

### **Status and Harvests of Sandhill Cranes**

Mid-continent, Rocky Mountain, Lower Colorado River Valley and Eastern Populations

### 2017

#### **Acknowledgments**

This report provides population status, recruitment indices, harvest trends, and other management information for the Mid-Continent (MCP), Rocky Mountain (RMP), Lower Colorado River Valley (LCRVP), and Eastern (EP) populations of sandhill cranes. Information was compiled with the assistance of a large number of biologists from across North America. We acknowledge the contributions of: D.P. Collins, P. Donnelly, J.L. Drahota, D.L. Fronczak, T.S. Liddick, and P.P. Thorpe for conducting annual aerial population surveys; W.M. Brown for conducting the RMP productivity survey; K.K. Fleming and M.H. Gendron for conducting the U.S. and Canadian Federal harvest surveys for the MCP; S. Olson and J. O'Dell for compiling harvest information collected on sandhill cranes in the Pacific Flyway; T. Cooper, S. Kelly and D.L. Fronczak for compiling population information for the EP; and D.S. Benning, R.C. Drewien and D.E. Sharp for their career-long commitment to sandhill crane management. We especially want to recognize the support of the state and provincial biologists in the Central, Pacific, and Mississippi Flyways for the coordination of sandhill crane hunting programs and especially the distribution of crane hunting permits and assistance in conducting of annual cooperative surveys.

## STATUS AND HARVESTS OF SANDHILL CRANES

# MID-CONTINENT, ROCKY MOUNTAIN, LOWER COLORADO RIVER VALLEY and EASTERN POPULATIONS 2017

James A. Dubovsky, Central Flyway Representative, Division of Migratory Bird Management, U.S. Fish and Wildlife Service, Lakewood, Colorado.

Abstract: The annual indices to abundance of the Mid-Continent Population (MCP) of sandhill cranes has been relatively stable since 1982, but indices have increased in recent years and show more interannual variability compared to historic values. The spring 2017 estimate of abundance for sandhill cranes in the Central Platte River Valley (CPRV), Nebraska, corrected for visibility bias, was 568,369 birds. This estimate is 40% above that of the previous year. The photo-corrected, 3-year average for 2015-17 was 453,519, which is within the established populationobjective range of 349,000-472,000 cranes. All Central Flyway States, except Nebraska, allowed crane hunting in portions of their States during 2016-17. An estimated 9,503 Central Flyway hunters participated in these seasons, which was 65% higher than the number that participated in the previous season. Hunters harvested 23,253 MCP cranes in the U.S. portion of the Central Flyway during the 2016-17 seasons, which was 90% higher than the harvest for the previous year and 55% higher than the long-term average. The retrieved harvest of MCP cranes in hunt areas outside of the Central Flyway (Arizona, Pacific Flyway portion of New Mexico, Minnesota, Alaska, Canada, and Mexico combined) was 17,200 during 2016-17. The preliminary estimate for the North American MCP sport harvest. including crippling losses, was 44,912 birds, which was a 52% increase from the previous year's estimate and a record for the population. The long-term (1982-2012) trends for the MCP indicate that harvest has been increasing at a higher rate than population growth. The fall 2016 pre-migration survey for the Rocky Mountain Population (RMP) resulted in a count of 22,264 cranes, 8% lower than the recordhigh count from 2015. The 3-year average was 22,087 sandhill cranes, which is slightly above the established population objective of 17,000-21,000 for the RMP. Hunting seasons during 2015-16 in portions of Arizona, Idaho, Montana, New Mexico, Utah, and Wyoming resulted in a harvest of 1,147 RMP cranes, a 63% increase from the previous year's harvest. The Lower Colorado River Valley Population (LCRVP) survey results indicate a 12% increase from 2,416 birds in 2016 to 2,716 birds in 2017. The 3-year average is 2,556 LCRVP cranes, which is above the population objective of 2,500. The Eastern Population (EP) sandhill crane fall survey index for 2016 (95,403) was a record-high count for the second consecutive year, slightly higher than the count in 2015, and a total of 757 cranes were harvested in Kentucky and Tennessee.

#### Introduction

The MCP of sandhill cranes, numerically the most abundant of all North American crane populations, is comprised of lesser (Antigone canadensis canadensis) and greater (A. c. tabida) subspecies of sandhill cranes. A third, intermediate-sized subspecies, the Canadian sandhill crane (A. c. rowanii), was identified in the MCP (Walkinshaw 1965); however, genetic investigations question the differentiation of this third subspecies (Rhymer et al. 2001, Peterson et al. 2003, Jones et al. 2005). The MCP was believed to have >500,000 individuals in the spring during the 1990s (Tacha et al.1994). The breeding range extends from northwestern Minnesota and western Quebec, then northwest through Arctic Canada, Alaska, and into The MCP wintering range includes western Oklahoma, New Mexico, southeastern Arizona, Texas, and Mexico (Fig. 1). Extensive spring aerial surveys on major concentration areas that are corrected for observer visibility bias provide annual indices of abundance used to measure population trends. These surveys are conducted in late March, at a time when birds that wintered in Mexico, Arizona, New Mexico, and Texas usually have migrated northward to spring staging areas, but before spring "break-up" conditions allow cranes to move into Canada (Benning and Johnson 1987). The MCP Cooperative Flyway Management Plan (Central, Mississippi and Pacific Flyway Councils 2006) established regulatory thresholds for changing harvest regulations that are based on an objective of maintaining sandhill crane abundances at 1982-2005 levels (i.e., spring index of 349,000- $472,000 \ [\bar{x} = 411,000 \pm 15\%]$ ). Sandhill crane hunters are required to obtain either a Sandhill Crane hunting permit or register under the Harvest Information Program (HIP) to hunt MCP cranes in the U.S. portion of the Central Flyway, Minnesota in the Mississippi Flyway, and Alaska. The permits or HIP registration records provide the sampling frame to conduct annual harvest surveys. In Canada, the harvest survey is based on the sales of Federal Migratory Bird Hunting Permits, which are required for all crane hunters.

