The distribution of wetlands in Illinois, 1980–1987

## INTRODUCTION

Wetlands once covered more than 8 million acres in Illinois, or 23% of the land (Havera 1985). As a result of human modification of the environment, an estimated 90% of these wetlands have been destroyed (Figure 1). Dramatic declines in the amount of wetlands have been accompanied by changes in their distribution (Figure 2). In Illinois, wetlands have been affected principally by conversion of the land for agricultural purposes and to a lesser extent by development pressure caused by human population growth.

In recent years, recognition of the functions and values of wetlands has spawned efforts to stop or reverse wetland loss. Management of wetland resources requires a knowledge of the location, extent, and character of the remaining wetlands.

The wetlands of Illinois were inventoried in the 1980s as part of the National Wetlands Inventory (NWI), an effort by the U.S. Fish and Wildlife Service (USFWS) to locate and classify all surface water—that is, wetlands and deepwater habitats (such as rivers and lakes). The Illinois Wetlands Inventory (IWI) is an enhanced version of the original NWI data, developed through joint efforts of the Illinois Department of Conservation, the Illinois Natural History Survey, and the USFWS.

The primary purpose of this document is to provide information on the character, extent, and distribution of

wetlands and deepwater habitats of Illinois based on IWI data. This publication is intended to serve as a reference for resource planners, managers, environmental scientists, policy makers, and others interested in wetland resources. It also provides valuable baseline data for future analyses.

Wetlands encompass a variety of areas commonly known as marshes, bogs, wet meadows, swamps, shallow ponds, and bottomland forests. These areas are usually associated with deepwater habitats or occupy depressions surrounded by upland.

USFWS definitions of wetlands and deepwater habitats were used for the NWI. The USFWS defined wetlands as “lands transitional between terrestrial and aquatic systems where the water table is usually at or near the surface or the land is covered by shallow water. For purposes of this classification, wetlands must have one or more of the following three attributes: (1) at least periodically, the land supports predominantly hydrophytes; (2) the substrate is predominantly undrained hydric soil; and (3) the substrate is nonsoil and is saturated with water or covered by shallow water at some time during the growing season of each year” (Cowardin et al. 1979, p. 3). Permanent water bodies greater than 6.6 ft (2 m) deep at low water are called “deepwater habitat” in the NWI (Cowardin et al. 1979).

Numerous definitions of wetlands have been developed in recent years. The term “wetland” describes a dynamic natural system for which exact boundaries are sometimes difficult to establish. Three key characteristics are emphasized in an ecological approach to a wetlands definition: hydrology, vegetation, and hydric soils (Cowardin et al. 1979). Hydrology refers to the distribution and movement of water on or below the earth’s surface. All wetlands are periodically saturated or inundated by shallow water during the growing season. Wetlands must have water for a sufficient period of time to stress plants and animals not adapted for life in soils covered by or saturated with water (Tiner 1989). Hydrophytes, plants which are able to survive in water or wet soils, have adapted to the lack of free oxygen available to the roots (Tiner 1989). Hydric soils lack free oxygen in their upper portion for a significant period during the growing season because of saturation or inundation with water (Tiner 1989). Drained hydric soils retain many of their original characteristics and, therefore, can be used to estimate wetland acreages prior to settlement (Cashin et al. 1992, Dahl 1990, Tiner 1990).

*Figure 1. The proportion of Illinois that used to be wetlands and the proportion of the original wetland acreage that remained by the 1980s. Of the approximately 8 million acres of wetlands in Illinois during presettlement times, less than 1 million acres remain.*

