) development, past management activities do not appear to have diminished this unit's ability to support resident lynx or to have created barriers to lynx movement, or to have had other landscape- or population-level effects.

In summary, much of this geographic unit occurs in national parks, designated wilderness and roadless areas, or other nondevelopmental land-use allocations, where management activities with the potential to adversely affect lynx habitat generally do not occur. Almost all lands with developmental land-use allocations in this unit are managed by the USFS to conserve and maintain lynx and hare habitats under management plans that were formally revised in 2007 in accordance with the NRLMD and based on the scientific findings and conservation recommendations of the LCAS. A small proportion of lands with developmental allocations occurs on BLM lands where management plans also were revised recently (2008 and 2010) to adopt conservation measures identified in the LCAS. Implementation of these USFS and BLM plans likely precludes landscape-level management-related adverse impacts to the vast majority of existing lynx and hare habitats in this unit. Nonetheless, past management activities that occurred prior to implementation of current regulations and other conservation efforts may exert continuing influence on current habitat quality in some places. Additionally, because lynx habitats in this unit are naturally highly-fragmented and, in most places, support low landscape-level hare densities, relatively minor impacts, especially to hare and lynx winter foraging habitats, may strongly influence lynx persistence in some parts of this unit.

Lynx Status: There are no reliable estimates of the historical or current number of resident lynx in this unit. As described in section 2.3.2.2 above, the historical record and recent research show that the GYA has supported resident lynx at least occasionally, but it is unclear whether the area consistently supported a persistent resident population over time or whether it naturally supported resident lynx only intermittently. Most historical and recent verified lynx records are from the southern portion of this unit in the Gros Ventre, Salt River, Wind River, and Wyoming mountain ranges in the Bridger-Teton National Forest. Reeve *et al*. (1986a, entire; 1986b, entire), who compiled all lynx records state-wide in Wyoming from 1856-1986, reported 22 verified ("certain") records and over 200 unverified ("probable") records based on trapping reports and observations of animals or tracks (Reeve *et al*. 1986a, pp. 64-70. Most records were from the northwestern corner of the State (Reeve *et al*. 1986a, pp. 28-29; 1986b, pp. 6-9), which overlaps much of the GYA geographic unit. McKelvey *et al*. (2000a, pp. 229-230) reported 30 verified records for Wyoming, including those in Reeve *et al*. as well as 2 resident lynx, a male

and a female, who were trapped, radio-marked, and monitored in the Wyoming Range over several years beginning in 1996 and who produced 6 kittens over 2 years. The female had 4 kittens in 1998 and 2 in 1999, though none of the kittens survived to independence, and the female died of starvation in March 2000 (Squires and Laurion 2000, p. 346; Squires *et al.* 2001, pp. 9, 26). The female's home range averaged 50 km^2 (19 mi^2) over the 3 years she was monitored, and the male's averaged 824 km^2 (318 mi^2) over 5 years (Squires *et al.* 2003, pp. 12-13). The male also made multiple long-distance exploratory movements (up to 728 km [452 mi], including multiple highway crossings) over 3 successive years (Squires *et al.* 2003, pp. 13-16; Squires and Oakleaf 2005, entire).

As described in section 2.3.2.2, several sources reported accounts of numerous lynx being trapped in the Wyoming Range in the early 1970s. However, nearly all these records are unverified and the various anecdotal reports provide conflicting numbers and years in which lynx were purportedly trapped. These conflicting anecdotal reports illustrate compellingly why only verified records are appropriate for evaluating historical lynx distribution (McKelvey *et al.* 2000a, pp. 208-210; 2008, pp. 553-554). Even if these anecdotal records were accurate, the large numbers of lynx reported in the early 1970s correspond to the second of 2 well-documented and unprecedentedly large irruptions of lynx from Canada into the northern contiguous United States, when dispersing/transient lynx occurred temporarily in many parts of the DPS range (McKelvey *et al.* 2000a, pp. 232-242). That the sudden increase in lynx suggested by these anecdotal records would have reflected a pulse of dispersing lynx associated with that large irruption is more plausible than the notion that a previously undocumented resident lynx population suddenly and simultaneously became vulnerable to trapping in only a handful of winters.

Other surveys, however, resulted in verified detections of a small number of lynx in the southern portion of this unit from 1999-2009, with records most consistent in the Wyoming Range, Togwotee Pass, Union Pass, the Bondurant Corridor, and in the Gros Ventre Range (Squires *et al.* 2001, pp. 9-14; Squires *et al.* 2003, pp. 9-11, 29-31; Endeavor Wildlife Research 2008, 2009, entire; Berg 2016, *pers. comm.*; Squires *in* Lynx SSA Team 2016a, pp. 20-21). At least 9 radio-marked lynx released in Colorado subsequently moved into or through the GYA unit from 1999-2010, with locations of several of these lynx concentrated in areas used previously by the native male and female described above (Devineau *et al.* 2010, p. 526; Hanvey 2016, *pers. comm.*; Ivan 2017, entire). In winter 2004-05, a male and female, both released in Colorado in spring 2004, occupied overlapping areas on the east side of the Wyoming Range (Ivan 2017, p. 3, figs. 20, 24). During the 2006 breeding season, a male and a female, both also released in Colorado in 2004, occupied overlapping areas farther north near Pinnacle Buttes along Highway 287 (Ivan 2017, p. 3, figs. 21, 23). However, there is no evidence that either of these pairs bred or that either female denned or produced kittens (Ivan 2017, p. 3). On the Shoshone National Forest in the northeastern part of this unit, analysis of DNA collected during winter surveys confirmed 7 lynx snow tracks in winter 2005/06 and a single track in 2006/07 (Endeavor Wildlife Research 2008, p. 2; Berg 2016, *pers. comm.*). Overall, during the 4 winters of 2004-05 through 2007-08, 26 snow tracks on the Bridger-Teton and Shoshone National Forests were confirmed by DNA analyses to be from 5 individual lynx (3 males, 2 females). One of the males had

previously been documented in Yellowstone National Park (see below). The other 2 males and both females were lynx that had been released in Colorado (Pilgrim 2016, *pers. comm.*).

Verified records of lynx are less common elsewhere in this unit, including in Yellowstone and Grand Teton national parks and the Custer-Gallatin National Forest. There were no verified records of lynx in Yellowstone National Park from 1920-1999 (McKelvey *et al.* 2000a, p. 230); however, surveys in 2001-2004 documented at least 3 individual lynx, including 2 kittens, in the eastern part of the park (Murphy *et al.* 2006, entire). On the Custer-Gallatin National Forest in Montana in the northern part of the unit, a single female was detected over 6 consecutive winters (2003/2004 - 2008/2009) but not subsequently (Gehman *et al.* 2010, pp. 2-4), and it appears that she did not encounter a male or produce kittens during the 6 years she was detected (Gehman *et al.* 2010, p. 4).

Recent surveys and research-related trapping efforts have failed to detect lynx in this unit after 2010 (79 FR 54791; Squires *in* Lynx SSA Team 2016a, pp. 20-21, 45; Hanvey 2016, *pers. comm.*). As discussed above and in section 2.3.2.2, it is uncertain whether this unit historically supported a small but persistent resident population that was recently extirpated, or if it historically and recently supported resident lynx only intermittently. Given the protected conservation status of millions of acres in this unit, its apparent recent inability to support resident lynx may be a reflection of naturally marginal and patchy habitats and relatively low hare abundance in much of the unit, resulting in only an intermittent ability of this unit to support resident lynx (Lynx SSA Team 2016a, p. 57). Conversely, the characteristics described above suggest that relatively small impacts could shift potential habitats in this unit from just barely able to support a persistent resident population to incapable of doing so. Further, the available evidence suggests that if this unit did support a persistent population, it was very likely a very small one, which would be more vulnerable to extirpation as a result of demographic, environmental, and genetic stochasticity, catastrophic events (McKelvey *et al.* 2000b, pp. 23-29), or a combination of these factors.

Factors Affecting Current Conditions

Regulatory Mechanisms - As described above for Unit 3, Federal management activities (e.g., timber harvest and precommercial thinning, perhaps fire suppression) that occurred prior to listing and before implementation of current Federal regulatory mechanisms likely impacted some lynx by altering the distribution and quality of hare and lynx habitats. However, because these activities occurred in low proportions of lynx habitat on Federal lands and impacts appear to have been localized, they were deemed a low-level to threat to lynx at the time of listing (65 FR 16072-16076; 68 FR 40091-40095). Nonetheless, past Federal management activities may continue to influence the current quality and distribution of lynx habitats in some parts of this unit. Current regulatory mechanisms and conservation measures associated with recently amended or revised Federal management plans are intended to conserve and restore lynx and hare habitats across large landscapes. Although their effectiveness has not been quantitatively evaluated, they have almost certainly reduced significantly the potential for adverse management-related impacts to lynx habitats in this unit.

Lynx trapping has been prohibited in Wyoming since 1973 (79 FR 54794) and in Montana since 1999 (MTFWP 2016, p. 7) and, as described in section 3.1.2, both states require measures to reduce the likelihood of trapping lynx incidentally when legally trapping other species. Since the DPS was listed in 2000, no lynx are documented to have been incidentally trapped in the Montana portion of this unit (MTFWP 2016, pp. 5-10) and we are aware of no incidental captures in northwestern Wyoming since listing.

Climate Change - As elsewhere, increased temperatures, reduced snowpack, earlier snowmelt, and increased drought leading to increased fire all have been documented in this geographic unit (e.g., Mote *et al.* 2005, entire; Pederson *et al.* 2013, entire; Riley *et al.* 2013, entire; Dennison *et al.* 2014, entire; USEPA 2015, entire; Harvey *et al.* 2016, entire; Siren *in* Lynx SSA Team 2016a, pp. 14-15; Westerling 2016, entire). A number of potential impacts to lynx have been described, and climate projections suggest these impacts are likely to result in future loss and increased fragmentation and isolation of lynx and hare habitats and declining lynx populations in the DPS (Carroll 2007, entire; Gonzalez *et al.* 2007, entire; ILBT 2013, pp. 69-71; 79 FR 54810-54811; Lawler and Wilsey *in* Lynx SSA Team 2016a, pp. 15-16; Siren *in* Lynx SSA Team 2016a, p. 15; see also sections 3.2, and 5.2.3). Although climate change has probably already had some impact on lynx habitats in this geographic unit, and such impacts are likely to continue to occur, there currently is no evidence that climate change has had population-level effects or has reduced the ability of this unit to support persistent resident lynx populations. However, such impacts would be difficult to document and, as described under *Habitat Status*, above, lynx habitats in this unit are naturally highly-fragmented and hare densities low in some places. Therefore, relatively minor impacts, especially to hare and lynx foraging habitats, may strongly influence lynx persistence in some parts of this unit.

Modeling vegetation and snow suitability for lynx across North America, Gonzalez *et al.* (2007, pp. 12, 15) indicated that boreal and temperate conifer forest biomes were broadly distributed across this geographic unit and that snow conditions suitable for lynx occurred with 95 percent probability from 1961-1990. (Future conditions based on this modeling are described in section 5.2.5). As described in section 3.2, climate change has also been implicated in recent increases in the frequency and intensity of outbreaks of boreal forest insect pests, with warmer winters resulting in increased insect survival and drought increasing conifer vulnerability to insects. This trend is expected to continue through the end of the century with continued climate warming (Bentz *et al.* 2010. pp. 607, 609).

Vegetation Management - The influence of vegetation management on the current condition of lynx and habitats in this unit is described above under Habitat Status and *Regulatory Mechanisms*, above.

Wildland Fire Management - As described above in section 3.4, wildfire suppression in this unit, as elsewhere in the West, has likely had little impact on lynx habitats (65 FR 16074; 68 FR 40093-94; USFS 2007, pp. 18, 20; USFS 2008a, p. 11; ILBT 2013, p. 76). Also as described in that section, wildfire frequency, size, and intensity have increased in this geographic unit, likely in response to climate warming and related increases in drought conditions (e.g., Dennison *et al.* 2014, entire; Harvey *et al.* 2016, entire; Westerling 2016, entire), with most large, stand-

replacing fires having occurred in the northern part of the unit, in Yellowstone National Park (see Harvey *et al.* 2016, fig. 1). Despite this increase, we are aware of no evidence that increased fire activity in the unit has thus far impacted resident lynx populations or reduced this unit's ability to continue to support resident lynx.

Habitat Loss and Fragmentation - As described above, the dominant land use in this unit, and that most likely to result in habitat loss and fragmentation, is timber harvest and associated vegetation management (e.g., precommercial thinning) and road construction on lands with developmental allocations. Much of this unit occurs in national parks, designated wilderness and roadless areas, or other nondevelopmental allocations. Even in areas with developmental allocations, the moist subalpine forests important to lynx have had less timber harvest and road construction, and have been modified much less than other drier forests (65 FR 16073). These activities appear not to have had population-level impacts on lynx or to have measurably reduced the ability of this geographic unit to support resident lynx. Few highways intersect lynx habitats in the Northern Rockies (ILBT 2013, p. 63) and there are few records of lynx killed by vehicle collisions in Montana (5) and Wyoming (1 [a Colorado-released lynx]; USFWS 2016c). Other potential sources of habitat loss and fragmentation include recreation, minerals/energy development, and backcountry roads and trails; these are all considered second tier anthropogenic influences (ILBT 2013, pp. 78-85) that are unlikely to exert population-level influences, despite potential impacts to individual lynx.

Other Factors - Connectivity/Immigration - As elsewhere in the range of the DPS, resident lynx populations in this geographic unit are thought to be influenced by connectivity with, and immigration of lynx from, populations in Canada (see section 2.2). However, whether, and if so to what the extent, the persistence of populations in this geographic unit may depend on regular or intermittent immigration of lynx from Canada remains uncertain, and historic, recent, and current immigration rates are unknown. Although this unit is not directly connected to lynx habitats and populations in Canada or elsewhere in the contiguous United States, no barriers to lynx dispersal from the north have been identified, and 9 lynx released in Colorado are known to have dispersed northward into and through this unit (Devineau *et al.* 2010, p. 526; Ivan 2017, entire), demonstrating that dispersal between the southern and northern Rockies is possible. As described above in Lynx Status, the large number of lynx reportedly trapped from a small area of the Wyoming Range in the early 1970s (Squires and Laurion 2000, p. 338) may suggest dispersers associated with the irruption of many lynx from Canada into the northern contiguous United States documented at that time (McKelvey *et al.* 2000a, pp. 235-242). No subsequent pulses of lynx dispersing from the north have been documented, and lynx trapping records suggest that the magnitude of lynx populations cycles in Alberta and British Columbia, the most likely source of lynx dispersing southward into this unit, dampened dramatically after the early 1980s (McKelvey *et al.* 2000a, p. 226; Bowman *in* Lynx SSA Team 2016a, p. 13; also see Appendix 5, 2015 10 13 - 5, pp. 4-5[24]).

[24] https://www.fws.gov/mountain-prairie/es/species/mammals/lynx/SSA2016/Appendices/Appendix%205%20Presentation%20PDFs/2015%2010%2013%20-%205%20-%20Bowman%20Lynx%20Southern%20Canada.pdf.

As described in section 3.2, a number of climate-mediated factors have been suggested as contributing to changes in the periodicity and amplitude of northern lynx and hare population cycles, which could alter the timing and magnitude of irruptions of lynx from Canada into the contiguous United States. If lynx populations in this geographic unit rely on immigration from Canada which is no longer occurring or has been substantially reduced relative to historical conditions, population declines and a reduced likelihood of persistence among resident populations would be expected. Although the extent to which this factor has influenced the current condition of lynx populations in this unit is unknown, it is possible that it has contributed to the recent apparent loss of resident lynx from this unit.

4.2.6 Unit 6 - Western Colorado

Unit Description - This geographic unit includes parts of the Southern Rocky Mountains of western Colorado. It encompasses approximately 25,294 km^2 (9,766 mi^2) of potential lynx habitat distributed west of US Interstate 25, with ownership that is 90 percent Federal (85 percent USFS, 3 percent BLM, 2 percent NPS), 9 percent private, and < 1 percent State. When it listed the DPS, the Service identified 26,305 km^2 (10,156 mi^2) of potential lynx habitat in the Southern Rockies (i.e., western Colorado and south-central Wyoming; [65 FR 16052]). In 2003, we estimated 31,027 km^2 (12,419 mi^2) of potential habitat within that area (68 FR 40076). Ivan *et al*. (2011e, entire) developed a predictive map of lynx habitat by using telemetry location data collected during CPWs lynx monitoring, and then estimated the amount of habitat associated with a high probability of detecting lynx. Our review of the vegetative characteristics of CPW's predictive map detected large areas of spruce-fir habitats that were excluded by their presentation of the habitat associated with the top 20 percent of predicted use (Ivan 2011e, p. 26). Therefore, we selected the top 30 percent of predicted use areas and the associated habitat to represent the amount of potential lynx habitat in this unit. Our estimate of potential habitat (above) falls between the Ivan *et al*. (2011e, p. 26) estimate (about 18,700 km^2 [7,220 mi^2]) and the USFS's habitat estimate (30,664 km^2 [11,839 mi^2]; USFS 2008b, p. 18), while retaining a greater than 60 percent probability of detecting lynx as described by Ivan *et al*. (2011e, pp. 32-33).

We excluded the northwest part of the State, bounded on the south by US Interstate 70 and the east by Colorado State Highway 13, because this area lacks sufficient habitat to support lynx. Small areas of similar potential lynx habitat extend into south-central Wyoming and north-central New Mexico, and some lynx released in Colorado traveled into or through those areas. However, there is no evidence that either area supports resident lynx, and we doubt their ability to do so. This unit is not directly connected to lynx habitats and populations in Canada or to other DPS populations, although lynx dispersing from the north apparently arrived intermittently into the area historically, and long-distance dispersal (emigration) of translocated lynx from this unit to many western states and to Canada have been documented. The Southern Rockies are separated from the rest of the Rocky Mountain chain, and thus from lynx habitat in northwestern Wyoming and further north, by sagebrush and desert shrub communities in the Wyoming Basin and the Red Desert of southern and central Wyoming, and the arid Green and Colorado River plateaus of western Colorado and eastern Utah. Because of extreme topographic relief

juxtaposed with highways, residential communities, and other human developments, lynx biologists have identified habitat connectivity as an important consideration for the Southern Rockies (ILBT 2013, p. 54). Relative to other DPS lynx populations, this unit is about 400 km (250 mi) southeast of the GYA geographic unit.

Habitat Description - Lynx habitat in the Southern Rockies occurs within the subalpine and upper montane forest zones, generally above 2,900 m (9,514 ft) elevation (Shenk 2009, p. 10). In the upper elevations of the subalpine zone, forests are typically dominated by subalpine fir and Engelmann spruce. As the subalpine zone transitions to the lower-elevation upper montane zone, spruce-fir forests begin to give way to lodgepole pine and aspen. On cooler, mesic mid-elevation sites, Engelmann spruce may retain dominance, intermixed with aspen, lodgepole pine, and Douglas-fir. Lodgepole pine reaches its southern limits in the central part of the geographic unit, while southwestern white fir occurs only in the San Juan Mountains. The lower montane zone is dominated by ponderosa pine and Douglas-fir, with pines typically dominating on lower, drier, more exposed sites, and Douglas-fir occurring on the more sheltered sites. Lower montane forests do not support snowshoe hares and are seldom used by lynx except during dispersal and exploratory movements.

In this unit, lynx most commonly use mature Engelmann spruce-subalpine fir forests with total canopy cover of 42–65 percent and a conifer understory canpoy of 15–20 percent, followed by mixed forests of Engelmann spruce-subalpine fir-aspen (Shenk 2008, p. 15; ILBT 2013, p. 52). Riparian and riparian-mix are the third most-used cover type, with a pattern of increasing use beginning in July, peaking in November, and dropping off in December. Large or medium willow-alder carrs and willow riparian communities provide important habitat for snowshoe hare, grouse, ptarmigan (winter), and other prey species (ILBT 2013, p. 52).

Habitat Status - Snowshoe hare (lynx foraging) habitat is naturally patchily-distributed in the Southern Rocky Mountains (ILBT 2013, p. 54), limiting hare abundance in this geographic unit. Dolbeer and Clark (1975, pp. 535, 539) estimated snowshoe hare density at 0.73 hares/ha (0.3 hares/ac) in Summit County in central Colorado, with the highest densities in mature and late-successional spruce-fir forests. However, this study was conducted in a very limited area and did not sample younger sapling-stage stands (15-40 years post-disturbance) to compare hare densities with those reported for mature and late-successional spruce-fir forests (USFWS 2008b, p. 32). Zahratka and Shenk (2008, pp. 910-911) estimated higher hare densities in mature Engelmann spruce-subalpine fir stands (0.08 to 1.32 hares/ha ([0.03 to 0.5 hares/ac]) than in mature lodgepole pine stands (0.06 to 0.34 hares/ha [0.02 to 0.14 hares/ac]) in Taylor Park, Colorado. In contrast, Ivan *et al*. (2014, p. 587) estimated highest (summer) hare densities in early (20-25 years old) seral lodgepole stands (0.2 to 0.66 hares/ha [0.08 - 0.27 hares/ac]); intermediate densities in mature spruce-fir stands (0.01 to 0.26 hares/ha [0.004 - 0.1 hares/ac]); and lowest densities in mid-seral (40-60 years old) lodgepole stands that had been pre-commercially thinned (0.01 to 0.03 hares/ha [0.004 - 0.01 hares/ac]). Densities were more similar across the 3 forest types during the winter months; however, in all forest types and all seasons, hare densities were < 1.0 hares/ha (< 0.4 hares/ac) and in most cases were < 0.3 hares/ha (< 0.12 hares/ac; Ivan *et al*. 2014, p. 589). In fact, only 1 stand type (early seral

lodgepole) in 1 summer (2006) had an estimated density (0.66 ± 0.14 hares/ha [0.27 ± 0.06 hares/ac]) that exceeded the 0.5 hares/ha (0.2 hares/ac) threshold suggested as a minimum needed to support resident lynx over time (Ivan *et al*. 2014, p. 587, fig. 2). The information summarized above suggests that hare densities in this unit are low to marginal compared to units that have historically supported persistent resident lynx populations, and they may be inadequate to support long-term lynx persistence.

Colorado is currently experiencing historically unprecedented bark beetle epidemics in lodgepole pine and spruce-fir forests. By 2015, the spruce beetle outbreak influenced approximately 95 percent of the mature spruce component of the subalpine cover types on the Rio Grande National Forest (Squires *et al.* 2016, *unpubl. report*, p. 1), which contains most of the potential lynx habitat in the San Juan Mountains. Recent statewide sampling, however, indicates that snowshoe hare occupancy is invariant to time since beetle outbreak or severity of the outbreak (Ivan and Seglund 2016, pp. 2, 5), which suggests that the ongoing epidemic will not be catastrophic to lynx in Colorado. However, red squirrels are an important alternate food source in this unit, and occupancy of that species has declined markedly with the beetle epidemic (Ivan and Seglund 2016, pp. 2-3), which may be of some concern during periods when snowshoe hare abundance naturally fluctuates downward.

All USFS land management plans within the unit were amended by the SRLA in 2008 to provide for the conservation of lynx (USFS 2008a, entire; USFWS 2008b, entire). In 2008, the USFS reported that most LAUs on National Forest System lands in the Southern Rockies fell within a range of 3-8 percent in a currently unsuitable condition, with only 1 LAU exceeding the 30 percent unsuitable threshold established in the SRLA (USFS 2008b, p. 19). Currently, the USFS reports that 51 of 202 LAUs (25 percent) exceed the 30 percent unsuitable condition (McDonald 2016, *pers. comm.*). These changes are mostly in response to the ongoing bark beetle infestations and wildfires that have occurred since 2008. No forest management activities have resulted in LAUs exceeding the threshold.

Similarly, since the DPS was listed, all BLM Field Offices (FOs) in Colorado have been conserving lynx discretionarily through application of conservation measures provided in the LCAS (Ruediger *et al.* 2000, entire; ILBT 2013, entire). Three BLM FO plans in Colorado have been amended or revised to conserve lynx following the 2013 LCAS on lands totaling approximately 126 km^2 (49 mi^2) of potential lynx habitat. One additional FO plan provides conservation measures for timber management actions only, but that FO administers only about 1 km^2 (0.39 mi^2) of potential lynx habitat. To date, the remaining FOs have not formally amended or revised their plans specifically to provide conservation for lynx. Combined, these plans guide management of approximately 645 km^2 (298 mi^2; about 2.6 percent of the geographic unit) of potential lynx habitat. Additionally, Rocky Mountain National Park has a fire management plan that includes conservation measures for lynx (Wrigley 2016, *pers. comm.*; Watry 2016, *pers. comm.*), although resident lynx have not been confirmed in the park. We are not aware of any specific lynx conservation strategies guiding activities on non-Federal lands in this geographic unit.

Lynx Status - The current number and distribution of resident lynx in Colorado are somewhat uncertain. However, experts suggest there may be 100-250 lynx in this unit, and we believe it is reasonable that lynx continue to occur in all national forests within the State. As of 2007, average annual survival among released lynx was 0.93 ± 0.03 within the study area in the San Juan Mountains and 0.82 ± 0.07 outside the study area boundary (Devineau *et al.* 2010, p. 5). Although 30 percent of known mortalities were due to human causes (being shot or hit by a vehicle; Devineau *et al.* 2010, p. 5), the estimate of survival within the study area was higher than those reported for natural, lightly trapped populations of lynx in the Yukon (0.75–0.90; Slough and Mowat 1996, entire; O'Donoghue *et al.* 1997, p. 155) or in the Northwest Territories (0.90; Poole 1994, p. 612). Successful reproduction, including by third- and fourth-generation offspring of translocated lynx, has been documented (Shenk 2008, p. 2); however, the average proportion of females that produced kittens (24 percent; Ivan *in* Lynx SSA Team 2016a, p. 22) and the kitten survival rate (0.23; Ivan 2016b, *pers. comm*.) were both lower in this geographic unit (during the period of intensive monitoring from 1999-2010) than rates reported for other geographic units where estimates were based on adequate sample sizes (Units 1 and 3; table 4).

The CPW has developed a minimally-invasive, long-term, state-wide monitoring program to track the distribution, stability, and persistence of lynx in Colorado (Ivan 2011e, entire) that may also eventually provide population trend information. As of 2016, this monitoring program detected evidence of recent lynx reproduction via camera captures of kittens accompanying adult females at 3 locations during the 2014-2015 and 2015-2016 monitoring efforts (Ivan *et al*. 2015, p. 1; Odell *et al*. 2016, p. 6). In addition, 38 percent of lynx captured during recent (2010-2015) RMRS research projects in Colorado have been young and/or unmarked cats (Ivan *in* Lynx SSA Team 2016a, p. 17), suggesting continued reproduction within Colorado. However, current reproductive rates are unknown. Finally, despite the large scale and almost complete mortality of the mature spruce component within the core release area of the San Juan Mountains, lynx continue to use and reproduce in the beetle-infested forests (Squires *et al.* 2016, *unpubl. report*, p. 2).

Factors Affecting Current Conditions

Regulatory mechanisms to conserve lynx habitats in Colorado are largely provided through Forest Service planning documents, as described above under Habitat Status. Because the majority (88 percent) of potential lynx habitat in Colorado is under Federal land management, actions occurring on other ownerships are unlikely to result in significant losses of lynx habitat within Colorado. However, habitat connectivity may be negatively affected by intense recreational use or development in key areas that are important for habitat connectivity, although this isn't a widespread phenomena or threat.

Although bark beetles are native insects and forests in the western United States have experienced regular insect infestations throughout their history, the current bark beetle epidemic is notable for its intensity and extensive geographic range. The causes of this epidemic include: relatively even-aged, dense, and homogenous forest conditions, which are highly susceptible to beetle attack, and which were created by large-scale logging in the late 1800s and subsequent

fire suppression efforts; warmer winters as a result of climate change (cold winters typically reduce beetle populations); and a multi-year drought that occurred in the mid-1990s through early 2000s, stressing the trees and making them more susceptible to beetle attack (USFS 2011b, p. 4).

In lodgepole pine forests, a mountain pine beetle epidemic typically kills the entire overstory and results in a stand-replacing disturbance event. In Colorado, more than 13,759 km^2 (5,312 mi^2) have been affected by mountain pine beetle and 6,390 km^2 (2,467 mi^2) have been affected by spruce beetle since 1996 (USFS 2015b, p. 3), a portion of which overlaps potential lynx habitat in this geographic unit. Even-aged mature and "dry" lodgepole pine stands characteristically have depauperate understory vegetation and are not capable of supporting dense populations of snowshoe hares. On moist sites, regeneration of beetle-killed lodgepole pine stands is expected to be relatively rapid (20-30 years), and the new stands will be dominated by a regenerating cohort of lodgepole pine or resprouting aspen. If these newly-established stands grow tall and dense enough to provide horizontal cover above the snow layer, they may produce excellent habitat for snowshoe hares and lynx for several decades, until the crowns again lift above the reach of snowshoe hares.

A spruce beetle epidemic kills the larger-diameter trees and can also result in a stand-replacing disturbance event. Because of the importance of spruce-fir forests for production and survival of snowshoe hares, widespread mortality of mature spruce-fir forests could impact lynx habitat for a long time.

ILBT (2013 p. 57; 61-62) states:

> *Plague, a flea-borne disease caused by the bacterium Yersinia pestis, which is not native to North America, was reported for the first time in lynx in Colorado (Wild et al. 2006). Pneumonic plague appeared to be the direct or indirect cause of death of 6 reintroduced lynx between 2000 and 2003. When translocated from Canada and Alaska, none of the lynx had antibody titers to Y. pestis; it appears likely that lynx were exposed to plague by infected prey after their release in Colorado.*
>
> *Vehicular collisions are a potentially important cause of mortality for lynx in portions of the southern Rockies. Thirteen of 102 mortalities documented for lynx translocated into Colorado were from vehicle collisions (Devineau et al. 2010). Brocke et al. (1990) suggested that translocated animals might be more vulnerable to highway mortality than resident lynx and this could have been a factor in Colorado at the time of listing. Currently, the majority of lynx mortalities caused by vehicle collision (13 of 16) occurred during the reintroduction period (1999-2006). Since early 2007, one year after the final reintroductions occurred, only 3 hit by vehicle mortalities have been reported, and only two of those occurred in Colorado (Broderdorp unpublished data 2016). A number of highways with high speed and high traffic volume pass through lynx habitat, such as I-70, I-80, US 50, US 550 and US 160. These highways are not a barrier to lynx movement, as repeated successful crossings by radio-telemetered lynx have been*

documented on I-70 and Highways 9, 40, 50, 91, and 114 (Ivan 2011b, c, 2012; J. Squires, personal communication 2012). At this time, it appears that hit by vehicle mortality may be a less significant mortality factor for lynx in Colorado.

As compared with other portions of the range of lynx, in Colorado more winter recreation and associated development overlaps with lynx habitat. Preliminary information from a study in Colorado indicates that some winter recreation uses may be compatible, but lynx may avoid some developed ski areas (J. Squires, personal communication 2012). It is possible that ski areas and 4-season resorts may reduce the amount and availability of lynx habitat within localized areas, in part by influencing the distribution or abundance of prey resources within the developed area. However, there is also considerable anecdotal evidence of lynx using ski areas.

Leg-hold trapping is currently prohibited under the state constitution of Colorado as a means of predator control or for commercial and recreational trapping. If a landowner can prove that all other non-lethal methods have been ineffective, a 30-day exemption may be granted for depredation cases. Incidental trapping mortality of lynx may be a minor risk during trapping seasons in southern Wyoming and surrounding states.

Predator control activities on federal lands, including coyote shooting or trapping, are common throughout most of this geographic area, mostly related to the grazing of domestic sheep. The majority of sheep grazing occurs on arid rangelands, but some grazing does occur during summer at the higher elevations, especially in south-central Colorado. Incidental capture of lynx is possible, but unlikely.

In summary, there are currently many more resident lynx in this unit than likely occurred historically, and many more than were known or suspected at the time the DPS was listed. There were even fewer verified records in this unit during the last century than in the GYA, and no reliable evidence of a resident breeding population. However, from 1999-2006, 218 Canadian and Alaskan lynx were released into the San Juan Mountains of southwestern Colorado. As a result of the subsequent reproduction of some of the released lynx and some of their offspring over several generations, resident lynx currently occupy this unit. When the DPS was listed in 2000, 27 of 41 radio-marked lynx released in 1999 were still alive. The State of Colorado has concluded that its efforts have established a viable lynx population, and the State's lynx experts suggest this unit may currently support 100-250 resident lynx (Ivan *in* Lynx SSA Team 2016a, p. 47). Recent (2010-2016) snow-tracking and camera surveys in the San Juan Mountains in the southern part of the unit documented evidence of continued lynx residency and reproduction.

Chapter 5: Future Conditions

In this chapter, we present our assessment of the future condition of the lynx DPS in terms of redundancy, representation, and resiliency. Given the uncertainty about the historical distribution of resident lynx in the contiguous United States and the current lack of reliable

estimates of the sizes, trends, and many demographic parameters for most DPS populations, it is difficult to confidently predict the future condition of the DPS or the likelihood that any given geographic unit will support resident lynx in the future. We lack data to build rigorous empirical population models for lynx across the DPS range, and uncertainty regarding the timing and magnitude of potential impacts to lynx from continued climate warming also limits our ability to predict the future condition of the DPS. Therefore, our assessment of the future condition of the DPS is based on our evaluation of the available scientific information regarding the factors identified by the ILBT as the most likely to have population-level impact to lynx in the DPS (ILBT 2013, pp. 68-78) and on the best professional judgments and opinions of lynx experts.

We provide brief summaries of the possible future conditions in each geographic unit, followed by a more detailed evaluation of the factors likely to influence lynx populations and habitats in each unit. We present and summarize the professional judgments and opinions of a panel of 10 lynx experts regarding the factors likely to influence the persistence of resident lynx populations in each of the 6 geographic units. We also present and summarize the experts' projections, based on consideration of those influencing factors, of the probability that each of the geographic units will continue to support resident breeding populations of lynx into the future (at years 2025, 2050, and 2100), and the sources of uncertainty that influenced their confidence in their predictions. Although we did not ask experts to evaluate different specific scenarios (e.g., climate models using different greenhouse gas emissions scenarios), we did ask them to provide the highest and lowest probabilities that each unit would continue to support resident lynx populations in the future, in addition to what they considered the "most likely" probability (see figs. 9-15, below).

Formal elicitation of expert opinion where empirical information is unavailable or inadequate is an appropriate and scientifically supported approach (Morgan 2014, entire). However, we remind readers that the output remains the experts' best professional judgment, which is subjective and, therefore, inherently different than experimentally collected data subjected to rigorous statistical analyses. For purposes of useful and meaningful presentation and comparison among geographic units, it was necessary to combine, quantify, graph, and summarize the qualitative information provided by experts. However, we caution that the results we present below and describe more fully in this chapter should not be interpreted as precise, statistically robust estimates of the probability that resident lynx will persist in the DPS or in any individual geographic unit in the future. Readers should consider the inherent limitations and substantial uncertainties in expert responses, particularly over longer time periods.

After summarizing experts' inputs, we then present our evaluation of the scientific literature regarding how certain anthropogenic factors may influence future conditions for resident lynx in each geographic unit. The factors we consider for each geographic unit include regulatory mechanisms (the factor for which the DPS was originally listed under the ESA) and the anthropogenic influences identified by the Interagency Lynx Biology Team (ILBT) as having the potential for population-level impacts to lynx in the DPS (climate change, vegetation management, wildland fire management, and habitat loss/fragmentation; ILBT 2013, pp. 68-78; see also chapter 3, above). Other factors were also evaluated for some geographic units if the

Core Team member most familiar with that unit felt those factors could pose meaningful, even if less likely, risks to the unit's continued ability to support resident lynx. After considering all of the above, we present our conclusions regarding the future conditions for resident lynx populations in each geographic unit and we discuss the extent to which our conclusions agree with or differ from the projections provided by the lynx expert panel we consulted and, if they differ, why.

Implicit in our evaluation of the future for lynx in the contiguous United States is our recognition and consideration of a possible future in which the DPS is not listed under the ESA. However, given (1) the history of lynx management, research, monitoring, and habitat conservation efforts by State wildlife and natural resource agencies in most states throughout the DPS range; (2) similar efforts by Federal land managers and related formal amendments or revisions to their land management plans to address the threat for which the DPS was listed (the inadequacy of previous regulatory mechanisms); (3) Tribal wildlife conservation efforts and philosophies; and (4) the DPS's listing and consultation history, we do not evaluate the unlikely hypothetical future in which all protections and conservation efforts would disappear if the DPS was not listed. Rather, although some protections could be relaxed (e.g., less stringent analyses of project-related impacts, potential for some states to reinstitute limited trapping harvest), we assume that Federal, State, and Tribal agencies and some private landowners would continue to manage for the conservation of resident lynx populations in those places that can support them in the DPS range. Our evaluation, therefore, considers the possibility of future relaxing of some lynx conservation measures and efforts, but not the complete absence of all protections for lynx. Some of the experts we consulted indicated that their projections assumed the status quo (i.e., continued protections under the ESA and current Federal and State land management policies). Others indicated their projections were not influenced by regulatory considerations but that doing so would not have altered their estimates; they felt that factors influencing lynx persistence on the landscape are independent of ESA listing status (Lynx SSA Team 2016a, p. 52).

As mentioned above, we do not define and evaluate specific and explicit climate change or greenhouse gas emissions scenarios or attempt to quantify differences in DPS viability or the persistence of resident lynx populations in individual geographic units based on differences in the rate and extent of potential impacts associated with projected continued climate warming. This is because of the limited resolution and inherent uncertainty of available climate models and the inadequacy of existing demographic data for projecting lynx population sizes and trends in the DPS over time, including their potential responses to a range of climate-mediated potential future habitat conditions. Therefore, this SSA does not constitute or include a formal climate change vulnerability assessment (Glick *et al*., editors, 2011, entire) for the lynx DPS. Instead, underlying our evaluation in this SSA is the recognition that the lynx, as a broadly-distributed boreal forest-and snow-associated predator that relies heavily on a single, similarly-specialized prey species, and whose habitats are naturally influenced by climate-mediated disturbance factors (e.g., wildfire, forest insects, wind/ice storms, etc.), is likely highly sensitive and broadly exposed to the impacts of climate change and has limited adaptive capacity to respond to it. Therefore, we (along with the experts we consulted and the ILBT) consider lynx populations in the DPS vulnerable to the projected impacts of continued climate warming. While

we recognize that the pace and extent of impacts would be expected to differ under specific emissions or modeling scenarios, the limitations described above preclude us from quantifying those differences and their potential influence on the likelihood that resident lynx will persist in the DPS or in individual geographic units.

5.1 Summary of Future Conditions DPS-wide

Overall, our evaluation of the scientific literature and expert input suggests that resident lynx populations are likely to persist in each of the geographic units where they currently occur in the near-term (though year 2025), and in all or most of those units at mid-century (year 2050; see table 1, above, and figs. 9-15, below). Over the longer-term (out to year 2100 and beyond), populations in each of the geographic units and, therefore, in the DPS as a whole, are likely to be smaller and their distributions reduced. These anticipated declines are likely to be most influenced by projected loss and increasing fragmentation and isolation of boreal forests and favorable snow conditions resulting from continued climate warming and related impacts (e.g., increased wildfire and forest insect activity, diminished hare populations; Lynx SSA Team 2016a, p. 58). This outcome seems likely regardless of which climate emissions scenario is used to model future conditions, although the timing, extent, and magnitude of impacts is uncertain and would likely vary by scenario.

In addition to climate change, forest management also has the potential to influence (negatively or positively) hare and lynx habitats in the DPS range. Forest management on private lands that lack lynx conservation commitments may contribute to future declines in the amount and quality of lynx habitats, particularly in Maine and perhaps also in Minnesota (private lands contribute minimally to lynx habitats in the other geographic units – see table 2 in chapter 1). Uncertain future forest ownership and markets for forest products, shifts in silvicultural practices, and development pressures on private lands all may affect the resiliency of future lynx populations in these 2 units. Increased frequency, size, and intensity of wildfires and forest insect outbreaks, both driven by climate warming, are of concern for western geographic units.

Although all 5 geographic units that currently support resident populations (all units except the GYA) are, individually, expected by lynx experts (based on the median of experts' "most likely" persistence probabilities) to continue to do so at 2025 and through 2050, only 1 unit (Northwestern Montana/Northeastern Idaho; Unit 3) had an expert-estimated probability of persistence greater than 50 percent (i.e., persistence more likely than not) by the end of the century (see fig. 12, below). Expert input suggests that all other geographic units individually have a 50 percent or greater probability of functional extirpation (i.e., no longer capable of supporting resident lynx populations) by the end of the century, although all experts expressed substantial uncertainty regarding projections that far into the future (figs. 10, 11, and 13-15, below; also see Lynx SSA Team 2016a, pp. 36-49).

Cumulatively, expert responses suggest a high (about 80 percent) "most-likely" probability that resident lynx populations will persist in all 5 units that currently support them (all units except the GYA) in the near term (year 2025; see fig. 9, column 2; row 2, below). Expert responses

similarly suggest a high (80 percent) likelihood that at least 4 of the 5 units will continue to support resident lynx at mid-century, and a cumulative probability just under 50 percent that all 5 will do so (see fig. 9, column 2; row 3, below). Over the longer term, expert responses cumulatively suggest a high (about 85 percent) likelihood that at least 2 of the 5 units will support resident populations at the end of the century; a more than 50 percent likelihood that 3 units will do so; but also a high (> 75 percent) likelihood that resident lynx populations will be functionally extirpated from 2 of the 5 units that currently support them by the end of the century (see fig. 9, column 2, row 4, below; see Cummings, 2016, pp. 6-20 for details on the data and software used to generate figs. 9-15, below). The experts we consulted expect the likelihood that lynx populations will persist to decline in each geographic unit in the future, although uncertainty increases with time from the present, and increases greatly for end-of-century projections (Lynx SSA Team 2016a, pp. 36-49; also see 5.2).

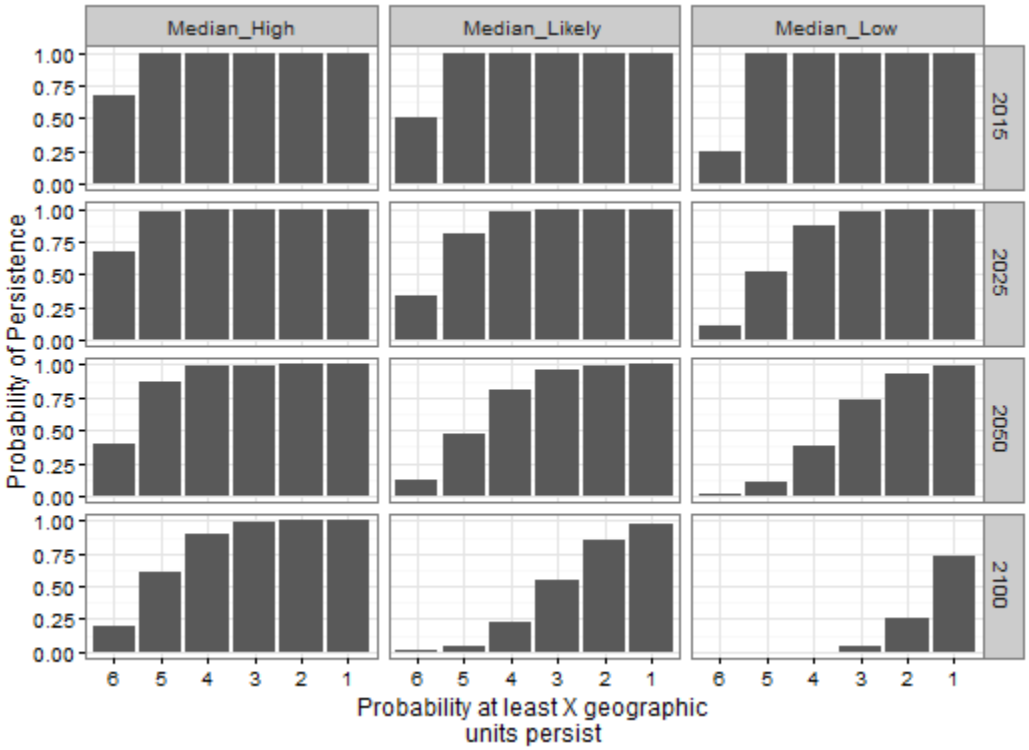

Figure 9. Summary of lynx experts' predictions regarding the probability of persistence of at least a given number of geographic units given the probability of persistence for each individual geographic unit. The y axis of each grid in figure 9 is the probability that at least the number of geographic units indicated by the x axis of the grid persist. The probability in a bar reaches 1 when there is no probability of fewer geographic units persisting. Moving from top to bottom, the grids show the probabilities by time period (2015 [current at time of expert elicitation], 2025, 2050, and 2100). Moving from left to right the grids show the range of expert responses by summary selection type and probability response. Therefore, looking down a column of grids provides a view of the trend in persistence through time and looking across a row of grids provides a view of the range of uncertainty in expert projections of persistence for a given time period.

Our evaluation generally concurs with the expert input we received. We believe that lynx populations and habitats in the DPS will decline over time largely as a result of continued climate warming and associated impacts, which are likely to exacerbate the potential adverse effects of other factors (e.g., forest management, potential increased competition from other hare predators). We acknowledge that under a "worse case" climate modeling scenario the boreal and subalpine forests and snow conditions associated with lynx occupancy could completely or largely disappear from some units (e.g., Minnesota; Galatowitsch *et al*. 2009, pp. 2015-2016) and be substantially reduced in the remainder before the end of the century. However, we are aware of no climate modeling that suggests the complete disappearance of potential lynx habitat from the entire contiguous United States by the end of the century. Complete loss of lynx habitat is perhaps more likely in the Northern Maine and Northeastern Minnesota units where there is little potential for elevational refugia compared to the more topographically diverse units (3 through 6) in the western United States. Under such a scenario, resident lynx would be unable to persist in some units and would be severely restricted in number and distribution in others, with any remaining resident populations more vulnerable to demographic and environmental stochasticity, genetic drift, and catastrophic events than they are currently.

Conversely, under a "better case" climate scenario (perhaps combined with a "better case" future forest management scenario), it is possible that resident lynx could continue to persist through the end of the century in all 5 geographic units that currently support them. Even under this scenario, however, we would expect smaller population sizes and reduced distributions in each unit resulting from the impacts of even moderate continued climate warming. We are aware of no models that predict climate cooling or climate-mediated improvement in lynx habitat conditions in the contiguous United States over the next century. We cannot quantify the likelihood of either of these extreme scenarios nor improve the accuracy or precision of, or our confidence in, the experts' predictions regarding persistence.

Considering this range of potential future climate conditions, associated uncertainties, and expert input, we conclude that over the short-term (through year 2025), resident lynx populations are very likely to persist in all 5 geographic units that currently support them. We likewise conclude they are likely to persist in the mid-term (through 2050) in all or most geographic units that currently support them, with corresponding maintenance of redundancy and representation, despite reduced lynx numbers and distribution and, therefore, reduced resiliency among all or most populations. Recognizing the high level of uncertainty associated with predications beyond mid-century, we nonetheless conclude it is very unlikely that resident lynx populations will persist through 2100 in all 5 of the geographic units that currently support them. That is, we believe that resident populations will likely persist at the end of the century in 2 or 3 of the 5 units that currently support them, but that resident populations may be functially extirpated from 2 to 3 of the units by then. Even where populations persist, they will be reduced in number and distribution and, therefore, resiliency.

The loss of viable resident lynx populations from 1 or more geographic units would represent reduced future redundancy, representation, and resiliency within the lynx DPS. With regard to

redundancy, however, our evaluation of the scientific literature and expert input indicates that no individual geographic unit that currently supports resident lynx is vulnerable to extirpation from a single catastrophic event. Given that, we conclude that the DPS as a whole is not vulnerable to extirpation from a catastrophic event (i.e., we find that there is a zero probability that a single catastrophic event could result in extirpation of resident lynx from any of the 5 geographic units that currently support them and, therefore, a zero probability of catastrophic extirpation of the entire DPS). As described above (section 1.3), we do not consider continued anthropogenic climate warming a catastrophic event; rather, we consider it a systemic, ongoing, and pervasive stressor, not a single temporally- and spatially-discrete event. We recognize that a sequence of discrete but spatially-clustered catastrophic events in lynx habitats over a short time could increase the potential for functional extirpation in 1 or more of the individual geographic units (especially the possibility of additional large wildfires in north-central Washington), thereby reducing redundancy within the DPS. However, as long as resident lynx remain geographically well-distributed in 1 or more units within the DPS, extirpation of the DPS from a single catastrophic event is very unlikely.

With regard to representation, although some lynx populations in the DPS units are demographically isolated from each other and the level of interaction between others is uncertain, there seems to be little risk of significant genetic drift. This is because of the currently observed and likely future high level of gene flow across most of the lynx's continental range, the species' well-documented dispersal capability, and the current and likely future connectivity and absence of significant barriers to dispersal between Canada and most DPS geographic units. Based on these factors and expert input, we find that there is no indication that the relatively low level of genetic diversity currently observed among lynx populations is likely to reduce DPS viability in the future (Lynx SSA Team 2016a, p. 51) and no indication that future gene flow is likely to be substantially reduced (79 FR 54793). This information suggests the current and likely future relative genetic health of the DPS. However, as noted in section 2.2, the potential for genetic drift among DPS populations would be expected to increase at some point in the future if lynx and hare habitats shift northward and upslope, as projected with continued climate warming, resulting in reduced connectivity and gene flow among smaller and more isolated lynx populations at the periphery of the range. This would result in (1) smaller and more distant potential source populations, reducing the likelihood and number of immigrant lynx reaching DPS populations, and (2) smaller effective population sizes among DPS populations, making them more vulnerable to drift, the consequences of which could include lower survival and reproduction rates and loss of adaptive potential.

How the potential loss of resident lynx from 1 or more geographic units may affect representation within the DPS in terms of ecological diversity is uncertain. Despite similarities in the fundamental components (vegetation, snow conditions, and hares) that define the ecological niche of lynx DPS-wide, differences in habitats and how lynx use them are apparent. For example, the amount of snow that seems to demarcate a boundary between lynx and bobcat occupancy in Maine (270 cm/yr [106 in/yr]) is almost twice that observed in Minnesota (140 cm/yr [55 in/yr]), and lynx in some parts of the West select mature forest stands, particularly in winter, while in other parts of the DPS, younger regenerating stands are most important. The

loss of resident lynx from any of the geographic units could result in the loss of behavioral and potential future genetic adaptations to the climate-mediated changes now occurring and likely to continue into the future at the southern edge of the lynx range. Such potential adaptability to diminished snow conditions, increasingly patchy and isolated boreal forests, and reduced hare abundance may be important to the taxon as a whole faced with a rapidly changing climate.

Because resident lynx populations in all geographic units that currently support them are expected to become smaller and more fragmented and isolated, each geographic unit and the DPS as a whole will be less resilient in the future. Our analyses and expert input suggest that resiliency will likely be sufficient to foster persistence of resident lynx in most units through mid-century but that its declining trajectory over time could result in extirpation of resident populations from 2 to 3 (of 5) units by the end of the century. Projected continued climate warming is expected to exert the greatest influence on the resiliency of individual populations, and thus continued presence of resident lynx in each geographic unit. Climate models project that boreal forests and snow conditions favorable for lynx at the southern periphery of the range will retreat northward and upslope with continued warming, further fragmenting and diminishing the quality of lynx and hare habitat within the DPS. Although uncertainty remains regarding the timing, extent, and biological consequences of such impacts, as habitat conditions decline, hare and lynx reproductive and survival rates are likely to decrease, resulting in population declines in both species. As snow conditions become less favorable, competitors (e.g., coyotes and bobcats) may outcompete and displace lynx. This in turn would reduce lynx abundance and density within populations, making populations more susceptible (i.e., less resilient) to stochastic events.

5.1.1 Summaries of Future Conditions in Each Geographic Unit

Unit 1 – Northern Maine: Although the Northern Maine geographic unit currently has extensive lynx habitat, the amount and distribution of high-quality habitat is projected to decline over the next 2 to 3 decades. Forestry practices, climate change, habitat loss and fragmentation, spruce budworm outbreaks, and development are most likely to drive future hare and lynx habitat in this unit. Lynx habitat and lynx densities are expected to decline by 50 to 60 percent by 2032 in response to aging of the budworm-era clearcuts and the effects of extensive partial harvesting since the 1989 passage of the Maine Forest Practices Act (Simons 2009, pp. 209, 217). In the next few decades, high-quality hare habitat is projected to decline from about 10 percent to 5 percent of the landscape (Simons-Legaard 2016, fig. 8, p. 10), perhaps more in line with likely historical conditions. High-quality habitat patches will likely become more fragmented, smaller, and more isolated, thus making the landscape less suitable for lynx than it currently is. For the next few decades the best habitat (young regenerating stands) will occur in the southern portion of current lynx distribution, where effects of climate change and potential competition with bobcats are likely to be greatest (Simons-Legaard *et al*. 2016, p. 1267). Absent long-term lynx management agreements, the future of lynx habitat in this unit is uncertain. Wood products markets will likely continue to change and could be affected by interest in carbon sequestration in response to climate change, with potential consequences for forest management in this unit. Recent rapid changes in private forest land ownership are likely to continue and could result in

subdivision of large ownerships. Non-forestry land uses (wind energy development, transmission line corridors, residential and resort development, and unmanaged conservation lands) may compete with forest management as the primary future land use. Conservation easements will limit development pressures in some areas and keep some lands as working forest, but forest practices (e.g., partial harvesting, northern hardwood management) may not create new lynx habitat or maintain the current historically high amount of high-quality habitat. Climate change is expected to affect this unit more than some others in the DPS because snow amount and duration already seem to be at thresholds for lynx and there are few potential elevational refugia. In the near term and beyond, snow quantity and quality will likely continue to deteriorate, which could cause lynx range to contract northward.

Our review of the published literature and input from lynx experts lead some members of the SSA Core Team to conclude that lynx could become extirpated from this unit before the end of the century. Climate change, increasing demand for hardwood forest products, a pending spruce budworm outbreak, and frequent forest disturbance all will likely contribute to the trend in the loss of spruce-fir forest and expansion of northern hardwoods, although the timeframe for conversion is uncertain. The lynx experts we consulted indicate the likelihood that resident lynx will persist in this unit will decline to about 50 percent by the end of the century, although there was wide variation and much uncertainty in opinions. After reviewing the scientific literature concerning climate change projections (diminishing snow conditions, lack of elevational refugia), some members of the Core Team were more pessimistic about the future of lynx in Maine than the lynx expert panel. In particular, we observed that there is great uncertainty about the future of forest management and future development on private forest lands. The lack of forest planning for lynx was not perceived or defined as a threat for this area when the DPS was listed. Nonetheless, forest management practices clearly have influenced that amount of high-quality lynx habitat and thus lynx numbers in this unit, and they are likely to continue to influence its population in the future. Currently, there are no long-term management plans in place on most privately-owned forest lands in this unit; State forest regulations have greatly influenced harvesting practices that have reduced landscape hare densities and will likely continue to do so; markets for forest products are depressed; and forest modeling projections (under current harvest scenarios) suggest that habitat will diminish and shift southward in the near term because of post-harvest succession and recede northward over the longer-term because of continued climate warming.

Unit 2 - Northeastern Minnesota: The direct and indirect effects of climate change are expected to affect lynx into the future in Minnesota. Specifically, boreal conifer forest is projected to contract northward, resulting in increased habitat loss and fragmentation and increased isolation of Minnesota lynx with diminishing forest conditions in southern Ontario. Additionally, the quantity, quality, and duration of snow are projected to decline; potentially resulting in increased competition and hybridization with bobcats as snow conditions favorable to lynx are diminished. The likelihood that resident lynx will persist in this unit is projected to decrease over time with increasing uncertainty through the end of the century, driven in the near term by decreaseing quality, quantity and persistence of snow and over the long term from loss of spruce-fir forests. We expect the SNF will continue to implement lynx conservation measures in accordance with

its Forest Plan, thus continuing to minimize several risk factors and promote the conservation of lynx into the future. If the DPS is de-listed, the species would be placed on the Forest's Regional Forester Sensitive Species list for at least 5 years, which would give it a higher priority than other species for monitoring and management during that time. We also expect that MNFRC guidelines will remain in place into the future and that voluntary actions will continue on State and private lands. However, it is unclear on what proportion of State and private lands these voluntary actions will be implemented into the future. Further, these guidelines are generalized for listed species and give no specific direction for lynx. Taking these factors into consideration, median "most likely" probabilities of persistence generated by lynx experts were high for the near- and mid-term (> 95 percent at year 2025; 80 percent at year 2050), but declined to 35 percent (with great uncertainty) by 2100. We concur with the expert panel that resident lynx are likely to persist in this unit at 2025 and 2050. However, after reviewing the scientific literature concerning climate change projections (diminishing snow conditions, loss of boreal forest, lack of elevational refugia, and the potential for increased competition, disease, and insect outbreaks), some members of the SSA Core Team were slightly less optimistic about the long-term future of lynx in Minnesota than the lynx expert panel. The Core Team concluded that the climate-mediated conversion of boreal forest to temperate forest and the loss of favorable snow conditions could occur at a rate and extent that would result in a lower likelihood of persistence than projected by experts, including the possibility that resident lynx could be extirpated from this unit by the end of the century.

Unit 3 - Northwestern Montana/Northeastern Idaho: As in other units, climate change is projected to reduce the future amount, distribution, and quality of lynx habitat in this unit via northward and upslope contractions of favorable snow and forest vegetation conditions. This would result in increased fragmentation and isolation of habitats and smaller and more isolated lynx populations. Increased wildfire frequency and extent and perhaps other climate-mediated factors (forest insect outbreaks, changes in northern hare/lynx cycles that may influence immigration into this unit) could also reduce future lynx habitats and populations in this unit. Fire- and insect-related habitat losses would likely be temporary, resulting subsequently in improved habitat conditions when impacted areas regenerate the dense vegetative structure conducive to hare abundance. Continued forest management to conserve and maintain the vast majority of lynx habitats in this unit would benefit resident lynx in the future, though it is unlikely to offset the projected adverse consequences of continued climate warming. Lynx experts felt that future extirpation of lynx from this unit from reduced genetic health or a catastrophic event is unlikely. However, the extent to which the future demographic and genetic health of lynx populations in this unit may be influenced by immigration is unknown. Considering the factors above, lynx experts felt this geographic unit has the highest likelihood of continuing to support resident lynx into the future in the near term (year 2025; median probability of persistence > 0.95), at mid-century (median = 0.90), and end-of-century (median = 0.78), despite a declining probability of persistence and greater uncertainty with increasing time from present, as in all units. After reviewing the scientific literature and evaluating the factors that may influence lynx persistence in this unit, we concur with the experts' conclusion that this geographic unit is likely the most secure in the DPS. We conclude that it is very likely to continue to support resident lynx in the short term (through 2025) and through mid-century, although the number of lynx, the

amount and distribution of high-quality habitat, and landscape-level hare densities are all likely to decline by mid-century as a result of continued climate warming and associated impacts. We also agree that this unit is more likely than not to support some resident lynx at the end of this century, although at that time we expect lynx numbers and distribution would be substantially reduced from the current condition and would, therefore, be more vulnerable to demographic, environmental, and genetic stochasticity and to catastrophic events, resulting in reduced resiliency.

Unit 4 - North-central Washington: Over the past 25 years, wildfires have (perhaps temporarily) eliminated or reduced the quality of about a third of lynx habitat within the North Cascades, which has significantly affected the status of and current viability of the lynx population in this geographic unit. As elsewhere, continued climate warming is anticipated to reduce the future quality and distribution of lynx habitat in Washington, potentially further exacerbating the recent losses of lynx habitat from wildfires. Projected warming may increase wildfire frequency and severity, which may result in further losses of lynx habitat. Climate change is also expected to reduce the quantity and quality of snow, potentially resulting in permanent reductions in the quantity and distribution of lynx habitat in this unit. These potential climate-driven reductions of lynx habitat could isolate resident lynx within this unit and reduce connectivity with neighboring lynx populations in the other geographic units and Canada. Continued forest management on both Federal and State lands would benefit lynx populations in Washington but is unlikely to ameliorate the potential negative effects related to climate change. Considering the recent reduction in lynx habitat and the projected impacts of climate change, experts indicated persistence probabilities of 60 to 90 percent (median = 80 percent) over the near-term (year 2025), 30 to 80 percent (median = 70 percent) at mid-century, and less than 50 percent (median = 38 percent) by the end of the century for resident lynx in this geographic unit. After considering the best available scientific information and input from lynx experts, the Core Team is generally in agreement with experts regarding the likelihood of long-term persistence of Canada lynx in this geographic unit. We expect this unit will continue to support a small resident lynx population through mid-century but that its ability to do so beyond then is questionable, and that functional extirpation of lynx from this unit by the end of the century is more likely than not.