The RMP is comprised exclusively of greater sandhill cranes that breed in isolated river valleys, marshes, and meadows of the U.S. portions of the Central and Pacific Flyways (Drewien and The highest nesting concentrations are located in western Montana and Bizeau 1974). Wyoming, eastern Idaho, northern Utah, and northwestern Colorado. The RMP migrates through the San Luis Valley (SLV) in Colorado and winters primarily in the Middle Rio Grande Valley, New Mexico, with smaller numbers wintering in the southwestern part of New Mexico, in southeastern Arizona, and at several locations (~14) in the Northern Highlands of Mexico (Fig. 2). During 1984-96, the RMP was monitored at spring stopover areas in the SLV. However, cranes from the MCP also began to use this area, which confounded estimates of RMP abundance. In 1995, a fall pre-migration (September) survey replaced the spring count as the primary tool for monitoring population change. The RMP Cooperative Flyway Management Plan established a population objective (17,000-21,000 birds), and identifies surveys used to monitor recruitment and harvest levels that are designed to maintain a stable abundance (Pacific Flyway Council and Central Flyway Council 2016). The plan contains a formula for calculating allowable annual harvests consistent with the goal of staying within the range of the population objective. All sandhill crane hunters in the range of the RMP must obtain a state permit to hunt cranes, which provides the sampling frame for independent harvest estimates and allows for assignment of harvest quotas by state. In many areas, harvest estimates are supplemented by periodic mandatory check-station reporting.

The LCRVP is numerically the least abundant of the six migratory populations of sandhill cranes recognized in the U.S. (Drewien et al. 1976, Drewien and Lewis 1987). The LCRVP is comprised exclusively of greater sandhill cranes that breed primarily in northeastern Nevada, with smaller numbers in parts of Idaho and Utah (Fig. 3), and winters in the Colorado River

Valley of Arizona and Imperial Valley of California. LCRVP cranes have the lowest reported recruitment rate (4.8%) of any sandhill crane population in North America (Drewien et al. 1995). In the fall, these cranes leave breeding areas during late September-early October, congregate at several staging areas, and migrate through eastern Nevada to wintering areas. Wintering areas historically extended south along the Colorado River to near its delta with the Gulf of California. However, the current wintering distribution is concentrated at Cibola National Wildlife Refuge, on adjacent areas belonging to the Colorado River Indian Tribes in southwestern Arizona, areas within and near the Sonny Bono Salton Sea NWR in southern California, and the Gila River in Arizona. Collectively, these areas are believed to winter in excess of 90% of the total cranes in the LCRVP. Spring migration is generally initiated as early as the first week of February. Since 1998, an aerial cruise survey has been conducted that covers the four main winter concentration areas.

The EP, which consists of greater sandhill cranes, has rebounded from near extirpation in the late 1800's (Walkinshaw 1949, 1973; Leopold 1949). Management actions, such as regulating take and the protection and restoration of habitat, allowed this population to increase to a level that exceeded 30,000 cranes by 1996 (Meine and Archibald 1996). The majority of EP cranes breed across the Great Lakes region (Wisconsin, Michigan, Ontario, and Minnesota); however, the range of this population is currently expanding in all directions (Fig. 4). By early fall, EP cranes leave their breeding grounds and congregate in large flocks on traditional staging areas throughout the breeding range. During migration, EP cranes use traditional stopover areas which include Jasper-Pulaski Fish and Wildlife Area in northwest Indiana and Hiawassee State Wildlife Refuge in southeast Tennessee. Historically, EP cranes primarily wintered in southern Georgia and throughout Florida (Walkinshaw 1973, Lewis 1977, Tacha et al. 1992, Meine and Archibald 1996). Recent annual Midwinter Survey data, conducted by state and federal agencies, show substantial numbers of cranes wintering farther north into Kentucky and Tennessee (2013-2017 U.S. Fish and Wildlife Service Reports, unpublished data).

#### **Mid-Continent Population of Sandhill Cranes**

No sport hunting seasons for MCP cranes were allowed in the U.S. between 1918-60. In the Central Flyway, areas open to hunting were gradually expanded during 1961-74, but since that time have remained relatively stable. Operational hunting seasons are now held annually in portions of Colorado, Kansas, Montana, New Mexico, North Dakota, Oklahoma, South Dakota, Texas, and Wyoming. Nebraska is the only Central Flyway state that does not have a sandhill crane sport hunting season. Areas open to crane hunting in the Central Flyway during 2016-2017 are shown in Fig. 5. Beginning in 2010, Minnesota, a Mississippi Flyway state, opened a limited hunt in the northwest portion of the state.