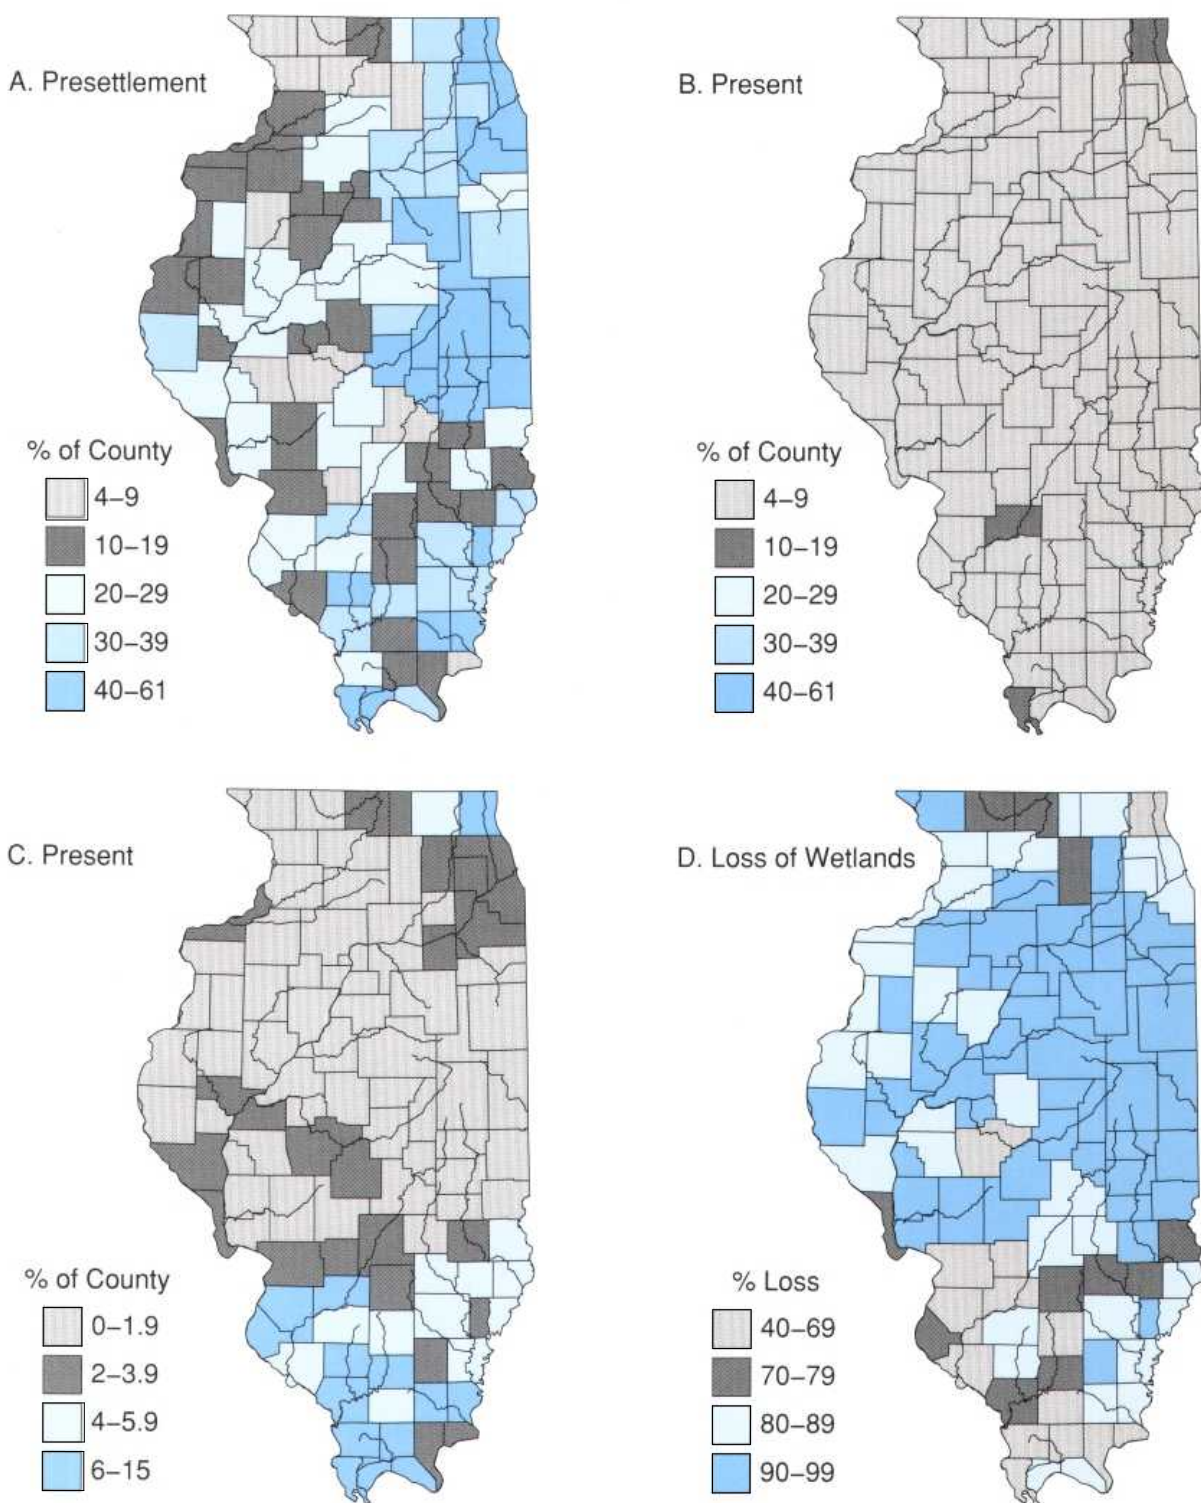

Figure 2. Presettlement and present extent of wetlands and percent loss of wetlands in Illinois counties. Presettlement wetlands were determined from data on hydric soils (Havera 1985). Present wetlands were determined using natural wetlands from the Illinois Wetlands Inventory (1980-1987). Parts A and B use the same legend, which allows direct comparison between the two maps. The legend for part C is adjusted to better depict the present distribution.

## METHODS AND PROCEDURES

The IWI is a spatial database that stores location, shape, and descriptive information about wetlands and deepwater habitats using ARC/INFO software in a geographic information system (GIS) environment. Every wetland and deepwater habitat feature mapped in the IWI is described by spatial parameters such as area and perimeter, as well as ecological and physical descriptors such as dominant vegetative type, substrate type, duration of saturation or inundation, and human modification. In the IWI, descriptive codes assigned to each wetland and deepwater habitat feature include both an NWI code and an IWI classification code.

### INVENTORY METHODS

The NWI used high-altitude aerial photography supplemented with other sources of data for identification and mapping of wetlands and deepwater habitats. Information was transcribed to U.S. Geological Survey 7.5-minute quadrangle base maps (1:24,000 scale). The standard final NWI product is a hardcopy map showing the location, configuration, and NWI codes of wetlands and deepwater habitats (Figure 3). A cooperative agreement between the State of Illinois and the USFWS resulted in the creation of a digital database from the NWI maps for Illinois.

The primary source for mapping Illinois' wetlands was 1:58,000 color infrared photographs taken as part of the National High Altitude Photography Program. The photographs were taken from the spring of 1980 through the spring of 1987. Photo interpretation was conducted using mirror stereoscopes. Collateral data sources used to aid in wetland detection and classification included 7.5-minute topographic maps from the U.S. Geological Survey and soil surveys by the Soil Conservation Service of the U.S. Department of Agriculture.

A special issue in identifying wetlands was the inclusion or exclusion of farmed areas. Most original wetlands that are now farmland were not classified as wetlands in the NWI. Hydric soils that were completely drained and are no longer capable of supporting hydrophytes were not classified as wetlands by the NWI (USFWS 1985). Farmed wet areas were classified as wetlands in the NWI if the area remained wet for a sufficient period of time to meet NWI criteria. Where possible, these areas were noted through use of special modifiers for farming and/or partial drainage.

Several steps were taken to assure the quality of the data. To reduce inconsistencies, all photo interpretations

were supervised by the same person. Field investigations were conducted to verify accurate identification and classification of wetlands through photo interpretation, particularly for areas with problematic wetland signatures or classifications (e.g., farmed wetlands). Regional NWI staff reviewed the photography for correct delineations and classifications, and the national NWI staff in St. Petersburg, Florida, spot-checked photos to ensure adherence to the national quality control standards.