Unit 5 - Greater Yellowstone Area (GYA): As elsewhere, climate change is projected to reduce the future amount, distribution, and quality of lynx habitats in this unit via northward and upslope contractions of favorable snow and forest vegetation conditions. This would result in increased fragmentation and isolation of habitats and smaller and more isolated lynx populations. Because potential habitats in much of this unit already are naturally highly fragmented and perhaps only marginally capable of supporting resident lynx, and because it appears to have never supported more than a small number of residents, its ability to do so in the future is tenuous. Lynx experts felt that the small number of lynx this unit appears capable of supporting and its relative isolation from other lynx populations make it more vulnerable to genetic drift and extirpation from catastrophic events or demographic or environmental stochasticity. However, the extent to which the future demographic and genetic health of lynx populations in this unit may be influenced by immigration is unknown. Increased wildfire frequency and extent and perhaps other climate-mediated factors (forest insect outbreaks, changes in northern hare/lynx cycles

that may influence immigration into this unit) could also reduce future lynx habitat in this unit. Continued forest management to conserve and maintain the vast majority of lynx habitats in this unit would benefit resident lynx in the future, though it is unlikely to offset the projected adverse consequences of continued climate warming. Considering the factors above, lynx experts felt this geographic unit has the lowest likelihood of supporting resident lynx into the future in the near term (year 2025; median probability of persistence = 0.52), at mid-century (median = 0.35), and end-of-century (median = 0.15), with a declining likelihood of persistence and greater uncertainty with increasing time from present, as in all units. After reviewing the scientific literature and evaluating the factors that may influence lynx persistence in this unit, we concur with the experts' conclusion that this geographic unit is the least secure in the DPS. We find that conditions for lynx in this unit are naturally marginal, both its historical and current ability to support a persistent resident lynx population are questionable, and that continued climate warming and associated impacts are likely to further diminish its already limited ability to support resident lynx. We conclude, based on the protected status (national park, designated wilderness, and non-developmental land use allocations) of vast areas and climate models that project some areas of adequate vegetation and snow conditions through the end of the century, that this unit may continue to occasionally or intermittently support a small number of resident lynx and some reproduction throughout the remainder of the century. However, we conclude that it is very unlikely to support a persistent resident population over the short-term (through 2025), even less likely that it will do so at mid-century, and it is highly improbable that this geographic unit will support resident lynx by the end-of-century.

Unit 6 - Western Colorado: Regulatory mechanisms that provide for the conservation of lynx in Colorado consist of State regulations prohibiting unauthorized take of lynx and amendments of USFS and BLM management plans, which limit vegetation management (among other things) covering approximately 85-90 percent of the lynx habitat within this geographic unit and provide guidance to limit habitat fragmentation. Climate change is expected to negatively affect vegetation and influence snow conditions in this unit. The elevation gradient in Colorado may provide refugia from deteriorating snow conditions in the future. Assuming that snow levels will increase in elevation, lynx habitat is likely to become more fragmented by areas that no longer retain appropriate snow conditions and vegetation. However, we anticipate large areas of snow persistence to remain through the end of the century. Wildland fire will likely result in temporarily reduced habitat quality to some extent; however, affected areas are likely to regenerate and provide excellent habitat conditions to support hares and lynx. Given projected climate warming, some areas that currently support snowshoe hare populations may experience vegetation type conversion that may not support snowshoe hares in the future. Considering the factors above, lynx experts felt this geographic unit has a high likelihood of continuing to support resident lynx into the future in the near term (year 2025; median probability of persistence = 0.90) and at mid-century (median = 0.80), and a reasonable likelihood of doing so at end-of-century (median = 0.50), despite a declining probability of persistence and greater uncertainty with increasing time from present, as in all units. This unit would be expected to continue to support resident lynx in the future if survival and reproductive rates similar to those estimated during intensive monitoring are maintained over the long-term. However, given the lack of evidence of historical occupancy by resident populations, the naturally limited and fragmented potential habitat,

generally low hare densities, low proportions of females that produce kittens, and low kitten survival rate, along with projected impacts of climate warming on all or most of these paramenters, we are less optimistic than the lynx expert panel regarding the likelihood that this unit will continue to support resident lynx over the long-term.

Table 5, below, summarizes expert predictions of future lynx persistence and Core Team summary of factors thought likely to influence the future resiliency of lynx populations in each geographic unit.

Table 5. Expert-predicted future (2025, 2050, and 2100) persistence[1] of resident lynx populations in individual geographic units of the Canada lynx DPS and supporting evidence and uncertainties.

Geographic Unit	Median lynx expert probability of persistence (%)[2] (range [%])[3] at years 2025, 2050, and 2100	Key evidence	Uncertainties
Unit 1	2025: 96 (80-100) 2050: 80 (65-95) 2100: 50 (40-80)	• 50% decline from current habitat projected by 2032; habitat shift to the south edge of current range • Slight recovery of habitat by end of century depending on forestry trends • Continued demographic and genetic connectivity to southern Quebec, New Brunswick populations • Climate models predict deteriorating snow quality, depth and duration; more severe than other units • Little potential elevation refugia	• Future forest management trends and habitat conditions on private forest lands in Maine and Canada • Future shifts in land ownership, forest products markets, and development • Extent and pace of deteriorating snow conditions • Response of hares (pelage mismatch), bobcat, and fisher to changing snow regime • Extent and pace of spruce-fir loss • Future hare population trends • Disease and parasites in lynx • Effects of lynx trapping in Quebec
Unit 2	2025: 96 (88-100) 2050: 80 (60-90) 2100: 35 (10-60)	• Smaller population could be susceptible to stochastic effects • Habitat conditions on SNF will remain stable or improve if managed for softwoods • Continued demographic and genetic connectivity to southern Ontario populations • Climate models predict deteriorating snow quality, depth and duration; loss of boreal forest • Little elevation gradient: lake-effect snow may retain refugia to 2050 but not 2100	• Future forest management trends and habitat conditions on private forest lands in Minnesota and Ontario • Extent and pace of deteriorating snow conditions • Adequacy of immigration from southwest Ontario • Response of bobcat and fisher to changing snow regime • Rate of spruce-fir decline • Future hare population trends • Disease and parasites in lynx • Effect of lynx-bobcat hybridization
Unit 3	2025: 98 (95-100) 2050: 90 (70-100) 2100: 78 (50-90)	• Some habitat loss from increased wildfire, otherwise habitat should remain stable with USFS/BLM management • Continued demographic and genetic connectivity to southern Alberta and BC populations • Potential elevational refugia • Recent loss of small sub-population in	• Extent and frequency of fire in hare-lynx habitat • Extent and frequency of insect outbreaks • Extent and pace of deteriorating snow conditions • Adequacy of immigration from southern Alberta and BC

		Garnet Range ● Increasing fire frequency	● Response of bobcat, cougar, coyote to changing snow regime ● Extent and pace of elevational migration of spruce-fir ● Mismatch in elevation between appropriate snow regime for lynx and spruce-fir ● Future hare population trends
Unit 4	2025: 80 (60-95) 2050: 70 (30-80) 2100: 38 (5-50)	● Habitat and population low because of recent fires; could be suscept ble to stochastic effects ● Continued demographic and genetic connectivity to southern British Columbia populations ● Elevation is not sufficient to provide long-term refugia from deteriorating snow quality, depth, and duration ● State uplisted from T to E (2016)	● Extent and frequency of fire in hare-lynx habitat ● Extent and frequency of insect outbreaks ● Extent and pace of deteriorating snow conditions ● Adequacy of immigration from southern BC ● Response of bobcat, cougar, coyote to changing snow regime ● Extent and pace of elevational migration of spruce-fir ● Future hare population trends
Unit 5	2025: 52 (10-70) 2050: 35 (15-60) 2100: 15 (5-50)	● Very low hare densities in much of unit ● Habitat should remain stable with USFS, BLM, and NPS management ● No direct connectivity with Canada populations; little immigration from DPS populations ● Potential elevational refugia ● Smaller population could be susceptible to stochastic effects	● Persistent vs. ephemeral historical presence ● Adequacy of immigration ● Extent and frequency of fire and insect outbreaks ● Extent and pace of deteriorating snow conditions ● Response of bobcat, cougar, coyote to changing snow regime ● Extent and pace of elevational migration of spruce-fir ● Future hare population trends ● Extent to which high elevation may provide climate and snow refugia
Unit 6	2025: 90 (60-100) 2050: 80 (50-85) 2100: 50 (20-70)	● Habitat loss from increased wildfire and insect outbreaks, otherwise habitat will remain stable with USFS management ● Isolation from other lynx populations ● Elevation may provide refugia from deteriorating snow quality, depth and duration ● Uncertainty about stability of recently-introduced lynx population	● Persistent vs. ephemeral historical presence ● Demographic and genetic effects of isolated population ● Extent and frequency of fire and insect outbreaks ● Extent and pace of deteriorating snow conditions ● Response of bobcat, cougar, coyote to changing snow regime ● Extent and pace of elevational migration of spruce-fir ● Mismatch in elevation between appropriate snow regime for lynx and spruce-fir ● Future hare population trends

[1]We asked 10 recognized lynx experts to provide their estimates of the probability that resident lynx populations or subpopulations would persist in each geographic unit, even if reductions in lynx numbers and distributions were anticipated (i.e., the probability that resident lynx would *not* be functionally extirpated from the unit).

[2]Median “most likely” probabilities of persistence provided by 10 lynx experts for each geographic unit considering the current status of lynx populations and current and likely future stressors to those populations.
[3]The full range of “most likely” probabilities of persistence provided by the 10 lynx experts.

5.2 Future Conditions - Detailed Descriptions by Geographic Unit

In this section, we present and summarize the formally-elicited opinions of a panel of 10 lynx experts regarding the likelihood that each geographic unit will continue to support resident breeding lynx populations into the future (at years 2025, 2050, and 2100), the factors they think will influence lynx persistence, and the sources of uncertainty that influenced their confidence in their predictions. We then present our evaluation of factors that may influence future conditions for resident lynx in each geographic unit, our conclusions regarding future conditions in each geographic unit, and whether our conclusions concur with or differ from projections provided by the lynx expert panel we consulted.

As mentioned above, we remind readers that the text and figures presented here are intended to convey and summarize expert opinions, which are subjective. The graphs we provide are intended to illustrate individual and cumulative expert opinion and uncertainty, and to allow comparsions of projections of possible future lynx persistence among all geographic units. We do not imply, and readers should not infer, that these depictions represent statistically robust, accurate, or precise estimates of the actual likelihood that resident lynx will persist in the DPS or in any individual geographic unit in the future, and readers should consider the inherent limitations and substantial uncertainties in expert responses, particularly over longer time periods. In figures 10-15 below, responses for each lynx expert for each of the 3 probability-of-persistence levels, (i.e., highest, most likely, and lowest probabilities) are represented by the hollow red, filled green, and hollow blue points, respectively. The black X mark is the median of the most likely responses across the experts in each response year. The red, green, and blue dashed lines connect the median of the highest, most likely, and lowest probability-of-persistence responses across the experts in each response year. The edges of the gray areas were defined by the entire range of expert responses, from the largest of the highest-probability responses to the smallest of the lowest-probability responses. The median lines and gray areas are provided as a summarizing visualization to aid comprehension of the experts’ responses and their range, and should not be viewed as a substitute for individual responses or presented outside the context of the accompanying discussion. The gray area between red and blue dashed lines can be viewed as the median uncertainty across all 10 experts.

5.2.1 Unit 1 - Northern Maine

<u>Expert Projections of Lynx Persistence</u>

All of the experts that we consulted indicated an initially high and subsequently declining likelihood that resident lynx will persist in Maine through the end of the century, with uncertainty (range between lowest and highest estimates) also increasing over time (Lynx SSA Team

2016a, pp. 33-36). Climate change was an overriding near- and long-term stressor for lynx expressed by lynx experts.

Increased winter precipitation in the form of rain, reduced snow depth, and reduced snow durations were discussed by the experts. Experts believed that the effects of climate change would continue to increase as a stressor that would reduce lynx populations by mid- to end-of-century. Snow conditions would continue to deteriorate, potentially resulting in increased competition with bobcats and increased predation by fisher. We heard varying prognoses from experts regarding the speed at which climate-induced loss of spruce-fir forest may occur. The scientific literature suggests that loss of spruce-fir could occur relatively quickly in the Northeast, and several experts noted that an increase in northern hardwood composition of the forest is already occurring. One expert provided information that suggests that balsam fir could actually increase in the short-term (over the next few decades), but that the long-term prognosis is not favorable for natural spruce-fir regeneration. Decline or loss of spruce-fir could be accelerated by forest disturbance (e.g., budworm outbreaks or forest management affecting large acreages of lynx habitat annually).

In addition to climate change, lynx experts expressed a number of near-term stressors related to forest management in northern Maine. Land management objectives were uncertain because of frequent changes in private forest land ownership. Experts acknowledged uncertainty concerning the severity of and response by new landowners to future spruce budworm outbreaks. Experts believed that investment landowners are unlikely to respond to future budworm outbreaks as they did in the 1970s-80s (extensive clearcuts, herbicide application). Experts also acknowledged concerns about the effects of the aging of past clearcuts beyond conditions that support high-quality hare and lynx habitat.

Although uncertainty increases with time from the present, experts generally agreed that climate-related loss of favorable snow conditions (amount, consistency, and duration), loss of spruce-fir forest, and potential competition from bobcats would be expected to reduce the likelihood that lynx will persist in this unit. Experts also were uncertain about whether hare numbers would rebound to past higher levels or remain at current lower levels.

Taking all of these factors into consideration, experts provided “most likely” persistence probabilities of 80 to 100 percent (median = 96 percent) in the near-term (year 2025), 65 to 95 percent (median = 80 percent) at mid-century, and 40 to 80 percent (median = 50 percent) at the end of the century (fig. 10). As they did for most other geographic units, all experts indicated an initially high and subsequently decreasing likelihood that resident lynx will persist in this unit, with uncertainty increasing substantially over time.

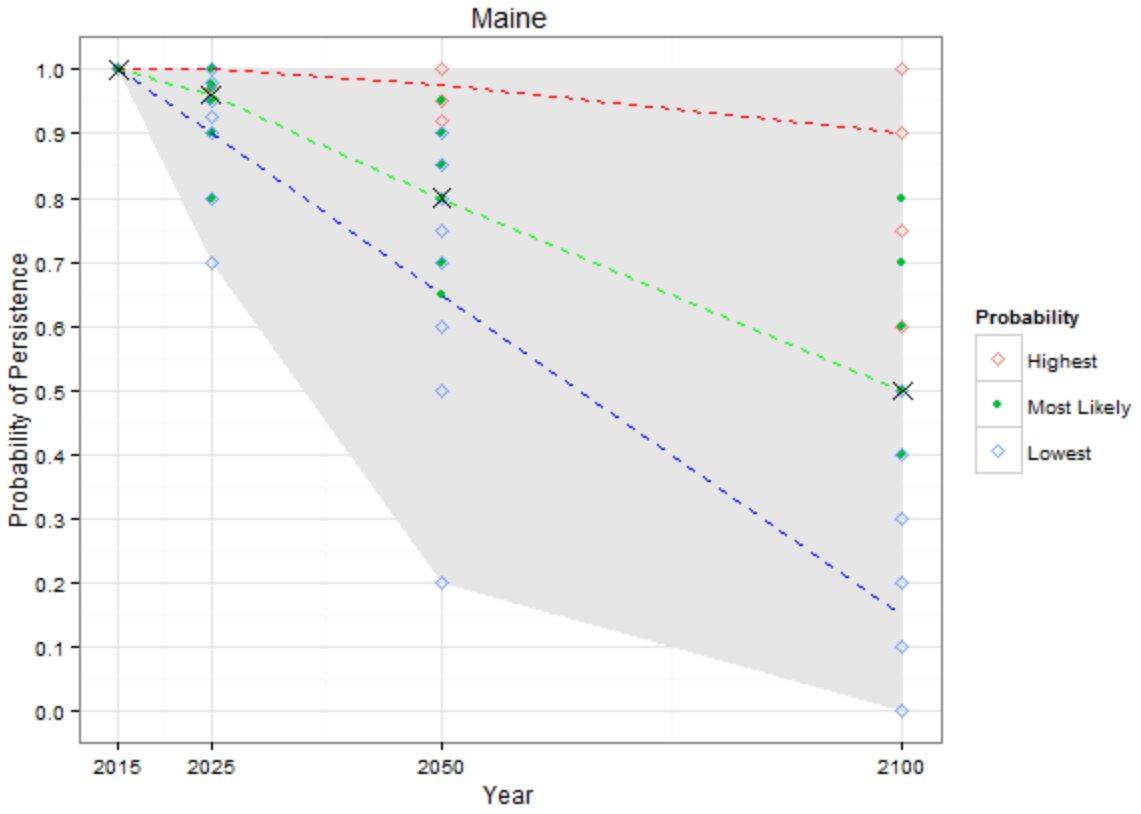

Figure 10. Lynx expert estimates of the probability that the Northern Maine Geographic Unit will continue to support resident lynx in the future (at years 2025, 2050, and 2100).

Service Evaluation of Factors Potentially Influencing Future Conditions

Regulatory Mechanisms - As described above (section 4.2.1), past forest management practices (large-scale clearcutting) have created an unnaturally high amount of high-quality hare habitat in this unit, resulting in a resident lynx population that is probably larger than typically occurred historically under natural conditions. Also as described above, a shift in forest management from clearcutting to various forms of partial harvesting that began in 1989 with passage of the Maine Forest Parctices Act (MFPA) is unlikely to maintain or recreate this extensive high-quality habitat. Therefore, we expect lynx habitat and numbers to decline in this unit over the next several decades, perhaps to levels more consistent with likely historical conditions.

If timber harvest continues using methods and at rates similar to those that have predominated since passage of the MFPA (see section 4.2.1), lynx habitat at year 2030 is modeled to decline by about 50 percent from current anthropogenically incluenced high levels (Simons-Legaard 2016, pp. 9-10). Habitat modeling indicates that the maturation of previously clearcut areas will result in a decline in high-quality hare habitat (i.e., lynx foraging habitat) in this unit from 7-12 percent of the landcape in 2010, to about 3-8 percent by year 2030, then increasing to 5-16

percent by 2060 (Simons-Legaard 2016, p. 10, fig. 8). After 2030, however, projected outcomes for lynx habitat become more uncertain and depend on assumptions about habitat definitions and harvest rates. Lynx in Maine selected for regenerating, conifer-dominated forest (> 75 percent conifer; Vashon *et al.* 2008b, pp. 1490, 1492-1494). If one defines high-qulaity lynx habitat as stands having greater than 75 percent spruce-fir, then such habitat will decline by about 50 percent by 2030 and then stabilize or increase slightly through 2060 (Simons-Legaard 2016, pp. 9,16; fig. 8).

The projections above do not consider a nearly 60 percent decline in snowshoe hare densities that has occurred in Maine from a period of high hare density in 2001-2006 (1.8 - 2.2 hares/ha [0.7 – 0.9 hares/ac] in regenerating conifer) to a period of lower hare density in 2008-2015 (0.8 – 1.0 hares/ha [0.3 – 0.4 hares/ac]; Harrison *et al*. 2016, entire). This decline occurred across all forest stand types and across a broad geographic area of Maine (Scott 2009, p. 36; Harrison *et al*. 2016, entire), and a decline in hare density also occurred in the adjacent Gaspe region of southern Quebec (Assells *et al.* 2007 *in* Scott 2009, p. 41-42). Hares remained at these lower densities through 2015 (Harrison *et al*. 2016, p. 55). If future hare populations remain low, then Maine habitats will likely have a lower capacity for supporting resident lynx. How current and likely future hare densities in this unit compare to densities under historical disturbance patterns is unknown.

The habitat projections above also do not consider the effects of future spruce budworm outbreaks. After low levels of infestation for the last 20 years, Maine appears poised for another spruce budworm outbreak. Budworm numbers are increasing toward epidemic levels in southern Quebec and northern New Brunswick.Significant defoliation could occur in Maine in the next few years, and the outbreak may last about a decade (Wagner *et al.* 2015; pp. 12-16). Although research has clearly demonstrated that landowner response to the last outbreak resulted in unintended benefits for lynx from 1 to 3 decades later, our ability to project what effects the next outbreak will have on lynx habitat is limited because land ownership has changed since the last outbreak. To reduce risk from spruce budworm, some financial investment owners may cut younger spruce-fir stands that still support elevated hare densities. Some may be less inclined to intensively manage for spruce-fir and may switch to an emphasis on northern hardwoods. It is unlikely that current landowners will broadly apply pesticides to control spruce budworm or herbicides to promote spruce-fir regeneration after stands are defoliated. The MFPA may constrain clearcutting of infested stands, even with recently-enacted changes intended to reduce the regulatory burden for landowners. Despite these uncertainties, landowner response to the pending budworm outbreak will likely have important implications for the short- and long-term persistence of lynx habitat in northern Maine (Simons-Legaard 2016, pp. 16-17).

Climate Change – Because this geographic unit generally lacks potential elevational refugia (Carroll 2007, p. 1102; Siren *in* Lynx SSA Team 2016a, pp. 15 and experts, p. 37), its lynx population may be more vulnerable to deteriorating snow conditions than populations in the more topographically diverse western units, and changes in snow conditions could further restrict lynx distribution (Hoving 2001, pp. 27-28; Hoving *et al.* 2005, p. 749; Carroll 2007,

entire). This unit's only potential elevational refugia under reduced snow scenarios are in the mountains of western Maine, where favorable snow conditions may only persist as very small, isolated "sky islands" that would be unlikely to support lynx. Carroll (2007, entire) modeled the Maine lynx population assuming non-cycling hare populations and snow conditions expected under intermediate to high emissions climate models (Kiehl and Gent 2004, entire). He predicted a 59 percent decline in the lynx population (the non-cycling hare population model) by mid-century because of climate change alone, with larger declines projected from interactions between climate change and other factors (potential increased trapping in Canada and lynx population cycling; Carroll 2007, p. 1100). Wildlife experts in Maine ranked lynx as highly vulnerable to climate change (> 66 percent loss in species range/population and extirpation within 50 to 100 years; Whitman *et al.* 2013, pp. 19, 74).

Climate change is already affecting the Northeast, and the rate of change is faster than expected, with large changes observed since 1970 (Rustad *et al.* 2012 p. 6). Rapid winter warming in recent decades is believed to be exacerbated by an albedo feedback caused by the diminished persistence of snow in winter (Hayhoe *et al.* 2006, p. 25). Average winter temperatures are increasing about 0.4°C/decade (0.8°F/decade) with the greatest warming occurring in the coldest winter months (January-February; Burakowski *et al.* 2008, p. 1). Northeast climate models predict average winter temperature increases of 2.0°C (3.6°F; low emission) to 2.9°C (5.2°F; high emission) by mid-century and 3.1°C (5.6°F; low emissions) to 5.3°C (9.5°F; high emissions) by late century (Notaro *et al.* 2014, p. 6529). The largest increases in temperature are expected in northern Maine (Siren *in* Lynx SSA Team 2016a, Appendix 3; Rawlins *et al.* 2012, p. 9) where temperatures may increase 2.5° to 2.8°C (4.5° to 5.0°F) by 2050 (Fernandez *et al.* 2015, p. 3). In response to climate change, interest in wind development has grown in northern and western Maine, which has the potential to impact high-elevation habitats and potential spruce-fir refugia (Publicover 2013, p. 2).

Gonzalez *et al.* (2007, pp. 12-13 and 15-18) modeled distribution of boreal forest and future snow conditions under 9 different low, medium, and high emission scenarios and predicted reduced probablility of suitable snow (from 95 percent during 1961-1990, to 90 percent predicted for 2071-2100) and very minor changes in forest cover type in Maine by the end of the century. Although there are uncertainties about future climate warming, if projections are accurate, the area capable of supporting resident lynx in Maine could be expected to recede northward and lynx populations to decline substantially in this unit over the next 100 years (Vashon *et al.* (2012, p. 60). If future trends in increasing temperature and decreasing snow occur as projected, then at some time in the future lynx would be unlikely to persist in Maine.

Snow Duration - The current average snow duration in Maine is at or below the 4-month snow persistence threshold believed necessary to support lynx (section 4.2.1; Gonzalez *et al.* 2007, p. 7). Snow duration declined by 16 days in the Northeast from 1970 to 2001 (Wake 2005, p. 15) and is expected to diminish by another 2 weeks in Maine by mid-century (Fernandez *et al.* 2015, p. 10). It is projected to decline by 25 percent (low emissions) to 50 percent (high emissions) from current conditions by the end of the century (Hayhoe *et al.* 2006, pp. 21-25). Similarly,

Notaro *et al.* (2014, p. 6543) projected an average decrease of 28 days (low emission) to 47 days of snow cover (high emissions) by the end of the century.

Snow Depth - The current average annual snowfall in northern Maine is at or below the 270-cm/yr. (106-in/yr) threshold below which lynx are unlikely to occur (Hoving *et al.* 2005, p. 749; section 4.2.1), and it is expected to decline in the future with projected continued climate warming. From 1965-2005, Northeast winter snowfall has decreased by about 4.6 cm/decade (1.8 in/decade), with the greatest decreases occurring in December and February (Burakowski *et al*. 2008, p. 1). By the end of the century, large areas of the Northeast will experience 15-percent (under a low-emissions scenario) to 25-percent (high-emissions scenario) reductions in snowfall (Ning and Bradley 2015, p. 6). Similarly, Notaro *et al.* (2014, p. 6529) concluded that average snowfall in the northeastern United States and southeastern Canada will decline by 59 cm (23 in; 31 percent) under a low-emissions scenario) to 92 cm (36 in; 48 percent) under a high-emissions scenario by the end of the century because a higher proportion of winter precipitation is projected to fall as rain rather than snow. Hayhoe *et al*. 2006, (pp. 22-25) predicted that under moderate and high climate scenarios there would be large reductions in the length of the snow season with < 25-50 percent reductions in the number of snow days by 2070-2099.

Snow Quality - Winter precipitation in Maine is projected to increase by 10 to 15 percent by the end of the century (Hayhoe *et al.* 2006, p. 28) with a greater proportion of winter precipitation falling as rain (Huntington *et al.* 2004, entire; Hayhoe *et al.* 2006, p. 23; Ning and Bradley 2015, entire). Snow density and compaction (caused by wet, heavy snow or rain on snow events in winter) will likely continue to increase in the region in the future (Karl *et al.* 1993, entire; Dudley and Hodgkins 2002, pp. 8-10, 19-20; Huntington *et al.* 2004, p. 2632; Huntington 2005, entire; Hodgkins and Dudley 2006, entire).

Loss of Boreal Forest - The boreal spruce-fir forest type has come and gone from New England during the post-glacial period. It nearly disappeared from the Northeast during the interglacial warming period 1000 years ago, then moved south into New England only in the past few centuries during the “Little Ice Age” (Schauffler and Jacobson 2002, entire; DeHayes *et al.* 2000, entire). Continued anthropogenic climate warming is projected to cause another northward contraction of spruce-fir forest in the Northeast with potential negative consequences for both lynx and snowshoe hares (Gonzalez *et al.* 2007, entire). Because of its sensitivity to climate and its mobile nature, the spruce-fir forest type in the Northeast, including northern Maine, is projected to decline substantially in response to climate change even under low-emissions scenarios and could disappear completely under higher-emissions scenarios (Iverson and Prasad 2001, pp. 192-193; Prasad *et al.* 2007, entire; Beckage *et al.* 2008, entire; Iverson *et al.* 2008, p. 403; Ollinger *et al.* 2008, p. 17; Jacobson *et al.* 2009, p. 27; Tang and Beckage 2010, entire; Whitman *et al.* 2010, p. 12; Andrews 2016, p. 20). Even under the lowest emissions scenarios, spruce-fir forest would be reduced by the end of the century (Williams and Liebhold 1997, pp. 210-214; Prasad *et al.* 2007, entire; Mohan *et al*. 2009, pp. 221-222), although some spruce-fir may persist at the highest elevations (Tang and Beckage 2010, pp. 148-156) and along the eastern coast (Jacobson *et al.* 2009, pp. 26-29) where cooler conditions

would likely persist. Climate change is anticipated to increasingly fragment the boreal forest in northern New England (Iverson *et al.* 2008, pp. 400-405), which would diminish the amount and quality of lynx habitat (Simons 2009, pp. 221-222). Recent shifts of northern hardwoods to higher elevations formerly occupied by boreal forests have also been attributed to regional warming over the last century (Beckage *et al*. 2008, entire).

Spruce (red, black, and white) and balsam fir are the most important boreal forest conifer tree species in the Northeast and will be affected by climate change in different ways. Mechanisms of injury to spruce-fir include winter injury from freeze-thaw cycles, spring drought (because of reduced snowpack), and reduced seed germination (Auclair *et al.* 2010, pp. 694-695). Thus, the range of spruce-fir is limited by summer heat and drought. Mohan *et al.* (2009) projected that the suitable area for balsam fir would be 80 percent lower by 2100 under an average- to high-emissions scenario. In contrast, Ollinger *et al.* (2008, p. 8) projected increasing growth rates for balsam fir and red spruce to mid-century, after which they would decline. Andrews 2016 (p. 53, 104) modeled future climate envelopes for spruce and fir species in Maine under a moderate emissions scenario and predicted northward shifts in these species. The results suggest that areas of suitable climate for these tree species would diminish in northern New England by 2030, white and black spruce would disappear from northern Maine by 2060, and balsam fir and red spruce would dwindle to only a few high altitude locations by 2060. However, suitable habitat for spruce and fir species would remain in northern and coastal highlands of New Brunswick and Cape Breton Island Nova Scotia.

The timescale of the spruce-fir decline in the Northeast is difficult to predict because of the many variables that influence shifting of the forest species composition (emissions scenarios, the long lifespan and slow dispersal rates of trees, frequency of disturbance, competition from advancing hardwoods and invasive tree species, complex interactions with moisture, and synergistic effects with other pollutants). Support for an accelerated decline includes evidence that spruce-fir is already in decline and is being replaced in Maine by northern hardwoods (oak, pine, red maple). Since 1995, the area of forest land classified as the northern hardwoods type in Maine has increased 8.9 percent (by about 2,400 km^2 [927 mi^2]) and the area in the spruce-fir forest type group has decreased 8.5 percent (1,987 km^2 [767 mi^2]; McCaskill *et al*. 2016, p. 2). Although forest disturbance often favors northern hardwoods, it may, in some situations, favor balsam fir and help it persist longer in a warming climate (Scheller and Mladenoff 2005, p. 318). A pending spruce budworm outbreak and frequent disturbance from forest management could accelerate conversion to northern hardwoods. Other climate-related forest disturbances (forest pests, diseases) could further accelerate conversion to northern hardwoods (Iverson *et al.* 2008, p. 404).

In contrast, some authors note that trees migrate slowly in response to a changing climate and are long-lived. Therefore, a time lag may occur in shifting forest composition from spruce-fir to northern hardwoods (Mohan *et al.* 2009, p. 221; Zhu *et al.* 2012, pp. 1048-1051). Some northern Maine industrial forest landowners could “adapt” to climate change by intentionally favoring spruce-fir (e.g., by plantations and use of herbicides).

Finally, there is uncertainty concerning the influence of climate change on balsam fir, a short-lived, shade-tolerant conifer that dominates much of the understory in the Acadian forest and is an important component of lynx habitat in the Northern Maine Unit. McWilliams *et al.* 2005 (p. 8) noted that balsam fir increased in Maine's forest inventory in the early 2000s because this species seems to respond favorably to frequent disturbance. Forest models projected increases in spruce-fir biomass over the next century because of partial harvesting and periodic budworm outbreaks, but did not take climate change into consideration (Simons-Legaard *et al.* 2013, entire). In contrast, Iverson *et al*. 2008 (p. 400) identified balsam fir as the tree species in Maine most sensitive to a warming climate, and they projected large declines, with only 29 percent (low emissions) to 16 percent (high emissions) persisting by the end of the century. Climate change will influence precipitation and temperature, forest management strategies, and forest disturbance (fire frequency and spruce budworm), all of which will interact in complex ways to influence balsam fir at the southern edge of its range. Carter (1996, pp. 1092-1093), Iverson *et al.* (1999, pp. 400, 403), and Goldblum and Rigg (2005, p. 2714) documented balsam fir growth rates and growth potential would decline under likely climate warming scenarios (about a 2.2°-2.8°C (4°-5°F) temperature increase by the end of the century and reduced snow conditions). Some have projected the extirpation of spruce-fir forest types in the Great Lakes States (Scheller and Mladenoff 2005, entire) and New England (Iverson *et al*. 2008, entire. 403). Balsam fir has prolific seed production following forest disturbance such as harvesting (Seymour 1992, p. 217), and has proliferated under the current climate and forest management regime dominated by partial harvesting (Olson *et al.* 2013, entire). Balsam fir is a relatively short-lived tree (about100 years), and is unlikely to persist long if climate change affects seed and germinations rates. Given anticipated climate changes, especially early snow melt and low spring precipitation, fir may increase for the next few decades but is unlikely to regenerate in the future Maine forest (Simons-Legaard 2015, *pers. comm.*).

Vegetation Management - Habitat suitable for lynx is expected to decline in the future (see Regulatory Mechanisms section above). By 2020, all of the extensive areas that were clearcut in the 1970s and 1980s will be greater than 35 years of age and no longer likely to support high hare densities. For the foreseeable future, partial harvesting will continue as the primary means of forest management. Although partially harvested forests with well-developed understory structure may provide foraging opportunities via increased prey access (Fuller *et al.* 2007, 1984-1985), snowshoe hare densities are approximately 50 percent less in landscapes dominated by partially harvested stands (Robinson 2006, pp. 5-37; Fuller and Harrison 2010, p. 1276). Thus changing forest management practices have and will continue to reduce landscape hare density possibly below levels that can support lynx.

Sources of uncertainty concerning future habitat conditions in northern Maine include changes in forest policy, timber harvesting methods, changing timberland ownership, response to budworm outbreaks, and timber markets - all of which have occurred in the recent past and will undoubtedly shape forest management in the future (Simons-Legaard *et al.* 2016, p. 8). Currently, the landscape is owned primarily by financial investors who may be less inclined to intensively manage for spruce and fir after the next outbreak of the spruce budworm (Wagner *et al.* 2015, p. 4).

The dramatic shift from clearcutting to partial harvesting presents a challenge for lynx conservation in this unit for the next several decades (Legaard *et al*. 2015, p. 21). Lynx habitat is expected to peak and then remain stable through about 2012-2020 and then decline (Simons 2009, pp. 153-165, 202-220; Simons-Legaard *et al.* 2016, p. 6). After 2020, aging of the former clearcuts and extensive partial harvesting are projected to result in a 50 to 65 percent decline in lynx habitat by 2032 (Simons 2009, p. 217). Lynx habitat will decline from about 9.5 percent of the landscape (current condition) to about 5.0 percent of the landscape (Simons-Legaard 2016, fig. 8, p. 10). By 2032, the Northern Maine Unit may support less than half the number of resident lynx that it does today (Simons 2009, pp. 209, 217).

In the future, lynx habitat is projected to become fragmented into smaller, isolated parcels and shift southward into areas currently occupied by bobcats and fishers, where snow conditions are unlikely to favor lynx occupancy (Simons 2009, pp. 153-165; Simons-Legaard *et al.* 2016, pp. 1, 6; Simons-Legaard 2016, p. 8). By 2022, the number of patches of high-quality hare habitat is modeled to increase by 57 percent, but the average size of patches would decline by 87 percent and patches would become more isolated (Simons-Legaard *et al.* 2016, pp. 5-6). The proximity index of high-quality habitat patches is expected decline by 78 percent within lynx home ranges. Although lynx habitat in this geographic unit is currently peaking, fragmentation may diminish its future ability to support as many resident lynx as it does currently (Simons-Legaard *et al.* 2016, p. 8).

Beyond 2030, assumptions concerning future climate change, land ownership, and harvest rates introduce greater uncertainty. The most optimistic forest management models (greatest harvest rates, no climate change, no spruce budworm) project that lynx habitat will likely decline over the next few decades then gradually increase to about 10 percent of the landscape by 2060 (Simons-Legaard 2016, fig. 8, p. 9). Other models (lowest harvest rates, no climate change, no spruce budworm) project about 5 percent of northern Maine will likely have high-quality hare habitat from 2030 to 2060 (Simons-Legaard 2016, fig. 8, p. 9), although the habitat will be much more fragmented and patch sizes will be smaller (Simons-Legaard *et al.* 2016, entire).This could represent a return to conditions similar to those that occurred historically prior to the landscape-scale clearcutting the created the current condition, perhaps resulting in commensurate changes in Maine'slynx population.

A shift toward managing private timberlands as softwood plantations could offset losses in spruce-fir and become a form of adaptation to climate change effects of reducing spruce-fir forest types. Jack pine plantations are extensive in adjacent New Brunswick (Etheridge *et al.* 2005, p. 1966). A forest company that has planted extensive spruce plantations in New Brunswick recently purchased nearly 4,047 km^2 (1,563 mi^2) of forestland in northern Maine where it is doing the same. Spruce plantations are becoming more common on this ownership in Maine, but not on others. Stand structure and intensive management of plantations are highly variable (e.g., pruning, thinning, herbicide treatments), thus hare densities and use by lynx vary (Roy *et al.* 2010, entire). Hares can achieve higher densities in plantations depending on the amount of lateral (horizontal) cover, but for shorter periods of time; about 10 to 17 years after

cutting and planting in New Brunswick (Parker 1984, p. 163) and 15 to 25 years in Quebec (Roy *et al.* 2010, p. 585). This is in contrast to about 15 to 35 years in naturally regenerating spruce-fir stands after harvest (Simons-Legaard *et al.* 2016, p. 4). The future of plantations in the northern Maine unit is uncertain. Most investment landowners have short-term investment horizons and are unlikely to invest in plantations.

Natural stand-replacing disturbances in this unit are rare and infrequent and, other than spruce budworm outbreaks, are unlikely to significantly affect future habitat conditions (Hoving *et al.* 2004, p. 292). At its peak in 1975, budworm affected nearly all of Maine's 8 million acres of spruce and fir with greatest mortality (up to 49 percent) of balsam fir and less for the spruce species (Livingston 1998, pp. 26-27). A very large outbreak has thus far defoliated 60,700 km^2 (over 23,000 mi^2) of spruce-fir in southern Quebec, immediately north of Maine (Wagner *et al.* 2015, pp. 2-3), and it is projected to expand into northern Maine in 2018-2021, potentially putting much of Maine's 23,472 km^2 (9,063 mi^2) of spruce-fir stands across the State at risk of defoliation. However, despite the severe defoliation of spruce-fir forests in southern Quebec, some project a weaker outbreak in Maine because spruce and fir trees are younger and less susceptible and there is a higher hardwood component in northern Maine forests (Wagner *et al.* 2015, p. 18-22). A typical outbreak lasts for a decade.

Forest management strategies for addressing the coming budworm outbreak vary and include applying insecticides (although land area sprayed is expected to be small compared to the previous outbreak), pre-emptively cutting mature spruce-fir before defoliation, stopping precommercial and commercial thinning, and salvaging dead and diseased trees (Wagner *et al.* 2015, pp. 38-48). The nature and aggressiveness of forest management response to budworm outbreaks could greatly affect future outcomes for lynx habitat (see section 4.2.1). The next budworm outbreak and subsequent forestry response is a disturbance agent that may accelerate changes in forest composition influenced by climate change, especially toward increased northern hardwood and reduced spruce-fir. The nature of land ownership is greatly changed from the 1970s and 1980s, and landowner response is expected to be diverse depending on their objectives and investment horizons. The pending budworm outbreak cast additional uncertainty on the status of lynx habitat in this geographic unit beyond 2030.

Climate change, forest management and budworm outbreaks will interact to influence the future trajectory of spruce-fir forest in Maine. All 3 variables have yet to be modeled simultaneously (Legaard 2016, *pers. comm*.). Assuming current forest management trends persist to the end of the century, spruce-fir dominated forest is expected to continue to decline (Legaard *et al.* 2013, entire). The combination of budworm-induced mortality and salvage harvesting will have a negative effect on spruce-fir (Legaard *et al.* 2013, entire). However, after a budworm outbreak the biomass and area of mixed-hardwood/softwood forest would be expected to increase through this century primarily because of the proliferation of regenerating balsam fir (see discussion above; Legaard *et al.* 2013). Mixed forests having a high (greater than 50 percent) hardwood component are not believed to support high hare densities (Scott 2009, p. 109) or to be preferred by lynx (Vashon *et al.* 2008b, pp. 1492-1493). It is uncertain whether lynx can adapt to lower landscape hare densities associated with mixed hardwood-softwood forest. They

may persist, but at lower densities as they currently do in the western units of the DPS. However, the probability of persistence is further diminished by deteriorating snow conditions and potentially increased populations of bobcats and other competitors.

Wildland Fire Management - Susceptibility of the northern Maine unit to fire may be enhanced by a severe spruce budworm outbreak because of the amount of dead and dying spruce-fir (Stocks 1987, entire), although there were no large fires after the last outbreak. Fire risk is currently very low in this unit and a continuous decrease in fire frequency is predicted with climate change in eastern Canada because of increased precipitation and decreased drought (Bergeron and Flannigan 1995, entire; Flannigan *et al.* 1998, entire). Climate is expected to become more variable (i.e, wider extremes of summer drought and precipitation) during the next century (Gregory & Mitchell 1995, entire; Gregory *et al.* 1997, pp. 684-685), which could create fire conditions in unusually dry years (Flannigan *et al.* 1998, p. 475). Maine's policy is to immediately suppress wildfire, thus large, stand-replacing fires are expected to be infrequent in this region in the future. Notable large fires in Maine include a 1.2 million-ha (3 million-ac) fire in 1825 and an 81,000 ha (200,000-ac) fire in 1947.

Habitat Fragmentation - The future of the 40,470-km^2 (15,630-mi^2), sparsely populated "North Woods" of Maine is highly uncertain and has been the subject of intense public debate (Baldwin *et al.* 2007, entire). Land use and zoning in the state's "unorganized townships" are the responsibility of the Land Use Planning Commission (LUPC) in the Maine Department of Conservation. The LUPC revised its Comprehensive Land Use Plan (Maine Land Use Regulation Commission 2010, entire), and described principal values in guiding future land management decisions: maintaining working forests, provide for traditional recreational opportunities, protect high-value natural resources, and encourage long-term conservation. The North Woods has long been considered a public resource or "commons," even though privately owned (Judd 2007, p. 9). This land was traditionally owned by a few large timber companies, but since the 1980s there has been turnover in ownership largely by investments companies and subdivision of large parcels (Hagan *et al.* 2005, entire). Financial investors, primarily Real Estate Investment Trusts (REITS) and Timber Investment Management Organizations (TIMOs), focus on maximizing the asset value of timberlands and are increasingly likely to seek revenue from non-timber resources if they generate a higher return. These new owners operate over relatively short (5- to 15-year) time horizons and are willing to consider multiple means of monetizing their asset, including development and real estate sales (Legaard *et al*. 2013, entire). If left unchecked, these pressures may continue to promote dispersed development throughout this region. Parcelization and subdivision has increased, particularly in the southern third of the jurisdiction (Maine Department of Conservation 2010, p. 72-73). The LUPC has limited ability to address stressors on Maine's North Woods, including resale and subdivision trend. This trend is likely to continue into the foreseeable future and will make management of large, forested landscapes for lynx even more difficult.

Historically, development has stayed mostly on the edges of the North Woods jurisdiction with the exception of scattered seasonal dwellings and sporting camps in the interior, but this could change in the future. Between 1971 and 2005, the LUPC permitted 8,136 new dwellings in

unorganized townships, increasing the number of residences by 66 percent during this time period (Maine Land Use Regulation Commission 2010, p.80). Between 1971 and 2005, the LUPC also issued 1,353 development permits for new uses scattered throughout the unorganized townships (Maine Land Use Regulation Commission 2010, pp. 97-99), with most (42 percent) being recreational facilities (boat launches, campsites, gatehouses, recreational lodges). Most development has occurred in areas that abut organized communities and near public roads. Within the interior, most development has occurred along lakeshores and other waterfront. However, the amount of hillside and ridge development is growing and this trend is likely to continue (Maine Land Use Regulation Commission 2010, p. 136), which will likely further fragment lynx habitat.

We have an incomplete understanding of the effects of outdoor recreation on lynx and their habitat (ILBT 2013, p. 80). Future trends in outdoor recreation in northern Maine are also uncertain (Vail 2007, entire). A portion of the North Maine Woods is a gated road system that encompasses about 1.4 million ha (3.5 million ac). Visitation by outdoor recreationists is currently about 175,000 per year and declining. Likewise, visitors to Baxter State Park and the Allagash Wilderness Waterway have declined (Vail 2007, p. 107). Aside from a vigorous discussion of the recently-designated Katahdin Woods and Waters National Monument or a master tourism plan for the area (Vail 2007, pp. 112-113), there could be stagnant or declining participation in traditional outdoor recreational activities in the future (Vail 2007, p. 107). Alternately, increased numbers of second homes and resorts could increase visitor numbers in the future. Snowmobiling may be an exception and has risen in popularity in northern Maine, but it too may decline because of declining snow (see section 3.2). The effects of new or expanded downhill ski development on fragmentation of lynx habitat are expected to be minimal. Future trends in outdoor recreation and associated effects on lynx, hares, and their habitat in northern Maine are uncertain.

Within the last 5 years, 2 landowners developed concept plans for rezoning for large-scale development of hundreds of house lots and resort development within designated lynx critical habitat. Under one concept plan, 975 houses and 2 resorts would be constructed on about 14 km^2 (5.5 mi^2) and a 1,469-km^2 (567-mi^2) conservation easement would be established. A second concept plan would allow development on about 8 km^2 (3 mi^2) of land and establishment of a 59-km^2 (23-mi^2) conservation easement. Although these developments have not been built, they may portend future trends in land use.

Energy production is emerging as a potentially significant economic factor in this unit, with the potential for grid-scale industrial wind and solar power, biomass, biofuels, and other energy sources. Wind energy resources are high within the lynx critical habitat (National Renewable Energy Laboratory 2010[25]), and wind development in the lynx critical habitat are likely to accelerate in the foreseeable future. Two large wind energy projects are being considered in designated lynx critical habitat in this unit; if built, each would cover about 450-650 km^2 (180-250 mi^2) and become 2 of the largest such projects in Maine. Mining is not a traditional land use

[25] http://apps2.eere.energy.gov/wind/windexchange/wind_resource_maps.asp?stateab=mecitation; last accessed 5.25.2016.

in this unit, but a large mining operation is being considered within designated lynx critical habitat. Extraction operations for gravel (for road building) are widely-scattered throughout the unit.

The area designated as lynx critical habitat is heavily-roaded, particularly with forestry roads. While accurate numbers are difficult to obtain, approximately 1,500 miles of public roads and over 20,000 miles of private roads exist within unorganized areas of Maine (Maine Department of Conservation 2010). There has been discussion of an east-west limited access highway through northern Maine and extending Interstate 95 north from Houlton to Presque Isle, which, if constructed, would further fragment habitat (Maine Department of Transportation 1999; Beck *et al.* 2012, p. 38).

An increasing area of the designated lynx critical habitat in this unit is likely to be placed under conservation easements that will limit future development and fragmentation of lynx habitat. Maine has the largest amount of land under easement of any state, and there are about 8,094 km^2 (3,125 mi^2) of conservation easements in lynx habitat in northern Maine (Pidot 2011). Continued expansion of areas under conservation easement is uncertain and will depend on willing landowners and funding available for purchase of easements. Conservation easements often include abandonment of some development rights, but they may allow for wind power development and other land uses that may not be compatible with lynx conservation. Easements in Maine allow forest management, but they rarely prescribe specific management that would benefit lynx and other species of conservation concern. If market conditions continue, trends toward forest certification will likely continue in Maine for the foreseeable future. Currently, 8 million acres are enrolled in Maine by SFI and FSC (Wagner et al. 2016, p. 31). Certification has the potential to address lynx management in the future.

The Core Team believes that all development trends portend increased loss and fragmentation of lynx habitat in the Northern Maine Unit. As habitat is lost and fragmented as a result of development and forest maturation and management, it will become increasingly difficult to influence landscape-scale forest management that could benefit lynx. However, whether (and if so, when) future development may result in population-level impacts to lynx in this unit is uncertain.

Conclusion

After reviewing the scientific literature concerning snow and climate change and acknowledging other potential stresssors unique to this unit (e.g., lack of forest planning for lynx, land ownership turnover, and development pressures), the Core Team believes that lynx habitat and numbers in Maine will diminish substantially in the future. We believe the number of resident lynx in Maine is at an historically (unnaturally) high level and will likely decrease over the next several decades, perhaps to levels more like natural historical conditions, and perhaps (but with increasing uncertainty) to even lower numbers in the more distant future (end of this century). Given current trends (diminishing snow conditions, extensive partial harvesting and fragmentation of spruce-fir forest, possible pelage mismatch for hares, increasing populations of

bobcat and fishers in a lower-snow environment),we believe landscape level hare densities are likely to decline in northern Maine. Extended periods of lower hare numbers would likely reduce the number of lynx and the probability that this unit would continue to support a persistent resident lynx population in the future.

We concur with expert assessments concerning trends in forest management, but we also note that development pressures in northern Maine did not receive much discussion at our expert elicitation workshop. We believe development pressures (residential and commercial development, energy development, transmission lines, roads, mining) may increasingly become competing land uses on private lands in northern Maine. We also expect continued turnover and subdivision of private forest lands in northern Maine, which could accelerate opportunities for non-forestry land uses. Turnover in land ownership has provided opportunities to conserve some areas of the North Maine Woods through purchase of conservation easements and fee title acquisitions, including a new Katahdin Woods and Waters National Monument. However, conservation easements do not fully protect these lands from some kinds of development that could adversely affect lynx and their habitat. For example, many conservation easements allow large-scale, industrial wind power development. We conclude that various forms of development in northern Maine will continue in the future.

The Core Team believeslynx in Maine would be more exposed to potential adverse impacts in a future scenario without Federal listing. The lynx is not State-listed in Maine but it is considered a species of special concern. There is rarely a nexus for Service review of forestry projects under section 7 of the ESA (i.e., no Federal funding or permits are typically required for forest management on private lands). Nevertheless, because of its Federal listing, the Canada lynx are a priority species for planning by Federal, Tribal, State, and private forest landowners. Although few private landowners have thus far made formal commitments to intentionally manage their forests for lynx, by virtue of their Federal listing status they at least consider the possibility of doing so in the future. This is particularly true of landowners who must plan for Federal listed species as a requirement of their enrollment in green certification programs. Without Federal listing, there would be no incentive or motivation for private forest landowners to change the current paradigm of partial harvesting and intentionally engage in forest management to benefit lynx. With current Federal listing, there is a nexus for the Service to review other projects in northern Maine (e.g., Army Corps of Engineers permits for wetland impacts); for new highways, transmission lines, large-scale energy development, mining, and residential and commercial development. Without Federal listing, few of these projects would consider lynx. Critical habitat has been an important consideration in the Federal review of the aforementioned kinds of development projects. Critical habitat also has had a positive influence on land conservation in northern Maine, with land trusts and non-governmental organizations using the lynx and their critical habitat as justification for seeking funds for conservation easements. This justification for habitat protection would no longer be valid if the DPS was not Federally-listed. The Core Team concludes that a future scenario without Federal listing would result in increased habitat loss and fragmentation and would result in reduced justification for habitat protection initiatives in northern Maine.

Lynx would be at greater risk without ESA section 9 prohibitions against take. There is currently a closed season on lynx, but it is uncertain whether legal trapping of lynx would resume in Maine if the DPS was not listed. If the DPS was not listed, it is possible that State-managed trapping could resume in this and perhaps other geographic units. We expect that would only occur if scientific evidence strongly suggested the presence of a harvestable surplus of lynx and that harvest quotas would be carefully managed to ensure that the viability of resident lynx populations would not be diminished. If the DPS was not listed, Maine's incidental take permit for trapping would not apply, and it is possible that some protective measures to minimize injury, take, and mortality of lynx could be diminished. Habitat mitigation for lethal take of lynx associated with the Maine trapping HCP also would cease. About 10 lynx have been illegally shot and reported or otherwise discovered since listing. Illegal shooting and non-reporting could increase without Federal protection. We believe several high-profile Federal law enforcement cases have helped to reduce illegal shooting of lynx.

After considering the lynx expert's opinions and the best available scientific information, the Core Team is less optimistic than the experts regarding the long-term (end-of-century) persistence of resident lynx in this unit. All potential stressorss – forest management, climate change, habitat loss and fragmentation, and development – are increasing in frequency, intensity, and extent. The amount of high-quality hare and lynx habitat created by clearcutting in the 1970s and 1980s recently peaked at unprecedented high levels that are unlikely to be achieved again. Because of state law, forest management has shifted dramatically away from clearcutting to many forms of partial harvesting, which on average support less than half the hare densities of regenerating clearcuts. Forest land ownership has, and continues to change, further subdividing private forest lands. Furthermore, hare densities have declined by half and have remained at these lower levels. Lynx habitat in the next few decades will shift south to areas that will be more influenced by climate change and northward range expansion by bobcats. Thus, we conclude that the carrying capacity to support lynx is diminishing, and the lynx population will decline as the quantity and quality of boreal forest habitat declines. There are few commitments by private forest landowners to manage specifically for lynx conservation.

After reviewing the best available scientific information, we believe that climate change will be a significant stressor to lynx in the Maine unit; perhaps more so than expressed by experts. Unlike other units, as snow condition decline there is little potential for elevational refugia for lynx in Maine. Spruce-fir is being replaced by northern hardwoods because of climate change. Frequent forest cutting and disturbance, including a pending spruce budworm outbreak, could accelerate conversion to northern hardwoods. We acknowledge that the rate of spruce-fir decline is uncertain, but note that some of the science reviewed indicates the spruce-fir forest type could nearly disappear from Maine by late-century under both low and high emissions scenarios. Climate change models portend declining snow conditions from low- to high-emissions. Because increases in temperature are thus far tracking high emissions scenarios we are less optimistic for snow conditions that favor lynx by mid- to late-century. In the past decade, interest in development has increased in lynx critical habitat, especially proposals for large-scale residential and resort development and extensive wind energy development that could cover hundreds of square miles. We conclude that these stressors, individually and cumulatively,

indicate diminished populations of lynx and their habitat. If these stressors are not abated, we believe that the probability of persistence will be lower by mid-century and that lynx will have a greater likelihood of extirpation by the end of the century than projected by experts.

5.2.2 Unit 2 - Northeastern Minnesota

Expert Projections of Lynx Persistence

The experts that we consulted indicated an initially high and subsequently declining probability of persistence of resident lynx in Minnesota, with increasing uncertainty through the end of the century (Lynx SSA Team 2016a, pp. 37-38). Near term drivers of the projected decline were climate-driven reduction in snow quality, quantity, and persistence; potential increased competition from bobcats; and forest insects. Long term drivers were climate-driven loss of spruce-fir forests; further reductions in snow quality, quantity, and persistence; potential competition from bobcats; and potential increases in wildfire activity.

Climate change was primarily associated with loss of boreal forest but also could potentially increase disease or insect outbreaks, and is likely to affect the amount of precipitation falling as good quality snow in the area of the state supporting lynx habitat. We heard varying prognoses from experts on the speed at which climate-induced loss of boreal forest will occur. The scientific literature suggests (and 1 of the climate change experts indicated) that loss of spruce-fir could occur relatively quickly in the Midwest and Northeast (but possibly more slowly elsewhere in the DPS because of potential elevational refugia), and all noted that an increase in northern hardwood composition of the forest is already occurring. Connectivity to lynx in Ontario reduces the likelihood of local extirpation in this geographic unit, but the likelihood would increase if connectivity was to become compromised in the future if habitat recedes northward and becomes increasingly fragmented on both sides of the border, as expected with continued climate warming.

Despite uncertainty, experts generally agreed that climate-related loss of favorable snow conditions (amount, consistency, and duration), loss of boreal forest, and potentially increased bobcat competition and hybridization are likely to reduce the probability of lynx persistence in this unit. Experts expressed uncertainty about the likelihood and severity of future insect outbreaks (and how this could affect future lynx habitat) and the potential introduction and spread of diseases.

Taking all of these factors into consideration, experts provided “most likely” persistence probabilities of 88 to 100 percent (median = 96 percent) in the near-term (year 2025), 60 to 90 percent (median = 80 percent) at mid-century, and 10 to 60 percent (median = 35 percent) at the end of the century (fig. 11). As they did for most other geographic units, all experts indicated an initially high and subsequently decreasing likelihood that resident lynx will persist in this unit, with uncertainty increasing substantially over time.

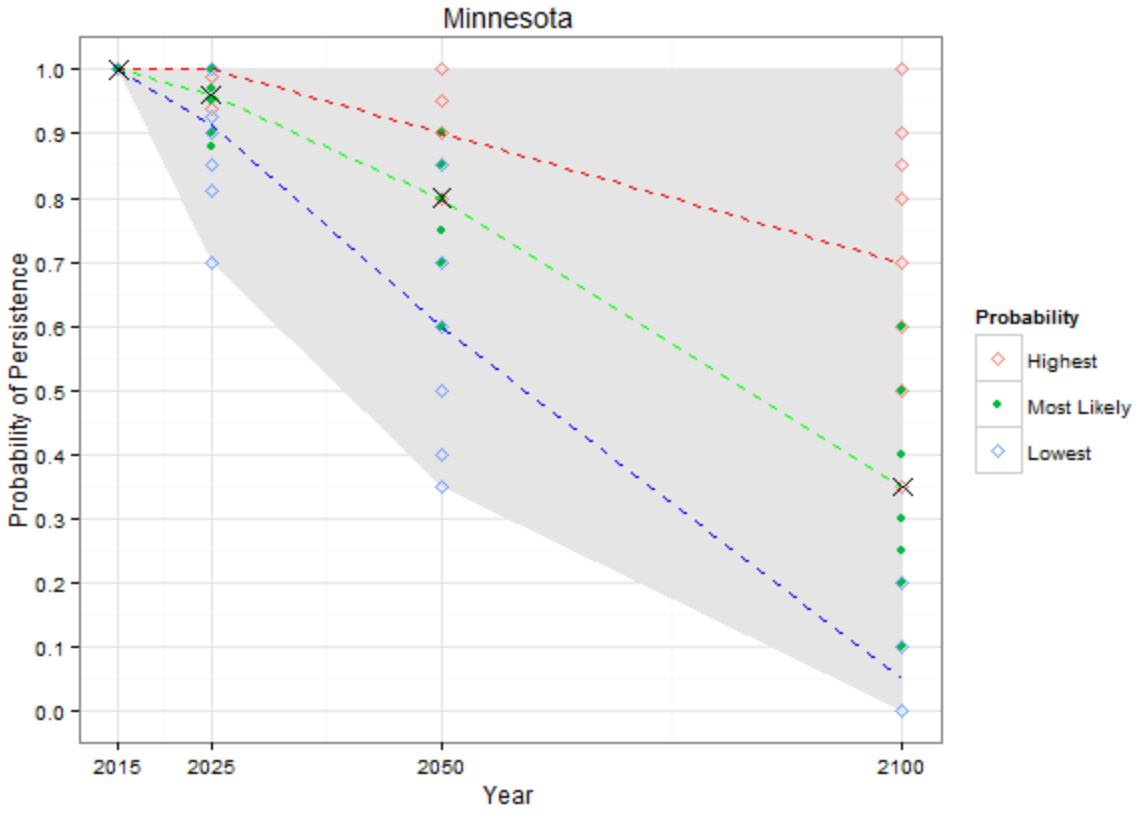

Figure 11. Lynx expert estimates of the probability that the Northeastern Minnesota Geographic Unit will continue to support resident lynx in the future (at years 2025, 2050, and 2100).

Service Evaluation of Factors Potentially Influencing Future Conditions

Regulatory Mechanisms - In Minnesota, the vast majority of lynx habitat that supports a long-term persistent lynx breeding population is administered by the SNF. This area includes designated critical habitat (79 FR 54782). The SNF consults with the FWS to consider the effects of any projects on lynx and its critical habitat and is anticipated to do so as long as the species is listed under the ESA. The SNF is currently implementing the 2004 SNF Plan (USFS 2004a, entire), which has direction based on the LCAS (Ruediger et al. 2000, entire) and the Canada Lynx Conservation Agreement (CA) between the Forest Service and the Service (USFS and USFWS 2000, entire), for all forest activities that occur within LAUs. Active management of forest lands can maintain, restore, or create lynx habitat, and the SNF has a long-term commitment to doing so. If the SNF continues to follow vegetation and wildland fire management and other applicable recommendations in accordance with the LCAS (including consideration of new scientific information as it becomes available) in its Forest Plan, we expect that several risk factors will continue to be minimized and managed to promote the conservation of lynx within the SNF into the future. Management of lynx and its habitat on SNF land will remain in place until the forest amends or revises its LRMP. We expect that management

direction for lynx addressing vegetation management, wildland fire management, and habitat fragmentation on National Forest System lands will be incorporated into the revised or amended Forest Plans (LRMPs). Although management of lynx habitat and lynx conservation efforts on the SNF could change in the future if the DPS was not listed, the species would be placed on the Regional Forester's Sensitive Species list for a minimum of 5 years, which gives it a higher priority than other species for monitoring and management during that time.

The Chippewa and the Chequamegon-Nicolet National Forests occur outside the Northeastern Minnesota geographic unit and the area considered to be core lynx habitat (i.e., where lynx are persistent and are reproducing). However, because lynx occasionally occur on these forests, the Forest Plans for both also include direction based on the LCAS and the CA between the Forest Service and the Service for all forest activities that occur within LAUs (USFS 2004b, entire; USFS 2004c, entire). These 2 forests consult with the FWS to consider the effects of any projects on lynx and are anticipated to do so as long as the species is listed under the ESA. It is unclear if lynx habitat management and conservation efforts on these national forests would change if the DPS was not listed in the future.

