mapping conventions (National Wetlands Inventory, 1990). These interpretations served as the basis for evaluating recent wetland trends.

The two sets of photographs were compared using a Bausch and Lomb SIS-95 zoom stereoscope. Changes were delineated on mylar overlays attached to the NAPP photographs. Cause of change was recorded for each polygon. The minimum mapping unit for wetlands was generally 0.5 acre, except for ponds, which were mapped when 0.1 acre or larger in size. Changes as small as 0.1 acre were detected. Wetland boundaries were improved and previously undetected wetlands were added to the original maps because the larger scale and more apparent signs of wetland hydrology of the NAPP photos improved our ability to detect and classify wetlands. Delineated changes and map refinements were then transferred to an NWI map using an Ottico Meccanica Italiana stereo facet plotter. Quality control of all photointerpretation was performed by a second photointerpreter. Tables were then prepared to present the study's findings.

RESULTS

Current Status

In 1988-89, Calvert County contained about 10,734 acres of wetlands (roughly 7.8% of the County's land surface), excluding linear fringing wetlands along narrow streams. Table 1 summarizes the acreage of the different wetland types found in the County. Palustrine wetlands predominated with 7,102 acres, representing 66% of the County's total wetland acreage. Nontidal deciduous forested wetlands accounted for 73% (5,159 acres) of all palustrine wetlands, and about 48% of the County's wetland total. Tidal palustrine wetlands totaled 1,179 acres, representing 17% of the County's freshwater wetlands.

Estuarine wetlands comprised about 33.8% (3,632 acres) of the County's wetlands. Emergent wetlands (e.g., salt and brackish marshes) were the predominant type, accounting for almost 82% (2,973 acres) of the County's estuarine wetlands. These wetlands are located along tidal rivers and creeks emptying into Chesapeake Bay. Slightly brackish marshes (oligohaline) are most common along the Patuxent River, and its tributaries north of Buzzard Island Creek.

Recent Wetland Trends

Wetland trends results are presented in Tables 2 through 9. The following discussion highlights the more significant or interesting findings.

Vegetated Wetlands

Between 1981-82 and 1988-89, approximately 29 acres of vegetated wetlands were converted to upland (Table 2). Most of these losses affected palustrine emergent wetlands, and to a lesser extent, palustrine forested and estuarine emergent wetlands. Agriculture and

road and highway construction were the most significant causes of vegetated wetland loss, with recreational facilities development also significant (Table 3). About 127 acres of vegetated wetland changed from one type to another. Upland conversion impacted the temporarily flooded palustrine wetland type more than others (Table 4). Approximately 141 acres of palustrine forested wetlands were converted to upland or changed to other wetland types (Table 5). Vegetated wetland gain from upland was limited to approximately 0.4 acres (Table 6). Most gains in particular types of vegetated wetlands came from other vegetated wetland types (Table 6). Beaver activity affected 57 acres of vegetated wetlands (Table 7).

Nonvegetated Wetlands

About 28 acres of new ponds were created from upland, and over 42 acres were constructed in vegetated wetlands (Table 8). Less than 1 acre of ponds were converted to upland, while roughly 12 acres changed to vegetated wetlands. Approximately 43% of the new ponds built in uplands were the result of farm pond construction (Table 9).

CONCLUSION

The County had approximately 7.8% of its land mass covered by wetlands. Wetlands totaling 10,734 acres (in 1988-89) were identified in the County by the Service's National Wetlands Inventory. Palustrine wetland was the dominant type, representing 66.2% of the wetlands in the County.

Between 1981-82 and 1988-89, the County lost about 74 acres of vegetated wetlands, with roughly 29 acres converted to upland. Temporarily flooded wetland was the type most frequently converted to upland. Pond construction added about 70 acres of palustrine nonvegetated wetlands, but this gain was reduced to about 58 acres by pond losses to upland and vegetated wetlands.

The overall trend for the County's wetlands was losses of vegetated wetlands and gains in nonvegetated wetlands (mostly ponds). The significance of the increase in ponds to fish and wildlife species has not been assessed and remains a point for discussion. The losses of vegetated wetlands, however, represent known losses of valuable fish and wildlife habitats and areas providing other valued functions, including flood water storage, water quality enhancement, and local water supply.

While this report documents recent trends in the County's wetlands, it does not address changes in the quality of the remaining wetlands. As development increases, the quality of wetlands can be expected to deteriorate due to agricultural runoff, increased sedimentation, groundwater withdrawals, increased water pollution, and other factors, unless adequate safeguards are taken to protect not only the existence of wetlands, but their quality.

ACKNOWLEDGMENTS

Funding for this project was provided by the Maryland Department of Natural Resources, Water Resources Administration through an existing cooperative agreement with the Service. David G. Burke was the project coordinator, and we appreciate his interest in monitoring wetland trends in Maryland.

Wetland maps and digital data were compiled by the U.S. Fish and Wildlife Service's National Wetlands Inventory Office at St. Petersburg, Florida. Special appreciation is extended to Becky Stanley and Linda Shaffer for their assistance. Photointerpretation was performed by the senior author and quality controlled by Glenn Smith. John Eaton compiled trend statistics, tables, and graphics for this report. Todd Nuerminger tabulated raw data.