Draft maps at a scale of 1:24,000 were produced using Bausch and Lomb zoom transfer scopes. Draft maps were sent for review and comment to the USFWS, U.S. Army Corps of Engineers, Soil Conservation Service, U.S. Environmental Protection Agency, Illinois Department of Conservation, and the 98 soil and water conservation districts in Illinois. The USFWS NWI staff conducted field checks and examined draft maps to ensure proper placement of wetland polygons and accurate classification.

In a program unique to Illinois, public input was sought to improve the accuracy of the maps and to create public awareness of the mapping effort. Through a contract with the Illinois Department of Conservation, a series of 37 public meetings was organized by soil and water conservation districts. More than 1,000 people attended these meetings throughout the state. Attendees were asked to verify the NWI description of lands with which they were familiar; there was at least a 95% concurrence with the NWI description.

Digitization of the data was performed from the 1:24,000 maps by a contractor under the supervision of the USFWS. Digital data files were sent by the USFWS to the Illinois Natural History Survey in MOSS format and converted to ARC/INFO format via a program developed in house. Hardcopy maps were produced from the database at the 1:24,000 scale, overlaid on the NWI hardcopy maps, and checked for errors. The digital database includes wetlands and deepwater habitats down to 0.01 acre.

### CLASSIFICATION SYSTEMS

**National Wetlands Inventory Classification.** The NWI classifies wetlands and deepwater habitats with a hierarchical system with six levels: system, subsystem, class, subclass, water regime modifiers, and special modifiers (Figure 4). The following discussion provides an overview of the NWI classification system as it applies to Illinois. More detailed discussions are available in Cowardin et al. (1979) and Tiner (1989).