Additionally, the Minnesota Department of Natural Resources (MNDNR) manages approximately 36 percent of the lynx habitat in this unit, and privately-owned lands make up about 16 percent of the unit. Under the Sustainable Forest Resource Act of 1995 (revised in 2014), the Minnesota Forest Resources Council (MNFRC) has developed guidelines for site-level timber harvesting and forest management (MNFRC 2013, entire; MNFRC 2014, entire). These voluntary guidelines are intended for private and State landowners and include some general recommendations for wildlife but are not specific to lynx (MNFRC 2014, pp. 4-5). It is expected that the MNFRC guidelines will remain in place into the future and that voluntary actions will continue. Private landowners, however, do not have an official commitment to land management. We cannot say with any certainty what proportion of privately owned land will follow those guidelines into the future, because following the guidelines is voluntary. The MNFRC guidelines are less comprehensive and are not specific to lynx, and therefore may not be as beneficial to lynx and lynx habitat as the lynx and hare specific direction followed by the Forests.

The NPS manages Voyageurs National Park, which is also within the Minnesota unit. Voyageurs National Park protects an area of 882 km^2, of which 534 km^2 (62 percent) is covered by forests and other uplands (Moen *et al.* 2012, p. 348), but does not have lynx specific direction in its management plan (NPS 2002, entire). The National Park consults with the FWS to consider the effects of any projects to lynx (NPS 2002, p. 26) and is anticipated to do so as long as the species is listed under the ESA. Lynx documented on and near Voyageurs National Park are probably transient animals (Moen *et al.* 2012, p. 348).

Approximately 1 percent of the Minnesota unit is managed by the Grand Portage Band of Chippewa, which has been actively working on lynx conservation since 2004. Timber sales and harvest practices on the reservation follow an integrated plan for priority wildlife management, sustainable economic development, and recreational uses. The Band's timber management

practices benefit snowshoe hares (Deschampe 2008, entire) and are expected to continue into the future.

In response to a 2008 court ruling, the MNDNR drafted a plan (currently under review by the Service) to minimize the likelihood that lynx would be incidentally trapped during otherwise legal trapping of other furbearers in Minnesota. As described above in section 3.1.2, the MNDNR designated a Lynx Management Zone (LMZ) where it enforces special trapping regulations to minimize the incidental take of lynx (MNDNR 2016a, pp. 53-55). In 2015, the MNDNR als issued emergency trapping rules in the LMZ mandating additional restrictions on the types of traps that may be used (MNDNR 2015, entire) to further reduce the likelihood of incidental take. If the DPS was not listed, we expect that the State would continue efforts to reduce incidental trapping of lynx. Although we consider it unlikely, it is possible that State-managed trapping of lynx could resume in the future if the DPS was not listed.If that were to occur, we assume the State would proceed only after demonstrating the level of harvest the population could sustain and carefully developing, enforcing, and monitoring a strict trapping quota system to ensure that harvest level would not be exceeded.

Climate Change - The direct and indirect effects of climate warming are expected to affect lynx in Minnesota (Siren *in* Lynx SSA Team 2016a, pp. 15 and Moen *in* Lynx SSA Team 2016a, p. 19) and could restrict their future range. As described in section 3.2, new information on regional climate change and potential effects to lynx habitat that has become availalbe since the DPS was listed suggests that lynx distribution and habitat is likely to shift northward in latitude and upward in elevation within its currently occupied range as temperatures increase. Because of its generally flat topography, this geographic unit presents little opportunity for elevational migration of lynx and lynx habitat. Other protential impacts of climate change include (1) diminishing snow depth, quality, and duration, perhaps resulting in increased competition from bobcats, coyotes, and other terrestrial hare predators and increased hybridization with bobcat, (2) conversion of spruce-fir to northern hardwoods, and (3) potential future isolation of resident lynx in this unit because of diminishing forest conditions in southern Ontario.

Gonzalez *et al.* (2007, pp. 8, 12-19) predicted the persistence of boreal forest and historical (1961-1990) snow suitability for lynx (95 percent historical and future probability of suitable snow) in this unit through 2071-2100, and suggested that the SNF could provide a potential refugium for lynx. Notaro *et al.* (2015, pp. 1668-1669) projected changes in lake effect snowfall using downscaled climate models (Abdus Salam International Centre for Theoretical Physics (ICTP) Regional Climate Model version 4 (RegCM4; Elguindi *et al.* 2011 and Giorgi *et al.* 2012 as cited in Notaro *et al.* 2015) for the Great Lakes Basin. Siren (*in* Lynx SSA Team 2016a, p. 15) stated that climate models show an increase in lake effect snow in the eastern Great Lakes until 2050, with a decline later in the century, with an overall decline in the amount and duration of snowpack in the Midwest.

Historical lynx records occurred in areas with at least 4 months (120 days) of continuous snow coverage (Gonzalez *et al.* 2007, p. 7). In northern Minnesota from 1959-1979, the number of days with snow cover ≥ 2.5 cm (1 in) ranged from 130 to 160 days; ≥ 15 cm (6 in), from 85 to

130 days; ≥ 30 cm (12 in), from 50 to 100 days; and ≥ 61 cm (24 in), from 10 to 30 days (Kuehnast *et al.* 1982, pp. 7-9). In the future, Notaro *et al.* (2015, p. 1675) projected a general reduction in the frequency of heavy lake-effect snowstorms during the twenty-first century, with the exception of projected mid-century increases around Lake Superior when local air temperatures are expected to remain low enough for precipitation to fall largely in the form of snow. The snow season in the Great Lakes basin is likely to become substantially compressed during the twenty-first century with dramatic increases in rainfall (Notaro *et al.* 2015, pp. 1676-1678). The Minnesota unit may be more vulnerable to snowpack loss due to lack of elevational refugia (Siren *in* Lynx SSA Team 2016a, p. 15).

Normal annual snowfall from 1981-2010 in northeastern Minnesota ranged from 140 to 241 cm/yr (55 to 95 in/yr)[26] and is projected to decline across the Great Lakes Basin in the future (Notaro *et al.* 2015, p. 1675). Snow conditions favorable for lynx (depth, consistency, and persistence) are projected to deteriorate in the Great Lakes Region. Notaro *et al.* (2015, pp. 1671-1674) projected a dramatic decline of Great Lakes ice cover that will become confined to the northern shallow lakeshores during mid-to-late winter by the end of the century. Ultimately, this leads to increased rainfall, not snowfall, as these projected reductions in ice cover and greater dynamically induced wind fetch lead to enhanced lake evaporation and total lake-effect precipitation (Notaro *et al.* 2015, pp. 1674-1678).

Climate change is projected to cause some northward contraction of boreal conifer forest in Minnesota (Gonzalez *et al.* 2007, p. 16, 18), with some potential loss of habitat at the southern portion of lynx habitat in the State but persistence of boreal forest in this geographic unit (Gonzalez *et al.* p. 2007, p. 19). Gonzalez *et al.* (2007, pp. 8, 13) also projected that northeastern Minnesota, including the SNF, would continue to have snow conditions suitable for lynx at the end of the century, and may serve as a refugium for lynx in the Lower 48 States. However, Moen (*in* Lynx SSA Team 2016a, p. 19) questioned this result, noting that the Gonzalez *et al*. model predicted a much larger distribution of suitable snow conditions than the area currently occupied by lynx in Minnesota. Moen presented preliminary snow modeling results that project snow conditions suitable for lynx could shrink significantly by 2055, be limited to extreme northeastern Minnesota by 2070, and could be entirely absent from the state by 2095 (Moen and Catton *in* Lynx SSA Team 2016a, p. 19). Frelich (*in* Lynx SSA 2016, p. 14), concluded that Minnesota could lose the boreal biome completely, possibly within the next 60 to 70 years, with unmitigated climate change. Similarly, Galatowitsch *et al*. (2009, pp. 2015-2016) concluded that the boreal forest of the Northern Superior Uplands (which encompass this geographic unit) will likely be lost by 2069 as a result of warmer summers and more frequent and longer droughts associated with climate change. If a refugium for lynx does persist in this unit in the future, it would likely only consist of the small area in Cook County (the extreme northeastern corner of the unit) with slightly higher elevations (518-701 m [1,700-2,300 ft) than the majority of the area that is now considered lynx core habitat and would, therefore, support a much smaller number of resident lynx than likely occur in the unit now. Although uncertainties remain, as elsewhere, about the timing and magnitude of future climate-driven impacts, lynx

[26] http://www.dnr.state.mn.us/climate/summaries_and_publications/normals_snow_1981_2010.html; accessed 5.24.2016.

populations in Minnesota are expected to recede northward and decline over the next century (Lynx SSA Team 2016a, pp. 37-38).

Vegetation Management - Vegetation management similar to that conducted under current Forest Plans will likely continue into the future on Forest Service lands in Minnesota as long as the DPS is listed. These activities include timber harvest (thinning, clear-cutting, shelterwood, partial cut, and uneven-aged cutting); wildlife restoration projects that involve tree cutting, shearing, burning, seeding, and planting; prescribed burning for ecological purposes, hazardous fuel reduction, and site preparation; and mechanical site preparation. If the DPS is de-listed, the species would be placed on the Forest's Regional Forester Sensitive Species list for a minimum of 5 years, which gives it a higher priority than other species for monitoring and management during that time; however, it is unclear what the forest management would entail during or after that period of time.

Vegetation, timber, and minerals management authorized under current Forest Plans in Minnesota have the potential to adversely affect lynx and lynx critical habitat by reducing habitat quality for denning, foraging, and dispersal; disrupting travel, resting, and foraging patterns; disturbing denning females; and reducing habitat quality for lynx prey species, especially snowshoe hares. Depending on the timing, frequency, intensity, extent, amount, or other conditions, impacts may be variable among similar projects. Using the LCAS as a basis, the Forest Plans have incorporated a number of components that would reduce the risk of those impacts into the future. We expect that management direction for lynx addressing vegetation management on National Forest System lands in the future will be incorporated into revised or amended forest plans, using LCAS as a basis. Future Forest Plan revisions will likely maintain broad direction to design and implement vegetation management projects to maintain or restore conditions for lynx foraging and denning habitat and to maintain or improve juxtaposition of required habitat types and connectivity.

Over the long term, the Forest Plan will alter vegetation patterns on the landscape. Suitable hare habitat was predicted to decrease over time with implementation of the Forest Plan, but has actually increased since 2004 (USFWS 2011b, p. 51). Management activities that create unsuitable conditions for hare generally include clear-cut and seed tree harvest, and might include management-ignited fire, mechanical site preparation, salvage harvest, and shelterwood and commercially-thinned harvest, depending on unit size and remaining stand composition and structure. Suitable hare habitat is predicted to remain above the range of natural variation, which is essentially a description of conditions that existed prior to European settlement (1600 – 1900 A.D.) of the area (USFS 2004a, p. 105). Further, unsuitable habitat for lynx would vary only slightly with continued implementation of the Forest Plan and would remain distinctly below the maximum of 15 percent unsuitable in a decade prescribed in the LCAS and incorporated into the Forest Plan. Current (2010) unsuitable habitat levels are below what was predicted in the 2004 (USFWS 2011b, pp. 51-52). Because suitable habitat on National Forest System lands alone is such a high percentage within LAUs and the SNF is the majority landowner within most LAUs, we expect that in the future, the Forest would not approach the LCAS maximum of 30

percent of lynx habitat on all ownerships in an unsuitable condition within an LAU at any time, which would be ensured by corresponding guidance in the Forest Plan.

Wildland Fire Management - Unlike the Maine unit, the susceptibility of the Minnesota unit to fire may be reduced by periodic spruce budworm outbreaks. Measurable defoliation from spruce budworms has occurred in Northeastern Minnesota continuously since 1954 and is expected to continue into the future (Russell and Albers 2016, entire). Modeling to evaluate the relative strength of interactions between spruce budworm outbreaks and fire disturbances in the BWCAW showed that budworm disturbance can partially mitigate long-term future fire risk by periodically reducing live ladder fuel within the forest types of the BWCAW but will do little to reverse the compositional trends caused in part by reduced fire rotations there (Sturtevant *et al.* 2012, pp. 1286-1292). The SNF manages for wildfires through preventative measures such as fuels reductions, but does not manage for wildfires in the BWCAW. Natural successional changes and those associated with natural phenomena, such as wildfire or windstorms, are the dominant force in BWCAW ecosystems and are expected to continue to be in the future.

Habitat Fragmentation - Ravenscroft *et al.* (2010, p. 329) considers northeastern Minnesota forest landscape as largely unfragmented. The BWCAW remains intact and contiguous with Canada. Within the SNF, natural disturbances and vegetation management activities make up most of the annual human-caused fragmentation in actively managed portions of the Forest. These areas typically re-vegetate within 3 to 5 years, depending on the forest type and number and type of activities (USFS 2011a, p. 119). The SNF's Forest Plan (USFS 2004a, Appendix E) provides direction on limiting lynx habitat fragmentation and the Forest actively consolidates habitat through land acquisitions and exchanges. The Forest direction limiting habitat fragmentation is expected to continue as long as the DPS is listed.

Fragmentation, Development, and Human Access - Throughout the SNF and northern Minnesota, human activities have reduced connectivity between patches of suitable lynx habitat. Development for residential and commercial uses, as well as roads, railroads, and utility corridors have all interrupted linkage corridors. Still, much of the land within the Forest remains undeveloped and lynx habitat remains relatively intact and well connected. This is particularly true on the SNF, which has a "high standard" road density of roughly 0.45 mi/mi^2 outside the BWCAW.

Human access to lynx habitat occurs by foot and motorized vehicle, including recreational and off-road motor vehicles (RMVs and ORVs), and generally occurs on trails, low standard roads, and temporary roads developed for management operations, particularly timber harvests, and more recently, minerals exploration. While open, these roads provide access to lynx habitat. As northern Minnesota has become more developed and the human population has increased, the SNF has sustained increased visitation in recent years (USFS 2011a, p. 5) which increases the opportunity for human-lynx encounters, especially by trappers. Lynx are likely to continue to be incidentally trapped at the current rate as a result of continued access via low standard roads and trails on the Forest. Any corridor open to RMVs provides the potential for Forest visitors to incidentally trap, shoot, or collide with lynx. Temporary road construction for minerals

exploration projects may contibute significantly to temporary road densities and increase human access during the time the roads are being used. Temporary roads in mineral exploration projects may stay open longer (1-15 years) than those predicted by the Forest Plan EIS for resource management (1-5 years). If these sites are left accessible to the public, then human-lynx conflicts may increase. Additionally, intersections of new roads, closed temporary roads and/or roads open to the public are likely to become parking areas for cars, which would indirectly increase public access. Further, these corridors could increase potential competition through increased snow compaction. Effective road closures, however, may reduce the potential effects to lynx and their habitat.

Energy and Mineral Development - Mining (e.g., iron ore and taconite mining) is occurring at several locations in or near the lynx core habitat area in northeastern Minnesota (MNDNR 2016c, entire). Large-scale mining operations on non-Forest land could result in irreversible or irretrievable loss of lynx and hare habitat. Minerals exploration has increased and is occurring at many locations in northeastern Minnesota, which may lead to more large-scale mining projects. Vegetation clearing for minerals exploration projects may have temporary impacts to lynx and hare habitat at drill pad sites, although impacts from pad sites are expected to be minimal and temporary because the foot print of individual drill pads is typically small and the cleared land is expected to re-vegetate. Drill pad site preparation includes vegetation clearing on small patches of land (average of approximately 0.6 ha [1.6 ac]). This cleared land may provide snowshoe hare habitat after it has time to revegetate. Mineral exploration activities use existing Forest roads but also may require construction of new roads and may potentially add a significant number of road miles. Land exchanges associated with proposed mining sites could result in a loss of lynx and hare habitat under Forest management, but may also result in consolidation or gain of habitat with newly acquired lands (*e.g*, the Forest may able to consolidate lands that they can then manage for lynx). Stone quarry extraction operations are also scattered throughout the unit (MNDNR 2016c, entire) and may impact lynx and hare habitats.

Conclusion

We concur with the expert panel that this unit is very likely to continue to support resident lynx in the near-term (2025) and mid-term (2050). However, after reviewing the scientific literature concerning climate change projections (diminishing snow conditions, northward contraction of boreal forest, lack of elevational refugia, potential for increased competition, disease, and insect outbreaks), some Core Team members were less optimistic about the future of lynx in Minnesota than the lynx expert panel. Depending on future emissions levels, the likelihood that this unit will continue to support resident lynx at the end of the century may be lower than the 35 percent (median most likely) estimate based on expert opinion. The threat for which the lynx was listed, lack of specific conservation direction, associated regulations, and lynx forest management planning has not been addressed on private lands in Minnesota, except through voluntary guidance. There is some uncertainty about the future of forest management and future development on private forest lands in Minnesota and in adjacent lands in Ontario, although there are some basic voluntary management guidelines for private lands in Minnesota. Further, if the DPS is de-listed, there is uncertainty whether the lynx direction on Forest lands would

continue into the future. It is projected that habitat will diminish and recede northward over the mid- to longer-term because of continued climate warming. Hybridization and competition with bobcat also may increase with diminishing snow conditions because of continued climate warming, and it is uncertaint how insect outbreaks or disease may affect habitat and lynx in this unit.

The Core Team believes the Minnesota lynx populations would be expected to decline more rapidly in a future scenario without Federal listing. The lynx is designated as a species of special concern (MNDNR 2013, p. 2), a less restrictive designation than state threatened or endangered. There is a closed season on lynx, and it is expected that intentional take would continue to be prohibited until the population reached sustainable levels defined by the state. In Minnesota, the large proportion of lynx core area owned by the Forest Service provides a nexus for USFWS review of Forest projects under section 7 of the Endangered Species Act (i.e., there is rarely federal funding spent on forestry and no federal permits required for forest management on private lands), which would be lost post de-listing. Because of their Federal listing, Canada lynx are recognized as a priority species for planning by Federal, Tribal, State, and private forest landowners. Voluntary guidelines that consider the Federal listing status may guide private landowners to consider measures to help conserve listed species in the future. Without Federal listing driving voluntary conservation guidelines, however, there could be reduced incentive for some private forest landowners to intentionally engage in forest management to benefit lynx. With current Federal listing, there is a nexus for the USFWS to review other projects in northeastern Minnesota (e.g., Army Corps of Engineers permits for wetland impacts) for new highways, transmission lines, large-scale energy development, mining, and residential and commercial development. Without Federal-listing, the agencies funding or permitting these projects would not be required to consider impacts to lynx and designated critical habitat. The Core Team concludes that a future scenario without Federal listing would likely result in increased habitat loss and fragmentation and reduced incentive for habitat protection initiatives in northeastern Minnesota.

Lynx would be at greater risk without Endangered Species Act section 9 prohibitions against take. In a future scenario without Federal listing, Minnesota's incidental take planning effort for trapping would become moot, likely resulting in diminished protective measures to minimize injury, take, and mortality of lynx. Even with these prohibitions and protections, incidental trapping of 16 lynx has been reported in Minnesota since listing, resulting in at least 6 mortalities. It is uncertain if lynx would become a legally trapped furbearer in Minnesota if the DPS was not listed (although a legal wolf hunt was reinstated after that species was delisted in Minnesota, so regulated trapping could also be considered for lynx if the DPS was not listed). Seven lynx have been illegally shot and reported or otherwise discovered since listing. Illegal shooting and non-reporting could increase without Federal protection. Education efforts by Federal and State agencies and law enforcement agents may have helped to reduce illegal shooting of lynx in this unit. With a diminished snow regime, populations of bobcats could increase and expand north and eastward into areas currently occupied by lynx. Incidental take of lynx from bobcat trapping and hunting activities would likely increase without Federal listing. Similarly, fisher, fox, and coyote populations may increase in a diminished snow regime in

northern Minnesota and trapping would be expected to occur there that could lead to greater incidental take of lynx. We believe that despite a closed hunting and trapping season, incidental take would continue and possibly increase and could become a significant stressor to a population of lynx that could be substantially diminished between mid- and late-century.

After considering the best available scientific information, including the opinions of lynx experts summarized above, the Core Team was less optimistic than the experts about the long-term (end-of-century and beyond) likelihood that resident lynx will persist in this geographic unit. All potential stressors –climate change, habitat loss and fragmentation, mining and development – are increasing in frequency, intensity, and extent. Lynx habitat in the next few decades will likely shift north to areas that will be more influenced by climate change and northward range expansion by bobcats. Thus, we conclude that this unit's ability to support resident lynx will likely diminish in the future, and the lynx population will likely decline as the quantity and quality of boreal forest habitat declines. Although there are voluntary forest management measures to consider listed species on private forest lands, there are no commitments by private forest landowners to manage specifically for lynx conservation. We also believe that climate change will be a significant stressor to lynx in this unit; slightly more so than expressed by most of the experts. Snow depth and duration in the area currently supporting resident lynx are projected to decline significantly by the end of the century, likely to the detriment of both hare and lynx populations. Unlike most other units, as snow condition decline there is little potential for elevational refugia for lynx in Minnesota except, perhaps, a small area of slightly higher elevation in the extreme northeastern corner of the unit. The boreal forest in this unit is already being replaced by northern hardwoods because of climate warming. Frequent forest cutting and disturbance, including a potential insect outbreak, could accelerate conversion to northern hardwoods. We acknowledge that the rate of boreal decline is uncertain, but note that some of the modeling we reviewed suggests that the spruce-fir forest type could nearly disappear from Minnesota by late-century under both low and high emissions scenarios. Climate models also portend declining snow conditions under low- and high-emissions scenarios. Because increases in temperature are thus far tracking high emissions scenarios, we are less optimistic for snow conditions that favor lynx by mid- to late-century. In the past decade, interest in development has increased in lynx critical habitat, especially proposals for large-scale mining developments. Although we expect resident lynx to persist in this unit through 2025 and 2050, we conclude that the stressors described above, individually and cumulatively, could diminish lynx habitat and numbers in this unit. If these stressors are not abated, we believe that resident lynx in this unit will face a slightly greater risk of extirpation by the end of the century than was predicted by lynx experts.

5.2.3 Unit 3 - Northwestern Montana/Northeastern Idaho

Expert Projections of Lynx Persistence

When considering the probability that this unit would continue to support resident lynx in the future, experts noted that despite projected losses of favorable forest and snow conditions, climate models project that some boreal forest will persist in this unit and that it will maintain

some areas of suitable snow into the future. Experts also noted that lynx in this unit primarily occupy public lands, which are actively managed for lynx into the future. Experts also considered recent and projected future increases in wildfire frequency, size, and intensity (Lynx SSA Team 2016a, pp. 41-43). Additionally, because of its connectivity to lynx populations and habitats in Canada, its large geographic extent, and the relatively large number and broad distribution of resident lynx it is thought to support, experts felt that future extirpation of lynx from this unit from either reduced genetic health or a catastrophic event is unlikely (Lynx SSA Team 2016a, pp. 25-34).

Overall, experts assigned a higher likelihood of persistence in this unit compared to the other geographic units. Most lynx habitats in this unit occur on Federal lands that are managed for lynx conservation, but 1 expert noted that little has been done to document whether lynx are responding to this management. The recent sale of large tracts of private commercial timberlands in the central part of this unit to The Nature Conservancy has increased protection for lynx via conservation easements managed for lynx. Habitats in some areas should improve in the near future as previously cut or burned areas mature into dense stands. Unlike the Maine and Minnesota geographic units (but similar to most other western units), high elevations in this unit could buffer the effects of climate change by providing for the upslope migration of lynx habitats and snow conditions that climate models predict. However, this would result in even patchier and more isolated islands of habitat in high elevation areas that would be more prone to extirpation from catastrophic or stochastic events. Competition from coyotes and bobcats seem to be less of a concern for this unit.

This unit has unimpeded connectivity with Canada, but some experts questioned whether this geographic unit depends on intermittent immigration of lynx from Canada, and whether the historical lynx population cycles in Canada believed to have fueled such immigration are still occurring or will into the future. There doesn't appear to be much demographic input from recent cycles. There is evidence of lynx from this unit moving north into Canada, but little evidence of demographic interactions among the 3 subpopulations (Purcell Mountains, Seeley Lake, and Garnet Mountains) in this unit. Experts noted that the Garnet Mountains subpopulation at the southern end of this unit may have recently become extirpated (a single lynx was later [February, 2016] confirmed by DNA analysis in this area, suggesting the potential for natural recolonization of this range, but no other lynx were documented during winter 2016/2017).

Discussion among experts indicated that fire was more of a concern for this unit. Increased fire extent and severity or other catastrophic events and small subpopulation effects in separated mountain ranges could affect lynx persistence in the future in some parts of this unit. Fire exclusion in this area for the last 100 years likely resulted in the accumulation of fuels; however, this unit may have a reduced probability of a catastrophic fire over time because of recent changes in management and recent fires that may have reduced fuels. Out to the year 2050 and beyond, some experts felt there may be more pressure on lynx populations in this unit from continued increases in fire extent and severity. Other experts expressed a different opinion of the overall effect of fire in this unit, indicating that it may actually improve habitat over time, and

that whether fires improve or degrade habitat depends on the frequency, intensity, size and spatial extent of future fires.

Experts discussed the possibility for increased precipitation and warmer temperatures in this unit because of climate change, and how this might affect lynx habitats. Boreal/subalpine forest may move up in elevation as described above; however, experts expected a shift in forest composition and diminished lynx habitat quality in the future with climate change. It is unknown how much the distribution of dry ponderosa pine (non-habitat for lynx) will increase with climate change, but it is likely to happen at some level. One expert cautioned that some climate modelers estimated that vegetation will lag about 50 years behind the projected changes in temperature and precipitation. Snow levels in lower elevation areas are already decreasing in some areas, which could lead to smaller areas for lynx to use in winter in the future.

Taking all of these factors into consideration, experts provided “most likely” persistence probabilities of 95 to 100 percent (median = 98 percent) in the near-term (year 2025), 70 to 100 percent (median = 90 percent) at mid-century, and 50 to 90 percent (median = 78 percent) at the end of the century (fig. 12). As they did for most other geographic units, all experts indicated an initially high and subsequently decreasing likelihood that resident lynx will persist in this unit, with uncertainty increasing substantially over time.

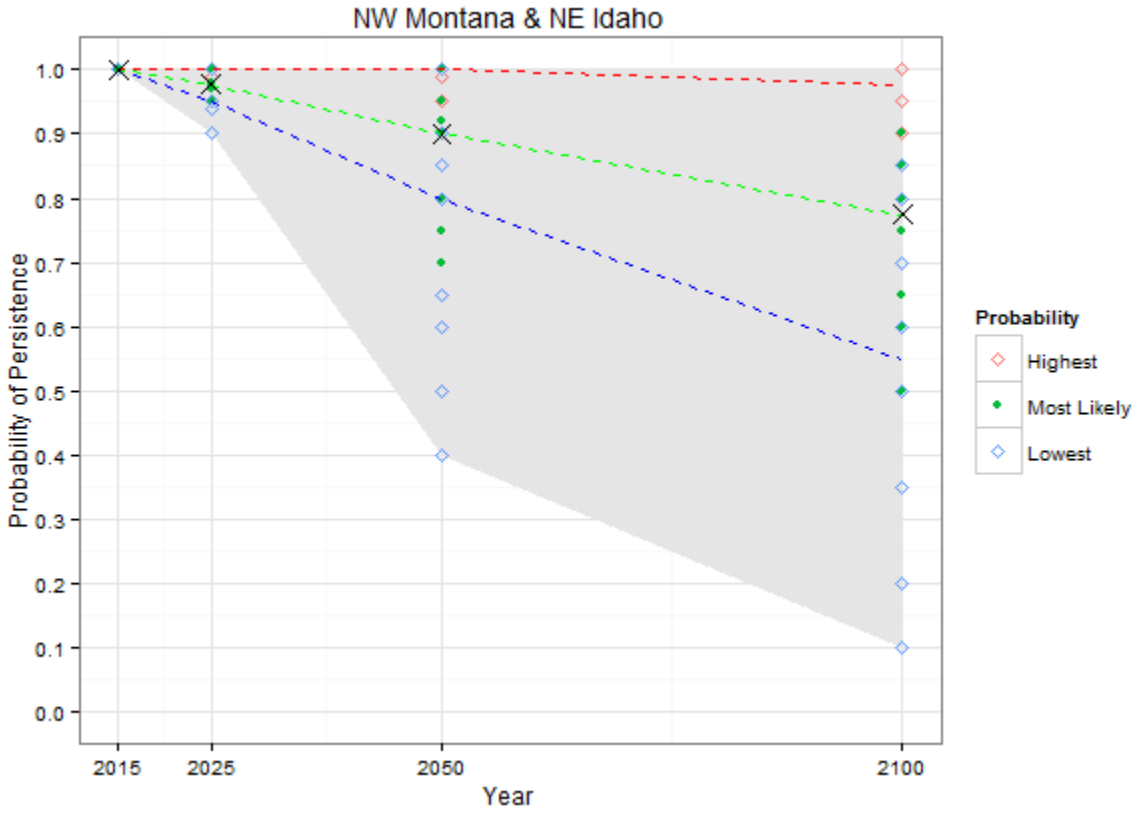

Figure 12. Lynx expert estimates of the probability that the Northwestern Montana/Northeastern Idaho Geographic Unit will continue to support resident lynx in the future (at years 2025, 2050, and 2100).

Service Evaluation of Factors Potentially Influencing Future Conditions

Regulatory Mechanisms - Federal, State, and Tribal regulations and land management direction could change in the future, but such changes and their potential impacts on lynx populations and habitats are difficult to predict. Because most (84 percent) of this geographic unit consists of Federal lands, the regulations and guidance that govern management of those lands have the greatest potential to influence future lynx habitats and populations in this unit. When Forest Service, Park Service, and BLM management plans are revised or amended, they require opportunities for public participation in accordance with several statutes (e.g., the National Environmental Policy Act [NEPA], National Forest Management Act [NFMA], National Parks and Recreation Act, Federal Land Policy and Management Act [FLPMA]; USFWS 2014 pp. 26-34, also see 3.1). If plan amendments or revisions may affect listed species, management agencies must consult with the Service in accordance with section 7 of the ESA. If in the future the lynx DPS is determined by the Service to no longer warrant listing under the ESA (i.e., if the DPS is removed from the *Federal Lists of Endangered and Threatened Wildlife and Plants*), the ESA requires the Service, in cooperation with the States, to monitor the DPS for a minimum of 5 years to assess its ability to sustain itself without the ESA's protective measures. If, within the designated monitoring period, threats to the DPS change or unforeseen events affect its stability, then the DPS could be relisted or the monitoring period extended. Given these requirements, we expect that future Federal management direction will continue to include regulations and guidance protective of lynx, although specific measures may change as new information becomes available.

We anticipate that future Federal management direction will include continued management of national parks, designated wilderness and roadless areas, and other areas with nondevelopmental land-use allocations to maintain natural ecological processes, which should maintain natural disturbance regimes and landscape-level habitat mosaics to which lynx are adapted (although continued climate warming [see below] may preclude maintenance of historical disturbance and landscape patterns). Regardless of the future listing status of the DPS, these lands will continue to be managed in accordance with the acts described above, as well as the National Park Service Organic Act and the Wilderness Act.

We also expect that Federal management into the future will include continued management of lands with developmental allocations to avoid or minimize potential impacts of vegetation management (timber harvest, thinning, salvage logging, other silvicultural prescriptions), wildland fire management (fire suppression, fuels reduction, prescribed fires), energy exploration and development, recreation, or other management activities with the potential to affect lynx. Current and likely future objectives include (1) managing vegetation to mimic or approximate natural disturbance and succession processes while maintaining habitat components necessary for lynx conservation; (2) providing a mosaic of habitat conditions through time that supports dense horizontal cover, high hare densities, and winter hare habitat in both young regenerating and mature multi-story forest stands; (3) using fire (natural and prescribed) to restore ecological process and maintain or improve lynx habitat, and (4) focusing vegetation management in areas with potential for improving winter hare habitat (BLM 2004a,

pp. 2-3; USFS 2007, Attachment 1, p. 2). Although specific standards and guidelines may change as new scientific information and management techniques become available, we anticipate continued Federal management designed to conserve or restore the capacity of the areas that historically or recently supported resident lynx populations, including the Northwestern Montana/Northeastern Idaho Geographic Unit, to continue to do so in the future.

On non-Federal lands (about 16 percent of this unit), as described above (sections 3.1.1 and 4.2.3, Habitat Status), recent acquisitions and conservation easements on some of the private lands in this unit will also reduce the likelihood of future adverse impacts to important lynx habitats. Similarly, the MTDNRC HCP includes a 50-year commitment to manage most (64 percent) State lands in this unit to conserve lynx foraging, denning, and connectivity habitats. Additionally, the Confederated Salish and Kootenai Tribe's objective to manage wildlife and habitats on the Flathead Reservation for future generations (section 3.1.2, Tribal Management) suggests continued management to conserve lynx habitats on Tribal lands.

Given the commitments and management objectives and practices described above, implementation of current and future regulatory mechanisms will likely continue to support conservation and restoration of lynx habitats in this unit and improve the likelihood that it will continue to support resident lynx into the future.

If the DPS was not listed, it is possible that State-managed trapping could resume in this and perhaps other geographic units. We expect that would only occur if scientific evidence strongly suggested the presence of a harvestable surplus of lynx and that harvest quotas would be carefully managed to ensure that the viability of resident lynx populations would not be diminished.

Climate Change - The recent evidence of climate change and the numerous mechanisms by which continued warming may affect future conditions for lynx and the potential consequences for the DPS and specific geographic areas are described in detail in section 3.2. Also, as noted above in section 4.2.3, evidence of warming and related impacts (increased temperatures, reduced snowpack, earlier snowmelt, and increased drought leading to increased fire) have already been documented in the Northern Rocky Mountains, including this geographic unit. Climate projections suggest these impacts are likely to continue and to result in future northward and upslope contractions of the snow conditions and boreal/subalpine vegetation communities that support lynx. This is expected to cause loss and increased fragmentation and isolation of lynx and hare habitats and, therefore, declining and more vulnerable lynx populations in the DPS and in this geographic unit (Carroll 2007, entire; Gonzalez *et al.* 2007, entire; ILBT 2013, pp. 69-71; 79 FR 54810-54811; Lawler and Wilsey *in* Lynx SSA Team 2016a, pp. 15-16; Siren *in* Lynx SSA Team 2016a, p. 15).

Snow conditions in this unit are projected to become less favorable, with an overall decrease in snowpack after mid-century as a result of a shorter snowfall season, fewer days with snowfall, and a lower proportion of winter precipitation in the form of snow (more as rain; Siren *in* Lynx SSA Team 2016a, p. 15). In this unit, the probability of snow conditions comparable to those

associated with historical lynx occurrence records is modeled to decline from 90-95 percent from 1961-1990 to 50 percent across much of the unit by the end of this century (years 2071-2100), although some parts of this unit are projected to retain favorable snow conditions (Gonzalez *et al.* 2007, pp. 12-14; Lynx SSA Team 2016a, pp. 15, 41). Tennant *et al*. (2015, pp. 2818-2820) simulated snowpack loss in the Northern Rockies (ID, MT, WY) and predicted that watersheds between 1,000 - 2,000 m (3,281 – 6,562 ft) elevation would experienced the greatest snowpack losses, while those > 2000 m (6,562 ft) would be more resilient to significant warming. Given the greater predicted snowpack persistence at some elevations used by lynx in this unit and the considerable area of potential climate refugia in mountainous terrain (Dobrowski 2011, pp. 1027-1029; Curtis *et al*. 2014, entire; Holden *et al*. 2015, entire; Morelli *et al*. 2016, entire), at least a portion of lynx distribution in this unit is likely resilient to climate-driven losses in snowpack (IDFG 2017a, p. 7).

There will likely be a lag time between the loss of favorable snow conditions and an eventual shift or contraction in vegetative communities (Lynx SSA Team 2016a, pp. 43, 59; also see section 3.2), but continued warming is projected to convert much of the boreal forest in this unit to temperate conifer forest by the end of the century (Gonzalez *et al.* 2007, pp. 15-17). The ability of lynx and hare populations to persist during this lag and to adjust to future habitat distributions is uncertain, but habitat quality, quantity, distribution, and connectivity are expected to decline, likely compromising this unit's future ability to support resident lynx populations.

Climate change has also been linked to increased wildfire size, frequency, and intensity in this geographic unit, and to increased frequency and extent of forest insect outbreaks in other parts of the DPS. These factors are likely to have temporary impacts on future lynx habitat, with regeneration to hare and lynx foraging habitat 20-40 years post-disturbance, depending on local climate, elevation, and topography. However, if extensive areas are affected, the ability of these landscapes to continue supporting resident lynx may be compromised, and lynx populations may be unable to persist until favorable vegetation conditions return. This is especially true where habitats and populations are naturally fragmented and patchily-distributed, and where landscape-level hare densities are already marginal, which appears to be the case for much if not all of this geographic unit.

Climate change has also been implicated in observed declines in the amplitude of northern hare and lynx population cycles (Yan *et al.* 2013, p. 3269). If lynx populations in this geographic unit are influenced (as is suspected) by intermittent immigration from the north, and if climate change diminishes the likelihood of future immigration via muted northern lynx population cycles, the future persistence of resident lynx in this unit is uncertain (see also Other Factors, below).

Given the factors described above, recent and projected future climate warming will likely reduce this geographic unit's ability to continue to support resident lynx into the future. The timing and magnitude of climate-driven impacts are uncertain; however, all are anticipated to adversely affect, and none are expected to benefit, lynx populations in this geographic unit. Climate model uncertainties and resolution limits, combined with our imperfect understanding of

historical and current lynx numbers and habitat distributions, preclude quantifying future habitat quality and distribution or lynx population dynamics in this unit. Nonetheless, it appears likely that continued climate warming will reduce future habitat quality and quantity and, therefore, the likelihood that this geographic unit will support resident lynx in the future.

Vegetation Management - Future vegetation management and, therefore, its implications for future lynx habitats and populations in this unit, are closely linked to the current and future regulatory mechanisms described above. As noted, we expect future vegetation management on all Federal and most non-Federal lands in this unit to continue to focus on maintaining and restoring lynx habitats by implementing standards, guidelines, and BMPs based on the best available scientific information. We expect these measures to continue to benefit lynx by limiting detrimental effects of timber harvest, thinning, fuels management, etc., and by encouraging the use of these activities to restore, improve, or create high-quality hare and lynx foraging habitats where feasible.

Wildland Fire Management - As noted in sections 3.4 and 4.2.3, past wildfire management, including fire suppression, does not appear to have altered the historical fire regime in lynx habitats in the western contiguous United States, including this geographic unit. Also as noted there and in sections 3.1.1 and the Regulatory Mechanisms section of this chapter, current Federal management restricts, with few exceptions, fire management (fuels reductions, prescribed fires, etc.) impacts to lynx habitats, and it promotes the use of such activities and wildfire response to conserve and restore lynx and hare habitats. We expect such conservation-focused fire management to continue and, therefore, to benefit lynx rather than to affect them detrimentally in the future.

However, as also noted in section 4.2.3, increased wildfire frequency, size, and intensity have been documented in this geographic unit, and that pattern is anticipated to continue in the future with continued climate warming. Although this increased wildfire activity does not appear to have diminished this unit's current ability to support resident lynx, it could do so in the future depending on the location, timing, and extent of future fires. As described in section 3.4, increases in fire frequency and size could rapidly convert large areas to the temporarily unsuitable stand-initiation successional stage, thus reducing the amount and altering the distribution of higher-quality habitats and potentially compromising this unit's ability to support a resident lynx population until burned habitats recover. Because lynx habitats are naturally patchily-distributed and landscape-level hare densities already marginal in many parts of this unit, it is possible that very large wildfires or many fires over a short time period could shift some parts of this unit from being just barely capable of supporting resident lynx to being incapable of doing so in the future. Although fire suppression was considered a potential risk factor for lynx in the DPS range, given the trends discussed above and the likely continued increase in future fire activity resulting from continued climate warming and drying, it may be necessary to reconsider whether fire suppression in some lynx habitats could benefit lynx by reducing the potential for extirpation of resident populations, especially in places already apparently only marginally capable of supporting them.

Habitat Loss/Fragmentation - As described above in section 4.2.3, lynx habitats in this unit are naturally fragmented but otherwise appear to be largely intact relative to historical conditions in most of this geographic unit. Although some localized impacts of past timber harvest and related activities have likely occurred, anthropogenic habitat loss or fragmentation does not appear to have broadly diminished this unit's ability to support resident lynx. Current and probable future management for conservation of lynx habitats suggests that broad-scale habitat loss or fragmentation resulting from timber harvest and other development activities are unlikely. The most likely sources of future habitat loss and fragmentation in this unit are the climate-mediated influences discussed above: increased wildfire activity and the projected contraction of vegetation and snow conditions favorable for lynx. Increased frequency, size, and severity of forest insect outbreaks, also driven by climate warming, has been documented in other geographic units and could occur in this unit in the future, too, resulting in temporary habitat loss and increased (though also temporary) fragmentation.

Additional highway construction and other transportation developments are likely in this unit, but the future locations, size, and potential impacts of such projects are difficult to predict. We are not currently aware of plans for specific major highway/road projects in this unit that would potentially impact lynx habitats and increase future habitat loss or fragmentation. Other potential sources of future habitat loss and fragmentation include recreation, minerals/energy development, and backcountry roads and trails; these are all considered second tier anthropogenic influences (ILBT 2013, pp. 78-85) that are unlikely to exert population-level influences, despite potential impacts to individual lynx.

Other Factors: *Connectivity/immigration* – As described above and in section 4.2.3, maintaining connectivity between this geographic unit and lynx populations in Canada is thought to be important, although it is uncertain if or to what degree immigration of lynx from Canada is essential to the persistence of lynx in this unit. A number of climate-mediated factors have been suggested as contributing to changes in the periodicity and amplitude of northern lynx and hare population cycles (see section 3.2), which could alter the timing and magnitude of lynx immigration into the contiguous United States from Canada. If lynx populations in this unit rely on immigration from Canada which is no longer occurring or has been substantially reduced relative to historical conditions, population declines and a reduced probability of persistence among resident populations would be expected.

Although the extent to which this factor may influence lynx populations in this unit is unknown, the population growth rate estimated for the Seeley Lake area ($\lambda = 0.92$, declining trend 1999-2007; Squires *in* Lynx SSA Team 2016a, p. 20) may reflect a gradual decline of a resident lynx population that needs but is not receiving adequate immigration. If this growth rate was applied continuously to a hypothetical resident population of 250 lynx (the midpoint of the range in the number of resident lynx this geographic unit may support based on expert opinion [Lynx SSA Team 2016a, p. 41]), the population would decline to 100 lynx after 11 years, about 50 lynx after 20 years, and roughly 20 individuals after 30 years. Vulnerability to demographic, environmental, and genetic stochasticity would increase as lynx numbers decreased, resulting eventually in an increased likelihood of functional extirpation of lynx from this unit (i.e., a lower

probability that the unit would continue to support a persistent resident lynx population). However, Schwartz (2017, p. 4) noted that very low immigration rates (less than 1 female/year on average for a theoretical population of 100 lynx) could provide population stability or even growth, suggesting that the Seeley Lake population and perhaps other DPS populations are probably being sustained by low levels of undetected immigration. Additionally, as noted above, the lynx population in the Purcell Mountains in the northwestern part of this unit was estimated to be increasing (λ = 1.16, 2003-2007; Squires *in* Lynx SSA Team 2016a, p. 20) over the last 4 years of the period for which the Seeley Lake population was estimated to be declining. In the absence of information on historic, recent, and likely future rates of immigration and its contribution to the persistence of lynx populations in this geographic unit, impacts of potentially reduced future immigration are difficult to project and are largely speculative at this time.

Conclusion

After reviewing the scientific literature and evaluating the factors that may influence lynx persistence in this unit, we concur with the experts' conclusion that this geographic unit is likely the most secure in the DPS. We conclude that it is very likely to continue to support resident lynx in the short term (through 2025) and through mid-century, although the number of lynx, the amount and distribution of high-quality habitat, and landscape-level hare densities are all likely to decline by mid-century as a result of continued climate warming and associated impacts. We also agree that this unit is more likely than not to support some resident lynx at the end of this century, although at that time we expect lynx numbers and distribution would be substantially reduced from the current condition and would, therefore, be more vulnerable to demographic, environmental, and genetic stochasticity and to catastrophic events, resulting in diminished resiliency. We acknowledge that under a *status quo* or increasing greenhouse gas emissions scenario the rate of climate-mediated loss, fragmentation, and isolation of habitat could, perhaps in concert with other factors (e.g., continued increases in wildfire size, frequency, and intensity and decrease in or complete loss of immigration from Canada), result in the functional extirpation of resident lynx from this unit before the end of the century. We also acknowledge, however, that there is great uncertainty with all persistence predictions that far into the future.

5.2.4 Unit 4 - North-central Washington

Expert Projections of Lynx Persistence

Compared to most other units, expert predicted a lower probability of persistence for this unit over the short term, and then a similar declining trajectory, with increasing uncertainty, by the end of the century, reflecting a more pessimistic outcome for this geographic unit than most other units (Lynx SSA Team 2016a, pp. 43-45). Experts felt that the probability of lynx persistence in this unit could decrease sharply over the next 10-20 years because of extensive recent fires in lynx habitats and the time needed for these areas to regenerate back to good hare/lynx habitat. However, 1 expert predicted an increase in persistence probability by mid-century as habitats impacted by recent large-scale fires regenerate into optimal hare-lynx

habitat. After that, the probability could rebound (or decline more slowly) over the longer term as these large areas return to prime habitat providing high hare densities.

Experts agreed that the current small population is likely at greater risk of extirpation because of stochastic events, particularly if large fires in lynx habitat continue to occur in the near future as they have in the recent past. A small population also could be more susceptible to disease, though no diseases have been documented among lynx in this unit. Experts discussed the extent to which small lynx populations could be reduced before they would become highly susceptible to stochastic demographic effects. It was suggested that 15-20 breeding individuals might be the minimum needed to avoid such susceptibility. Unimpeded connectivity between Canada and this unit could allow lynx to repopulate recently burned areas after the habitat recovers. Lynx in this unit are likely the southern portion of a larger population in Canada, not really a separate, isolated small population. Factors that influenced expert persistence probabilities for this unit included fire, habitat loss, and the future loss of favorable snow conditions predicted by climate change models.

Taking these factors into consideration, experts provided “most likely” persistence estimates of 60 to 95 percent (median = 80 percent) in the near-term (year 2025), 30 to 80 percent (median = 70 percent) at mid-century, and 5 to 50 percent (median = 38 percent) at the end of the century (fig. 13). Compared to most other geographic units, experts indicated greater uncertainty regarding short-and mid-term term persistence in this unit but, as for other units, uncertainty was greatest at the end of the century.

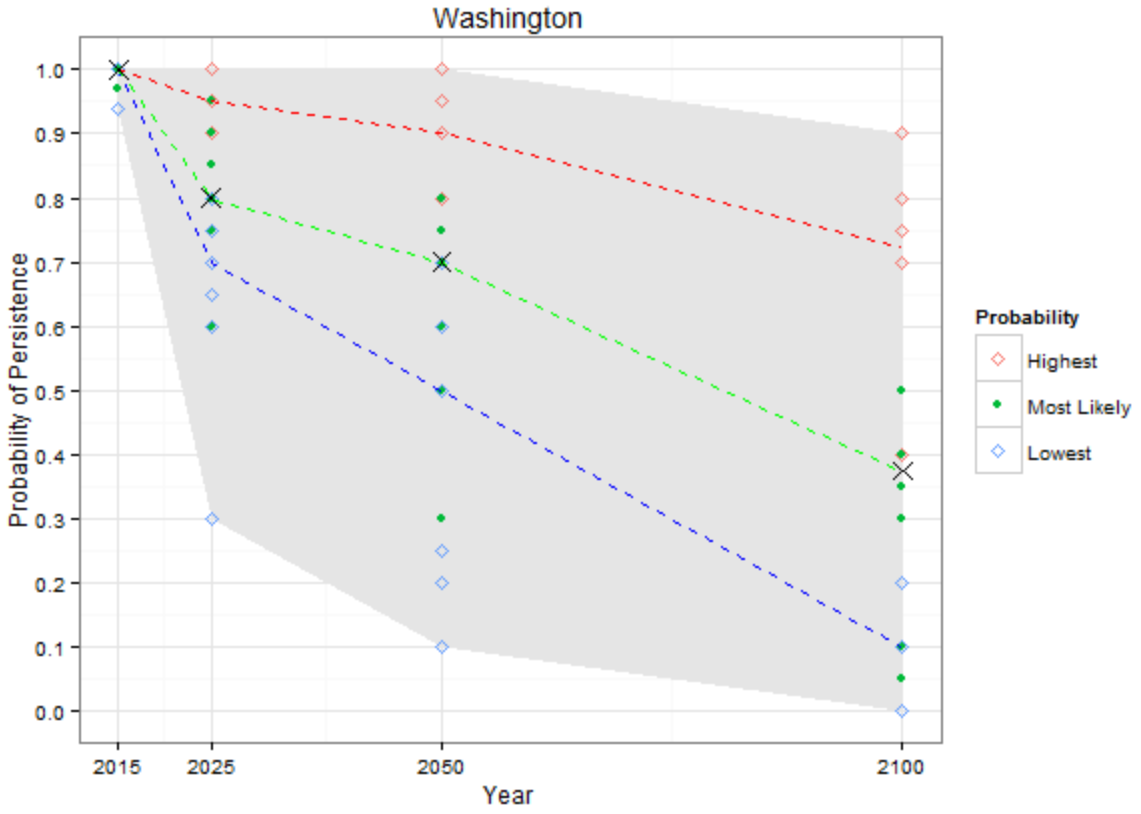

Figure 13. Lynx expert estimates of the probability that the North-central Washington Geographic Unit will continue to support resident lynx in the future (at years 2025, 2050, and 2100).

Service Evaluation of Factors Potentially Influencing Future Conditions

Regulatory Mechanisms - As described above (section 4.2.4), regulatory mechanisms currently in place guide forest management in this geographic unit for lynx conservation. We do not anticipate that existing regulatory protections for lynx would diminish appreciably in the future even if the DPS was no longer listed. On USFS lands, we anticipate that either the CA will remain in place (and/or be extended), or the OWNF and CNF will revise or amend their respective LRMPs to incorporate direction for lynx management similar to the formally amended LRMPs that have been implemented on all other national forests in the DPS range (see section 3.1.1). Currently, both the OWNF and CNF are in the process of amending or revising their LRMPs. We expect that management direction for lynx conservation addressing vegetation management, wildland fire management, and habitat fragmentation on National Forest System lands will be incorporated into the revised or amended LRMPs. We expect that both the OWNF and CNF will be required to manage for lynx and their habitat into the future because both forests will have incorporated lynx management direction into their respective LRMPs. We acknowledge that LRMPs can be amended or revised; however, LRMPS are typically in place for 15 years or longer, and the Service, other Federal and State agencies, and the public would have opportunities to comment on any proposed amendments or revisions to LRMPs through

the NEPA process. Therefore, we expect that both the OWNF and CNF will continue managing for lynx and their habitat into the future regardless of the DPS's listing status.

On State lands in this unit, the WADNR has committed to implementing its Lynx Habitat Management Plan until lynx are delisted or until 2076, whichever is shorter (WADNR 2006, p. 6). Additionally, the WADNR's internal policies encourage consideration of lynx habitat on lands it manages including participating in efforts to recover and restore endangered and threatened species, providing upland wildlife habitat, and establishing Riparian Management Zones. In accordance with legal obligations specified in the State's Forest Resource Plan, the WADNR will contribute to the future of Washington's lynx population by improving habitat conditions and reducing the likelihood of adverse effects on the habitat it manages (WADNR 2006, p. 6). Therefore, although some protections for lynx could be relaxed in the future if the DPS was not listed under the ESA, we anticipate that both Federal and State regulators would continue to manage for lynx conservation in this geographic unit.

Climate Change –Recent warming likely contributed to recent increases in wilfire activity in this unit and is likely to continue to do so in the future. Westerling *et al.* (2006, pp. 942-943) compiled information on large wildfires in the western United States from 1970-2004 and found that large wildfire activity has increased significantly from the mid-1980s with higher large-wildfire frequency, longer wildfire duration, and longer wildfire seasons. The greatest increases occurred in high elevation forest types including lodgepole pine and spruce fir in the northern Rockies (i.e., lynx habitat). They also found that fire exclusion (suppression) had little impact on natural fire regimes; rather, climate appeared to be the primary driver of increasing wildfire risk.

Koehler's (1990a, p. 847) estimated adult lynx density of 2.3 lynx/100 km^2 was obtained in an area supporting high-quality lynx habitat in the Meadows area of north central Washington (at least relative to other lynx habitat in Washington). Much of the lynx habitat in the Meadows was impacted by the recent large, stand replacing fires, resulting in further fragmentation of lynx habitat in the northern Cascades. Thus, the lynx densities Koehler observed in his study area may not be currently supported, because as habitat becomes more fragmented and isolated (i.e., marginal), the carrying capacity for a particular species declines.

As in other units, continued climate warming is projected to cause northward and upward shifts in spruce-fir habitats and snow conditions thought to favor lynx. In addition to potentially affecting fire return intervals, fire severity (intensity, size), and insect outbreaks, climate change is likely to affect the amount of precipitation falling as snow at elevations typically supporting lynx habitat in this geographic unit. Climate change is expected to impact the quantity, quality, and duration of snow in the Cascades. Mote (2003b, pp. 272, 274), who evaluated temperature trends in the Pacific Northwest using data collected by weather stations from 1930 to 1995, determined that the temperature increased in the Pacific Northwest and more precipitation fell in the spring and summer months, especially at elevations below 1,800 m (5,900 ft). Additionally, Mote (2003a, pp. 2-3) determined that an increasing temperature and precipitation trend from 1950 to 2000 is correlated with a 40 percent decrease in the snow water equivalent in the Cascades. Mote *et al.* (2005, p.45) determined that the Cascades are very sensitive to

temperature changes, with large increases in temperature potentially resulting in significant declines in snowpack. Corroborating Mote's results, Stoelinga *et al.* (2010, p. 2474) determined that the Cascade snowpack has declined by up to 40 percent in the latter half of the twentieth century, which resulted from increased temperatures. Furthermore, temperatures are predicted to continue increasing by 2° to 5°C (3.6° to 9°F) over the next century and are expected to cause further and accelerated losses in snowpack in the Cascades (Mote *et al.* 2005, p. 48). Continued declines of snowpack in the Cascades through 2025 are predicted to range from 9 percent (Stoelinga *et al.* 2010, p. 2486) to 29 percent (Elsner *et al.* 2010 *cited in* Stoelinga *et al.* 2010, p. 2486), which may also affect lynx densities supported in the Cascades.

Finally, some of the best lynx habitat in this geographic unit occurs on plateaus that may be more vulnerable to impacts of climate change because of the absence of higher elevation areas to which habitats and lynx could migrate in response to climate warming (Lynx SSA Team 2016a, p. 42). Thus, in addition to the recent losses of lynx habitat to large wildfires, coupled with increasing wildfire risk, the potential for the Cascades to support a viable lynx population may be further reduced because of projected climate-mediated decreases in snow quantity and quality. Overall, our review of the published literature on this subject leads the Core Team to conclude that climate change poses the greatest risk to the long-term persistence of lynx in this geographic unit.

Conclusion

After considering the best available scientific information and the opinions of lynx experts summarized above, the Core Team generally agrees with the experts that this geographic unit, like most others, has a relatively high likelihood of continuing to support a resident lynx population over the short-term (2025) and at mid-century (2050), but a lower probablility of doing so, with more uncertainty, by the end of the century (2100). As described above, the potential effects of climate change on the quantity and quality of snow, as well as the projected northward and upslope movement of spruce-fir and subalpine fir forests are likely to result in further fragmentation and reduction of lynx habitat within this geographic unit by the end of the century. More fragmented and smaller habitat patches are likely to support a smaller and more isolated lynx population that will be more vulnerable to stochastic environmental and demographic events. Over the past 25 years, wildfires have reduced lynx habitat in this geographic unit by almost 40 percent and likely reduced its carrying capacity for lynx by a similar amount. Additional future losses of lynx habitat resulting from climate-driven increases in wildfire size, frequency, and intensity may pose the greatest near-term threat to the persistence of this population. Connectivity between this unit and Canada is likely to remain intact in the future. Because lynx are highly mobile and able to traverse large areas of non-lynx habitat, we do not anticipate that climate change, in and of itself, will significantly affect connectivity between this geographic unit and the larger lynx population in southern British Columbia. This connectivity may contribute to maintaining a persistent, albeit smaller, lynx breeding population in this geographic unit into the future.

5.2.5 Unit 5 - Greater Yellowstone Area

Expert Projections of Lynx Persistence

Current and future factors expressed by experts as influencing probability of persistence for this unit included small population size, forest disease and insect pests, and fire (Lynx SSA Team 2016a, pp. 45-46). Some experts doubt that the GYA unit currently supports a resident breeding population of lynx. Experts indicated that climate models predict that some parts of the GYA unit could provide refugia from climate change impacts because of their high elevations and potential to maintain winter snow levels into the future. Summer conditions in this unit, however, could be drier in the future, resulting in increased fire frequency, extent, and intensity, and additional temporary habitat loss. However, regeneration of these areas and the extensive areas that have burned in the recent past may provide good habitat over the next several decades. Some experts suggested that lynx emigrating to this unit from Colorado could occupy such improved habitats in the near future. Colorado lynx have made exploratory movements into the GYA in summer months, and analysis of available data could improve our understanding of Colorado lynx movement into and use of the GYA. It is possible that lynx from Colorado could maintain lynx in GYA.

Taking these factors into consideration, experts provided “most likely” persistence estimates of 10 to 70 percent (median = 52 percent) in the near-term (year 2025), 15 to 60 percent (median = 35 percent) at mid-century, and 5 to 50 percent (median = 15 percent) at the end of the century (2100; fig. 14). Unlike other units, the expert graphs for this unit were widely variable and had high uncertainty at all time frames. This was the only unit for which most experts believed the current probability of persistence is low (i.e., that it is uncertain whether this area currently supports a resident lynx population). Some experts increased persistence likelihoods into mid-century based on the possibility that large areas impacted by the 1980s-era wildfires may by then regenerate into hare/lynx habitat, and on possible continued dispersal of lynx from Colorado into this unit. Unlike other units, where expert confidence in their predictions was initially high but decreased greatly beyond mid-century, expert uncertainty in this unit was high for all timpe periods and was related to uncertainty about whether resident lynx currently occur in the GYA.

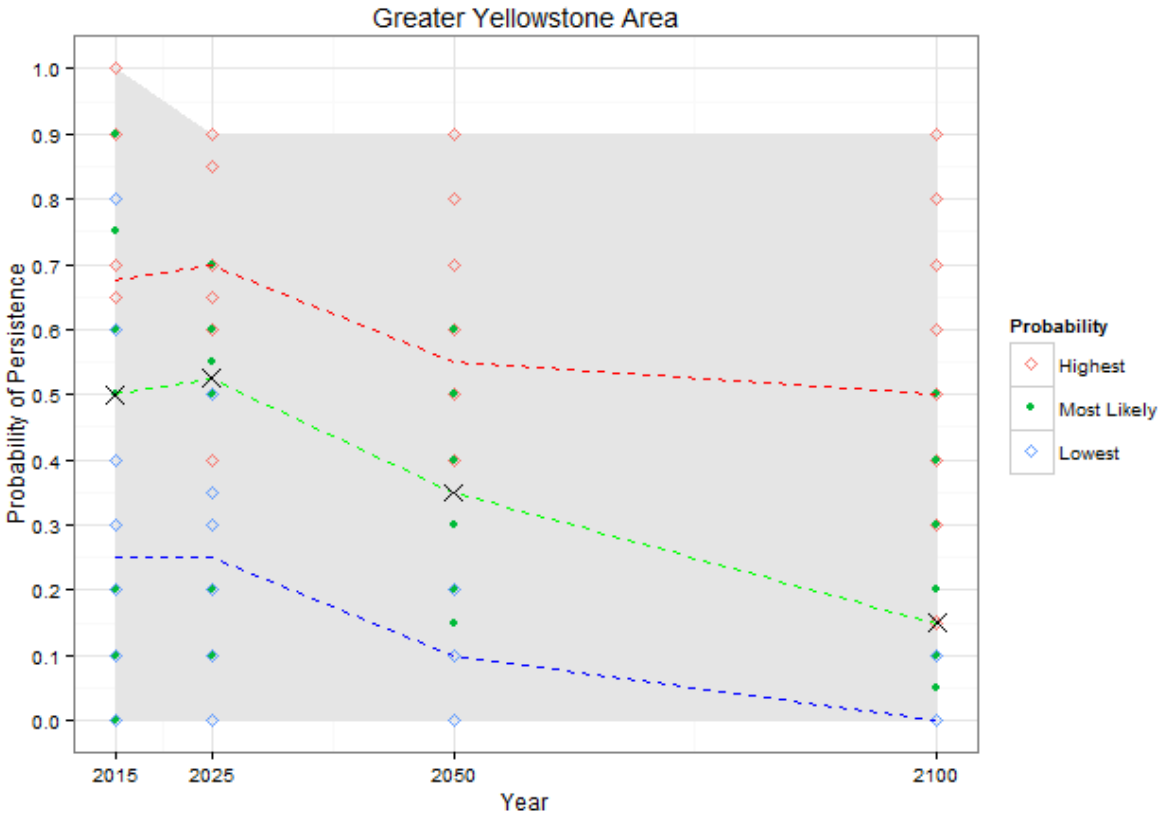

Figure 14. Lynx expert estimates of the probability that the Greater Yellowstone Area Geographic Unit will continue to support resident lynx in the future (at years 2025, 2050, and 2100).