During 1961-74, hunters gradually improved their knowledge of sandhill cranes and improved their hunting success. During 1975-85, a tradition of sandhill crane hunting became established. Together with improvements in equipment (decoys, calls, clothing, blinds, etc.) and a shift from pass-shooting and hunting on roosts to decoy-hunting in fields, crane hunter success increased (Sharp and Vogel 1992). Dubovsky and Araya (2008) found that in the late 1990s and early 2000s hunters were more successful in harvesting 2 or 3 cranes per day than they were during the early 1980s. Average seasonal bags declined in the Central Flyway during the late 1990s and early 2000s, but increased and have remained relatively stable during the last decade (Fig. 13).

For most states, sandhill crane seasons began in relatively small areas, and expanded incrementally in subsequent years as experience with the seasons was gained. For example,

sandhill crane seasons in North Dakota resumed in 1968 after being closed following the signing of the Migratory Bird Treaty Act in 1918. During 1968-79, the number of counties open for crane hunting increased from 2 to 8, and increased to 30 during 1980-92 and were grouped into two zones that were west of Highway 281. Beginning in 1993, the zones were eliminated and Federal frameworks were fully utilized for the designated hunting area (Sharp and Cornely 1997). In 2001, designated hunt areas in North Dakota and Texas were expanded, with the new areas having reduced frameworks of 37 days compared to 58 in other areas and also a reduced daily bag. In 2014, North Dakota increased season length in the eastern zone to 58 days but kept the 2 bird daily bag limit; harvest data suggested there would be negligible effects on that segment of the population. Kansas was the most recent Central Flyway state to initiate a crane hunting season in 1993. Initially, crane hunting was open only in portions of 17 counties, but by 2003 the area was expanded to 62 counties, essentially the entire western portion of the state (Sharp et al. 2010). Also, during early years of these seasons, bag limits and shooting hours often were more restrictive than Federal frameworks allowed.

MCP harvest areas have remained relatively consistent from year to year; however, the levels of harvest vary with respect to many factors including changes in hunting pressure, land use, and environmental factors. Most shifts in annual harvests occur locally, but large-scale changes in harvest distributions also have occurred. Since the late 1990s, harvests have generally increased in Saskatchewan, while harvests have declined in North Dakota (Fig. 6). Causal factors for these changes have not been determined, but are likely different because birds staging in Saskatchewan are largely from the West-central Canada-Alaska breeding affiliation whereas those in North Dakota are from the East-central Canada-Minnesota breeding affiliation (Krapu et al. 2011). Increased hunting pressure in Saskatchewan, mainly by non-resident U.S. hunters (Araya et al. 2010), has likely contributed to increases in harvests whereas declines in harvests in North Dakota appear to be more complex and involve several interrelated factors, likely including changes in hunting pressure, land-use changes, and environmental conditions.

The MCP included at least 510,000 sandhill cranes in March 1982, the last extensive survey involving high-altitude vertical photography of major spring migration staging concentrations. Beginning in 1982, an intensive photo-corrected ocular-transect survey of Nebraska's CPRV and ocular assessments from other spring staging areas have been used to monitor the annual status and trends for this population (Table 1). Use of the CPRV count in the development of annual harvest recommendations relies on the premise that a high proportion (>90%) of the MCP are in the CPRV at the time of the annual survey. Recent research with radio-tracked birds suggests that the proportion of MCP cranes in the CPRV during the survey varies by year (Pearse et al. 2015). Annual variability in weather patterns can reduce the percentage below 90% in some years. However, conducting the survey a few days earlier or a few days later likely would not result in a 'better' count (i.e., a higher proportion of birds being in the CPRV), because birds migrate into and out of the area continuously (Pearse et al. 2015).

The March 2017 photo-corrected ocular estimate for the CPRV was 568,369 cranes (Table 1, Fig. 7), which was 40% higher than the count from March 2016 (405,716) (Liddick 2017). The natural log-transformed annual photo-corrected estimates for the CPRV portion of the survey indicate a slightly increasing population trend (P = 0.04) likely due to the higher counts in several of the recent surveys (Fig. 8). The annual estimates also appear to have more interannual variability in recent years relative to historic values. The 3-year-average index for photo-corrected counts during 2015-17 is 453,519 cranes, which is 4% lower than the previous 3-year average of 470,030 but within the management objective level (349,000-472,000) for this population (Fig. 9).

Since 1975, special Sandhill Crane Hunting Permits, or more recently HIP certification, have been required for crane hunters participating in seasons in the Central Flyway. Additionally, a limited MCP sandhill crane hunt was offered in Minnesota starting in 2010, for which a stateissued permit was required for hunters to participate. A sample of these permittees is mailed questionnaires soon after the completion of each hunting season. The resulting responses enable estimation of hunting activities and success (Martin 2007). Estimated numbers of hunters registering as sandhill crane hunters in Texas had been increasing since 1997 when crane hunting was included in the combination licenses issued by the state, with a record high of 122,553 permits issued in 2008. In 2009, Texas revised their licensing system and crane hunters now must go to selected locations to obtain their permit, which resulted in a 91% decrease in the number of hunters identified as crane hunters from 2008. Thus, the number of crane hunters in Texas likely did not decrease as suggested by the data; rather, the number of hunters classified as crane hunters by the Texas registration process declined. During the 2016-17 season in the Central Flyway, 31,905 hunters were either HIP-certified or obtained crane hunting permits, which were not limited in number (Table 2), with 9.503 of these individuals hunting at least one time (Table 3, Fig. 10). The number of active hunters in the Central Flyway was 65% higher than the previous year (Fig. 10). During 2016-17, the number of hunters in Texas (71%) and North Dakota (16%) combined comprised 87% of all sandhill crane hunters in the Central Flyway. Minnesota issued 1,954 permits and had 964 active hunters in their first season but participation has declined over the subsequent six years and is perhaps leveling out. In 2016, Minnesota issued 1,139 permits and had 471 active hunters (5% decrease and 11% increase, respectively, from 2015).