*Systems*, the broadest level in the classification system,

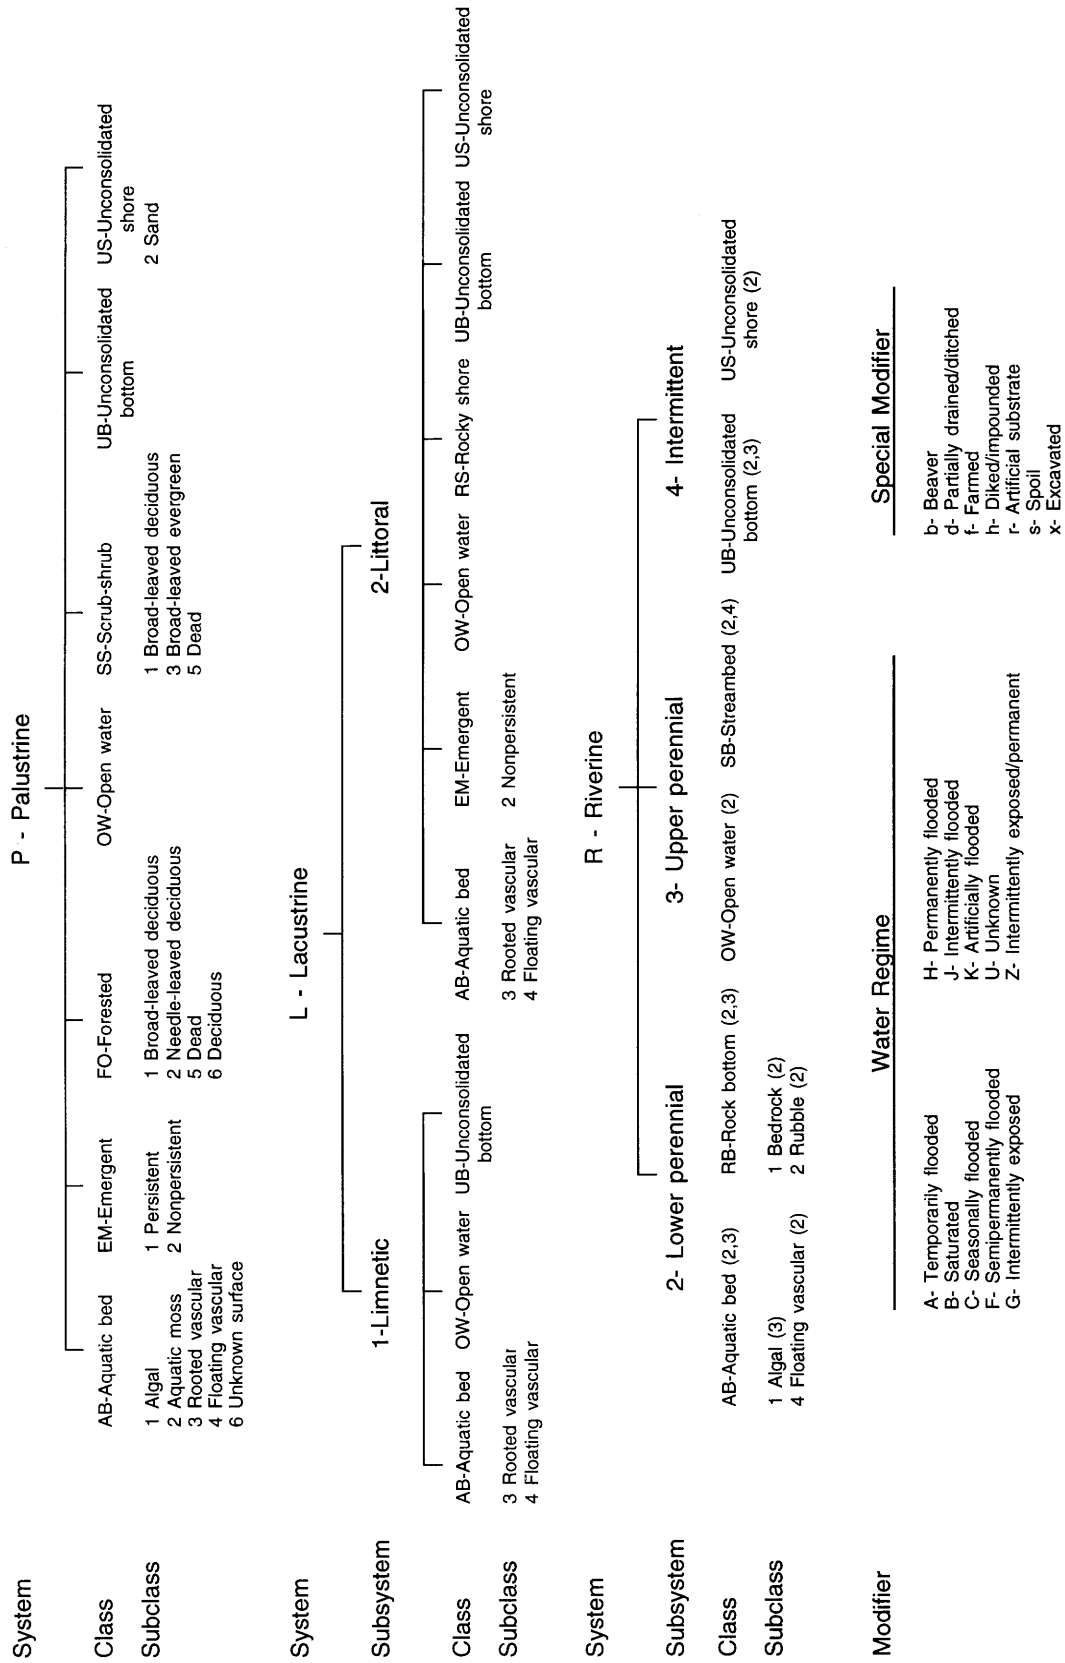

Figure 4. National Wetlands Inventory classification system (Cowardin et al. 1979) modified for Illinois. (Numbers after riverine classes and subclasses indicate applicable subsystems.)

Table 1. Classes and modifiers of the National Wetlands Inventory in Illinois and their descriptions (based on Cowardin et al. 1979 and Tiner 1989).

CLASS	DESCRIPTION
Vegetative cover $\geq$ 30%	
FO Forested wetland	Woody vegetation 20 ft (6 m) or taller
EM Emergent wetland	Erect, rooted, herbaceous hydrophytes
SS Scrub-shrub wetland	Woody vegetation < 20 ft (6 m) tall
AB Aquatic bed	Plants grow on or below the surface of the water
Vegetative cover < 30%	
Permanently flooded	
OW Open water	Unknown bottom
RB Rock bottom	Stone, boulder, or bedrock cover 75% or more of substrate
UB Unconsolidated bottom	Substrate is at least 25% particles smaller than stones
Not permanently flooded	
SB Streambed	Channel completely dry at low water periods
RS Rocky shore	75% or more bedrock, stones, or boulders
US Unconsolidated shore	Less than 75% coverage of bedrock, stone, or boulders
MODIFIER	
Water Regime	
A Temporarily flooded	Surface water for only brief periods during growing season with water table usually well below the soil surface for most of the season
B Saturated	Substrate saturated to the surface for extended periods during the growing season but surface water seldom present
C Seasonally flooded	Surface water for extended periods in growing season but not at the end of the growing season
F Semipermanently flooded	Surface water throughout the growing season in most years
G Intermittently exposed	Surface water throughout the year except in extreme droughts
H Permanently flooded	Surface water throughout the year in all years
J Intermittently flooded	Substrate usually exposed, variable presence of surface water without detectable seasonal periodicity
K Artificially flooded	Flooding controlled by pumps or siphons in combination with dikes or dams
Z Intermittently exposed/permanent	See descriptions for G and H
Special Modifier	
b Beaver	Created by beaver activity
d Partially drained/ditched	Artificially drained but can still support hydrophytes
f Farmed	Altered for the production of crops but hydrophytes could reestablish
h Diked/impounded	Barrier obstructs inflow (dike) or outflow (impoundment) of water
r Artificial	Substrates placed by humans
x Excavated	Lies in a basin or channel excavated by humans

or more of the area; if lacking vegetation, the area is small and shallow (< 20 acres and < 6.6 ft [2 m] deep) and lacks wave-formed or bedrock shoreline. Palustrine wetlands include forested wetlands such as swamp and bottomland forest, emergent wetlands such as shallow marsh/wet meadow and deep marsh, open water (e.g., ponds), and scrub-shrub wetlands.

*Forested wetlands* are characterized by woody vegetation 20 ft (6 m) or more tall covering 30% or more of the area. The duration of saturation or inundation by water differentiates swamps from bottomland forest in the IWI classification.

*Swamps* are defined in this classification as forested wetlands where water is present on a permanent or semipermanent basis. This category includes "true" swamps and some bottomland forests. Swamps characterized by species such as bald cypress and tupelo are limited to far southern Illinois (White 1978); these "true" swamps represent a northern extension of the once vast bottomland hardwood swamps of the southern coastal states. The swamp category also includes bottomland forest classified with the semipermanently to permanently flooded water regimes. An example of this occurred at the confluence of the Sangamon River with the Illinois River; this area is

<sup>a</sup> See Figure 4 for description of subsystem types.

<sup>b</sup> Includes codes with either a single class or with class as dominant type in combination with other classes. For example, forested wetlands are designated with codes PFO, PFO/EM, PFO/SS, etc.

characterized by bottomland forest species such as silver maple, ash, cottonwood, elm, and willow (S. Havera, Illinois Natural History Survey, personal communication).

*Bottomland forests* are defined in the IWI classification as temporarily or seasonally flooded forested wetlands that lack continuously standing water. This definition is based on water regime as opposed to proximity to streams or rivers. Bottomland forests range from areas of frequent flooding with a poorly developed understory (water regime C) to drier wetlands that have a greater diversity of plant species (water regime A).