Service Evaluation of Factors Potentially Influencing Future Conditions

Regulatory Mechanisms - As noted above in section 5.2.3, Federal, State, and Tribal regulations and land management direction could change in the future, but such changes and their potential impacts on lynx populations and habitats are difficult to predict. Federal lands account for over 97 percent of this geographic unit; therefore, regulations and guidance that govern management of those lands have the greatest potential to influence future lynx habitats and populations. Also as described above, revisions or amendments to Federal management plans require opportunities for public participation in accordance with NEPA, NFMA, National Parks and Recreation Act, and FLPMA (USFWS 2014 pp. 26-34; also see 3.1) and consultation with the Service in accordance with section 7 of the ESA. If the DPS is delisted in the future, the ESA requires a minimum of 5 years of monitoring to assess its ability to sustain itself without the ESA's protective measures. If, during that time, threats to the DPS change or unforeseen events affect its stability, then the DPS could be relisted or the monitoring period extended. Given these requirements, we expect that future Federal management direction will continue to include regulations and guidance protective of lynx, although specific measures may change as new information becomes available.

We anticipate that future Federal management direction will include continued management of national parks, designated wilderness and roadless areas, and other areas with nondevelopmental land-use allocations to maintain natural ecological processes, which should maintain natural disturbance regimes and landscape-level habitat mosaics to which lynx are adapted (although continued climate warming [see below] may preclude maintenance of historical disturbance and landscape patterns). Regardless of the future listing status of the DPS, these lands will continue to be managed in accordance with the acts described above, as well as the National Park Service Organic Act and the Wilderness Act.

We also expect that Federal management into the future will include continued management of lands with developmental allocations to avoid or minimize potential impacts of vegetation management (timber harvest, thinning, salvage logging, other silvicultural prescriptions), wildland fire management (fire suppression, fuels reduction, prescribed fires), energy exploration and development, recreation, or other management activities with the potential to affect lynx. Current and likely future objectives include (1) managing vegetation to mimic or approximate natural disturbance and succession processes while maintaining habitat components necessary for lynx conservation; (2) providing a mosaic of habitat conditions through time that supports dense horizontal cover, high hare densities, and winter hare habitat in both young regenerating and mature multi-story forest stands; (3) using fire (natural and prescribed) to restore ecological process and maintain or improve lynx habitat, and (4) focusing vegetation management in areas with potential for improving winter hare habitat (USFS 2007, Attachment 1, p. 2; BLM 2008, pp. A18-10 - A18-15; BLM 2010, pp. A-9 - A-12). Although specific standards and guidelines may change as new scientific information and management techniques become available, we anticipate continued Federal management designed to conserve or restore potential lynx habitats in this geographic unit in the future.

Given the commitments and management objectives and practices described above, implementation of current and future regulatory mechanisms will likely continue to support conservation and restoration of lynx habitats in this unit and improve the likelihood that it will support resident lynx into the future. Because non-Federal lands make up such a small proportion of this geographic unit, we believe it is unlikely that regulatory mechanisms on those lands will influence this unit's future ability to support resident lynx.

If the DPS was not listed, State-managed trapping could resume in this geographic unit, as elsewhere. We expect that would occur only if scientific evidence strongly suggested the presence of a harvestable surplus of lynx and that harvest quotas would be carefully managed to ensure that the viability of resident lynx populations would not be diminished.

Climate Change - The recent evidence of climate change and the numerous mechanisms by which continued warming may affect future conditions for lynx and the potential consequences for the DPS and specific geographic areas are described in detail in section 3.2. Also, as noted above in section 4.2.5, evidence of warming and related impacts (increased temperatures, reduced snowpack, earlier snowmelt, and increased drought leading to increased fire) have already been documented in the Northern Rocky Mountains, including this geographic unit.

Climate projections suggest these impacts are likely to continue and to result in future northward and upslope contractions in the snow conditions and boreal and subalpine vegetation communities that support lynx. This is expected to cause loss and increased fragmentation and isolation of lynx and hare habitats and, therefore, declining and more vulnerable lynx populations in the DPS and in this geographic unit (Carroll 2007, entire; Gonzalez *et al.* 2007, entire; ILBT 2013, pp. 69-71; 79 FR 54810-54811; Lawler and Wilsey *in* Lynx SSA Team 2016a, pp. 15-16; Siren *in* Lynx SSA Team 2016a, p. 15).

Snow conditions in this unit are projected to become less favorable, with an overall decrease in snowpack after mid-century as a result of a shorter snowfall season, fewer days with snowfall, and a lower proportion of winter precipitation in the form of snow (more as rain; Siren *in* Lynx SSA Team 2016a, p. 15). In this unit, the probability of suitable snow conditions is projected to decline from 90-95 percent from 1961-1990 to 50 percent across much of the unit by the end of this century (years 2071-2100), though some parts of this unit are projected to retain adequate snow (Gonzalez *et al.* 2007, pp. 12-14; Lynx SSA Team 2016a, pp. 15, 46). There will likely be a lag time between the loss of favorable snow conditions and an eventual shift or contraction in vegetative communities (Lynx SSA Team 2016a, pp. 43, 59; also see 3.2), but continued warming is projected to convert much of the boreal forest in this unit to temperate conifer forest by the end of the century (Gonzalez *et al.* 2007, pp. 15-17). The ability of lynx and hare populations to persist during this lag and to adjust to future habitat distributions is uncertain, but habitat quality, quantity, distribution, and connectivity are expected to decline, likely further compromising this unit's ability to support resident lynx populations, which is already questionable.

Climate change has also been linked to increased wildfire size, frequency, and intensity in this geographic unit, including the extensive fires in Yellowstone National Park in 1988, which burned over one-third of the park. Climate warming has also been linked to increased frequency and extent of forest insect outbreaks in other parts of the DPS. These factors are likely to have temporary impacts on lynx habitat, with regeneration to hare and lynx foraging habitat 20-40 years post-disturbance, depending on local climate, elevation, and topography. However, if extensive areas are affected, the ability of landscapes in the GYA to support resident lynx may be further compromised, and resident lynx may be unable to persist until favorable vegetation conditions return. This is especially true where potential habitats are naturally fragmented and patchily-distributed, and where landscape-level hare densities are already marginal, which appears to be the case for much of this geographic unit.

Climate change has also been implicated in observed declines in the amplitude of northern hare and lynx population cycles (Yan *et al.* 2013, p. 3269). If lynx populations in this geographic unit are influenced by intermittent immigration from the north, and if climate change diminishes the likelihood of future immigration via muted northern lynx population cycles, the future persistence of resident lynx in this unit is uncertain (see also Other Factors, below).

Given the factors described above, recent and projected future climate warming will likely further reduce this geographic unit's ability to support resident lynx into the future. The timing and

magnitude of climate-driven impacts are uncertain; however, all are anticipated to adversely affect, and none are expected to benefit, lynx and habitats in this geographic unit. Climate model uncertainties and resolution limits, combined with our imperfect understanding of historical and current lynx numbers and habitat distributions, preclude quantifying future habitat quality and distribution or lynx population dynamics in this unit. Nonetheless, it appears likely that continued climate warming will further reduce habitat quality and quantity and, therefore, the likelihood that this geographic unit will support resident lynx in the future.

Vegetation Management - Future vegetation management and, therefore, its implications for future lynx habitats and populations in this unit, are closely linked to the current and future regulatory mechanisms described above. As noted, we expect future vegetation management on all Federal lands in this unit to continue to focus on maintaining and restoring lynx habitats by implementing standards, guidelines, and BMPs based on the best available scientific information. We expect these measures to continue to benefit lynx by limiting detrimental effects of timber harvest, thinning, fuels management, etc., and encouraging the use of these activities to restore, improve, or create high-quality hare and lynx foraging habitats where feasible.

Wildland Fire Management - As noted in sections 3.4 and 4.2.5, past wildfire management, including fire suppression, does not appear to have altered the historical fire regime in lynx habitats in the western contiguous United States, including this geographic unit. Also as noted there and in sections 3.1.1 and the Regulatory Mechanisms section of this chapter, current Federal management restricts, with few exceptions, fire management (fuels reductions, prescribed fires, etc.) impacts to lynx habitats, and it promotes the use of such activities and wildfire response to conserve and restore lynx and hare habitats. We expect such conservation-focused fire management to continue and, therefore, to benefit lynx rather than to affect them detrimentally in the future.

However, as also noted in section 4.2.5, increased wildfire frequency, size, and intensity have been documented in this geographic unit, and that pattern is anticipated to continue in the future with continued climate warming. Although the extent to which increased wildfire activity has impacted this unit's current ability to support resident lynx is uncertain, such impacts may become more likely in the future depending on the timing and extent of future fires. As described in section 3.4, increases in fire frequency and size could rapidly convert large areas to the temporarily unsuitable stand-initiation successional stage, thus reducing the amount and altering the distribution of higher-quality habitats and potentially compromising this unit's ability to support resident lynx until burned habitats recover. Because lynx habitats are naturally patchily-distributed and landscape-level hare densities already marginal in many parts of this unit, it is possible that very large wildfires or many fires over a short time period could cause a shift in some parts of this unit from just barely capable of supporting resident lynx to incapable of doing so in the future. Although fire suppression was considered a potential risk factor for lynx in the DPS range, given the trends discussed above and the likely continued increase in future fire activity resulting from continued climate warming and drying, it may be necessary to reconsider whether fire suppression in some lynx habitats could benefit lynx by reducing the

potential for extirpation of resident populations, especially in places already apparently only marginally capable of supporting them.

Habitat Loss/Fragmentation - As described above in section 4.2.5, lynx habitats in this unit are naturally fragmented but otherwise appear to be largely intact relative to historical conditions in most of this geographic unit. Although some localized impacts of past timber harvest and related activities have likely occurred, anthropogenic habitat loss or fragmentation does not appear to have broadly diminished this unit's ability to support resident lynx. Current and probable future management for conservation of lynx habitats suggests that broad-scale habitat loss or fragmentation from timber harvest and other development activities are unlikely. The most likely sources of future habitat loss and fragmentation in this unit are the climate-mediated influences discussed above: increased wildfire activity and the projected contraction in vegetation and snow conditions favorable for lynx. Increased frequency, size, and severity of forest insect outbreaks, also driven by climate warming, has been documented in other geographic units and could occur in this unit in the future, too, resulting in temporary habitat loss and increased (though also temporary) fragmentation.

Additional highway construction and other transportation developments are likely in this unit, but the future locations, size, and potential impacts of such projects are difficult to predict. We are not currently aware of plans for specific major highway/road projects in this unit that would potentially impact lynx habitats and increase future habitat loss or fragmentation. Other potential sources of future habitat loss and fragmentation include recreation, minerals/energy development, and backcountry roads and trails; these are all considered second tier anthropogenic influences (ILBT 2013, pp. 78-85) that are unlikely to exert population-level influences, despite potential impacts to individual lynx.

Other Factors: *Connectivity/immigration* – This geographic unit is not directly connected to lynx populations in Canada or elsewhere in the DPS range, although lynx released into Colorado have dispersed northward into and through this unit. There is no reliable evidence of intermittent immigration into this unit during past irruptions of lynx from Canada, as has been documented in other parts of the contiguous United States, although anecdotal occurrence reports (see section 2.3.2.2) may suggest a pulse of immigrants in the early 1970s during the second of 2 unprecendented irruptions. Nonetheless, as elsewhere in the DPS, immigration may influence the persistence of resident lynx in this unit. If continued climate warming or other factors further reduce the chances that dispersing lynx will reach this unit and contribute to its demographic and genetic health, either through habitat loss and fragmentation in potential dispersal corridors or declines in the amplitude of northern hare and lynx population cycles, the likelihood that the unit will support resident lynx in the future may also decline. However, as in Unit 3 above, because we lack information of historic, recent, and likely future rates of immigration and its contribution to the persistence of lynx populations in this geographic unit, impacts of potentially reduced future immigration are difficult to project and are largely speculative at this time.

Conclusion

After reviewing the scientific literature and evaluating the factors that may influence lynx persistence in this unit, we concur with the experts' conclusion that this geographic unit is the least secure in the DPS. We find that conditions for lynx in this unit are naturally marginal, its historical or current ability to support a persistent resident lynx population are questionable, and continued climate warming and associated impacts are likely to further diminish its already limited ability to support resident lynx. We conclude that it may continue to occasionally or intermittently support a small number of resident lynx and some reproduction over the short term (through 2025), but that it is very unlikely to support a persistent resident population over that time frame, even less likely that it will do so at mid-century (2050), and highly improbable that this geographic unit will support resident lynx by the end-of-century (2100).

5.2.6 Unit 6 - Western Colorado

Expert Projections of Lynx Persistence

Some experts indicated that beetle kill and fire could potentially create poor habitat conditions in large areas of this unit by mid-century, but that forest regeneration after these impacts could result in good lynx/hare habitats. Others expressed uncertainty about whether fire and insect impacts would be temporary or permanent, especially considering climate change and the potential for conversion from boreal/subalpine forests to other forest types. Higher-quality lynx habitat in this unit occurs primarily in 2 areas and is patchily-distributed. Lynx in this unit may occur as several smaller, relatively isolated subpopulations, which are likely more vulnerable to stochastic events. This unit's relative isolation may limit exchange with other lynx populations, increasing the likelihood of genetic drift and reducing the chance of demographic rescue or recolonization if lynx in the unit become extirpated. There was discussion about whether ski areas may affect daily movements of lynx, and whether hares may be declining in ski areas. There is some evidence of lynx using ski areas in summer months but avoiding them during the ski season. Two-thirds to three-quarters of the lynx in this unit are in its southern portion in the San Juan Mountains. There is a large area (Weminuche Wilderness) that has not been well surveyed for lynx, so it is possible that lynx also could be using that area.

Taking these factors into consideration, experts provided "most likely" persistence estimates of 60 to 100 percent (median = 90 percent) in the near-term (year 2025), 50 to 85 percent (median = 80 percent) at mid-century (2050), and 20 to 70 percent (median = 50 percent) at the end of the century (2100; fig. 15). Most experts indicated an initially high and subsequently decreasing likelihood that resident lynx will persist in this unit, with uncertainty increasing substantially over time; however, experts also expressed substantial uncertainty over the near- and mid-term.

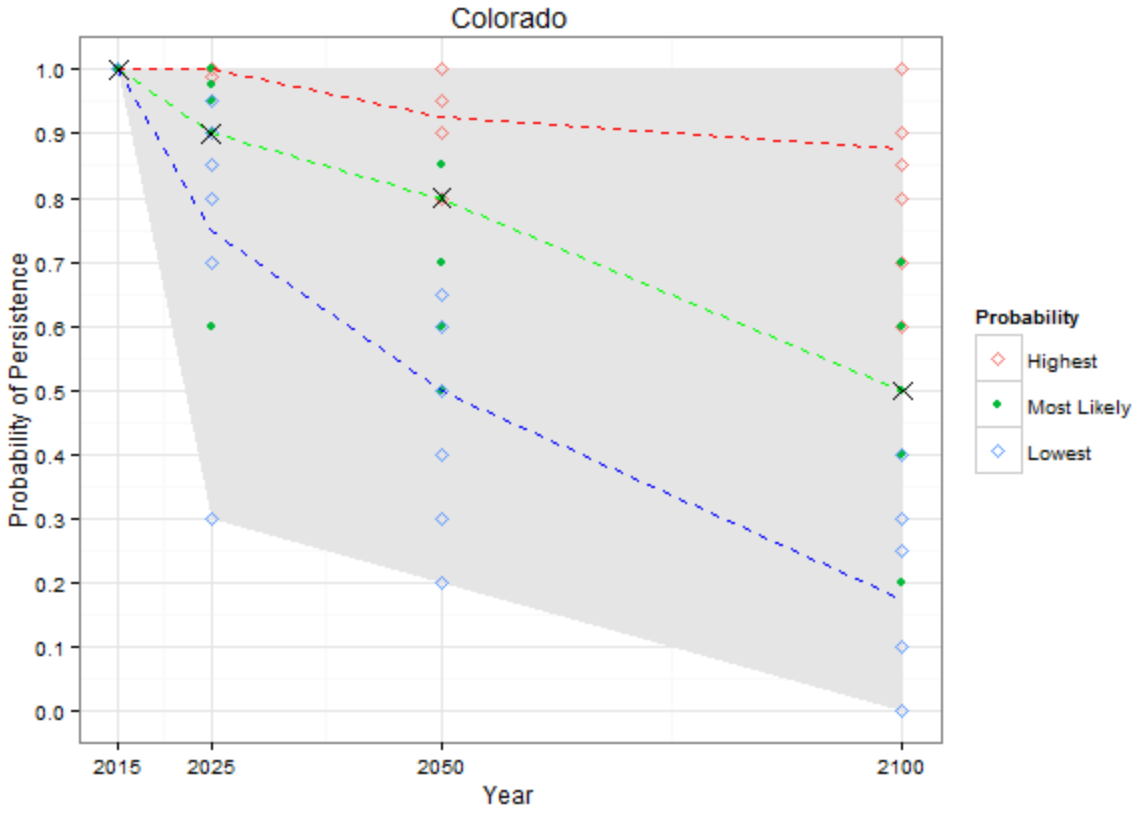

Figure 15. Expected probability of persistence for the Western Colorado Geographic Unit at present, 2015, and in 2025, 2050 and 2100.

Service Evaluation of Factors Potentially Influencing Future Conditions

Regulatory Mechanisms - Regulatory mechanisms for the conservation of lynx in the Southern Rockies consist of 7 amended USFS management plans in south-central Wyoming and Colorado. We concluded that the Southern Rockies Lynx Amendment substantively reduced the threat identified for previously inadequate regulatory mechanisms by addressing the major adverse impacts of Forest Service land management on lynx (USFWS 2008b, p. 70-71). Lynx habitat on all other ownerships makes up the remaining 15 percent of potential lynx habitat in Colorado, of which, only 5 percent is in Federal ownership. Other ownerships include state, county, municipal, etc., and private lands. Some BLM resource management plans have not been amended to include conservation specifically for lynx. Lynx habitat on BLM ownership mostly consists of narrow forest extensions connected to larger blocks of habitat on adjacent USFS lands. Generally these extensions are insufficient on their own to support a lynx home range. Additionally, the Gunnison Field Office is the only BLM unit that contains sufficient habitat to map and identify LAUs. The State of Colorado manages lynx as a State endangered species (C.R.S. 33-2-105), prohibiting take of the species with exceptions for protection of human life (C.R.S. 33-6-205) and incidentally during depredation management (not caused by lynx; C.R.S. 33-6-207).

Climate Change -In the Southern Rockies, warmer winters, earlier spring snowmelt, and a reduction in the extent of snow cover are expected consequences of climate change (ILBT 2013, p. 61). Using a variety of climate models, McKelvey *et al.* (2011, entire) predicted an overall 40 percent decline in persistent snow, but that snow would persist in large areas late in the 21st century, including the high elevations of Colorado.

"All of the climate models under all representative concentration pathways (RCPs) project that Colorado's climate will warm substantially by 2050. Under RCP 4.5 (medium-low emissions scenario), Colorado's annual temperatures are projected to warm by 1.4° to 2.8°C (2.5° to 5°F) by mid-century relative to the observed 1971–2000 baseline. Under RCP 8.5 (high emissions scenario), Colorado's annual temperatures are projected to warm by 1.9° to 3.6°C (3.5° to 6.5°F) by mid-century. Summers are projected to warm slightly more than winters under both RCPs. Beyond mid-century, the warming trend is projected to continue into the late-21st century under all RCPs except RCP 2.6. By the period centered on 2070 (2055–2084), annual temperatures in Colorado are projected to warm under RCP 4.5 by 1.4° to 3.6°C (2.5° to 6.5°F) relative to the 1971–2000 baseline. Under RCP 8.5, the projected warming is 3.1° to 5.3°C (5.5° to 9.5°F) relative to the 1971–2000 baseline." [Lukas *et al.* 2014, p. 61]

An analysis of projected 21st century temperature trends as a function of elevation in the Northern Hemisphere mid-latitudes from CMIP5 models shows more warming at higher elevations during winter, particularly in the daily minimum temperature (Rangwala *et al.* 2013 [cited in Lukas *et al.* 2014, p. 63]). "However, …, the global climate models do not represent the topography of Colorado very well, so it is difficult to discern whether the warming projected for the higher elevation regions (> 10,000') in the state is substantially different from that projected for lower elevations" (Lukas *et al.* 2014, p. 63).

On average, the climate models indicate a seasonal shift in precipitation for Colorado, with increasing winter precipitation, and in some areas a decrease in late spring precipitation (Lukas *et al.* 2014, p. 65). Although recent climate projections suggest that snow water equivalent (the amount of water held in a given amount of snow) may decline less in Colorado than in other areas of the Southwest, it is nonetheless projected to decline by 26 percent by the end of this century (Garfin *et al*. 2014, p. 466). This will likely translate to a reduction in the areas that will continue to have snow conditions that provide a competitive advantage to lynx over bobcats and other hare predators. Additionally, when specifically modeling potential impacts of climate change on lynx, researchers concluded that potential snow and boreal forest habitat refugia were most likely to occur in the Bridger-Teton National Forest in northwestern Wyoming, the Superior National Forest in northeastern Minnesota, and across western Canada, while high-elevation parts of Colorado are among the areas vulnerable to the loss of potential lynx habitat in the long term (Gonzalez *et al*. 2007, pp. 4, 8). Decker and Fink (2014, pp. 66-69) concluded that spruce-fir habitats in Colorado are only moderately vulnerable to the effects of climate change by mid-century under a moderate emissions scenario. Even if suitable snow conditions persist in Colorado and boreal and subalpine forests move upslope with continued climate warming, the amount of potential lynx habitat, already considered patchy and relatively isolated,

will likely decrease, becoming even more patchy and isolated and less capable of supporting lynx populations over time (79 FR 54794-54795).

We believe that continued climate warming will likely result in loss of favorable snow conditions, upslope migration of boreal forests, and increased frequency, size and intensity of wildlfires and forest insect outbreaks in this geographic unit. We believe these factors will exacerbate the naturally highly-fragmented distribution of potential lynx habitat in this geographic unit and further diminish what already appear to be marginal hare densities in most of this unit. As a result, we expect this unit's ability to continue to support a resident lynx population will become more tenuous in the future than it is currently and likely was historically.

Vegetation Management - In the past decade, vegetation management within lynx habitat has been predominantly salvage of dead and dying timber caused by a mountain pine beetle infestation in the northern part of the state (generally north of Interstate 70), and a spruce bark beetle infestation south of the interstate. Salvage operations may temporarily impact understory regeneration, if present, reducing the capacity of the stand to support higher snowshoe hare densities. Assuming the existing USFS plans retain their current conservation framework, USFS lands should continue to provide sufficient habitat for lynx through the end of the century. Vegetation management on the small amount of non-Federal ownerships within lynx habitat is unlikely to cause significant concern for lynx conservation in Colorado through the remainder of the century.

Wildland Fire Management - "It is generally acknowledged that in the Southern Rocky Mountains fire suppression has altered historical vegetative patterns. This effect has been most pronounced within vegetation communities where fire regimes are of low intensity or mixed severity. It is generally agreed that spruce-fir habitats have been little affected by fire suppression because the fire regimes within this type tend to be stand-replacing events occurring at long intervals (100+ years). Depending on the moisture regime, large stand-replacing fires within lynx habitat may produce young age class snowshoe hare habitat after approximately 10-30 years. Although this vegetative condition may provide some high-quality snowshoe hare habitat, mature forests are also very important as winter foraging habitat." (USFS 2008b, p. 36).

Habitat Fragmentation - Sources of current habitat fragmentation include high-speed high-volume highways, high mountain valley developments, vegetation management, ski/recreation area development, and wildland fire. Currently, only vegetation management on USFS lands is managed to limit lynx habitat fragmentation. Highways are likely to be expanded to accommodate increasing traffic volume as mountain valley communities continue to develop and expand. While these linear features already exist on the landscape, widening of the cleared right-of-way, as well as lynx behavioral avoidance of highway rights-of-way because of increasing traffic volume reduces available habitat function for lynx. Many ski areas in Colorado are located within lynx habitat and will likely be expanded in the future through permanent removal of vegetation to create conventional ski runs, reducing tree density and clearing understory vegetation to create glade conditions, which reduces lynx habitat. The magnitude of

fragmentation caused by these sources has not been quantified, but is unlikely to remove enough lynx habitat to influence lynx persistence in Colorado.

Conclusion

Based on the best scientific information available, the Core Team is less optimistic than the expert panel about the future of lynx in western Colorado. Our uncertainty stems primarily from the historic record of lynx in Colorado, where evidence of lynx presence is questionable for much of the last century prior to CPW's reintroduction program. In addition, several demographic parameters of this new population (proportion of females that produce kittens and kitten survival), are very low compared to other units (1 and 3) where these parameters have been estimated based on adequate sample sizes. Further, the naturally limited and fragmented habitats and generally low hare densities, which were apparently incapable of supporting persistent resident populations historically, are likely to worsen with continued climate warming. This unit's greater distance and relative isolation from other lynx populations in the DPS and Canada, which may have prevented dispersing lynx from reaching this unit during the unprecedented irruptions from Canada into the northern contiguous United States in the early 1960s and early 1970s, also cast doubt on the likelihood that this unit will receive the demographic and genetic support from the north that is thought to be important to the maintenance of DPS populations. Because of these factors and uncertainties, we doubt that resident lynx will persist in this unit through the end of the century (2100), although we concur with experts that lynx will persist over the short-term (2025) and possibly until mid-century (2050).

We have considered the future of lynx in Colorado in the absence of the protections offered by the ESA. We believe that as long as the current regulatory mechanisms provided by the State of Colorado to prevent take of lynx and the USFS SRLA conservation framework remains in place, lynx are likely protected from take, and their habitat requirements likely met in a significant majority of the potential habitat within the state. Projected future climate warming is likely to result in reduction of available habitat and increased fragmentation resulting in larger areas of non-habitat between habitat blocks. Vegetative changes caused by climate change will likely reduce the amount of habitat in private and BLM ownership due to the anticipated upslope shift in vegetation that supports snowshoe hares and lynx.

The movement capability of lynx is well documented, and lynx in Colorado will likely continue to exploit the available habitat despite gaps between functional habitat blocks. Colorado is isolated from source populations in the northern part of the range relative to the other units, which likely increases the possibility of genetic drift in this unit. Expert elicitation revealed some uncertainty whether ski areas or other development may affect connectivity within the unit. However, the Core Team is less concerned about this particular issue because we cannot foresee the development of barriers that would prevent lynx from accessing available lynx habitat in the future.

Chapter 6: Synthesis

This section synthesizes the needs, current condition, and likely future condition of the Canada lynx in the contiguous United States DPS with respect to the conservation biology principles of representation, redundancy, and resiliency. Its purpose is to provide an understanding of the range-wide status of the DPS that is as clear as possible given irresolvable uncertainties regarding historical distribution and population sizes, as well as uncertainty about current population sizes and trends, other key demographic information (e.g., immigration and recruitment rates and their influence on population stability/persistence), and the timing and magnitude of projected climate-mediated impacts and other long-term stressors.

Species' Needs

Throughout its range, the Canada lynx is a habitat and prey specialist requiring large (hundreds to thousands of square kilometers) boreal forest landscapes with dense horizontal cover and robust populations of its primary prey, the snowshoe hare. Resident lynx populations are generally restricted to areas with abundant hares and long (4+ months) winters with deep, persistent snow, which is believed to confer lynx a seasonal competitive advantage over other terrestrial predators of hares. Lynx in the contiguous United States have ecological requirements similar to those of lynx in Canada and Alaska, and throughout the species' range hare abundance is the primary driver of lynx population dynamics. Recent research in the DPS range supports the hypothesis that hare densities consistently near or above 0.5 hares/ha (0.2 hares/ac) are necessary to support persistent resident lynx populations (see section 2.2.1). However, the DPS is at the southernmost margin of the species' range, where boreal forests transition to temperate conifer and hardwood forests, and where hare abundance and snow conditions generally become less favorable with decreasing latitude. Because of this, habitat is naturally less extensive and generally more fragmented within the DPS range than in the core of the species' range in Canada and Alaska. As a result, lynx in much of the DPS range are naturally less abundant and more patchily-distributed than in the core of the species' range (except during decadal lows in hare population cycles, when both hares and lynx occur temporarily in the north at densities lower than most in the range of the DPS). Maintaining connectivity with lynx populations in Canada is thought to be important to the persistence of DPS populations; however, whether, and if so to what extent, the demographic and/or genetic health of DPS populations relies on periodic immigration from Canadian populations remains uncertain.

Current Conditions and Threats

Resiliency, the ability to withstand stochastic disturbance events, and redundancy, the ability to withstand catastrophic events, are currently exhibited in the lynx DPS by the persistence of individual lynx populations and their broad distribution across the geographic scope of the DPS. Available information indicates that 5 out of 6 geographic units in the DPS (all but the GYA) currently contain resident breeding lynx populations. Although we lack precise historical and

current population-size estimates for all of the geographic units, lynx experts familiar with each unit provided their estimates of the number of resident lynx each unit could potentially support.

- Northern Maine (Unit 1) – This unit has likely supported resident lynx since at least the southward re-expansion of boreal spruce-fir forests into the northeastern United States during and following the Little Ice Age (see section 3.2). Currently, northern Maine is thought to support many more resident lynx than likely occurred historically, and many more than was known or suspected at the time the DPS was listed. This unit currently contains an unnaturally-high amount of high-quality hare habitat; the result of dense conifer regeneration following landscape-level clearcutting in the 1970s and 1980s in response to a large spruce budworm outbreak. These dense young regenerating conifer stands are much more extensive than they are thought to have been historically under natural disturbance regimes. However, habitat extent probably peaked in the late 1990s and early 2000s, and habitat quality is projected to decline in these stands over the next few decades as they age beyond 35-40 years post-harvest. This unit currently is thought to support the largest resident population in the DPS; perhaps 750-1,000 individual lynx (Vashon *in* Lynx SSA Team 2016a, p. 18). This geographic unit may also be the source of dispersing lynx that recently recolonized northern New Hampshire as well as several that temporarily established residency in northern Vermont. Some reproduction has been verified recently in both states, although neither was occupied when the DPS was listed, and resident lynx were thought to have been extirpated from New Hampshire.

- Northeastern Minnesota (Unit 2) – This unit supports many more resident lynx than was suspected when the DPS was listed, although how the current population compares to historical conditions is uncertain. When the DPS was listed, it was uncertain whether this unit supported any resident lynx or if historic records were of dispersing lynx associated with cyclic irruptions from Canada. Trapping records indicate strongly cyclic increases in lynx abundance in this unit in the 1930s through 1970s in association with decadal irruptions of lynx dispersing south from Canada. This unit currently supports a resident lynx population thought to number from 50-200 (Moen *in* Lynx SSA Team 2016a, p. 19). There is no information to suggest that this unit historically supported a larger resident population or a more extensive distribution of habitat capable of doing so.

- Northwestern Montana and Northeastern Idaho (Unit 3) – Recent research, monitoring, and habitat mapping refinements indicate that habitats capable of supporting resident lynx in this and other western geographic units are naturally less abundant and more patchily-distributed than was thought when the DPS was listed. For example, earlier estimates that western Montana supported 1,000 or more lynx were based on broad assumptions regarding habitat suitability and lynx distribution that are not supported by current understanding of lynx habitat requirements (see section 4.2.3). Currently, this unit is thought to be capable of supporting 200-300 resident lynx. How the current population compares to historical conditions is uncertain, but we find no evidence that this unit historically supported a larger resident population or a substantially broader distribution of habitat capable of doing so. Lynx habitats in this unit are naturally patchy

and fragmented due to topography and elevational and moisture (aspect) constraints. Wildfires have burned over 5,200 km^2 (2,008 mi^2; nearly 20 percent of the unit) of forest in this unit since 2000, although the amount that occurred in lynx habitat is uncertain. During the 2017 fire season alone, roughly 1,150 km^2 (444 mi^2; over 4 percent of the unit) burned, including the Rice Ridge and Reef fires, which together burned over 690 km^2 (267 mi^2) in the core of the Seeley Lake population's habitat[27]. Population-level impacts of these fires have not yet been demonstrated.

- North-central Washington (Unit 4) – Extensive wildfires over the past several decades have (probably temporarily) reduced the amount of high-quality lynx habitat and have likely caused a decline in lynx carrying capacity in this unit from perhaps 50 lynx (based on this unit's proportional contribution to the larger Okanogan LMZ) before the large fires to roughly 30 lynx currently (Lewis 2016, pp. 4-6). The Diamond Creek wildfire burned another large block of lynx habitat in the northern part of this unit in 2017. Because of this, the current number of resident lynx in this unit is likely lower than it was historically and when the DPS was listed. Additional fires in this unit before previously burned areas recover (10-40 years post-burn) would further reduce lynx numbers and make this geographic unit more vulnerable to extirpation. Because of these habitat impacts and remaining stressors to lynx, the Washington Department of Fish and Wildlife recently submitted, and the State Fish and Wildlife Commission adopted, a proposal to uplist lynx from threatened to endangered within the State.

- The Greater Yellowstone Area (GYA, Unit 5) – Based on evaluation of verified historic records, it is uncertain whether this geographic unit historically supported a small but persistent resident population or supported resident lynx only ephemerally. There are very few verified lynx records in the GYA from 1920-1999, but several resident lynx and evidence of reproduction were verified in the late 1990s and early 2000s (around the time the DPS was listed). In addition, at least 9 radio-marked lynx released in Colorado (see below) dispersed northward into or through this unit from 2003-2010, but no lynx have been detected in the GYA since 2010. Most places surveyed in Yellowstone National Park had hare densities clearly too low to support resident lynx. However, parts of the Wyoming Range south of the park, where many historical and most recent occurrences in this unit have been concentrated, had hare densities among the highest documented in the DPS range. No population estimates are available, but expert opinion suggests that this unit may only support 0-10 lynx, and we find no reliable evidence that it once supported a larger or persistent resident population.

- Western Colorado (Unit 6) – There currently are many more resident lynx in this unit than likely occurred historically, and many more than were known or suspected at the time the DPS was listed. There were even fewer verified records in this unit during the last century than in the GYA, and no reliable evidence of a resident breeding population. However, from 1999-2006, 218 Canadian and Alaskan lynx were released into the San

[27] https://inciweb.nwcg.gov/state/27/0/

Juan Mountains of southwestern Colorado. As a result of the subsequent reproduction of some of the released lynx and some of their offspring over several generations, resident lynx currently occupy this unit. When the DPS was listed in 2000, 27 of 41 lynx released in 1999 were still alive. The State of Colorado has concluded that its efforts have established a viable lynx population, and the State's lynx experts suggest this unit may currently support 100-250 resident lynx (Ivan *in* Lynx SSA Team 2016a, p. 47). Recent snow-tracking and camera surveys in the San Juan Mountains in the southern part of the unit documented evidence of continued lynx residency and reproduction.

The apparent long-term (historical and current) persistence of resident lynx populations in at least 4 of the 6 geographic units (Units 1-4) and the absence of reliable information indicating that the current distribution and relative abundance of resident lynx are substantially reduced from historical conditions suggest the historical and recent resiliency of lynx populations in the DPS. The current resident population in Unit 6 has also demonstrated resiliency thus far. The large sizes and broad geographic distributions of the areas occupied by resident lynx populations likewise indicate historical and current redundancy in the DPS sufficient to preclude the possibility of extirpation from catastrophic events.

Representation, the ability of a species to adapt to changing environmental conditions over time, is characterized by the breadth of genetic and ecological diversity within and among populations (Lynx SSA Team 2016a, p. 25). Information provided by lynx experts and geneticists indicates high rates of dispersal and gene flow and, therefore, generally low levels of genetic differentiation across most of the species' range, including the DPS (Lynx SSA Team 2016a, pp. 12-14, 55-56). Hybridization with bobcats has been documented but is not considered a substantial current threat to the DPS (Lynx SSA Team 2016a, p. 13). Despite differences in forest community types and topographic/elevation settings, lynx across the range of the DPS occupy a similarly narrow and specialized ecological niche defined by specific vegetation structure, snow conditions, and the abundance of a single prey species. Thus, lynx naturally have little ability to adapt to changing environmental conditions (i.e., shift to other forest habitats, snow conditions, or prey species). However, although some small populations may have become extirpated recently, resident lynx in the DPS remain broadly distributed across the range of ecological settings that seems to have supported them historically in the contiguous United States. There are no indications of current threats to the genetic health or adaptive capacity of lynx populations in the DPS, and the current level of representation does not appear to represent a decrease from historical conditions.

The lack of regulations protecting lynx habitat from potential threats on Federal lands at the time of listing has been largely addressed by formal and binding amendments or revisions to most Federal land management plans within the DPS range. Although uncertainty remains about the efficacy of this improved regulatory framework, Federal lands are now being managed specifically to protect and restore lynx habitats, with the goal of supporting continued lynx presence on these lands. Most Federal lands, which constitute 64 percent of lynx habitat evaluated in this SSA, are found in the western United States.

Climate change is occurring at a global and, thus, a DPS-wide scale. Climate warming has reduced snow amount, duration, and quality (in terms of conditions thought to be favorable for lynx); it has been linked to increased frequency, size, and severity of wildfires and forest insect outbreaks; and it likely has already resulted in some changes in forest vegetative communities. Climate warming has also been suggested as contributing to changes in the amplitude, periodicity, and synchronicity of northern hare population cycles, which could alter (and perhaps have already altered) the timing and magnitude of lynx dispersal from Canada into the contiguous United States. If lynx populations in the DPS depend on immigration from Canada which is no longer occurring or has been reduced substantially relative to historical conditions, population declines and an increased likelihood of extirpation among resident DPS populations would be expected. However, whether, and if so to what extent, these climate-mediated factors have influenced current lynx numbers, other demographic parameters, and/or habitat quality and distribution is uncertain and has not been quantified across the range of the DPS or in individual geographic units. Despite uncertainty regarding its influence over current conditions for lynx, climate modeling and expert opinion concur that continued climate warming will adversely impact lynx in the DPS at some point in the future (also see *Future Conditions and Threats*, below).

There are other current stressors that are not occurring across the entire DPS range but which affect lynx in 1 or more geographic units. For example, in northern Maine, where most high-quality lynx habitat occurs on private commercial timber lands and is the result of past timber harvest, changes in State forestry regulations (the Maine Forest Practices Act of 1989) that govern private forest management may currently be facilitating decreases in habitat quantity, quality, and distribution, and may result in reduced lynx numbers (also see *Future Conditions and Threats*, below). The lack of binding lynx conservation commitments on most private lands may exacerbate this risk to current lynx habitats in Maine. However, the current amount and distribution of high-quality lynx and hare habitats created in Maine by past timber harvest is thought to be several times higher than the likely natural historical condition. In North-central Washington, recent large-scale wildfires have resulted in the temporary loss of over a third of lynx habitat, likely reducing this unit's current lynx population and potentially compromising its current ability to support a resident population until habitats recover. Increased wildfire activity also has impacted lynx habitats in the other western geographic units (Northwestern Montana/Northeastern Idaho, the GYA, and Western Colorado), but the extent to which it may have influenced the current condition of lynx populations in those units is uncertain.

Future Conditions and Threats

In our future condition analysis, including expert elicitation, we considered three time periods (2025, 2050, and 2100), with greater uncertainty in predicting effects to lynx and lynx habitat the further out we look into the future. Compared to the other time periods, predictions out to 2100 are complicated by considerably higher uncertainty. Overall, our evaluations of the scientific literature and expert input suggest that resident lynx populations in each of the geographic units are likely to be smaller and their distributions reduced in the future. These anticipated declines are most likely to be influenced by projected loss and increasing fragmentation and isolation of

boreal forests and favorable snow conditions resulting from continued climate warming and related impacts (e.g., increased wildfire and forest insect activity, diminished hare populations; Lynx SSA Team 2016a, p. 58). Forest management on private lands that lack lynx conservation commitments may also contribute to future declines, particularly in northern Maine. In each geographic unit, the probability that resident lynx populations will persist is expected to decline through the end of the century, with uncertainty about the rate of decline increasing with time from the present. The loss of resident lynx from 1 or more geographic unit would represent reduced future resiliency, redundancy, and representation within the lynx DPS.

The resiliency of lynx populations in individual geographic units is the primary determinant of the future viability of the lynx DPS. Our analyses and expert predictions suggest a declining probability of persistence (loss of resiliency) for each of the geographic units within the DPS throughout the rest of this century (the analysis did not extend beyond 2100). Projected climate warming is expected to exert the greatest influence on the resiliency of individual populations, and thus continued presence of resident lynx in each geographic unit. Climate models project that boreal forests and snow conditions favorable for lynx at the southern periphery of the range will retreat northward and upslope with continued warming, further fragmenting and diminishing the quality of lynx and hare habitat within the DPS. Although uncertainty remains regarding the timing, extent, and biological consequences of such impacts, as habitat conditions decline, hare populations are also likely to decline and lynx mortality rates are likely to increase and reproductive rates decrease. As snow conditions become less favorable, other terrestrial hare predators (e.g., bobcats and coyotes) may outcompete and displace lynx. This in turn would reduce lynx abundance and density within populations, making populations more susceptible to stochastic events.

Here we present future condition analysis summaries for each geographic unit (also see table 1 and figure 2):

- Northern Maine (Unit 1) – We concur with the expert panel that the resident lynx population in this unit is very likely to persist at 2025 and at 2050. Over the longer-term (at 2100), we expect continued climate warming to reduce the amount and quality of lynx habitat in this unit and exacerbate other potential stressors (commercial and energy developments, changing forestry practices and land ownership patterns, etc.), further reducing lynx numbers and decreasing the population's resilience. Some climate models indicate substantial loss of boreal forest and favorable snow conditions under higher emissions scenarios, and this unit generally lacks potential elevational refugia that would support upslope movement of lynx habitats and populations. Therefore, we suggest that the likelihood that this unit will support a resident lynx population at 2100 may be somewhat lower than expert projections, although the timing and extent of future climate-mediated habitat decline is highly uncertain.

- Northeastern Minnesota (Unit 2) – We concur with the expert panel that the resident lynx population in this unit is very likely to persist at 2025 and at 2050. Over the longer-term (at 2100), we expect continued climate warming to reduce the amount and quality of lynx

habitat in this unit, likely reducing lynx numbers and decreasing the population's resilience. Under higher emissions scenarios, some climate models project substantial loss of boreal forest and favorable snow conditions in this unit before the end of the century. Like Maine, this unit also lacks potential elevational refugia that would support upslope movement of lynx habitats and populations. Therefore, we suggest that the likelihood that resident lynx will persist in this unit at 2100 may be somewhat lower than expert projections, although the timing and extent of climate-mediated habitat decline is highly uncertain.

- Northwestern Montana and Northeastern Idaho (Unit 3) – We concur with the expert panel that resident lynx are very likely to persist in this unit at years 2025 and 2050, and likely to do so at 2100. Over the longer-term, we expect continued climate warming and associated impacts, perhaps especially increased wildfire activity, to reduce the amount and quality of lynx habitat in this unit, reducing lynx numbers and likely decreasing the population's resilience. Although the timing and extent of climate-mediated habitat decline is highly uncertain and fire-driven habitat loss typically would be temporary, wildfire size, frequency, and intensity have increased in this unit over the past few decades, and this pattern is expected to continue with projected climate warming.

- North-central Washington (Unit 4) – We concur with the expert panel that the resident lynx population in this unit is very likely to persist at years 2025 and 2050. Over the longer-term (2100), we expect continued climate warming to reduce the amount and quality of lynx habitat in this unit, further reducing lynx numbers and likely decreasing the population's resilience. Therefore, we concur with experts that this unit has a relatively lower likelihood of supporting a resident population at 2100, although the timing and extent of climate-mediated habitat decline is highly uncertain.

- The Greater Yellowstone Area (GYA, Unit 5) – Given the uncertainty whether this unit historically or recently supported a persistent resident population and the lack of evidence that it is currently occupied by resident lynx, we concur with experts that it is very unlikely to support a resident population in the future.

- Western Colorado (Unit 6) – We concur with the expert panel that resident lynx in this unit are likely to persist at year 2025. However, given this unit's apparent historical inability to support a persistent resident population, its relative isolation from other lynx populations, its naturally fragmented habitat and generally very low hare densities, and its generally lower proportion of females producing kittens and low kitten survival, we believe it is less likely than expert projections to support a resident population at 2050 or at 2100. It is possible that hare densities will increase over the next several decades as large areas of forest regenerate from recent extensive insect and fire impacts. However, we expect any increase in hares to be temporary and accompanied by a longer-term insect- and fire-driven decrease in red squirrel (an important alternate prey species in this unit) abundance.

The loss of resident lynx populations in any geographic units would also reduce the level of redundancy and could diminish representation within the DPS. With regard to redundancy, however, we find that none of the 5 geographic units that currently support resident lynx is vulnerable to extirpation from a single catastrophic event. Given that, we conclude that the DPS as a whole is not vulnerable to extirpation from a catastrophic event. We recognize that a sequence of discrete but spatially-clustered catastrophic events in lynx habitats over a short time could increase the potential for functional extirpation in 1 or more of the individual geographic units (especially the possibility of additional large wildfires in north-central Washington), thereby reducing redundancy within the DPS. However, as long as resident lynx remain geographically well-distributed in 1 or more units within the DPS, extirpation of the DPS from a single catastrophic event is very unlikely.

With regard to representation, although some lynx populations in the DPS units are demographically isolated from each other and the level of interaction between others is uncertain, there seems to be little risk of significant genetic drift. This is because of the currently-observed and likely future high level of gene flow across most of the lynx's continental range, the species' well-documented dispersal capability, the current and likely future absence of significant barriers to dispersal between Canada and the DPS, and continued connectivity between most parts of the DPS and lynx populations in Canada. Furthermore, based on expert input, we conclude that there is no indication that the relatively low level of genetic diversity currently observed among lynx populations is likely to reduce DPS viability in the future (Lynx SSA Team 2016a, p. 51). This information suggests the current and likely future relative genetic health of the DPS. However, the potential for genetic drift would be expected to increase at some point in the future if lynx and hare habitats shift northward and upslope, as projected with continued climate warming, resulting in reduced connectivity and gene flow among smaller and more isolated lynx populations at the periphery of the range (Schwartz 2017, pp. 4-5; also see section 3.2).

How the potential loss of resident lynx from 1 or more geographic units may affect representation within the DPS in terms of ecological diversity is uncertain. Despite similarities in the fundamental components (vegetation, snow conditions, and hares) that define the ecological niche of lynx DPS-wide, differences in habitats and how lynx use them are apparent. For example, snow depth that seems to demarcate a boundary between lynx and bobcat occupancy in Maine (270 cm/yr [106 in/yr]) is almost twice that observed in Minnesota (140 cm/yr [55 in/yr]), and lynx in some parts of the West select mature forest stands, particularly in winter, while in other parts of the DPS, young regenerating stands are most important. The loss of resident lynx from any of the geographic units could result in the loss of behavioral and potential future genetic adaptations to the climate-mediated changes now occurring and likely to continue into the future at the southern edge of the lynx range. Such potential adaptability to diminished snow conditions, increasingly patchy and isolated boreal forests, and reduced hare abundance may be important to the taxon as a whole faced with a rapidly changing climate.

Given the high percentage of Federal land ownership in the West, regulatory commitments that these lands will continue to be managed in accordance with lynx conservation principles, and

the existence of potential high-elevation climate refugia to which lynx habitats and some lynx might move, the western geographic units (Units 3-6) may be more likely to support resident lynx longer under projected continued climate warming. Nonetheless, it is unlikely that any management actions can abate the long-term northward and upslope retreat of boreal forests and diminished snow conditions projected by climate models. Further, the size, frequency, and intensity of wildfires and forest insect outbreaks are expected to increase with continued climate warming, particularly in the western portion of the DPS, although we do not anticipate such events in-and-of-themselves are likely to cause the permanent loss of breeding lynx populations in any geographic unit.

Projections of climate-mediated losses of boreal forests and favorable snow conditions suggest impacts to lynx and hare populations throughout the DPS. However, persistence of resident lynx in Maine and Minnesota may be relatively lower than the western geographic units given the smaller percent of Federal lands and the absence of associated regulatory commitments to lynx conservation, and the lack of potential elevational refugia. Additionally, as noted above, changes to regulations governing timber harvest on private forest lands in Maine are unlikely to maintain the current historically-high amount and distribution of good lynx habitat or the current large population of resident lynx. These changes, which may affect over 90 percent of lynx habitats in northern Maine, are projected to result in substantial declines in habitat quality and distribution, and lynx numbers, over the next 10-30 years, primarily through restrictions on clearcutting and the proliferation of partial harvesting. On private forest lands, energy development (wind energy, mining), rapid turnover in ownership and parcelization of forest land, and uncertain forest markets may also reduce the future quality and quantity of lynx habitat.

DPS Viability

Resident lynx populations persisted historically and continue to persist in 4 geographic units (Units 1-4). It is uncertain whether Unit 5 (the GYA) historically supported a small persistent population or if lynx residency was ephemeral; currently, it appears not to support resident lynx. Available evidence suggests that Unit 6 (Colorado) did not historically support persistent lynx presence; however, a resident population has persisted there for more than a decade since the 1999-2006 releases described above. Considering the available information, we find no reliable evidence that the current distribution and relative abundance of resident lynx in the contiguous United States are substantially reduced from historical conditions. This suggests historical and current resiliency among lynx populations in the DPS.

The current broad distribution of resident lynx in large, geographically discrete areas (redundancy) makes the DPS invulnerable to extirpation caused by a single catastrophic event. Because we lack evidence that formerly persistent lynx populations have been lost from any large areas, it also seems that redundancy in the DPS has not been meaningfully diminished from historical levels. In fact, as a result of the current population in Colorado, redundancy in the DPS is likely greater, at least temporarily, now than it was historically.

Similarly, resident lynx remain broadly distributed across the range of habitats that has supported them historically, suggesting maintenance of the breadth and diversity of ecological settings occupied within the DPS range (representation). Additionally, observed high rates of dispersal and gene flow and, therefore, generally low levels of genetic differentiation across most of the lynx's range, including the DPS, suggest the past and recent genetic health of lynx populations in the DPS (representation; but see section 2.1). Because there are no indications of significant loss of or current stressors to the genetic health or adaptive capacity of lynx populations in the DPS, we find that the current level of representation within the DPS does not appear to indicate a decrease from historical conditions.

In the future, we expect lynx populations in each geographic unit to become smaller and more patchily-distributed due largely to projected climate-driven losses in habitat quality and quantity and related factors. However, the timing, rate, and extent of habitat decline due to projected climate warming and corresponding effects to lynx populations is highly uncertain. Despite some reduced resiliency, we conclude that resident lynx populations are very likely to persist in all 5 units that currently support them (Units 1-4 and 6) in the near-term (2025) and in all or most of those units at 2050, with corresponding maintenance of redundancy and representation in the DPS over that time span. We and the experts we consulted have low confidence in predicting the likely conditions of DPS populations beyond 2050. That said, smaller, more isolated populations would be less resilient and more vulnerable to demographic and environmental stochasticity and genetic drift and, therefore, at higher risk of extirpation. Although predictions out to 2100 are highly uncertain, it is possible that resident lynx populations could be functionally extirpated from some units by the end of the century. Should future extirpations occur, this would indicate a loss of resiliency, reduced redundancy and representation, and an increased risk of extirpation of the DPS.

Montana, Wyoming and other states as critical habitat for the lynx. The recovery plan would detail the additional steps needed to ensure the species' long-term survival.

But a coalition of conservation groups sued the government last year for not completing that document more than a decade after lynx received federal protections.

The plaintiffs in the case are Friends of the Wild Swan, Rocky Mountain Wild, Biodiversity Conservation Alliance and the San Juan Citizens Alliance.

ENDANGERED SPECIES: Judge sets deadline for lynx preservation plan (Thursday, June 26, 2014)

A federal judge yesterday accepted a 2018 deadline proposed by the Fish and Wildlife Service for the government to finish a recovery plan for the Canada lynx in the contiguous United States

Conservation groups sued the government last year for failing to complete a plan to save the big cat more than 10 years after it was listed as a threatened species Plaintiffs, including Friends of the Wild Swan, Rocky Mountain Wild, the Biodiversity Conservation Alliance and the San Juan Citizens Alliance, wanted the plan to be completed by 2016

Although he said the agency's "stutter-step" approach necessitated court intervention, U S District Judge Donald Molloy said he was reluctant to second-guess officials with tight budgets and competing priorities

It's hard to pin down population levels of the elusive forest-dwellers, found in 14 states Federal wildlife officials say the species faces a lower threat than other protected creatures (Matthew Brown, AP/*Seattle Post-Intelligencer*, June 25) -- **DTB**

I've copied Heather, Mary, Seth and Justin on this attorney-client privilege string to get their thoughts.

Heather, Mary, Seth, Justin:

We are required to submit twice-a-year (end of June and end of Dec.) updates to the court in the lynx recovery plan lawsuit case - these outline what progress we've made every 6 months toward our agreement to complete a recovery plan by Jan. 2018 unless we determine one is not needed. These updates are also available to plaintiffs. Last update indicated we would be sending draft SSA Report to peer reviewers by end of Dec. (which we didn't do as we are still working thru some formatting issues, but hope it goes out in next couple days) and State and other partners soon after.

When we completed the EE Workshop report, we posted it to our R6 lynx webpage and made it available to the public, including plaintiffs and other NGOs.

On Wed, Jan 4, 2017 at 8:45 AM, Zelenak, Jim <jim_zelenak@fws.gov> wrote:

I've copied Heather, Mary, Seth and Justin on this attorney-client privilege string to get their thoughts.

Heather, Mary, Seth, Justin:

We are required to submit twice-a-year (end of June and end of Dec.) updates to the court in the lynx recovery plan lawsuit case - these outline what progress we've made every 6 months toward our agreement to complete a recovery plan by Jan. 2018 unless we determine one is not needed. These updates are also available to plaintiffs. Last update indicated we would be sending draft SSA Report to peer reviewers by end of Dec. (which we didn't do as we are still working thru some formatting issues, but hope it goes out in next couple days) and State and other partners soon after.

When we completed the EE Workshop report, we posted it to our R6 lynx webpage and made it available to the public, including plaintiffs and other NGOs.

I'd say include that language in the message to Dana, so its in two places, the document itself, and the transmission of the document.

>
> > Some Notes from my conversation. I have cc'd Nathan so he can better explain his thinking and can perhaps work on some language to include in the draft SSA as it goes to Peer Review (and other "public")
> >
> > The SSA should not reveal the decision, but it is pre- decisional in that it is a work in process (we don't have to give up things while we are still working on, isn't this an exemption in FOIA correct??). Nathan thinks that once we send it out for peer review it may be "public" and we should then make it available to the group requesting it or post it?? Although we would want to state that the document does not yet have the benefit peer review nor our ability to respond to it and therefore we, the FWS, does not believe it is a completed product. Nathan thinks a disclaimer paragraph could be inserted (talk with him directly as he is thinking about it right now!!!).

Jodi has some concerns, below, about whether it is a deliberative document and whether providing plaintiffs/public with the draft SSA report would set a precedent that we don't maybe want to set.

Please provide your input/response and reply all so Dana and Jodi can consider.

Thanks,

Jim

Hi Marj. So Jim, Tom, and I took another run at this and tried to provide some additional clarification per your comments and questions without overstepping our knowledge limitations. Again, it would be great to have Kate give it a quick look, since our staff most familiar with Cottonwood are out. I attached the surname and NTR docs also - let me know if those need any additional adjustments. Again, Tom has made himself available for a call on Friday if needed. Thanks!

Jeff

> Hi Maria and Marjorie. The requested draft BP is attached. It so happens that our resident two experts on this issue (Jodi Bush and Katrina Dixon) are both out for the week and unreachable, so Tom Olenicki, Jim Zelenak and I did the best we could. Jim Zelenak (working on lynx CH) suggested that the BP be given a once-over by Kate Williams-Shuck in the SOL office, as she's apparently been working on this issue with Katrina - so you may want to consider that. Maria mentioned yesterday that you folks would take care of coordination with EA from this point, so thank you. Finally, I'll be

unavailable on Friday, but Tom Olenicki has graciously volunteered to participate in a phone call to represent the MT FO if needed. Please just let Tom know directly (406-449-5225, ext. 213) about any call details. Thanks for your assistance!

First blush (aka, not given it deep thought) is that it's a different because we are looking at the whole DPS and whether the whole DPS meets the definition of T or E.

However, I need to read the stuff about historic range. However, from Ben's summary, my first blush take is that we are okay here too.

It seems we should catch up on carnivores, especially given this case and the Cabinet Yak case. Should we set up a call?

In section 3.2.1, we said:

"This program has resulted in the release of 98 lynx from 2000 to 2015 (10 lynx died from traps or illegal shooting in traps) that were reported incidentally trapped in northern Maine (MDIFW 2014a, p. 75)."

You commented: "If you want to update, the sentence would read: This program has resulted in the release of 106 lynx from 2000 to 2016 (12 lynx died from traps or illegal shooting in traps) that were reported incidentally trapped in northern Maine."

I'd like to make the update, but also need an updated citation for what Anna commented would be the 2016 Annual Report.

Would that just be "(MDIFW 2016, p. XX)" If so, could you reply with the page number(s) and also add that full citation to the list you are working on?

Thanks.

Maricela,
What do you need to move this to Gary? We sent up the BP on the 5 YSR. As we move the 4(f) letter through to Noreen then the Director's office, how should we move that to Gary?
thanks,
Marj

Subject:	Lynx Bio-Team conf call
Date:	Wednesday, September 12, 2012 1:00:25 PM

Hi Group,

The Lynx Bio-Team will be having a conference call from **9:00 am – 1:00 pm (MDT) on Thursday, September 27th**. Please have your edits and comments related to the revised LCAS submitted to Nancy Warren and Bob Naney (using Track Changes) by the 21st so that this call can be used to discuss and resolve any remaining concerns. This is the time to look at the full document in detail, but please focus particular attention on Chapter 5 (Conservation Strategy). You should already have received a copy of the draft revision, but I've also included it here. Once the Bio-Team has completed our review, the Steering Committee will be briefed (they will be meeting in late October/early November).

For the call on Sept. 27th, please use the following call-in information:

Call-In Number: (b) (5) CIP

Access Code: (b) (5) CIP

It is great to be getting to this point and I'm looking forward to hearing you all on the 27th. Thank you for your continued commitment to lynx conservation.

Date:	Tuesday, September 17, 2013 5:32:56 PM

Hello Team,

Thanks for responding to the recent doodle poll. I really appreciate the fact that everyone responded. And, thanks to your flexibility, it looks like we actually have a date that will work for the ENTIRE team (a very rare event!).

So, I'd like to schedule our Lynx Bio-Team call for **Friday, Sept. 27 10:00 am – 12:00 pm, MDT**. Please use the call-in information below. I will soon provide you with further information for your review as a basis for some of our group discussion during the call. Basically, there are some things in Chapter 5 (Conservation Strategy) of the revised LCAS (I believe Nancy Warren sent you all a copy of the final draft in mid-August) that I'd like to discuss. So, if you have a few minutes, please review the conservation measures. I'll send you more specifics soon.

Call-in Number: (b) (5) CIP

Access Code: (b) (5) CIP

Thanks again. I look forward to our call. Have a good week!

How about we all get on the phone at 2pm to check in? (b) (5) CIP(b) (5) CIP

In discussing with Lowell, I believe we have a good plan from the state on mitigation. We are feeling comfortable that the mitigation as described in the ITP, in conjunction with the MOU, is sufficient. Let's discuss at 2pm.

We will get that largely done this afternoon.
>
> I understand Mark was working on permit condition questions per Lowell's request.
>
> Are we squared away with the mitigation piece? It seemed to us in reviewing the draft MOU that the State didn't understand what they need to do -- it is not just cutting 6000 acres -- it is offsetting take by creating and maintaining that much HQHH. And they said something that leads us to think maybe it might already be there without any treatments -- that is, 36% of trees "mid successional" soft wood.

To: Parkin, Mary
Subject: Re: Setting up a lynx SSA call for this week
Date: Tuesday, May 05, 2015 1:35:06 PM

Here you go, Mary.

(b) (5) CIP

Participant Passcode: (b) (5)

Leader Passcode: (b) (5)

Let me know if you want to dial in as "leader" or if we should - my Field Supervisor, Jodi Bush, will be joining here.

Are we planning for an hour? Longer? Do you have an agenda? Or will we just play it by ear? I think Jodi has some questions about process, costs/contracts, time lines, etc. And we can certainly provide an update based on the call she and I had yesterday with Seth.

Let me know if there is anything else you need from me or from Jodi before the call.

Thanks,

Jim

Kickoff Call for Canada Lynx Species Status Assessment (SSA): 10-11 am MDT

This purpose of this webinar is to discuss the project plan for assessing the status of the Canada lynx DPS in order to complete a 5-year review and, as warranted, a recovery plan for the DPS by January 2018. Most importantly, membership on the core SSA team and management team needs to be confirmed, based on a clear understanding of the expectations for each team member. A call agenda will be provided before Thursday.

I think you'll both be on the call, too. I just got off the phone with Jodi Busch, the Field Supervisor from the Helena, MT FO. I also heard about this in passing during a call with Ann earlier today. Soooo, Jodi was asking for your help, and I told her that you could help but I expressed reservations in how much time. She's going to send me an email with some additional info, which I can share with you. We should have a three-way discussion about how much staff involvement is needed, once you get a better sense of how much time is expected for all this SSA work.

> Dear Managers and Core Team Members :
>
> As you are aware, Region 6 is initiating a status review of the contiguous U.S. DPS of the Canada lynx as a first step in completing a court-ordered recovery plan for the DPS. The court's deadline for the plan is Jan. 15, 2018. The Montana ES Office is the lead office for this effort.
>
> We will be using the Species Status Assessment (SSA) framework to evaluate the current status of the DPS, determine the major drivers of the DPS's viability, and produce an SSA report, which will provide the scientific underpinnings for the recovery plan and any other future listing decisions we may need to make regarding the DPS (e.g., 5-year review, delisting/uplisting determinations if needed, etc.).
>
> Because the DPS spans parts of four other Service Regions (1, 2, 3, and 5), it is very important that field biologists most familiar with the status of lynx subpopulations in the DPS assist with and contribute meaningfully to the development, review, and completion of the SSA report and recovery plan.
>
> In particular, we will need dedicated assistance from the appropriate biologists in the Idaho and/or Washington FOs (R1) , Twin Cities FO (R3),

Maine FO (R5), and Colorado and/or Wyoming FOs (R6).