Federal frameworks in the Central Flyway allow daily bag/possession limits of 3/9, which most states selected. Portions of North Dakota, Texas and Minnesota have lower bag and possession limits of 2/6. Specific dates selected by states in the Central Flyway and Minnesota for 2016-17 were similar to those of previous hunting seasons (Table 4).

An index to crippling-loss rate (number of cranes lost/[number of cranes lost + retrieved]) in the U.S. portion of the Central Flyway has declined ( $R^2$  = 0.89, P < 0.01) from over 16% in 1975 to a preliminary estimate of about 4.2% during the most recent hunting season (Fig. 11). The number of days afield per hunter (2.68) was 12% lower than the previous year (Fig. 12) and is 13% lower than the long-term average of 3.09. The preliminary estimate of seasonal bag per hunter was 2.45 birds (Fig. 13), which is 22% higher than the long-term average of 2.01. The preliminary estimate of retrieved and unretrieved mortality associated with the sport harvest in the Central Flyway (24,273) was 85% higher than the previous year's estimate (Fig. 14). The increasing trend ( $R^2$  = 0.42, P < 0.01) in the Central Flyway's harvest of MCP cranes during 1975-2016 likely is related to the gradual increase in hunter opportunity combined with improved knowledge of crane behavior, hunting techniques, and hunter success (Sharp and Vogel 1992, Dubovsky and Araya 2008).

Cranes from the MCP also occur in the RMP hunt areas in Arizona, New Mexico, Alaska (Table 5), Canada, and Mexico. The estimate for the 2016-17 sport harvest in Canada (Manitoba and Saskatchewan) was 11,503 birds, an 8% increase from that of last year (Table 6). For Alaska, sandhill crane harvest in harvest zones 1-6 is believed to be mostly MCP cranes and those harvested in zones 7-12 are from the Pacific Population of lesser sandhill cranes. There also is some intermingling of MCP cranes with RMP cranes in portions of New Mexico and Arizona; however, periodic bag checks allow estimates of harvests for each population. The estimated harvest for the RMP hunt areas in Arizona, New Mexico, and Alaska combined was 1,732 cranes for 2016-17. In the 7th year of Minnesota's sandhill crane hunt the harvest (287 cranes) increased by 35% from the previous year. No annual harvest surveys are conducted in Mexico,

but annual MCP harvests probably are <10% of the retrieved harvest in the U.S. and Canada (R. Drewien and D. Nieman, personal communication). This assumed low level of harvest was supported by an independent assessment of harvest in Mexico (Kramer et al. 1995). The 2016-17 preliminary estimate of retrieved and unretrieved kill of MCP cranes by sport hunters was a record high of 44,912, which is a 52% increase from the previous year and a 32% increase from the average for 2000-09 (Table 7, Fig. 15).

To assess the relative rates of change between population size (abundance) and harvest, we periodically assess trends in these parameters. In the most recent analysis we used linear regression on the natural log-transformed values for these variables for the years 1982-2012. Because >10% of the MCP occurs outside the CPRV in the spring of some years, we combined the photo-corrected counts in the CPRV with the ocular cruise estimates from areas outside the CPRV for analyses of population abundance. For harvest, we used only the estimates of 'retrieved' harvest for the Central Flyway, Minnesota, RMP hunt areas in Arizona and New Mexico. Alaska, and Canada, because crippling-loss rates for the latter three areas are unknown and there are no empirical estimates of harvest from Mexico. Regression of the logtransformed values indicate a significant slope for the abundance values (P = 0.06;  $R^2 = 0.11$ ; slope = +0.8% per year change), suggesting a slightly increasing trend in the abundance of cranes over the time frame. The regression of the harvest values also indicates an increase in the rate of harvest over that same time period (P < 0.01;  $R^2 = 0.55$ ; slope = +1.8% per year) (Fig. 16). These results suggest that the increase in the rate of harvest is increasing faster than the rate of growth in crane abundance, and the divergent trends cannot continue indefinitely. Methods have been developed (e.g., Araya and Dubovsky 2008, Dubovsky and Araya 2008) that will assist managers in structuring changes in harvest regulations should such a need arise in the future. Results suggest that a bag-limit reduction of one bird per day may reduce statespecific harvests by 4%-23%, whereas fairly large restrictions in season framework dates may be needed to realize a perceptible decrease in harvest. The regression analyses detailed above will be updated in next year's report.

Subsistence harvest levels of MCP sandhill cranes historically were poorly documented. However, the 1997 U.S./Canada Migratory Bird Treaty Amendment identified improvements that should be made to sandhill crane harvest-monitoring programs in both the U.S. and Canada. Harvest surveys conducted during 2006-2015 on the Yukon-Kuskokwim (Y-K) Delta, Alaska, reported an average MCP harvest of 3,418 adults and fledged young and an average of 1,494 eggs (data from Naves 2010a, 2010b, 2011, 2012, 2014, 2016). The harvest estimate for birds is relatively similar to the 1985-2005 average (Wentworth 2007) of 3,148 adults and fledged young taken by subsistence hunters on the Y-K Delta, but that for eggs is 183% higher than the 1985-2005 average of 528 eggs. Efforts are being made to gather additional information on subsistence harvests for the remainder of Alaska, Siberia, and Canada.