*Emergent wetlands* are dominated by rooted, herbaceous hydrophytic vegetation such as sedges, rushes, forbs, and grasses. Vegetation may remain visible throughout the year or die back in the nongrowing season. Water regimes range from saturated soils with brief periods of standing water (wet meadow) to permanently inundated areas (deep marsh). Wet meadows and marshes were once common in the state (Sanderson et al. 1979, Illinois Department of Conservation 1988). They are often part of larger wetland complexes such as ponds, lakes, and rivers. Emergent wetlands are extremely productive ecosystems and support large numbers of plant and animal species. *Shallow marsh/wet meadow* is a category characterized by

standing water that is present for brief to moderate periods during the growing season. *Deep marsh* is characterized by standing water or soil saturation on a semipermanent to permanent basis during the growing season.

*Open water wetlands* are nonvegetated areas less than 20 acres that are covered by water less than 6.6 ft (2 m) deep. This includes ponds, borrow pits, small reservoirs, and open water areas within a marsh or swamp.

*Scrub-shrub wetlands* are characterized by woody vegetation less than 20 ft (6 m) tall covering 30% or more of the area. Scrub-shrub wetlands can be a successional stage in the transition of an emergent wetland to forest, or they may represent a climax community such as the shrub bogs of northeastern Illinois.

*Lacustrine wetlands* are areas in which the water is less than 6.6 ft (2 m) deep, are larger than 20 acres, and are situated in a topographic depression or dammed river channel; these areas generally have less than 30% persistent vegetative cover. This type includes natural and artificial lakes and impoundments. Lacustrine wetlands are divided into three types: *shallow lake*, *lake shore*, and *emergent lake*. Shallow lakes are characterized by shallow open water. Lake shore wetlands are generally limited to the edges of large rivers and the shores of wave-affected

Table 3. Illinois wetland plants characteristic of IWI classification types (Illinois Department of Conservation 1988; J. Taft, Illinois Natural History Survey, personal communication).

#### PALUSTRINE WETLANDS

##### Bottomland forest

Bluebell	<i>Mertensia virginica</i>
Box elder	<i>Acer negundo</i>
Common phlox	<i>Phlox divaricata</i>
Cottonwood	<i>Populus deltoides</i>
Devil's beggarticks	<i>Bidens frondosa</i>
Goldenglow	<i>Rudbeckia laciniata</i>
Pin oak	<i>Quercus palustris</i>
River birch	<i>Betula nigra</i>
Sedge	<i>Carex grayi</i>
Shellbark hickory	<i>Carya laciniata</i>
Silver maple	<i>Acer saccharinum</i>
Smooth hedge nettle	<i>Stachys tenuifolia</i>
Stout woodreed	<i>Cinna arundinacea</i>
Sycamore	<i>Platanus occidentalis</i>
Sweetgum	<i>Liquidambar styraciflua</i>
Wood nettle	<i>Laportea canadensis</i>

##### Swamp

Bald cypress	<i>Taxodium distichum</i>
Copper iris	<i>Iris fulva</i>
Featherfoil	<i>Hottonia inflata</i>
Overcup oak	<i>Quercus lyrata</i>
Pumpkin ash	<i>Fraxinus profunda</i>
Swamp white oak	<i>Quercus bicolor</i>
Swamp red maple	<i>Acer rubrum</i> var. <i>drummondii</i>
Swamp rose	<i>Rosa palustris</i>
Virginia willow	<i>Itea virginica</i>
Water tupelo	<i>Nyssa aquatica</i>

##### Shallow marsh/wet meadow

Blue skullcap	<i>Scutellaria lateriflora</i>
Common bur reed	<i>Sparganium eurycarpum</i>
Cordgrass	<i>Spartina pectinata</i>
Fowl mannagrass	<i>Glyceria striata</i>
Marsh marigold	<i>Caltha palustris</i>
Reed canarygrass	<i>Phalaris arundinacea</i>
Roughleaf goldenrod	<i>Solidago patula</i>
Sedge	<i>Carex sartwellii</i>
Southern blue flag	<i>Iris shrevei</i>
Spotted water hemlock	<i>Cicuta maculata</i>
Swamp dock	<i>Rumex verticillatus</i>
Swamp milkweed	<i>Asclepias incarnata</i>
Tickseed sunflower	<i>Bidens aristosa</i>
Tussock sedge	<i>Carex stricta</i>
Winged loosestrife	<i>Lythrum alatum</i>

##### Deep marsh

Arrowleaf	<i>Sagittaria lateriflora</i>
Bluejoint grass	<i>Calamagrostis canadensis</i>
Bulrush	<i>Scirpus atrovirens</i>
Common cattail	<i>Typha latifolia</i>
Common reed	<i>Phragmites australis</i>
Halberd-leaved rose mallow	<i>Hibiscus laevis</i>
Marsh spikerush	<i>Eleocharis palustris</i>
Rice cutgrass	<i>Leersia oryzoides</i>
River bulrush	<i>Scirpus fluviatilis</i>

<i>Juncus balticus</i>
<i>Cakile edentula</i>

##### *Gratiola neglecta*

<i>Bidens frondosa</i>
<i>Lobelia siphilitica</i>
<i>Lindernia dubia</i>
<i>Salix exigua</i>
<i>Equisetum hyemale</i>
<i>Stachys tenuifolia</i>
<i>Nasturtium officinale</i>
<i>Justicia americana</i>

##### *Gratiola neglecta*

<i>Penthorum sedoides</i>
<i>Phyla lanceolata</i>
<i>Lindernia dubia</i>
<i>Rorippa sessiliflora</i>
<i>Cyperus strigosus</i>

lakes. Emergent lake wetlands have a zone of emergent vegetation that extends from the shore to approximately 6.6 ft (2 m) in depth.

*Riverine wetlands* are largely shallow (< 6.6 ft [2 m] deep) rivers and streams within nonimpounded channels; they are either unvegetated or vegetated with nonpersistent emergent plants or aquatic plant beds. *Perennial* riverine wetlands are characterized by flowing water throughout the year. In *intermittent* riverine wetlands, water flows for only part of the year.

The IWI classification system divides deepwater habitat into two categories: lacustrine and riverine. *Deepwater lakes* are water bodies deeper than 6.6 ft (2 m) that occupy topographic depressions or that are impounded river channels. Flowing water deeper than 6.6 ft (2 m) in unimpounded channels characterizes *deepwater rivers*.