As I indicated in our phone conversation, your staff member has been identified as a participant in the "core" team. This email is to confirm with you that you approve your staffs involvement as "core" team members in the development, review, and completion of the SSA report and subsequent Canada Lynx recovery plan.

As we discussed, I estimate that this effort could take anywhere from 10 to 25% of their time.

It will be especially important that the Core Team biologists assist with:

(1) collection and interpretation of information relating to the status of and potential threats to those subpopulations;
(2) in coordination with guidance from the SSA facilitation team, contacting and arranging participation by lynx experts most familiar with the status, ecology, population dynamics, and habitat needs of those subpopulations; and
(3) writing, editing, and reviewing relevant parts of the SSA report, five-year review, and recovery plan, if needed.

In addition, Core Team members are expected to coordinate with internal Service Staff in their region and area of coverage and in that same area - to be the Service Point person for Canada Lynx with our external partners during the process.

Thank you for your commitment of staff. This is an important effort and we are excited to get started.

On May 28 we are having a general conference call discussing where we are and the next steps. That information is below. If you have any questions about the process -please give me a call. Thanks JB

Subject: Canada Lynx SSA Core Team

Dear Managers and Core Team Members :

As you are aware, Region 6 is initiating a status review of the contiguous U.S. DPS of the Canada lynx as a first step in completing a court-ordered recovery plan for the DPS. The court's deadline for the plan is Jan. 15, 2018. The Montana ES Office is the lead office for this effort.

We will be using the Species Status Assessment (SSA) framework to evaluate the current status of the DPS, determine the major drivers of the DPS's viability, and produce an SSA report, which will provide the scientific underpinnings for the recovery plan and any other future listing decisions we may need to make regarding the DPS (e.g., 5-year review, delisting/uplisting determinations if needed, etc.).

Because the DPS spans parts of four other Service Regions (1, 2, 3, and 5), it is very important that field biologists most familiar with the status of lynx subpopulations in the DPS assist with and contribute meaningfully to the development, review, and completion of the SSA report and recovery plan.

In particular, we will need dedicated assistance from the appropriate biologists in the Idaho and/or Washington FOs (R1) , Twin Cities FO (R3), Maine FO (R5), and Colorado and/or Wyoming FOs (R6).

As I indicated in our phone conversation, your staff member has been identified as a participant in the "core" team. This email is to confirm with you that you approve your

staffs involvement as "core" team members in the development, review, and completion of the SSA report and subsequent Canada Lynx recovery plan.

As we discussed, I estimate that this effort could take anywhere from 10 to 25% of their time.

It will be especially important that the Core Team biologists assist with:

(1) collection and interpretation of information relating to the status of and potential threats to those subpopulations;
(2) in coordination with guidance from the SSA facilitation team, contacting and arranging participation by lynx experts most familiar with the status, ecology, population dynamics, and habitat needs of those subpopulations; and
(3) writing, editing, and reviewing relevant parts of the SSA report, five-year review, and recovery plan, if needed.

In addition, Core Team members are expected to coordinate with internal Service Staff in their region and area of coverage and in that same area - to be the Service Point person for Canada Lynx with our external partners during the process.

Thank you for your commitment of staff. This is an important effort and we are excited to get started.

On May 28 we are having a general conference call discussing where we are and the next steps. That information is below. If you have any questions about the process - please give me a call. Thanks JB

Date: Tuesday, June 16, 2015 4:58:51 AM

Well believe it or not -there is no phone service except pay phone at the hotel (of which there is only one). I tried my calling card last nite and it doesn't work and of course we have no internet in the Park (Did I say I am at Glacier NP?) in the rooms. Only in the lobby. and its terribly slow.

In any case I'm done here early weds morning and heading back. Can we try a call early afternoon then? I'll check my email as I can -to get the time. Thanks. JB

Subject: Fwd: Invitation for Instant Net Conference
Date: Monday, June 22, 2015 5:30:19 PM
Attachments: 2015 06 22 Draft Lynx SSA Expert matrix.docx

Hi Team:

Below is info for joining a webinar tomorrow - mostly so we can do some real-time additions to the SSA Cardinal Questions table (which Core Team folks have been working on, yes?), and to the attached draft expert elicitation matrix (feel free to fill in names of experts in your geography). the column headings are pretty general right now - focusing on the limiting parts of the CH PCE (boreal forest, hares, and snow), as well as habitat and climate modeling, and connectivity with Canada. We made need to refine/adjust. We also need to talk some about the project plan and just how we think we might be able to meet the project schedule.

Call-in info is the same:

(b) (5) CIP
Passcode: (b) (5)

Talk to you all tomorrow!

Thanks,

Jim

p.s. I plan on taking notes today, which I'll then distribute to you all. One thing, if you want to turn the webex over to me for the expert matrix, I'll need a refresher on what to do technically. for today, it might be most efficient if, on the expert matrix, you and I tag-team the discussion while you type in any additional names on screen.

Between now and the next call, I'll work with you and Heather on how to share screens. Just been too long since I've done it.

Mary

Hi folks,

Wanted to be sure you saw this request for PL/ARD signatures on the lynx SSA/RP/5-year project plan. Let me know if you have any questions or concerns.

Also, please let me know when your PL signs; Terry will want to know that they are okay with the plan before she signs.

Thank you,
Sarah

Subject: SIGNATURE NEEDED: Final Lynx Project Plan

Attached is the final Lynx Project Plan for the SSA, Recovery Planning and Five-year Review in both word and pdf format. I am requesting via this email your signature on page 10 of that document. Comments on the draft project plan were received in late April and early May and we have incorporated those changes into the attached document.

For ease of collating signatures please use any of the following methods to add your signature

to the document.

1. Open the attached pdf document in Adobe Reader. Click on the fill and sign tab and make a selection for your signature of the document. **Save and send back to Jim Zelenak.**

2. Sign a hardopy of the signature page (10), **scan and send back to Jim Zelenak.**

3. Add your signature in the word document by adding /s/ Your Name. **Save and send back to Jim Zelenak.**

You should have also received notice of what will be our monthly internal FWS coordination calls on the process from Jim Zelanak.

We will be conducting these calls the first tuesday of every month at 10am Mtn time.

Call in information is as follows: (b) (5) CIP, passcode: (b) (5) CIP.

Shortly I will also be sending out another letter for our state partners. As we know, the States are particularly interested in being engaged in our Lynx recovery planning process. To that end, the letter updates where we are now and identifies a monthly coordination call with our state partners to keep them appraised of our progress. It would be helpful if versions of this state letter were sent out from your offices. Please use the version I provide to you as a template.

Thank you for your help and as always feel free to give me a call if you have questions or concerns. JB

Hi Lynn,

Lisa is out for the day, so I forwarded this on to Pete. I reviewed their draft in May and I don't think it has changed much since then - looks good to me.

Have a nice weekend!

Thanks,
Tam

Hi Jim,

I think we could take Jodi's response and develop a general statement to give to all those who will be interacting with state partners. Let's talk about this on the call today.

I do believe that we need to have a clear, strong message about the appropriate role of the states (and other partners) in this science-driven process, as miscommunication is a possibility. This would then be something we could disseminate before next week's monthly call and address any questions folks might have.

Cheers,
Mary

> We are not. The SSA Service leads have been pretty clear -at least to us - that the Service is developing the SSA and are the core team (with some assistance from USGS). Having said that we will be reaching out to key individuals -with the state, academia and other entities to help us with the science. Their roles will be fluid and will depend upon the questions we are attempting to ask. We are also planning on monthly calls to keep them up to date as the process goes forward. Given the sheer number of states involved, this seemed the best course of action. Am happy to talk about this further if you would like. JB

We will be conducting these calls the first tuesday of every month at 10am Mtn time.
Call in information is as follows: (b) (5) CIP , passcode: (b) (5) CIP .

Shortly I will also be sending out another letter for our state partners. As we know, the States are particularly interested in being engaged in our Lynx recovery planning process. To that end, the letter updates where we are now and identifies a monthly coordination call with our state partners to keep them appraised of our progress. It would be helpful if versions of this state letter were sent out from your offices. Please use the version I provide to you as a template.

As previously discussed, Idaho FWO identified Bryon Holt as our lead on this lynx SSA project. As a member of the lynx core team, he will need to coordinate with his counterparts in Washington, Boise, Oregon, others?, within R1. The lynx effort is expected to require 10-25% time, which I am sure will ebb and flow.

As you also know, we have refocused Bryon's time and talents onto caribou, lynx, and grizzly bear recovery planning and implementation issues. Bryon is working internally to finalize the caribou classification rule. And his participation is key on the team of partners revising a foundation for future caribou recovery plan. He's also currently assigned one significant consultation: Bog Creek Road, which we anticipate will be LAA grizzly bears.

In order for Bryon to effectively execute these select, priority projects (lynx SSA, caribou classification, caribou recovery planning, and Bog Creek grizzly bear consultation), it will be critical for the office to minimize additional collateral assignments until work products clear. It is equally important for Bryon to carefully out-plan his schedule to avoid conflicts and avoidable delays. With careful planning and disciplined focus, Bryon should be able to handle these items for the foreseeable future.

I am making this point because I as a supervisor, and we as organization, had previously hoisted numerous, conflicting number 1 priorities upon Bryon; resulting in inadequate progress and frustration for our internal and external partners on important projects.

Thanks for your consideration. - Ben

Dear Managers and Core Team Members :

As you are aware, Region 6 is initiating a status review of the contiguous U.S. DPS of the Canada lynx as a first step in completing a court-ordered recovery plan for the DPS. The court's deadline for the plan is Jan. 15, 2018. The Montana ES Office is the lead office for this effort.

We will be using the Species Status Assessment (SSA) framework to evaluate the current status of the DPS, determine the major drivers of the DPS's viability, and produce an SSA report, which will provide the scientific underpinnings for the recovery plan and any other future listing decisions we may need to make regarding the DPS (e.g., 5-year review, delisting/uplisting determinations if needed, etc.).

Because the DPS spans parts of four other Service Regions (1, 2, 3, and 5), it is very important that field biologists most familiar with the status of lynx subpopulations in the DPS assist with and contribute meaningfully to the development, review, and completion of the SSA report and recovery plan.

In particular, we will need dedicated assistance from the appropriate biologists in the Idaho and/or Washington FOs (R1) , Twin Cities FO (R3), Maine FO (R5), and Colorado and/or Wyoming FOs (R6).

As I indicated in our phone conversation, your staff member has been identified as a participant in the "core" team. This email is to confirm with you that you approve your staffs involvement as "core" team members in the development, review, and completion of the SSA report and subsequent Canada Lynx recovery plan.

As we discussed, I estimate that this effort could take anywhere from 10 to 25% of their time.

It will be especially important that the Core Team biologists assist with:

(1) collection and interpretation of information relating to the status of and potential threats to those subpopulations;
(2) in coordination with guidance from the SSA facilitation team, contacting and arranging participation by lynx experts most familiar with the status, ecology, population dynamics, and habitat needs of those subpopulations; and

(3) writing, editing, and reviewing relevant parts of the SSA report, five-year review, and recovery plan, if needed.

In addition, Core Team members are expected to coordinate with internal Service Staff in their region and area of coverage and in that same area - to be the Service Point person for Canada Lynx with our external partners during the process.

Thank you for your commitment of staff. This is an important effort and we are excited to get started.

On May 28 we are having a general conference call discussing where we are and the next steps. That information is below. If you have any questions about the process - please give me a call. Thanks JB

Hi All:

General agenda for today's call is:

1. Discuss coordination with States and other partners - Jodi's letter, talking points;

2. Planning for expert elicitation meeting in fall - location, venue, associated staff travel, etc.

3. Your questions/concerns.

Talk to you soon.

Jim

Subject: Re: [Update] Lynx SSA Coordination Call
Date: Wednesday, July 08, 2015 10:17:13 AM

Hi Jessica,

Yes, but I'll be involved peripherally because Tam is the R3 rep for the SSA core team. However, I was the lynx "go-to" person in WY, so will provide assistance if needed to the person who filled in behind me. I took notes yesterday because Tam wasn't available and didn't know if anyone else would!

Hi All:

Here are notes from yesterday's lynx SSA coordination call.

Thanks very much to Ann Belleman for drafting these.

Share with other FWS folks as needed.

Thanks,

Jim

Subject:	Re: Requesting assistance from FWS"s Science Applications regarding climate change, for the upcoming SSA on Lynx!
Date:	Thursday, July 09, 2015 12:22:23 PM

Thanks, Kurt.

I should have been specific about the call next Mon., July 13.

(b) (5) CIP, passcode: (b) (5) CIP

I will have my request better organized by then, but in short, we're working on reaching out to candidates for the lynx SSA expert elicitation meeting we plan to have Sept. - Oct., likely in Minneapolis, and we think we will need some climate modeling expertise. There are only a small handful of papers on lynx/CC (Carrol 2007; Gonzalez et al. 2007; the paper Kate co-authored with Kevin Johnston and Oswald Schmitz; also Stenseth et al 2004 [sort of]).

I think we will need someone who can help us translate and understand, possibly down-scale models to portray reasonably likely CC effects on boreal forest distribution and disturbance (fire/insects) regimes and snow conditions at its southern margin in the northern Lower-48, maybe southern Canada, too, over a couple time frames - maybe 40 & 80 or 50 & 100 years?

I also could use some help filtering and applying to lynx/hares/boreal forest the relevant info from the most recent IPCC and National Climate Assessment reports.

Anyway, hope you can joins us next Monday so we can discuss.

Thanks again,

Jim

Hi Heather and Jim,

I am happy to help as I can. Certainly a lot of relevant work has been done. The challenge will be making sense of it all! Would you like to schedule a call to get the ball rolling?

Kurt

On Tue, Jul 7, 2015 at 10:31 AM, Bell, Heather <heather_bell@fws.gov> wrote:

Kate, thanks so much this is excellent!
Kurt I assume we might hear from you soon? Feel free to connect with Jim Zelenak directly as he is the Lynx guy and has a good idea of what our needs are. Mary Parkin and I are assisting Jim in organizing the SSA process.
Much Appreciated and looking forward to working with Science Apps!

Hi Heather,

Thanks for your email. Sounds like some very interesting questions - Kurt and I are talking to Seth about the best way that Science Applications can assist.

Are you all already working with Nancy Green on this? I imagine she would have some recommendations for relevant climate change information?

Thanks,

Kate

On Mon, Jul 6, 2015 at 2:49 PM, Bell, Heather <heather_bell@fws.gov> wrote:

Kate, given your programs climate change focus and your knowledge of the SSA Framework (you kindly reviewed and provided comments on the draft SSA Framework earlier this year) I am hoping you will be amenable to reviewing this request!

We are undertaking a Species Status Assessment for the Canadian Lynx in preparation for a 5-year review and, if applicable, recovery planning. The lead for the SSA, Jim Zelanak, believes that some assistance in understanding the effects of climate change on this wide ranging species would be critical in our assessment. We are struggling a bit on where the best place is to go for assistance given the many states this species (DPS) covers. Would you be willing to help us out either directly or in finding the best source for information?

Here is a short blurb Jim provided on the issue:

"Because the lynx is a boreal forest species reliant on snowshoe hares for food and persistent snow to out-compete other hare predators, we need to evaluate the potential effects of climate change on lynx populations within the DPS. We request your help in in identifying resources and experts who might best inform our evaluation of how climate warming may impact boreal forest habitats, including the size, intensity, and periodicity of forest fires and insect outbreaks, as well as snowshoe hare populations and abundances, and the distribution and persistence snow conditions favorable to lynx."

Thank you for your consideration of this request!

We will be conducting these calls the first tuesday of every month at 10am Mtn time.
Call in information is as follows: (b) (5) CIP passcode: (b) (5) CIP.

Shortly I will also be sending out another letter for our state partners. As we know, the States are particularly interested in being engaged in our Lynx recovery planning process. To that end, the letter updates where we are now and identifies a monthly coordination call with our state partners to keep them appraised of our progress. It would be helpful if versions of this state letter were sent out from your offices. Please use the version I provide to you as a template.

Thank you for your help and as always feel free to give me a call if you have questions or concerns. JB

Subject: [Update] Lynx SSA - Coordination Call with States - July 29, 1 pm MDT

Date: Tuesday, July 28, 2015 5:40:31 PM

Please check your Google Calendar for this call, which will be our first with the States regarding the Canada lynx SSA. The call will begin with a presentation on the SSA process as applied to the lynx, (similar to the webinar presented on the July 7 FWS coordination call). We'll then conduct a "listening" session with State participants. The role of FWS folks on the call will be to listen in and, if needed, address particular questions raised by the States.

Jodi Bush is sending an email to State and FWS participants, along with the set of PowerPoint slides that will constitute the presentation.

Lynx SSA - Coordination Call with States - 1 pm MDT

First coordination call with States about lynx SSA. Will include webinar presentation of SSA framework and background for lynx SSA, discussion of State roles and expert selection/workshop, and possibly other topics, tbd. Webinar info and full guest list to follow.

When Wed Jul 29, 2015 3pm – 4:30pm Eastern Time

Hi Tam,

According to your schedule, it looks like you're working today so will be available for this update call at 11 am CT.

I'm trying to figure out how best to integrate with the lynx SSA as a non-core team person and ex-WY lynx bio. For e.g., should I call in today ... is there a need for me to help with the expert elicitation meeting in the fall (behind the scenes organizational stuff) ... etc. I called Lisa and left her a message asking these questions and whether I should just coordinate with you and/or her, etc.

Any thoughts?

Hi All:

Internal FWS Lynx SSA coordination call today at 10 AM Mountain Time.

(b) (5) CIP
Passcode: (b) (5)

I anticipate a short call to update folks on last week's State coordination call, discuss planning for the expert elicitation meeting this fall, and see if folks have questions.

Attached is the draft list of candidates for the expert elicitation meeting that the core team has been working on. We have reached out informally to most to gauge their interest and availability for a meeting this fall (mid-Oct. to mid-Nov.). We will share a different version of this list with our State partners soon to solicit their input. Kurt Johnson with Science Applications at HQ is helping out with potential climate change experts, and the core team will work with him soon to narrow the list of potential climate change modeling folks who might attend the expert workshop.

Talk to you soon.

Jim

Subject: Re: Reminder - Lynx SSA Coordination Call
Date: Tuesday, August 04, 2015 10:54:44 AM

Hi Ann - Good questions. I think you should talk it over with Lisa, but it is probably a good idea to be on these monthly all FWS calls - since you are most in tune with what is going on in the MN/WI Nat'l Forests. I'm not entirely clear who the intended audience/participants are for these monthly calls, however...I assumed it was any interested FWS person who deals with lynx issues and who wants to stay in tune with what the core team is doing, the SSA, etc.

Jim hasn't talked to me yet about the expert elicitation meeting in terms of logistics and behind the scenes coordination. I'll let you know if Jim requests some help. I'm pretty sure it will be scheduled for the week of Oct. 13th.

Thanks,
Tam

>
> I'm trying to figure out how best to integrate with the lynx SSA as a non-core team person and ex-WY lynx bio. For e.g., should I call in today ... is there a need for me to help with the expert elicitation meeting in the fall (behind the scenes organizational stuff) ... etc. I called Lisa and left her a message asking these questions and whether I should just coordinate with you and/or her, etc.

Hi All:

Internal FWS Lynx SSA coordination call today at 10 AM Mountain Time.

(b) (5) CIP
Passcode: (b) (5)

I anticipate a short call to update folks on last week's State coordination call, discuss planning for the expert elicitation meeting this fall, and see if folks have questions.

Attached is the draft list of candidates for the expert elicitation meeting that the core team has been working on. We have reached out informally to most to gauge their interest and availability for a meeting this fall (mid-Oct. to mid-Nov.). We will share a different version of this list with our State partners soon to solicit their input. Kurt Johnson with Science Applications at HQ is helping out with potential climate change experts, and the core team will work with him soon to narrow the list of potential climate change modeling folks who might attend the expert workshop.

Talk to you soon.

Jim

Hi Jim,
Would you please pass along the pdf you presented at last week's state coordination meeting? Thanks much.

Also, in response to the conversation on today's call regarding keeping track of the admin record and FOIA type documents, wanted to pass along what we have been doing for the west coast fisher DPS listing evaluation. We created an email account to which the core team ccs all emails that would be considered part of the record. Of course, the key is that everybody actually does this throughout the process; speaking for myself, I was pretty religious about doing so the first few months, but now I'm not so consistent (same story for many others on the team). However, the one advantage is that when it comes time to compile the record, as I scan through my emails I will know that all those that were sent to the fisher email address are already part of the record and don't need to be provided, so I can weed those out quickly. The downside is that somebody in the fisher lead office will have to pore through all the emails in the fisher account to organize them, whereas some of that organization might otherwise have occurred by the originating office. Anyway, something to consider.
Sue

Date: Tuesday, August 11, 2015 11:13:44 AM

Hi Team,

Mary, Heather, and Tam are all at the R3 SSA Workshop and so unable to attend. However, I'd like to have a brief call with the rest of you at our usual time (these are still not showing up on my Google calendar - yours?).

Anyway, 10 AM Mountain time, 9 AM Pacific, and noon eastern.

Attached is the final Lynx Project Plan for the SSA, Recovery Planning and Five-year Review in both word and pdf format. I am requesting via this email your signature on page 10 of that document. Comments on the draft project plan were received in late April and early May and we have incorporated those changes into the attached document.

For ease of collating signatures please use any of the following methods to add your signature to the document.

1. Open the attached pdf document in Adobe Reader. Click on the fill and sign tab and make a selection for your signature of the document. **Save and send back to Jim Zelenak.**

2. Sign a hardopy of the signature page (10), **scan and send back to Jim Zelenak.**

3. Add your signature in the word document by adding /s/ Your Name. **Save and send back to Jim Zelenak.**

You should have also received notice of what will be our monthly internal FWS coordination calls on the process from Jim Zelanak.
We will be conducting these calls the first tuesday of every month at 10am Mtn time.
Call in information is as follows: (b) (5) CIP passcode: (b) (5) CIP.

Shortly I will also be sending out another letter for our state partners. As we know,

the States are particularly interested in being engaged in our Lynx recovery planning process. To that end, the letter updates where we are now and identifies a monthly coordination call with our state partners to keep them appraised of our progress. It would be helpful if versions of this state letter were sent out from your offices. Please use the version I provide to you as a template.

Thank you for your help and as always feel free to give me a call if you have questions or concerns. JB

I'm at NCTC for Recovery class.

Lunch is scheduled for 12:15 Eastern Time, and I believe we agreed that we'd try to have the SSA FIT call then. I'llk try to find a room or call from my cell.

Same numbers as usual:

(b) (5) CIP
(b) (5)

We'll see how this goes and, if well, I'll email CORE Team later to set up that call for tomorrow.

Jim

From: McCollough, Mark
To: Laury Zicari
Subject: Lynx call at noon today
Date: Monday, October 05, 2015 11:01:46 AM

Laury:

My cell phone does not work here. I've tried calling you this morning and left you a message. Your calendar says that you are at a MEDOT meeting.

Given the turn of events relating to Maine, you are welcome to join our lynx core team call at noon today. I suspect that Jodi Bush will be on the call given similar last-minute events from the State of Montana.

This is the call-in number that we usually use: Phone (b) (5) CIP Passcode (b) (5) If there is anything different I will email.

It will be a great loss if Dan does not attend the meeting. I don't know if it would help if you called Dan. I could do the same, but want to hear what is discussed at noon.

Knowing that not all the experts can "present" at the meeting next week, I asked Dan and Erin to represent Jen's research as appropriate and to please give the State credit for whatever data are presented. They were both very willing to do this.

I am concerned about could be presented by MDIFW next week. I went over Dan and Erin's data with them last week so understood what would have been presented. I will have no idea what will be presented by MDIFW or their latest interpretations. I don't want to be in the position of being caught off guard and having to contest experimental design of studies and interpretations of lynx status opposite to those the Service believes represent the best available science.

You may want to be part of the call at noon - our last before next week's meeting.

Mark

Thanks, Mark.

We do have an implementation team call at 11 Mountain Time (Mary, Heather, Jonathan Cummings) and I will let them know about the Maine issue. Feel free to join that call if you'd like to discuss Dan and Jen, etc..

(b) (5) CIP , passcode: (b) (5)

However, none of us had the time to do so. I truly thought that Dan would be the best presenter since he had the most experience and peer-reviewed publications. I know Dan well enough that he would have been diplomatic about presenting any information that came from the State.

However, we have a timeline that we are required to meet and a process that we have been asked to use and state partners that we have agreed to bring into the process. We will do the best we can to meet those commitments - even when we are faced with controversy within states between academia and state science.

Jim:

I think that Erin could present the Maine summary. If that is the case, I request that Jen present first and Erin last. I know that Dan spent considerable time on the Maine presentation last week. I spent 2 hours with him and subsequently sent a number of figures, maps, etc. for the presentation. I hope he would share the presentation he prepared with Erin.

I have not called Dan, and may call him after our call at noon to see where things stand.

I was not aware of the deepness of the dispute, and was surprised by the reaction of Jen last week and Dan today. Dan is not always in agreement with the scientific rigor and interpretations that the State has produced - published and unpublished. The State has sometimes opposed and discounted the UMaine research, even the conclusions of peer-reviewed publications on which the State biologists were coauthors. Likewise, the Service had concerns about some of the interpretations of lynx and hare status, home range, and habitat needs presented in the State's trapping HCP.

Having met with both Dan and Erin last week, I was comfortable with the scientific integrity of the information they would have presented. I will have no opportunity to preview what the State will present.

This is unfortunate.

Mark

On Mon, Oct 5, 2015 at 11:01 AM, Zelenak, Jim <jim_zelenak@fws.gov> wrote:

Thanks, Mark.

Dan called me just before his email arrived and I didn't have a chance to read it until after he hung up. Sounded like his mind was made up, though I tried to explain many of the same things you did in your email reply to him. It would be nice to give every researcher all the time needed to describe each research effort, but that could take a whole week and we'd never get to the elicitation part of it.

I hope he will reconsider, but I'm doubtful. Guess I didn't understand the depth of the divide between the university and the state. If nothing else, it may have opened a spot on the agenda for Erin - do you think she would be agreeable to contributing to the Maine population update presentation?

On Mon, Oct 5, 2015 at 8:31 AM, McCollough, Mark <mark_mccollough@fws.gov> wrote:

> Dan:
>
> I ask that you please re-consider...
>
> The expert elicitation meeting is meant to be an ongoing discussion of lynx/hare ecology throughout the DPS. Although the agenda reflects a series of presentations, it is not supposed to be a conference - it is designed to be a dialogue. Your input is greatly needed. Lynx/hare ecology has similarities, but there are significant differences throughout their range, particularly as it pertains to Maine.
>
> Given your 15 years of experience, you are recognized as a lynx/hare expert for the Northeast. No one has better peer-reviewed data and publication record, which is why the USFWS asked you to prepare the Maine presentation. We really want you to be present and be able to discuss the research results from Maine - much of which the Service funded along with forest industry. Your absence would be a great loss to our expert elicitation process. Our process is dependent on the best available science. Please reconsider.
>
> Having worked in a state agency and taught wildlife policy, I think you can understand the difficult political position that the USFWS is in trying to balance state interests with our task of developing a lynx recovery plan. The "best" available science should be apparent. The group of scientists assembled can ask critical questions and should be able to assess the rigor and quality of the information presented. I know that you pride yourself for being true to the scientific process, and that will be apparent.
>
> I have expressed my concerns to Jim about the differences of opinion concerning USFWS, State, and UMaine concerning the status of lynx, hares, and their habitat in Maine. I had hoped that we could discuss these differences in a professional manner.
>
> I am in a difficult position. You know how I feel about the science and the quality of your work. However, as a core member of the USFWS team, I have limited ability to be involved in the discussion, and although I feel qualified to represent your (our) research, I cannot make the Maine presentation. Nor could I begin to represent your depth of knowledge on the subject. You truly are our expert.
>
> Thus, as a friend and colleague, I would ask that you please reconsider. Perhaps Jim can talk to you as he did with Jen last Friday.

> Thank you, Mark

On Mon, Oct 5, 2015 at 10:09 AM, Daniel Harrison <harrison@maine.edu> wrote:

> 5 October 2015
>
> Dear Jim,

This morning I received the agenda for the expert elicitation workshop and the phone message that you sent on Friday afternoon 10/2. I was asked verbally to attend as the invited expert representing Maine sometime in August and have been juggling to fit this important meeting into an October agenda that includes 3 other out-of-state trips, including a 3-day trip to Hadley, MA to work with FWS on our collaborative forest bird project, and a myriad of university deadlines --- while also serving as Chair of a growing academic department. I have been working to compile science updates for Maine lynx population based on 7 graduate theses, 7 refereed publications, and 6 papers *in prep* that address the first empirical data on long-term trends in hare populations in Maine's Acadian forests, reliance of hare in southern populations during periods of high and low hare density, social, behavioral and habitat responses of lynx to shifting hare densities, and historical and current distributional changes of lynx in Maine. My topical approach was based on a long list of items that I was asked to cover in previous e-mails and discussions and via meetings with with FWS biologists associated with lynx conservation.

Based on your phone call and draft agenda, the presentation on eastern lynx populations, which represent the vast majority of lynx occurring in the coterminous 48 states, is allotted only 1/7th of the agenda for population status updates. There also is no time scheduled for a discussion of hare populations in the eastern portion of the DPS. Furthermore, your phone message received this morning indicates that you now want me to split the Maine presentation with another invited expert representing the Maine Department of Inland Fisheries and Wildlife. You have further requested that I work to dovetail my presentation with that speaker. I am leaving tomorrow for another FWS workshop and would not have another day in the office prior to departing for the lynx meeting, so that will not be practical. This is also a difficult request given that MDIFW has repeatedly expressed a politically-based agenda to have eastern lynx listed as a separate DPS and for that new DPS to be de-listed based on unpublished, non-peer reviewed science. The peer-reviewed science from my lab has been consistently refuted by that agency based on inconvenient results that run contrary to that agenda. Thus, condensing my presentation to 15 minutes on short notice and asking me to integrate my science-based talk with the unpublished and non-peer reviewed data that has not been shared with me is untenable. I also do not wish to get involved in an open debate of the value of peer-reviewed science versus non-peer reviewed observations at a scientific meeting.

Regretfully, I have decided not to attend the Lynx SSA Expert Solicitation Workshop. My decision is based on the fact that there would be redundancy with 4 invited experts present from Maine, the late notice of the agenda does not allow me to meet your requests given my competing timelines, and the exceptionally brief opportunity to share eastern findings does not warrant 4 days out of office. Further, the likely presence of a political agenda in what had been described to me as a science-based meeting will likely be counter-productive. Those political discussions occur via many venues and I thought this meeting was intended to be science-based. Most importantly, a fifteen minute opportunity to share 2 decades of research, and which would required 4 days out of office, including travel, does not fit into a schedule dominated by a host of other research and university deadlines.

Obviously, I have numerous concerns with how this meeting has been planned and the poor and untimely communication with experts representing the eastern portion of the DPS. Regardless, I wish you all a productive meeting and hope that the outcomes can contribute is some way to lynx conservation and recovery.

Sincerely,

Dan Harrison

> Greetings lynx experts and other presenters!
>
> I've attached the draft agenda for the Oct. 13-15 lynx expert elicitation workshop in Minneapolis. It may be revised slightly as the timing of one or two presentations is still being discussed, but it should give you a feel for what to expect at the workshop.
>
> As you will see, except where there may be several presenters on a given topic or where one presenter will cover several topics or populations, we have assigned half-hour slots to most presentations. This is to include 20 minutes for presentations and 10 minutes for questions and discussion.
>
> I've reached out to most presenters to discuss the topics we hope you will cover. For those presenting the status updates on the individual lynx populations in the DPS, we would like the focus to be on the current versus historic and likely future status and threats to lynx in each particular geographic area (as opposed to updates on specific recent research efforts that otherwise do not address those areas). In addition to presenters, we will welcome discussion/ input from others on the expert panel who are familiar with lynx populations in specific geographic areas.
>
> For all presenters, we ask that you include notes within your presentations, as the presentations themselves will become part of the administrative record as we move forward with completing the SSA report and beginning the recovery planning process. Several of our State, Federal and Tribal partners have also asked that the presentations and other workshop materials be made available, and we hope to honor those requests. After the workshop, we will summarize the notes and proceedings, and we will distribute those to presenters and experts for your review before we distribute them to other interested parties.
>
> I've also attached (1) a one-pager with definitions of the "3 Rs" - Representation, Resiliency and Redundancy - which we consider when evaluating a species' likely viability; (2) a species status assessment (SSA) fact sheet that you may have seen before; and (3) a white paper describing the expert elicitation process and the need and methods to avoid conflicts with the Federal Advisory Committee Act (FACA) and the Administrative Procedures Act (APA).

Please review each of these documents before the workshop.

Next week, I will also send out some examples of the kinds of questions we will be trying address at the workshop, and some draft conceptual models we've worked up to try to illustrate factors/pathways that may influence lynx in the DPS in terms of the 3 Rs.

I'm really looking forward to seeing everyone in a few weeks and learning from your combined experience and expertise. Thanks again for agreeing to help us with the lynx SSA.

Have a great weekend!

Jim

I see that you are planning to stay on the line a bit after the regular conference call but I need to run off for a late lunch to pick up a new pair of lenses across town and need to split right at one. I have an appointment.

I would appreciate a note afterwards if that is not too much trouble so I know the lay of the land. Mark will be on the call and if you prefer I can just check in with him. thanks.

Jim: I will try to participate, but will be at a workshop and may not be able to get away.

I wrote a draft introduction to climate change and ME climate section (attached). Both need more work, but want to share what I have been working on to avoid duplication. You're welcome to post on google.docs to make it easier for everyone to edit.

Below is the webinar link/info for the RD lynx briefing on Monday 4/11. No passcode needed for the webinar. I can change host name to yours if you prefer.

Conference line call-in number (b) (5) CIP
Participant passcode: (b) (5)

RO - Mike, Marjorie, Seth, and Craig Hansen
SSA Team - Heather B., Mary Parkin, Jonathan Cummings, Mark McCullough, Tamara Smith, Bryon Holt, Kurt Broderdorp

If you just want to send it to RO and CC me, I can forward to SSA Team.

Thanks.

We are still needing signatures on the project plan from:

WYFO (Mark Sattleberg)
WAFO (Eric Rickerson)
R2 ARD (Name?)
NEFO (Tom Chapman)
R6 ARD (Mike T - wants to sign last).

You should have also received notice of what will be our monthly internal FWS coordination calls on the process from Jim Zelanak.
We will be conducting these calls the first tuesday of every month at 10am Mtn time.
Call in information is as follows: (b) (5) CIP, passcode: (b) (5) CIP.

Shortly I will also be sending out another letter for our state partners. As we know, the States are particularly interested in being engaged in our Lynx recovery planning process. To that end, the letter updates where we are now and identifies a monthly coordination call with our state partners to keep them appraised of our progress. It would be helpful if versions of this state letter were sent out from your offices. Please use the version I provide to you as a template.

Thank you for your help and as always feel free to give me a call if you have questions or concerns. JB

Thanks Tom! We haven't needed much of Tony's time for the lynx SSA. But there will be a time in the near future when we could use his review of sections pertaining to NH and VT. Thanks, Mark

Its hard to start writing this SSA from scratch. Furthermore, its hard to know how much information to include in a "light" version. What do decision-maker's want or not want? The example SSAs are a bit helpful, but not the best examples for representing a species for which we have lots of information. My sense is that by taking more time to capture the more detailed information in this SSA, then we save time in the future by not having to repeat/rewrite it again. Or do the powers that be expect something simpler?

Mark

Oops, when I checked the calendar a little while ago, I saw the call wasn't on there, so I duplicated the last previous core team call I could find on the calendar, which began at 9:30 MT. I'll change it immediately, and I do plan to be on the call, Jim.

I'll spend some time later today (I have to leave for an appt now) getting the calendar invites up to speed. Will check with you, Jim, to make sure their correct.

Cheers,
Mary

Hi Jim -

I am available to be on the call tomorrow morning at 10AM MT, if others are available then...

Thanks!
Tam

On Fri, Jun 26, 2015 at 10:59 AM, Bush, Jodi <jodi_bush@fws.gov> wrote:

Attached is the final Lynx Project Plan for the SSA, Recovery Planning and Five-year Review in both word and pdf format. I am requesting via this email your signature on page 10 of that document. Comments on the draft project plan were received in late April and early May and we have incorporated those changes into the attached document.

For ease of collating signatures please use any of the following methods to add your signature to the document.

1. Open the attached pdf document in Adobe Reader. Click on the fill and sign tab and make a selection for your signature of the document. **Save and send back to Jim Zelenak.**

2. Sign a hardopy of the signature page (10), **scan and send back to Jim Zelenak.**

3. Add your signature in the word document by adding /s/ Your Name. **Save and send back to Jim Zelenak.**

You should have also received notice of what will be our monthly internal FWS coordination calls on the process from Jim Zelanak.
We will be conducting these calls the first tuesday of every month at 10am Mtn time.
Call in information is as follows: (b) (5) CIP, passcode: (b) (5) CIP

Shortly I will also be sending out another letter for our state partners. As we know, the States are particularly interested in being engaged in our Lynx recovery planning process. To that end, the letter updates where we are now and identifies a monthly coordination call with our state partners to keep them appraised of our progress. It would be helpful if versions of this state letter were sent out from your offices. Please use the version I provide to you as a template.

Thank you for your help and as always feel free to give me a call if you have questions or concerns. JB

Subject: Core Team Call tomorrow

Hi Team,

I'd like to have a call tomorrow at our usual time (10 Mountain) and number (b) (5) CIP (b) (5) CIP).

Let me know if you can or cannot make it.

I'd like to have everyone ready to discuss the current outline of the document on the drive - I've made some changes in trying to organize things - and to discuss the major gaps and how we best get them filled.

Would also like to touch on any responses to peer review "feelers" that folk shave been sending out, and whether/when we need to start letting RO folks know that we will need some level of in-house review before we go out to peer reviewers. I think Jodi has a plan for the latter, though I'm not certain of the details yet.

Also any thoughts/concerns you all may have.

Thanks.

Subject: Lynx SSA call tomorrow
Date: Monday, May 16, 2016 1:45:15 PM

Hi All:

As I discussed last week with the Core Team, I'd like to have a call again this week and get back to weekly Core Team calls for the next little while to check-in on progress and clarify assignments, etc. as we try to get this SSA report wrapped up.

Because it's been a little while since we've had regular calls with the rest of the team, I thought we could have dual Core/Implementation teams call tomorrow, so I'm hoping Mary, Heather and Jonathan will be able to join and provide guidance on some parts of the documents and on getting the appropriate versions of the conceptual model(s) and summary tables finalized and ready to import to the report.

Anyway, Mary will send out a calendar invite soon, but please dial in at our normal Core Team time of 10 Mountain Time at the usual number/passcode:

(b) (5) CIP
(b) (5)

Look forward to talking with you all tomorrow.

Thanks,

Jim

Subject: Re: Lynx SSA Calendar Invites
Date: Monday, June 06, 2016 11:16:17 AM

Hi Mary,

Jodi has recommended that we keep the internal FWS updates separate from the state coordination calls.

Given that, could you send a calendar reminder/invite for tomorrow, Tues. June 7, 10 AM Mountain Time to the email list below, and include the title call-in info here?:

Title: Lynx SSA Coordination Call - Internal FWS
(b) (5) CIP
Passcode: (b) (5)

I suspect a very quick call to let folks know where we're at with the SSA report (scrambling to finish it) and to see if folks have questions.

If I don't hear back from you (if you are traveling, on leave, or otherwise occupied), by about 2-3 today, i will just send an email.

Thanks,

Jim

Hi All:

Hope Core Team can make the call this morning at 10 Mountain Time. FIT Team and managers welcome, too. Will have a quick rundown on where we are with the SSA Report and what sections remain to complete; other items as necessary.

It was nice to step away from the SSA for almost a week. I did not take my computer along, and I slept better most nights than I have at home lately. It was also nice to see friends and family again, and for Abby to "meet" some of her cousins who haven't' seen her since she was 2 (and of course she has no memories of that).

I never did get to see small-whorled pogonia in WV - I think there were only a very few known occurrences in the state...

No need to apologize - you've already done more than your share on the SSA, and I know you have other responsibilities. Bryon and Kurt also could not be on the call, so it was a brief discussion with Tam, Mary and Jonathan. I've been meaning to send an email to let you and the others know what we discussed and to get some thoughts on time lines for having sections finished.

If I'm disappointed in anything, it is in my own inability to pull this document toward some semblance of completion. I'm still struggling to write some of the pop. requirements section and to get thru Ch. 3, 4 and 5. Not sure why, but writing this is like pulling teeth for me lately. Every time I make a little progress, i think of other details/nuances that seem important to discuss.

I don't have any requests for additional particular work - I guess if you have time and feel inclined you could work on polishing the fragmentation section - I have not had a chance to carefully review what you put together there (or your other sections for that matter).

I will send a follow-up email to the Core Team in a few minutes asking everyone to have their Ch. 4 and 5 sections finished and as tight and concise as possible by the end of next week (that's when Tam thought she might have time to get hers done). It looks like you are mostly done, maybe completely, but if you have time to edit out any redundancies and tighten things up, that would be great. I don't anticipate me or the others going into the level of detail you provided for your unit. At some point, we will likely have to edit for consistency among units, but I can't worry about that at the moment.

Wish I was joining you at NCTC for the climate change course.

Thanks for your continuing efforts Mark.

>
> We have a new supervisor-of-the-month who raised her eyebrows when I said I had set aside a BA from early April from USDA APHIS for their mammal trapping program in ME, VT, NH (consultation on lynx). So, I've had to work on that last week. The document was in rough shape and likely needs to be redeveloped as a programmatic consultation on a wide variety of animal damage control and rabies projects. I still need another day or two to

complete. I also have a draft EA from April from the Corps for a piping plover beach that needs a response. In other words, work has backed up because of the SSA and I need to do some things to ease the pressure.

I hope to be back to SSA work next week.

Let me know if there is anything in particular you would like me to work on.

I will be gone to NCTC for a climate change class (that I hope will help with the lynx and Furbish's lousewort SSAs) the week of July 11. I will be taking the next week for annual leave to visit my parents in PA.

I'm working on the SSA review between my travels. I should have Ch. 3 to you some time soon. With my travel, and without Ch. 6 (and the portions of 4 and 5 that most closely support Ch. 6) complete I'm going to hold off on reviewing those until they are complete and I'm through travels (I return August 8th).

In regards to figures, there is room for updating the conceptual models to match the text and simplify them (e.g., removing the demographic portion of the resiliency diagram). I would encourage a summary table of current condition in some form, whether the one developed in Denver or an adaptation the team develops.

I wont be able to join the calls this week or next, but can comment via email if you want my input on anything.

Jonathan

Jim:

I will be on the call today and ready to dive back into the SSA. Sorry for my absence the last 2 or 3 weeks.

I still have a backlog of section 7 consultations hanging over my head and I am still required to work on sorting out our office files - left in shambles by the mover. There's just not enough hours in the day.

Thanks for you time and contributions on the call today.

Heather asked that I follow up with an email about assignments we discussed for Core Team, so:

1. Make sure your unit parts of chapters 4 and 5 are as tight as you can make them, addressing the template items for each. In Ch. 5, the last part of the unit-specific sections should be "lynx viability" - where you should summarize the expert workshop results and import the probability of persistence graph for your unit and discuss if need be. Tam has already take a stab at this, so take a look at her Ch. 5/Unit 2.

2. Review and comment on Chapters 1-3 with an eye to anything that might be repeated in later chapters - if so, look for opportunities to reduce redundancy by referring to the earlier sections if appropriate/applicable.

3. Review figures/conceptual models and make any comments/suggestions that you think might improve them (except for the map, which we've already discussed and will work thru another time soon).

4. Also see (at link below to the drive) the spreadsheet Jonathan pulled together while we were working on a current conditions table in Denver: Take a look at the various sheets and think about how we might generate a table that would be useful in the SSA report (at the end of Ch. 4). I'd welcome thoughts on or efforts at turning it into a table for the report.

https://docs.google.com/spreadsheets/d/1BkxJiAfXH4QyqXv86A-Bj0VBfHyTJtwQXBd9Le0giZw/edit#gid=1917623158

4. Provide bullets or general thoughts for the DPS-wide summaries at the ends of Ch. 4 and 5, and for the synthesis section.

5. As Kurt mentioned, make sure you add any new citations to the list and move pdfs to the drive (only docs that are not already in the LCAS 2013 lit cited file).

I'm probably forgetting something, but I think that's most of it.

I'll send out a reminder for the state coordination call tomorrow and hope you can join that, too.

Thanks again.

>
> Jodi and I talked yesterday, and she wants me to hand her something to review by COB today, recognizing that there still will be some gaps - (mine). She recognizes the time line issues and is concerned. I also let her know that I was struggling with getting the doc finished, and she thinks I'm too worried about perfecting/polishing things, and asked me to fill as much of the gaps as I can - which is my goal today. She also sees that I'm stressed, have been working weekends and not sleeping too well - so she has asked me to step away from it for a few days after I give it to her at the end of the day today. So I will do that.
>
> Anyway, you all have filled in your parts, please make sure you feel they are ready for the first step of internal FWS review.
>
> Also, on last week's call, I requested that each member pull together a summary paragraph or bullets for their unit for the summary/DPS-wide wrap-up for both Ch. 4 and Ch. 5 - your most important points for the current and future condition for your unit. Please see what Mark and Tam have done for sections 4.2 and 5.2, and try to add your summaries/bullets by COB today.
>
> Mark and I also discussed some potentially useful table/summary templates from the recent Alexander Archipelago Wolf SSA (link below), and Mark will be working today on pulling those into the lynx drive document today. See pages 123-127 of the wolf SSA and start thinking about what info you could contribute based on your unit assessment to tables similar to 26 and 27 in the wold doc.

Hi Team,

We have our weekly call today at 10 Mountain Time.

Jodi and I will discuss where we're at and how we might best move forward. Mark and I will discuss some potentially useful templates from the Alexander Archipelago Wolf SSA that might be useful in helping us wrap things up. We've been talking particularly about pp. 123-127 of the wolf SSA. Take a look if you are interested:

https://www.fws.gov/alaska/fisheries/endangered/pdf/aa_wolf/AA_wolf_SSA_Final.pdf

Usual number and passcode:

(b) (5) CIP
(b) (5)
CIP

Talk to you all in a bit.

Thanks.

Hi Jim,

First, I plan to be on the call but may be a tad late, as I need to pick up my son from therapy right around then.

Second, apologies for not getting further in my review to date. I've been swamped by another time-sensitive project (these days it seems to be a matter of trading off between one urgent project and another), but will continue reviewing as quickly as possible.

Third, the wolf SSA report looks like the best example so far for the lynx. The tables laying out the evidence and uncertainties relative to the 3Rs are particularly useful.

Talk with you all soon,
Mary

Hi All:

After talking briefly with Justin, we thought it would be good to have the Core Team (as well as FIT) on the call tomorrow (Sept. 20) so everyone is up to date, we can talk about what remains to be reviewed by the Core Team before the draft SSA report is ready for broader internal Service review, and our options for progress given the access/editing challenges on Google Drive.

Core Team also needs to discuss several of the draft tables currently in the doc.

So please join the call if you can. 10 AM Mountain Time, usual number and passcode:

(b) (5) CIP
Passcode (b) (5) CIP

We will also have the webinar up so we can work through the document together (likely a word version given access issues). Webinar access information at bottom.

Hope Core and FIT members can attend.

Thanks,

Hi Jim and all,

I won't be able to make the call and the Executive Summary is still in process, but I think this is the least important thing to discuss at this point!

I'll try to catch up with you before I head out (of the country) next week.

Cheers,
Mary

Jodi - does this replace this afternoon's briefing? Also, the ARDs will be in a meeting together, so probably can't join on the 18th. Paul

You are invited to join a meeting hosted by Jodi Bush. Meeting details are listed below.

Meeting Date: 10/18/2016
Meeting Time: 1:00 PM MOUNTAIN TIME

Instant Net Conference Details:

Meeting Number: (b) (5) CIP
Meeting Passcode:
Meeting Host: BRENT ESMOIL

Join Instructions for Instant Net Conference:

1. Join the meeting now:
(b) (5) CIP(b) (5) CIP(b) (5) CIP(b) (5) CIP(b) (5) CIP(b) (5) CIP
2. Enter the required fields.
3. Indicate that you have read the Privacy Policy.
4. Click on Proceed.

When	Tue Oct 18, 2016 3pm – 4pm Eastern Time
Where	RD conference room for RO staff call in (b) (5) CIP PC (b) (5) CIP (Noreen only (b) (5) CIP) (map)
Video call	https://plus.google.com/hangouts/_/doi.gov/noreen-walsh
Calendar	paul_phifer@fws.gov
Who	• noreen_walsh@fws.gov - organizer • stephanie_potter@fws.gov - creator • Robyn Thorson • heather_bell@fws.gov • jwcummings@usgs.gov • Justin Shoemaker • Jodi Bush • mary_parkin@fws.gov • tamara_smith@fws.gov • sarah_hall@fws.gov • Tom Melius • Wendi Weber • kurt_broderdorp@fws.gov • Seth Willey • jim_zelenak@fws.gov • paul_phifer@fws.gov • mark_mccollough@fws.gov • Michael Thabault • bryon_holt@fws.gov • ted_koch@fws.gov • theresa_rabot@fws.gov • rollie_white@fws.gov • Marjorie Nelson • Martin Miller - optional • Alisa Shull - optional • Marilet Zablan - optional

Going? **Yes** - **Maybe** - **No** more options »

---

yes, it replaces todays meeting. Sorry about the change. Noreen is going on leave for a while so we were trying to squeeze it in before we leave.

The call is just informational on where we are at etc. Similar to what we talked about on phone earlier this week. but with more detail for RDs. Alot of recap from our April meeting.

I will send you any documents we prep for it (working on those now). Feel free to give me a call if you have questions. JB

INFORMATION/ BRIEFING MEMORANDUM FOR THE REGIONAL DIRECTOR

DATE: October 18, 2016

FROM: Jodi Bush, Supervisor, Montana Ecological Services Office, (406) 449-5225.

SUBJECT: Status of Lynx SSA Process for RD Briefing

We have completed a DRAFT Species Status Assessment (SSA) report for the contiguous U.S. distinct population segment (DPS) of the Canada lynx (Figure 1). The SSA was undertaken as part of the new recovery planning process. Additionally it is going to inform our response to a court order to complete a recovery plan by January 15, 2018 "…unless the Service finds that such a plan will not promote the conservation of the [lynx]"). The SSA assembles the best available information on the current status and likely future viability of the DPS. It is intended to inform multiple Service needs including a determination by Service decision makers of whether (1) the DPS continues to warrant protection under the Endangered Species Act (Act) and (2) a recovery plan is needed to guide conservation and recovery of the DPS. It may also identify potential recovery criterion (as informed by the subsequent decision meeting) and those actions needed to achieve recovery. A status recommendation will be documented in a five-year status review based on the final SSA report.

BACKGROUND

The Service designated the lynx DPS as threatened in 2000 because of the inadequacy, at that time, of existing regulatory mechanisms on federal lands. In 2003, in response to a court ruling, we reaffirmed the DPS's status as threatened. We completed a recovery outline in 2005, designated critical habitat for the DPS in 2006, and, in 2007, again in response to a court order, clarified our determinations of "significant portion of the range" and that all lynx in the contiguous U.S. constitute a single DPS. We revised the critical habitat designation in 2009 and again in 2014 in response to a court order. We reinitiated the 5-year status review in January, 2015 and commenced the SSA in April, 2015. In September 2016, the court remanded the 2014 critical habitat rule for further evaluation of Colorado and five national forests in Idaho and Montana.

KEY POINTS

- We announced the re-initiation of a five-year status review on January 13, 2015. Shortly thereafter, we embarked on the SSA framework. Information in the SSA will be used by Service decision makers to inform classification decisions, recovery planning direction, and other determinations required by the Act.
- Through the SSA framework we have assessed the species' needs, current and future condition including viability of the DPS using a compilation of the best available scientific and commercial data, including empirical data, published literature, and expert input.
- We engaged State, Tribal and other Federal, and Canadian partners and other stakeholders, as well as Service managers. We coordinated with State partners and internal Service managers through separate monthly coordination calls.
- In the fall of 2015, we convened a workshop for scientific experts to address the current and likely future status of the DPS. The participants included state agencies, biologists from other federal agencies, and academic researchers to elicit input from experts across the range of the DPS.

- Information solicited from the 10 member lynx expert panel addressed the viability of the DPS based on the 3Rs (Representation, Redundancy, Resiliency) and what is known about climate science related to lynx. The resultant workshop report is one component of the SSA.
- We just completed the DRAFT SSA report and have forwarded it for internal review to Service staff in each region with lynx (Regions 1, 2, 3, 5, and 6). This review will be expedited and will focus on the science. Once completed and revisions made, the SSA will be provided to our Peer Review consultant and to State and Federal partners for their review and comment.
- Using the Service's open peer review contract, we hired ATKINS to conduct a Peer Review for us on the scientific findings in SSA. That contract is let and will commence as soon as the Service has completed our internal review.

TIMELINE

- Expert Workshop FINAL Report — April, 2016
- SSA Report
  - DRAFT Completed — October 14, 2016
  - Internal Review Complete — October 24, 2016
  - Peer/Partner Reviews Complete — December 31, 2016

  - FINAL (if necessary) — January 2018

IMPORTANT MESSAGES

- Several decision points were agreed to in April 2016 regarding the SSA.
  - Because the climate change science is important in our decision, we asked if we needed better information to address likely impacts to lynx from CC? *Based on the additional timeline needed to gather that information, ARDs determined no.*
  - Because the decision makers will need the information on a range of climate change scenarios for their decision, we asked if they were comfortable with the range of climate scenario years from the panel report? Present, mid-century (2050), and end of century (2100*)? ARDs indicated they were.*
  - Because our partners have a strong interest in this process, we asked if when conducting Peer review of SSA, whether we wanted our State counterparts to receive it at the same time? *Based on discussions with ARDs, we will provide State counterparts with an opportunity to review the SSA during the PEER review.*
  - Finally, because the SSA is a science document not a decision document we asked if the managers wanted a recommendation from the SSA team? *The ARDs agreed that the five-year review would be the place for a recommendation from the team.*
- We are behind in the development of the recovery planning process by 6 to 9 months.

Peter and Glenn: You are certainly welcome to participate in the webinar at 3:00 this afternoon on the lynx SSA. (See details below.) I'm not sure who else may participate from R5 as I believe Paul is away and Marty is in PA. Glenn may be on the call? Mary probably will be also.

We have completed the draft SSA and it has been distributed for in-house review. There is a relatively quick turnaround for our review before it is distributed to states and peer reviewers.

The lynx core team authors have been instructed to review the document one more time as we experienced some problems at the end with Google Drive. I will have my review completed by Friday and will forward my track changes to both of you (and Marty). Marty said that Paul would like to see our R5 comments before we respond to R6.

Thanks, Mark

INFORMATION/ BRIEFING MEMORANDUM FOR THE REGIONAL DIRECTOR

DATE: October 18, 2016

FROM: Jodi Bush, Supervisor, Montana Ecological Services Office, (406) 449-5225.

SUBJECT: Status of Lynx SSA Process for RD Briefing

We have completed a DRAFT Species Status Assessment (SSA) report for the contiguous U.S. distinct population segment (DPS) of the Canada lynx (Figure 1). The SSA was undertaken as part of the new recovery planning process. Additionally it is going to inform our response to a court order to complete a recovery plan by January 15, 2018 "…unless the Service finds that such a plan will not promote the conservation of the [lynx]"). The SSA assembles the best available information on the current status and likely future viability of the DPS. It is intended to inform multiple Service needs including a determination by Service decision makers of whether (1) the DPS continues to warrant protection under the Endangered Species Act (Act) and (2) a recovery plan is needed to guide conservation and recovery of the DPS. It may also identify potential recovery criterion (as informed by the subsequent decision meeting) and those actions needed to achieve recovery. A status recommendation will be documented in a five-year status review based on the final SSA report.

BACKGROUND

The Service designated the lynx DPS as threatened in 2000 because of the inadequacy, at that time, of existing regulatory mechanisms on federal lands. In 2003, in response to a court ruling, we reaffirmed the DPS's status as threatened. We completed a recovery outline in 2005, designated critical habitat for the DPS in 2006, and, in 2007, again in response to a court order, clarified our determinations of "significant portion of the range" and that all lynx in the contiguous U.S. constitute a single DPS. We revised the critical habitat designation in 2009 and again in 2014 in response to a court order. We reinitiated the 5-year status review in January, 2015 and commenced the SSA in April, 2015. In September 2016, the court remanded the 2014 critical habitat rule for further evaluation of Colorado and five national forests in Idaho and Montana.

KEY POINTS

- We announced the re-initiation of a five-year status review on January 13, 2015. Shortly thereafter, we embarked on the SSA framework. Information in the SSA will be used by Service decision makers to inform classification decisions, recovery planning direction, and other determinations required by the Act.
- Through the SSA framework we have assessed the species' needs, current and future condition including viability of the DPS using a compilation of the best available scientific and commercial data, including empirical data, published literature, and expert input.
- We engaged State, Tribal and other Federal, and Canadian partners and other stakeholders, as well as Service managers. We coordinated with State partners and internal Service managers through separate monthly coordination calls.
- In the fall of 2015, we convened a workshop for scientific experts to address the current and likely future status of the DPS. The participants included state agencies, biologists from other federal agencies, and academic researchers to elicit input from experts across the range of the DPS.

- Information solicited from the 10 member lynx expert panel addressed the viability of the DPS based on the 3Rs (Representation, Redundancy, Resiliency) and what is known about climate science related to lynx. The resultant workshop report is one component of the SSA.
- We just completed the DRAFT SSA report and have forwarded it for internal review to Service staff in each region with lynx (Regions 1, 2, 3, 5, and 6). This review will be expedited and will focus on the science. Once completed and revisions made, the SSA will be provided to our Peer Review consultant and to State and Federal partners for their review and comment.
- Using the Service's open peer review contract, we hired ATKINS to conduct a Peer Review for us on the scientific findings in SSA. That contract is let and will commence as soon as the Service has completed our internal review.

TIMELINE

- Expert Workshop FINAL Report — April, 2016
- SSA Report
  - DRAFT Completed — October 14, 2016
  - Internal Review Complete — October 24, 2016
  - Peer/Partner Reviews Complete — December 31, 2016
  - FINAL Report Complete — January 15, 2017
- Decision Meeting — January 30, 2017
- Five-year Review
  - DRAFT — February 07, 2017
  - FINAL — February 28, 2017
- Recovery Plan
  - DRAFT using REV process (if necessary) — May 2017??
  - FINAL (if necessary) — January 2018

IMPORTANT MESSAGES

- Several decision points were agreed to in April 2016 regarding the SSA.
  - Because the climate change science is important in our decision, we asked if we needed better information to address likely impacts to lynx from CC? *Based on the additional timeline needed to gather that information, ARDs determined no.*
  - Because the decision makers will need the information on a range of climate change scenarios for their decision, we asked if they were comfortable with the range of climate scenario years from the panel report? Present, mid-century (2050), and end of century (2100*)? ARDs indicated they were.*
  - Because our partners have a strong interest in this process, we asked if when conducting Peer review of SSA, whether we wanted our State counterparts to receive it at the same time? *Based on discussions with ARDs, we will provide State counterparts with an opportunity to review the SSA during the PEER review.*
  - Finally, because the SSA is a science document not a decision document we asked if the managers wanted a recommendation from the SSA team? *The ARDs agreed that the five-year review would be the place for a recommendation from the team.*
- We are behind in the development of the recovery planning process by 6 to 9 months.

INFORMATION/ BRIEFING MEMORANDUM FOR THE REGIONAL DIRECTOR

DATE: October 18, 2016

FROM: Jodi Bush, Supervisor, Montana Ecological Services Office, (406) 449-5225.

SUBJECT: Status of Lynx SSA Process for RD Briefing

We have completed a DRAFT Species Status Assessment (SSA) report for the contiguous U.S. distinct population segment (DPS) of the Canada lynx (Figure 1). The SSA was undertaken as part of the new recovery planning process. Additionally it is going to inform our response to a court order to complete a recovery plan by January 15, 2018 "…unless the Service finds that such a plan will not promote the conservation of the [lynx]"). The SSA assembles the best available information on the current status and likely future viability of the DPS. It is intended to inform multiple Service needs including a determination by Service decision makers of whether (1) the DPS continues to warrant protection under the Endangered Species Act (Act) and (2) a recovery plan is needed to guide conservation and recovery of the DPS. It may also identify potential recovery criterion (as informed by the subsequent decision meeting) and those actions needed to achieve recovery. A status recommendation will be documented in a five-year status review based on the final SSA report.

BACKGROUND

The Service designated the lynx DPS as threatened in 2000 because of the inadequacy, at that time, of existing regulatory mechanisms on federal lands. In 2003, in response to a court ruling, we reaffirmed the DPS's status as threatened. We completed a recovery outline in 2005, designated critical habitat for the DPS in 2006, and, in 2007, again in response to a court order, clarified our determinations of "significant portion of the range" and that all lynx in the contiguous U.S. constitute a single DPS. We revised the critical habitat designation in 2009 and again in 2014 in response to a court order. We reinitiated the 5-year status review in January, 2015 and commenced the SSA in April, 2015. In September 2016, the court remanded the 2014 critical habitat rule for further evaluation of Colorado and five national forests in Idaho and Montana.