#### **Rocky Mountain Population of Greater Sandhill Cranes**

The RMP was not hunted in the U.S. from 1918-80. Arizona initiated the first modern-day season in 1981. Since that time hunting programs have been guided by a cooperative management plan, including a harvest strategy that has been periodically updated and endorsed by the Central and Pacific Flyways (Kruse et al. 2008). The harvest strategy for the RMP calculates an allowable harvest based on crane survey counts and recruitment relative to the population objective. Thus, allowable harvest changes annually based on the current status of the birds.

Counts conducted in the SLV during the spring migration suggested that the number of RMP cranes was relatively stable during 1984-96 (Table 8). However, survey biologists found that these estimates contained increasing numbers of the MCP (lesser subspecies). An adjustment, using ground-derived proportions, was made to correct for the lesser subspecies but was not a viable approach for the long-term (Benning et al. 1996). In 1996, the survey was discontinued (Fig. 18). In 1997, an attempt was made to survey these cranes during the fall (October) in the SLV, but MCP cranes also were present at that time. Biologists concluded that neither a spring nor a fall count in the SLV would result in a reliable index to the abundance of the RMP. As an alternative, a cooperative 5-state September pre-migration staging-area survey, experimentally tested in 1987 and 1992, has been ongoing operationally since 1995. Because no other crane population comingles with them during that time, the September pre-migration survey for the RMP appears to be a good alternative to either a spring or fall survey in the SLV and was designated as the official count for the RMP in 1997 (Table 9). Although operational in 1995 and 1996, the survey was variable in timing and survey effort. What appears to lower population estimates (Fig. 18) in 1995 and 1996 is likely more an artifact of inconsistent survey effort (R. Drewien, personal communication).

The Cooperative Flyway Management Plan (Pacific Flyway Council and Central Flyway Council 2016) recommends using the most recent three-year running average of the September survey to determine status of the RMP. The 2016 September pre-migration survey resulted in 22,264 cranes counted, an 8% decrease from the record-high count in 2015 (Thorpe et al. 2016). The 3-year average is 22,087 which is 3% higher than the previous 3-year average and slightly above the established population objective (17,000-21,000) (Fig. 19).

During 1986-95, important breeding areas in the Intermountain West experienced extremely dry conditions and indices of recruitment (% juveniles) were low (generally between 4-6%) (Fig. 20). A return to more favorable breeding conditions during 1996-99 resulted in higher recruitment rates (8-12%), but drier conditions resulted in lower production during 2000-02. Since 2003 recruitment rates generally have been above-average due to improved wetland habitats and favorable spring and summer breeding conditions. The recruitment rate of 8.8% (8% above the long-term [1972-2015] average of 8.2) and a mean brood size of 1.18 (Brown 2016) indicated average nesting and brood rearing habitat in 2016.

Special limited hunting seasons during 2016-17 resulted in a harvest of 1,147 RMP sandhill cranes (Table 8), which was 63% higher than the previous year's harvest (Fig. 17) and consistent with a higher allowable harvest due to increased abundance of the cranes (2013-2015 average, Table 9). Based on slightly improved population status and recruitment indices for the 2014-16 period (Figs. 19, 20), management guidelines allow for a maximum allowable take of 2,362 birds during the 2017-18 hunting season, a 21% increase from that for the 2016-17 season.

#### **Lower Colorado River Valley Population of Greater Sandhill Cranes**

The LCRVP is the smallest of the migratory populations of sandhill cranes in North America. The range of this population is believed to overlap ranges with the Rocky Mountain and Central Valley populations. Historically, winter counts of the LCRVP were not well-coordinated or conducted using a consistent methodology. However, efforts have been made to standardize areas surveyed and the timing of the survey to obtain more accurate counts and increased ability to determine trends in population abundance. Beginning in 1998, a coordinated winter aerial cruise survey with a fixed-wing aircraft has been conducted at the four major wintering areas: Cibola NWR, the Colorado River Indian Tribes wetland areas, Sonny Bono Salton Sea

NWR, and the Gila River. Collectively, these counts are believed to contain in excess of 90% of the total number of cranes in this population. The counts are not corrected for cranes present but not seen by aerial crews, and therefore have unknown bias and precision. The survey resulted in 2,716 birds in 2017, a 12% increase from the previous year's count (Table 11, Fig. 21). The current 3-year average for the winter count is 2,556 LCRVP cranes.

The LCRVP was not hunted after the signing of the Migratory Bird Treaty Act in 1918. In 2007, the Service completed an Environmental Assessment entitled "Proposed hunting regulations for the Lower Colorado River Valley Population of Greater Sandhill Cranes in the Pacific Flyway" (U.S.D.I. 2007). In 2008, the Service determined that a small allowable harvest (about 30) could be allowed on this population in years when the 3-year average of winter counts exceeded 2,500. The hunting season is guided by a cooperative management plan (Pacific Flyway Council 1995) which includes methodology for determining allowable harvests and allocation of the harvest. Once a hunting season is initiated, this season would be experimental for 3 years. After the 3 years, the season would be reviewed and revised if necessary.

A limited youth hunting season for this population was conducted during 2010 in Arizona, the only state that has hunted these cranes. No LCRVP cranes were harvested. The Pacific Flyway currently has no plans to conduct hunts in the near future.