The IWI classification was designed to allow for the separation of wetlands and deepwater habitats that are “natural” from those that are “modified/artificial” based on modification or creation by dike, impoundment, or excavation (i.e., NWI codes with special modifiers h or x). The natural category most closely represents what remains of the state’s original wetlands. Modified/artificial areas include farm ponds, sewage lagoons, and reservoirs. Some wetlands classified as modified/artificial were present in presettlement times, such as some floodplain and backwater areas of the Illinois and Mississippi rivers, but their original hydrology has been substantially altered through the construction of levees and drainage projects. The modified/artificial category does not necessarily represent a gain in wetland acreage.

Field testing of the IWI classification was conducted at Northern Illinois University under contract to the Illinois Department of Conservation (Luman 1989). The use of this classification was found to be an acceptable alternative to the more complicated NWI classification. Luman (1989) also established that after a period of time a significant number of NWI descriptions of individual wetlands were no longer accurate, mostly due to annual variation in hydrology and community succession (e.g., scrub-shrub to forested). Classification using the Illinois system was more accurate over time because the combination of water regimes into broader groups accounted for some of the annual variation in hydrology.

## DATA ANALYSIS

A statewide summary of wetland and deepwater habitat data for Illinois is presented in Table 4. Information is

summarized by IWI classification type in the appendixes as follows: 7.5-minute quadrangle maps and a corresponding table constitute Appendixes A and D, respectively; county maps and corresponding tables make up Appendixes B and E, respectively; and hydrologic basin maps and tables are found in Appendixes C and F, respectively. Distribution of the IWI classification types is represented on the appendix maps by five size classes based on dividing the total acreage for the given type into five groups with approximately equal acreages.

The summary table for quadrangle data (Appendix D) includes acreage, percentage, and ranking for wetlands and for natural wetlands. County and basin data are summarized by IWI classification types; the county and basin tables present the total acreage for the county or basin, acreage of wetland or deepwater habitat type, rank of the wetland or deepwater habitat type by acreage among the counties or basins, percentage of wetland or deepwater habitat type relative to county or basin area, and rank by percentage among counties or basins (Appendixes E and F). Both the acreage and percentage of wetland or deepwater habitat type are useful for determining the relative abundance of a given type, particularly when comparing areas of different sizes. For example, Adams and Alexander counties have approximately the same total wetland acreage, but Alexander County ranks first among the 102 counties in terms of the percentage of the county occupied by wetlands whereas Adams County ranks 44th (Appendix E).

An analysis by NWI classifications provided information not available from analysis with the IWI classification categories. The breakdown of the data by vegetative type or substrate (class), hydrological regime (water regime), and human impact (special modifier) provided additional parameters with which to characterize the wetlands and deepwater habitats of Illinois.

## RESULTS

### SURFACE WATER

Of nearly 36 million acres of surface area in Illinois, wetlands and deepwater habitats (i.e., surface water) represented 4.9% (1.76 million acres) of the total in 1980–1987 (Table 4). Seventy-one percent of the surface water was wetland, and 29% was deepwater habitat. Surface water acreage was dominated by bottomland forest wetlands (43.2%); other major types included deepwater

lake (mostly impoundment lakes on river channels; 19.0%), deepwater river (9.5%), and shallow marsh/wet meadow (9.3%).

### WETLANDS

Wetlands of all types occupied about 1.25 million acres, or 3.5% of the total area of Illinois. Most wetlands were palustrine (93.2%), with small amounts of lacustrine (4.4%) and riverine (2.3%) acreage. Bottomland forest was by far the most abundant wetland type, representing 60.5% of the total wetland acreage (Figure 5). The next most abundant type was shallow marsh/wet meadow, constituting 13.0% of the total wetland acreage. Other wetland types in order of decreasing abundance were open water, lacustrine (shallow lake, lake shore, and emergent lake), scrub-shrub, deep marsh, riverine (intermittent and perennial), and swamp. Wetlands were concentrated in northeastern Illinois, along the Illinois River, and in southern Illinois (Appendix A). The counties with the highest wetland acreages were Jackson, Clinton, St. Clair, Lake, and Franklin (Appendix E, Table E1). Alexander County had the highest percentage of land area occupied by wetlands (14.7%), followed by Clinton, Lake, Calhoun, and Franklin counties; wetlands occupied less than 3% of the land area in half the counties in Illinois. Wetlands were most common in the Big Muddy River basin, where approximately one-tenth of the state's wetlands occurred, followed by the lower Kaskaskia, the middle Kaskaskia, the Illinois from East Peoria to Beardstown, and the Little Wabash river basins (Appendix F, Table F1).

The natural wetlands category constituted 917,765 acres, or nearly three-quarters of the total wetland acreage in the state. Seventy-one percent of the natural wetland acreage was bottomland forest, and 16.0% was shallow marsh/wet meadow. Each of the other nine wetland types accounted for 4.2% or less of the natural wetlands. The wetland types with at least 75% natural acreage were perennial riverine, shallow marsh/wet meadow, bottomland forest, and scrub-shrub. Natural wetlands were concentrated in the southern third and the northeastern corner of the state (Appendix A). Counties with the highest natural wetland acreages were Clinton, Jackson, Lake, St. Clair, and Wayne (Appendix E, Table E1). Alexander and Lake counties had the highest percentages of natural wetlands relative to total area in the county (14.4% and 10.2%, respectively); half the counties had less than 2% of their land area occupied by natural wetlands. Natural wetlands were most common in the basins of the Big Muddy River, the lower Kaskaskia River, the Little Wabash

River, the middle Kaskaskia River, and the Mississippi River from Reily Lake to Cairo (Appendix F, Table F1).

Approximately one-fourth of the wetlands were modified or created by dike, impoundment, or excavation. Open water wetlands and bottomland forest accounted for 37.8% and 32.2%, respectively, of the 336,126 acres in this category. Open water, lake shore, and shallow lake were the wetland types most affected by dike, impoundment, or excavation. Modified/artificial wetlands were concentrated along the Illinois and Mississippi rivers and in the Big Muddy and middle Kaskaskia river basins (Appendixes A; F, Table F1). The highest modified/artificial acreages were found in Mason, Fulton, Calhoun, Adams, and Woodford counties (Appendix E, Table E1).