KEY POINTS

- We announced the re-initiation of a five-year status review on January 13, 2015. Shortly thereafter, we embarked on the SSA framework. Information in the SSA will be used by Service decision makers to inform classification decisions, recovery planning direction, and other determinations required by the Act.
- Through the SSA framework we have assessed the species' needs, current and future condition including viability of the DPS using a compilation of the best available scientific and commercial data, including empirical data, published literature, and expert input.
- We engaged State, Tribal and other Federal, and Canadian partners and other stakeholders, as well as Service managers. We coordinated with State partners and internal Service managers through separate monthly coordination calls.
- In the fall of 2015, we convened a workshop for scientific experts to address the current and likely future status of the DPS. The participants included state agencies, biologists from other federal agencies, and academic researchers to elicit input from experts across the range of the DPS.

- Information solicited from the 10 member lynx expert panel addressed the viability of the DPS based on the 3Rs (Representation, Redundancy, Resiliency) and what is known about climate science related to lynx. The resultant workshop report is one component of the SSA.
- We just completed the DRAFT SSA report and have forwarded it for internal review to Service staff in each region with lynx (Regions 1, 2, 3, 5, and 6). This review will be expedited and will focus on the science. Once completed and revisions made, the SSA will be provided to our Peer Review consultant and to State and Federal partners for their review and comment.
- Using the Service's open peer review contract, we hired ATKINS to conduct a Peer Review for us on the scientific findings in SSA. That contract is let and will commence as soon as the Service has completed our internal review.

TIMELINE

- Expert Workshop FINAL Report — April, 2016
- SSA Report
  - DRAFT Completed — October 14, 2016
  - Internal Review Complete — October 24, 2016
  - Peer/Partner Reviews Complete — December 31, 2016
  - FINAL Report Complete — January 15, 2017
- Decision Meeting — January 30, 2017
- Five-year Review
  - DRAFT — February 07, 2017
  - FINAL — February 28, 2017
- Recovery Plan
  - DRAFT using REV process (if necessary) — May 2017??
  - FINAL (if necessary) — January 2018

IMPORTANT MESSAGES

- Several decision points were agreed to in April 2016 regarding the SSA.
  - Because the climate change science is important in our decision, we asked if we needed better information to address likely impacts to lynx from CC? *Based on the additional timeline needed to gather that information, ARDs determined no.*
  - Because the decision makers will need the information on a range of climate change scenarios for their decision, we asked if they were comfortable with the range of climate scenario years from the panel report? Present, mid-century (2050), and end of century (2100*)? ARDs indicated they were.*
  - Because our partners have a strong interest in this process, we asked if when conducting Peer review of SSA, whether we wanted our State counterparts to receive it at the same time? *Based on discussions with ARDs, we will provide State counterparts with an opportunity to review the SSA during the PEER review.*
  - Finally, because the SSA is a science document not a decision document we asked if the managers wanted a recommendation from the SSA team? *The ARDs agreed that the five-year review would be the place for a recommendation from the team.*
- We are behind in the development of the recovery planning process by 6 to 9 months.

Figure 1. Six geographic units within the range of the contiguous U.S. distinct population segment of Canada lynx (Lynx canadensis) that currently support or recently supported (GYA) resident lynx populations.

Hi Jodi,

Thank you for sending all of this information. Unfortunately, I have a mandatory office-wide meeting at 1:00 pm today and cannot be on your call. If there are webinar materials that you could send me, I would very much appreciate receiving a copy for review.

Thank you!

Best regards,
Patricia

No worries, Bryon.

We will probably do a similar presentation/webinar on the next all-FWS coordination call - Tues., Nov 1, and notice of that will go out to all the ROs and FOs in the range.

Jodi and I also discussed bumping the State coordination call from next Wed. to the following Wed. (Nov.2), and giving a similar webinar for that update. I will send that out later this week also.

We will also have our weekly Core/FIT call next Tues. at 10 Mountain Time. I'll send out reminder for that later this week.

Thanks again for joining today.

Update on Canada Lynx Species Status Assessment

October 18, 2016

Overview

- What are we doing?
  - Completing SSA to inform recovery planning
    - Court order to finalize RP by Jan. 2018
    - Unless we determine RP not needed (i.e., the DPS is recovered)
- Why?
  - SSA provides analysis needed to re-evaluate the status of the DPS
  - SSA will then be used in decision context of 5-year review (before proceeding with recovery planning)

Objectives

- Share Status of the SSA
- Discuss Timeline
- Identify Next Steps

Lynx Basics

- Boreal forest species dependent on snowshoe hares and favorable snow conditions
- At southern periphery of ranges in contiguous US
- Habitat becomes patchy; hare densities and snow conditions become suboptimal/marginal for supporting lynx populations
- Mainland-island metapopulation structure (?)
- Historical cyclic "irruptions" of lynx from Canada into northern U.S. when hares crashed (currently?)

Background

- Contiguous U.S. lynx DPS listed as T in 2000
  - Factor D - inadequacy, at that time, of existing regulatory mechanisms on federal lands
- CH designated 2006, revised 2009 and 2014
  - Sept. 2016 - Court remanded 2014 CH rule
    - Ruled Service was arbitrary and capricious in not designating CH in Colorado
    - Inadequate evaluation of PCE on 5 NFs in MT and ID
    - We have not determined next steps in our response to this litigation

Background

- 2005 Recovery Outline focused on interim conservation measures in 6 "Core" areas
  - Historic/current resident population(s); reproduction; 0.5 hares/ha; >= 1,250 km^2 habitat
  - S. Rockies (western CO and south central WY) - "provisional" core area

Current DPS Distribution

- 6 geographic areas known or thought to support resident lynx populations in the DPS:
  - 1. Northern Maine (& northernmost NH and VT)
  - 2. Northeastern Minnesota
  - 3. Northwestern Montana/Northeastern Idaho
  - 4. North-central Washington
  - 5. GYA of southwest Montana/northwest Wyoming
  - 6. Western Colorado – introduced population

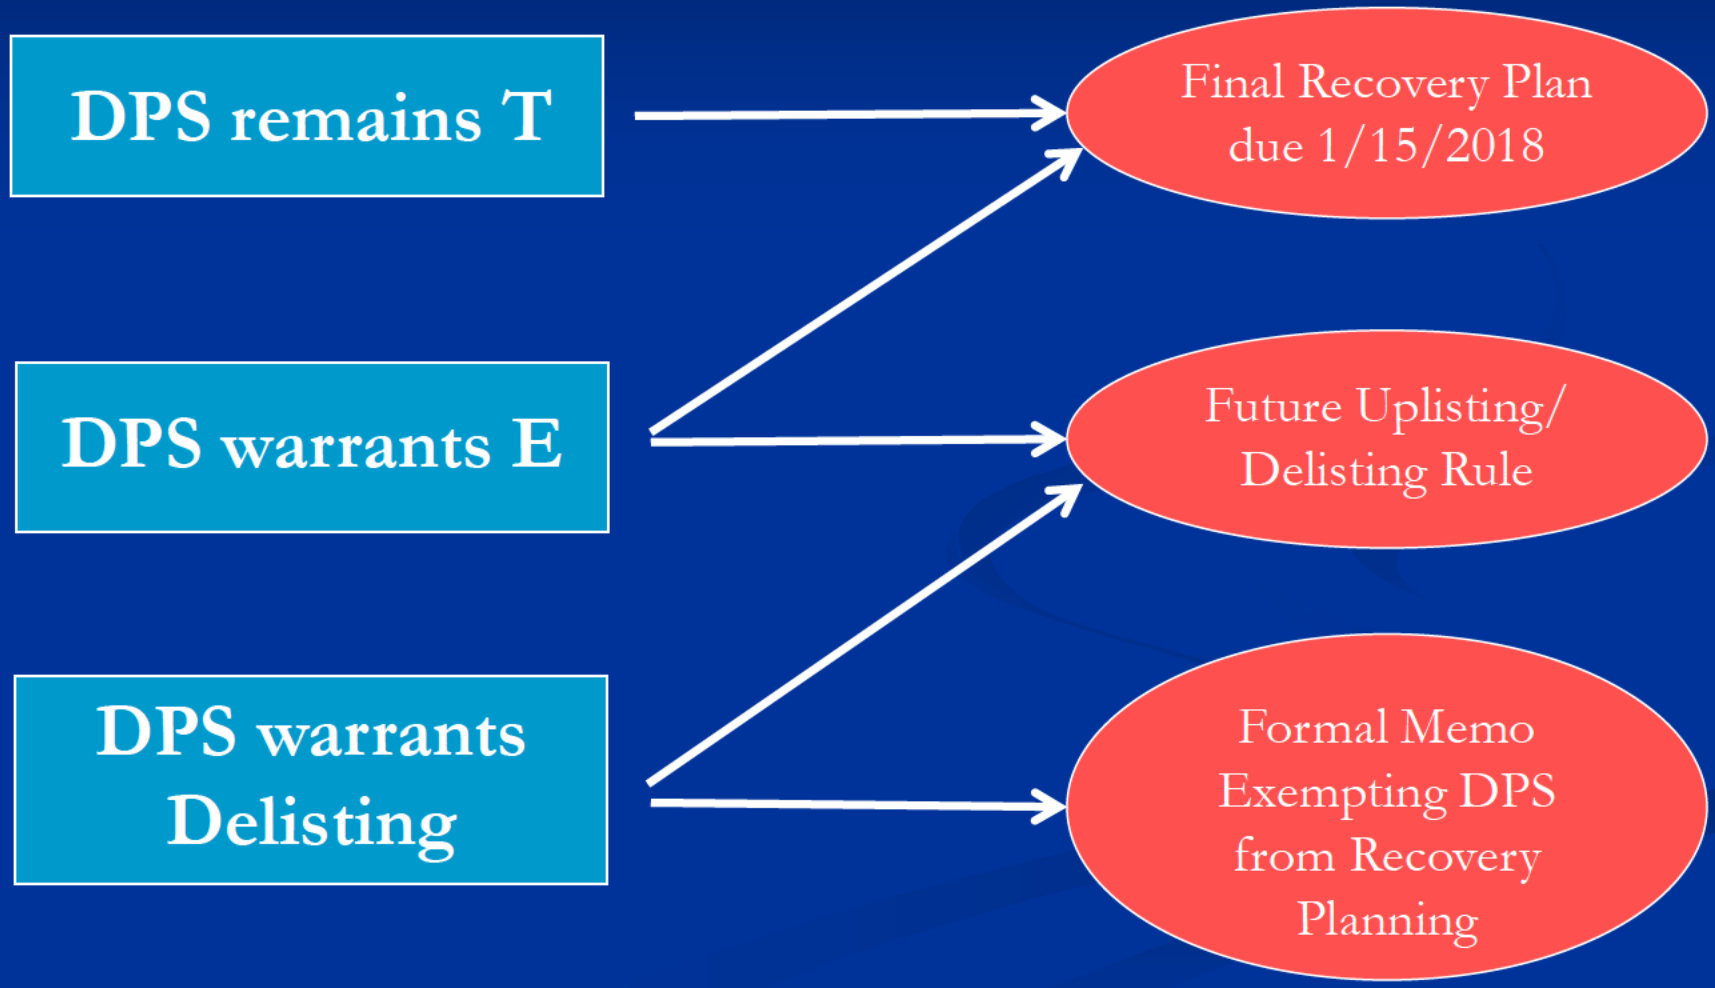

Figure 1. Six geographic units within the range of the contiguous U.S. distinct population segment of Canada lynx (*Lynx canadensis*) that currently support or recently supported (GYA) resident lynx populations.

Key Points

- January 2015 - announced re-initiation of five-year status review
- March 2015 – determined need to complete SSA
- Information in the SSA will be used by FWS decision makers to inform:
  - Recovery planning direction
  - Classification decisions
  - Other determinations required by the ESA

Potential Findings

Key Points

- Through the SSA process we have:
  - Assessed the current status of, threats to, and future viability of the lynx DPS
  - Compiled and summarized the best available scientific and commercial data, including empirical data, published literature, and expert input
  - Prioritized information and used modeling to best evaluate potential future conditions, threats and viability

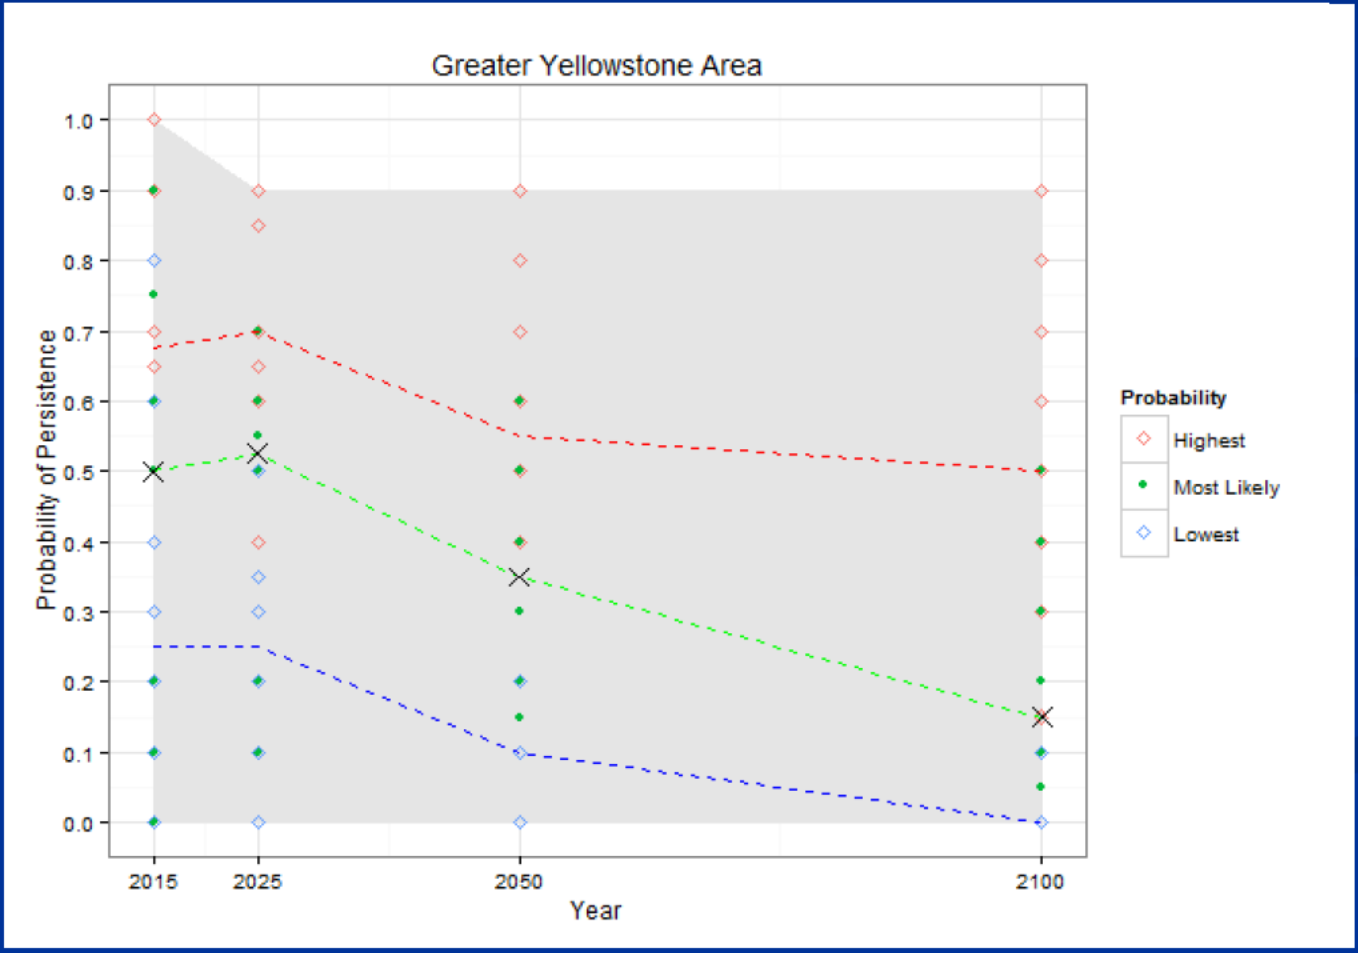
Key Points

- We continue to engage State, Tribal and other Federal, and Canadian partners and other stakeholders
- We continue to work and coordinate with other regions across DPS range
- Monthly State and internal FWS coordination calls/webinars

Expert Elicitation Workshop

- October 2015 – Lynx SSA Team (FWS & USGS) convened a workshop with lynx experts to address current and likely future status of lynx populations in the DPS
  - 10 members of expert panel included state and federal biologists and academic researchers across the range of the DPS and southern Canada
  - The resultant workshop report is one component of the SSA

Expert Elicitation Workshop



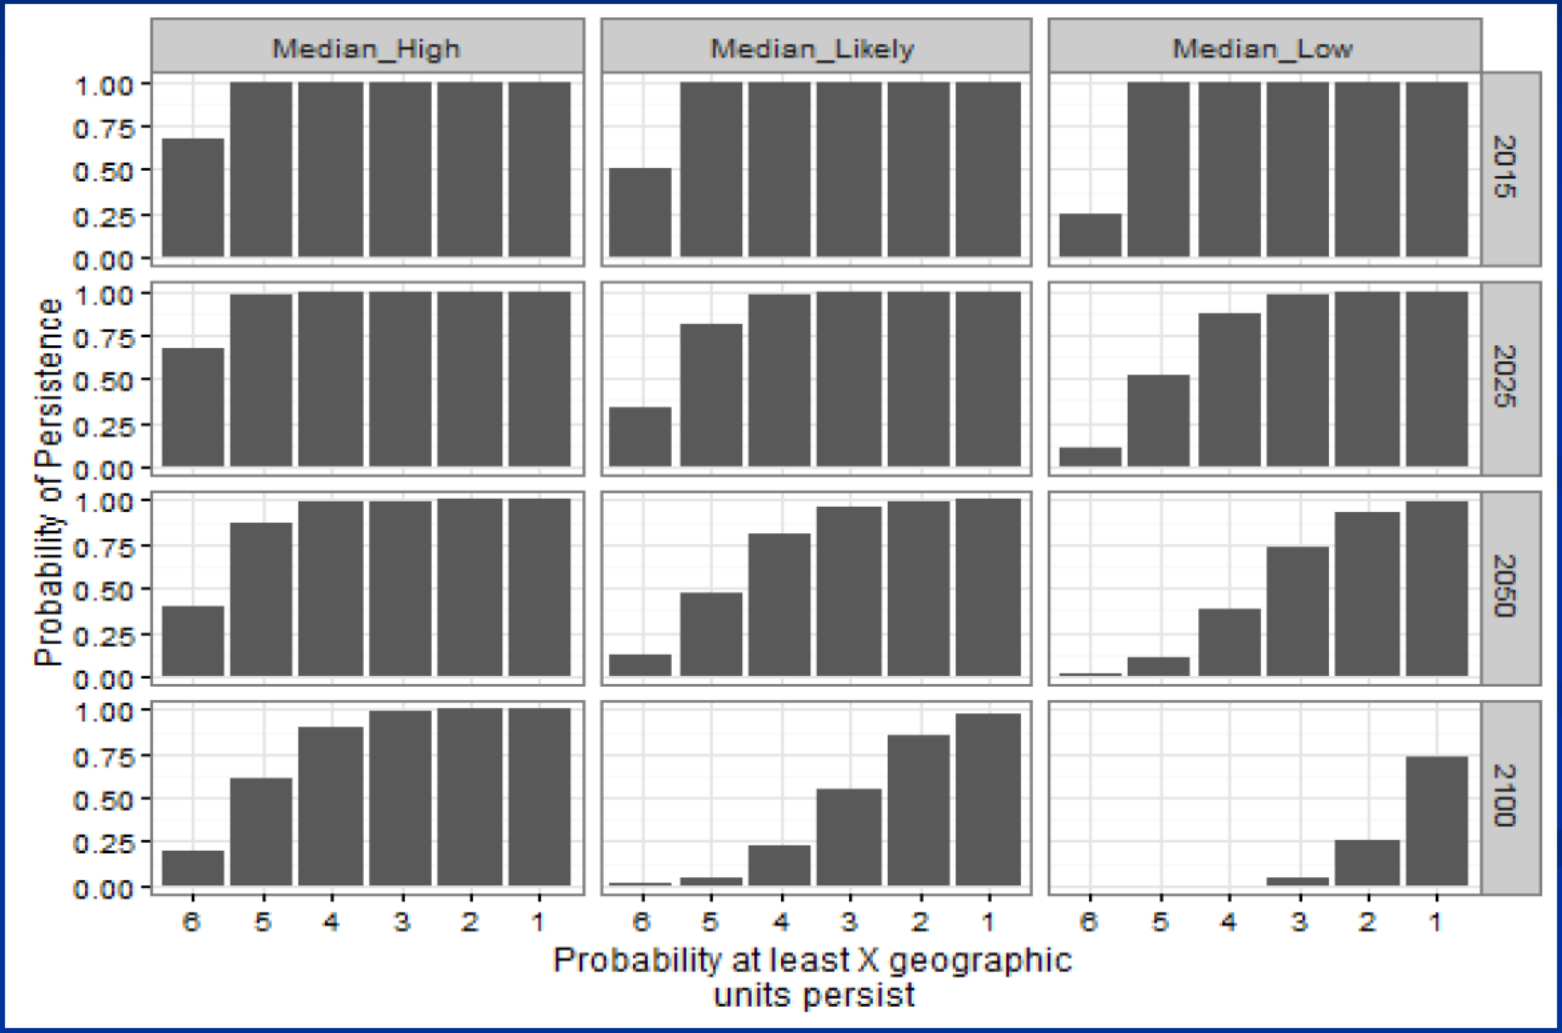
- Responses: Representation
  - Few threats to the genetic fitness or adaptive capacity of lynx in the DPS
    - High gene flow; no major barriers to dispersal
  - Adaptability and evolutionary capacity of the DPS does not appear to have been diminished and is unlikely to become so, independent of threats that may impact the redundancy and persistence of lynx populations

Expert Elicitation Workshop

- Responses: Redundancy
  - DPS as a whole is not vulnerable to extirpation from a single catastrophic event
    - No catastrophic event that could result in the functional extirpation of the entire DPS
  - No or a very low likelihood of functional extirpation of any of the individual geographic units due to a single catastrophic event

Expert Elicitation Workshop

- Responses: Resiliency – expert panel predicted persistence of lynx in each geographic unit, e.g.:



Expert Elicitation Workshop

- Responses: Resiliency
  - All 5 occupied units have >70% expectation of supporting resident lynx populations by year 2050
  - Declining likelihood and greater uncertainty by 2100 – only one unit has >50% probability of persistence
  - Responses suggest overarching threat to long-term persistence of DPS is climate change
    - Loss of snow conditions favorable for lynx
    - Subsequent (lagged) loss of boreal forest habitats
    - Timing and magnitude of such losses are uncertain

Expert Elicitation Workshop

- Overall message of the expert workshop report

Draft SSA Report

- Compiles information on historic and current DPS distribution
- Assesses needs of individuals and populations
- Describes factors with potential population-level influences on the DPS
- Evaluates current and likely future conditions of lynx populations in each geographic unit in terms of the 3 Rs
- SSA Team generally agrees with lynx experts; perhaps less optimistic about some areas

Draft SSA Report - Results

- DPS currently exhibits adequate redundancy and representation; populations in most geographic areas exhibit adequate resiliency
- Resident lynx likely to persist in most units through 2050
- Loss of residents (functional extirpation) from 2 or 3 units (of 5) by 2100; much uncertainty
- Continued climate warming is largest threat
- Regulations to conserve lynx on federal lands are now in place; effectiveness uncertain/untested
- Forest management on private lands remains a significant issue in Maine, perhaps in Minnesota

Next Steps

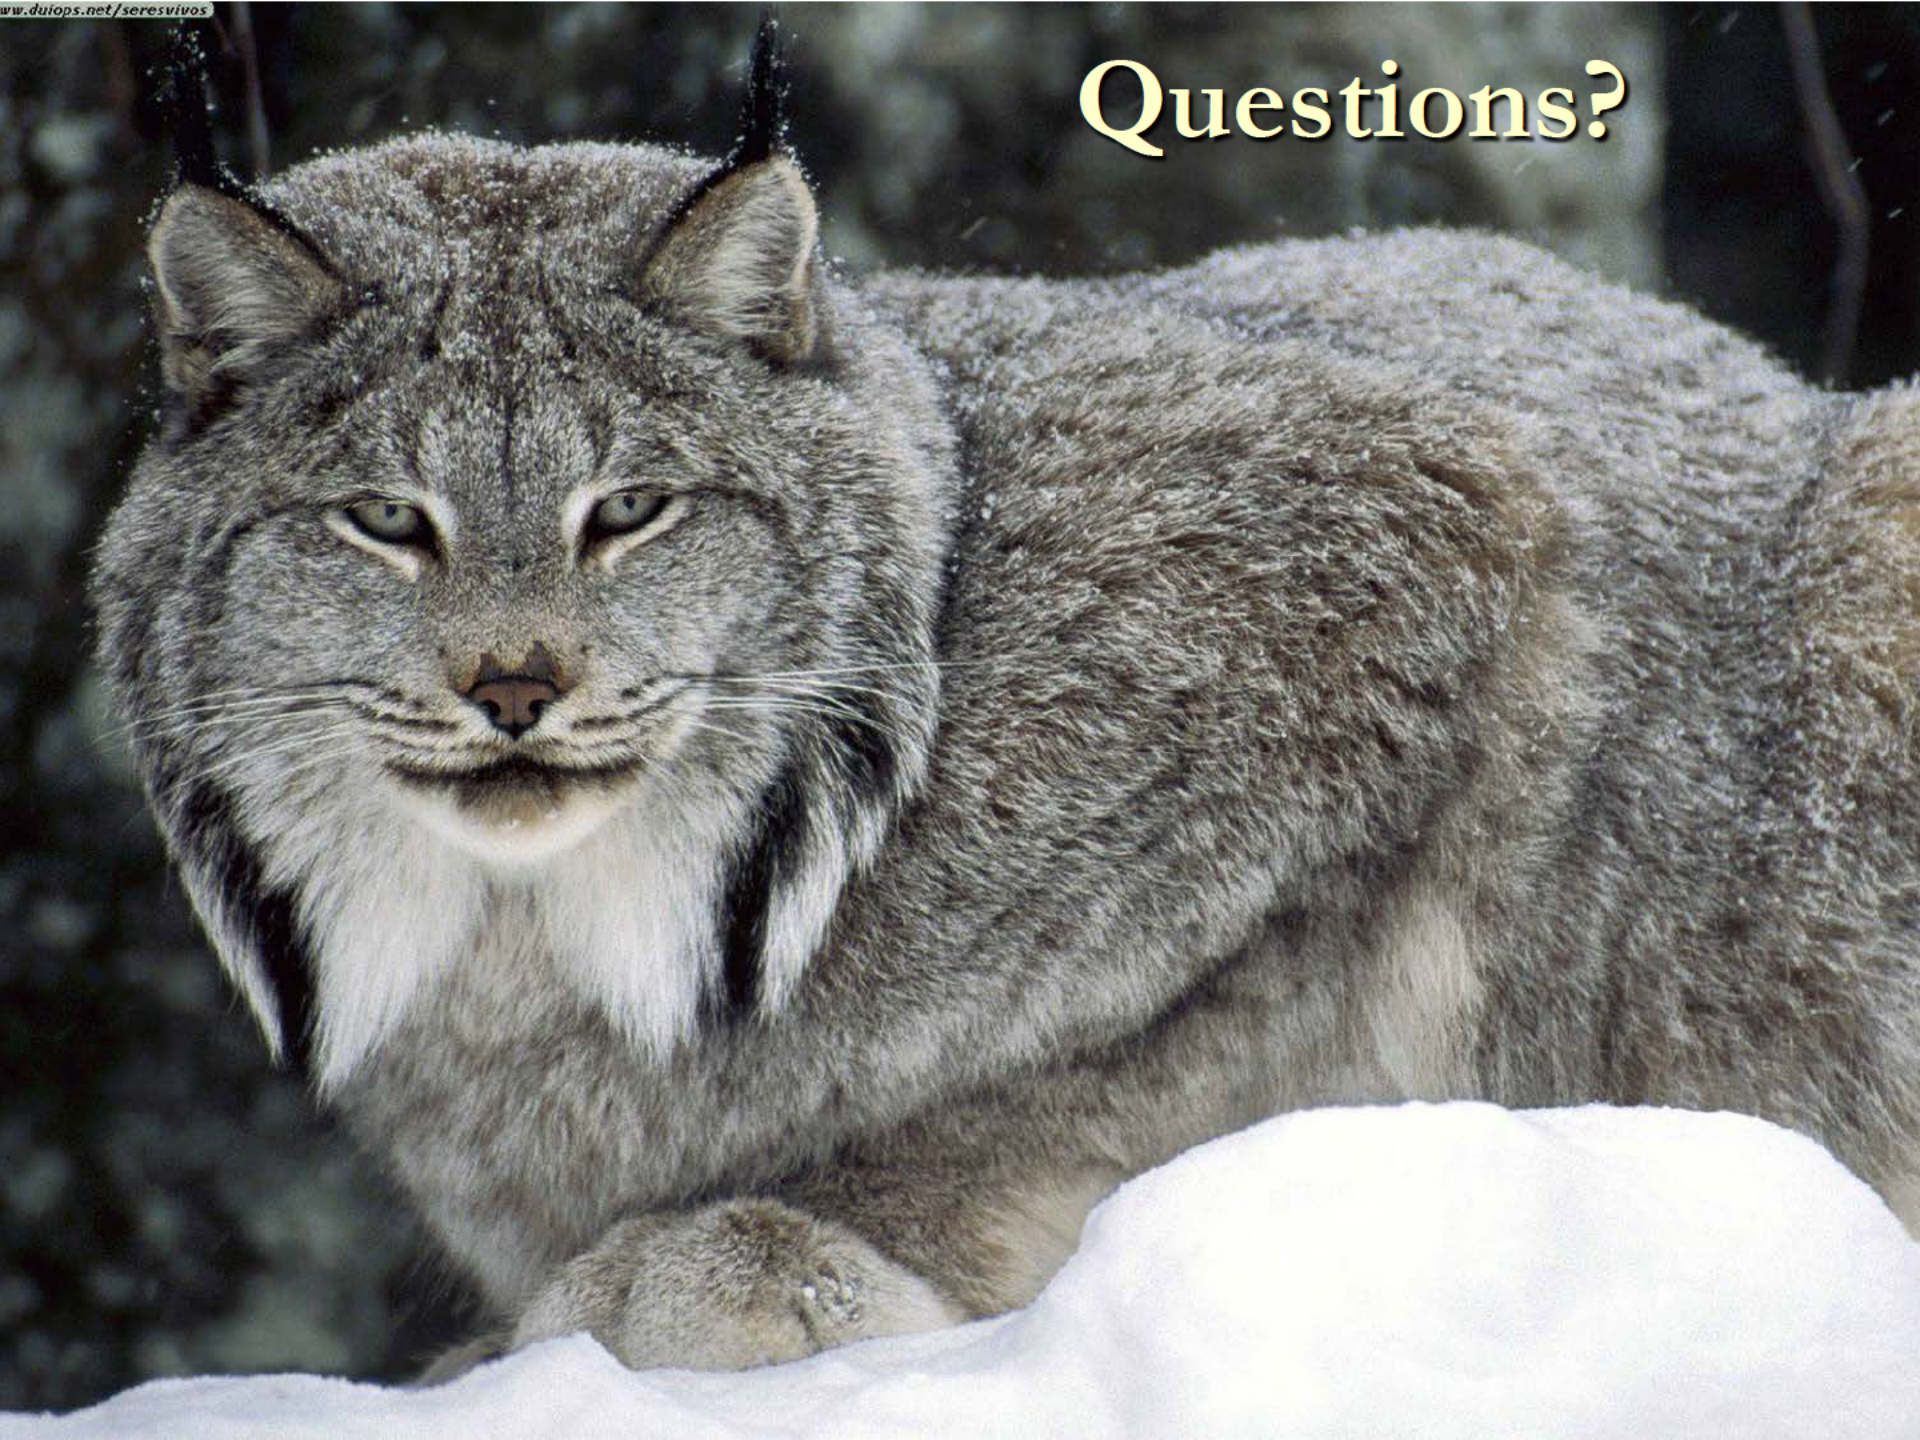
- DRAFT SSA Report is undergoing internal Service scientific review
- After that review and revision, a final draft SSA will be provided to Peer Reviewers through our contractor
- Concurrent with Peer Review, we will share with State, Federal and Tribal(?) partners; invite their review/ comments on the science
- All reviewers (FWS, peer reviewers, partners) will be asked to focus their comments on the science of the SSA Report (not subsequent listing determinations or recovery planning issues)

Next Steps

- Once comments and peer reviews are in, the FINAL SSA Report will be completed
- A Decision Team will meet to discuss SSA results and the DPS status review
- Based on the SSA Report and results of the Decision Team meeting, a DRAFT five year review document will be developed
- After internal review, a FINAL five year review document will be completed, wrapping up the updated status review
- Depending on the RDs decision, recovery planning will proceed from that point or not

Revised Timeline

- Expert Workshop Report — April 2016
- DRAFT SSA Report — October 14, 2016
  - Internal Review Complete — ~October 24, 2016
  - Peer & Partner Review Complete — ~December 31, 2016
- FINAL SSA Report Complete — ~January 15, 2017
- Decision Meeting — ~January 30, 2017
- Five-year Review
  - Draft — ~February 7, 2017
  - Final — ~February 28, 2017
- Draft Recovery Plan (if necessary) — MAY 2017??
- Final Recovery Plan (if necessary) — JANUARY 2018



Decision Points

We asked ARDs in spring 2016:

- Do we need better information to address likely impacts to lynx from CC? Based on the additional timeline needed to gather that information, ARDs determined no.
- Are we comfortable with the time frames used to assess viability of the DPS as presented in the panel report - near term (year 2025), mid-century (2050), and end of century (2100)? ARDs indicated they were.
- When conducting peer review of SSA, do we want our State counterparts to receive it at the same time? Based on discussions with ARDs, we will provide State counterparts with an opportunity to review the SSA during the peer review.
- Do managers want any recommendation from team in the SSA? ARDs agreed that the five-year review would be the place for a recommendation from the team (after discussing with Decision Team).

Main Messages

- We are making progress but we are behind in the recovery planning process by over 9 months
- We are hopeful that the SSA process and report will facilitate a quick, streamlined, REV-compliant draft recovery plan by May 2017 so we can complete the final by Jan. 2018
- In general, the FWS Lynx SSA Team feels comfortable with the outcomes from the expert panel workshop and the DRAFT SSA Report

Peter and Glenn: You are certainly welcome to participate in the webinar at 3:00 this afternoon on the lynx SSA. (See details below.) I'm not sure who else may participate from R5 as I believe Paul is away and Marty is in PA. Glenn may be on the call? Mary probably will be also.

We have completed the draft SSA and it has been distributed for in-house review. There is a relatively quick turnaround for our review before it is distributed to states and peer reviewers.

The lynx core team authors have been instructed to review the document one more time as we experienced some problems at the end with Google Drive. I will have my review completed by Friday and will forward my track changes to both of you (and Marty). Marty said that Paul would like to see our R5 comments before we respond to R6.

Thanks, Mark

INFORMATION/ BRIEFING MEMORANDUM FOR THE REGIONAL DIRECTOR

DATE: October 18, 2016

FROM: Jodi Bush, Supervisor, Montana Ecological Services Office, (406) 449-5225.

SUBJECT: Status of Lynx SSA Process for RD Briefing

We have completed a DRAFT Species Status Assessment (SSA) report for the contiguous U.S. distinct population segment (DPS) of the Canada lynx (Figure 1). The SSA was undertaken as part of the new recovery planning process. Additionally it is going to inform our response to a court order to complete a recovery plan by January 15, 2018 "…unless the Service finds that such a plan will not promote the conservation of the [lynx]"). The SSA assembles the best available information on the current status and likely future viability of the DPS. It is intended to inform multiple Service needs including a determination by Service decision makers of whether (1) the DPS continues to warrant protection under the Endangered Species Act (Act) and (2) a recovery plan is needed to guide conservation and recovery of the DPS. It may also identify potential recovery criterion (as informed by the subsequent decision meeting) and those actions needed to achieve recovery. A status recommendation will be documented in a five-year status review based on the final SSA report.

BACKGROUND

The Service designated the lynx DPS as threatened in 2000 because of the inadequacy, at that time, of existing regulatory mechanisms on federal lands. In 2003, in response to a court ruling, we reaffirmed the DPS's status as threatened. We completed a recovery outline in 2005, designated critical habitat for the DPS in 2006, and, in 2007, again in response to a court order, clarified our determinations of "significant portion of the range" and that all lynx in the contiguous U.S. constitute a single DPS. We revised the critical habitat designation in 2009 and again in 2014 in response to a court order. We reinitiated the 5-year status review in January, 2015 and commenced the SSA in April, 2015. In September 2016, the court remanded the 2014 critical habitat rule for further evaluation of Colorado and five national forests in Idaho and Montana.

KEY POINTS

- We announced the re-initiation of a five-year status review on January 13, 2015. Shortly thereafter, we embarked on the SSA framework. Information in the SSA will be used by Service decision makers to inform classification decisions, recovery planning direction, and other determinations required by the Act.
- Through the SSA framework we have assessed the species' needs, current and future condition including viability of the DPS using a compilation of the best available scientific and commercial data, including empirical data, published literature, and expert input.
- We engaged State, Tribal and other Federal, and Canadian partners and other stakeholders, as well as Service managers. We coordinated with State partners and internal Service managers through separate monthly coordination calls.
- In the fall of 2015, we convened a workshop for scientific experts to address the current and likely future status of the DPS. The participants included state agencies, biologists from other federal agencies, and academic researchers to elicit input from experts across the range of the DPS.

- Information solicited from the 10 member lynx expert panel addressed the viability of the DPS based on the 3Rs (Representation, Redundancy, Resiliency) and what is known about climate science related to lynx. The resultant workshop report is one component of the SSA.
- We just completed the DRAFT SSA report and have forwarded it for internal review to Service staff in each region with lynx (Regions 1, 2, 3, 5, and 6). This review will be expedited and will focus on the science. Once completed and revisions made, the SSA will be provided to our Peer Review consultant and to State and Federal partners for their review and comment.
- Using the Service's open peer review contract, we hired ATKINS to conduct a Peer Review for us on the scientific findings in SSA. That contract is let and will commence as soon as the Service has completed our internal review.

TIMELINE

• Expert Workshop FINAL Report	April, 2016
• SSA Report	
o DRAFT Completed	October 14, 2016
o Internal Review Complete	October 24, 2016
o Peer/Partner Reviews Complete	December 31, 2016
o FINAL Report Complete	January 15, 2017
• Decision Meeting	January 30, 2017
• Five-year Review	
o DRAFT	February 07, 2017
o FINAL	February 28, 2017
• Recovery Plan	
o DRAFT using REV process (if necessary)	May 2017??
o FINAL (if necessary)	January 2018

IMPORTANT MESSAGES

- Several decision points were agreed to in April 2016 regarding the SSA.
  - Because the climate change science is important in our decision, we asked if we needed better information to address likely impacts to lynx from CC? *Based on the additional timeline needed to gather that information, ARDs determined no.*
  - Because the decision makers will need the information on a range of climate change scenarios for their decision, we asked if they were comfortable with the range of climate scenario years from the panel report? Present, mid-century (2050), and end of century (2100*)? ARDs indicated they were.*
  - Because our partners have a strong interest in this process, we asked if when conducting Peer review of SSA, whether we wanted our State counterparts to receive it at the same time? *Based on discussions with ARDs, we will provide State counterparts with an opportunity to review the SSA during the PEER review.*
  - Finally, because the SSA is a science document not a decision document we asked if the managers wanted a recommendation from the SSA team? *The ARDs agreed that the five-year review would be the place for a recommendation from the team.*

- We are behind in the development of the recovery planning process by 6 to 9 months.

Update on Canada Lynx Species Status Assessment

November 1, 2016

Overview

- What are we doing?
  - Completing SSA to inform recovery planning
    - Court order to finalize RP by Jan. 2018
    - Unless we determine RP not needed (i.e., the DPS is recovered)
- Why?
  - SSA provides analysis needed to re-evaluate the status of the DPS
  - SSA will then be used in decision context of 5-year review (before proceeding with recovery planning)

Objectives

- Share Status of the SSA
- Discuss Timeline
- Identify Next Steps

Lynx Basics

- Boreal forest species dependent on snowshoe hares and favorable snow conditions
- At southern periphery of ranges in contiguous US
- Habitat becomes patchy; hare densities and snow conditions become suboptimal/marginal for supporting lynx populations
- Mainland-island metapopulation structure (?)
- Historical cyclic "irruptions" of lynx from Canada into northern U.S. when hares crashed (currently?)

Background

- Contiguous U.S. lynx DPS listed as T in 2000
  - Factor D - inadequacy, at that time, of existing regulatory mechanisms on federal lands
- CH designated 2006, revised 2009 and 2014
  - Sept. 2016 - Court remanded 2014 CH rule
    - Ruled Service was arbitrary and capricious in not designating CH in Colorado
    - Inadequate evaluation of PCE on 5 NFs in MT and ID
    - We have not determined next steps in our response to this litigation

Background

- 2005 Recovery Outline focused on interim conservation measures in 6 "Core" areas
  - Historic/current resident population(s); reproduction; 0.5 hares/ha; >= 1,250 km^2 habitat
  - S. Rockies (western CO and south central WY) - "provisional" core area

Current DPS Distribution

- 6 geographic areas known or thought to support resident lynx populations in the DPS:
  - 1. Northern Maine (& northernmost NH and VT)
  - 2. Northeastern Minnesota
  - 3. Northwestern Montana/Northeastern Idaho
  - 4. North-central Washington
  - 5. GYA of southwest Montana/northwest Wyoming
  - 6. Western Colorado – introduced population

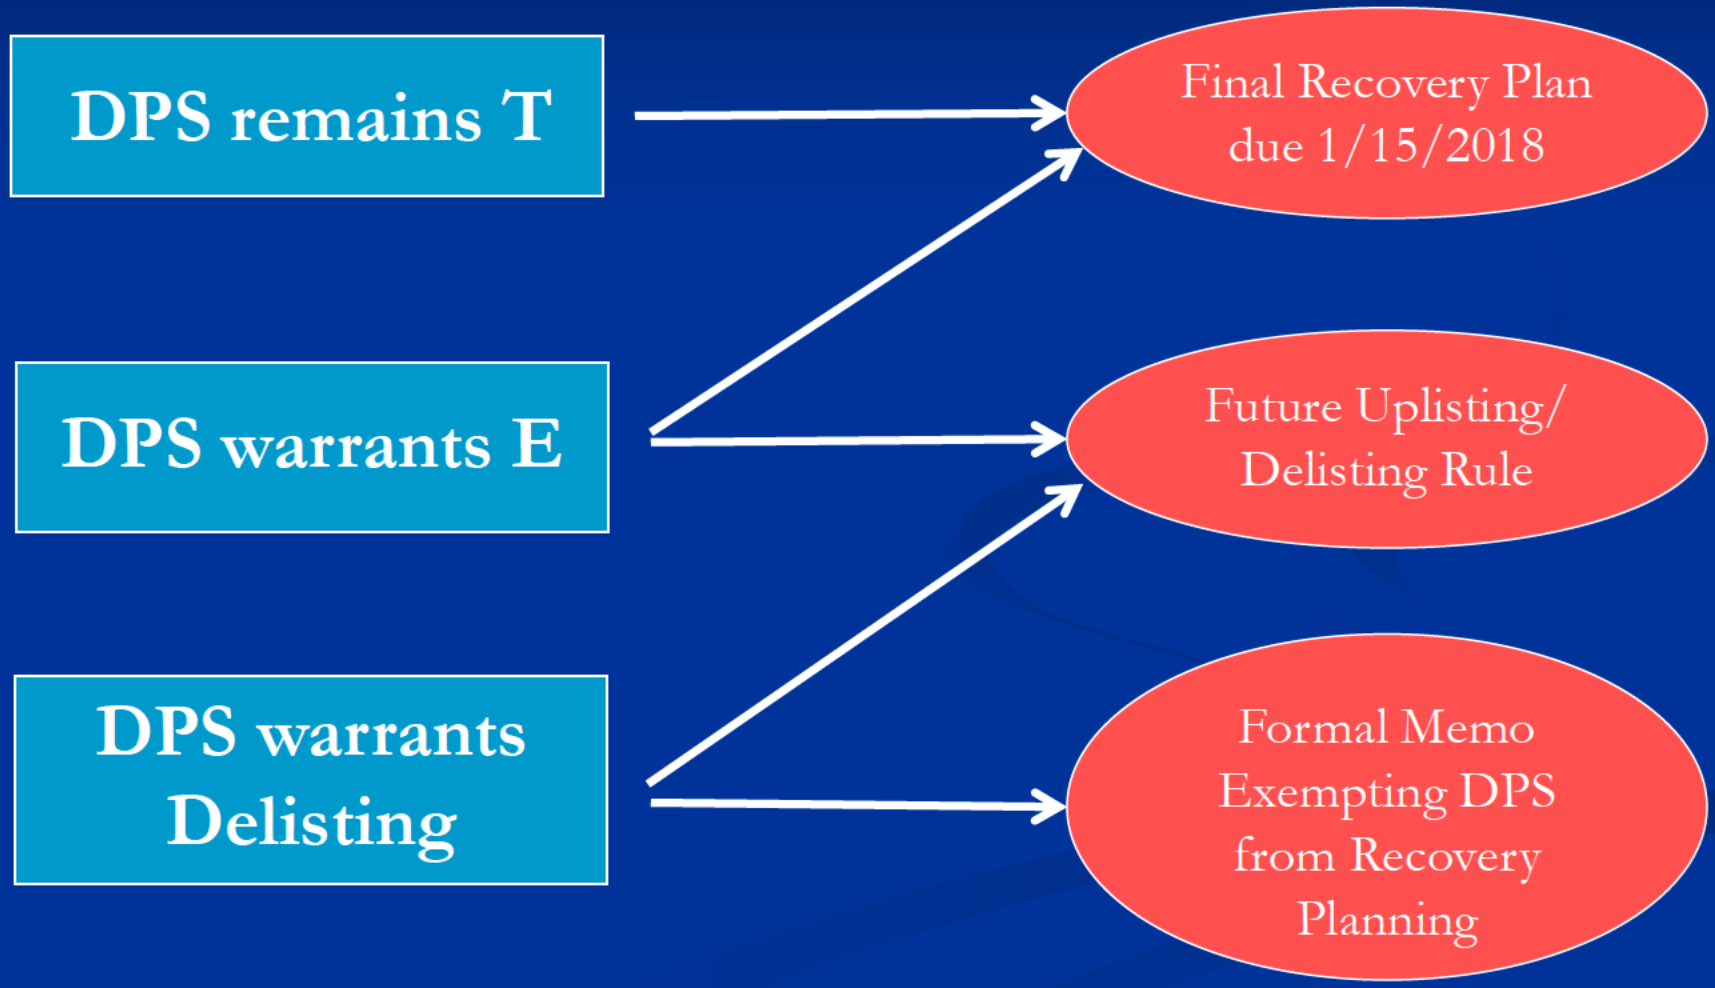

Figure 1. Six geographic units within the range of the contiguous U.S. distinct population segment of Canada lynx (*Lynx canadensis*) that currently support or recently supported (GYA) resident lynx populations.

Key Points

- January 2015 - announced re-initiation of five-year status review
- March 2015 – determined need to complete SSA
- Information in the SSA will be used by FWS decision makers to inform:
  - Recovery planning direction
  - Classification decisions
  - Other determinations required by the ESA

Potential Findings

Key Points

- Through the SSA process we have:
  - Assessed the current status of, threats to, and future viability of the lynx DPS
  - Compiled and summarized the best available scientific and commercial data, including empirical data, published literature, and expert input
  - Prioritized information and used modeling to best evaluate potential future conditions, threats and viability

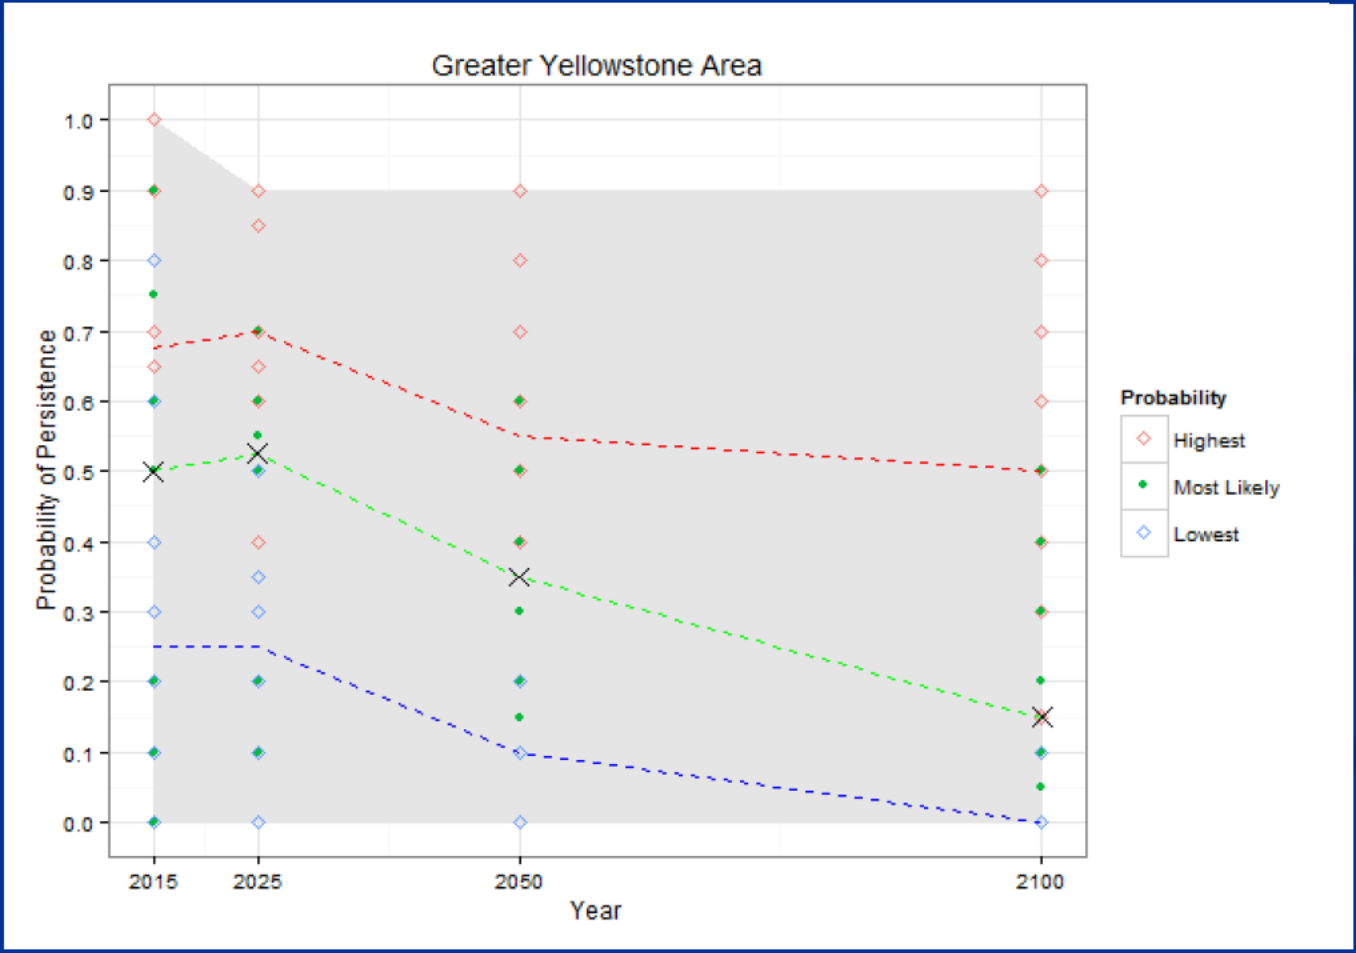
Key Points

- We continue to engage State, Tribal and other Federal, and Canadian partners and other stakeholders
- We continue to work and coordinate with other regions across DPS range
- Monthly State and internal FWS coordination calls/webinars

Expert Elicitation Workshop

- October 2015 – Lynx SSA Team (FWS & USGS) convened a workshop with lynx experts to address current and likely future status of lynx populations in the DPS
  - 10 members of expert panel included state and federal biologists and academic researchers across the range of the DPS and southern Canada
  - The resultant workshop report is one component of the SSA

Expert Elicitation Workshop



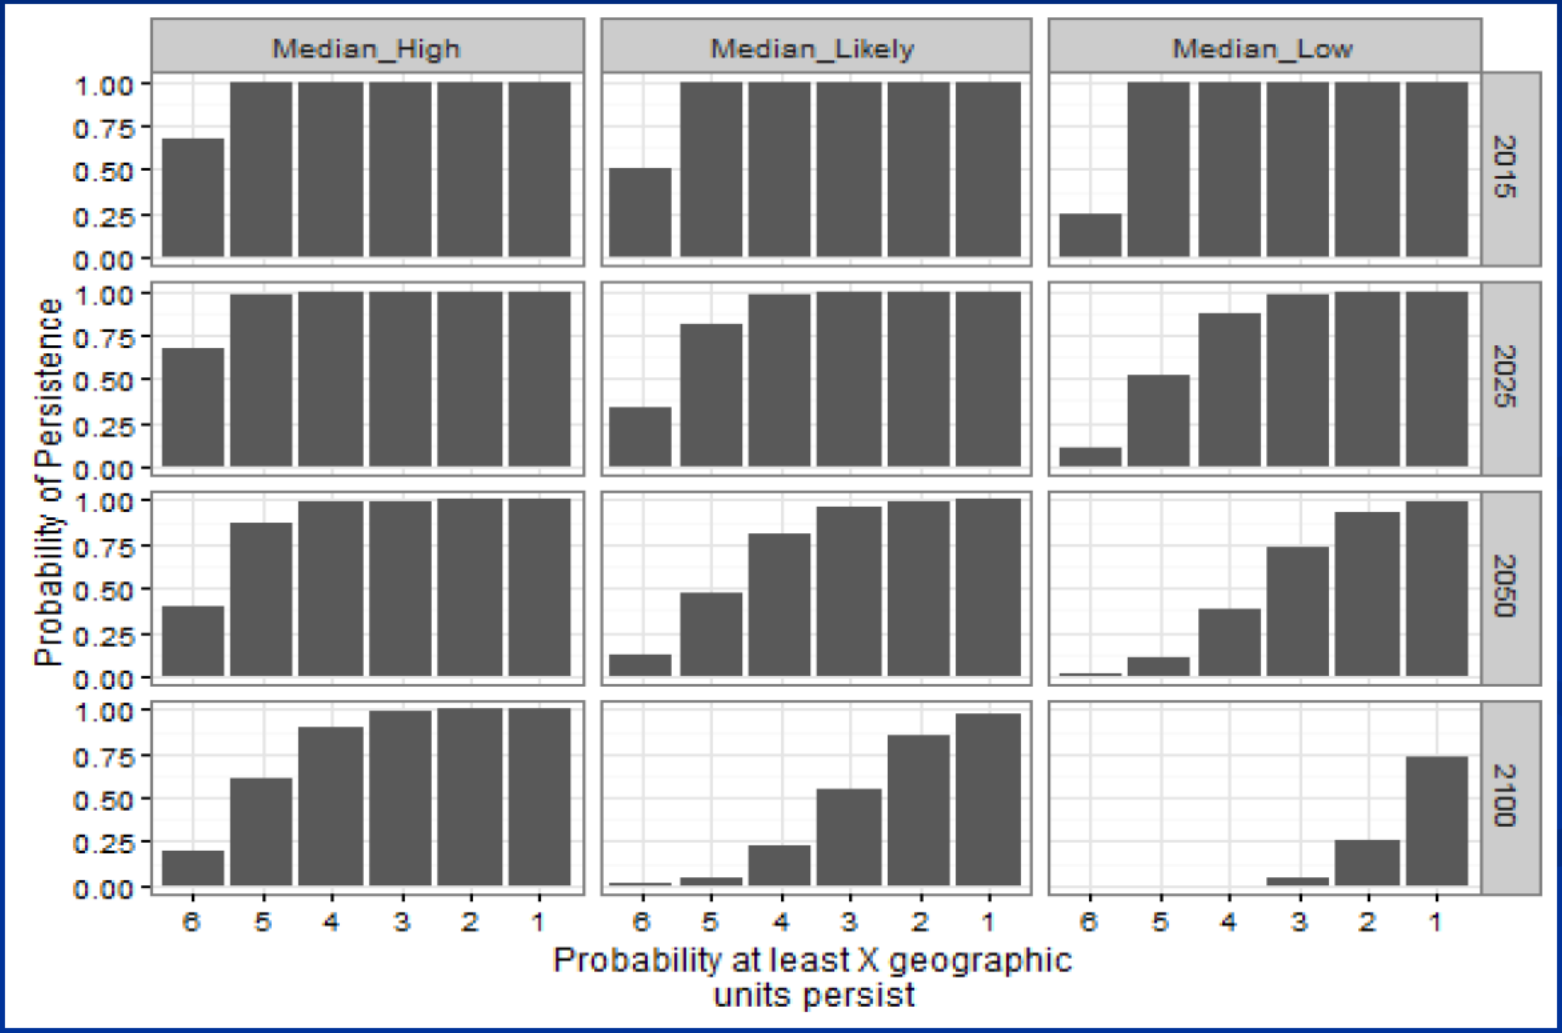
- Responses: Representation
  - Few threats to the genetic fitness or adaptive capacity of lynx in the DPS
    - High gene flow; no major barriers to dispersal
  - Adaptability and evolutionary capacity of the DPS does not appear to have been diminished and is unlikely to become so, independent of threats that may impact the redundancy and persistence of lynx populations

Expert Elicitation Workshop

- Responses: Redundancy
  - DPS as a whole is not vulnerable to extirpation from a single catastrophic event
    - No catastrophic event that could result in the functional extirpation of the entire DPS
  - No or a very low likelihood of functional extirpation of any of the individual geographic units due to a single catastrophic event

Expert Elicitation Workshop

- Responses: Resiliency – expert panel predicted persistence of lynx in each geographic unit, e.g.:



Expert Elicitation Workshop

- Responses: Resiliency
  - All 5 occupied units have >70% expectation of supporting resident lynx populations by year 2050
  - Declining likelihood and greater uncertainty by 2100 – only one unit has >50% probability of persistence
  - Responses suggest overarching threat to long-term persistence of DPS is climate change
    - Loss of snow conditions favorable for lynx
    - Subsequent (lagged) loss of boreal forest habitats
    - Timing and magnitude of such losses are uncertain

Expert Elicitation Workshop

- Overall message of the expert workshop report

Draft SSA Report

- Compiles information on historic and current DPS distribution
- Assesses needs of individuals and populations
- Describes factors with potential population-level influences on the DPS
- Evaluates current and likely future conditions of lynx populations in each geographic unit in terms of the 3 Rs
- SSA Team generally agrees with lynx experts; perhaps less optimistic about some areas

Draft SSA Report - Results

- DPS currently exhibits adequate redundancy and representation; populations in most geographic areas exhibit adequate resiliency
- Resident lynx likely to persist in most units through 2050
- Loss of residents (functional extirpation) from 2 or 3 units (of 5) by 2100; much uncertainty
- Continued climate warming is largest threat
- Regulations to conserve lynx on federal lands are now in place; effectiveness uncertain/untested
- Forest management on private lands remains a significant issue in Maine, perhaps in Minnesota

Next Steps

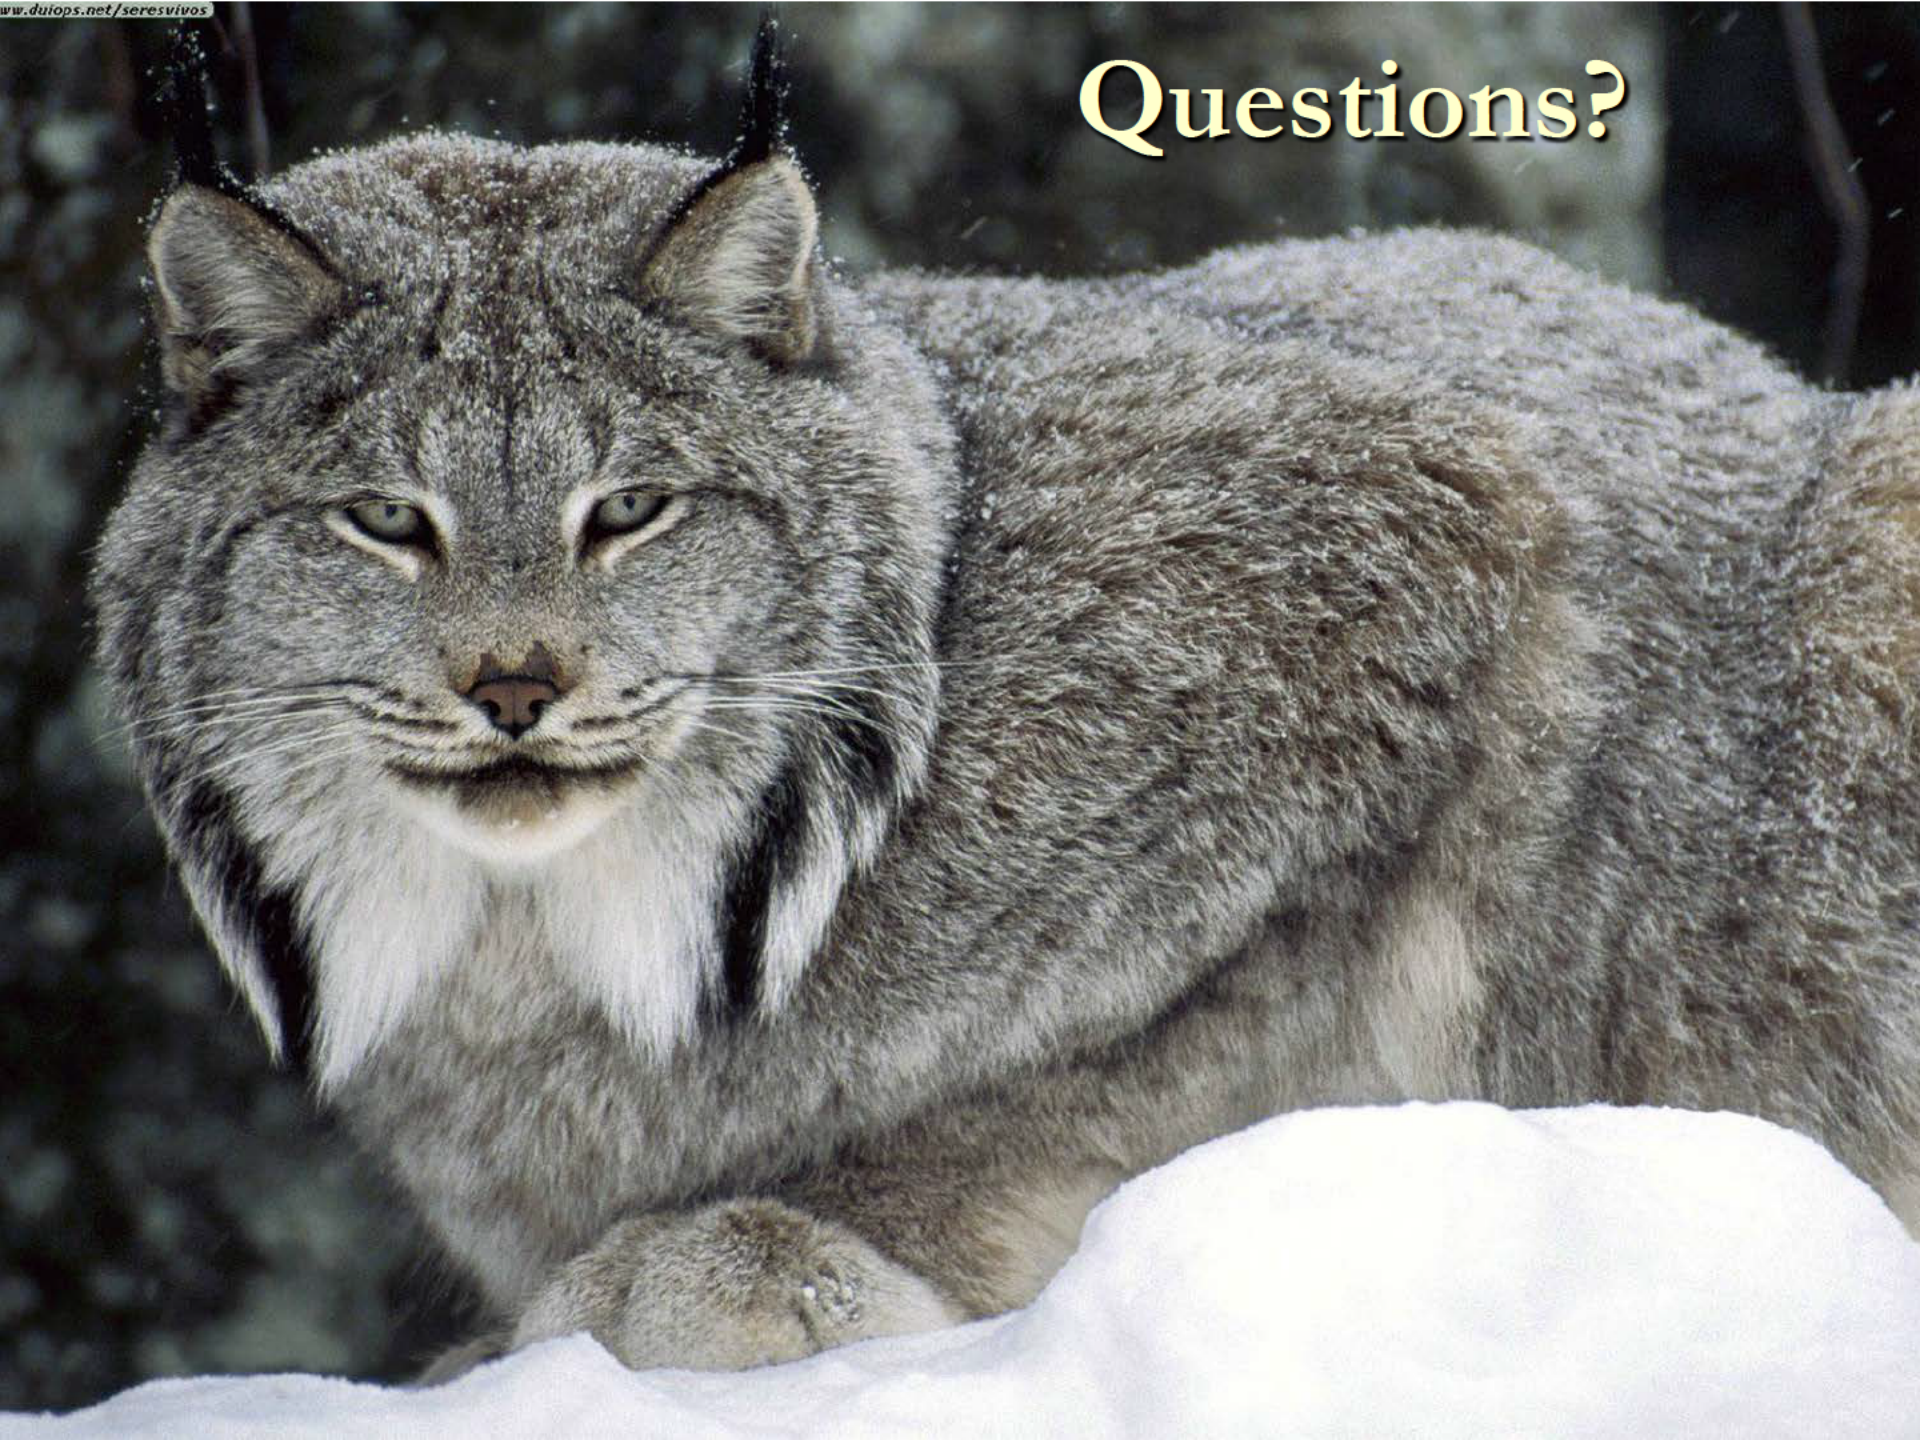
- DRAFT SSA Report is undergoing internal Service scientific review
- After that review and revision, a final draft SSA will be provided to Peer Reviewers through our contractor
- Concurrent with Peer Review, we will share with State, Federal and Tribal partners; invite their review/ comments on the science
- All reviewers (FWS, peer reviewers, partners) will be asked to focus their comments on the science of the SSA Report (not subsequent listing determinations or recovery planning issues)

Next Steps

- Once comments and peer reviews are in, the FINAL SSA Report will be completed
- A Decision Team will meet to discuss SSA results and the DPS status review
- Based on the SSA Report and results of the Decision Team meeting, a DRAFT five year review document will be developed
- After internal review, a FINAL five year review document will be completed, wrapping up the updated status review
- Depending on the RDs decision, recovery planning will proceed from that point or not

Revised Timeline

- Expert Workshop Report — April 2016
- DRAFT SSA Report — October 14, 2016
  - Internal Review Complete — ~October 24, 2016
  - Peer & Partner Review Complete — ~December 31, 2016
- FINAL SSA Report Complete — ~January 15, 2017
- Decision Meeting — ~January 30, 2017
- Five-year Review
  - Draft — ~February 7, 2017
  - Final — ~February 28, 2017
- Draft Recovery Plan (if necessary) — MAY 2017??
- Final Recovery Plan (if necessary) — JANUARY 2018



Decision Points

We asked ARDs in spring 2016:

- Do we need better information to address likely impacts to lynx from CC? Based on the additional timeline needed to gather that information, ARDs determined no.
- Are we comfortable with the time frames used to assess viability of the DPS as presented in the panel report - near term (year 2025), mid-century (2050), and end of century (2100)? ARDs indicated they were.
- When conducting peer review of SSA, do we want our State counterparts to receive it at the same time? Based on discussions with ARDs, we will provide State counterparts with an opportunity to review the SSA during the peer review.
- Do managers want any recommendation from team in the SSA? ARDs agreed that the five-year review would be the place for a recommendation from the team (after discussing with Decision Team).