#### **Eastern Population of Greater Sandhill Cranes**

In 1979, the U.S. Fish and Wildlife Service initiated a coordinated fall index survey of historic EP migratory staging areas in the Mississippi and Atlantic Flyways. This survey is conducted annually in late October by volunteers and agency personnel who count the number of cranes at staging areas throughout the EP range (S. Kelly, U.S. Fish and Wildlife Service, personal communication). Overall, the survey documented a long-term increasing trend in EP cranes with an average growth rate in the population of 3.9% per year (1979-2009) (Amundson and Johnson 2010). A more recent analysis indicates the growth rate has increased to 4.4% per year (U.S. Fish and Wildlife Service, unpublished data). The most recent fall count from 2016 was 95,403, which was slightly higher than the 2015 index of 94,869, and a record count for the second consecutive year. The 3-year average is 91,250 (Table 12, Figure 22). This index is not a statistically designed population estimate; however, the index does reasonably represent a population estimate for EP cranes.

In 2010, the Mississippi and Atlantic Flyway Councils endorsed a management plan for EP cranes (Ad Hoc Eastern Population Sandhill Crane Committee 2010). One of the plan's provisions included guidelines for potential harvest of this population when the 3-year average of the fall survey is above 30,000 cranes. Kentucky and Tennessee initiated experimental hunting seasons in 2011 and 2013, respectively; the season in Kentucky became operational in 2015 and that for Tennessee was approved for operational status beginning with this year's (2017) season. Seasons are allowed between September 1 and January 31 and have a maximum length of 60 days. Actual season dates have been from mid-December to mid-January in Kentucky and late November to late January in Tennessee (Table 13). According the hunt plan, each state is allowed to issue a number of tags to hunters based on each state's fiveyear average peak crane abundance. Hunters in both states are required to complete mandatory crane identification training, tag and report harvested birds, and complete a postseason survey. In Kentucky, 267 permits were issued and hunters harvested 50 cranes during the inaugural season in 2011-12 (Table 14). In the 2016-17 season, 336 permits were issued and hunters harvested 171 cranes (Harper 2017). Data provided by the Tennessee Wildlife Resources Agency indicated that in each of their four seasons 400 permits were issued to hunters. During the initial 2013-14 season 350 cranes were harvested, whereas hunters harvested 393 cranes during the 2014-15 season, 161 cranes during the 2015-16 season, and 586 during the 2016-17 season (J. Feddersen, Tennessee Wildlife Resources Agency, personal communication) (Table 14).

#### **Priority Research Efforts and Needs for Management of Sandhill Cranes**

 On April 7-9, 2009, a workshop was conducted to discuss the status of North American sandhill cranes and to update research and management priorities. A published document providing outcomes and priority information needs from that first workshop (Case and Sanders 2009) is available at: https://www.fws.gov/birds/surveys-and-data/weblessmigratory-game-birds/sandhill-cranes.php.

Many of those initial priority information needs have been, or are being addressed by the research and management community. Therefore, a second workshop was convened during April 14-15, 2014 in Lafayette, Louisiana. The purpose of the workshop was to review progress to date on the original priorities, and to develop a revised list of priorities based on that information. Workshop participants finalized an updated priority needs document (Brandt et al. 2016) with the following priorities:

Priority 1. Assessing Finer Scale Management of the Mid-Continent Population- Over the last decade, U.S. Geological Survey (USGS) researchers and partners have gathered much information about the MCP, specifically data regarding migration distribution and chronology, delineation of breeding affiliations, and potential harvest pressure on various segments of the MCP. Most of this research has been published (Krapu et al. 2011, 2014). Results indicate that four, largely geographically distinct, breeding affiliations can be identified that have different migration patterns and those groups may differ in their exposure to hunting pressure from east to west. Although research has not been completed to determine whether vital rates used in management (i.e., survival, recruitment) differ among breeding affiliations, data are sufficient to warrant examination as to whether management of the MCP should be targeted toward finer scales of the population. Future work should conduct an assessment of differences in vital rates among the breeding affiliations, and if such differences exist, determine whether managers can derive estimates of those parameters through operational monitoring programs to tailor management to smaller segments of the overall population.

Priority 2. <u>Assessing Effects of Habitat Changes on the Rocky Mountain Population of Sandhill Cranes</u>- Identification of the ecological stressors affecting cranes is essential to informing meaningful conservation for the RMP across its entire range (i.e., breeding, staging, and wintering). For example, their longevity, delayed maturation, and low recruitment may be masking habitat impacts already occurring, further heightening the need to understand impacts of range-wide habitat changes to RMP cranes. Overcoming this information gap will better inform harvest management of the RMP, and provide land managers with decision-support tools to strategically focus conservation resources in areas of highest biological benefit.

Priority 3. <u>Improving the monitoring of Eastern Population Greater Sandhill Cranes</u>-The Eastern Population (EP) of greater sandhill cranes has expanded in both population size and geographic range in the last several decades (Amundson and

Johnson 2010). Two states (Tennessee and Kentucky) within the Mississippi Flyway have implemented hunting seasons for EP cranes and other states are likely to explore opportunities in the future. In response to the first priorities document, Amundson and Johnson (2010) completed a critical review of existing fall survey data, which is currently used to formulate harvest-management recommendations. They also assessed other data sources, including the North American Breeding Bird Survey (BBS) and the Christmas Bird Count (CBC), for their adequacy of indexing population abundance. Their analyses indicated that the fall survey tracks abundance well, but not the geographic expansion of the population. The fall survey traditionally occurs during the last week of October under the assumption that the majority of EP cranes that breed in Canada have migrated to traditional staging areas in the U.S. and are available to be counted. Recent satellite telemetry studies (Fronczak 2014, Hanna et al. 2014, and D. Sherman, Ohio DNR, unpublished data) have identified that cranes breeding in Canada are in the U.S. during the current timing of the fall survey; however, between 20%-30% of marked EP cranes that summer in Wisconsin and Michigan are not present on staging areas during the current survey period and therefore are not available to be counted during the survey. A better understanding of the abundance and migration of birds in these areas is needed to complement the current information of EP distribution and migration chronology and further evaluate the adequacy of the fall survey for assessing population status.