In Illinois, palustrine wetlands occupied 1.17 million acres. Approximately three-quarters of the palustrine wetland acreage was natural. Palustrine habitat was concentrated in northeast Illinois, along the Illinois River, and in southern Illinois (Appendix A). Counties with the most palustrine acreage were Jackson, St. Clair, Clinton, Lake, and Wayne (Appendix E, Table E2). The Big Muddy River basin had the most palustrine acreage, followed by the basins of the lower Kaskaskia River, Little Wabash River, middle Kaskaskia River, and Illinois River from East Peoria to Beardstown (Appendix F, Table F2).

Of the 14,939 acres classified as swamp, two-thirds were found in the southern part of the state in the Big Muddy, the lower and upper Cache, and Ohio river basins (Appendix F, Table F3). Only a portion of the total acreage for this category was swamp characterized by species such as bald cypress and water tupelo. The Illinois Natural Areas Inventory identified approximately 2,000 acres of undisturbed or lightly disturbed swamp in the state in 1978 (White 1978). Dead woody vegetation occupied 1,681 acres of the swamp category; these areas are commonly associated with artificial impoundments (Cowardin et al. 1979).

Bottomland forest occupied 758,693 acres, most of which were natural. Bottomland forested wetlands were concentrated in the southern third of the state and along the Illinois and Mississippi rivers (Appendix A). The highest acreages were in Clinton, Jackson, St. Clair, Wayne, and Franklin counties (Appendix E, Table E3). Bottomland forests were most common in the Big Muddy, the lower and middle Kaskaskia, the Little Wabash, and the Embarras river basins (Appendix F, Table F3).

Shallow marsh/wet meadow accounted for 162,913 acres, of which 90% were natural. Among all the wetland types, this type had the highest percentage of acreage affected by drainage and farming. The six counties with the most shallow marsh/wet meadow acreage—McHenry,

Lake, Will, Cook, Kane, and DuPage—are all in northeastern Illinois, and together they accounted for nearly one-third of the total shallow marsh/wet meadow acreage in the state (Appendix E, Table E4). Basins with the highest shallow marsh/wet meadow acreage were the upper Fox, the Des Plaines, the Kishwaukee, the Mississippi from Hartford to Reily Lake, and the Rock River (Appendix F, Table F4).

There were 38,708 acres of deep marsh; about two-thirds were classified as natural. Lake County had the highest deep marsh acreage (9,003 acres), followed by McHenry County (Appendix E, Table E4). One-third of the deep marsh acreage was located in four counties in northeastern Illinois (Lake, McHenry, Cook, and Will). Only eight counties had more than 1,000 acres of deep marsh. Deep marshes were also concentrated near impoundment lakes such as Shelbyville and Carlyle (Appendix A).

Open water wetlands accounted for 11% (143,345 acres) of the total wetland acreage. Unlike the other palustrine categories, this type was largely (89%) modified by dikes, impoundment, or excavation. The county with the highest open water wetland acreage was Fulton, followed by St. Clair, Cook, Macoupin, and Williamson counties (Appendix E, Table E5). The river basins with the highest open water acreages were the Big Muddy, Spoon, lower Kaskaskia, Des Plaines, and lower Illinois (Appendix F, Table F5).

The IWI classified 50,366 acres as scrub-shrub wetlands. Concentrations of scrub-shrub wetlands were located along the Illinois River (particularly Cass and Mason counties) and in the southern counties of Saline, Randolph, and Jackson (Appendixes A; E, Table E5).

Only 4.4% of the state's wetlands were classified as lacustrine. The 51,868 acres of shallow lake habitat were concentrated along the Illinois River in Woodford, Mason, and Peoria counties, and in Lake and Jefferson counties (Appendixes A; E, Table E6). Less than 3,000 acres of lake shore were identified; nearly half occurred in Fayette and Clinton counties, largely associated with Lake Carlyle (Appendixes A; E, Table E6). The total area of emergent lake wetlands was 772 acres; about two-thirds of this occurred in the Big Muddy basin (Appendix F, Table F6).

Riverine wetlands accounted for 2.3% of the wetlands in the state, occupying a total area of 29,358 acres. In Illinois, perennial riverine wetlands constituted 14% of riverine wetlands; the highest acreages occurred in Alexander and Pike counties (Appendix E, Table E7). Intermittent riverine wetlands accounted for 86% of riverine wetlands. The counties with the highest acreages of intermittent riverine wetlands were LaSalle, Jackson,

Pike, Fulton, and Hancock (Appendix E, Table E7). This type was most common in the Big Muddy, Illinois, Spoon, and La Moine river basins (Appendix F, Table F7).

### DEEPWATER HABITAT

Deepwater habitat covered about half a million acres, or 1.4% of the state's surface area. Counties with the highest acreages of deepwater habitat were Calhoun, Clinton, Rock Island, Carroll, and Hancock (Appendix E, Table E8). Deepwater habitat acreage was highest in the upper Mississippi, Illinois, and Big Muddy river basins.

Thirty percent of the deepwater habitat was natural, and most of this was riverine. Natural deepwater habitat was concentrated in Alexander, Randolph, Madison, Lake, and Monroe counties (Appendix E, Table E8). The highest acreages of natural deepwater habitat were in the lower Mississippi and Illinois river basins, followed by the Rock and upper Fox river basins (Appendix F, Table F8).

Nearly 70% of the deepwater habitat acreage in Illinois was classified as modified/artificial, most of which was lacustrine. Counties with the highest acreages of modified/artificial deepwater habitat were Calhoun, Clinton, Rock Island, Carroll, and Hancock (Appendix E, Table E8). This habitat was most common in the Big Muddy, the Mississippi above St. Louis, and the Illinois river basins (Appendix F, Table F8).