Main Messages

- We are making progress but we are behind in the recovery planning process by over 9 months
- We are hopeful that the SSA process and report will facilitate a quick, streamlined, REV-compliant draft recovery plan by May 2017 so we can complete the final by Jan. 2018
- In general, the FWS Lynx SSA Team feels comfortable with the outcomes from the expert panel workshop and the DRAFT SSA Report

Of course - share internally. The one today for States/partners will be largely the same; only a few slides (internal FWS deliberations/discussions) omitted.

On Tue, Nov 1, 2016 at 4:25 PM, Kosterman, Megan <megan_kosterman@fws.gov> wrote:

> Thanks Jim! A PDF is great. May I share the PDF with Bryon Holt, and Kim Garner/Kathleen Hendricks from our Boise office (USFWS employees only)? They all wanted to participate in the meeting today but were unable to attend. If you prefer I don't share the PDF, that is fine also, I will just send them my meeting notes.

---

Please see Mark's and Marty's comments below (and Marty's detailed comments in the attached doc). We need to discuss this on the weekly Core/FIT teams call tomorrow and agree to an appropriate and efficient way to respond in the next draft of the SSA Report.

I hope you all can join the call.

Lynx Core Team:

I'm not sure if you all received a copy of Marty Miller's comments from Region 5. Jim said that they are also posted on the Google Drive. Here is a copy of Marty's comments. Given our marching orders from today's call, I would recommend that you look at Marty's comments, especially for Chapter 5. I think it will help you to understand the kind of clarification he is asking for to address points #1 and #2 in his email below.

Jim, maybe you can take a look at how each of the Core Team members address Marty's points #1 and #2 and address Marty's point #3 - our ultimate, collective conclusion. This conclusion ties into today's discussion about listing (without addressing listing in the SSA). Marty seems to indicate we can walk a fine line between making OUR assessment of lynx persistence, assumptions, and uncertainty without addressing listing in the SSA (see point #3).

It's still unclear to me whether the Core Team will formally or informally be asked for our opinion on listing and when this might happen. Up to now, we've been instructed not to discuss listing in the context of the SSA. But as we move very soon into the decision phase, maybe the Core Team should discuss our individual and collective thoughts about listing. Perhaps after we address Marty's points below, we will be in a better position to do so.

This all would be far better done on a napkin in the pub in Denver.

Have a good Thanksgiving.

Mark

Subject: Lynx SSA comments
To: Mark McCollough <Mark_McCollough@fws.gov>
Cc: Mary Parkin <mary_parkin@fws.gov>

Mark - Here are my comments on the lynx SSA. I focused on the Future Conditions and Synthesis chapters. I have three major comments:

1. Establishing the proper context for the future: This is a future with lynx not being listed. The document presents a delisting scenario in its evaluation of the Federal management future of the MT/ID Unit. I explain in my comments that, while the conclusions about what the future will look like may be OK, the way we get there needs to be revised. And this context needs to be established for evaluation across all units, actors (Federal agencies, states, landowners, etc.), and consequences (not just regulatory mechanisms).

2. Explaining how the experts' opinions inform our conclusions: The document does not explain what we think about the experts' opinions (agree or disagree and why). I was expecting this explanation for each unit in Chapter 5 in the "Service Evaluation" section, which follows the "Expert Projections,' but these two discussion appear to be independent. We continue to refer to the experts' opinions about persistence to the very end without ever saying whether we agree with them (and explaining why).

3. Drawing meaningful conclusions: The ultimate conclusions we make (the DPS has a decreasing probability of persistence into the future) is meaningless as it can be said of every species on earth. I recommend we present "our" conclusions on persistence. If we thought it was valuable to know what the experts think about persistence, we need to at least present our conclusions on persistence. I understand we are advised not to present our conclusions in a manner that too closely resembles a conclusion about listing being warranted or not. But we're too far down the "probability of persistence" road to avoid presenting our conclusions on this. And we need to do it in a way that describes the magnitude of the risk, not statements that are generalized to the point of being meaningless.

Many of the comments I made on the Executive Summary I did not bother repeating in the Chapters.

Let me know if you have any questions.
Marty

5.2.1 Results of Expert Elicitation (workshop report, Summary table of probabilities of persistence)
Chapter 6: Synthesis

Executive Summary

Background

This report presents the results of a species status assessment (SSA) conducted for the contiguous United States distinct population segment (DPS) of Canada lynx (*Lynx canadensis*). The DPS was listed in 2000 as threatened under the Endangered Species Act (ESA) because of the inadequacy of regulatory mechanisms on federal lands. The SSA will provide the scientific basis for the statutorily required 5-year status review for this listed species and other decisions the Service is required to make in accordance with the ESA. The SSA provides an evaluation of the current and future status of lynx in six geographic units within the DPS that currently support or recently supported resident breeding populations. The units are distributed across the northern contiguous U.S. from Maine to Washington and south along the Rocky Mountains to western Colorado. These geographic units combined represent approximately the southern two percent of the species' entire breeding range (ninety-eight percent occurs in Canada and Alaska). The units are relatively isolated from each other, although four of the six units are directly connected to lynx populations and habitats in Canada. These SSA geographic units are:

Unit No.	Name	Size (km^2)
Unit 1	Northern Maine	28,909
Unit 2	Northeastern Minnesota	21,101
Unit 3	Northwestern Montana/Northeastern Idaho	26,997
Unit 4	North-central Washington	5,176
Unit 5	Greater Yellowstone Area	23,687
Unit 6	Western Colorado	25,294

The SSA relied on both the available scientific literature and the professional judgments and opinions of recognized lynx experts to (1) describe the ecological requirements and population dynamics of the species, (2) evaluate the historical and current status of lynx populations in the six geographic units and the factors that appear to have influenced these populations, and (3) assess the likely future viability of the DPS through the end of the century in terms of representation, redundancy, and resiliency (the "3 Rs").

Lynx are habitat and prey specialists and require boreal forests having long winters with deep, fluffy snow. These conditions provide lynx with a competitive advantage over other predators for exploiting their primary prey, the snowshoe hare. Lynx habitat and, thus, lynx are naturally less abundant and more patchily distributed in the DPS than in the core of the species' range in Canada and Alaska. This is because the DPS occurs at the southernmost margin of the

Comment [MJM1]: This comes across too much as "deferring" to expert opinion. We need to "own" the conclusions. We need to make it clear hat "our" assessment was informed by the experts' opinions – that we didn't automatically accept the expert's opinions. We need to explain the reasons behind the experts' opinions, explain why we agree or disagree, and then state the conclusions as our own.

Comment [MJM2]: The document sometimes uses historic and sometimes historical. Recommend being consistent. Recommend "historical" to avoid confusion with he "momentous" meaning of "historic."

Comment [MJM3]: The purpose of the SSA should be to assess the full risk profile of the species, not just its "likely" future. The viability of the species should be a descrip ion of the risk to its persistence, which may be influenced by possible future scenarios that are less than likely.

species' range and of the environmental thresholds of snow quality, depth, and persistence; hare density; and boreal forest conditions that lynx require. Maintaining connectivity between the DPS and lynx populations in Canada is thought to be important, but whether DPS populations rely on intermittent immigration of lynx from Canada, and, if so, to what extent, remain uncertain.

Research and surveys undertaken since the listing of the DPS in 2000 have significantly improved our knowledge of the distribution, habitats, and population status of resident breeding lynx populations. For example, although we knew there were resident lynx in Maine, we did not have an understanding of population size or trend. We now know that northern Maine currently supports the largest resident population in the DPS; we also understand that past timber management has created the current abundance of high-quality lynx habitat, and we believe that there are many more lynx in Maine now than was likely under historic natural disturbance regimes and habitat distributions. Similarly, when the DPS was listed, we were uncertain as to whether Minnesota supported a resident breeding population, but we now know that a persistent population occupies the northeastern corner of the state. Research also suggests that lynx and habitats in the western U.S. are naturally less abundant and more patchily distributed than was thought at the time of listing, and lynx may have been recently extirpated from several areas thought to have previously supported small resident populations (the Kettle Mountains in northeastern Washington, the Garnet Mountains in western Montana, and the Greater Yellowstone Area). We also know that recent extensive wildfires in north-central Washington have temporarily reduced the amount of high-quality lynx habitat and have probably caused a decline in lynx numbers there. Finally, as a result of the release of 218 Canadian and Alaskan lynx from 1999 to 2006, and their subsequent survival and reproduction, resident lynx currently occupy parts of western Colorado.

Comment [MJM4]: To dis inguish from regulatory status as E or T.

SSA Framework

The framework for conducting an SSA takes into consideration the life history and ecological requirements of the species to understand how the species maintains itself over time. Relative to the ecological requirements of the lynx within the DPS, we assessed current conditions at the individual, population, and range-wide levels, and the likely changes in the environment that may influence the future condition of individuals, populations, and the DPS and thus the viability of the DPS.

Comment [MJM5]: The contribution to risk from less-than-likely changes to he environment also need to be assessed.

The SSA uses the conservation biology principles of representation, redundancy, and resiliency (the "3 Rs") as the framework for assessing current and future conditions. Resiliency describes the ability of the species to withstand stochasticity, redundancy describes the ability of the species to withstand catastrophic events, and representation describes the ability of the species to adapt over time to long-term changes in the environment. The 3 Rs can be influenced by any number of factors. For the lynx, these factors included the original reason for listing the lynx DPS as threatened: inadequacy of regulatory mechanisms. Other factors included climate change, vegetation management, wildfires, and habitat connectivity

SSA Assumptions and Uncertainties

A fundamental hypothesis underlying the SSA is that the ability of lynx to persist in the DPS is a function of metapopulation dynamics with Canada, i.e., the DPS is infused intermittently with lynx from Canada following high hare cycles.

Overall, uncertainties abound with regard to lynx demography and effects of various stressors on DPS populations. The primary sources of uncertainty for this analysis include a lack of empirical data regarding population sizes and trends, the extent of immigration of lynx from Canada ~~to the persistence of U. S. populations~~, trends in hare populations, and effects of habitat management on lynx. Most importantly given the importance of climate change as a stressor, we lack information on the pace and extent of changes in snow quality, depth, and persistence and how ~~this~~these changes affect~~s~~ the relationship between lynx and their competitors.

For purposes of the SSA, we forecasted potential effects and trends through the end of this century. This time frame is based on the level of uncertainty about climate change and other effects on lynx populations; it is also a long enough time frame to detect lynx population trends across the DPS.

Current Conditions

Currently, ~~four~~ of the six DPS units, four (Northern Maine, Minnesota, Northwestern Montana, and Western Colorado) demonstrate high levels of resiliency. The North-central Washington Unit (Unit 4) was also considered resilient until recent wildfires consumed an extensive amount of habitat, likely resulting in a diminished population that may be susceptible to stochastic events. The Greater Yellowstone area historically supported resident lynx, but it is unclear whether the area still supports a breeding population due to the distance and relative isolation of the unit from Canada as well as the less than favorable habitat conditions and snowshoe hare densities.

As shown in the table above, five of the six units are larger than 20,000 km^2; the other is over 5,000 km^2. Land ownership within the units varies from mostly private in Maine, to a mix of private, State, and ~~f~~Federal lands in Minnesota, to mostly ~~f~~Federal lands in the West. Overall, ~~f~~Federal lands account for nearly 64 percent of the areas encompassed by the SSA units. Of non-~~f~~Federal areas, private lands make up almost 27 percent of the total followed by State and Tribal lands. Available data indicate that distribution within the DPS remains similar to historical patterns and that the number of units across the DPS has not been meaningfully diminished from historical levels, given the uncertainty about the past occupancy of the Greater Yellowstone area by a resident breeding lynx population.

Given the resiliency of most geographic units and the ~~improbability~~ low likelihood that a~~ny imminent~~ catastrophic event will cause the extirpation of an entire unit or, especially, the DPS as a whole in the near term, redundancy is not currently a~~n~~ issue for the lynx DPS. Also, because

Comment [MJM6]: This doesn't make sense in this phrase.

Comment [MJM7]: This is inconsistently referred to as Northwestern Montana and Northwestern Montana/Northeastern Idaho. Recommend being consistent.

Comment [MJM8]: Resiliency relates to the ability to withstand stochas icity. How is it a factor in drawing this conclusion about redundancy?

Comment [MJM9]: This seems to be saying we know of at least one catastrophic event hat will happen soon but won't cause extirpation. This is at odds with our definition of a catastrophic event as an event that would or has high potential to cause extirpation. Because he kinds of catastrophic events we typically deal with are unpredictable, we can't say a catastrophic event is imminent unless it's already started. A catastrophic event has a low likelihood of occurring within a short period of ime and a higher likelihood over a longer period of time. I think what we're trying to say is simply hat a catastrophic event is not likely to happen in the near term.

Comment [MJM10]: I was confused by this wording. We're in the business of assessing risk over decades into he future, so a factor hat affects that long-term risk would be an issue for us to evaluate now and therefore would be curren ly an issue. I think what we're trying to say is that it is "not an issue for the near-term persistence of the DPS."

lynx are genetically similar throughout the entire range of the species, and because we did not find any diminishment of adaptability and evolutionary capacity of DPS populations based on the known historical record, we do not consider representation to be a current issue for lynx.

The original reason for which the DPS was listed, inadequacy of regulatory mechanisms, has been largely ameliorated on public lands within the western geographic units. Climate change, vegetation management, wildfires, and habitat fragmentation are now stressors of more heightened concern. We know that wildfires are causing depletion of lynx in some areas in the West, particularly in the North-~~C~~central Washington Unit. We also know that past vegetation management in the ~~n~~Northern Maine Unit has resulted in a lynx population that is currently the largest in the DPS. Conversely, stressors such as climate change and associated habitat alterations, while currently occurring, may not demonstrate demographic effects on lynx within the next decade.

Future Conditions

Resiliency of individual geographic units, which function independently of each other, is the primary determinant of future lynx DPS viability. Overall, our analysis indicates a ~~reduced~~decreasing probability of persistence for ~~all~~each geographic unit~~s~~ within the DPS over the rest of the century (noting that the analysis did not extend beyond that 2100 time frame). It further indicates a consequent permanent loss of two to four of the six units, i.e., loss of resiliency, by the end of the century.

Representation and redundancy are lesser factors for DPS viability~~,~~ for several reasons. Although the populations in the DPS units are demographically isolated from each other, there is little risk of significant genetic drift within the DPS, likely due to most areas being relatively well connected with Canadian populations; this is indicative of relative genetic health through the end of the century. Furthermore, based on expert input, there is no indication that the relatively low level of genetic diversity is likely to reduce DPS viability in the future (USFWS 2016, p. 51). Because of the ability of lynx to widely disperse, and because it is unlikely that insurmountable barriers to lynx dispersal between Canada and the DPS will emerge, we do not expect representation to become a concern through the turn of the century.

With regard to redundancy, neither the scientific literature nor expert input provide a basis for concluding that any catastrophic event could cause extirpation of any one geographic unit. It is even ess likey that a single catastrophic event will eliminate all populations in the DPS. It is important to note, however, that a sequence of less-than-catastrophic events could result in extirpat~~e~~ion of one or more ~~individual~~ units over time, thereby reducing redundancy within the DPS.

The likelihood of persistence of individual populations, and thus geographic units, is expected to decrease by 2100 primarily because of climate change effects on snow conditions and boreal forests. The other long-term threat is forest management practices that are not conducive to landscape hare densities able to support lynx, although this stressor may be limited to one geographic unit. Threats affecting the future condition of the DPS are summarized below.

Comment [MJM11]: See comment above.

Comment [MJM12]: By itself, this sounds like a good thing. Explain how this is a "heightened concern."

Comment [MJM13]: Is this the imeframe that defines current condition? If not, say instead something like "may not cause demographic effects for a decade or more."

Comment [MJM14]: Reduced from what?

This is a meaningless statement. Every species has a decreasing probability of persistence with increasing time. Describe the decrease in terms of its magnitude and significance.

Comment [MJM15]: Is this change correct? Or are you trying to say one or more units have increasing probabilities but the DPS as a whole has a decreasing probability?

Comment [MJM16]: Wouldn't loss of populations be a loss of redundancy, not resiliency? The loss of a population is a loss of redundancy; the means by which a population is lost is the decrease in resilience over ime that leads to the ultimate outcome of loss of the population.

Comment [MJM17]: I assume this is based on he "most likely" future scenario. What is he risk of loss of more than two to four units? We need to know the full risk profile.

Comment [MJM18]: But is there a meaningful risk?

Comment [MJM19]: But is there a meaningful risk?

Comment [MJM20]: "Could" simply means "possible" and is ambiguous. Would be better to say there is "no meaningful risk" of a catastrophic event causing extirpa ion of any one unit.

Comment [MJM21]: The odds of all of several events happening is always less than he odds of any single event happening. Describe this risk in more absolute terms rather han in terms of a meaningless comparison.

Comment [MJM22]: I read his as referring to a sequence of catastrophic events, each one causing ex irpation of a unit. Made this change to avoid that interpretation.

Comment [MJM23]: Isn't this statement saying the same hing as the last sentence in he first paragraph of this section? This sentence says the loss of popula ions "could" occur; the sentence in the first paragraph describes this as predicted to happen. Recommend being more precise.

Comment [MJM24]: This is a meaningless statement. Every species has a decreasing likelihood of persistence over time. What we're talking about here is our prediction of a decrease of a certain magnitude that is due to certain factors. Recast the sentence to something like "The predicted decrease in th...

Based on climate change models, the effects of climate change on snow and boreal forest conditions are foreseen as the primary stressor limiting future viability of lynx in the DPS. The southernmost boreal habitats are predicted to retreat northward and upslope, fragmenting and diminishing the quality of lynx and hare habitat within the DPS (although some uncertainty remains regarding the timing, extent, and biological consequences of such impacts). As habitat conditions decline, mortality rates are likely to increase and reproductive rates decrease. This in turn will reduce abundance and density of individuals within populations, making lynx populations more susceptible to stochastic events.

Given the percent of ~~f~~Federal land ownership, ~~-~~regulatory assurances that these lands will be managed in accordance with lynx conservation, and a stronger possibility that lynx populations will be able to relocate to higher elevations, western geographic units are more likely to support lynx longer than other units under projected climate change scenarios. Nonetheless, we are unaware of any management action that can abate the long-term retreat of boreal forests and changed snow conditions. Further, climate-induced frequency and intensity of wildfires and disease events ~~is~~are expected to increase, particularly in the western portion of the DPS, although we do not anticipate such events ~~in and of themselves~~ alone to cause the permanent loss of breeding lynx populations in the North~~west~~-central Washington Unit or any other unit.

With regard to the eastern geographic units (Minnesota and Maine), suitable boreal forest and snow conditions are projected to decline more severely than in the western units. Lynx habitat conditions in Maine are also likely to decline significantly by the end of the century as private forest management practices, particularly a decline in clearcutting, result in succession detrimental to snowshoe hare and lynx needs.

DPS viability

Although there is no evidence from the historical record that Canada lynx have declined within the DPS, a number of threats acting at the DPS and individual geographic unit scales indicate a moderate to high likelihood of declines (i.e., loss of two to four units) by the turn of the century. While it is more likely than not that any given individual unit—~~n~~Northern Maine, ~~n~~Northeastern Minnesota, ~~n~~Northwestern Montana, ~~w~~Western Colorado, and possibly ~~n~~North-central Washington—will persist to mid-century, t is unlikely all that five will persist to that point. By the end of the century, we expect populations to persist primarily in units having high-elevation refugia, e.g., northwestern Montana and possibly western Colorado, although Colorado would be an isolated unit. Lynx may also persist at the end of the century in Maine, depending on the severity of climate change effects and trends in development and private forest management. Uncertainty increases at mid- to late-century concerning the timing and extent of various stressors that will affect lynx and hare habitat and snow regimes, especially those related to climate change. However, review of the best available science in concert with input from lynx experts indicates that all units will exhibit declines by 2025, with the negative DPS-wide trajectory continuing to the end of the century, and (with no evidence to the contrary) beyond that time frame.

We conclude that the eventual loss of resiliency indicated by extirpation of geographic units will also reduce redundancy and, possibly, representation. These losses in resiliency, redundancy,

Comment [MJM25]: I can't tell what this is referring to. North-central Washington or Northwestern Montana.

Comment [MJM26]: This is good to know, but what I really want to know is the probability that all five will not persist to that point – i.e., the risk of ex inction.

Comment [MJM27]: But what is he risk that hey don't?

Comment [MJM28]: But what is he risk that hey will not?

and representation will put the Canada lynx U.S. DPS at increasing risk of extinction over the course of this century, and in all probability, the risk will continue to increase after that point.

Comment [MJM29]: This is a meaningless statement. All species are at increasing risk of extinction over time.

Chapter 1: Introduction

The U.S. Fish and Wildlife Service (Service) designated lynx in the contiguous U.S. as a distinct population segment (DPS) and listed it as threatened under the Endangered Species Act of 1973, as amended (ESA) in 2000 (65 FR 16052-16086). On May 8, 2014, the United States District Court for the District of Montana ordered the Service to complete recovery planning for the lynx DPS (U.S. District Court MT 2014a, p. 8). On June 25, 2014, the same court ordered the Service to complete a recovery plan by January 15, 2018 "…unless the Service finds that such a plan will not promote the conservation of the [lynx]" (U.S. District Court MT 2014b, p. 2). Thus, we conducted this SSA (version 1.0) to summarize the best available information on the current status and likely future viability of the DPS. This SSA will inform a determination by Service decision makers of whether (1) the DPS continues to warrant protection under the ESA and (2) a recovery plan is needed to guide conservation and recovery of the lynx DPS.

1.1 Background

The Canada lynx is a North American wild cat that is most strongly associated with northern-latitude boreal forests (taiga) of Canada and Alaska (McCord and Cardoza 1982, p. 729; Agee 2000, pp. 39-41; Aubry *et al*. 2000, pp. 373-374; Mowat *et al*. 2000, p. 272). It relies heavily on adequate populations of its primary prey, the snowshoe hare (*Lepus americanus*), to support survival, reproduction, recruitment, and, therefore, population persistence (Ruggiero *et al*. 2000a, p. 110; Mowat *et al*. 2000, p. 270; Steury and Murray 2004, pp. 128, 136-138; U.S. Fish and Wildlife Service 2005, p. 2; Interagency Lynx Biology Team [ILBT] 2013, pp. 30-34; 79 FR 54808-54809). Lynx survival and distribution is also influenced by snow conditions. It is generally restricted to areas that receive deep, powdery, and persistent snow that allows lynx, with their proportionately longer limbs and very large feet, to outcompete other terrestrial hare predators that are less efficient in such conditions (McCord and Cardoza 1982, pp. 748-749; Quinn and Parker 1987, p. 684; Buskirk *et al*. 2000a, pp. 89-94; Buskirk *et al*. 2000b, pp. 400-401; Ruggiero *et al*. 2000b, pp. 445–449; Hoving 2001, p. 75; Hoving *et al*. 2005, p. 744-749; Carroll 2007, entire; Gonzalez *et al*. 2007, entire; ILBT 2013, pp. 25-26; 79 FR 54809).

Lynx are generally considered secure, widespread, abundant, and distributed throughout most of their historic ranges in Canada and Alaska, which, combined, account for roughly 98 percent of the species' distribution. Lynx are distributed across approximately 5.5 million km^2 (2.1 million mi^2) in Canada (Environment Canada 2014, p. 2) and 534,454 km^2 (206,354 mi^2) in Alaska (University of Alaska Center for Science Conservation 2016, entire; Reimer 2016, pers. comm.). The southern peripheries of the boreal forest and the distributions of snowshoe hares and lynx extend into the northern contiguous U.S. (Bittner and Rongstad 1982, p. 146; McCord and Cardoza 1982, p. 729; Agee 2000, pp. 39-41; Aubry *et al*. 2000, pp. 379-382; Hodges 2000, pp. 163-173; McKelvey *et al*. 2000a, pp. 242-253), where the six geographic units evaluated in this

SSA represent the remaining 2 percent of the species' breeding distribution (approximately 131,168 km^2 [50,644 mi^2]; see Figure 1 and Table 1, below). Lynx populations in the DPS seem to function as peripheral subpopulations (islands) of a larger (mainland) metapopulation centered in north-central Canada (McKelvey *et al*. 2000b, p. 25; 68 FR 40077; also see 2.2 below), and the demographic and genetic health and persistence of DPS populations are thought to be influenced by connectivity with, and immigration of lynx from, larger populations in Canada (McKelvey *et al.* 2000b, pp. 21, 33; Schwartz *et al.* 2002, entire; 78 FR 59434, 59447; 79 FR 54815).

Lynx were documented historically in 24 of the Lower 48 States (McKelvey *et al.* 2000a, pp. 207-232), but records in many places are associated with cyclic "irruptions" of large numbers of lynx dispersing from southern Canada when hare populations crashed; many of these occurrences were in anomalous habitats, and lynx were unable to persist and establish populations in most of these areas (Gunderson 1978, entire; Thiel 1987, entire; McKelvey *et al.* 2000a, pp. 242, 253; Aubry 2006, pp. 1-2; ILBT 2013, p. 23; see also section 2.3.2, below). Habitats capable of supporting persistent resident lynx populations in the contiguous U.S. occur over a much smaller geographic area that includes parts of the Northeast (primarily northern Maine), western Great Lakes (northeastern Minnesota), Rocky Mountains (northern Idaho, northwestern Montana; perhaps also parts of northeastern Washington, the Greater Yellowstone Area (GYA) of southwestern Montana and northwestern Wyoming, and parts of western Colorado), and the eastern Cascade Mountains of northern Washington (68 FR 40077-40080; U.S. Fish and Wildlife Service 2005, p. 3; 79 FR 54806-54807; Lynx SSA Team 2016, pp. 6-7). Although uncertainty remains regarding the historic distribution of resident lynx in the contiguous U.S., and breeding populations may have been lost from some places, neither broad-scale breeding range contraction nor substantial population decline in the contiguous U.S. has been documented based on verified occurrence data (68 FR 40099; 72 FR 1187; 79 FR 54798, 54815; McKelvey *in* Lynx SSA Team 2016, p. 11; also see section 2.3.2, below).

The Service designated lynx in the contiguous U.S. as a DPS and listed it as threatened under the ESA in 14 states in 2000 because of the inadequacy, at that time, of existing regulatory mechanisms on federal lands (65 FR 16052). In 2003, in response to a court memorandum opinion on the 2000 listing rule, the Service reaffirmed its determination of the lynx DPS and its status as threatened under the ESA (68 FR 40076). The Service completed a recovery outline in 2005 (U.S. Fish and Wildlife Service 2005, entire), designated critical habitat for the DPS in 2006 (71 FR 66008) and, in 2007, again in response to a court order, clarified its determinations of "significant portion of the range" and that all lynx in the contiguous U.S. constitute a single DPS (72 FR 1186). Also in 2007, the Service initiated a 5-year status review of the DPS (72 FR 19549). The Service revised the critical habitat designation for the DPS in 2009 (74 FR 8616) and 2014 (79 FR 54782) and, concurrent with the latter, rescinded the state-based definition of the DPS boundary to formally extend ESA protection to lynx "where found" in the contiguous U.S., including New Mexico and other states that were not included in the original DPS range (79 FR 54804). The Service reinitiated the 5-year status review in 2015 (https://www.fws.gov/mountain-prairie/pressrel/2015/01132015_ServiceConductingFiveYearReviewCanadaLynx.php), and that

review will be informed by this SSA report. On September 7, 2016, the U.S. District Court for the District of Montana remanded the 2014 critical habitat designation to the Service for further consideration.

The six geographic units evaluated in this SSA encompass all areas of the contiguous U.S. that currently support or are believed to have recently supported persistent resident lynx populations (Figure 1). Five of the six geographic units were designated as “Core Areas” in the Recovery Outline (USFWS 2005, pp. 4-6, 21, 23), and western Colorado was designated a “Provisional Core Area” (USFWS 2005, pp. 6, 21, 23). With the exception of western Colorado, these units also encompass and closely mirror the areas the Service designated as critical habitat in 2014 (79 FR 54782). Some areas adjacent to but outside these geographic units are known or suspected to intermittently support lynx home ranges and occasional reproduction. Uncertainty remains as to whether resident lynx populations occurred historically in other areas not encompassed by the geographic units evaluated here.

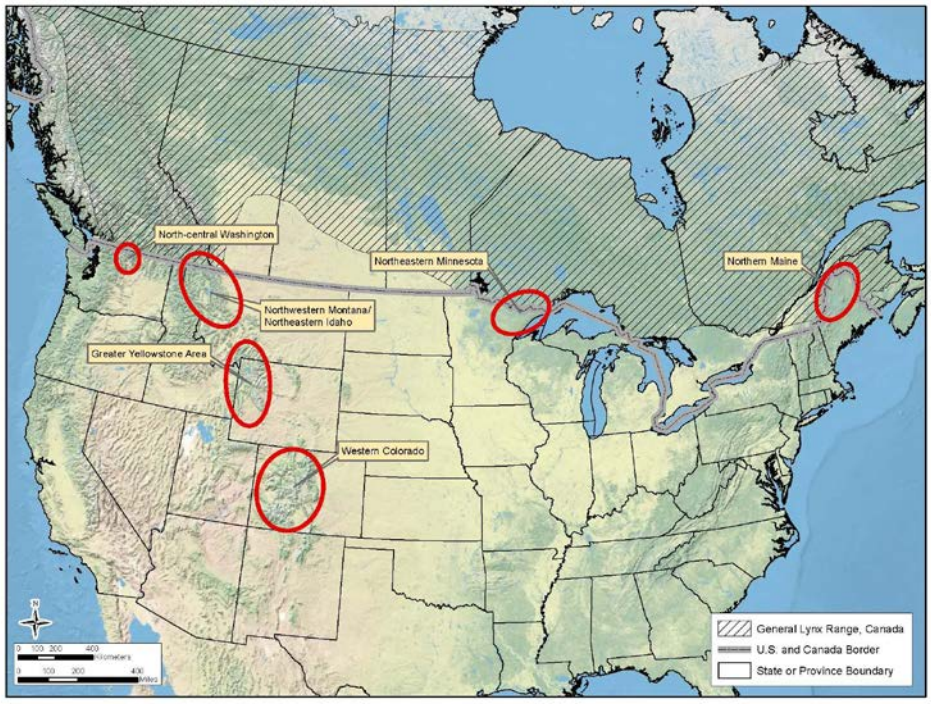

Figure 1. Six geographic units within the range of the contiguous U.S. distinct population segment of Canada lynx (*Lynx canadensis*) that currently support or recently supported (GYA) resident lynx populations relative to the general range of lynx in Canada. Range in Canada based on Poole (2003), Koen *et al.* (2014), and Vashon (2015).

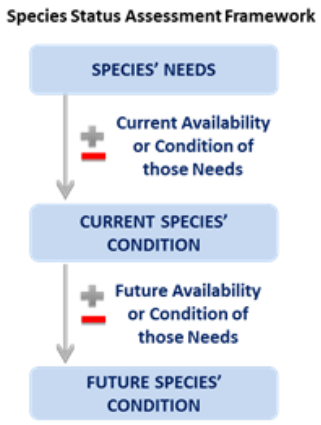
The six geographic units include federal, private, State, and Tribal lands. The amounts in each ownership vary among the units, with private lands predominating in Maine, a mix of ownerships in Minnesota, and federal lands predominating in the western units (Table 1).

Table 1. Lynx SSA Unit Sizes and Percent Ownership.



Unit[1]	Unit Size (km^2)	Percent of SSA Area	Land Ownership/Management (Percent)[2]						
			Federal				Private	State	Tribal
			All Federal	USFS	NPS	BLM			
1	28,909	22.0	0	0	0	0	91.6	7.3	0.9
2	21,101	16.1	47.4	44.9	2.5	0.01	15.5	36.2	1.0
3	26,997	20.6	84.3	69.3	13.6	1.5	8.0	4.1	3.5
4	5,176	3.9	91.5	84.6	6.7	0.1	0.3	8.2	0
5	23,687	18.1	97.6	79.7	16.7	1.1	2.2	0.3	0
6	25,294	19.3	90.1	85.2	1.8	3.1	9.3	0.6	0
All Units	131,164	100	63.6	55.6	6.8	1.1	26.5	8.8	1.1

[1] Unit 1 - Northern Maine; Unit 2 - Northeastern Minnesota, Unit 3 - Northwestern Montana/ Northeastern Idaho, Unit 4 - North-central Washington, Unit 5 - the Greater Yellowstone Area (southwestern Montana/Northwestern Wyoming), Unit 6 - Western Colorado.

[2] Unit sizes and ownership for units 1-5 are those calculated for the areas designated in 2014 as lynx critical habitat, including some Tribal, State and private lands that met the criteria for critical habitat but which were excluded from the designation in accordance with section 4(b)(2) of the Endangered Species Act. Unit 6 size and ownership were calculated by the Service's Western Colorado Field Office in coordination with Colorado Parks and Wildlife based on telemetry data from radio-marked lynx.

1.2 SSA Framework and Report

The Service is engaged in a number of efforts to improve the implementation of the ESA (see http://www.fws.gov/endangered/improving_ESA/). As part of this effort, our Endangered Species Program has developed the Species Status Assessment (SSA) Framework to guide how we assess the best scientific and commercial data available when evaluating the biological status of species. In conducting an SSA, we take into consideration the life history and ecological requirements of the species to understand how the species maintains itself over time (captured under the broad heading of "species needs"); the current condition of the species at the individual, population, and range-wide levels in terms of meeting those needs; and the likely changes in the environment that may influence the species' future condition and, thus, the viability of the species.

The SSA Framework defines viability as a description of the ability of a species to sustain populations in the wild beyond a biologically meaningful time frame[1]. Throughout the assessment, the SSA uses the conservation biology principles of resiliency, redundancy, and representation (collectively known as the "3 Rs") as a lens to evaluate the current and future condition of the species. Briefly, resiliency describes the ability of the species to withstand stochastic events; redundancy describes the ability of the species to withstand catastrophic events; and representation describes the ability of the species to adapt over time to long-term changes in the environment. As a result, the SSA characterizes a species' ability to sustain populations in the wild over time based on the best scientific understanding of current and future abundance and distribution within the species' ecological settings. Importantly, the SSA neither results in, nor predetermines, any decisions by the Service under the ESA.

The Species Status Assessment Report (SSA Report) is a summary of the information assembled, reviewed, and assessed by the Service and is based on the best scientific and commercial data available at the time of the assessment. Completed SSA Reports and supporting material can be found at the collaborative repository of the National Park Service and the USFWS called "ServCat" at the following IP address: *http://www.fws.gov/Refuges/NaturalResourcePC/landM/serviceCatalog.html*.

1.3 Analytical Approach/Methods

We used the SSA Framework (October 2015, version 3.3) described above to evaluate the current status of resident lynx in the contiguous U.S. as well as the likelihood that the geographic areas supporting resident lynx in the DPS would continue to do so in the near term and at mid- and end-of-century (years 2025, 2050, and 2100). We framed our evaluation in

[1] Viability is not a specific state, but rather a continuous measure of the likelihood that the species will sustain populations in the wild over time. USFWS. 2015. Species Status Assessment Framework. Version 3.3. October 2015.

terms of the 3 Rs using conceptual modeling (Figure 2) based on available published literature, other information on the historic and current status of and threats to lynx in the DPS and, where empirical data are lacking, on formally-elicited expert opinion and best professional judgment (Lynx SSA Team 2016, entire).

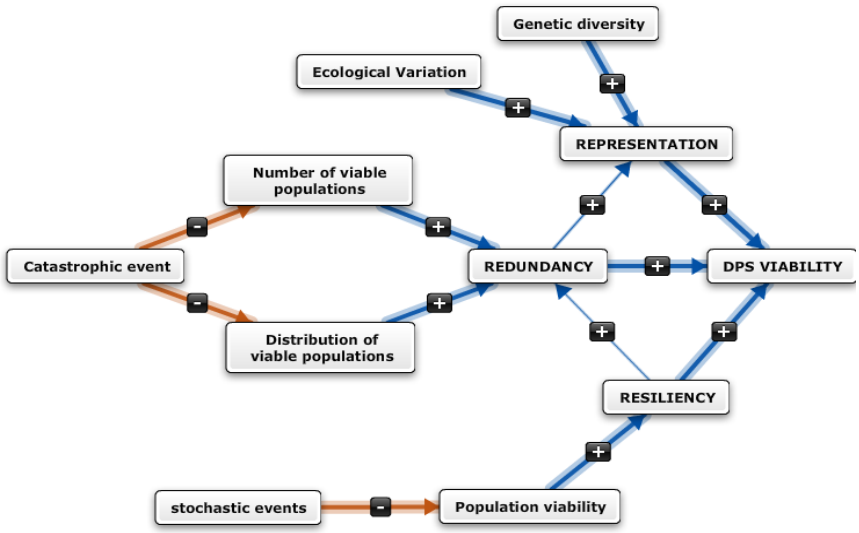


Figure 2. Conceptual model of the factors thought to influence the 3 Rs as they pertain to lynx viability.

We applied the definitions from the SSA Framework for the principles of redundancy, representation, and resiliency, provided in section 1.2, to Canada lynx as described below. We evaluated redundancy and representation at the scale of the DPS as a whole, and resiliency at the scale of lynx populations within each of the six geographic units.

To evaluate **redundancy** for the lynx DPS, we considered the current and likely future geographic distributions of resident breeding populations and whether the DPS is currently vulnerable to extirpation due to catastrophic event or would be in the future. Figure 3 shows examples of relationships among factors that may influence redundancy within the lynx DPS.

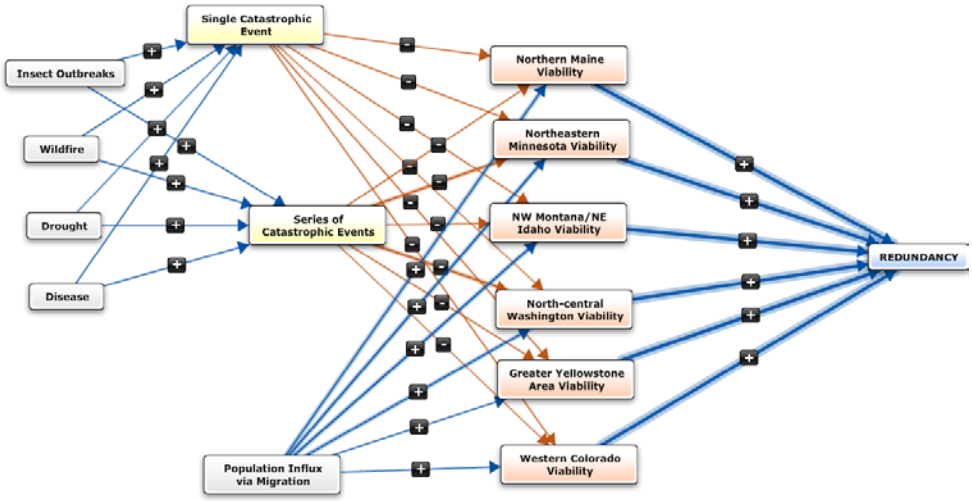

Figure 3. Conceptual model of factors thought to influence redundancy within the lynx DPS.

To evaluate **representation** for the lynx DPS, we considered measures of genetic diversity and heterozygosity, the current and likely future ecological diversity of geographic areas occupied by resident breeding populations, and the documented dispersal capabilities of the species, as shown in Figure 4 below.

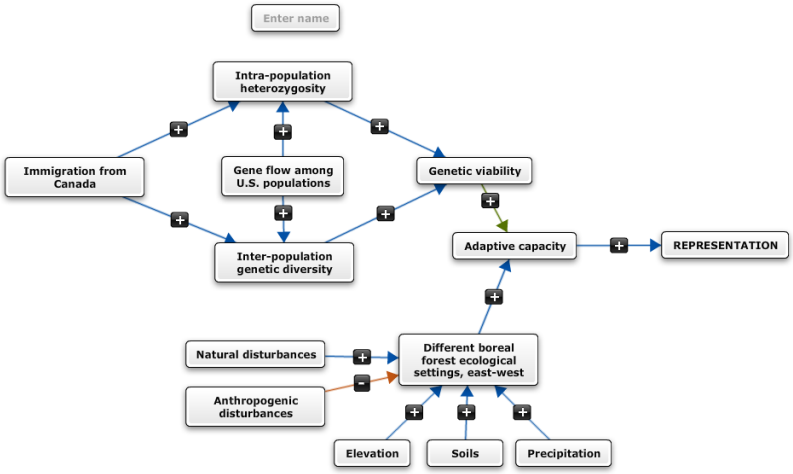

Figure 4. Conceptual model of factors thought to influence representation within the lynx DPS.

Because we lack reliable estimates of population sizes and trends, growth rates, and other long-term demographic data for most populations in the DPS, our evaluation of the **resiliency** of lynx

populations in the DPS was based largely on consideration of recent status updates and formally-elicited expert opinion regarding the likelihood that DPS populations will remain viable into the future. The relationships among factors that influence DPS resiliency are shown in Figure 5 below.

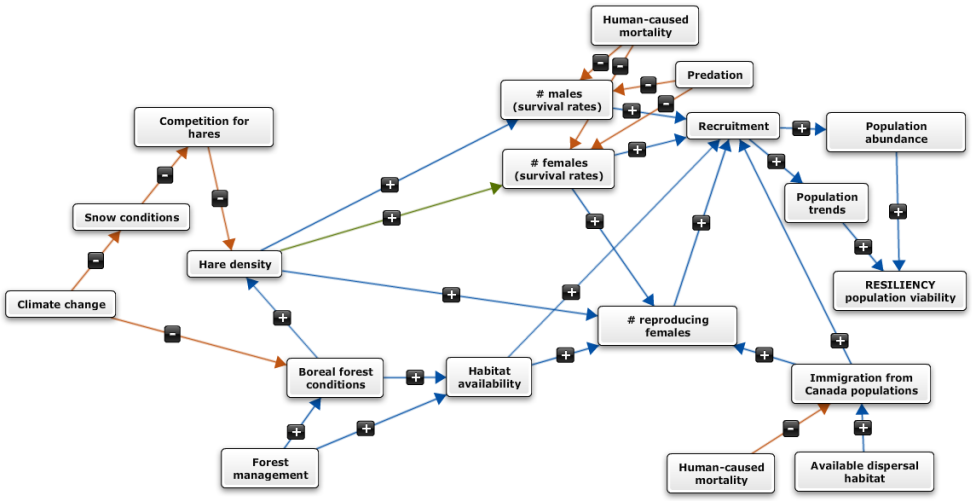

Figure 5. Conceptual model of factors thought to influence the resiliency of lynx populations within the DPS.

Chapter 2: Lynx Ecology

In this chapter, we describe the physical characteristics, taxonomy, and genetics of the Canada lynx, its life history and population dynamics, and its taxon-wide and DPS distributions. We rely heavily on recent summaries of this information provided in the revised *Canada Lynx Conservation Assessment and Strategy* (LCAS; ILBT 2013, entire), the Service's recent proposed (2013) and final (2014) rules to revise the designation of critical habitat for the DPS (78 FR 59430-59474; 79 FR 54782-54846), and the results of an October 2015 lynx expert elicitation workshop (Lynx SSA Team 2016, entire). We also provide a summary of the pertinent ecological requirements of lynx at the individual, population, and DPS levels. These ecological requirements form the basis of our analyses conducted in Chapters 3 through 5.

2.1 Species Taxonomy, Description, and Genetics

The Canada lynx (order Carnivora; family Felidae) is one of four species within the genus *Lynx* (Kerr 1792), which also includes the bobcat (*L. rufus*, Schreber 1777), the Eurasian lynx (*L. lynx*, Linnaeus 1758), and the Iberian or Spanish lynx (*L. pardinus*, Temminck 1827). There are

three recognized subspecies of Canada lynx: *Lynx canadensis canadensis* (Kerr 1792), *L. c. mollipilosus* ("Arctic lynx," Stone 1900), and *L. c. subsolanus* ("Newfoundland lynx," Bangs 1897) (Integrated Taxonomic Information System online database, http://www.itis.gov, retrieved April 14, 2016).

The Canada lynx is a medium-sized cat with long legs and large, well-furred paws. In winter, the lynx's fur is dense and has a grizzled appearance with a grayish-brown mix of buff or pale brown fur on the back, and a grayish-white or buff-white fur on the belly, legs, and feet. In summer, its fur is more reddish to gray-brown (McCord and Cardoza 1982, p. 730). It has long tufts of black hairs extending from the tips of its ears, a short, completely black-tipped tail, and often a distinct dish-like facial ruff of pale hairs tipped black. Lynx generally measure 75 to 90 cm (30 to 35 in) long and weigh 6 to 14 kg (14 to 31 lb) (Quinn and Parker 1987, Table 1; Moen *et al.* 2010a, Figure 2; Maine Department of Inland Fisheries and Wildlife 2012, unpublished data), and males are 13-25 percent larger than females (Mowat *et al.* 2000, p. 267). The lynx's large feet and long legs make it highly adapted for traversing and hunting in deep, powdery snow, where its low foot-loading (weight per surface area of foot) is thought to provide a competitive advantage (Buskirk *et al.* 2000a, p. 90; 2000b, p. 400; ILBT 2013, pp. 26, 36, 81) over other terrestrial predators of snowshoe hares, the lynx's primary prey. In southern Canada and the northern contiguous U.S, where the southern edge of the lynx range overlaps the northern edge of the bobcat range, the two species are easily confused because of their similar size and appearance. However, the lynx's longer ear-tufts, larger feet, and black-tipped tail distinguish it from the bobcat, which has shorter ear tufts, small feet, white on the underside of the tail, and is much more common and abundant than lynx in most of the contiguous U.S..

Overall, genetics research suggests high gene flow across most of the continental range of lynx, likely because of high dispersal rates, large dispersal distances, and the absence of significant barriers to genetic interchange throughout much of the lynx range, including the DPS (Schwartz *in* Lynx SSA Team 2016, pp. 11-12). Genetic evidence also indicates interactions between lynx populations even where physical barriers appear most likely to restrict gene flow. For example, although *L. c. subsolanus* on Newfoundland Island is genetically (Row *et al.* 2012, pp. 1262-1266; Koen *et al.* 2015, p. 528) and morphologically (Khidas *et al.* 2013, pp. 597-601) distinct from mainland lynx, there is evidence of genetic exchange between the two areas, indicating that some lynx are able to cross the 15-60 km-wide (9-37 mi) Strait of Belle Isle that separates them (Koen *et al.* 2015, p. 527). Similarly, despite some differences in functional genetic markers (unique alleles) in lynx south versus north of the St. Lawrence Seaway/River in eastern Canada, which suggest the potential for evolutionarily significant differences in those areas, recent analyses reveal genetic exchange among lynx on either side, indicating that some lynx successfully navigate this barrier (Koen *et al.* 2015, pp. 524-528; Bowman *in* Lynx SSA Team 2016, p. 12-13).

Schwartz *et al.* (2003, entire) documented reduced genetic variation (lower mean number of alleles per population and lower expected heterozygosity) among peripheral lynx populations compared to populations in the core of the lynx geographical range in Canada and Alaska. While recognizing that small changes in genetic variation can lead to large changes in

population fitness, the authors noted that the differences between core and peripheral populations in their study were small enough to suggest a lack of significant population subdivision (i.e., no indication of genetic isolation, substantial genetic drift, or potential genetic ‘‘bottlenecks’’ among DPS populations; Schwartz *et al.* 2003, p. 1814; 79 FR 54793). This finding is consistent with their earlier work, which documented high levels of gene flow (the highest yet documented for any carnivore) between core and peripheral lynx populations despite large separation distances (Schwartz *et al.* 2002, entire). Their results did not suggest that reduced genetic variation among peripheral populations was because of human disturbance (i.e., habitat loss/ fragmentation on the southern periphery of the geographic range; Schwartz *et al.* 2003, p. 1814), but they did imply that the persistence of lynx populations in the contiguous U.S. depends on dispersal from larger (core) populations (Schwartz *et al.* 2002, p. 522). Currently, there is no indication that the levels of connectivity and gene flow between lynx populations in the DPS and those in the core of the lynx’s range are inadequate to maintain the genetic health of DPS populations. Given the connectivity of most DPS units with lynx populations and habitats in Canada, the noted dispersal capabilities of lynx, evidence of dispersal in both directions across the Canada-U.S. border (Aubry *et al.* 2000, pp. 386-387; Squires *et al.* 2006a, p. 38; Moen *et al.* 2010b, pp. ii, 17, 19; Vashon *et al.* 2012, p. 22), and the small number of immigrants thought necessary to maintain genetic variability in peripheral populations (McKelvey *et al.* 2000b, pp. 23-24), genetic isolation, biologically meaningful genetic drift, or potential genetic ‘‘bottlenecks’’ appear unlikely among most DPS populations in the future (79 FR 54793).

Within the contiguous U.S., minor genetic sub-structuring has been documented among lynx subpopulations in western Montana (Schwartz *in* Lynx SSA Team 2016, p. 12 and Appendix 5). Additionally, lynx-bobcat hybridization has been documented in Minnesota, Maine and New Brunswick (Schwartz *et al.* 2004, entire; Homyack *et al.* 2008, entire), where male bobcats bred with female lynx to produce fertile offspring with lynx-like ear tufts, intermediate foot-size, and bobcat-like fur (ILBT 2013, p. 35). In Minnesota from 2000 to 2015, DNA analyses documented 13 distinct hybrid individuals (Moen and Catton *in* Lynx SSA Team 2016, pp. 13, 19); no hybrids have been documented in the western portion of the lynx’s range (Schwartz *in* Lynx SSA Team 2016, p. 12).

2.2 Life History and Population Dynamics

All aspects of lynx life history are inextricably tied to its primary prey, the snowshoe hare (Figure 6). Snowshoe hares comprise a majority of the lynx diet throughout its range (Nellis *et al.* 1972, pp. 323–325; Brand *et al.* 1976, pp. 422–425; Koehler 1990, p. 848; Apps 2000, pp. 358–359, 363; Aubry *et al.* 2000, pp. 375–378; Mowat *et al.* 2000, pp. 267–268; von Kienast 2003, pp. 37–38; Squires *et al.* 2004a, p. 15, Table 8, Olson 2015, pp. 60-69), and hare abundance is the major driver of lynx population dynamics. Lynx den site selection, litter sizes, pregnancy, as well as recruitment, survival (kitten, subadult and adult) and dispersal rates, and population age structure, home range sizes, density, and distribution are all strongly influenced by hare abundance (Koehler and Aubry 1994, pp. 75-76, 80-83; Apps 2000, entire; Aubry *et al.* 2000, pp. 375-390; Mowat *et al.* 2000, pp. 270-294; ILBT 2013, pp. 18, 22-24, 26-34).

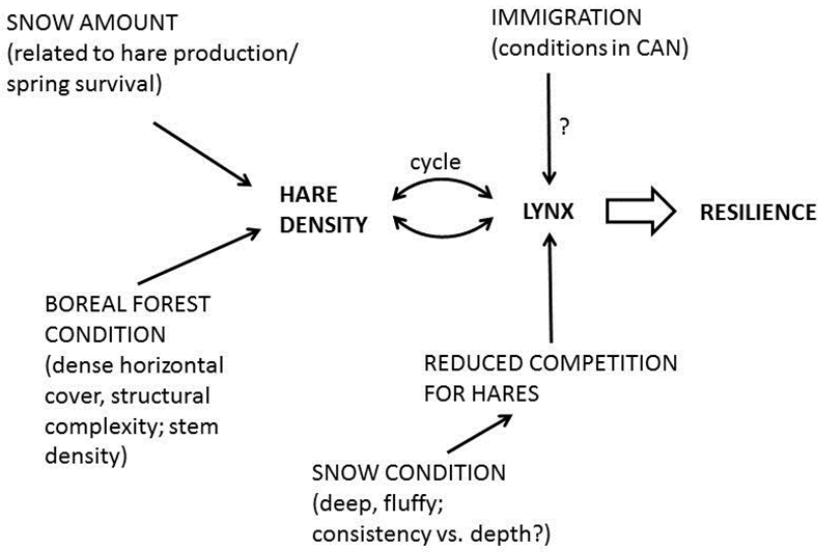

Figure 6. Generalized relationship between habitat conditions and hare and lynx population dynamics and their influence on lynx population resiliency.