Priority 4. Improving Population Abundance Estimates for the Mid-Continent Population-The current survey used to estimate abundance of the MCP has been in place since 1982, and it was believed the survey would account for >90% of the total MCP. A review of the abundance estimates indicated that (1) although historically the data indicate that the 90% threshold has been met in the majority of years, in recent years the threshold has not been met as frequently, and (2) the year-to-year variation in point estimates of crane abundance are biologically improbable given information on recruitment and survival, suggesting a systemic problem with the survey methodology. The first issue was identified in the 2009 priority information needs document. As a result, information was analyzed to assess the appropriateness of the timing of the annual survey. Results indicated that in 4 of the 7 years examined <90% of the marked cranes were in the CPRV at the time of the survey. Although recent work suggests the estimates derived are the best possible using the current methods, year-to-year variation in those counts are biologically untenable (Pearse et al. 2015). Given the changing landscape (e.g., timing of spring phenology, reduction in food availability) that could affect timing of migration and distribution of birds in the surveyed area, managers need to know whether the current monitoring scheme and/or fixed timing of the survey is still sufficient, or if alternative methods would be more appropriate.

2. Monographs on the geographic distribution and spring migration ecology of Mid-Continent Population sandhill cranes were published in 2011 and 2014 by Gary Krapu, Dave Brandt, Ken Jones, Doug Johnson, Paul Kinzel, and Aaron Pearse (Wildlife Monographs 175, 189). The results provide information from many years of satellite telemetry work which followed the cranes throughout their annual cycle, and have important implications for management of the MCP in the future.

- 3. The agricultural landscape on which sandhill cranes depend for a portion of their annual cycle has undergone dramatic changes in recent years. Published research indicates that the percentage of cropland in the CPRV that is being planted to soybeans, which are not valuable nutritionally for cranes, is increasing whereas the percentage planted to corn is decreasing (Pearse et al. 2010). In years when availability of corn is reduced, some cranes may not be able to increase lipid reserves as much as they did historically, due not only to increased crane numbers but also increased waterfowl abundance, particularly snow geese. If corn acreage and availability decline further, major changes could occur in the abundance or condition of cranes using the area. Changes in agricultural practices in other areas of the country (e.g., San Luis Valley of Colorado) also may be impacting other populations of cranes.
- 4. Work is being conducted on the annual distribution of sandhill crane populations in the west, particularly those of the LCRVP, the RMP, and the Central Valley Population (e.g., Collins et al. 2016). Researchers have used satellite telemetry to better understand movements and ranges of birds within these populations, and results suggest more overlap in ranges occurs than was previously thought. Additional work would assist managers in accurately delineating population boundaries, which could enhance management of the individual populations.
- 5. Current methods for estimating sandhill crane abundance involve diurnal surveys in fixed-winged aircraft with a pilot/observer and ≥1 other observer. During the day, sandhill cranes are widely dispersed over the landscape in feeding and loafing flocks, so a large amount of area must be surveyed to ensure a majority of cranes are counted to generate reasonably accurate estimates. In the mid-2000s, researchers from the U.S. Geological Survey attempted to estimate the number of MCP sandhill cranes roosting on portions of the CPRV at night (Kinzel et al. 2006), when birds are concentrated on stretches of the river. Although never implemented operationally due to cost and some logistical issues, such an approach may be more efficient than the current method of estimating sandhill cranes during the day. Researchers and biologists with the U.S. Geological Survey and the U.S. Fish and Wildlife Service Division of Migratory Bird Management are exploring the efficacy of nighttime surveys using the latest Unmanned Aerial Systems (i.e., drone) and camera technologies.

Preliminary

S:\CF\_D\projects\speciesandpopulations\sandhillcranes\Status Reports\Shcranerep.xls

K.L. In the second (HIP) or a point-of-sale electronic record (without cost) used to identify crane hunters in lieu of a special sandhill crane hunting permit

<sup>&</sup>lt;sup>3</sup> States began charging a fee for crane hunting permits which reduces the number of permits issued to hunters that only occasionally come into contact with sandhill cranes.

<sup>&</sup>lt;sup>4</sup> NM uses a combination of electronic and paper permits.

<sup>&</sup>lt;sup>5</sup> SD uses a special question in their HIP questionnaire to identify sandhill crane hunters; TX hunters can only obtain crane permits in selected locations.

<sup>&</sup>lt;sup>6</sup> All hunters put in stratum "did not hunt" or "no" in state HIP sample frame, so no estimate is available.

Table 3. Estimated active Mid-Continent sandhill crane hunters¹ in the Central Flyway and Minnesota.

<sup>&</sup>lt;sup>1</sup> Those permittees reporting hunting cranes 1 or more times

<sup>&</sup>lt;sup>2</sup> Preliminary

<sup>&</sup>lt;sup>3</sup> All hunters put in stratum "did not hunt" or "no" in state HIP sample frame, so no estimate is available.

