Alaska Peninsula and Becharof

*National Wildlife
Refuge*

Bird List

Covering approximately 4.6 million acres (larger than Connecticut and Rhode Island combined), the Alaska Peninsula/Becharof National Wildlife Refuge includes an immense variety of

Peregrine Falcon
©Rod Cyr

habitats and is home to more than 200 species of birds. Established in 1980, the Refuge conserves fish and wildlife populations and habitats in their natural diversity.

Introduction

The Alaska Peninsula/Becharof National Wildlife Refuge is a long, thin refuge; reaching from the Gulf of Alaska coast, over the Aleutian Mountains and a number of large inland lakes, to the middle of the Bristol Bay Coastal Plain. The Refuge stretches from the Katmai National Park's southern boundary to American Bay on the Gulf of Alaska and Port Moller on the Bristol Bay coast, and is interrupted by Aniakchak National Monument and Preserve. Becharof Lake, completely within Becharof NWR, is the largest lake in the wildlife refuge system. The landscape is shaped by the Pacific Ocean, active volcanoes and glaciers, meandering rivers and sub-arctic weather cells. Habitats include near-shore marine, coastal shores and cliffs, alpine tundra, forest, shrub and a mostly treeless tundra/shrubland/wetland complex at lower elevations.

This diversity of the Refuge's landforms and habitats contributes to a diverse avifauna. Starting at the Gulf of Alaska, coastal waters support a variety of seabirds, other cliff dependent species, and wintering waterfowl. The land rises sharply to the Aleutian Mountains, where alpine species of landbirds, shorebirds, cliff nesting raptors, and the elusive Kittlitz's Murrelet find homes. The mountains fall to shrub covered hills and large glacially formed lakes, surrounded by shrub and cottonwood forest in the south and spruce/birch forest in the north. These provide habitat for another suite of waterbirds, landbirds, and raptors. The boreal species associated with spruce forests are found mostly north of the Becharof boundary. The land gradually falls to the Bristol

Bay lowlands; which are covered in wetlands, meadows, and dwarf shrub and crossed by meandering rivers. These provide nesting grounds for waterfowl, waterbirds, cranes, shorebirds, landbirds, and some raptors. An isolated population of Marbled Godwit nests in and near the Ugashik River drainage. Continuing northeast to the Bering Sea coast, huge tides build large tidal flats that are visited by migrating birds, especially waterfowl and shorebirds, in spring and fall.

Another contributor to high species diversity is the fact that the Alaska Peninsula is a crossroads for both North America and Pacific migrations. While many species come here to breed, others move here for the winter. Sometimes accidentals from Asia or southern North America may also be encountered by the astute birder.

Bird Viewing

Wildlife viewers benefit from patience, skill, a good pair of binoculars or spotting scope, a notebook, and bird book. Make observations first, and then check the book or bird list. While songbirds are best detected in the morning in spring, other species may be viewed throughout the day. Shorebird abundance on the marine coast is often dictated by tide level. To assist the bird viewer, the likely region/habitat where species are most commonly found is noted. The Refuge covers a vast area with few modern conveniences such as roads, and birding on the Alaska Peninsula can be challenging because of the difficult access to areas outside the village road corridors and the limited window of timing of some species. Advanced planning is needed, especially for targeted species. To better plan your trip a general idea of abundance is given by season.

Brown bears may be found anywhere in this area during spring, summer and fall. Read brochures on bear safety, get tips from the Visitor Centers, or talk to knowledgeable staff about how to stay safe. Travel in groups of more than two if possible, and let people know where you are headed.

Unusual Sightings

Because this is such a huge area and has only been a refuge since 1980, information for some regions, and especially for the winter months, is very spotty. Please report sightings of species not on the list (including a photo if possible) to the Refuge Manager (address on back cover). Please report nests or recently fledged young for species not marked as breeders. Also report species observed outside of a marked season. Reports should include location, date, notes, and observer's name and contact information.

*Gray-crowned
Rosy-finch*

Abundance

- denotes a species that is known to breed in this area
- c common—species occurs regularly in suitable habitat and often in large numbers
- u uncommon—species occurs fairly regularly in suitable habitat, but in small numbers or distribution is irregular
- r rare—species occurs regularly, but in very small numbers and not often seen
- a accidental—species occurs a few times every 50 years
- i irruptive—species cyclic and dependent on a specific resource
- d domestic flocks