Lynx are highly specialized predators of snowshoe hares and are dependent on landscapes with high-density snowshoe hare populations for survival and reproduction (McCord and Cardoza 1982, p. 744; Quinn and Parker 1987, pp. 684-685; Aubry *et al.* 2000, pp. 375-378). Lynx and snowshoe hares are strongly associated with what is broadly described as boreal forest (Bittner and Rongstad 1982, p. 154; McCord and Cardoza 1982, p. 743; Quinn and Parker 1987, p. 684; Agee 2000, p. 39; Aubry *et al.* 2000, pp. 378-382; Hodges 2000a, pp. 136-140 and 2000b, pp. 183-191; McKelvey *et al.* 2000a, pp. 211-232). The predominant vegetation of boreal forest is conifer trees, primarily species of spruce (*Picea* spp.) and fir (*Abies* spp.) (Elliot-Fisk 1988, pp. 34-35, 37-42). Snowshoe hares feed on conifers, deciduous trees, and shrubs (Hodges 2000b, pp. 181-183) and are most abundant in forests with dense understories that provide forage, cover to escape from predators, and protection during extreme weather (Wolfe *et al.* 1982, pp. 665-669; Litvaitis *et al.* 1985, pp. 869-872; Hodges 2000a, pp. 136-140 and 2000b, pp. 183-195). Over much of the lynx's range, hare densities are higher in regenerating, earlier successional forest stages because they often have greater understory structure than mature forests (Buehler and Keith 1982, p. 24; Wolfe *et al.* 1982, pp. 665-669; Koehler 1990, pp. 847-848; Hodges 2000b, pp. 183-195; Homyack 2003, pp. 63, 141; Griffin

2004, pp. 84-88). However, snowshoe hares also can be abundant in mature forests with dense understories, particularly in the Northern Rocky Mountains (Griffin 2004, pp. 53-54; Griffin and Mills 2009, pp. 1492-1496; Hodges *et al.* 2009, p. 876; Squires *et al.* 2010, pp. 1653-1657; Berg *et al.* 2012, pp. 1483-1487). These mature forests may be a source of hares for other adjacent forest types (Griffin and Mills 2009, pp. 1492, 1495-1496), and they may provide especially important winter foraging habitats (Squires *et al.* 2010, pp. 1655-1657), which may be the most limiting habitat for lynx (Squires *et al.* 2010, pp. 1655-1657; ILBT 2013, pp. 17, 27). They also are more temporally-stable (i.e., they provide high-quality hare habitat for a longer period of time) than regenerating stands, which may foster high hare densities for a variable window of time between stand-initiation and stem-exclusion stages of succession, after which they may persist, in the absence of disturbance, for many years as lower-quality hare habitat (ILBT 2013, pp. 62, 71, 127).

Lynx habitat can generally be described as moist boreal forests that have cold, snowy winters and a snowshoe hare prey base (Quinn and Parker 1987, pp. 684-685; Agee 2000, pp. 39-47; Aubry *et al.* 2000, pp. 373-375; Buskirk *et al.* 2000b, pp. 397-405; Ruggiero *et al.* 2000b, pp. 445-447). Because lynx population dynamics, survival, and reproduction are closely tied to snowshoe hare availability, snowshoe hare habitat is the primary component of lynx habitat. However, lynx do not occur everywhere within the range of snowshoe hares in the contiguous U.S. (Bittner and Rongstad 1982, p. 146; McCord and Cardoza 1982, p. 729). This may be due to inadequate abundance, density, or spatial distribution of hares in some places, or the absence of snow conditions that would allow lynx to express a competitive advantage over other hare predators, or a combination of these factors (79 FR 54809).

The boreal forest landscape is naturally dynamic. Forest stands within the landscape change as they undergo succession after natural or human-caused disturbances such as fire, insect epidemics, wind, ice, disease, and forest management (Elliot-Fisk 1988, pp. 47-48; Agee 2000, pp. 47-69). As a result, lynx habitat within the boreal forest landscape is a shifting mosaic of habitat patches of variable and continually changing quality (68 FR 40077). These stands of differing ages and conditions provide lynx foraging or denning habitat (or may provide these in the future depending on patterns of disturbance and forest succession), and some serve as travel routes for lynx moving between foraging and denning habitats (McKelvey *et al.* 2000c, pp. 427-434; Hoving *et al.* 2004, pp. 290-292). Lynx generally concentrate hunting activities in areas where snowshoe hare densities are high (Koehler *et al.* 1979, p. 442; Ward and Krebs 1985, pp. 2821-2823; Murray *et al.* 1994, p. 1450; O'Donoghue *et al.* 1997, pp. 155, 159-160 and 1998, pp. 178-181; Fuller and Harrison 2010, entire; Simons-Legaard *et al.* 2013, pp. 573-575). Because understory density within a forest stand changes over time, hare habitat quality and corresponding hare densities also shift continually across boreal forest landscapes.

Hare populations in the core of the lynx range in Canada and Alaska undergo well-documented dramatic 8 to 11 year cycles during which hare numbers may fluctuate 10 to 25 fold or more, with peak densities as high as 23 hares/hectare (ha; 9.3 hares/acre [ac]) and lows of 0.1/ha (0.04/ac) (Hodges 2000a, pp. 117-121; Vashon 2015, p. 4). Hare densities are generally lower at the southern periphery of lynx distribution, and hare population cycles are generally much

less pronounced or absent entirely among some hare populations in southern Canada and in the contiguous U.S. (Hodges 2000b, pp. 163–173; Hodges *et al.* 2009, pp. 870, 875–876; Scott 2009, pp. 1–44; Environment Canada 2014, p. 1; Hodges *in* Lynx SSA Team 2016, pp. 16-17). In the contiguous U.S., stand-level hare densities may exceed 2 hares/ha (0.8 hares/ac) (Walker 2005, pp. 20, 85; McCann 2006, p. 15; Robinson 2006, pp. 26-36, 62-75; Homyack *et al.* 2007, pp. 10-11; Griffin and Mills 2009, p. 1492; Vashon *et al.* 2012, p. 14), but in many parts of the DPS, landscape-level densities are lower, ranging from just above to well below the 0.5 hares/ha (0.2/ac) density thought necessary to sustain lynx home ranges and populations (Hodges 2000b, pp. 168-169, 185; Ruggiero *et al.* 2000b, pp. 446–447; Squires and Ruggiero 2007, pp. 313-314; Maletzke *et al.* 2008, pp. 1476-1477; Zahratka and Shenk 2008, pp. 910-911; Hodges *et al.* 2009, pp. 873-877; Ivan 2011a, pp. 91-92, 95-102; Berg *et al.* 2012, p. 1483; ILBT 2013, pp. 24, 26, 90).

During lows in snowshoe hare populations, lynx prey opportunistically on other small mammals, especially red squirrels (*Tamiasciurus hudsonicus*), and birds, but alternate prey species do not sufficiently compensate for low availability of snowshoe hares, and lynx populations cannot persist over time in areas with consistently low hare densities (Brand *et al.* 1976, pp. 422–425; Brand and Keith 1979, pp. 833–834; Koehler 1990, pp. 848–849; Mowat *et al.* 2000, pp. 267–268). Nonetheless, even in areas with relatively low or marginal hare densities, hares constitute the majority of the biomass in lynx diets (Koehler and Aubry 1994, p. 85; Apps 2000, pp. 362-363; Aubry *et al.* 2000, pp. 375-378; Roth *et al.* 2007, pp. 2740-2741; Squires and Ruggiero 2007, pp. 310-313; Hanson and Moen 2008, p. 9; Maletzke *et al.* 2008, pp. 1475-1477; Shenk 2009, pp. 13, 16; Ivan *in* Lynx SSA Team 2016, Appendix 3, pp. 13-14).

Lynx typically mate in March and April, and kittens are born from late April to mid-June after a 60- to 70-day gestation period (Koehler and Aubry 1994, p. 81; Mowat *et al.* 2000, p. 285). Female lynx typically reach reproductive maturity in their second year (at 22 months of age); however, when hares are abundant, females may breed at 10 months of age and produce kittens as 1-year-olds (Koehler and Aubry 1994, p. 81; Mowat *et al.* 2000, p. 285). Males do not seem to breed as yearlings, and they do not contribute to rearing of young (ILBT 2013, p. 30). Lynx dens are typically located in areas of dense cover, where coarse woody debris, such as downed logs and windfalls, provides security and thermal cover for lynx kittens (McCord and Cardoza 1982, pp. 743-744; Koehler 1990, pp. 847-849; Slough 1999, p. 607; Squires and Laurion 2000, pp. 346-347; Organ *et al.* 2008, entire; Squires *et al.* 2008, pp. 1497, 1501-1505; Moen and Burdett 2009, entire). Dens have been documented in both mature and younger boreal forest stands (Mowat *et al.* 2000, pp. 274-275; Squires *et al.* 2008, p. 1497; ILBT 2013, pp. 29-30; 78 FR 59441-59442; 79 FR 54809-54810; Organ *et al.* 2008, entire), and the amount of structure (e.g., downed, large, woody debris, tip-up mounds) seems to be more important than the age of the forest stand for lynx denning habitat (Mowat *et al.* 2000, pp. 274-275, Organ *et al.* p. 1516). Denning habitat is not thought to be a limiting factor for lynx in the DPS (Moen *et al.* 2008a, p. 1512; Organ *et al.* 2008, pp. 1514, 1516–1517; Squires *et al.* 2008, p. 1505; ILBT 2013, p. 30; 79 FR 54790). Dens must be near foraging habitat to allow females to adequately provision dependent kittens, and females seem to select den sites near prey sources to minimize time spent away from kittens while foraging (Moen *et al.* 2008a, p. 1507; Vashon *et al.*

2012, p. 16; ILBT 2013, p. 29). Females attend kittens at the natal den site and one or more alternate or maternal dens until kittens are about 6-10 weeks old (Squires *et al.* 2008, p. 1502; Vashon *et al.* 2012, p. 17; ILBT 2013, p. 29). Thereafter, kittens remain with their mothers through their first winter, apparently learning from her how to hunt and capture prey, initially on a small portion of her home range, but by fall on the larger area the female used before kittens were born (Mowat *et al.* 2000, pp. 269, 278). Juveniles remain closely associated with their mothers until February or March, when family groups begin to break up, with young typically dispersing in April and May (Mowat *et al.* 2000, pp. 278-279) to establish their own home ranges. Female offspring may establish home ranges overlapping or adjacent to their mother's home range and maintain mother-daughter bonds throughout their lives (Mowat *et al.* 2000, pp. 279-280). Male home ranges may slightly overlap adjacent male home ranges. While male home ranges typically overlap one to three female home ranges, and female home ranges are partially or completely encompassed by a male's home range, core areas within home ranges appear to be exclusive except during the breeding season (Koehler and Aubry 1994, pp. 90-91; Mowat *et al.* 2000, pp. 276-280; Vashon *et al.* 2012, pp. 17, 22-23). Fidelity to home ranges over several years has been documented for both sexes, but shifts and abandonment of home ranges have also been documented (Koehler and Aubry 1994, p. 91; Mowat *et al.* 2000, p. 277). Lynx have been documented to live up to 16 years in the wild (Kolbe and Squires 2006, entire).

Lynx populations in Canada fluctuate in response to the cycling of hare populations (Elton and Nicholson 1942, pp. 241–243; Hodges 2000a, pp. 118–123; Mowat *et al.* 2000, pp. 265–272), with synchronous fluctuations in lynx numbers emanating from the core of the Canadian population and spreading over vast areas, generally lagging hare numbers by one year (McKelvey *et al.* 2000a, pp. 232, 239; Mowat *et al.* 2000, pp. 266, 270). When hares are abundant, lynx have higher pregnancy rates and larger litter sizes, higher kitten survival, and lower adult mortality, resulting in rapid population growth during the increase phase of the hare cycle (Slough and Mowat 1996, pp. 955–956; Mowat *et al.* 2000, pp. 266, 270–272, 281–289). When hare populations are low, female lynx produce few or no kittens that survive to independence (Nellis *et al.* 1972, pp. 326–328; Brand *et al.* 1976, pp. 420, 427; Brand and Keith 1979, pp. 837–838, 847; Poole 1994, pp. 612–616; Slough and Mowat 1996, pp. 953–958; O'Donoghue *et al.* 1997, pp. 158–159; Aubry *et al.* 2000, pp. 388–389; Mowat *et al.* 2000, pp. 285–287). When hares decline, lynx mortality rates increase, largely because of starvation, and home range sizes and dispersal/ emigration rates also increase (Ward and Krebs 1985, pp. 2821–2823; O'Donoghue *et al.* 1997, pp. 156, 159; Poole 1997, pp. 499–503; Mowat *et al.* 2000, pp. 265–272, 278, 281–294). Lynx numbers decline dramatically during the ''crash'' phase of the hare cycle (Slough and Mowat 1996, p. 956; Mowat *et al.* 2000, pp. 283-285), when many lynx starve and many others abandon home ranges and disperse in search of food, with many of the latter also dying, often soon after initiating dispersal (Mowat *et al.* 2000, p. 293).

In Canada, lynx abundance may be 3 to 17 times higher at the peak versus the low of the hare cycle, with lynx densities reaching 30-45/100 km^2 (78-117/100 mi^2) in optimal dense regenerating forests 15-40 years post-fire, 8-20/100 km^2 (21-52/100 mi^2) in older forests or further south, and < 3/100 km^2 (< 8/100 mi^2) at the hare cycle low (Slough and Mowat 1996, pp.

952, 955; Mowat *et al.* 2000, p. 283; Hatler and Beal 2003, pp. 2, 5; Environment Canada 2014, p. 1). In southern Canada, where hares are less abundant and hare population cycles are muted or absent, lynx populations may be stable at 2-3/100 km^2 (5-8/100 mi^2) (Environment Canada 2014, p. 1). Lynx densities estimated in the contiguous U.S. have ranged from 9.2-13/100 km^2 (24-34/100 mi^2), including kittens, in Maine's highest-quality habitat when hares were abundant (Vashon *et al.* 2008, pp. 1483-1484; Vashon *et al.* 2012, pp. 14-15) to 2.3/100 km^2 (6/100 mi^2) in Washington when hare abundance was low (Koehler 1990, pp. 847-850). Correspondingly, hare abundance may also influence lynx home range size. Ward and Krebs (1985, pp. 2819-2820) documented a 3-fold increase in home range size in southwestern Yukon, from 13 km^2 (5 mi^2) on average when hares were abundant and increasing to 39 km^2 (15 mi2) when hare density was low. Poole (1994, pp. 613-614) documented a similar trend in the Northwest Territories, where lynx home range size increased from 17 km^2 (7 mi^2; males and females combined) when hares were abundant, to 44 km^2 (17 mi^2) and 62 km^2 (24 mi^2) for males and females, respectively, when hare numbers declined. In contrast, Breitenmoser *et al.* (1993, p. 552) reported no change in lynx home range size despite a 10-15 fold increase in lynx density as hare abundance increased in the southern Yukon. Similarly, in Maine, lynx home range size did not increase when hare densities declined from 2/ha (0.8/ac) to 1/ha (0.4/ac) (Mallett 2014, pp. 53-93). In general, hare and lynx densities are lower and lynx home ranges larger at the southern periphery of the lynx's range, including most of the contiguous U.S., and are similar to those of northern populations during the low phase of the hare population cycle (Koehler and Aubry 1994, p. 93; Aubry *et al.* 2000, pp 382-385; Apps 2000, pp. 362-367).

Lynx populations in the contiguous U.S. seem to function as subpopulations or southern extensions of larger populations in northern and eastern Canada (McKelvey *et al.* 2000b, pp. 21, 25, 33; 65 FR 16052–16082; 68 FR 40077–40099; 71 FR 66025–66035; 74 FR 8616–8641; Koen *et al.* 2015, pp. 527-528). Populations in the DPS are relatively isolated from one another, though most are directly connected via dispersal to lynx populations in Canada (McKelvey *et al.* 2000b, pp. 25-34; U.S Fish and Wildlife Service 2005, p. 2). Lynx disperse in both directions across the Canada–U.S. border (Aubry *et al.* 2000, pp. 386-387; Moen *et al.* 2010b, pp. ii, 17, 19; Vashon *et al.* 2012, p. 22), and this connectivity and interchange with lynx populations in Canada is thought to be important to the conservation of lynx populations in the DPS. (McKelvey *et al.* 2000b, p. 33; Schwartz *et al.* 2002, p. 522; U.S Fish and Wildlife Service 2005, p. 2; ILBT 2013, p. 34, 42, 47, 54, 60, 65; Squires *et al.* 2013, p. 187). However, whether and, if so, to what the extent the demographic and genetic health and persistence of populations in the DPS depend on regular or intermittent immigration of lynx from Canada remains uncertain (McKelvey *et al.* 2000a, pp. 241-242; 79 FR 54793).

2.2.1 Ecological Requirements of Individuals

At the most fundamental level, the needs of an individual lynx are met if:

1) it is born to a female that occupies a home range containing
    a) secure denning habitat,

b) adequate hare abundance to support lactation during the early kitten stage and later provisioning of the kitten with hare meat,
c) habitat (boreal forest and snow) conditions that reduce the likelihood and effect of competition from other hare predators, and
d) a low likelihood of encounters with lynx mortality agents (predators, trappers, vehicles, etc.);

2) the mother's home range occurs within a larger landscape that also contains adequate hare abundance and available habitat into which the yearling lynx may disperse and establish its own home range after the period of maternal dependence, with low likelihood of adverse competition and mortality; and

3) the larger landscape also supports other secure lynx home ranges and ensures the opportunity to encounter a lynx of the opposite sex, breed successfully, and contribute to the recruitment of at least one offspring into the breeding population during its lifetime.

In cyclic northern lynx populations, there is a strong element of timing that determines whether these individual needs will be met. During the decline and low phases of the hare population cycle, few kittens are born, very few survive until their first winter, and recruitment may collapse completely or nearly so for several successive years (Slough and Mowat 1996, entire; Mowat *et al.* 2000, pp. 266, 285-287). Therefore, even in the core of the species' range, a kitten born during a period of declining or low hare abundance is very unlikely to survive to independence, breed successfully, and replace itself within the breeding population in its lifetime. Conversely, a kitten born during the increase or high phase of the hare population cycle is much more likely to survive, establish a home range, breed successfully, and replace itself via recruitment of one or more of its offspring into the breeding population.

In southern lynx populations (southern Canada and the contiguous U.S.), hare population cycles are of lower amplitude or absent (Hodges 2000b, pp. 163–173; Hodges *et al.* 2009, pp. 870, 875–876; Scott 2009, pp. 1–44; Environment Canada 2014, p. 1; Hodges *in* Lynx SSA Team 2016, pp. 16-17), and hare and lynx abundances and lynx demographic rates are typically like those of northern populations during hare lows (Koehler and Aubry 1994, p. 93; Aubry *et al.* 2000, pp 382-385; Apps 2000, pp. 362-367). Therefore, the likelihood that an individual lynx will have its ecological requirements met sufficiently so that it may replace itself in the breeding population is probably consistently relatively low, perhaps similar to lynx born during hare declines/lows in the north. Also in the south, there are more diverse assemblages of potential competitors and predators, more natural patchiness and anthropogenic fragmentation of lynx habitat (fewer areas with adequate hare densities and favorable snow conditions distributed broadly across large landscapes), and higher road densities and, thus, greater potential for lynx-vehicle collisions (Wolff 1980, p. 128; Buskirk *et al.* 2000a, entire). These factors probably further reduce the likelihood that an individual lynx in the southern periphery of the range will survive, reproduce successfully, and have one or more offspring recruited into the resident breeding population.

Individual lynx require large areas of boreal forest landscapes to support their home ranges, provide hares in adequate abundance to meet their nutritional needs, provide breeding opportunities, and facilitate dispersal and exploratory travel. Female home ranges must also provide secure denning habitat in close proximity to foraging areas with high hare densities to allow females to adequately provision dependent kittens, and females appear to select den sites near prey sources to minimize time spent away from kittens while foraging (Moen *et al.* 2008a, p. 1507; Vashon *et al.* 2012, p. 16; ILBT 2013, p. 29). The size of lynx home ranges is strongly influenced by the quality of the habitat, particularly the abundance of snowshoe hares, in addition to other factors such as gender, age, season, and density of the lynx population (Aubry *et al.* 2000, pp. 382–385; Mowat *et al.* 2000, pp. 276–280). Generally, females with kittens have the smallest home ranges, likely related to their need to stay close to dens and dependent kittens, and males have the largest home ranges (Moen *et al.* 2005, p. 11; Burdett *et al.* 2007, p. 463; ILBT 2013, p. 24).

The increased natural patchiness and fragmentation of high-quality hare habitat where boreal forest conditions transition to temperate forest types require individual lynx in many parts of the DPS to maintain relatively large home ranges that include patches of higher hare densities within a matrix of lower-quality habitats with lower hare densities (ILBT 2013, p. 126; 78 FR 59434; also see 2.3.3, below). Larger home ranges likely require more energy output associated with greater foraging effort (Apps 2000, p. 364) and possibly increased exposure to predation and other mortality factors than lynx face in the core of their range (78 FR 59438). Annual home range sizes reported for lynx in the contiguous U.S. (Table 2, below) vary greatly across the DPS but are generally larger in the west than the east; however, differences should be interpreted with caution because different methods, sample sizes, and estimators were used to generate them (ILBT 2013, pp. 23-24).

Table 2. Reported annual home range sizes for Canada lynx in the contiguous United States.

Geographic Unit	Reported Lynx Home Range Size km^2 (mi^2)		References (pages)

Comment [30]: Some of these home ranges seem to be presented as a range of values and others (e.g., ME, GYA) are a single value (a mean?). We should be consistent and present a mean and range, if these data are available.

W Colorado	75-704 (29-272)	103-387 (40-149)	Shenk 2008 (10)

Juvenile and adult lynx require about 400 and 600 grams (14 and 21 ounces) of food per day (for adults, 0.4-0.5 hares/day, 170-200 hares/year), respectively, to meet their basic nutritional requirements (Saunders 1963, p. 390; Nellis *et al.* 1972, pp. 324-325). Available research suggests that landscape-level hare densities >= 0.5 hares/ha (0.2/ac) are necessary to support lynx home ranges and resident breeding populations; lynx home range abandonment, dispersal, and mortality increase when hare densities are lower; and lynx may be unable to survive where landscape hare densities are below 0.3/ha (0.12/ac) (Ward and Krebs 1985, pp. 2819-2822; Slough and Mowat 1996, entire; Ruggiero *et al.* 2000b, pp. 446-447; ILBT 2013, pp. 26, 125). Recent research in the contiguous U.S. supports this - in northern Maine, areas with landscape hare densities of 0.74/ha (0.30/ac) supported resident breeding lynx, but areas with hare densities below 0.5/ha (0.2/ac) were not occupied by lynx (Simons-Legaard *et al.* 2013, pp. 567, 574-575). Likewise, in northeastern Minnesota, resident lynx maintained home ranges where landscape hare densities were 0.64/ha (0.26/ac). Voyageurs National Park, where hare density was estimated at 0.35/ha (0.14/ac), did not support resident breeding lynx (Moen *et al.* 2012, pp. 352–354).

In addition to adequate hare density, individual lynx require landscapes in which they are unlikely to encounter predators (mountain lion [*Puma concolor*], coyote [*Canis latrans*], wolverine [*Gulo gulo*], gray wolf [*Canis lupus*], fisher [*Pekania pennanti*], and other lynx) (ILBT 2013, pp. 33, 35). Although lynx have co-evolved with predators, the influence of predation on lynx populations is unknown (ILBT 2013, pp. 35-36), and mountain lions and coyotes are now more widespread and abundant in the southern periphery of the lynx distribution than they seem to have been historically (Buskirk *et al.* 2000a, p. 83; Gompper 2002, entire). Lynx also need landscapes where they are unlikely to suffer reduced fitness because of competition with other hare predators, or encounter traps or other anthropogenic causes of mortality. Except for fisher and marten (*Martes americana*), lynx predators and potential terrestrial competitors for hares (the species above plus bobcat; maybe red fox [*Vulpes vulpes*] in some situations) all have higher foot-loading (weight per surface area of the foot), making them less efficient at traveling and hunting in the deep powdery snow conditions favorable for lynx (Buskirk *et al.* 2000a, pp 86-95, Krohn *et al.* 2005, entire) and, therefore, likely limiting, at least seasonally, interactions between lynx and these species. Analysis of lynx occurrence data in the contiguous U.S. suggests that lynx require at least four months (December through March) of continuous snow coverage (Gonzalez *et al.* 2007, p. 7). Where snow conditions do not consistently favor lynx, increased potential for predation and competition would be expected (Peers *et al.* 2013, p. 8). Finally, individual lynx are more likely to survive, breed, and replace themselves in the breeding population if they occupy home ranges where trapping is prohibited or trapping pressure is low (Slough and Mowat 1996, entire), high-speed/ high-volume roadways are absent (ILBT 2013, pp. 77-78), and other potential anthropogenic causes of lynx mortality are minimal.

In summary, individual lynx require large landscapes with hare densities that maximize their chances of (1) surviving to independence, (2) establishing and maintaining a home range, (3) breeding successfully, and (4) contributing genes to future generations (Breitenmoser *et al.*

1993, p. 552). These landscapes also must provide conditions that allow lynx to compete sufficiently for hares and minimize the likelihood of predation and other sources of lynx mortality. The available science suggests that landscape-level hare densities consistently >= 0.5 hares/ha (0.2/ac) and favorable snow depth and conditions for about 4 months are needed to support lynx occupancy, reproduction, and recruitment. At the southern periphery of lynx distribution, some places, including within the range of the DPS, seem to be at minimum thresholds to meet these requirements or to do so inconsistently.

2.2.2 Ecological Requirements of Populations and the DPS

Lynx populations require essentially the same things that individual lynx do (see Figure 5 and section 2.2.1, above), but on a larger landscape with hare densities and habitat conditions capable of consistently supporting multiple home ranges, breeding and dispersal opportunities, and reproductive and survival rates such that recruitment and immigration will, on average over the long term, equal or exceed mortality and emigration (Pulliam 1988, pp. 652-654). To support persistent lynx populations, such landscapes must provide for the survival of at least some resident lynx even when hares are least abundant and/or other habitat features (e.g., snow conditions) are least favorable so that the population can recover, perhaps aided by immigration, when hare numbers and/or other habitat conditions recover or improve. As with individual lynx, populations are more likely to persist in landscapes where the effects of competition, predation, and human-caused mortality (e.g., trapping, vehicle collisions) are relatively lower.

In a mainland-island metapopulation structure like that thought to govern lynx population dynamics, the persistence of peripheral island populations is determined by colonization and extinction rates (McKelvey *et al.* 2000b, p. 25). Colonization is driven by the number of islands, the distances between them, and the species' dispersal capabilities and timing. Extinction rates are determined by population size and demographic and environmental stochasticity, with extinction more likely in smaller and more isolated populations (McKelvey *et al.* 2000b, pp. 25-31). Lynx populations in the DPS are at the periphery of the species' range and may behave as islands in a mainland-island metapopulation construct. In such a system, larger islands with higher habitat quality and in closer proximity to the mainland would be more likely to support persistent resident populations and to sometimes act as "sources" that produce surplus animals that may disperse to other islands. Smaller islands with lower habitat quality or at greater distance from the mainland may, in contrast, act as "sinks" that depend on immigration from source populations (McKelvey *et al.* 2000b, p. 30), and which may support resident lynx only occasionally, intermittently, or temporarily.

Formal population viability analyses (PVAs) have not been published for lynx populations in the DPS and may not be possible given limited data and natural temporal variation in demographic rates (McKelvey *et al.* 2000a, pp. 22, 30). Although some demographic data are available for most lynx populations in the DPS, most are limited to relatively few, small study areas or relatively short durations. There remains uncertainty about whether, and if so to what extent, the demographic health of DPS populations relies on immigration from northern (Canadian)

populations; and immigration rates are not known for DPS populations (McKelvey *et al.* 2000a, pp. 24-34). These factors likely preclude development of meaningful DPS-wide or unit-specific empirical population viability models (McKelvey *et al.* 2000b, p. 22).

Slough and Mowat (1996, p. 952, Table 4) calculated population growth rate (lambda, λ) = 2.03 (annual doubling) during the 4-year increase-to-peak phase for a lynx population in the core of the species' range in southern Yukon. This period of rapid growth was followed by a rate of λ = 1.01 (stable) during the first year of a hare decline, and λ = 0.10 and λ = 0.46 (rapid decline) during the first two years of the lynx population decline when hares were scarce. (Note – the value λ = 0.01 presented in Slough and Mowat (1996, p. 952, Table 4) appears to be an error; the correct value for λ in a population in which the estimated number of individuals declined from 135 in 1992 to 13 in 1993 should be 13/135 = 0.10 [as presented above]). However, the natural range in λ that would be expected among peripheral, isolated, or semi-isolated lynx populations where hares are non-cyclic or weakly-cyclic (i.e., in DPS populations), versus those that would signal long-term population decline or instability is unknown. Despite this, and the limitations noted above, Squires (*unpubl. data in* Lynx SSA Team 2016, p. 20) calculated population growth rates in northwestern Montana of λ = 0.92 for lynx in the Seeley Lake area (i.e., declining population trend, 1999-2007) and λ = 1.16 for lynx in the Purcell Mountains (increasing trend, 2003-2007). Likewise, McCollough (2016 *unpubl. data*; USFWS, Vortex10, deterministic population simulation) used demographic data from Vashon *et al.* 2012 (pp. 17-21) to calculate finite growth rates during a period of high hare density (λ = 1.16; increasing trend) and during a period of low hare density (λ = 0.88; decreasing trend) for the lynx population in northern Maine (see also section 4.1.1, below).

Although minimum viable population sizes have not been derived for lynx populations in the DPS, the Service's Recovery Outline (USFWS 2005, p. 5) suggested landscapes of at least 1,250 km^2 (483 mi^2) with sufficient boreal/subalpine habitat, hare densities (at least 0.5 hares/ha [0.2/ac]), and snow conditions favorable for lynx ("fluffy and/or deep...for sufficient periods to favor the competitive advantage of lynx"). These are the minimum landscape size and habitat conditions thought necessary to support a minimum lynx population of at least 25 adults based on a lynx density of one lynx per 50 square kilometers (USFWS 2005, p. 5). McKelvey *et al.* (2000b, p. 29) noted that extinction (extirpation) risk should decrease with increasing population size, and that extinction resulting from demographic stochasticity is very unlikely even for a population (generally; not specific to lynx) with as few as 20 reproducing females. Kramer-Schadt *et al.* (2005, entire) developed a spatially explicit population model for Eurasian lynx in Germany which they combined with demographic scenarios to evaluate the likely success of potential reintroduction efforts; they concluded that at least 10 females and 5 males would be required to establish a population with an extinction probability less than 5 percent over 50 years. Rodriguez and Delibes (2003, entire) evaluated extinction among populations of Iberian lynx; they found that extinction occurred only in small populations that occupied habitats of less than 500 km^2 and that extinction within 35 years was unlikely among populations occupying areas of at least 500 km^2 of adequate habitat quality.

In summary, lynx populations need large boreal forest landscapes with snow conditions (consistency, depth, and duration) that allow lynx to outcompete other terrestrial hare predators. These landscapes must have hare densities capable of supporting (1) multiple lynx home ranges, (2) reproduction and recruitment most years, and (3) at least some survival even during years when hare numbers are low. To persist, lynx populations must exhibit recruitment and immigration rates that exceed mortality and emigration rates on average over the long-term. Immigration may be particularly important to the persistence and stability of lynx populations at the southern periphery of the range, including those within the DPS, where hare densities are generally low and hare populations are either non-cyclic or weakly-cyclic compared to northern populations. Low hare densities reduce the likelihood that lynx recruitment will consistently equal or exceed mortality, and non-cyclic or weakly-cyclic hare populations are unlikely to allow the rapid lynx population recovery observed in northern lynx populations when hare numbers increase dramatically after cyclic population crashes. Although immigration rates for DPS populations are unknown, as is the rate and periodicity of immigration needed to provide demographic stability among them, connectivity with and immigration from lynx populations in Canada is believed to be important to the persistence of lynx populations in the DPS (McKelvey *et al.* 2000a, pp. 232-242; 2000b, pp. 32-34; Schwartz *et al.* 2002, entire; U.S. Fish and Wildlife Service 2005, p. 2; ILBT 2013, pp. 34, 42, 47, 54, 60, 65; Squires *et al.* 2013, p. 187; 79 FR 54789).

2.3 Historic and Current Lynx Distribution

2.3.1 Lynx Distribution and Status in Canada and Alaska

The Canada lynx is broadly distributed across northern North America from eastern Canada to Alaska (McCord and Cardoza 1982, p. 729; Poole 2003, p. 361; Vashon 2015, p. 4; Alaska Center for Conservation Science 2016, p. 1). It is strongly associated with the expansive, continuous boreal forests of those areas, and its range largely overlaps that of its primary prey, the snowshoe hare, also a boreal forest specialist (Bittner and Rongstad 1982, p. 146; Mowat *et al.* 2000, pp. 268-269; Aubry *et al.* 2000, p. 375). In Canada, lynx are thought to occupy about 5.5 million km^2 (over 2.1 million mi^2), which represents 95 percent of their historic range in that country (Environment Canada 2014, p. 2), and over 89 percent of the species' entire distribution. Nationally in Canada, lynx are classified as secure, widespread, and abundant; they are managed for long-term population stability, with a conservative estimate of 110,000 individuals during cyclic lows; and no acute, widespread threats to lynx have been identified (Environment Canada 2014, entire; Vashon 2015, pp. 1-6). Provincially, lynx status is considered secure in British Columbia, Manitoba, Ontario, Quebec, Newfoundland and Labrador, Northwest Territories, and the Yukon; sensitive in Alberta and Saskatchewan; at risk/endangered in New Brunswick and Nova Scotia; and undetermined in Nunavut (Environment Canada 2014, pp. 3-4; Vashon 2015, p. 1). Lynx were extirpated from Prince Edward Island (0.1 percent of lynx range in Canada) by the late 1800s, and on the mainland the southern margin of assumed lynx range has contracted northward in Quebec, southeastern

Ontario, Manitoba, Saskatchewan, and Alberta (Poole 2003, p. 361; Bayne *et al.* 2008, pp. 1192-1195; Koen *et al.* 2014, pp. 757-760).

In Alaska, lynx are distributed across roughly 534,454 km^2 (206,354 mi^2) of boreal forest habitats (University of Alaska Center for Science Conservation, http://akgap.uaa.alaska.edu/species-data/canadian-lynx-annual-distribution/#content, accessed 4/28/2016; Reimer 2016, pers. comm.), which represents about 8.7 percent of the species' distribution. Lynx in Alaska are apparently secure, with low to moderate threats, and populations appear stable statewide, although total abundance is unknown (Alaska Natural Heritage Program 2008, pp. 2-4). In both Alaska and Canada, lynx trapping is managed through regulated seasons and harvest levels, which are adjusted to avoid overexploitation, especially during the low phase of the hare-lynx population cycle (Alaska Natural Heritage Program 2008, pp. 2-6; Vashon 2015, pp. 5-6). Along the Canada-U.S. border in provinces adjacent to DPS lynx populations, lynx trapping is prohibited in New Brunswick (adjacent to northeastern Maine) but regulated trapping is permitted in Quebec (adjacent to northwestern Maine, northern New Hampshire, and northern Vermont), Ontario (adjacent to northeastern Minnesota), Alberta (adjacent to northwestern Montana), and British Columbia (adjacent to northwestern Montana, northern Idaho, and northern Washington).

2.3.2 Lynx Distribution in the Contiguous United States

2.3.2.1 Defining Lynx Distribution at the Periphery of the Range

Several aspects of lynx population dynamics and dispersal patterns have resulted in inconsistent approaches and difficulty in defining the range and/or distribution of the species, especially at the margins (74 FR 66942). These, combined with uncertainty and ambiguity in the historical record of lynx occurrence, with early assessments based largely on trapping harvest records of questionable accuracy, particularly where lynx and bobcats overlap, and a reliance on anecdotal or unverified occurrence information (McKelvey *et al.* 2000a, pp. 208-210; 65 FR 16054), confound efforts to accurately portray the species' historical distribution in the contiguous U.S. and to assess the current distribution relative to historic conditions (79 FR 54814-54815; McKelvey *in* Lynx SSA Team 2016, p.11). They also have resulted in inaccurate portrayals of lynx distribution and misperceptions that the historic range of lynx in the contiguous U.S. was once much more extensive than is ecologically possible (68 FR 40080; 74 FR 66942).

The range of the lynx must be considered differently from those of other species that are less mobile and have more stable population dynamics. Because the lynx is highly mobile and has cyclic population dynamics that are tied to cyclic snowshoe hare populations, numbers of lynx naturally fluctuate and become extremely low at times during a cycle. Additionally, where snowshoe hare populations are not adequate, resident lynx populations cannot be sustained. Because of this, resident lynx populations never occurred everywhere boreal forest existed in the contiguous U.S. Where the boreal forest was naturally more patchy and marginal, the habitat was incapable of supporting an adequate snowshoe hare population that in turn was incapable of supporting a resident lynx population over time. As a result, only a few areas in the

contiguous U.S. historically supported an adequate quantity and quality of habitat to support resident lynx populations over time, and many historical lynx occurrences across a large area of the contiguous U.S. were likely dispersers. The occurrence of dispersing lynx is unpredictable, and dispersing lynx will likely continue to periodically move into areas that are not lynx habitat (68 FR 40077).

The dramatic, cyclic fluctuations in lynx populations across much of the range as they track cyclic hare populations and the mass synchronous dispersals (irruptions) of large numbers of lynx into the contiguous U.S. when northern hare populations crashed are well-documented (Elton and Nicholson 1942, entire; Gunderson 1978, entire; Thiel 1987, entire; McKelvey *et al.* 2000a, pp. 219, 232-242; Mowat *et al.* 2000, pp. 281-294; ILBT 2013, p. 33). These events have resulted in records of lynx occurrence, in some cases very rarely, in others sometimes in large numbers and with intermittent (cyclic) regularity, in places that otherwise lack evidence of persistent lynx presence or the habitats and hare densities necessary to support a resident lynx population (U.S. Fish and Wildlife Service 2005, pp. 3-4; 79 FR 54787-54789, 54793-54795, 54812-54823). Many records of lynx in the contiguous U.S. appear to be related to such events, including the unprecedented ‘‘explosions’’ of lynx observed in the early 1960s and 1970s (Gunderson 1978, entire; McKelvey *et al.* 2000a, pp. 232-242). During these events, many lynx occurred in anomalous habitats, exhibited unusual behavior, suffered high mortality, and numbers declined dramatically within a few years of irruptive peaks (Gunderson 1978, entire; Thiel 1987, entire; McKelvey *et al.* 2000a, p. 242). Because dispersing lynx typically do not persist in these areas of temporary range expansion, disappearing fairly quickly after irruptions, van Zyll de Jong (1971, p. 16), suggested that only areas that support lynx populations throughout both the low and the high phases of the “10-year cycle” (i.e., across the natural range of hare densities) should be considered to constitute the species’ range. In its 2003 remanded determination, the Service determined that lynx in the contiguous U.S.exist either as resident populations or as dispersers, that dispersing lynx are often found repeatedly and for variable amounts of time in habitats that cannot sustain breeding populations over time (though some breeding may occur occasionally in some of these areas), and that such areas probably contribute little to the persistence of lynx in the DPS (68 FR 40077, 40079-80). This repeated dispersal into habitats that ultimately cannot support the species (‘‘sink’’ habitats) often leads to confusion among scientists and the public about where lynx populations may be viable (74 FR 66938).

In addition to distinguishing between historical occurrence records associated with irruptions/ dispersal and those suggesting resident lynx populations, the “mainland-island” metapopulation structure thought to govern lynx populations in the DPS (McKelvey *et al.* 2000b, pp. 25-31; see Section 2.2, above) and the transitional (and, therefore, increasingly fragmented and isolated) and spatially- and temporally-shifting nature of lynx habitat at the southern periphery of the range (Koehler and Aubry 1994, pp. 78-79; McKelvey *et al.* 2000b, pp. 29-30; 74 FR 66940; 79 FR 54814) also present challenges in defining the distribution of lynx. Both factors suggest that some areas of the contiguous U.S. may naturally support resident lynx only temporarily or occasionally when habitat conditions (both boreal forest vegetation supporting abundant hares and snow conditions favoring lynx) are adequate and/or when immigration is sufficient to offset

the lower productivity and recruitment rates expected among lynx populations in marginal or suboptimal habitats. McKelvey *et al.* (2000b, pp. 21, 29-31) described such habitats as "... source-sink mosaics that shift with disturbance and succession," and the contribution, if any, of these places (especially those that act more often as "sinks" than "sources") to the maintenance and persistence of lynx populations in the DPS remains questionable (74 FR 66938).

Finally, the southern periphery of the lynx's range, where lynx are rare in many places, overlaps with the northern distribution of the much more common bobcat; the two species are difficult to distinguish in the field, they often were not reliably differentiated in historical trapping records (McKelvey *et al.* 2000a, pp. 208-209), and errors in early accounts of lynx distribution based on anecdotal information seem likely (Halfpenny and Miller 1980, pp. 1, 3-8; Meaney 2002, pp. 3-5, Hoving *et al.* 2003, pp. 366-367; Krohn 2010, p. 33). Because of the large effect that relatively few errors in identification can have on assessments of the distribution of rare animals, especially those that are easily confused with a similar and more common species, McKelvey *et al.* (2000a, p. 209; 2008, pp. 553-554) suggest that anecdotal information should be interpreted with caution, and only verified occurrence data should be used to assess historical and current lynx distributions.

These complexities of lynx population dynamics and our incomplete understanding of the limited lynx occurrence data, combined with a naturally dynamic and transitional habitat, make it difficult, if not impossible, to precisely delineate the historic or current distribution of resident lynx populations in the contiguous U.S. (Koehler and Aubry 1994, p. 79; 68 FR 40084). While recognizing these limitations, we use our best professional judgment of the best scientific and commercial data available to make conclusions about the range of the lynx for the purposes of this SSA. In the following section, we describe the types and distributions of potential lynx habitats in the contiguous U.S., and our current understanding of the historical and current distributions of resident lynx populations in the DPS considering the factors discussed above.

2.3.2.2 Lynx Distribution within the DPS Range

The southern periphery of boreal forest vegetation extends into parts of the northern contiguous U.S., where it transitions to the Acadian forest in the Northeast (Seymour and Hunter 1992, pp. 1, 3), deciduous temperate forest in the Great Lakes regions, and subalpine forest in the Rocky Mountains and Cascade Mountains in the west (Agee 2000, pp. 40-41). In much of the DPS range, these boreal forest landscapes become naturally patchy and transitional because they are at the southern edge of the boreal forest range, and they are limited, particularly in the west, by elevation and/or aspect (Ruediger *et al.* 2000, p. 4-16; 68 FR 40090). There also is increased prevalence of non-forested land uses (e.g., agriculture, development) at the southern periphery of boreal forests. These factors generally limit snowshoe hare populations in the contiguous U.S. from achieving landscape densities similar to those of the expansive northern boreal forest in Alaska and Canada, where hares are generally more abundant and more evenly distributed across the landscape (Wolff 1980, pp. 123-128; Buehler and Keith 1982, pp. 24, 28; Koehler 1990, p. 849; Koehler and Aubry 1994, p. 84; Aubry *et al.* 2000, pp. 373-375, 382, 394). Consequently, important foraging habitat for lynx is often more limited and fragmented in the

contiguous U.S. than in boreal forests of northern Canada and Alaska (Berg and Inman 2010, p. 6), and overall habitat quality is typically lower.

The habitats that lynx use in the contiguous U.S. are characterized by patchily-distributed moist forest types with relatively higher hare densities in a matrix of other habitats (e.g., hardwoods, dry forest, non-forest) with lower landscape hare densities (ILBT 2013, p.126; 78 FR 59434). In these areas, lynx incorporate the matrix habitat (non-boreal forest habitat elements) into their home ranges and use it for traveling between patches of boreal forest that support higher hare densities where most lynx foraging occurs. In some areas, patches of habitat containing snowshoe hares become so small and fragmented that the landscape cannot support lynx home ranges (ILBT 2013, p. 77) or populations over time (68 FR 40077). Additionally, the presence of more snowshoe hare predators and competitors at southern latitudes may inhibit the potential for high-density hare populations (Wolff 1980, p. 128). As a result, lynx generally occur at relatively low densities in the contiguous U.S. compared to the high lynx densities that occur in the boreal forest of Canada when hares are abundant (Aubry *et al.* 2000, pp. 375, 393-394) or the densities of species such as the bobcat, which is a habitat and prey generalist.

Snow conditions also determine the distribution of lynx (Ruggiero *et al.* 2000b, pp. 445-449), which are morphologically and physiologically adapted for hunting snowshoe hares and surviving in areas that have cold winters with deep, fluffy snow for extended periods. These adaptations provide lynx a competitive advantage over potential competitors, such as bobcats or coyotes (McCord and Cardoza 1982, p. 748; Buskirk *et al.* 2000a, pp. 86-95; Ruediger *et al.* 2000, pp. 1-11; Ruggiero *et al.* 2000b, pp. 445, 450), which have a higher foot load (more weight per surface area of foot), causing them to sink into the snow more than lynx. Therefore, bobcats and coyotes cannot hunt efficiently in fluffy or deep snow and are at a competitive disadvantage to lynx. Long-term snow conditions presumably limit the winter distribution of potential lynx competitors such as bobcats (McCord and Cardoza 1982, p. 748) or coyotes. These adaptations may also help lynx avoid predators such as mountain lions (Squires and Laurion 2000, p. 346), which also have higher foot-loading (Buskirk *et al.* 2000a, p. 90; Krohn *et al.* 2005, p. 123), making them less efficient in deep and fluffy snow conditions.

Based on verified historical data, lynx occurrence has been documented in 24 states in the contiguous U.S. (McKelvey *et al.* 2000a, 207-232) and, more recently, in a 25th after some of the lynx released into southwestern Colorado dispersed into northern New Mexico (Colorado Division of Wildlife 2000, p. 3; 74 FR 66938), which had previously lacked verified evidence of lynx occurrence (USFS 2009, entire; 74 FR 66940-66943). Of these, and based on our current understanding of lynx and hare habitat requirements, the Service concludes that records in at least 11 states (Connecticut, Illinois, Indiana, Iowa, Massachusetts, Nebraska, Nevada, New Mexico, North Dakota, Pennsylvania, and South Dakota) most likely represent occasional dispersing lynx that arrived in places with no historic or recent evidence of the habitat quality or quantity necessary to support a persistent resident lynx population (68 FR 40099; 74 FR 66940-66942; 79 FR 54807, 54817). These states are not within the distribution of resident lynx in the DPS, and we conclude that they naturally lack the necessary habitat, hare densities, and snow

conditions and that they were not capable historically and are not capable now of supporting resident lynx populations.

The Service originally identified the DPS as occurring in forested portions of the remaining 14 states (Colorado, Idaho, Maine, Michigan, Minnesota, Montana, New Hampshire, New York, Oregon, Utah, Vermont, Washington, Wisconsin, and Wyoming; 65 FR 16052, 16085). Some of these states, and parts of others, are thought to have historically supported only dispersing lynx or to have only occasionally supported resident breeding lynx (68 FR 40099; 74 FR 66940). Such areas were included within the range of the DPS because of the possibility that lynx could establish small, local populations in them and perhaps contribute to the persistence of the DPS, though evidence of this was lacking (68 FR 40080; 74 FR 66938). In its 2003 remanded determination for the lynx DPS, the Service concluded that (1) potential lynx and hare habitats in Michigan, Oregon, Utah, Vermont, and Wisconsin were relatively small, isolated, and of marginal quality, and that available information suggested that these states did not historically or recently support resident lynx populations; (2) it was uncertain whether Colorado, New York, and Wyoming historically supported resident populations or only occasional dispersers; (3) New Hampshire probably supported a small resident populations that had been extirpated; and (4) the remaining states (Idaho, Maine, Minnesota, Montana, and Washington) had the best historic and recent evidence of resident breeding populations (68 FR 40082, 40086-40095, 40097-40101). Below we provide our current understanding of these state groupings and the information available since the 2003 remand that informs this understanding.

Michigan, Oregon, Utah, Vermont, and Wisconsin - Additional information and analysis available since 2003 support the determination that Michigan (Linden 2006, pp. 83-90) and Oregon (Aubry 2006, pp. 1-2) did not historically or recently support resident lynx populations, and no evidence has emerged suggesting that resident populations occurred historically or recently in Utah or Wisconsin (ILBT 2013, pp. 45, 58). The best available information continues to suggest that resident lynx did not historically and do not currently occur in Michigan, Oregon, Utah, and Wisconsin; that habitats in these states are naturally incapable of supporting resident breeding populations; and that historic and potential future occurrences of lynx in these states most likely represent occasional dispersing lynx. We conclude, therefore, that these states did not historically, do not currently, and in the future are very unlikely to, contribute to the persistence and conservation of lynx in the contiguous U.S.

In contrast, nine lynx occurrences were confirmed in the 530-km^2 (205-mi^2) Nulhegan Basin of northeastern Vermont from 2003 to 2014, and breeding was confirmed in 2012; intensified surveys since then have resulted in only a single photograph of a lynx in 2014 (Bernier 2015, pp. 1-3; Bernier 2016, *pers. comm.*). This new information indicates that this small area of northernmost Vermont is at least occasionally capable of supporting a small number of resident breeding lynx, but that its ability to support a persistent resident population over time remains doubtful. Based on assessments of the amount and quality of potential lynx and hare habitat, snow conditions, and the presence and distribution of lynx competitors and predators (Hoving *et al.* 2005, pp. 746-749; Bernier 2015, entire), we conclude it is unlikely that northern Vermont can support a persistent resident lynx population (79 FR 54820-54821); that it only occasionally

supports lynx reproduction when hare abundance and snow conditions are temporarily adequate; that it most likely represents a “sink” rather than a “source” for the regional lynx population, and that this likely represents its natural historical condition.

Colorado, New York, and Wyoming - When the Service listed the DPS in 2000, it believed that a resident lynx population occurred historically in the Southern Rocky Mountains of western Colorado and southeastern Wyoming, that lynx were also historically resident in northwestern Wyoming (part of the Northern Rocky Mountains), and that the Adirondack Mountains of northern New York may historically have supported a resident population that was by then extirpated (65 FR 16055-16056; 16058-16059). In the 2003 remand, the Service noted inconsistencies and likely errors in historic lynx reports for the Southern Rockies, questioned its original conclusion that Colorado historically supported an isolated resident population, and concluded that it was uncertain whether a resident population occurred historically in Colorado or if historic records were of periodic dispersing lynx during “extremely high populations cycles” and that a resident population never existed in southeastern Wyoming (68 FR 40081, 40091). The Service also noted that in 1999 and 2000 the Colorado Division of Wildlife (now Colorado Parks and Wildlife [CPW]) introduced 96 lynx from Canada and Alaska into southwestern Colorado (with plans to release an additional 186 lynx from 2003-2009) in an effort to reestablish a resident lynx population, that reproduction among some of the released lynx had been documented by 2003, but that it was too early to determine whether the program would be successful (68 FR 40091). In that rule, the Service also concluded that, despite evidence of reproduction in northwestern Wyoming (part of the GYA), potential habitat there is naturally marginal (patchier and composed of drier forest types), may be incapable of supporting a resident lynx population, and that lynx in northern Wyoming are most likely dispersers (68 FR 40090). Also in 2003, the Service concluded that it was possible resident lynx occurred in northern New York prior to 1900 but the potential habitat there is small, marginal, and likely has only supported dispersing lynx since then, and that an effort to reintroduce lynx there failed quickly, suggesting the habitat is incapable of supporting a resident population (68 FR 44486-44487).

In Colorado, after the initial release of 96 lynx in 1999 and 2000, none were released in 2001 or 2002 while protocols were evaluated and refined based on monitoring of the initially-released lynx (Shenk 2010, pp. 1, 4; Ivan *in* Lynx SSA Team 2016, p. 22). From 2003-2006, another 122 lynx were released, bringing the total to 218 (Devineau *et al.* 2010, p. 526). Reproduction was documented in 2003-2006 and 2009-2010, with 48 dens documented in that time, including a third generation of Colorado-born lynx (Shenk 2010, p. 5; Ivan *in* Lynx SSA Team 2016, p. 22). In 2010, CPW determined that all benchmarks for its lynx program had been met and had resulted in the establishment of a viable, self-sustaining lynx population (Ivan, 2011a, pp. 11, 12). Intensive monitoring of the population ceased in 2010 and was replaced by an effort to develop a minimally-invasive long-term monitoring program (Ivan 2011b, entire), which used snow-tracking surveys and camera traps to document continued lynx presence in the core release area of the San Juan Mountains in 2010-11 and again in 2014-15, with evidence of reproduction also documented during that time (CPW 2015, p.1; Ivan *in* Lynx SSA Team 2016, pp. 22-23). In its 2014 revised critical habitat designation for the DPS, the Service concluded

that the historic record of verified lynx occurrence in Colorado combined with naturally highly-fragmented and isolated potential habitat and generally low snowshoe hare densities suggest that Colorado and the Southern Rockies were unlikely to have historically supported a persistent resident lynx population and that the long-term persistence of the introduced population is uncertain (79 FR 54787-54789, 54793-54795, 54816-54817). The current size of the resident lynx population in Colorado is unknown but thought to number between 100 and 250 (Ivan *in* Lynx SSA Team 2016, p. 47). We continue to believe that available information suggests Colorado did not historically support a persistent resident lynx population and that the long-term persistence of the introduced population remains uncertain.

Information and analyses since the 2003 remand support the conclusion that New York has inadequate habitat quantity and quality (both vegetation and snow conditions) to support a resident lynx population (Hoving *et al.* 2005, pp. 746, 749). Based on Hoving *et al.* (2005) and our evaluation of the verified records of historic occurrence presented by McKelvey *et al.* (2000a, pp. 215-217), we conclude that the Adirondack Mountains of northern New York have not recently and likely did not historically support a persistent resident lynx population, are likely incapable of doing so, that verified historic records were most likely of dispersing lynx, and dispersing lynx may currently and in the future continue to occur rarely and temporarily in northern New York.

In northwestern Wyoming, additional information available since 2003 documented continued presence of a small number of lynx as recently as 2010, including some evidence of reproduction during that time, and documentation of Colorado-released lynx that dispersed into and through Wyoming (Squires *et al.* 2003, entire; Squires and Oakleaf 2005, entire; Murphy *et al.* 2006, entire; Endeavor Wildlife Research 2008, 2009, entire; Berg 2016 pers. comm.; Hanvey 2016, pers. comm.; Ivan 2016, pers. comm.; Murphy 2016, pers. comm.). However, more recent surveys and research-related trapping efforts have failed to detect lynx in this area or elsewhere in Wyoming since 2010 (79 FR 54791; Squires *in* Lynx SSA Team 2016, pp. 20-21, 45). In the 2014 revised critical habitat designation, the Service noted:

> Although the GYA has a long history of lynx presence and recent evidence of reproduction (Squires and Laurion 2000, entire; Squires *et al.* 2001, entire; Murphy *et al.* 2006, entire), there are relatively few verified records of lynx from Yellowstone National Park and surrounding areas (65 FR 16058, 68 FR 40090). Additionally, lynx habitat in the GYA is naturally marginal (patchier and composed in many places of drier forest types), less capable of supporting snowshoe hares (Hodges *et al.* 2009, entire), and farther from source populations than most other parts of the DPS range (68 FR 40090). Given the naturally marginal habitat in this largely protected area, we believe it is unlikely that the GYA ever supported more than a handful of lynx home ranges in any given year. We find no evidence that the GYA once supported a larger or more robust lynx population than the small one suggested by verified historic and recent records and survey efforts (79 FR 54791).

We concluded that the historic record and recent evidence of lynx occupancy and reproduction suggested the presence of a small but persistent resident lynx population in the GYA of northwestern Wyoming and southwestern Montana (79 FR 54791, 54796-54797, 54825-54826); however, the consistency of occupancy over time remains uncertain (Lynx SSA Team 2016, pp. 11, 45, 57). Uncertainty about whether this area consistently or only intermittently supported resident lynx historically makes it difficult to interpret their recent apparent absence from the area (Lynx SSA Team 2016, p. 57). If residency was intermittent historically, the current apparent absence of resident lynx might be a natural condition related to the area's largely marginal or suboptimal habitat conditions - i.e., it may naturally be capable of supporting resident lynx only intermittently when habitat conditions and hare densities are optimal. In that case, future intermittent residency would be expected, but only if lynx dispersing from a source population immigrate to the GYA when habitat conditions and hare densities return to more favorable levels. Conversely, if the GYA always historically supported a small number of resident lynx but no longer does, it may suggest that some factor or factors have acted to tip the quality of the area's habitat from just barely capable of supporting a small resident population to no longer capable of doing so, resulting in extirpation. We conclude that this uncertainty cannot be resolved based on the available information but, given the protected conservation status of millions of acres in the GYA unit (Yellowstone and Grand Teton National Parks; all or parts of the Absaroka-Beartooth, Bridger, Gros Ventre, Lee Metcalf, Northern Absaroka, Teton, and Washakie Wildernesses), its historic inability to support a robust, persistent resident population and its apparent recent inability to support any resident lynx may be a reflection of naturally marginal and patchy habitats and relatively low hare abundance in much of the unit, resulting in only an intermittent ability of this unit to support resident lynx. We also note that extensive areas of the GYA were burned by the large, intense wildfires of 1988, and that these areas may soon (perhaps in the next 5-15 years) regenerate to a stage containing the dense horizontal conifer structure favorable for hares and, therefore, lynx foraging habitat, perhaps increasing the likelihood that the GYA may support resident lynx again in the near future (Lynx SSA Team 2016, p. 46).

In southern Wyoming, all recent occurrences of lynx appear to be of Colorado-released lynx that moved into or through the area (see Devineau *et al.* 2010, Fig. 1, p. 526), including one female who in 2004 established a den in the Snowy Mountains and produced kittens that did not survive (Bjornlie 2016, pers, comm.; Ivan 2016, pers. comm.). Based on the available information, we conclude that southern Wyoming did not historically or recently support a resident lynx population and is not now capable of doing so.

New Hampshire - There were 18 confirmed lynx records indicating 28 individual lynx in northern New Hampshire from 2006 to 2013, with evidence of reproduction in 2010 and 2011 (79 FR 54820). An additional 8 lynx detections were documented in 2014 (Siren 2014, p. 7), 24 lynx track intercepts were recorded during snow-tracking surveys during the winter of 2014-2015 (Siren 2016, p. 1), and surveys in 2016 also detected lynx (Siren 2016, pers. comm.). Most records since 2006 are in the vicinity of Pittsburg in the northernmost reaches of the state, though lynx detections in 2015 and 2016 suggest a southern expansion from the area of 2006-2014 detections (Siren 2016, p. 1; Siren 2016, pers. comm.). Despite recent evidence of lynx

residency and reproduction, the Service concluded in the 2014 revised critical habitat designation that, based on modeling of the amount of potentially suitable habitat and favorable snow conditions (Hoving *et al.* 2005, pp. 739, 749; Litvaitis and Tash 2005, p. A-298), it is unlikely that northern New Hampshire will support a resident breeding population over the long-term (79 FR 54820-54821). Siren (2014, p. 10) suspected that the relatively few lynx detections documented in 2012-2014 may be related to the presence and abundance of bobcat, coyote, and fisher populations in northern New Hampshire. We conclude that northern and central New Hampshire likely supported a small resident lynx population historically that was extirpated during the latter half of the 20th century. We are uncertain whether lynx detections in northernmost New Hampshire over the past decade may represent the natural reestablishment of a small resident breeding population in the state or if it is a temporary phenomenon related to an expanding source population in neighboring northern Maine (79 FR 54821). Although bobcat populations have increased and expanded their range in this region in recent decades (Lavoie *et al.* 2009, pp. 873-874), severe winters and deep snow can substantially limit their populations (Reed 2009, pp. 29-33; McCord, 1974, pp. 433-434). Maine's bobcat harvest declined substantially after two deep snow winters in 2008 and 2009 (Maine Department of Inland Fisheries and Wildlife 2015, p. 37). It is possible that these anomalous deep snow winters provided a temporary competitive advantage to lynx in northern New Hampshire.

Idaho, Maine, Minnesota, Montana, and Washington - These states (along with New Hampshire, above) have the strongest historical evidence of continuous lynx presence and recent evidence of resident lynx populations (McKelvey *et al.* 2000a, pp. 211-228; 68 FR 40086-40095, 40097-40101; McKelvey *in* Lynx SSA Team 2016, p. 11). Historic lynx records exist for much of Idaho, but many, especially in the central and southern part of the state, occurred in anomalous habitats or were associated with large irruptions of lynx from Canada to the northern contiguous U.S. in the early 1960s and early 1970s (McKelvey *et al.* 2000a, pp. 225-227). The historic record and recent surveys (summarized at 79 FR 54818-54820; also see U.S. District Court ID 2016, pp. 18-24) suggest that only dispersing lynx occur throughout most of Idaho, habitats in many parts of the state are drier forest types that support lower densities of hares, and resident lynx seem to be confined to the Purcell, Selkirk, and possibly the Cabinet mountain ranges in the northern panhandle. The number of resident lynx in northern Idaho is unknown but certainly small based on the amount of potential habitat, and resident lynx here are part of a larger population that occurs primarily in northwestern Montana and southeastern British Columbia.

Maine has a long history of continual lynx presence, with evidence of a persistent resident population in much of the northern half of the state, which currently supports the largest lynx population in the DPS (Krohn 2010, entire; McKelvey *et al.* 2000a, pp. 211-212; Hoving *et al.* 2003, entire; Vashon *et al.* 2012, pp. 50-60; 79 FR 54784-54785, 54792, 54822-54824; Vashon *in* Lynx SSA Team 2016, p. 18). The lynx population in Maine is much larger than was suspected at the time of listing or the 2003 remand (potential habitat exists to support possibly 750-1,000+ individuals [Vashon *in* Lynx SSA Team 2016, p. 18], though a reliable population estimate is lacking). The current abundance of lynx is supported by the broad distribution of high-quality hare habitat that resulted from extensive, large-scale clearcutting in the 1970s and