Table 4. Season dates (month/day) for the hunting of Mid-continent sandhill cranes in the Central Flyway states and Minnesota.

A proportion of the Alaskan harvest is composed of lesser sandhill cranes from the Pacific Coast Population
 Harvest data are from state harvest surveys for only the MCP portion of the state, except in 1977-81, 1986, 1991, and 1998-99 where federal MQS state totals are prorated by the long-term percent MC cranes; data from 2000 forward are MC portion from HIP.

<sup>&</sup>lt;sup>4</sup> The MC harvest for AZ and NM represents MC sandhill cranes that were harvested in RMP areas and are not represented in the CF MC Sandhill Crane Federal Harvest Survey

<sup>&</sup>lt;sup>5</sup> Minnesota initiated a hunt in the NW portion of state.

<sup>&</sup>lt;sup>6</sup> All hunters put in stratum "did not hunt" or "no" in state HIP sample frame, so no estimate is available.

<sup>HIP sample frame from state was incomplete.
\* No estimate is available.</sup>

<sup>&</sup>lt;sup>1</sup> Preliminary

<sup>08/15/17</sup> 

<sup>&</sup>lt;sup>2</sup> Unknown harvests (Mexico) were assumed to be 10% of harvests in the U.S. and Canada.

<sup>&</sup>lt;sup>3</sup> Unretrieved kill as reported by hunters is used for the Central Flyway; for the remainder of harvest areas, it is assumed to be 20% of retrieved harvests.

 $<sup>^{\</sup>rm 4}$  There is no estimate available for AK in that year.

<sup>&</sup>lt;sup>5</sup> Estimates (except Canada) biased low because of HIP sampling issues in SD and AK that resulted in estimates of zero harvest for each.

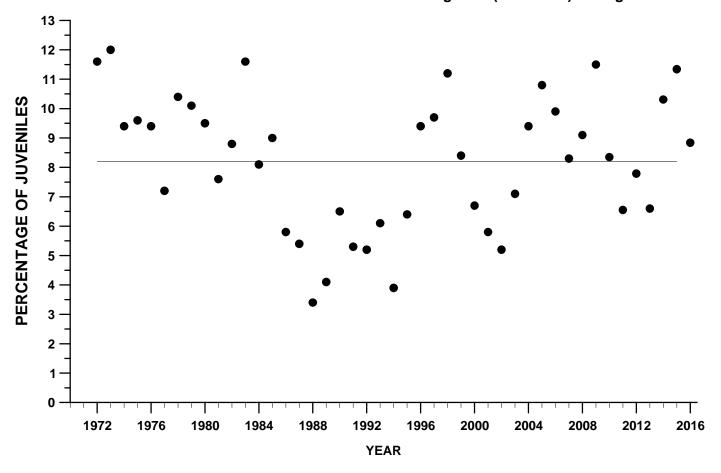

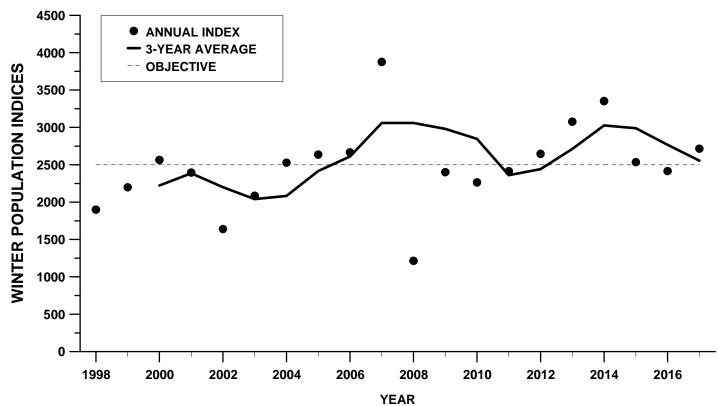

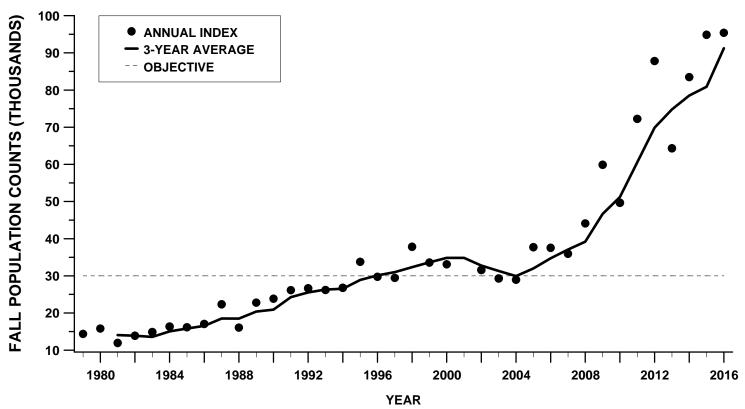

Figure 21. Annual and three-year average of winter counts of the Lower Colorado River Valley Population of sandhill cranes in Arizona and California.

In 2008, the survey was not complete. The 3-YR average for that year was calculated using 2005-07. In 2009 and 2010, the estimate for 2008 was not included in the 3-YR average

Figure 22. Annual and three-year average of fall counts of the Eastern Population of sandhill cranes.

- Survey was not conducted in 2001. The 3-yr average for 2001 was calculated using data from 1998-2000.
- In 2002 and 2003, the 3-yr averages did not include 2001.
- New survey areas are still being added which is partially responsible for the increasing count.