Approximately two-thirds of the deepwater habitat in Illinois was lacustrine, and one-third was riverine. Much of the acreage for lacustrine deepwater habitat was concentrated in the Big Muddy River basin and, because this category includes impounded river channels, in the Mississippi and Illinois basins (Appendix F, Table F9). The counties with the highest acreages of lacustrine deepwater habitat were Calhoun, Clinton, Rock Island, Carroll, and Hancock (Appendix E, Table E9). Deepwater riverine acreage was concentrated in the lower Mississippi River basin, particularly Alexander, Randolph, Monroe, and Madison counties, and in the Rock River basin.

### NWI CLASSIFICATION ANALYSIS

Ninety percent of the wetlands and deepwater habitats in Illinois were classified using 29 NWI codes (of the 617 used in Illinois) (Table 5). The four most abundant NWI codes in Illinois constituted 59% of the surface water. Two of the four types were bottomland forested wetlands—PFO1A (temporarily flooded) and PFO1C (seasonally flooded)—which together accounted for more than one-

third of the state's total surface water acreage and half of the state's wetland acreage. The other two types were permanently flooded deepwater habitats—L1UBHH (impounded lacustrine areas with unconsolidated bottom, i.e., impounded rivers) and R2UBH (lower perennial riverine with unconsolidated bottom). Twenty-two of the 29 NWI codes describe wetlands; 12 were natural and 10 were modified/artificial.

Class, water regime, and special modifier breakdowns for wetlands and deepwater habitats are given in Table 6 and are illustrated in Figure 6. Of the 10 classes used in Illinois, nine describe wetlands. Three classes—forested, emergent, and unconsolidated bottom—accounted for 91% of the total wetland acreage. All the forested and nearly all the emergent acreages were palustrine wetlands. Approximately one-quarter of the total unconsolidated bottom acreage described wetlands; wetlands with an unconsolidated bottom were three-quarters palustrine and one-quarter lacustrine. All scrub-shrub acreage was palustrine wetlands. All acreage of the streambed class was riverine wetlands, nearly all of which was intermittent riverine wetlands. Forty-one percent of the open water class acreage was wetlands, about two-thirds of which were palustrine and one-third lacustrine. Acreage of the aquatic bed class was mostly wetlands (96%), two-thirds of which were palustrine and one-third lacustrine. Only wetlands were described as having an unconsolidated shore, and half of these areas were perennial riverine. Only 1 acre of lake shore wetland was classified as rocky shore. The designation of rock bottom was applied to 29 acres, all deepwater perennial riverine.

Water regimes for wetlands range from temporarily to permanently flooded. Slightly more than half the wetlands in the state were classified as temporarily flooded (A), the dry end of the soil moisture continuum, and about one-quarter were seasonally flooded (C). Wetlands with water regime A were predominantly forested (86.5%). Sixty percent of the acreage with water regime C was forested wetlands, 32% was emergent wetlands, and 6% was scrub-shrub wetlands. The third most abundant water regime, intermittently exposed (G), was about three-quarters open water wetlands (PUB). The semipermanently flooded (F) water regime mostly described emergent and intermittent riverine wetlands. Permanently flooded (H) was predominantly a descriptor of deepwater habitat; wetlands with an H regime were mostly shallow lakes and open water wetlands. Artificially flooded (K) wetland areas included forested, open water, emergent, shallow lake, and scrub-shrub wetlands.

Special modifiers were applied to about one-third of the total wetland acreage and two-thirds of the total

Table 5. The 29 most abundant National Wetlands Inventory (NWI) codes in Illinois. The percentage of each NWI code relative to total wetland or deepwater habitat acreage is shown. Classification of codes as natural or modified/artificial is indicated.

NWI code	IWI classification	Acres	% of wetland acreage	% of deep- water acreage	Natural	Modified/ artificial
PFO1A	Bottomland forest	516,394	41.2	–	X

deepwater habitat acreage in Illinois. For wetlands, the predominant modifier was diked/impounded (special modifier h), which was applied to 21.4% of the total wetland acreage. The excavated (x), partially drained/ditched (d), and farmed (f) modifiers were applied to 5.5%, 3.2%, and 2.1% of the total wetland acreage, respectively.

Forty-one percent of diked/impounded wetlands were forested; 29% and 9% were open water and emergent

wetlands, respectively. Approximately three-quarters of the wetlands acreage with the excavation modifier was open water wetlands. Eighty-one percent of the acreage with the drainage modifier was emergent wetlands. The farmed modifier was applied to 26,415 acres, virtually all emergent wetlands. Thirty-three acres of wetlands with artificial substrate and 14 acres of wetlands created by beavers were identified.

Table 6. Acreages for Illinois wetlands and deepwater habitats by National Wetlands Inventory class, water regime, and special modifier.

### Class

### Water Regime

### Special Modifier

Figure 6. Percentages of Illinois wetland acreages by National Wetlands Inventory class, water regime, and special modifier, 1980–1987. All NWI codes included class and water regime; special modifiers were used where applicable.

## ACKNOWLEDGMENTS

This project was made possible by funding from the Illinois Department of Conservation and the Illinois Department of Energy and Natural Resources. Funding for the Illinois Wetlands Inventory was provided through a cost-sharing agreement between the U.S. Fish and Wildlife Service and the State of Illinois. Many contributed to the creation of the Illinois Wetlands Inventory, including the National Wetlands Inventory staff (especially Robin Gebhard) in St. Petersburg, Florida, Martel Laboratories (photo interpretation and digitization of the data), Ron Erickson (NWI Regional Coordinator), and Karen High (IDOC). The knowledge and assistance of Mark Joselyn and other staff of the Illinois Geographic Information System was invaluable throughout the project. We thank John Taft, Michael Jeffords, and Christine Mayer for their invaluable assistance. We gratefully acknowledge the help of Steve Havera, Ralph Tiner, and Ron Larkin for critical review of this document and John Ballenot and Audrey Hodgins of the editorial staff at the Illinois Natural History Survey for their help in producing this publication. Finally, we thank family and friends for their support and encouragement.
